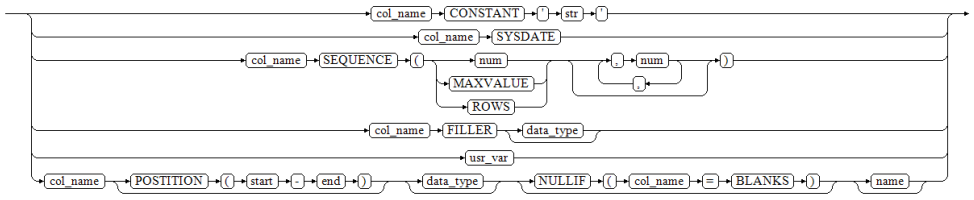
- **load_column_usrvar_list** indicates the syntax options for assigning values to columns, generating sequence values, and filtering data during data import. The syntax format is as follows:

```
{
 col_name CONSTANT 'str' | col_name SYSDATE |
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
 col_name SEQUENCE ( {num | MAXVALUE | ROWS} [ {, num} [, ...]] ) |
 col_name FILLER [data_type] | usr_var |
 col_name [ POSTITION ( start - end ) ] [ data_type ] [ NULLIF ( col_name = BLANKS )] [ name ]
}
```



NOTE

If **disable_unsupported_copy_load_options** is enabled, an error will be reported when options in **Native Syntax** are used.

Parameters

- **LOCAL**

  Specifies the location of the file to be imported.

  If **LOCAL** is not specified and **file_name** is a relative path, data is imported to the data directory by default.

  If the **LOCAL** parameter is specified, **file_name** must be set to an absolute path. If **file_name** is set to a relative path, data is imported to the location of the database binary file by default, that is, *$GAUSSHOME*/**bin/**.

- **REPLACE | IGNORE**

  Specifies an option for handling any data conflicts or errors during file import.

  - Specifying the **REPLACE** option

    If the imported data conflicts with existing data in the target table, the conflicting rows will be replaced. If the imported file contains fewer columns than the target table, the database will issue an alarm in loose mode or raise an error in strict mode.

  - Specifying the **IGNORE** option

    If the imported data conflicts with existing data in the target table, the conflicting rows will be skipped. If the imported file contains fewer columns than the target table, unspecified columns in the table will be filled with default values, and an alarm will be issued.

  - Specifying neither **REPLACE** nor **IGNORE**

    - If the LOCAL option is not specified, the database will raise an error upon data conflicts with existing rows in the target table. If the imported file contains fewer columns than the target table, the database will issue an alarm in loose mode or raise an error in strict mode.
    - When the **LOCAL** option is specified, the behavior mirrors that of the **IGNORE** option.

- **PARTITION**

  If the table to be imported is a partitioned table, this parameter specifies a partition. If the data is inconsistent with the specified partition range, an error is reported.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **CHARACTER SET**

  Specifies the encoding format of a data file. The default value is the current client-side encoding format.

- **FIELDS | COLUMNS**
  - **TERMINATED BY**

    Specifies the delimiter between columns. The default value is **"\t"**.

    NOTE

    The specified newline character cannot be the same as the delimiter.

  - **[OPTIONALLY] ENCLOSED BY**

    Specifies the quotation mark character. The default value is **''**.

    The **OPTIONALLY** parameter is optional and has no practical effect.

    The quotation mark can only be a single character and cannot be a character string.

  - **ESCAPED BY**

    Specifies the escape character. The default value is **"\"**.

    NOTE

    - The escape character must be a single character, not a string.
    - When a non-empty escape character is specified, the database checks whether this character, together with the subsequent sequence, matches the defined escape sequence. If a match is found, the database converts them into the designated characters. Otherwise, the escape character is ignored, and data import proceeds. The supported escape sequences are controlled by the presence of the **new_escape_string** option in the GUC parameter **load_data_behavior_compat_options**.

- **LINES**
  - **STARTING BY**

    Specifies the style of the starting column in the data file to be imported.

  - **TERMINATED BY**

    Specifies the newline character style of the imported data file.

    NOTE

    The **new_escape_string** option in the GUC parameter **load_data_behavior_compat_options** controls whether to escape the specified row terminator.

- **IGNORE**

  Specifies that the first *number* rows of the data file are skipped during data import.

- **col_name_or_user_var**

  Specifies an optional list of columns to be copied.

  Value range: any columns. All columns will be copied if no column list is specified.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- The parameter for specifying columns cannot be used to specify a column repeatedly.
- When columns are specified using the LOAD DATA syntax, **col_name_or_user_var** can only be specified as existing columns but not user variables.

- **SET**

  Specifies the column value, which can be an expression or **DEFAULT**.

  NOTE

  - The expression does not support column names.
  - If no implicit conversion exists between the expression result type and the type of the assigned column, an error is reported.

Examples

```
-- Prepare the environment.
gaussdb=# CREATE DATABASE test_load WITH DBCOMPATIBILITY = 'MYSQL';
gaussdb=# \c test_load
test_load=# SET b_format_version='5.7';
test_load=# SET b_format_dev_version='s2';

-- Prepare the files to be imported.
test_load=# CREATE TABLE load_data_tmp1(a int, b int);
test_load=# INSERT INTO load_data_tmp1 VALUES(1,1),(2,2),(3,3);
test_load=# \copy load_data_tmp1 to '/home/omm/load1.csv';
test_load=# CREATE TABLE load_data_tmp2(a int, b int);
test_load=# INSERT INTO load_data_tmp2 VALUES(1,2);
test_load=# \copy load_data_tmp2 to '/home/omm/load2.csv';
test_load=# CREATE TABLE load_data_tmp3(a int, b int);
test_load=# INSERT INTO load_data_tmp3 VALUES(4,4),(5,5);
test_load=# \copy load_data_tmp3 to '/home/omm/load3.csv';
test_load=# CREATE TABLE load_data_tmp4(a char(50));
test_load=# INSERT INTO load_data_tmp4 VALUES('"load test quote"'), ('\'load test single_quote\'');
test_load=# \copy load_data_tmp4 to '/home/omm/load4.csv';

-- Create a table.
test_load=# CREATE TABLE load_data_tbl1(load_col1 INT UNIQUE, load_col2 INT, load_col3 CHAR(10));

-- Insert a data record into the table.
test_load=# INSERT INTO load_data_tbl1 VALUES(0,0,'load0');

-- Copy data from the /home/omm/load1.csv file to the load_data_tbl table, specify a column name, and
set the value of the load_col3 column to load.
test_load=# LOAD DATA INFILE '/home/omm/load1.csv' INTO TABLE load_data_tbl1(load_col1, load_col2)
SET load_col3 = 'load';
-- The values imported to the load_col3 column later are all load.
test_load=# SELECT * FROM load_data_tbl1 ORDER BY load_col1;
load_col1 | load_col2 | load_col3
-----------+-----------+-----------
         0 |         0 | load0
         1 |         1 | load
         2 |         2 | load
         3 |         3 | load
(4 rows)

-- Copy data from the /home/omm/load2.csv file to the load_data_tbl table and specify IGNORE to
ignore conflicts.
test_load=# LOAD DATA INFILE '/home/omm/load2.csv' IGNORE INTO TABLE load_data_tbl1;
-- Data in the load_data_tbl1 table remains unchanged, and conflicting data is skipped.
test_load=# SELECT * FROM load_data_tbl1 ORDER BY load_col1;
load_col1 | load_col2 | load_col3

test_load=# DROP TABLE load_data_tbl2;
test_load=# DROP TABLE load_data_tbl3;
```

1.13.15.2 LOCK

Description

LOCK TABLE obtains a table-level lock.

GaussDB always tries to select the lock mode with minimum restrictions when automatically requesting a lock for a statement referenced by a table. Use LOCK if users need a more strict lock mode. For example, suppose an application runs a transaction at the **READ COMMITTED** isolation level and needs to ensure that data in a table remains stable in the duration of the transaction. To achieve this, you could obtain **SHARE** lock mode over the table before the query. This prevents data from being concurrently modified, ensuring that subsequent queries can read committed and persistent data. It is because the **SHARE** lock mode conflicts with

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

the **ROW EXCLUSIVE** lock acquired by writers, and your **LOCK TABLE name IN SHARE MODE** statement will wait until any concurrent holders of **ROW EXCLUSIVE** mode locks commit or roll back. Therefore, once you obtain the lock, there are no uncommitted writes outstanding; furthermore none can begin until you release the lock.

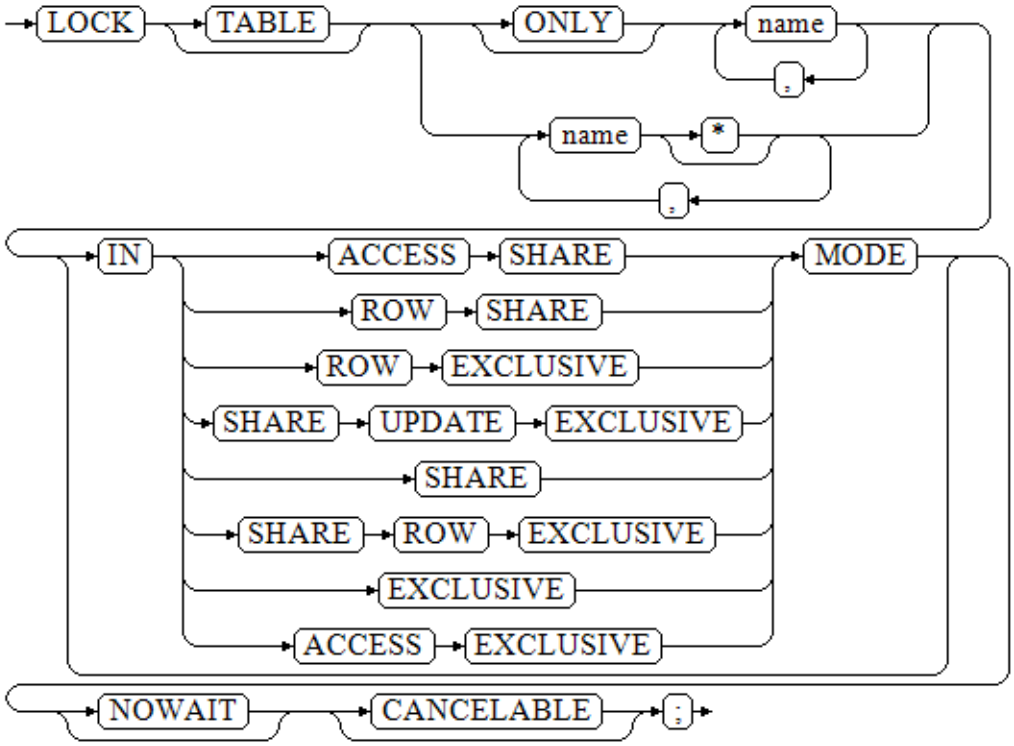
Precautions

- LOCK TABLE is useless outside a transaction block: the lock would remain held only to the completion of the statement. If LOCK TABLE is out of any transaction block, an error is reported.
- If no lock mode is specified, then **ACCESS EXCLUSIVE**, the most restrictive mode, is used.
- LOCK TABLE ... **IN ACCESS SHARE MODE** requires the SELECT permission on the target table. All other forms of LOCK require table-level UPDATE and/or the DELETE permission.
- There is no UNLOCK TABLE statement. Locks are always released at transaction end.
- LOCK TABLE only deals with table-level locks, and so the mode names involving **ROW** are all misnomers. These mode names should generally be read as indicating the intention of the user to acquire row-level locks within the locked table. Also, **ROW EXCLUSIVE** mode is a shareable table lock. Note that all lock modes have the same semantics as long as LOCK TABLE is involved. The only difference lies in whether locks conflict with each other. For details about the rules, see **Table 1-404**.
- If the xc_maintenance_mode parameter is not enabled, an error is reported when an ACCESS EXCLUSIVE lock is applied for a system catalog.
- Only the redistribution tool can use the automatic CANCEL service API.

Syntax

```
LOCK [ TABLE ] {[ ONLY ] name [, ...]| {name [ * ]} [, ...]}
    [ IN {ACCESS SHARE | ROW SHARE | ROW EXCLUSIVE | SHARE UPDATE EXCLUSIVE | SHARE | SHARE
ROW EXCLUSIVE | EXCLUSIVE | ACCESS EXCLUSIVE} MODE ]
    [ NOWAIT ][CANCELABLE];
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.



Parameters

Table 1-404 Lock mode conflicts

Requested Lock Mode/ Current Lock Mode	ACCESS SHARE	ROW SHARE	ROW EXCLUSIVE	SHARE UPDATE EXCLUSIVE	SHARE	SHARE ROW EXCLUSIVE	EXCLUSIVE	ACCESS EXCLUSIVE
ACCESS SHARE	-	-	-	-	-	-	-	X
ROW SHARE	-	-	-	-	-	-	X	X
ROW EXCLUSIVE	-	-	-	-	X	X	X	X
SHARE UPDATE EXCLUSIVE	-	-	-	X	X	X	X	X

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Requested Lock Mode/ Current Lock Mode	ACCESS SHARE	ROW SHARE	ROW EXCLUSIVE	SHARE UPDATE EXCLUSIVE	SHARE	SHARE ROW EXCLUSIVE	EXCLUSIVE	ACCESS EXCLUSIVE
SHARE	-	-	X	X	-	X	X	X
SHARE ROW EXCLUSIVE	-	-	X	X	X	X	X	X
EXCLUSIVE	-	X	X	X	X	X	X	X
ACCESS EXCLUSIVE	X	X	X	X	X	X	X	X

LOCK parameters are as follows:

- **name**

  Specifies the name (optionally schema-qualified) of an existing table to lock.

  Tables are locked one-by-one in the order specified in the LOCK TABLE statement.

  Value range: existing table names.

  NOTE

  You can use database links to perform operations on remote tables. For details, see "Feature Usage Guidelines > Database Links" in *Developer Guide*.

- **ONLY**

  If **ONLY** is specified, only that table is locked. If it is not specified, the table and all its sub-tables are locked.

- **ACCESS SHARE**

  Allows only read operations on a table. In general, any SQL statements that only read a table and do not modify it will acquire this lock mode. The SELECT statement acquires an **ACCESS SHARE** lock on referenced tables.

- **ROW SHARE**

  Allows concurrent read of a table but does not allow any other operations on the table.

  SELECT FOR UPDATE and **SELECT FOR SHARE** automatically acquire the **ROW SHARE** lock on the target table and add the **ACCESS SHARE** lock to other referenced tables except **FOR SHARE** and **FOR UPDATE**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

For a partitioned table, **SELECT FOR SHARE** obtains the **ROW EXCLUSIVE** lock of the partition object on the DN for concurrency control.

- **ROW EXCLUSIVE**

  Allows concurrent read of a table but does not allow modification of data in the table. **ROW EXCLUSIVE** is the same as **ROW SHARE**. **UPDATE**, **DELETE**, and **INSERT** automatically acquire this lock on the target table and add the **ACCESS SHARE** lock to other referenced tables. Generally, all statements that modify table data acquire the **ROW EXCLUSIVE** lock for tables.

- **SHARE UPDATE EXCLUSIVE**

  Protects a table against concurrent schema changes and **VACUUM** runs.

  The VACUUM (without FULL), ANALYZE, and CREATE INDEX CONCURRENTLY statements automatically request this lock.

- **SHARE**

  Allows concurrent queries of a table but does not allow modification of the table.

  The CREATE INDEX (without CONCURRENTLY) statement automatically requests this lock.

- **SHARE ROW EXCLUSIVE**

  Protects a table against concurrent data changes, and is self-exclusive so that only one session can hold it at a time.

  No SQL statements automatically acquire this lock mode.

- **EXCLUSIVE**

  Allows concurrent queries of the target table but does not allow any other operations.

  This mode allows only concurrent ACCESS SHARE locks; that is, only reads from the table can proceed concurrently with a transaction holding this lock mode.

  No SQL statements automatically acquire this lock mode on user tables. However, it will be acquired on some system catalogs in case of some operations.

- **ACCESS EXCLUSIVE**

  Guarantees that the holder is the only transaction accessing the table in any way.

  Acquired by the **ALTER TABLE**, **DROP TABLE**, **TRUNCATE**, **REINDEX**, **CLUSTER**, and **VACUUM FULL** commands.

  This is also the default lock mode for LOCK TABLE statements that do not specify a mode explicitly.

- **NOWAIT**

  Specifies that LOCK TABLE does not wait for any conflicting locks to be released. If the lock cannot be obtained immediately, the command exits and an error message is displayed.

  If a table-level lock is obtained without specifying **NOWAIT** and other mutex locks exist, the system waits for other locks to be released.

- **CANCELABLE**

  Allows the waiting thread to send CANCEL signals to the holding threads and waiting threads.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Only the redistribution tool can use this parameter. An error message is displayed when the parameter is used by users.

Examples

- SHARE ROW EXCLUSIVE

```
-- Create a schema.
gaussdb=# CREATE SCHEMA tpcds;

-- Create the tpcds.reason table.
gaussdb=# CREATE TABLE tpcds.reason (
r_reason_sk         INTEGER      NOT NULL,
r_reason_id         CHAR(16)     NOT NULL,
r_reason_desc       INTEGER
);

-- Insert multiple records into the table.
gaussdb=# INSERT INTO tpcds.reason VALUES (1, 'AAAAAAAABAAAAAAA', '18'),(5,
'AAAAAAAACAAAAAAA', '362'),(7, 'AAAAAAAADAAAAAAA', '585');

-- Create a table named reason_t1.
gaussdb=# CREATE TABLE tpcds.reason_t1 AS TABLE tpcds.reason;

-- Start a transaction.
gaussdb=# START TRANSACTION;

-- Use the SHARE ROW EXCLUSIVE MODE lock mode to lock a table.
gaussdb=# LOCK TABLE tpcds.reason_t1 IN SHARE ROW EXCLUSIVE MODE;

-- If you perform the DELETE operation on another device, the operation is blocked.
gaussdb=# DELETE FROM tpcds.reason_t1 WHERE r_reason_sk = 7;

-- End the transaction and release the lock.
gaussdb=# COMMIT;
```

- ROW EXCLUSIVE

```
-- Start a transaction.
gaussdb=# START TRANSACTION;

-- After the UPDATE statement is executed, request a ROW EXCLUSIVE lock on the referenced table.
gaussdb=# UPDATE tpcds.reason_t1 SET r_reason_desc=180 WHERE r_reason_sk=1;

-- When the ALTER TABLE statement is executed on another device, the operation is blocked.
gaussdb=# ALTER TABLE tpcds.reason_t1 ADD r_reason_asc int;

-- End the transaction and release the lock.
gaussdb=# COMMIT;
```

- ACCESS EXCLUSIVE

```
-- Start a transaction.
gaussdb=# START TRANSACTION;

-- After the TRUNCATE statement is executed, request an ACCESS SHARE lock on the referenced table.
gaussdb=# TRUNCATE tpcds.reason_t1;

-- When the SELECT statement is executed on another device, the operation is blocked.
gaussdb=# SELECT * FROM tpcds.reason_t1;

-- End the transaction and release the lock.
gaussdb=# COMMIT;

-- Drop the tpcds.reason_t1 table.
gaussdb=# DROP TABLE tpcds.reason_t1;

-- Drop the tpcds.reason table.
gaussdb=# DROP TABLE tpcds.reason;

-- Drop the schema.
gaussdb=# DROP SCHEMA tpcds CASCADE;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

1.13.15.3 LOCK BUCKETS

Description

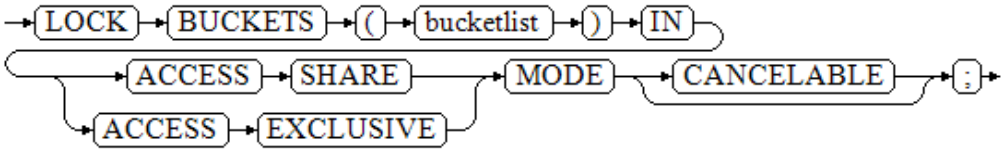
Bucket-based lock.

Precautions

- It can be called only during hash bucket scaling out.
- LOCK BUCKETS is useless outside a transaction block: the lock would remain held only to the completion of the statement. If LOCK BUCKETS is out of any transaction block, an error is reported.

Syntax

```
LOCK BUCKETS (bucketlist) IN {ACCESS SHARE|ACCESS EXCLUSIVE} MODE [CANCELABLE];
```



Parameters

Parameters of LOCK BUCKETS are as follows:

- **bucketlist**

  Specifies the list of buckets to be locked.

  Value range: For each bucket, the value range is [0,1023].
- **ACCESS SHARE**

  Allows only read operations on a bucket.
- **ACCESS EXCLUSIVE**

  Guarantees that the holder is the only transaction accessing the bucket in any way.
- **CANCELABLE**

  Allows the waiting thread to send CANCEL signals to the holding threads and waiting threads.

Examples

```
gaussdb=# START TRANSACTION;

gaussdb=# LOCK BUCKETS (0,1,2,3) IN ACCESS EXCLUSIVE MODE;

gaussdb=# COMMIT;
```

1.13.16 M

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

1.13.16.1 MARK BUCKETS

Description

Used by the scale-out tool to notify the kernel of the buckets that have been migrated.

Precautions

It can be called by administrators only during hash bucket scale-out.

Syntax

```
MARK BUCKETS (bucketlist) FINISH FROM datanode_name TO datanode_name;
```

Parameters

- **bucketlist**

  Specifies the list of buckets that have been migrated.

  Value range: For each bucket, the value range is [0,1023].

- **datanode_name**

  Specifies the name of the node involved in bucket migration.

  Value range: character strings complying with **Identifier Naming Conventions**.

Examples

```
gaussdb=# MARK BUCKETS (0,1,2,3) FINISH FROM datanode1 TO datanode3;
```

1.13.16.2 MERGE INTO

Description

MERGE INTO conditionally matches data in a target table with that in a source table. If data matches, UPDATE is executed on the target table; if data does not match, INSERT is executed. You can use this syntax to run UPDATE and INSERT at a time for convenience.

Precautions

- You have the INSERT and UPDATE permissions for the target table and the SELECT permission for the source table.
- MERGE INTO cannot be executed during redistribution.
- If the source table of the MERGE INTO operation contains data columns that are dynamically anonymized, the result of inserting data to or updating data in the target table is the anonymized value and cannot be restored.
- The STREAM plan of MERGE INTO does not allow concurrent DELETE and UPDATE operations, but other plans do.
- The MERGE INTO statement does not support triggers.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Syntax

```
MERGE [/*+ plan_hint */] INTO table_name [ [ AS ] alias ]
USING { { table_name | view_name } | subquery } [ [ AS ] alias ]
ON ( condition )
[
  WHEN MATCHED THEN
  UPDATE SET { column_name = { expression  | DEFAULT } |
         ( column_name [, ...] ) = ( { expression  | DEFAULT } [, ...] ) } [, ...]
  [ WHERE condition ]
]
[
  WHEN NOT MATCHED THEN
  INSERT { DEFAULT VALUES |
  [ ( column_name [, ...] ) ] VALUES ( { expression  | DEFAULT } [, ...] ) [, ...] [ WHERE condition ] }
];
```

Parameters

- plan_hint clause

  Follows the MERGE keyword in the /*+ */ format. It is used to optimize the plan of a MERGE statement block using hints. For details, see "Hint-based Optimization" in *SQL Optimization Guide*. In each statement, only the first **/*+** *plan_hint* ***/** comment block takes effect as a hint. Multiple hints can be written.

- INTO clause

  Specifies the target table that is being updated or has data being inserted. If the target table is a replication table, the default value of a column (such as auto-increment column) in the target table cannot be the volatile function. If **enable_stream_operator** is set to **off**, the target table must contain a primary key or UNIQUE and NOT NULL constraints.

  - **table_name**

    Specifies the name of the target table.

  - **alias**

    Specifies the alias of the target table.

    Value range: character strings complying with **Identifier Naming Conventions**.

- USING clause

  Specifies the source table, which can be a table, view, or subquery. If the target table is a replication table, the USING clause cannot contain non-replication tables.

  - **table_name | view_name**

    Name of the source table or view.

  - **subquery**

    A subquery that provides the rows to be merged into the target table.

- ON clause

  condition

  Specifies the condition used to match data between the source and target tables. Columns in the condition cannot be updated.

- WHEN MATCHED clause

  Performs UPDATE if data in the source table matches that in the target table based on the condition. For details about the syntax, see **UPDATE**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Distribution keys cannot be updated. System catalogs and system columns cannot be updated.

- WHEN NOT MATCHED clause

  Performs INSERT if data in the source table does not match that in the target table based on the condition. For details about the syntax, see **INSERT**.

  An INSERT clause cannot contain multiple VALUES.

  The order of WHEN MATCHED and WHEN NOT MATCHED clauses can be reversed. One of them can be used by default, but they cannot be both used at one time. Two WHEN MATCHED or WHEN NOT MATCHED clauses cannot be specified at the same time.

- **DEFAULT**

  Specifies the default value of a column.

  The value is **NULL** if there is no default value.

- WHERE condition

  Specifies the conditions for the UPDATE and INSERT clauses. The two clauses will be executed only when the conditions are met. The default value can be used. System columns cannot be referenced in WHERE condition. You are advised not to use numeric types such as int as conditions because such types can be implicitly converted to bool values (non-zero values are implicitly converted to **true** and **0** is implicitly converted to **false**), which may cause unexpected results.

Examples

```
-- Create the target table products and source table newproducts, and insert data to them.
gaussdb=# CREATE TABLE products
(
product_id INTEGER,
product_name VARCHAR2(60),
category VARCHAR2(60)
);

gaussdb=# INSERT INTO products VALUES (1501, 'vivitar 35mm', 'electrncs');
gaussdb=# INSERT INTO products VALUES (1502, 'olympus is50', 'electrncs');
gaussdb=# INSERT INTO products VALUES (1600, 'play gym', 'toys');
gaussdb=# INSERT INTO products VALUES (1601, 'lamaze', 'toys');
gaussdb=# INSERT INTO products VALUES (1666, 'harry potter', 'dvd');

gaussdb=# CREATE TABLE newproducts
(
product_id INTEGER,
product_name VARCHAR2(60),
category VARCHAR2(60)
);

gaussdb=# INSERT INTO newproducts VALUES (1502, 'olympus camera', 'electrncs');
gaussdb=# INSERT INTO newproducts VALUES (1601, 'lamaze', 'toys');
gaussdb=# INSERT INTO newproducts VALUES (1666, 'harry potter', 'toys');
gaussdb=# INSERT INTO newproducts VALUES (1700, 'wait interface', 'books');

-- Run MERGE INTO.
gaussdb=# MERGE INTO products p
USING newproducts np
ON (p.product_id = np.product_id)
WHEN MATCHED THEN
  UPDATE SET p.product_name = np.product_name, p.category = np.category WHERE p.product_name !=
'play gym'
WHEN NOT MATCHED THEN
  INSERT VALUES (np.product_id, np.product_name, np.category) WHERE np.category = 'books';
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
MERGE 4

-- Query updates.
gaussdb=# SELECT * FROM products ORDER BY product_id;
 product_id |  product_name  | category
------------+----------------+----------
       1501 | vivitar 35mm   | electrncs
       1502 | olympus camera | electrncs
       1600 | play gym       | toys
       1601 | lamaze         | toys
       1666 | harry potter   | toys
       1700 | wait interface | books
(6 rows)

-- Drop tables.
gaussdb=# DROP TABLE products;
gaussdb=# DROP TABLE newproducts;
```

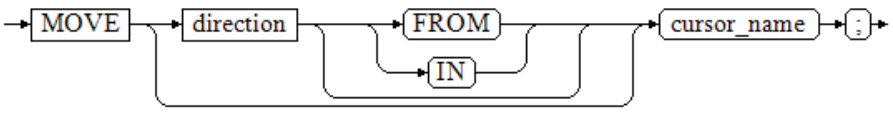
1.13.16.3 MOVE

Description

MOVE repositions a cursor without retrieving any data. MOVE works exactly like the **FETCH** statement, except MOVE only repositions the cursor and does not return rows.

Syntax

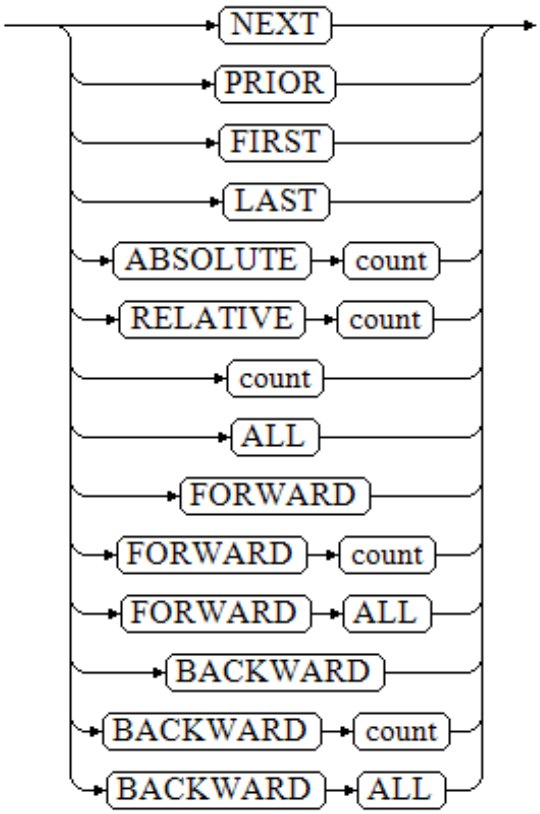
```
MOVE [ direction [ FROM | IN ] ] cursor_name;
```



The direction clause specifies optional parameters.

```
{ NEXT
  | PRIOR
  | FIRST
  | LAST
  | ABSOLUTE count
  | RELATIVE count
  | count
  | ALL
  | FORWARD
  | FORWARD count
  | FORWARD ALL
  | BACKWARD
  | BACKWARD count
  | BACKWARD ALL }
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.



Parameters

The parameters of MOVE and FETCH are the same. For details, see **Parameters** in **FETCH**.

NOTE

On successful completion, a MOVE statement returns a tag of the form **MOVE count**. The **count** is the number of rows that a FETCH statement with the same parameters would have returned (possibly zero).

Examples

```
-- Create a table and insert data into the table.
gaussdb=# CREATE TABLE tbl_test(c1 int);
gaussdb=# INSERT INTO tbl_test VALUES (generate_series(1,20));

-- Set up cursor1.
gaussdb=# BEGIN;
gaussdb=# CURSOR cursor1 FOR SELECT * FROM tbl_test ORDER BY 1;

-- Run the MOVE command to move the cursor backwards by five rows. No result is returned.
gaussdb=# MOVE FORWARD 5 FROM cursor1;
MOVE 5

-- Run the FETCH command to retrieve two rows of data.
gaussdb=# FETCH FORWARD 2 FROM cursor1;
 c1
----
  6
  7
(2 rows)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
-- Close the cursor and end the transaction.
gaussdb=# CLOSE cursor1;
gaussdb=# END;

-- Delete.
gaussdb=# DROP TABLE tbl_test;
```

Helpful Links

CLOSE and **FETCH**

1.13.17 P

1.13.17.1 PREDICT BY

Description

Uses a trained model to perform prediction tasks.

Precautions

This syntax is not supported currently.

1.13.17.2 PREPARE

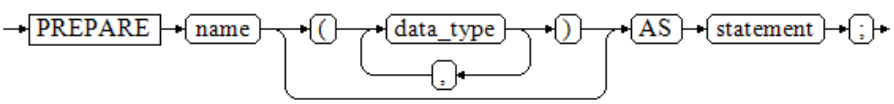
Description

Creates a prepared statement.

A prepared statement is a performance optimizing object on the server. When the PREPARE statement is executed, the specified query is parsed, analyzed, and rewritten. When EXECUTE is executed, the prepared statement is planned and executed. This avoids repetitive parsing and analysis. After the PREPARE statement is created, it exists throughout the database session. Once it is created (even if in a transaction block), it will not be deleted when a transaction is rolled back. Unless automatically deleted upon session termination, the PREPARE statement can only be deleted by explicitly calling **DEALLOCATE**.

Syntax

```
PREPARE name [ ( data_type [, ...] ) ] AS statement;
```



Parameters

- **name**

  Prepared statement name. It must be unique in the session.

- **data_type**

  Specifies the type of an argument.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **statement**

  Specifies a SELECT, INSERT, UPDATE, DELETE, MERGE INTO, or VALUES statement.

  NOTE

  During the parsing of the PREPARE statement, all parameters are parsed to the unknown data type by default. If the parsing involves the selection of operators or functions, follow the rules for handling parameters of the unknown type in **Operators** and **Functions**.

Examples

See **Examples** in section "EXECUTE."

DEALLOCATEand **EXECUTE**

1.13.17.3 PREPARE TRANSACTION

Description

Prepares the current transaction for two-phase commit.

After this statement, the transaction is no longer associated with the current session; instead, its state is fully stored on disk, and there is a high probability that it can be committed successfully, even if a database crash occurs before the commit is requested.

Once prepared, a transaction can be committed using **COMMIT PREPARED** or rolled back using **ROLLBACK PREPARED**. Those statements can be issued from any session, not only the one that executed the original transaction.

From the point of view of the issuing session, **PREPARE TRANSACTION** is not unlike a **ROLLBACK** statement: after executing it, there is no active current transaction, and the effects of the prepared transaction are no longer visible. (The effects will become visible again if the transaction is committed.)

If the **PREPARE TRANSACTION** statement fails for any reason, it becomes a **ROLLBACK** and the current transaction is canceled.

Precautions

- The transaction function is maintained automatically by the database, and should be not visible to users.
- Currently, the distributed system does not allow users to call the user-defined PREPARE TRANSACTION operation. This syntax is reserved only for local two-phase cleanup on CNs in maintenance mode (the GUC parameter **xc_maintenance_mode** is set to **on**) and does not ensure the global transaction capability.
- When running the **PREPARE TRANSACTION** statement, increase the value of **max_prepared_transactions** in configuration file **gaussdb.conf**. You are advised to set it to a value not less than that of **max_connections** so that one pending prepared transaction is available for each session.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Syntax

```
PREPARE TRANSACTION transaction_id;
```

Parameters

transaction_id

Specifies an arbitrary identifier that later identifies this transaction for **COMMIT PREPARED** or **ROLLBACK PREPARED**. The identifier must be different from those for current prepared transactions.

Value range: The identifier must be written as a string literal, and must be less than 200 bytes long.

Examples

```
-- Start a transaction in maintenance mode.
gaussdb=# SET XC_MAINTENANCE_MODE = ON;
SET

gaussdb=# BEGIN;
BEGIN

-- Prepare a transaction whose identifier is trans_test.
gaussdb=# PREPARE TRANSACTION 'trans_test';
PREPARE TRANSACTION

-- Cancel the transaction whose identifier is trans_test.
gaussdb=# ROLLBACK PREPARED 'trans_test';
ROLLBACK PREPARED
```

COMMIT PREPARED and **ROLLBACK PREPARED**

1.13.17.4 PURGE

Description

The PURGE statement can be used to:

- Clear tables or indexes from the recycle bin and release all space related to the objects.
- Clear the recycle bin.

Precautions

- The PURGE operation supports tables (PURGE TABLE), indexes (PURGE INDEX), and recycle bins (PURGE RECYCLEBIN).
- The permission requirements for performing the PURGE operation are as follows:
  - **PURGE TABLE**: The user must be the owner of the table and must have the USAGE permission on the schema to which the table belongs. When

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

separation of duties is disabled, system administrators have this authorization by default.

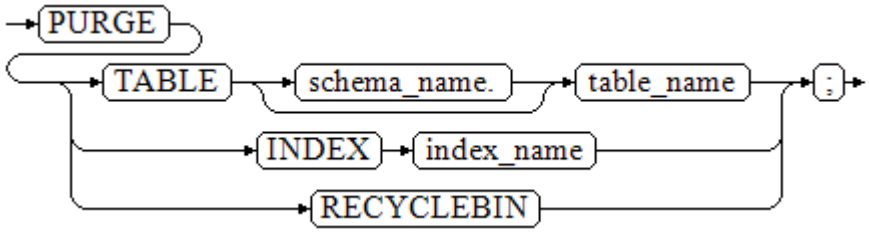
- **PURGE INDEX**: The user must be the owner of the index and must have the USAGE permission on the schema to which the index belongs. When separation of duties is disabled, system administrators have this authorization by default.
- **PURGE RECYCLEBIN**: Only users with the SYSADMIN or SYSDBA permissions can perform this operation. Common users do not have these permissions. Common users can purge only the objects owned by themselves in the recycle bin. In addition, the user must have the USAGE permission of the schema to which the objects belong. When the separation of duties is disabled, system administrators can purge all objects in the recycle bin by default.

Prerequisites

- The **enable_recyclebin** parameter has been enabled to enable the table-level recycle bin. For details about how to use the parameter, contact an administrator.
- The **recyclebin_retention_time** parameter has been set to specify how long objects will remain in the recycle bin before being automatically deleted. Contact an administrator for the parameter usage.

Syntax

```
PURGE { TABLE [schema_name.]table_name
      | INDEX index_name
      | RECYCLEBIN
    };
```



Parameters

- **schema_name**

  Specifies a schema name.
- **TABLE [schema_name.] table_name**

  Clears a specified table in the recycle bin. The table can be schema-qualified.
- **INDEX index_name**

  Clears a specified index in the recycle bin.
- **RECYCLEBIN**

  Clears all objects in the recycle bin.

Examples

```
-- Create the reason_t1 table.
gaussdb=# CREATE TABLE reason_t1(
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
    r_reason_sk    integer,
    r_reason_id    character(16),
    r_reason_desc  character(100)
) WITH(STORAGE_TYPE = ustore);

-- Create the reason_t2 table.
gaussdb=# CREATE TABLE reason_t2(
    r_reason_sk    integer,
    r_reason_id    character(16),
    r_reason_desc  character(100)
) WITH(STORAGE_TYPE = ustore);

-- Add indexes to the reason_t1 and reason_t2 tables.
gaussdb=#  CREATE INDEX idx_t1 on reason_t1(r_reason_id);
gaussdb=#  CREATE INDEX idx_t2 on reason_t2(r_reason_id);
gaussdb=#  DROP TABLE reason_t1;
gaussdb=#  DROP TABLE reason_t2;

-- View the recycle bin.
gaussdb=#  SELECT rcyname,rcyoriginname,rcytablespace FROM GS_RECYCLEBIN;
          rcyname            | rcyoriginname | rcytablespace
-----------------------------+---------------+---------------
 BIN$31C94EB4207$8001$0==$0 | reason_t1     |             0

 BIN$31C94EB420A$8004$0==$0 | reason_t2     |             0
 BIN$31C94EB420E$8004$0==$0 | idx_t2        |             0
(4 rows)

-- Purge the table.
gaussdb=#  PURGE TABLE reason_t1;
gaussdb=#  SELECT rcyname,rcyoriginname,rcytablespace FROM GS_RECYCLEBIN;
          rcyname            | rcyoriginname | rcytablespace
-----------------------------+---------------+---------------
 BIN$31C94EB420A$8004$0==$0 | reason_t2     |             0
 BIN$31C94EB420E$8004$0==$0 | idx_t2        |             0
(2 rows)

-- Purge the index.
gaussdb=# PURGE INDEX idx_t2;
gaussdb=# SELECT rcyname,rcyoriginname,rcytablespace FROM GS_RECYCLEBIN;
          rcyname            | rcyoriginname | rcytablespace
-----------------------------+---------------+---------------
 BIN$31C94EB420A$8004$0==$0 | reason_t2     |             0
(1 row)

-- Purge all objects in the recycle bin.
gaussdb=#  PURGE recyclebin;
gaussdb=#  SELECT rcyname,rcyoriginname,rcytablespace FROM GS_RECYCLEBIN;
        rcyname         | rcyoriginname | rcytablespace
------------------------+---------------+---------------
(0 rows)
```

1.13.18 R

1.13.18.1 REASSIGN OWNED

Description

Changes the owner of the database object.

REASSIGN OWNED changes the database object owner of an old role to a new role.

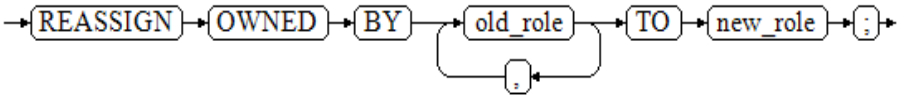
 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Precautions

- REASSIGN OWNED is often executed before role deletion.
- To run the REASSIGN OWNED statement, you must have the permissions of the original and target roles.

Syntax

```
REASSIGN OWNED BY old_role [, ...] TO new_role;
```



Parameters

- **old_role**

  Specifies the role name of the old owner.

- **new_role**

  Specifies the role name of the new owner. Note: Only the initial user can use the REASSIGN OWNED syntax to change the owner to the initial user.

Examples

```
-- Create the test_jim and test_tom users.
gaussdb=# CREATE USER test_jim PASSWORD '********';
gaussdb=# CREATE USER test_tom PASSWORD '********';

-- View the user with the same name as owner of the automatically created schema.
gaussdb=# \dn test*
   List of schemas
   Name   |  Owner
----------+----------
 test_jim | test_jim
 test_tom | test_tom
(2 rows)

-- Change the owner of all database objects owned by test_jim to test_tom.
gaussdb=# REASSIGN OWNED BY test_jim TO test_tom;

-- View the schema information. The owner of the test_jim schema is changed to test_tom.
gaussdb=# \dn test*
   List of schemas
   Name   |  Owner
----------+----------
 test_jim | test_tom
 test_tom | test_tom
(2 rows)

-- Delete the test_jim and test_tom users.
gaussdb=# DROP USER test_jim, test_tom CASCADE;
```

Helpful Links

DROP OWNED

1.13.18.2 REFRESH INCREMENTAL MATERIALIZED VIEW

Description

REFRESH INCREMENTAL MATERIALIZED VIEW refreshes a materialized view in incremental mode.

Precautions

- Incremental refresh supports only fast-refresh materialized views.
- To refresh a materialized view, you must have the SELECT permission on the base table.

Syntax

```
REFRESH INCREMENTAL MATERIALIZED VIEW mv_name;
```

Parameters

- **mv_name**

  Name of the materialized view to be refreshed.

Examples

```
-- Create an ordinary table.
gaussdb=# CREATE TABLE my_table (c1 int, c2 int);

-- Create a fast-refresh materialized view.
gaussdb=# CREATE INCREMENTAL MATERIALIZED VIEW my_imv AS SELECT * FROM my_table;

-- Write data to the base table.
gaussdb=# INSERT INTO my_table VALUES(1,1),(2,2);

-- Fast refresh the fast-refresh materialized view my_imv.
gaussdb=# REFRESH INCREMENTAL MATERIALIZED VIEW my_imv;

-- View the fast-refresh materialized view.
gaussdb=# SELECT * FROM my_imv;
 c1 | c2
----+----
  1 |  1
  2 |  2
(2 rows)

-- Delete the fast-refresh materialized view.
gaussdb=# DROP MATERIALIZED VIEW my_imv;

-- Delete the my_table table.
gaussdb=# DROP TABLE my_table;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

1.13.18.3 REFRESH MATERIALIZED VIEW

Description

REFRESH MATERIALIZED VIEW refreshes materialized views in complete-refresh mode.

Precautions

- Full refreshing can be performed on both complete- and fast-refresh materialized views.
- To refresh a materialized view, you must have the SELECT permission on the base table.

Syntax

```
REFRESH MATERIALIZED VIEW mv_name;
```

Parameters

mv_name

Name of the materialized view to be refreshed.

Examples

```
-- Create an ordinary table.
gaussdb=# CREATE TABLE my_table (c1 int, c2 int);

-- Create a complete-refresh materialized view.
gaussdb=# CREATE MATERIALIZED VIEW my_mv AS SELECT * FROM my_table;

-- Create a fast-refresh materialized view.
gaussdb=# CREATE INCREMENTAL MATERIALIZED VIEW my_imv AS SELECT * FROM my_table;

-- Write data to the base table.
gaussdb=# INSERT INTO my_table VALUES(1,1),(2,2);

-- Completely refresh the complete-refresh materialized view my_mv.
gaussdb=# REFRESH MATERIALIZED VIEW my_mv;

-- Completely refresh the fast-refresh materialized view my_imv.
gaussdb=# REFRESH MATERIALIZED VIEW my_imv;

-- Delete the fast-refresh materialized view.
gaussdb=# DROP MATERIALIZED VIEW my_imv;

-- Delete the complete-refresh materialized view.
gaussdb=# DROP MATERIALIZED VIEW my_mv;

-- Delete the my_table table.
gaussdb=# DROP TABLE my_table;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Helpful Links

ALTER MATERIALIZED VIEW, **CREATE INCREMENTAL MATERIALIZED VIEW**, **CREATE MATERIALIZED VIEW**, **CREATE TABLE**, **DROP MATERIALIZED VIEW**, and **REFRESH INCREMENTAL MATERIALIZED VIEW**

1.13.18.4 REFRESH SYSTEM OBJECT

Description

Updates the version information of system objects to the system catalog **GS_SYSTEM_OBJECTS_VERSION** to determine the changes of system objects during the upgrade.

It can be called during the upgrade from a version earlier than 507.0. This is an internal syntax; its use is therefore discouraged.

Precautions

- This statement can be called only in the upgrade phase. That is, this statement can be executed only when the GUC parameter **upgrade_mode** is not set to **0**.
- Only the initial user has permission to execute this statement.

Syntax

```
REFRESH SYSTEM OBJECT;
```

1.13.18.5 REINDEX

Description

Rebuilds an index using the data stored in the index's table, replacing the old copy of the index.

There are several scenarios in which REINDEX can be used:

- An index has become corrupted, and no longer contains valid data.
- An index has become "bloated", that is, it contains many empty or nearly-empty pages.
- You have altered a storage parameter (such as fillfactor) for an index, and wish that the change takes full effect.
- After an index becomes invalid, its statistics are not updated. You are advised to reindex it.

Precautions

- REINDEX DATABASE and REINDEX SYSTEM cannot be performed in transaction blocks.
- Currently, only REINDEX INDEX and REINDEX TABLE are supported for global secondary indexes.

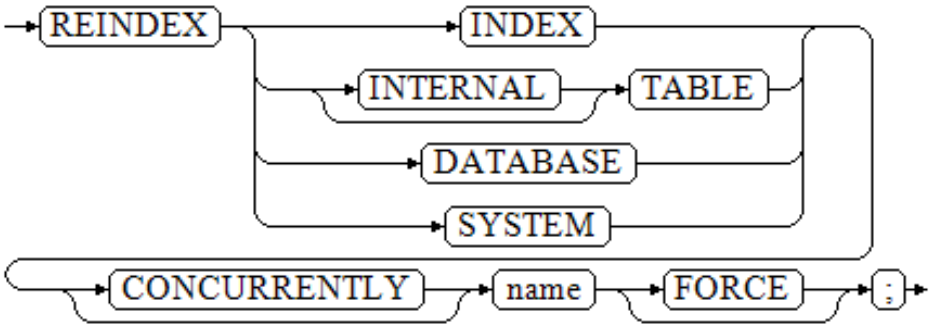
 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- When REINDEX is executed, if the index option **lpi_parallel_method** is set to **PARTITION** and the table option **parallel_workers** is set to a value greater than 0, indexes are rebuilt in parallel by partition. If the **lpi_parallel_method** option is not set or is set to **AUTO**, indexes are rebuilt in parallel by page by default.
- When REINDEX CONCURRENTLY is used to rebuild indexes online, the index sequence in the table changes, and the query plan may change.
- REINDEX [CONCURRENTLY] does not support the modification of the RCR and PCR types of UB-tree indexes. That is, the index type after REINDEX is the same as that when the index is created.
- REINDEX CONCURRENTLY rebuilds indexes online. Indexes based on the **rowid** system column cannot be rebuilt.

Syntax

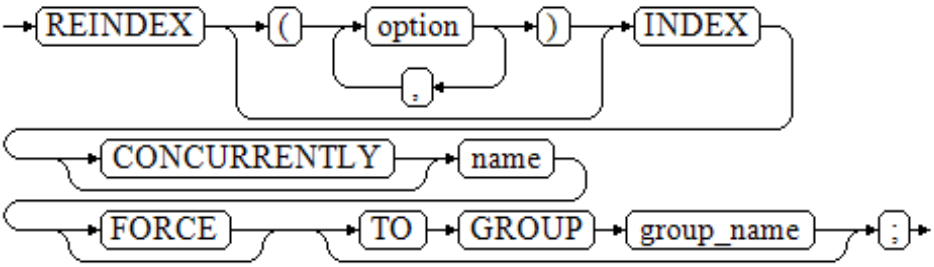
- Rebuild an ordinary index.

```
REINDEX { INDEX | [INTERNAL] TABLE | DATABASE | SYSTEM } [ CONCURRENTLY ] name [ FORCE ];
```



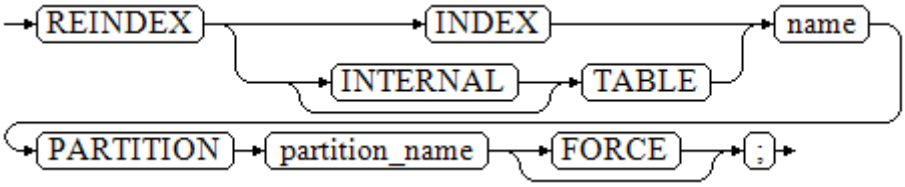
- Rebuild the index and convert the type.

```
REINDEX [ ( option [, ...] ) ] { INDEX } [ CONCURRENTLY ] name [ FORCE ] [TO GROUP group_name];
```



- Rebuild an index partition.

```
REINDEX { INDEX | [INTERNAL] TABLE } name
   PARTITION partition_name [ FORCE ];
```



Parameters

- **INDEX**

  Rebuilds the specified index.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **TABLE**

  Rebuilds all indexes of a specified table. The TOAST table (if any) of the table is reindexed as well. If an index on the table has been invalidated by running **alter unusable**, the index cannot be rebuilt. Indexes in the TOAST table cannot be rebuilt when specifying the **CONCURRENTLY** option.

- **DATABASE**

  Rebuilds all indexes within the current database. Indexes in the TOAST table within the current database cannot be rebuilt when specifying the CONCURRENTLY option.

- **SYSTEM**

  Rebuilds all indexes on system catalogs within the current database. Indexes on user tables are not processed.

- **option**

  Currently, **CROSSBUCKET** and **TABLEOIDTRANS** are supported. For **CROSSBUCKET**, the value can only be **ON** or **OFF**. For **TABLEOIDTRANS**, the value cannot be specified.

  a. **CROSSBUCKET** controls whether the index of a hash bucket table is converted to a cross-bucket index (CBI) or local-bucket index (LBI) during the REINDEX process. This conversion supports only the index of the distributed hash bucket table and does not support the GSI index. In the current version, only the session of the scale-out process can use the online index type conversion.

  b. **TABLEOIDTRANS** controls whether the internal data format of the GSI index on a hash bucket table is converted during index rebuilding.

- **CONCURRENTLY**

  Rebuilds an index (with ShareUpdateExclusiveLock) in non-blocking DML mode. When an index is rebuilt, other statements cannot access the table on which the index depends. If this keyword is specified, DML is not blocked during the recreation. Indexes in system catalogs cannot be rebuilt online. REINDEX INTERNAL TABLE CONCURRENTLY, REINDEX SYSTEM CONCURRENTLY, and REINDEX INVALID INDEX CONCURRENTLY are not supported. When REINDEX DATABASE CONCURRENTLY is executed, all indexes on user tables in the current database are rebuilt online (indexes on system catalogs are not processed). REINDEX CONCURRENTLY cannot be executed within a transaction. Online index rebuilding supports only B-tree and UB-tree indexes, ordinary indexes, global indexes, and local indexes. PCR UB-tree indexes and subpartitions are not supported. GSIs can be rebuilt online using REINDEX INDEX CONCURRENTLY, but expression GSIs and partial GSIs cannot be rebuilt online. During online GSI rebuild, do not execute DDL statements concurrently with other DDL statements. Otherwise, deadlocks or errors may occur. You can reconnect to the client and try again. Online parallel index rebuilding supports only ordinary indexes, global indexes, local indexes, and GSIs of Astore and Ustore. Other online index rebuilding specifications are inherited from the current version. If online index rebuilding fails, the system automatically clears the new indexes to prevent resource occupation in scenarios such as manual cancellation, duplicate unique index key values, insufficient resources, thread startup failure, and lock timeout. The automatic index clearing process includes a phase where the system must wait for other database transactions to end. As a result, issues such as lock timeout and deadlock may occur, causing index clearing failures. If the system

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

cannot automatically clear invalid new indexes (for example, due to database crashes, FATAL, or PANIC), you need to manually clear invalid new indexes (using the DROP INDEX statement) and temporary tables (using the DROP TABLE statement) as soon as possible to prevent further resource occupation. Generally, the suffix of an invalid index is **_ccnew**. For GSIs, the prefix of an invalid new index is **ccgsi_tmp_index**_. In the distributed system, failed indexes in DNs are automatically cleared and those in CNs need to be manually cleared. If a critical error occurs, the metadata of the failed indexes cannot be found on some nodes in the distributed system. The DROP INDEX statement cannot be used to drop these indexes. You need to use the DROP INDEX IF EXISTS statement to drop them. The execution of REINDEX INDEX CONCURRENTLY adds a four-level session lock to the table and its first several phases are similar to those of CREATE INDEX CONCURRENTLY. Therefore, the execution may be suspended or deadlocked, which is similar to that of CREATE INDEX CONCURRENTLY. For example, if two sessions perform the REINDEX CONCURRENTLY operation on the same index or table at the same time, a deadlock occurs. For details, see **CONCURRENTLY** in **CREATE INDEX**.

NOTE

This keyword is specified when an index is rebuilt. For Astore, you need to complete two full table scans for building. During the first scan, a new index is created without blocking read and write operations. During the second scan, the changes in the first scan are merged and updated. For Ustore, you need to complete a full table scan. During the scan, data generated by concurrent DML operations is inserted into the temporary table named **index_oid_cctmp**. After the scan is complete, you merge the temporary table to the new index suffixed with **_ccnew{n}** (for GSIs, the prefix is **ccgsi_tmp_index**_), delete the temporary table, exchange the old and new indexes, mark the old index as dead, enable the new index, and rebuild the index.

If an online index rebuild operation is performed during the generation of a WDR snapshot, the error message "Could not open relation with OID %u." may be displayed, causing the WDR snapshot generation to fail. This is an expected behavior. After the index rebuild is complete, generate the WDR snapshot again.

- **name**

  Specifies the name of the index, table, or database whose index needs to be rebuilt. Tables and indexes can be schema-qualified.

  NOTE

  REINDEX DATABASE and SYSTEM can create indexes for only the current database. Therefore, **name** must be the same as the current database name.

- **FORCE**

  It is provided solely for syntax compatibility and does not serve any practical purpose.

- **TO GROUP group_name**

  Rebuilds the index to the specified node group named **group_name**. This option is used only in the scale-out process.

- **partition_name**

  Name of the index or table to be reindexed.

  The options are as follows:

  – If REINDEX INDEX is used, specify the name of an index.

  – If REINDEX TABLE is used, specify the name of a table.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTICE

- REINDEX DATABASE and REINDEX SYSTEM cannot be performed in transaction blocks.
- REINDEX and REINDEX CONCURRENTLY do not support separate operations on TOAST tables or TOAST indexes.
- During the execution of REINDEX CONCURRENTLY, an error may be reported for the stream plan involving indexes. Before executing REINDEX CONCURRENTLY, you can use an SQL patch or add hints to SQL statements to disable streaming and use the PGXC plan.

Examples

```
-- Create the table tbl_test and insert data into the tables.
gaussdb=# CREATE TABLE tbl_test(c1 int,c2 varchar) WITH (storage_type = ustore);
gaussdb=# INSERT INTO tbl_test VALUES (1, 'AAAAAAA'),(5, 'AAAAAAB'),(10, 'AAAAAAC');

-- Create an index and check the index size.
gaussdb=# CREATE INDEX idx_test_c1 ON tbl_test(c1);
gaussdb=# SELECT pg_size_pretty(pg_total_relation_size('idx_test_c1')) AS size;
  size
--------
 176 kB
(1 row)

-- Insert 10,000 data records and then delete the data. It is found that the index becomes larger.
gaussdb=# INSERT INTO tbl_test VALUES (generate_series(1,10000),'test');
gaussdb=# DELETE FROM tbl_test WHERE c2 = 'test';
gaussdb=# SELECT pg_size_pretty(pg_total_relation_size('idx_test_c1')) AS size;
  size
--------
 504 kB
(1 row)

-- After an independent index is rebuilt, the index size is restored to the initial size.
gaussdb=# REINDEX INDEX idx_test_c1;
gaussdb=# SELECT pg_size_pretty(pg_total_relation_size('idx_test_c1')) AS size;
  size
--------
 176 kB
(1 row)

-- Rebuild a single index online.
gaussdb=# REINDEX INDEX CONCURRENTLY idx_test_c1;

-- Rebuild all indexes in the table tbl_test.
gaussdb=# REINDEX TABLE tbl_test;

-- Rebuild all indexes in the table tbl_test online.
gaussdb=# REINDEX TABLE CONCURRENTLY tbl_test;

-- Drop the tbl_test table.
gaussdb=# DROP TABLE tbl_test;
```

Suggestions

- INTERNAL TABLE

  This scenario is used for fault recovery. You are advised not to perform concurrent operations.
- DATABASE

  You are advised not to reindex a database in a transaction.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- SYSTEM

  You are advised not to reindex a system catalog in a transaction.

1.13.18.6 RELEASE SAVEPOINT

Description

RELEASE SAVEPOINT destroys a savepoint previously defined in the current transaction.

Destroying a savepoint makes it unavailable as a rollback point, but it has no other user visible behavior. It does not undo the effects of statements executed after the savepoint was established. To do that, use **ROLLBACK TO SAVEPOINT**. Destroying a savepoint when it is no longer needed allows the system to reclaim some resources earlier than transaction end.

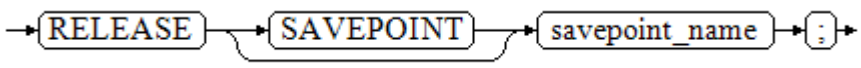
RELEASE SAVEPOINT also deletes all savepoints that were established after the named savepoint was established.

Precautions

- Releasing a savepoint name that was not previously defined will cause an error.
- It is not possible to release a savepoint when the transaction is in an aborted state.
- If multiple savepoints have the same name, only the one that was most recently defined is released.

Syntax

```
RELEASE [ SAVEPOINT ] savepoint_name;
```



Parameters

savepoint_name

Specifies the name of the savepoint you want to destroy.

Examples

```
-- Create a schema.
gaussdb=# CREATE SCHEMA tpcds;

-- Create a table.
gaussdb=# CREATE TABLE tpcds.table1(a int);

-- Start a transaction.
gaussdb=# START TRANSACTION;

--Insert data.
gaussdb=# INSERT INTO tpcds.table1 VALUES (3);

-- Create a savepoint.
gaussdb=# SAVEPOINT my_savepoint;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
--Insert data.
gaussdb=# INSERT INTO tpcds.table1 VALUES (4);

-- Delete the savepoint.
gaussdb=# RELEASE SAVEPOINT my_savepoint;

-- Query the table content. The table should contain both 3 and 4.
gaussdb=# SELECT * FROM tpcds.table1;
 a
---
 3
 4
(2 rows)

-- Commit the transaction.
gaussdb=# COMMIT;

-- Query the table content again. You can see 3 and 4 at the same time.
gaussdb=# SELECT * FROM tpcds.table1;
 a
---
 3
 4
(2 rows)

-- Drop the table.
gaussdb=# DROP TABLE tpcds.table1;

-- Delete the schema.
gaussdb=# DROP SCHEMA tpcds CASCADE;
```

Helpful Links

SAVEPOINT and **ROLLBACK TO SAVEPOINT**

1.13.18.7 RENAME TABLE

Description

In the same statement, changing the name of a single table or multiple tables does not affect the stored data.

Precautions

- To change the name of a single table, this syntax is equivalent to RENAME in ALTER TABLE.
- Changing the names of multiple tables is equivalent to running RENAME in ALTER TABLE for multiple times. However, changing the names of local and non-local temporary tables at the same time is not supported.

Syntax

Modify the table name.

```
RENAME { TABLE | TABLES } { table_name TO new_table_name } [,...];
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

If you run this command when **sql_compatibility** is set to **'MYSQL'**, **b_format_version** set to **'5.7'**, and **b_format_dev_version** set to **'s2'**, the following situations may occur:

- If the new table name starts with "#mysql50#" and is followed by other characters, "#mysql50#" will be ignored.
- If the old and new table names are the same, no error is reported.

Parameters

- **TABLE | TABLES**

  TABLE and TABLES can be used interchangeably, regardless of the number of tables operated in the statement.

- **table_name TO new_table_name**

  table_name indicates the name of the table to be modified.

  new_table_name indicates the new table name.

  TO is the connection word.

Examples of Modifying Tables

- Rename a single table.

```
gaussdb=# CREATE TABLE aa(c1 int, c2 int);
gaussdb=# RENAME TABLE aa TO test_alt1;
gaussdb=# DROP TABLE test_alt1;
```

- Rename multiple tables.

```
gaussdb=# CREATE TABLE aa(c1 int, c2 int);
gaussdb=# CREATE TABLE bb(c1 int, c2 int);
gaussdb=# RENAME TABLE aa TO test_alt1, bb TO test_alt2;
gaussdb=# DROP TABLE test_alt1,test_alt2;
```

ALTER TABLE

1.13.18.8 REPLACE

Description

Inserts data into a table or replaces existing data in a table. If the data to be inserted has the primary key or unique key conflicts with the existing data, the REPLACE statement deletes the existing data and then inserts the new data.

You can use REPLACE in the following ways:

- Replace or insert values. That is, VALUES or VALUE is used to construct a row of records and insert the row into the table.
- Replace or insert the query. One or more rows of records are constructed based on the result set returned by SELECT and inserted into a table.
- Set the value of a specified column. Similar to value insertion, the default value is used for columns that are not specified.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Precautions

- To execute this statement, you must have the DELETE and INSERT permissions on the table.
- If the primary key or unique key does not conflict, you can directly insert the data. If the primary key or unique key conflicts, delete the original data and then insert the new data.
- The return format of the REPLACE operation is **REPLACE 0** *X*, where *X* indicates the number of DELETE and INSERT operations.
- In the REPLACE...SELECT syntax, the number of columns in **select_list** must be the same as the number of columns to be inserted.
- In the REPLACE...SET syntax:
  - If **col_name** has a default value, **SET col_name = col_name + 1** is equivalent to **SET col_name =** *Default value of col_name* **+ 1**.
  - If **col_name** has neither default value nor NOT NULL constraint, **SET col_name = col_name + 1** is equivalent to **col_name = NULL**.
  - If **col_name** does not have a default value but has a NOT NULL constraint, the data types that support a default value are timestamp, timestamp with time zone, time, time with time zone, interval, tinterval, smalldatetime, date, datea (valid only in ORA-compatible mode), uuid, name, point, polygon, circle, lseg, box, json, jsonb, xml, varbit, numeric, cidr, inet, macaddr, numrange, int8range, int4range, tsrange, tstzrange, daterange, hash16, hash32, bool, bytea, char, bigint, int, smallint, tinyint, text, raw, blob, clob, float4, float8, abstime, reltime, bpchar, varchar, nvarchar2, money, uint1, uint2, uint4, uint8, and enum. The default values are described in the following table.

Data Type	Default Value of col_name
int8, int4, int2, int1, float8, float4, numeric, uint1, uint2, uint4, and uint8	**0**. If **numeric** specifies a decimal place, the decimal place is displayed. For example, **NUMERIC (10, 3): 0.000**
text, clob, bpchar, varchar, char, nvarchar2, name, blob, raw, and varbit	Empty string.
numrange, int8range, int4range, tsrange, tstzrange, and daterange	empty
bytea	\x
money	$0.00
json, jsonb, and xml	'null'
macaddr	00:00:00:00:00:00
inet	0.0.0.0
cidr	0.0.0.0/32
point	(0,0)

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Data Type	Default Value of col_name
lseg	[(0,0),(0,0)]
box	(0,0),(0,0)
path	((0,0))
polygon	((0,0))
circle	<(0,0),0>
uuid	00000000-0000-0000-0000-000000000000
hash16	0000000000000000
hash32	00000000000000000000000000000000
bool	f
abstime	abstime '1970-01-01 00:00:00'
reltime	reltime '00:00:00'
interval	interval '00:00:00'
tinterval	tinterval(abstime '1970-01-01 00:00:00', abstime '1970-01-01 00:00:00')
timestamp	timestamp '1970-01-01 00:00:00'
timestamp with time zone	timestamptz '1970-01-01 00:00:00'
date	date '1970-01-01'
datea	datea '01-JAN-70'
time	time '00:00:00'
time with time zone	timetz '00:00:00'
smalldatetime	smalldatetime '1970-01-01 00:00:00'

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- The default value of the enumerated type (ENUM) is the first element. If the first element does not exist, **NULL** is returned.
- In ORA-compatible mode (**sql_compatibility = 'ORA'**), an empty string of the text, clob, blob, raw, bytea, varchar, nvarchar2, bpchar, char, name, byteawithoutorderwithqualcol, or byteawithoutordercol type is equivalent to null. If a column has a NOT NULL constraint, an error is reported when a reference column is used to insert data into a table.
- In MySQL-compatible mode (**sql_compatibility = 'MYSQL'**), if **b_format_version** is set to **'5.7'**, **b_format_dev_version** is set to **'s1'**, and **sql_mode** does not contain **strict_trans_tables**, **only_full_group_by**, **no_zero_in_date**, **no_zero_date**, or **error_for_division_by_zero**, then the default values of **timestamp** and **datetime** are **0000-00-00 00:00:00**, and the default value of **DATE** is **0000-00-00** under the NOT NULL constraint.
- The uint1, uint2, uint4, and uint8 data types are supported only in the MySQL-compatible mode (**sql_compatibility = 'MYSQL'**).
- If the default value of the function expression can be calculated during parsing, the default value is the calculated constant. Otherwise, the value is **NULL**.
- In other scenarios, the default value is **NULL**.
- When the datea type is entered in literal format, the entered character string must comply with the **nls_date_format** format; otherwise, an error may be reported or incorrect data may be generated.

- In the REPLACE... SET syntax, the current **col_name** value depends on the previous **col_name** value. If there is no previous **col_name** value, the default value is used. For example, in the **SET f1 = f1 + 1, f2 = f1** scenario, **f1** is equal to the default value of **f1** (assumed to **1**) plus 1, and **f2** is equal to the calculated value of **f1**, that is **2**.
- The REPLACE INTO statement does not support ROW triggers. For STATEMENT triggers, only INSERT STATEMENT is supported, and DELETE STATEMENT is not supported.
- Deferrable UNIQUE constraints or primary keys are not supported.
- If a table has multiple unique constraints and the inserted data violates multiple unique constraints, all the data that violates the constraints is deleted and new data is inserted. In this scenario, data may be deleted by mistake. Therefore, exercise caution when performing this operation.
- If multiple rows are inserted and these rows have unique constraint conflicts with data in the same row in the table, the REPLACE operation is performed in sequence.
- In **SET col_name = col_name + 1**, the length of **col_name** cannot exceed 1. For example, in **SET col_name = table_name.col_name + 1**, the length of **table_name.col_name** is 2. Formats such as B.A, C.B.A, and D.C.B.A are not supported.
- Tables containing global secondary indexes do not support the REPLACE syntax.
- When comparing floating-point data, note that precision loss may occur.
- If a row-level security policy is created on a table, REPLACE INTO is not supported.
- Foreign tables are not supported.
- Encrypted tables are not supported.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- MOTs are not supported.

Syntax

- Replace or insert values.

```
REPLACE [ INTO ] table_name
    [ PARTITION ( partition_name [, ... ] ) ]
    [ ( col_name [, ... ] ) ]
    { VALUES | VALUE } ( value [, ... ] ) [, ... ];
```

  The format of **value** is as follows:

```
{ expression | DEFAULT }
```

- Replace or insert the query.

```
REPLACE [ INTO ] table_name
    [ PARTITION ( partition_name [, ... ] ) ]
    [ ( col_name [, ... ] ) ]
    query;
```

- Set the value of a specified column.

```
REPLACE [INTO] table_name
    [ PARTITION ( partition_name [, ... ] ) ]
    SET col_name = value [, ... ];
```

  The format of **value** is as follows:

```
{ expression | DEFAULT }
```

Parameters

- **table_name**

  Specifies the name of the target table where data will be inserted.

  Value range: existing table names.

- **col_name**

  Specifies the name of a column in a table.

  - The column name can be qualified with a subcolumn name or array index, if needed.
  - Each column not present in the column list will be filled with a default value, either its declared default value or **NULL** if there is none. Inserting data into only some columns of a composite type leaves the other columns **NULL**.
  - The target column names (specified by **col_name**) can be listed in any order. If no list of column names is given at all, the default is all the columns of the table in their declared order.
  - The target columns are the first *N* column names, if there are only *N* columns provided by the VALUE clause and QUERY.
  - The values provided by the VALUE clause and QUERY are joined with the corresponding columns from left to right in the table.

  Value range: existing column names.

- **PARTITION (partition_name [, ...])**

  Inserts data to a specified partition. **partition_name** indicates the partition name.

  If the value of the VALUE clause is inconsistent with that of the specified partition, an exception is displayed.

- **value**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Specifies the value to be inserted. The value format is as follows:

```
{ expression | DEFAULT }
```

- **expression** indicates that a valid expression or value is assigned to the corresponding column.
  - If single quotation marks are inserted into a column, they must be escaped by using an additional pair of single quotation marks.
  - If the expression for any column is not of the correct data type, automatic type conversion will be attempted. If the attempt fails, data insertion fails, and the system returns an error message.
- **DEFAULT** indicates the default value of the corresponding column name. The value is **NULL** if there is no default value.

- **query**

  Specifies a query statement (SELECT statement) that uses the query result as the inserted data.

Examples

```
-- Create table test.
gaussdb=# CREATE TABLE test(f1 int primary key, f2 int, f3 int);

-- Insert three data records.
gaussdb=# INSERT INTO test VALUES(1, 1, 1), (2, 2, 2), (3, 3, 3);
INSERT 0 3

-- Replace or insert values.
gaussdb=# REPLACE INTO test VALUES(1, 11, 11);
REPLACE 0 2

-- Query the result.
gaussdb=# SELECT * FROM test WHERE f1 = 1;
 f1 | f2 | f3
----+----+----
  1 | 11 | 11
(1 row)

-- Replace or insert the query.
gaussdb=# REPLACE INTO test SELECT 2, 22, 22;
REPLACE 0 2

-- Query the result.
gaussdb=# SELECT * FROM test WHERE f1 = 2;
 f1 | f2 | f3
----+----+----
  2 | 22 | 22
(1 row)

-- Replace or insert the specified column.
gaussdb=# REPLACE INTO test SET f1 = f1 + 3, f2 = f1 * 10 + 3, f3 = f2;
REPLACE 0 2

-- Query the result.
gaussdb=# SELECT * FROM test WHERE f1 = 3;
 f1 | f2 | f3
----+----+----
  3 | 33 | 33
(1 row)

-- Drop table test.
gaussdb=# DROP TABLE test;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

1.13.18.9 RESET

Description

Restores GUC parameters to their default values. The default values are parameter default values complied in the **gaussdb.conf** configuration file.

RESET is an alternative spelling for:

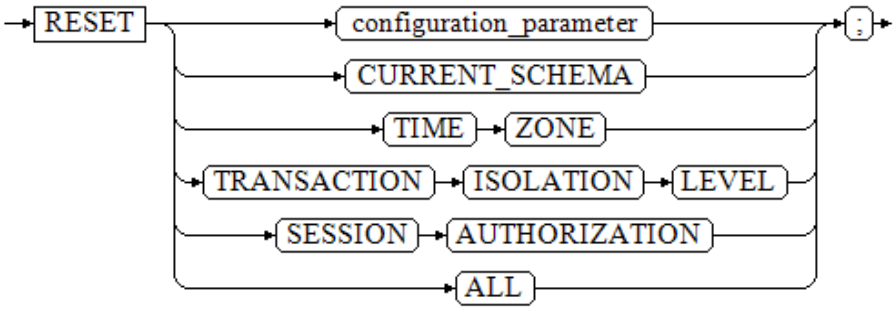
```
SET configuration_parameter TO DEFAULT;
```

Precautions

RESET and SET have the same transaction behavior. Their impact will be rolled back.

Syntax

```
RESET {configuration_parameter | CURRENT_SCHEMA | TIME ZONE | TRANSACTION ISOLATION LEVEL |
SESSION AUTHORIZATION | ALL };
```



Parameters

- **configuration_parameter**

  Specifies the name of a GUC parameter.

  Value range: GUC parameters. You can view them by running the **SHOW ALL** command.

  NOTE

  Some parameters that viewed by running **SHOW ALL** cannot be set by running **SET**, for example, **max_datanodes**.

- **CURRENT_SCHEMA**

  Specifies the current schema.

- **TIME ZONE**

  Specifies the time zone.

- **TRANSACTION ISOLATION LEVEL**

  Specifies the transaction isolation level.

- **SESSION AUTHORIZATION**

  Specifies the session authorization.

- **ALL**

  Resets all settable run-time parameters to default values.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Examples

```
-- Set the time zone to Italy.
gaussdb=# SET timezone TO 'Europe/Rome';
-- View the current time zone.
gaussdb=# SHOW timezone;
  TimeZone
-------------
 Europe/Rome
(1 row)

-- Set the time zone to the default value.
gaussdb=# RESET timezone;
-- View the current time zone.
gaussdb=# SHOW timezone;
 TimeZone
----------
 PRC
(1 row)

-- The preceding SQL statement is equivalent to the following two SQL statements. Set the time zone to the default value.
gaussdb=# SET timezone TO DEFAULT;
gaussdb=# ALTER SESSION SET timezone to DEFAULT;
```

SET and **SHOW**

1.13.18.10 REVOKE

Description

Revokes permissions from one or more roles.

Precautions

If a non-owner user of an object attempts to REVOKE permission on the object, the statement is executed based on the following rules:

- If the user has no permissions whatsoever on the object, the statement will fail outright.
- If an authorized user has some permissions, only the permissions with authorization options are revoked.
- If the authorized user does not have the authorization option, the REVOKE ALL PRIVILEGES form will issue an error message. For other forms of statements, if the permission specified in the statement does not have the corresponding authorization option, the statement will issue a warning.

Syntax

- Revoke the permission on a specified table or view.

```
REVOKE [ GRANT OPTION FOR ]
    { { SELECT | INSERT | UPDATE | DELETE | TRUNCATE | REFERENCES | ALTER | DROP | COMMENT | INDEX | VACUUM }[, ...]
    | ALL [ PRIVILEGES ] }
    ON { [ TABLE ] table_name [, ...]
        | ALL TABLES IN SCHEMA schema_name [, ...] }
    FROM { [ GROUP ] role_name | PUBLIC } [, ...]
    [ CASCADE | RESTRICT ];
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- Revoke the permission on a specified column in a table.

```
REVOKE [ GRANT OPTION FOR ]
    { {{ SELECT | INSERT | UPDATE | REFERENCES | COMMENT } ( column_name [, ...] )}[, ...]
    | ALL [ PRIVILEGES ] ( column_name [, ...] ) }
    ON [ TABLE ] table_name [, ...]
    FROM { [ GROUP ] role_name | PUBLIC } [, ...]
    [ CASCADE | RESTRICT ];
```

- Revoke the permission on a specified sequence.

```
REVOKE [ GRANT OPTION FOR ]
    { { SELECT | UPDATE | ALTER | DROP | COMMENT }[, ...]
    | ALL [ PRIVILEGES ] }
    ON { [ SEQUENCE ] sequence_name [, ...]
       | ALL SEQUENCES IN SCHEMA schema_name [, ...] }
    FROM { [ GROUP ] role_name | PUBLIC } [, ...]
    [ CASCADE | RESTRICT ];
```

- Revoke the permission on a specified database.

```
REVOKE [ GRANT OPTION FOR ]
    { { CREATE | CONNECT | TEMPORARY | TEMP | ALTER | DROP | COMMENT } [, ...]
    | ALL [ PRIVILEGES ] }
    ON DATABASE database_name [, ...]
    FROM { [ GROUP ] role_name | PUBLIC } [, ...]
    [ CASCADE | RESTRICT ];
```

- Revoke the specified CMK permission.

```
REVOKE [ GRANT OPTION FOR ]
    { { USAGE | DROP } [, ...] | ALL [PRIVILEGES] }
    ON CLIENT_MASTER_KEYS client_master_keys_name [, ...]
    FROM { [ GROUP ] role_name | PUBLIC } [, ...]
    [ CASCADE | RESTRICT ];
```

- Revoke the specified CEK permission.

```
REVOKE [ GRANT OPTION FOR ]
    { { USAGE | DROP } [, ...] | ALL [PRIVILEGES]}
    ON COLUMN_ENCRYPTION_KEYS column_encryption_keys_name [, ...]
    FROM { [ GROUP ] role_name | PUBLIC } [, ...]
    [ CASCADE | RESTRICT ];
```

- Revoke the permission on a specified directory.

```
REVOKE [ GRANT OPTION FOR ]
    { { READ | WRITE | ALTER | DROP } [, ...] | ALL [ PRIVILEGES ] }
    ON DIRECTORY directory_name [, ...]
    FROM { [ GROUP ] role_name | PUBLIC } [, ...]
    [ CASCADE | RESTRICT ];
```

- Revoke the permission on a specified external data source.

```
REVOKE [ GRANT OPTION FOR ]
   { USAGE | ALL [ PRIVILEGES ] }
    ON FOREIGN DATA WRAPPER fdw_name [, ...]
    FROM { [ GROUP ] role_name | PUBLIC } [, ...]
    [ CASCADE | RESTRICT ];
```

- Revoke the permission on a specified external server.

```
REVOKE [ GRANT OPTION FOR ]
    { { USAGE | ALTER | DROP | COMMENT } [, ...] | ALL [ PRIVILEGES ] }
    ON FOREIGN SERVER server_name [, ...]
    FROM { [ GROUP ] role_name | PUBLIC } [, ...]
    [ CASCADE | RESTRICT ];
```

- Revoke the permission on a specified function.

```
REVOKE [ GRANT OPTION FOR ]
    { { EXECUTE | ALTER | DROP | COMMENT } [, ...] | ALL [ PRIVILEGES ] }
    ON { FUNCTION {function_name ( [ {[ argmode ] [ arg_name ] arg_type} [, ...] ] )} [, ...]
       | ALL FUNCTIONS IN SCHEMA schema_name [, ...] }
    FROM { [ GROUP ] role_name | PUBLIC } [, ...]
    [ CASCADE | RESTRICT ];
```

- Revoke the permission on a specified stored procedure.

```
REVOKE [ GRANT OPTION FOR ]
    { { EXECUTE | ALTER | DROP | COMMENT } [, ...] | ALL [ PRIVILEGES ] }
    ON { PROCEDURE {proc_name ( [ {[ argmode ] [ arg_name ] arg_type} [, ...] ] )} [, ...]
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
    | ALL PROCEDURE IN SCHEMA schema_name [, ...] }
  FROM { [ GROUP ] role_name | PUBLIC } [, ...]
  [ CASCADE | RESTRICT ];
```

- Revoke the permission on a specified procedural language.

```
REVOKE [ GRANT OPTION FOR ]
  { USAGE | ALL [ PRIVILEGES ] }
   ON LANGUAGE lang_name [, ...]
   FROM { [ GROUP ] role_name | PUBLIC } [, ...]
   [ CASCADE | RESTRICT ];
```

- Revoke the permission on a specified schema.

```
REVOKE [ GRANT OPTION FOR ]
   { { CREATE | USAGE | ALTER | DROP | COMMENT } [, ...] | ALL [ PRIVILEGES ] }
   ON SCHEMA schema_name [, ...]
   FROM { [ GROUP ] role_name | PUBLIC } [, ...]
   [ CASCADE | RESTRICT ];
```

- Revoke the permission on a specified tablespace.

```
REVOKE [ GRANT OPTION FOR ]
   { { CREATE  | ALTER | DROP | COMMENT } [, ...] | ALL [ PRIVILEGES ] }
   ON TABLESPACE tablespace_name [, ...]
   FROM { [ GROUP ] role_name | PUBLIC } [, ...]
   [ CASCADE | RESTRICT ];
```

- Revoke the permission on a specified type.

```
REVOKE [ GRANT OPTION FOR ]
  { { USAGE | ALTER | DROP | COMMENT } [, ...] | ALL [ PRIVILEGES ] }
   ON TYPE type_name [, ...]
   FROM { [ GROUP ] role_name | PUBLIC } [, ...]
   [ CASCADE | RESTRICT ];
```

- Revoke the permission on a specified sub-cluster.

```
REVOKE [ GRANT OPTION FOR ]
   { { CREATE | USAGE | COMPUTE  | ALTER | DROP } [, ...] | ALL [ PRIVILEGES ] }
   ON NODE GROUP group_name [, ...]
   FROM { [ GROUP ] role_name | PUBLIC } [, ...]
   [ CASCADE | RESTRICT ];
```

NOTE

When the CREATE permission on a sub-cluster is revoked, the USAGE and COMPUTE permissions are revoked by default.

- Revoke the permission on a package object.

```
REVOKE [ GRANT OPTION FOR ]
  { { EXECUTE | ALTER | DROP | COMMENT } [, ...] | ALL [PRIVILEGES] }
  ON PACKAGE package_name [, ...]
  FROM {[GROUP] role_name | PUBLIC} [, ...]
  [ CASCADE | RESTRICT ];
```

- Revoke permissions from a role.

```
REVOKE [ ADMIN OPTION FOR ]
   role_name [, ...] FROM role_name [, ...]
   [ CASCADE | RESTRICT ];
```

- Revoke the SYSADMIN permission from a role.

```
REVOKE ALL { PRIVILEGES | PRIVILEGE } FROM role_name;
```

- Revoke the ANY permissions.

```
REVOKE [ ADMIN OPTION FOR ]
 { CREATE ANY TABLE | ALTER ANY TABLE | DROP ANY TABLE | SELECT ANY TABLE | INSERT ANY
TABLE | UPDATE ANY TABLE |
 DELETE ANY TABLE | TRUNCATE ANY TABLE | CREATE ANY SEQUENCE | CREATE ANY INDEX |
CREATE ANY FUNCTION | EXECUTE ANY FUNCTION |
 CREATE ANY PACKAGE | EXECUTE ANY PACKAGE | CREATE ANY TYPE | ALTER ANY TYPE | DROP ANY
TYPE | ALTER ANY SEQUENCE | DROP ANY SEQUENCE |
 SELECT ANY SEQUENCE | ALTER ANY INDEX | DROP ANY INDEX | CREATE ANY SYNONYM | DROP
ANY SYNONYM | CREATE ANY TRIGGER | ALTER ANY TRIGGER |
 DROP ANY TRIGGER
} [, ...]
 FROM [ GROUP ] role_name [, ...];
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- Revoke the permission on database links.
  ```
  REVOKE { CREATE | ALTER | DROP } [PUBLIC] DATABASE LINK FROM role_name;
  ```
- Revoke the permission on PUBLIC synonyms.
  ```
  REVOKE { CREATE | DROP } PUBLIC SYNONYM FROM role_name;
  ```
  Built-in roles (gs_role_public_synonym_create and gs_role_public_synonym_drop) can also be used to revoke the permission on PUBLIC synonyms.
  - Revoke the permission to create PUBLIC synonyms.
    ```
    REVOKE gs_role_public_synonym_create FROM role_name;
    ```
  - Revoke the permission to delete PUBLIC synonyms.
    ```
    REVOKE gs_role_public_synonym_drop FROM role_name;
    ```

Parameters

The keyword PUBLIC indicates an implicitly defined group that has all roles.

For details about the permission types and parameters, see **Parameters**.

Permissions of a role include the permissions directly granted to the role, permissions inherited from the parent role, and permissions granted to PUBLIC. Therefore, revoking the SELECT permission on an object from PUBLIC users does not necessarily mean that the SELECT permission on the object has been revoked from all roles because the SELECT permission directly granted to roles and inherited from parent roles remains. Similarly, if the SELECT permission is revoked from a user but is not revoked from PUBLIC users, the user can still run the SELECT statement.

If GRANT OPTION FOR is specified, the permission cannot be granted to others, but permission itself is not revoked.

If user A holds the UPDATE permission on a table and the **WITH GRANT OPTION** option and has granted them to user B, the permission that user B holds is called dependent permission. If the permissions or the grant option held by user A is revoked, the dependent permissions still exist. Those dependent permissions are also revoked if CASCADE is specified.

A user can only revoke permissions that were granted directly by that user. For example, if user A has granted permission with grant option (**WITH ADMIN OPTION**) to user B, and user B has in turn granted it to user C, then user A cannot revoke the permission directly from C. However, user A can revoke the grant option held by user B and use CASCADE. In this way, the permission of user C is automatically revoked. For another example, if both user A and user B have granted the same permission to C, A can revoke A's own grant but not B's grant, so C will still effectively have the permission.

If the role executing REVOKE holds permissions indirectly by using more than one role membership path, it is unspecified which containing role will be used to execute the statement. In such cases, you are advised to use SET ROLE to become the specific role, and then execute REVOKE. Failure to do so may lead to deleting permissions not intended to delete, or not deleting any permissions at all.

Examples

- Revoke the permission of role **jerry** from user **joe**.
  ```
  -- Create role jerry.
  gaussdb=# CREATE role jerry PASSWORD 'xxxxxxxxxx';
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
-- Grant the CREATE ANY TABLE permission to jerry and allow the role to grant the permission to
others.
gaussdb=# GRANT create any table TO jerry with admin option;

-- Create user joe and grant the permission of role jerry to it.
gaussdb=#  CREATE user joe PASSWORD 'xxxxxxxxxx';
gaussdb=#  GRANT jerry TO joe;

-- Revoke the permission of role jerry from user joe.
gaussdb=#  REVOKE jerry FROM joe;
```

- Revoke system permissions from user **tom**.

```
-- Create user tom.
gaussdb=# CREATE USER tom PASSWORD 'xxxxxxxxxx';

-- Grant system permissions to user tom.
gaussdb=# GRANT ALL PRIVILEGES TO tom;

-- Revoke system permissions from user tom.
gaussdb=# REVOKE ALL PRIVILEGES FROM tom;
```

- Revoke the SELECT permission on the **reason** table in schema **tpcds** from user **joe**.

```
-- Create schema tpcds.
gaussdb=# CREATE SCHEMA tpcds;

-- Create table reason in schema tpcds.
gaussdb=# CREATE TABLE tpcds.reason (
r_reason_sk         INTEGER      NOT NULL,
r_reason_id         CHAR(16)     NOT NULL,
r_reason_desc       VARCHAR(20)
);

-- Grant the query permission on the table tpcds.reason to joe.
gaussdb=# GRANT select ON tpcds.reason TO joe;

-- Revoke the SELECT permission on the reason table in schema tpcds from user joe.
gaussdb=# REVOKE SELECT ON TABLE tpcds.reason FROM joe;
```

- Revoke the ALTER permission on the fun1() function in schema **tpcds** from user **joe**.

```
-- Create function fun1().
gaussdb=# CREATE or replace FUNCTION tpcds.fun1() RETURN boolean AS
BEGIN
SELECT current_user;
RETURN true;
END;
/
-- Grant the ALTER permission on the fun1() function to user joe.
gaussdb=# GRANT ALTER ON FUNCTION tpcds.fun1() TO joe;

-- Revoke the ALTER permission on the fun1() function in schema tpcds from user joe.
gaussdb=#  REVOKE ALTER ON FUNCTION tpcds.fun1() FROM joe;
```

- Revoke the CONNECT permission on database **testdb** from user **joe**.

```
-- Create database testdb.
gaussdb=# CREATE DATABASE testdb;

-- Grant the CONNECT permission on database testdb to user joe.
gaussdb=# GRANT connect on database testdb TO joe WITH GRANT OPTION;

-- Revoke the CONNECT permission on database testdb from user joe.
gaussdb=# REVOKE CONNECT ON database testdb FROM joe;
```

- Clear data.

```
gaussdb=# DROP TABLE tpcds.reason;
gaussdb=# DROP FUNCTION tpcds.fun1();
gaussdb=# DROP SCHEMA tpcds CASCADE;
gaussdb=# DROP USER joe;
gaussdb=# DROP USER tom;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gaussdb=# REVOKE create any table FROM jerry;
gaussdb=# DROP ROLE jerry;
gaussdb=# DROP DATABASE testdb;
```

Helpful Links

GRANT

1.13.18.11 ROLLBACK

Description

Rolls back the current transaction and backs out all updates in the transaction.

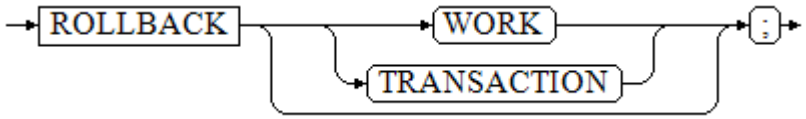
If a fault occurs during the running of a transaction, the transaction cannot be executed. The system cancels all completed operations on the database in the transaction, and the database status returns to the time when the transaction starts.

Precautions

If a ROLLBACK statement is executed out of a transaction, no error occurs, but a notice is displayed.

Syntax

```
ROLLBACK [ WORK | TRANSACTION ];
```



Parameters

WORK | TRANSACTION

Specifies the optional keyword that more clearly illustrates the syntax.

Examples

```
-- Create a table.
gaussdb=# CREATE TABLE test (id int, name text);

-- Start a transaction.
gaussdb=# START TRANSACTION;

-- Alter the table definition.
gaussdb=# ALTER TABLE test ADD COLUMN score int;

-- View the table definition.
gaussdb=# \d test;
     Table "public.test"
 Column |  Type   | Modifiers
--------+---------+-----------
 id     | integer |
 name   | text    |
 score  | integer |
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
-- Perform rollback.
gaussdb=# ROLLBACK;

-- The table definition is restored to the initial state.
gaussdb=# \d test;
     Table "public.test"
 Column |  Type   | Modifiers
--------+---------+-----------
 id     | integer |
 name   | text    |

-- Drop the test table.
gaussdb=# DROP TABLE test;
```

Helpful Links

COMMIT | END

1.13.18.12 ROLLBACK PREPARED

Description

Cancels a transaction ready for two-phase commit.

Precautions

- The function is only available in maintenance mode (when the GUC parameter **xc_maintenance_mode** is set to **on**). Exercise caution when enabling the mode. It is used by maintenance engineers for troubleshooting. Common users should not use the mode.
- Only the user who initiates a transaction or a system administrator can roll back the transaction.
- The transaction function is maintained automatically by the database, and should be not visible to users.

Syntax

```
ROLLBACK PREPARED transaction_id;
```

NOTE

The distributed environment does not support the ROLLBACK PREPARED syntax.

Parameters

transaction_id

Specifies the identifier of the transaction to be committed. The identifier must be different from those for current prepared transactions.

Examples

```
-- Start a transaction in maintenance mode.
gaussdb=# SET XC_MAINTENANCE_MODE = ON;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
SET

gaussdb=# BEGIN;
BEGIN

-- Prepare a transaction whose identifier is trans_test.
gaussdb=# PREPARE TRANSACTION 'trans_test';
PREPARE TRANSACTION

-- Cancel the transaction whose identifier is trans_test.
gaussdb=# ROLLBACK PREPARED 'trans_test';
ROLLBACK PREPARED
```

Helpful Links

COMMIT PREPARED and **PREPARE TRANSACTION**.

1.13.18.13 ROLLBACK TO SAVEPOINT

Description

ROLLBACK TO SAVEPOINT rolls back operations to a specified savepoint. Operations after the savepoint do not take effect.

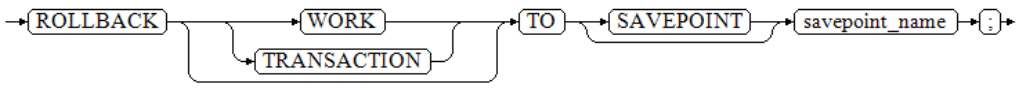
Rolls back all statements that were executed after the savepoint was established. The savepoint remains valid and can be rolled back to again later, if needed.

Precautions

- Rolling back to a savepoint name that has not been specified is an error.
- Cursors have somewhat non-transactional behavior with respect to savepoints. Any cursor that is opened inside a savepoint will be closed when the savepoint is rolled back. If a previously opened cursor is affected by a FETCH statement inside a savepoint that is later rolled back, the cursor remains at the position that FETCH left it pointing to (that is, the cursor motion caused by FETCH is not rolled back). Closing a cursor is not undone by rolling back, either. A cursor whose execution causes a transaction to abort is put in a cannot-execute state, so while the transaction can be restored using ROLLBACK TO SAVEPOINT, the cursor can no longer be used.
- Use ROLLBACK TO SAVEPOINT to roll back to a savepoint. Use RELEASE SAVEPOINT to destroy a savepoint but keep the results of the statements executed after the savepoint was established.

Syntax

```
ROLLBACK [ WORK | TRANSACTION ] TO [ SAVEPOINT ] savepoint_name;
```



Parameters

- **WORK | TRANSACTION**

  Specifies the optional keyword that more clearly illustrates the syntax.
- **savepoint_name**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Rolls back to a savepoint.

Examples

```
-- Start a transaction.
gaussdb=# START TRANSACTION;

-- Set the savepoint my_savepoint.
gaussdb=# SAVEPOINT my_savepoint;

-- Roll back to the savepoint my_savepoint.
gaussdb=# ROLLBACK TO SAVEPOINT my_savepoint;

-- Cursor positions are not affected by savepoint rollback.
gaussdb=# DECLARE foo CURSOR FOR SELECT 1 UNION SELECT 2;

-- Set the savepoint foo.
gaussdb=# SAVEPOINT foo;

-- Read a data record, which is the first one.
gaussdb=# FETCH 1 FROM foo;
 ?column?
----------
        1
-- Roll back to the savepoint foo.
gaussdb=# ROLLBACK TO SAVEPOINT foo;

-- Read a data record, which is the second one.
gaussdb=# FETCH 1 FROM foo;
 ?column?
----------
        2
-- Release a savepoint.
gaussdb=# RELEASE SAVEPOINT my_savepoint;

-- End the transaction.
gaussdb=# COMMIT;
```

SAVEPOINT and **RELEASE SAVEPOINT**

1.13.19 S

1.13.19.1 SAVEPOINT

Description

SAVEPOINT establishes a new savepoint in the current transaction.

A savepoint is a special mark in a transaction. It allows all commands that are executed after the savepoint was established to be rolled back, restoring the transaction state to what it was at the time of the savepoint.

Precautions

- Use ROLLBACK TO SAVEPOINT to roll back to a savepoint. Use RELEASE SAVEPOINT to destroy a savepoint but keep the effects of the commands executed after the savepoint was established.
- Savepoints can only be established when inside a transaction block. Multiple savepoints can be defined within a transaction.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- In the case of an unexpected termination of a distributed thread or process caused by a node or connection failure, or of an error caused by the inconsistency between source and destination table definitions in a COPY FROM operation, the transaction cannot be rolled back to the established savepoint. Instead, the entire transaction will be rolled back.
- According to the SQL standard, when a savepoint with the same name is created, the previous savepoint with the same name is automatically deleted. In GaussDB, the old savepoint is retained, but only the latest one is used during rollback or release. If the latest savepoint is released, the previous savepoint will again become accessible to ROLLBACK TO SAVEPOINT and RELEASE SAVEPOINT. Except for this, SAVEPOINT fully complies with the SQL standard.

Syntax

```
SAVEPOINT savepoint_name;
```

Parameter

savepoint_name

Specifies the name of the new savepoint.

NOTICE

When using SAVEPOINT, you are advised to release SAVEPOINT promptly to avoid too many nested subtransactions. It is recommended that the number of nested subtransactions be less than or equal to 10,000. If the number of nested subtransactions is too large, the current transaction performance may deteriorate.

Examples

```
-- Create a table.
gaussdb=# CREATE TABLE table1(a int);

-- Start a transaction.
gaussdb=# START TRANSACTION;

-- Insert data.
gaussdb=# INSERT INTO table1 VALUES (1);

-- Create a savepoint.
gaussdb=# SAVEPOINT my_savepoint;

-- Insert data.
gaussdb=# INSERT INTO table1 VALUES (2);

-- Roll back to the savepoint.
gaussdb=# ROLLBACK TO SAVEPOINT my_savepoint;

-- Insert data.
gaussdb=# INSERT INTO table1 VALUES (3);

-- Commit the transaction.
gaussdb=# COMMIT;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
-- Query the table content. The table should contain both 1 and 3 but not 2 because 2 is rolled back.
gaussdb=# SELECT * FROM table1;

-- Drop the table.
gaussdb=# DROP TABLE table1;
```

RELEASE SAVEPOINT and **ROLLBACK TO SAVEPOINT**

1.13.19.2 SECURITY LABEL ON

Description

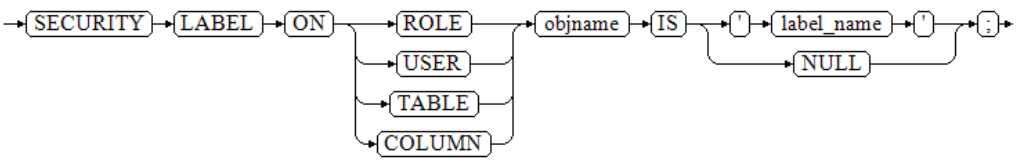
Applies, updates, or cancels a security label.

Precautions

An initial user, a user with the SYSADMIN permission, or a user who inherits the permissions of the built-in role gs_role_seclabel can update or cancel security labels.

Syntax

```
SECURITY LABEL ON { ROLE | USER | TABLE | COLUMN } objname IS {'label_name' | NULL};
```



Parameters

- **objname**
  - For **ROLE** and **USER**, **objname** indicates the user/role name.
  - For **TABLE**, **objname** indicates the table name, which can be prefixed with a schema name.
  - For **COLUMN**, **objname** indicates the name in the format of "table name.column name", which can be prefixed with a schema name.
- **label_name**

  Specifies the security label name.
- **NULL**

  Specifies that the security label is canceled.

Examples

```
-- Create a security label.
gaussdb=# CREATE SECURITY LABEL sec_label 'L1:G4';

-- Create a table.
gaussdb=# CREATE TABLE tbl(c1 int, c2 int);

-- Create a user.
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gaussdb=# CREATE USER bob WITH PASSWORD '********';

-- Apply a security label to the user.
gaussdb=# SECURITY LABEL ON ROLE bob IS 'sec_label';

-- Apply a security label to the table.
gaussdb=# SECURITY LABEL ON TABLE tbl IS 'sec_label';

-- Apply a security label to a column of the table.
gaussdb=# SECURITY LABEL ON COLUMN tbl.c1 IS 'sec_label';

-- Cancel the security label of the user.
gaussdb=# SECURITY LABEL ON ROLE bob IS NULL;
-- Cancel the security label of the table.
gaussdb=# SECURITY LABEL ON TABLE tbl IS NULL;

-- Cancel the security label of the column of the table.
gaussdb=# SECURITY LABEL ON COLUMN tbl.c1 IS NULL;

-- Delete table tb1.
gaussdb=# DROP TABLE tbl;

-- Delete user bob.
gaussdb=# DROP USER bob;

-- Delete the existing security label sec_label.
gaussdb=# DROP SECURITY LABEL sec_label;
```

Helpful Links

CREATE SECURITY LABEL and **DROP SECURITY LABEL**

1.13.19.3 SELECT

Description

Queries data from a table or view. The SELECT operation is akin to a filter layered over a database table. By specifying query criteria, you can sift through the database table to extract the desired data.

Precautions

- The owner of a table, users with the SELECT permission on the table, and users with the SELECT ANY TABLE permission can perform SELECT to read data in the table or view. When separation of duties is disabled, system administrators have this permission by default.
- SELECT supports JOIN between ordinary tables but does not support JOIN between ordinary tables and GDS foreign tables. That is, ordinary tables and GDS foreign tables cannot coexist in the same SELECT statement.
- Users performing a SELECT operation must have SELECT permission on the columns included in the SELECT statement.
- Only users with both SELECT and UPDATE permissions on a table can perform the FOR UPDATE or FOR SHARE operation on the table.
- Currently, the statement specifying a partition cannot perform global index scan.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Syntax

Query data.

```
[ WITH [ RECURSIVE ] with_query [, ...] ]
SELECT [/*+ plan_hint */] [ ALL | DISTINCT [ ON ( expression [, ...] ) ] ]
   { * | {expression [ [ AS ] output_name ]} [, ...] }
   [ FROM from_item [, ...] ]
   [ WHERE condition ]
   [ [ START WITH condition ] CONNECT BY [NOCYCLE]
   condition [ ORDER SIBLINGS BY expression ] ]
   [ GROUP BY grouping_element [, ...] ]
   [ HAVING condition [, ...] ]
   [ WINDOW {window_name AS ( window_definition )} [, ...] ]
   [ { UNION | INTERSECT | EXCEPT | MINUS } [ ALL | DISTINCT ] select ]
   [ ORDER BY {expression [ [ ASC | DESC | USING operator ] | nlssort_expression_clause ] [ NULLS { FIRST |
LAST } ]} [, ...] ]
   [ LIMIT { [offset,] count | ALL } ]
   [ OFFSET start [ ROW | ROWS ] ]
   [ FETCH { FIRST | NEXT } [ count ] { ROW | ROWS } ONLY [OFFSET offset_count]]
   [ {FOR { UPDATE | SHARE } [ OF table_name [, ...] ] [ NOWAIT | WAIT n | SKIP LOCKED ]} [...] ];
```

NOTICE

- When the SELECT statement plan is cached, the number of conditions in the WHERE IN candidate subset should be less than or equal to 100 to prevent high dynamic memory.
  - If the WHERE IN candidate subset is too large, the memory usage of the generated plan increases.
  - If the WHERE IN subsets constructed by concatenated SQL statements are different, the SQL template of the cache plan cannot be reused. A large number of different plans are generated, and the plans cannot be shared. As a result, a large amount of memory is occupied.
- In condition and expression, you can use the aliases of expressions in the **targetlist** (the list returned by the query) in compliance with the following rules:
  - Reference only within the same level.
  - Only reference aliases in **targetlist**.
  - Reference a prior expression in a subsequent expression.
  - Volatile functions cannot be used.
  - Window functions cannot be used.
  - Aliases cannot be referenced in the condition of JOIN ON.
  - An error is reported if the target list contains multiple aliases to be referenced.

- The subquery **with_query** is as follows:

  ```
  with_query_name [ ( column_name [, ...] ) ]
      AS [ [ NOT ] MATERIALIZED ] ( {select | values | insert | update | delete} )
  ```

- The specified query source **from_item** is as follows:

  ```
  {[ ONLY ] table_name [ * ] [ partition_clause ] [ [ AS ] alias [ ( column_alias [, ...] ) ] ]
  [ TABLESAMPLE sampling_method ( argument [, ...] ) [ REPEATABLE ( seed ) ] ]
  [ TIMECAPSULE {TIMESTAMP | CSN} expression ]
  |( select ) [ AS ] alias [ ( column_alias [, ...] ) ]
  |with_query_name [ [ AS ] alias [ ( column_alias [, ...] ) ] ]
  |function_name ( [ argument [, ...] ] ) [ AS ] alias [ ( column_alias [, ...] | column_definition [, ...] ) ]
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
|function_name ( [ argument [, ...] ] ) AS ( column_definition [, ...] )
|xmltable_clause
|from_item unpivot_clause
|from_item pivot_clause
|from_item [ NATURAL ] join_type from_item [ ON join_condition | USING ( join_column [, ...] ) ]}
```

  - Specify partition_clause in the query source **from_item** as follows:

    ```
    {PARTITION { ( { partition_name | subpartition_name } [, ...] ) | FOR (  partition_value [, ...] ) }
    | SUBPARTITION { ( subpartition_name ) | FOR (  subpartition_value [, ...] )}}
    ```

    NOTE

    - The specified partition applies only to partitioned tables.
    - If PARTITION specifies multiple partition names, the partition names can be the same. The union set of the partition ranges is used.

  - Specify xmltable_clause in the query source **from_item** as follows:

    ```
    XMLTABLE(
    xmlnamespaces_clause
    row_expression
    passing_clause
    columns_clause
    )
    ```

    - For xmlnamespaces_clause:

      ```
      {
         XMLNAMESPACES(
         {string AS identifier
         |
         DEFAULT string }
         [, { string AS identifier  |  DEFAULT string } ][...]
         ),
      }
      ```

    - For passing_clause:

      ```
      [
         PASSING [BY { REF | VALUE }] document_expression [BY { REF | VALUE }]
      ]
      ```

    - For columns_clause:

      ```
      [
         COLUMNS
         name { type [PATH column_expression] [DEFAULT default_expression] [NOT NULL |
      NULL] | FOR ORDINALITY }
         [, ...]
      ]
      ```

- The GROUP BY clause is as follows:

  ```
  {()
  |expression
  |( expression [, ...] )
  |ROLLUP ( { expression | ( expression [, ...] ) } [, ...] )
  |CUBE ( { expression | ( expression [, ...] ) } [, ...] )
  |GROUPING SETS ( grouping_element [, ...] )}
  ```

- The sorting order nlssort_expression_clause is as follows:

  ```
  NLSSORT ( column_name, ' NLS_SORT = { SCHINESE_PINYIN_M | generic_m_ci } ' )
  ```

- Simplified query syntax, equivalent to SELECT * FROM table_name.

  ```
  TABLE { ONLY {(table_name)| table_name} | table_name [ * ]};
  ```

Parameters

- **WITH [RECURSIVE] with_query [, ...]**

  Specifies one or more subqueries that can be referenced by name in the main query, which is equivalent to a temporary table. This subquery statement structure is called the common table expression (CTE) structure. When this

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

structure is used, the execution plan contains the CTE SCAN content. If RECURSIVE is declared, the SELECT subquery can reference itself by name.

Format of **with_query**:

```
with_query_name [ ( column_name [, ...] ) ] AS [ [ NOT ] MATERIALIZED ] ( {select | values | insert | update | delete} )
```

- **with_query_name** specifies the name of the result set generated by a subquery. Such names can be used to access the result sets of subqueries in a query.
- **column_name** specifies the column name displayed in the subquery result set.
- Each subquery can be a SELECT, VALUES, INSERT, UPDATE, or DELETE statement.
- To use the CTE structure, RECURSIVE must be declared after WITH. If there are multiple CTEs, you only need to declare RECURSIVE at the first CTE.
- You can use [NOT] MATERIALIZED to modify the CTE. Currently, only inline execution is supported for stream plans. In this case, this syntax does not take effect.
  - If **MATERIALIZED** is specified, the WITH query will be materialized, and a copy of the subquery result set is generated. The copy is directly queried at the reference point. Therefore, the WITH subquery cannot be jointly optimized with the SELECT statement trunk (for example, predicate pushdown and equivalence class transfer). When using **NOT MATERIALIZED** for modification, if the WITH query can be semantically executed as a subquery inline, it can be jointly optimized with the trunk SELECT statement (such as predicate pushdown and equivalence class transfer).
  - If the user does not explicitly declare the materialized attribute, comply with the following rules: If the CTE is referenced only once in the SELECT statement trunk to which it belongs and semantically supports inline execution, it will be rewritten as subquery inline execution. Otherwise, the materialized execution will be performed in CTE SCAN mode.

- **plan_hint clause**

  Optimizes the plan generated by the SELECT statement block. The hint is declared in the /*+ */ format after the SELECT keyword. For details about how to use hints for optimization, see "Hint-based Optimization" in *SQL Optimization Guide*. In each statement, only the first **/*+** *plan_hint* ***/** comment block takes effect as a hint. Multiple hints can be written in the comment block.

- **ALL**

  (Optional) Returns all rows that meet the SELECT query conditions. This is the default behavior of SELECT query.

- **DISTINCT [ON (expression [, ...])]**

  Removes all duplicate rows from the result set of the SELECT statement so that each row in the result set is unique.

  ON (expression[, ...]): retains only the data from the first row of the result set that complies with the expression operation.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 2022

NOTICE

- Specifying **DISTINCT ON** retains only the first row of the set of rows that comply with the expression and does not sort the set, so the result is not fixed. To return a unique row as expected, you are advised to also specify **ORDER BY** for data filtering.
- The DISTINCT ON expression does not support sorting of non-integer constants.

- **SELECT list**

  Specifies the name of a column in the table to be queried. The value can be a part of the column name or all of the column names. The wildcard (*) is used to represent the column name.

  You may use the AS *output_name* clause to assign an alias to the output column. The alias is usually used for displaying the output column.

  Column names can be expressed in the following ways:

  – Manually input column names which are separated by commas (,)
  – Use the results or columns calculated by the FROM clause as column names.
  – Use the keywords NAME, VALUE, and TYPE as column aliases.

- **FROM clause**

  Specifies one or more data source tables for a SELECT query.

  The FROM clause contains the following elements:

  – table_name

    Specifies the name of a table or view. The schema name can be added before the table name or view name as a limit, for example, schema_name.table_name.

    NOTE

    You can use database links to perform operations on remote tables and synonyms. For details, see "Feature Usage Guidelines > Database Links" in *Developer Guide*.

  – alias

    Assigns a temporary alias to a table or a complex table reference so that the reference of the table by other queries is easier.

    An alias is used for easier reference or to eliminate ambiguity for self-joins. If an alias is provided, it can be referenced directly instead of using the actual table name.

    NOTE

    To add an alias to **joined_table** generated by the JOIN operation and specified by parentheses in the format of **(joined_table)**, do not use non-reserved keywords UNPIVOT and PIVOT as the table alias.

  – TABLESAMPLE sampling_method (argument [, ...]) [REPEATABLE (seed)]

    Specifies a sampling method to retrieve a subset of rows in a table specified by **table_name**. The available sampling methods are as follows:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 2023

- SYSTEM(percent)

  Random sampling by data block. The value range of **percent** is [0,100], indicating the probability (in percentage) that each data block is selected.

- BERNOULLI(percent)

  Independent random sampling by row. The value range of **percent** is [0,100], indicating the probability (in percentage) that each row is selected.

- HYBRID(p1,p2)

  Hybrid random sampling. It consists of two steps: First, random sampling is performed on data blocks with probability **p1**. Second, independent random sampling by row is performed on the sampled data content with probability **p2**. The value range of both **p1** and **p2** is [0,100].

The REPEATABLE clause is optional and serves as an additional condition for **sampling_method**, and **seed** is the seed value used for generating random numbers within the sampling method, which can be any non-null constant value. When the table definition/data remains unchanged and multiple sampling operations are performed, if **REPEATABLE (seed)** is not specified, the system acquires a fresh random sample for each query using the automatically generated seed value, so the sample is not fixed. Once **REPEATABLE (seed)** is specified, a unique and fixed sample can be obtained.

– TIMECAPSULE { TIMESTAMP | CSN } expression

  Specifies a CSN or time point as a flashback query identifier where the table content is queried.

  - TIMECAPSULE TIMESTAMP

    Searches for the result set of a specified time point based on the date. *date* must be a valid past timestamp.

  - TIMECAPSULE CSN

    Queries the result set for a specified CSN in a table flashback. The CSN can be obtained from **snpcsn** recorded in gs_txn_snapshot.

  - expression

    Constants, functions, or SQL expressions.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 2024

NOTE

- Currently, flashback query cannot be performed on system catalogs, DFS tables, global temporary tables, local temporary tables, unlogged tables, views, sequence tables, shared tables, and inherited tables.
- After a statement (TRUNCATE, DDL, DCL, or VACUUM FULL) that modifies the table definition or affects physical storage of a table is executed between the flashback point and the current point, a flashback query cannot be performed on the table again because such attempt will fail. If a flashback is performed on tables that have undergone DDL operations, the error message "ERROR: The table definition of %s has been changed." is displayed. Similarly, when a flashback is performed on DDL operations involving table definition changes, the error message "ERROR: recycle object %s desired does not exist." is displayed.
- Flashback query supports scanning PCR UB-tree indexes. If no such indexes, flashback query supports only seq scan for full table scan.
- When the flashback point is too old, the source version cannot be obtained because the flashback version is recycled. As a result, the flashback fails and the error message "Restore point too old" is displayed.
- The flashback point is specified by TIMESTAMP. The maximum difference between the flashback point and the actual time is 3 seconds.
- After TRUNCATE is performed on a table, a flashback query or table flashback operation performed using TIMESTAMP will result in an error (Snapshot too old) ; while a flashback operation by using CSN will fail to find data or report an error (Snapshot too old).
- In the GTM-free scenario, each node uses the local CSN and does not have a globally unified CSN. Therefore, flashback by using CSN is not supported.

– column_alias

  Specifies the column alias.

– PARTITION

  Queries data in the specified partition in a partitioned table.

– partition_name

  Specifies the name of a partition.

– partition_value

  Specifies the value of the specified partition key. If a partitioned table has multiple partition keys, you can use PARTITION FOR to uniquely identify a partition.

– subquery

  Creates a temporary table to store the subquery's output.

– with_query_name

  It can be referenced by the name of the WITH query.

– function_name

  Function name.

– join_type

  ▪ [INNER] JOIN

    Inner join (equi-join). It returns only the rows that match the join condition in the join table.

  ▪ LEFT [OUTER] JOIN

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Left (outer) join. Two tables are concatenated, with the left table serving as the main table. All main table data is displayed, while child table data is shown depending on whether the join conditions are met. Unmatched data will be replaced with **NULL** values.

- RIGHT [OUTER] JOIN

  Right (outer) join. Two tables are concatenated, with the right table serving as the main table. All main table data is displayed, while child table data is shown depending on whether the join conditions are met. Unmatched data will be replaced with **NULL** values.

  You can convert the right (outer) join to a left (outer) join by exchanging the inputs on the left and right.

- FULL [OUTER] JOIN

  Returns all result rows of an inner join and all rows that do not match the join condition in the join table.

- CROSS JOIN

  CROSS JOIN is equivalent to INNER JOIN ON(TRUE), that is, rows that are not deleted by the conditions. These join types are just a notational convenience, since they do nothing you could not do with plain FROM and WHERE.

NOTE

You must declare a join condition (**ON join_condition** or **USING (join_column [,...])**) for INNER JOIN and OUTER JOIN, while it is not required for CROSS JOIN.

CROSS JOIN and INNER JOIN produce a simple Cartesian product, the same result as you get from listing the two items at the top level of FROM.

– ON join_condition

  Join condition, which specifies the matching rule of the joined objects, for example, **ON left_table.a = right_table.a**. You are advised not to use numeric types such as int for **join_condition** because such types can be implicitly converted to bool values (non-zero values are implicitly converted to **true** and **0** is implicitly converted to **false**), which may cause unexpected results.

– USING(join_column[, ...])

  ON left_table.a = right_table.a AND left_table.b = right_table.b ... abbreviation. Corresponding columns must have the same name.

– NATURAL

  Shorthand for a USING list that contains all columns in the two tables that have the same names.

– from item

  Specifies the name of the query source object connected.

– xmltable_clause

  Currently, xmltable_clause can be used only in ORA- or PG-compatible mode. xmltable_clause produces a virtual table based on data of the given XMLType (in ORA-compatible mode) or XML (in PG-compatible mode) type.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- xmlnamespaces_clause

  (Optional) It consists of XMLNAMESPACES followed by comma-separated XML namespace declaration clause. **string** indicates the full name of the namespace for which single quotation marks are used as boundary characters. **identifier** indicates the namespace alias for which double quotation marks are used as boundary characters. The alias can be used in row_expression and columns_clause. In the current version, DEFAULT cannot be used to declare the default namespace.

- row_expression

  row_expression is an XPath 1.0 expression with English single quotation marks as boundary characters. The document_expression in passing_clause is used as its context to obtain a group of XML nodes. These XML nodes are processed by columns_clause to generate each row of the virtual table.

  In ORA-compatible mode, **row_expression** can pass a sequence consisting of numbers or XML text, with single quotation marks (') as boundary characters and commas (,) as separators.

- passing_clause

  passing_clause starts with PASSING and its document_expression is the data of the XMLType (in ORA-compatible mode) or XML (in PG-compatible mode) type that is passed to XMLTABLE for processing. Currently, only single data records are supported. In ORA-compatible mode, an error is reported regardless of whether BY VALUE or BY REF is used. In PG-compatible mode, although BY VALUE or BY REF in the first and second places can be identified and received, no functional processing is performed.

- columns_clause

  (Optional) Specifies the information required for the columns to be generated in the virtual table, as shown in **Table 1-405**.

Table 1-405 COLUMNS information description

Information	Description
name	Column name.
type	Column type.
PATH	(Optional) column_expression is an expression of XPath 1.0. A node in the node set obtained by row_expression is used as the context of the node, and the data required by the value of the corresponding column in the row data generated by the node is obtained through processing by the node. There is an implicit conversion when it is converted to a result of the TYPE type. If the **PATH** part is not specified, **name** is regarded as column_expression.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Information	Description
DEFAULT	(Optional) If the value obtained from column_expression processing is **NULL**, the result obtained from calculating default_expression is used to replace **NULL**. default_expression is calculated only when necessary. If the expression is fixed, it is calculated only once.
NOT NULL | NULL	(Optional) In PG-compatible mode, specifies whether the column can be **NULL**. An error is reported if the column value is not the specified option.
FOR ORDINALITY	Indicates that the column is a row number column. Row numbers starting from 1 are filled for generated rows. Only one column can be marked as **FOR ORDINALITY**.

In ORA-compatible mode, columns_clause can be omitted. After columns_clause is omitted, **COLUMNS column_value XMLTYPE PATH '.'** is generated by default for subsequent processing.

In PG-compatible mode, columns_clause cannot be omitted.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

Currently, xmltable_clause has the following restrictions:

- The involved XPath expressions are XPath 1.0.
- Currently, XPath expressions such as **"namespace::*"** cannot be used in **row_expression**.
- Currently, XPath expressions such as **".."** cannot be used in **column_expression**.
- When the data obtained through column_expression is converted to the data of the TYPE type, in ORA-compatible mode, the data exceeds the typmod of the type will be truncated. Currently, this truncation occurs only when the typmod of the CHAR, CHARACTER, NCHAR, BPCHAR, VARCHAR, CHARACTER VARYING, VARCHAR2, and NVARCHAR2 data types, including those with (n), is greater than 0. In PG-compatible mode, an error is reported when the data exceeds the typmod of the type.
- Currently, the maximum size of the input XMLType (in ORA-compatible mode) or XML (in PG-compatible mode) type data is 1 GB.
- For upgrade from a version that does not support XMLTABLE to a version that supports XMLTABLE, the XMLTABLE syntax cannot be used during the upgrade observation period.
- Only ORA-compatible mode supports "*:nodename" within XPath, which means the namespace of *nodename* is ignored when selected.
- The non-reserved keyword XMLTABLE cannot be used as the name of a function of the Functions as Table Sources type.
- In ORA-compatible mode, when the input is a sequence consisting of numbers and XML text, the restrictions are as follows:
  - It cannot be used together with **passing_clause** or **columns_clause**.
  - The number of elements separated by commas (,) in the sequence ranges from 1 to 1024.
  - Expressions cannot be used as sequence elements.
  - The ampersands (>), quotation marks ("), and ampersands (&) in XML texts are not escaped to ">", """, and "&", respectively.
  - The XML text node name can contain only one or more spaces between the node name and the greater-than sign (>), and the output result does not delete the spaces between the node name and the greater-than sign (>).
  - This feature is not supported during the upgrade observation period.
- When the returning sequence of the xmlquery is nested in the xmltable, the XPath in **column_clause** can only be a period ('.').
- The period ('.') in the XPath cannot be followed by an index expression, for example, '.[6]', or a predicate expression, for example, '.[.>5]'.
- When ill-formed XMLType data in ORA-compatible mode is entered, spaces and carriage return characters used to control the writing format between nodes after the ill-formed part are parsed as text nodes, for example, the spaces and carriage return characters between the end tag of **node2** and the start tag of **node3** are parsed as text nodes.

  Input:

```
<root>
<node1>node1</node1>
malform
<node2>node2</node2>
<node3>node3</node3>
</root>
```

  Actual situation:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
<root><node1>node1</node1>
malform
<node2>node2</node2>
<node3>node3</node3>
</root>
```

Example:

```
-- Create an ORA-compatible database.
gaussdb=# CREATE DATABASE ora_db DBCOMPATIBILITY = 'ORA' ENCODING = 'utf8';
gaussdb=# \c ora_db
-- A sequence consisting of numbers and XML text is supported.
ora_db=# SELECT * FROM XMLTABLE('1, 2, <a>12</a>');
 column_value
--------------
 1
 2
 <a>12</a>
(3 rows)

ora_db=# \c postgres
gaussdb=# DROP DATABASE ora_db;
```

– unpivot_clause

Converts a column to a row.

```
UNPIVOT [ {INCLUDE | EXCLUDE} NULLS ]
   (
      unpivot_col_clause
      unpivot_for_clause
      unpivot_in_clause
   )
```

- {INCLUDE | EXCLUDE} NULLS

  (Optional) Specifies whether the transposition result contains rows with **NULL** values. If this clause is not specified, the unpivot operation filters rows with **NULL** values from the result set by default.

  INCLUDE NULLS: retains the rows with **NULL** values in the result set.

  EXCLUDE NULLS: filters rows with **NULL** values from the result set.

- unpivot_col_clause

  ```
  unpivot_col_element
  ```

  unpivot_col_element specifies the output column names. It stores the values of the columns to be transposed.

- unpivot_col_element

  ```
  { column | ( column [, column]... ) }
  ```

- unpivot_for_clause

  ```
  FOR { unpivot_col_element }
  ```

  unpivot_col_element specifies the output column names. It stores the alias and names of the column to be transposed.

- unpivot_in_clause

  ```
  IN ( unpivot_in_element [,unpivot_in_element...] )
  ```

  unpivot_in_clause specifies the columns to be transposed. The column names and values are stored in unpivot_col_element.

  unpivot_in_element

  ```
  { unpivot_col_element }[  AS { unpivot_alias_element } ]
  ```

  unpivot_col_element specifies the column to be transposed. If (column [, column]...) is used to specify the column to be

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

transposed, the *column* names are connected by underscores (_) and saved in the output columns. For example, IN ((col1, col2)) generates the column name **col1_col2** and saves it in the output column specified by unpivot_for_clause. The AS keyword can be used to specify an alias for the column to be transposed. After an alias is specified, the alias is saved in the output column instead of the name of column to be transposed.

- unpivot_alias_element

```
{ alias | ( alias [, alias]... )}
```

alias indicates the specified alias.

NOTE

Currently, unpivot_clause has the following restrictions:

- This parameter can be used only in ORA-compatible databases.
- The unpivot_clause clause cannot be used with hints.
- For unpivot_col_clause, the number of output columns specified by unpivot_col_element must be the same as that of unpivot_col_element contained in unpivot_in_clause.
- For unpivot_for_clause, the number of output columns specified by unpivot_col_element must be the same as the number of aliases specified by unpivot_alias_element contained in unpivot_in_clause.
- For unpivot_in_clause, the alias must be a constant or an expression that can be converted to a constant.
- For **unpivot_in_clause**, constant expressions support only IMMUTABLE functions.
- For all unpivot_col_element parameters contained in unpivot_in_clause, if the column types in the same position of these unpivot_col_element parameters are different, UNPIVOT attempts to convert the column types in order to convert the values of columns to be transposed to a public type. Similarly, for all unpivot_alias_element parameters, if the alias types of these unpivot_alias_element parameters in the same position are different, UNPIVOT attempts to do the similar type conversion.

– pivot_clause

Converts a row into a column.

```
PIVOT [ XML ]
( aggregate_function ( expr ) [[AS] alias ]
    [, aggregate_function ( expr ) [[AS] alias ] ]...
    pivot_for_clause
    pivot_in_clause
)
```

- aggregate_function (expr) [[AS] alias]

  Aggregates calculation on a given expression. The calculation result is saved in the output column specified by pivot_in_clause.

  [AS] alias specifies an alias for aggregate_function. The alias is recorded in the format of _alias after the output column name specified by pivot_in_clause.

- pivot_for_clause

```
FOR { column
    | ( column [, column]... )
    }
```

pivot_for_clause specifies the row to be transposed.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

column: represents the column to which the row will be transposed.

- pivot_in_clause

```
IN ( { { { expr
        | ( expr [, expr]... )
        } [ [AS] alias]
     }...
   }
 )
```

pivot_in_clause specifies the name of the output column. The column name can consist of one or more expressions. When a column name consists of multiple expressions, these expressions are connected by underscores (_) in sequence. That is, the output column name corresponding to (expr1, expr2) is "expr1_expr2". These expressions not only generate output column names, but also determine the time when the aggregate function is triggered. If the values of row to be transposed is the same as the value of these expressions, the results calculated by aggregate_function are saved in the output column names that consist of these expressions.

NOTE

Currently, pivot_clause has the following restrictions:

- This parameter can be used only in ORA-compatible mode.
- The pivot_clause clause cannot be used with hints.
- If more than one aggregate_function is specified, at most one aggregate_function is allowed to have no alias, the rest of the aggregate_function functions are required to specify an alias.
- XML supports only syntax but does not support functions.
- The expression in pivot_in_clause can be a constant or an expression that can be converted to a constant. If the expression is not a unary expression, specify an alias for the expression.
- For pivot_in_clause, constant expressions support only IMMUTABLE functions.
- When an alias is specified for expressions in pivot_in_clause through AS, non-reserved keywords can be used as aliases; otherwise, non-reserved keywords cannot be used as aliases.
- If the length of an output column name exceeds 63 characters, an error is reported.

- **WHERE clause**

  The WHERE clause forms an expression for row selection to narrow down the query range of SELECT.

  condition indicates any expression that returns a value of Boolean type. Only rows that meet this condition will be displayed. Do not use numeric types such as int for **condition** because such types can be implicitly converted to bool values (non-zero values are implicitly converted to **true** and **0** is implicitly converted to **false**), which may cause unexpected results.

  In a WHERE clause, you can use the operator (+) to convert a table join to an outer join. This operation does not comply with standard SQL syntax. During platform migration, syntax compatibility issues may occur. You are advised not to perform this operation. Using (+) simultaneously comes with the following restrictions:

  – (+) can appear only in the WHERE clause.
  – If the table join relationship has been specified in the FROM clause, then (+) cannot be used in the WHERE clause.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- The operator (+) can work only on columns of tables or views, instead of on expressions.
- If tables have multiple join conditions, (+) must be specified in all the conditions. Otherwise, (+) will not take effect, and the table join will be converted into an inner join without displaying any prompt information.
- Tables specified in a join condition where the operator (+) works cannot cross queries or subqueries. If tables where (+) works are not in the FROM clause of the current query or subquery, an error will be reported. If a peer table for the operator (+) does not exist, no error will be reported and the table join will be converted into an inner join.
- Except for the outer join expressions of the same single table, expressions where (+) is used cannot be directly connected through the OR operator.
- If a column where the operator (+) works is compared with a constant, the expression becomes a part of the JOIN condition.
- When a table is used as the outer table for multiple tables, if there is no join relationship between the corresponding inner tables, a Cartesian product is performed between the inner tables, and then an outer join is done between the inner tables and the outer table.
- "(+)" can appear only in the following expressions: comparison, BETWEEN AND/NOT BETWEEN AND, NOT, ANY/SOME, ALL, IN/NOT IN, NULLIF, IS DISTINCT FROM/IS NOT DISTINCT FROM, IS NULL/IS NOT NULL, or IS OF. (+) is not allowed in other types of expressions. In addition, these expressions cannot be connected through AND or OR.
- The operator (+) can be used to convert a table join only to a left or right outer join, instead of a full join. That is, the operator (+) cannot be specified on both tables of an expression.
- In ORA-compatible mode, spaces are allowed within the parentheses of (+), for example, "(+)" and "(+)".
- The "(+)" operator does not support automatic parameterization.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTICE

- For the WHERE clause, if special character "%", "_", or "\" is queried in LIKE, add the slash "\" before each character. In ORA-compatible mode, when the GUC parameter **standard_conforming_strings** is set to **on**, you can set the **behavior_compat_options** parameter to **ignore_like_default_escape** to use the backslash (\) as a common character for matching.

```
gaussdb=# CREATE DATABASE ora_db DBCOMPATIBILITY = 'ORA';
gaussdb=# \c ora_db;
ora_db=# SET standard_conforming_strings = on;
ora_db=# SET behavior_compat_options = ignore_like_default_escape;
ora_db=# SELECT 'aa\a' LIKE 'aa\a';
 ?column?
----------
 t
(1 row)
ora_db=# SELECT 'aaa' LIKE 'aa\a';
 ?column?
----------
 f
(1 row)
ora_db=# SET behavior_compat_options = '';
ora_db=# SELECT 'aa\a' LIKE 'aa\a';
 ?column?
----------
 f
(1 row)
ora_db=# SELECT 'aaa' LIKE 'aa\a';
 ?column?
----------
 t
(1 row)
ora_db=# \c postgres;
gaussdb=# DROP DATABASE ora_db;
```

- If the IN clause after a WHERE clause has no following parentheses, it supports only one element to be added after IN. The restriction only applies in ORA-compatible mode. In addition, the WHERE clause can contain only this IN condition. The element has the following restrictions:
  - Constant: such as character strings, integers, and floating points
  - Column name
  - CASE WHEN clause
  - Function
- The "(+)" operator supports validity check after the common expression is extracted. A common expression is defined as an expression with the same structure, including the sequence within the expression and the sequence number of placeholders within the expression.

```
SELECT * FROM a,a2 WHERE a.id(+) IS NULL AND a.id(+) = a2.id OR a.id(+) = a2.id AND a.id(+) =
1;
```

  After the common expression a.id (+) = a2.id is extracted, it can be converted into:

```
SELECT * FROM a,a2 WHERE a.id(+) = a2.id AND (a.id(+) IS NULL OR a.id(+) = 1);
```

  The converted expression meets the requirement that the left and right sides of the OR operator are outer join expressions of the same single table. Therefore, the verification is successful.

```
SELECT * FROM a,a2 WHERE a.id(+) IS NULL AND a2.id = a.id(+) OR a.id(+) = a2.id AND a.id(+) =
1;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

The expression sequences of a2.id = a.id(+) and a.id(+) = a2.id are different, and the common expression cannot be extracted. Therefore, the verification fails.

When using placeholders to bind parameters in a PREPARE statement or dynamically executing a query statement through a cursor, ensure that the placeholder sequence numbers in the common expression are the same.

```
PREPARE p1 AS SELECT * FROM a,a2 WHERE a.id IS NULL AND a.id(+) = $1 OR a.id(+) = $2 AND a.id = 1;
```

The placeholder sequence numbers of a.id(+) = $1 and a.id(+) = $2 are different ($1≠$2), which does not comply with the definition of the common expression. Therefore, the verification fails.

- **START WITH clause**

  The START WITH clause is usually used together with the CONNECT BY clause and indicates the initial condition of recursion: Data is traversed recursively and hierarchically. If this clause is omitted and the CONNECT BY clause is used alone, all rows in the table are used as the initial set. For details, see **CONNECT BY**.

- **CONNECT BY clause**

  CONNECT BY indicates a recursive join condition. It is used together with START WITH to implement data traversal and recursion.

  In the CONNECT BY condition, the PRIOR keyword can be specified for a column to indicate that the column is recursive. If NOCYCLE is added before the recursive join condition, recursion stops when a cyclic record is encountered.

NOTICE

A SELECT statement containing the START WITH *condition* CONNECT BY clause does not support the FOR SHARE or UPDATE lock.

The process of executing the START WITH statement is as follows:

a. The initial data set is selected based on the condition in the START WITH clause. For example, select ('A', 1, 0) first, and then set the initial data set as the working set.

b. If the working set is not empty, the data in the working set is used as the input for the next query. The filter criteria are specified in the CONNECT BY clause. The keyword PRIOR indicates the current record. For example, **prior id = fatherid** in the example indicates that the ID of the current record is **fatherid** of the next record.

c. Set the data set filtered out in **the previous step** as the working set and repeat **the previous step**.

```
gaussdb=#  CREATE TABLE test(name varchar, id int, fatherid int);
gaussdb=#  INSERT INTO test VALUES('A', 1, 0), ('B', 2, 1),('C',3,1),('D',4,1),('E',5,2);
gaussdb=#  SELECT * FROM test START WITH id = 1 CONNECT BY prior id = fatherid ORDER SIBLINGS BY id DESC;
 name | id | fatherid
------+----+----------
 A    | 1 |        0
 D    | 4 |        1
 C    | 3 |        1
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
 B    | 2 |       1
 E    | 5 |       2
(5 rows)
```

Currently, the default behavior of START WITH is width-first search. However, depth-first search can be implemented by working with **pseudocolumns**. Example:

```
gaussdb=# SELECT sys_connect_by_path(name,'-') as path, *, LEVEL FROM test START WITH id = 1
CONNECT BY fatherid=prior id ORDER BY path;
  path   | name | id | fatherid | level
---------+------+----+----------+-------
 -A      | A    |  1 |        0 |     1
 -A-B    | B    |  2 |        1 |     2
 -A-B-E  | E    |  5 |        2 |     3
 -A-C    | C    |  3 |        1 |     2
 -A-D    | D    |  4 |        1 |     2
gaussdb=# DROP TABLE test;
```

If a cycle exists in the data set, the database provides cycle detection. By default, an error is reported and no data is returned when a cycle is detected. If the NOCYCLE keyword is specified, the query can be executed normally, and recursion stops and exits when a cyclic record is encountered.

– Pseudocolumns: The database adds pseudocolumns to each selected data record so that users can learn about the position of the data in the recursive or tree structure.

  - **LEVEL**: level of a node. The level of the root node is **1**.
  - **CONNECT_BY_ISCYCLE**: returns whether the current node forms a cycle with its parent or child row.
  - **CONNECT_BY_ISLEAF**: specifies whether a node is a leaf node. If a node does not have any subnode, the node is a leaf node and **CONNECT_BY_ISLEAF** is set to **1**. Otherwise, it is set to **0**.

  For example (Assume that table **T1** already exists with the data structure as shown in **Table 1-406**):

```
SELECT * FROM T1 CONNECT BY PRIOR B=A AND LEVEL<=3;
```

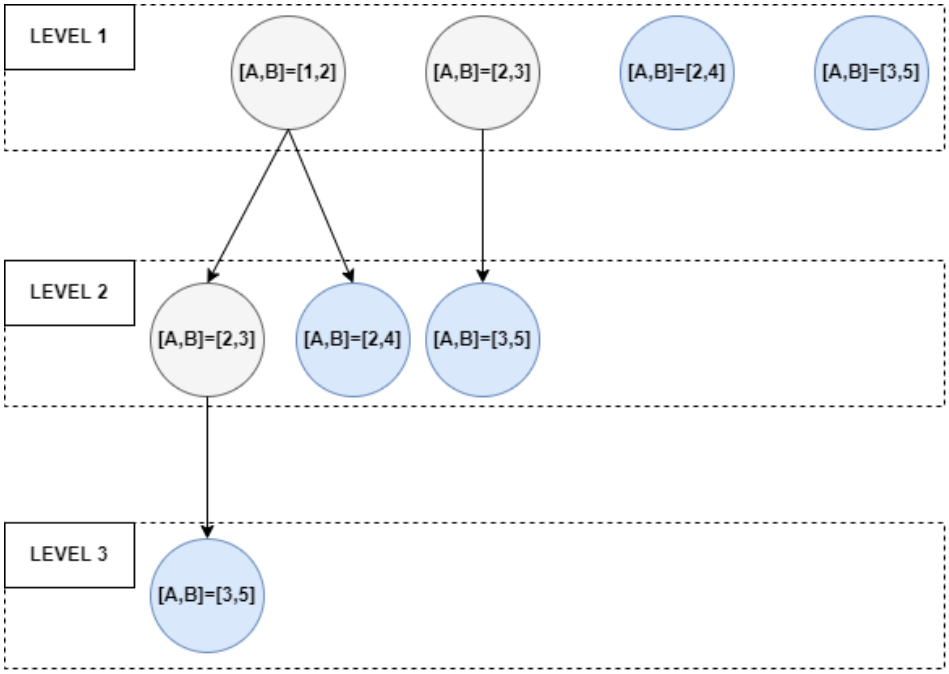
Table 1-406 T1 data structure

A	B
1	2
2	3
2	4
3	5

The tree structure of the result is shown in **Figure 1-15**, where the blue nodes are leaf nodes.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Figure 1-15 Logical structure of the execution



- Query functions: In addition to pseudocolumns, the database also provides query functions (for details, see **Hierarchical Recursion Query Functions**).
  - **sys_connect_by_path(col, separator)**: returns the connection path from the root node to the current row. **col** indicates the name of the column displayed in the path, and **separator** indicates the connector.
  - **connect_by_root(col)**: displays the top-level node of the node. **col** indicates the name of the output column.
- In addition to pseudocolumns and query functions, the PRIOR keyword can be used outside the CONNECT BY clause to modify columns. It can be used in the SELECT query column, DISTINCT clause, WHERE clause, GROUP BY clause, HAVING clause, WINDOW clause, and ORDER BY clause to display the parent row column value.
- In the hierarchical query, the search is performed strictly according to the depth-first order. If **ROWNUM** is used as the filter condition in START WITH or CONNECT, the value of **ROWNUM** is increased by 1 for each record to be returned. Then, the record is verified based on **ROWNUM** conditions. Records that do not satisfy the conditions are discarded and the value of **ROWNUM** is decreased by 1.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTICE

- The PRIOR keyword cannot be specified in the START WITH statement.
- In addition to **targetlist**, "prior (single column)" is parsed as "prior single column". User-defined functions named **prior** are not perceived.
- PRIOR can be specified only for columns in the table. It cannot be specified for expressions, pseudocolumns, or type conversions.
- In the CONNECT BY statement, columns modified by PRIOR cannot be in the same condition as pseudocolumns like level and rownum (such as **PRIOR a = level**), but can be in different conditions (such as **PRIOR a = b and level = 1**). Different conditions refer to the conditions joined by AND at the top layer of the CONNECT BY statement.
- In the START WITH and CONNECT BY clauses, pseudocolumns cannot be used for subconnection, for example, "rownum = (subquery)" or "rownum in (subquery)".
- You are advised not to use ROWNUM in the CONNECT BY clause. If ROWNUM is required, test it thoroughly to avoid unexpected results.
- When START WITH or CONNECT BY are called on the CTE defined by WITH AS, if there are multiple CTEs, ensure that the definition of each CTE does not depend on other CTEs.
- If no cycle exists in the data but the error message "runs into cycle" is reported, increase the value of **max_recursive_times**.
- **connect_by_isleaf**, **connect_by_iscycle** and **level** are of the int type.
- In hierarchical queries, **connect_by_isleaf**, **connect_by_iscycle**, and **level** will be parsed as pseudocolumns and will not be parsed as columns whose alias names in projection columns are the same as pseudocolumns.
- You are advised not to reference other views when defining views with hierarchical queries.
- Optimization suggestions for the START WITH clause:
  - Create indexes based on the conditions in the CONNECT BY clause to improve the performance of the START WITH clause.
  - Identify bottlenecks based on the plan collected by running EXPLAIN PERFORMANCE or in WDR. If the recursive operator (inner plan) of RECURSIVE UNION is the Hash JOIN operator, but the hash table is created for the temporary table **tmp_result** or the hash table in plan is materialized (that is, the batch size is greater than 1), the possible cause is that the value of **work_mem** is too small. As a result, the hash table cannot be created for the outer data table. You can increase the value of **work_mem** to improve performance.

    GaussDB optimizes tables with a small volume of data and caches table results in hash tables to improve performance. In this case, indexes are not required. However, if the data volume exceeds the limit specified by **work_mem**, the optimization becomes invalid. In this case, you can create indexes for optimization.
- If no value or **NULL** is used in the START WITH statement, the initial recursive condition is empty and an empty result is returned.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- If no value is used in the CONNECT BY statement, the recursive condition is empty and all results that meet the condition of the START WITH clause are returned.
- PRIOR-qualified columns support only the following types: INT8, INT1, INT2, OID, INT4, BOOL, CHAR, NAME, FLOAT4, FLOAT8, ABSTIME, RELTIME, DATE, DATEA (only effective in ORA-compatible mode), CASH, TIME, TIMESTAMP, TIMESTAMPTZ, SMALLDATETIME, UUID, INTERVAL, TIMETZ, INT2VECTOR, CLOB, NVARCHAR2, VARCHAR, TEXT, VECTOR, BPCHAR, RAW, BYTEA, NUMERIC, XID, CID, and TID. The operation of forcibly converting a type to any aforementioned type cannot avoid the whitelist restriction, for example, by running **PRIOR col::text** (where col is not a type in the aforementioned whitelist).
- When the PRIOR keyword is used to modify a column outside the CONNECT BY clause, the statement behavior is displayed based on the value of the **enable_startwith_prior_enhance** parameter. If this parameter is disabled, using the PRIOR keyword to modify a column is equivalent to not adding the PRIOR keyword. In this case, the current row and column values are displayed. If this parameter is enabled and the PRIOR keyword is used to modify a column in a clause (SELECT query column, DISTINCT clause, WHERE clause, GROUP BY clause, HAVING clause, WINDOW clause, or ORDER BY clause), the parent row column values are displayed. In addition, an error is reported in the following scenarios:
  - In a clause (SELECT query column, DISTINCT clause, WHERE clause, GROUP BY clause, HAVING clause, WINDOW clause, or ORDER BY clause) that supports PRIOR, PRIOR is used to modify the pseudo columns **LEVEL**, **CONNECT_BY_ISCYCLE**, and **CONNECT_BY_ISLEAF**.
  - In the SELECT statement with the CONNECT BY clause, PRIOR is used to modify columns in the ON condition and ORDER SIBLINGS BY clause.
  - In the statement without the CONNECT BY clause, the PRIOR keyword is used to modify columns.
- If PRIOR is used to modify different columns for multiple times in the same query statement, the data is considered duplicate only when the values of all modified columns are the same. That is, a cycle exists.
- If the **level**, **connect_by_isleaf**, or **connect_by_iscycle** column is used as the input parameter of the hierarchical recursive query function sys_connect_by_path or connect_by_root, it will be parsed as a pseudocolumn and an error will be reported.

- ORDER SIBLINGS BY clause

  The output of the START WITH statement is returned level by level. However, within each layer, the database automatically selects the optimal execution path, so the implementation sequence cannot be guaranteed. If you have requirements on the final output sequence, you can use ORDER SIBLINGS BY. The usage of ORDER SIBLINGS BY is the same as that of ORDER BY. ORDER SIBLINGS BY is used for sorting at each level during recursion.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTICE

The expression following ORDER SIBLINGS BY only supports sorting by calling non-aggregate and window functions for ordinary columns, column name offsets, and column names. It does not support calling system functions related to START WITH for column names or using pseudocolumns related to START WITH.

- **GROUP BY clause**

  Condenses query results into a single row all selected rows that share the same values for the grouped expressions.

  – CUBE ({ expression | (expression [, ...]) } [, ...])

    A CUBE grouping is an extension to the GROUP BY clause that creates subtotals for all of the possible combinations of the given list of grouping columns (or expressions). In terms of multidimensional analysis, CUBE generates all the subtotals that could be calculated for a data cube with the specified dimensions. For example, given three expressions (n=3) in the CUBE clause, the operation results in $2^n = 2^3 = 8$ groupings. Rows grouped on the values of *n* expressions are called regular rows, and the rest are called superaggregate rows.

  – GROUPING SETS (grouping_element [, ...])

    GROUPING SETS is an advanced extension of the GROUP BY clause. It allows you to explicitly define multiple GROUP BY options in a single query. Unlike CUBE or ROLLUP, GROUPING SETS precisely specifies the required grouping sets, and the database does not need to execute the complete aggregation set generated by CUBE or ROLLUP, thereby significantly improving query efficiency.

    NOTE

    When the GROUPING SETS clause is used, an error may be reported if the SQL query statement contains logical statements such as DISTINCT ON, ORDER BY, or multi-table equi-joins. You are advised to encapsulate the calculation logic of the GROUPING SETS clause into the inner subquery so that the grouping set calculation can be executed independently first.

    ```
    SELECT DISTINCT ON (a) a, b FROM t1 GROUP BY GROUPING SETS ((a, b), (b)) ORDER BY a, b DESC;
    ```

    It can be rewritten as:

    ```
    SELECT DISTINCT ON (a) a, b FROM (SELECT a, b FROM t1 GROUP BY GROUPING SETS ((a, b), (b))) AS sub_t ORDER BY a, b DESC;
    ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTICE

- If **sql_mode** contains the **ONLY_FULL_GROUP_BY** option, the following situations occur:
  - If the non-aggregate function column in the SELECT list is consistent with the column for GROUP BY, no error is reported.
  - If the non-aggregate function column in the SELECT list is inconsistent with the column for GROUP BY, the following situations may occur:
    - If the GROUP BY list contains a primary key or a unique non-null key, the SQL statement does not report an error.
    - Non-aggregate function columns in the SELECT list are also included in the GROUP BY or WHERE list. If included in the WHERE list, the columns in the WHERE clause must be in the form of a constant, and then no error will be reported.
    - If both the JOIN and GROUP BY clauses are contained, the following situations may occur:
      - LEFT JOIN

        In the syntax, when the ON clause is used for equality check between two columns, no error is reported if the GROUP BY clause contains columns from the LEFT JOIN table.

        For example, when LEFT JOIN operations are performed on tables **t1** and **t2**, if the condition in the ON clause is **t1.col1=t2.col2 ...**, the GROUP BY clause only needs to contain **t1.col1**.
      - RIGHT JOIN

        In the syntax, when the ON clause is used for equality check between two columns, no error is reported if the GROUP BY clause contains columns from the RIGHT JOIN table.

        For example, when RIGHT JOIN operations are performed on tables **t1** and **t2**, if the condition in the ON clause is **t1.col1=t2.col2 ...**, the GROUP BY clause only needs to contain **t2.col2**.
      - INNER JOIN/CROSS JOIN/STRAIGHT_JOIN

        In the syntax, when the ON clause is used for equality check between two columns, no error is reported if the GROUP BY clause contains either of the columns.
- If **sql_mode** does not contain the **ONLY_FULL_GROUP_BY** option, no restriction exists and no error will occur in the preceding error scenarios.
  - If SELECT contains both non-aggregate function columns and aggregate functions, it must be used together with GROUP BY. Otherwise, it will result in an error.
  - If a non-aggregate function column beyond the columns for GROUP BY contains multiple data records after it is grouped, due to differences in execution plans and DN data distribution, the queried column data is a random data record in the grouped data.
- The GROUP BY clause does not support sorting of non-integer constants.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **HAVING clause**

  Used together with the GROUP BY clause to select special groups. The HAVING clause compares some attributes of groups with a constant. Only groups that match the logical expression in the HAVING clause are displayed.

- **WINDOW clause**

  ```
  WINDOW window_name AS ( window_definition ) [, ...]
  ```

  – **window_name**: name referenced by **window_definition**.

  – window_definition:

  ```
  [ existing_window_name ]
  [ PARTITION BY expression [, ...] ]
  [ ORDER BY expression [ ASC | DESC | USING operator ] [ NULLS { FIRST | LAST } ] [, ...] ]
  [ frame_clause ]
  ```

  frame_clause: defines a window frame for window functions. Window functions (not all) depend on the window frame.

  window frame: indicates a group of related rows of the current query row.

  The format of frame_clause is as follows:

  ```
  [ RANGE | ROWS ] frame_start
  [ RANGE | ROWS ] BETWEEN frame_start AND frame_end
  ```

  Formats of **frame_start** and **frame_end**:

  ```
  UNBOUNDED PRECEDING
  VALUE PRECEDING
  CURRENT ROW
  VALUE FOLLOWING
  UNBOUNDED FOLLOWING
  ```

  NOTE

  Restrictions on scenarios where VALUE is used:

  - The table columns operated by the aggregate function or window function support only the INT1, INT2, INT4, INT8, FLOAT4, FLOAT8, NUMERIC, INTERVAL, TIME, TIMETZ, TIMESTAMP, TIMESTAMPTZ, DATEA (only effective in ORA-compatible mode), and DATE types.
  - The VALUE type supports only the INT1, INT2, INT4, INT8, INT16, FLOAT4, FLOAT8, NUMERIC, INTERVAL, and character string (only character strings that can be implicitly converted to numbers are supported) types.
  - The value of **VALUE** can only be a non-negative number.
  - Currently, **VALUE** only supports constants instead of variables and expressions as the upper and lower boundaries.

- **UNION clause**

  ```
  select_statement UNION [ALL] select_statement
  ```

  – **select_statement**: SELECT statement that does not contain the ORDER BY, LIMIT, or FOR UPDATE clause.

  – UNION operator: calculates the union of multiple row sets returned by **select_statement**.

  – **ALL**: optional. If it is not specified, the UNION result excludes duplicate rows.

  The UNION clause has the following restrictions:

  – The number of columns in multiple SELECT statements must be the same, and the data type and sequence of each column must be the same.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

  - Multiple UNION operators in the same SELECT statement have a default priority of executing from left to right. To alter the priority, use parentheses to specify the order.
  - FOR UPDATE cannot be specified either for a UNION result or for any input of a UNION.
  - A UNION subexpression can contain an ORDER BY or LIMIT clause enclosed in parentheses.

NOTICE

- It is recommended that the number of UNION ALL clauses be less than 100. If the number of UNION ALL clauses exceeds 100, ensure that the instance memory is sufficient.
- The following constraints apply when you perform set operations with **NULL**:
  - **NULL** can only be a projection column itself or a projection column in a subquery of the FROM statement.
  - In CTEs and recursive queries, complex subqueries (DISTINCT, GROUP BY, ORDER BY, and PARTITION BY statements) are not supported.

- **INTERSECT clause**

```
select_statement INTERSECT select_statement
```

  - **select_statement**: SELECT statement that does not contain the FOR UPDATE clause.
  - INTERSECT operator: calculates the intersection of multiple row sets returned by **select_statement** and deduplicates rows.

  The INTERSECT clause has the following restrictions:

  - Multiple INTERSECT operators in the same SELECT statement have a default priority of executing from left to right. To alter the priority, use parentheses to specify the order.
  - For UNION and INTERSECT operations on the execution results of multiple SELECT statements, INTERSECT has a higher priority than UNION.

- **EXCEPT clause**

```
select_statement EXCEPT [ ALL ] select_statement
```

  - **select_statement**: SELECT expressions that do not contain the FOR UPDATE clause.
  - The EXCEPT operator calculates the rows that are in the output of the left **select_statement** but not in the output of the right **select_statement**. Multiple EXCEPT operators in the same SELECT statement have a default priority of executing from left to right. To alter the priority, use parentheses to specify the order.
  - **ALL**: (Optional) If **ALL** is not specified, the result of EXCEPT does not contain any duplicate rows; if it is specified, a row with *m* duplicate rows in the left table and *n* duplicate rows in the right table appears max(*m* – *n*,0) times in the result.

  Currently, the FOR UPDATE clause cannot be declared for the results of EXCEPT or for any inputs of EXCEPT.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **MINUS clause**

  Has the same function and syntax as EXCEPT clause.

- **ORDER BY clause**

  Sorts data retrieved by SELECT in ascending or descending order. The ORDER BY clause does not support sorting of non-integer constants.

  - If an ORDER BY expression contains multiple columns, the columns are sorted based on the following behavior:
    - The expression is executed from left to right. The leftmost column is sorted first. If two columns are equal according to the leftmost expression, they are compared according to the next expression.
    - If they are equal according to all specified expressions, they are returned in an implementation-dependent order.
    - When used with the DISTINCT keyword, the columns to be sorted in ORDER BY must be included in the columns of the result set retrieved by the SELECT statement.
    - When used with the GROUP BY clause, the columns to be sorted in ORDER BY must be included in the columns of the result set retrieved by the SELECT statement.
  - When the clause is not used with the GROUP BY clause and the columns of the result set retrieved by the SELECT statement contain aggregate functions:
    - The ORDER BY clause is ignored if the columns of the retrieved result set do not contain any aggregate functions.
    - Only the sorting of the columns that contain aggregate functions is retained if the columns of the retrieved result set contain aggregate functions.
  - In an ORA-compatible database, when the **DISTINCT** keyword is specified, the columns or expressions referenced in the ORDER BY clause must be in the DISTINCT list.
    - The expression range supported by the ORDER BY clause must comply with the constraints of the ORDER BY clause.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

1. ORDER BY supports only operations on constants and entire expressions. It may not guarantee normal operations on constants and non-entire expressions.

```
-- Supported.
-- It is recommended that an entire expression be enclosed by parentheses for the operation on a constant and the entire expression.
SELECT DISTINCT c1*c2+c2*c1 FROM t1 ORDER BY c2*c1+c1*c2+1;
SELECT DISTINCT c1*c2+c2*c1 FROM t1 ORDER BY (c2*c1+c1*c2)+1;
SELECT DISTINCT c1*c2+c2*c1 FROM t1 ORDER BY 1+(c2*c1+c1*c2);

-- Not supported.
-- In terms of the operation on a constant and a non-entire expression, the position of the constant affects the structure verification logic of the expression, which may affect the normal operation.
SELECT DISTINCT c1*c2+c2*c1 FROM t1 ORDER BY 1+c2*c1+c1*c2;
SELECT DISTINCT c1*c2+c2*c1 FROM t1 ORDER BY c2*c1+1+c1*c2;
```

2. If the ORDER BY and DISTINCT expressions contain multiple forcible type conversions, the database parses and converts the forcibly converted expressions. If the parsed expression of ORDER BY is in the parsed list of DISTINCT, it passes the verification. Otherwise, it fails the verification. If the DISTINCT expression is inconsistent with the ORDER BY expression, the parsed results may be inconsistent.

```
-- Not supported.
-- The DISTINCT expression is inconsistent with the original expression of ORDER BY, and the parsed results are also inconsistent.
SELECT DISTINCT c1::int::char::int,c2::integer::int3::int4 FROM t1 ORDER BY c2::char::int + c1;

-- Supported.
-- The DISTINCT expression is inconsistent with the original expression of ORDER BY, but the parsed results are consistent.
SELECT DISTINCT c1::int::char::int,c2::integer::int3::int4 FROM t1 ORDER BY c2::char::int + c1::char::int;
SELECT DISTINCT c1::int::int::char::int::int,c2::integer::int3::int4 FROM t1 ORDER BY c2::char::int + c1::int::char::int;
SELECT DISTINCT c1::int::int::char::char::char::int::int,c2::integer::int3::int4 FROM t1 ORDER BY c2::char::int + c1::int::char::int;
```

3. The addition and multiplication operations in functions do not support swapping.

```
SELECT DISTINCT BIT_LENGTH(c1+c2) FROM t1 ORDER BY BIT_LENGTH(c2+c1);
```

4. If both DISTINCT and ORDER BY expressions contain function aliases, only aliases whose function attributes are STABLE and IMMUTABLE are supported.

```
-- Not supported.
-- The function attribute is VOLATILE.
SELECT DISTINCT DBE_RANDOM.GET_VALUE(c1+c2,100) AS c0 FROM t1 ORDER BY c0+1;

-- Supported.
-- The function attribute is STABLE.
SELECT DISTINCT add_numbers(c1,c2) AS c0 FROM t1 ORDER BY c0+1;
```

5. If ORDER BY is followed by only a constant, the constant indicates the position of a DISTINCT expression and must meet the limitations of ORDER BY.

```
-- Supported.
-- 1 indicates the first expression in the DISTINCT list.
SELECT DISTINCT c1,c2 FROM test_table ORDER BY 1;

-- Not supported.
-- 2 indicates the second expression in the DISTINCT list. Since the DISTINCT list contains only one expression, the system reports the error: "The expression at position 2 does not exist."
SELECT DISTINCT 1 FROM test_table ORDER BY 2;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

  - Addition and multiplication operations only support swapping when left and right expressions are consistent.

  NOTE

  To support Chinese pinyin order, set the encoding format to **UTF-8**, **GB18030**, **GB18030_2022**, **GBK**, or **ZHS16GBK** when initializing the database. The statements are as follows:

  ```
  initdb –E UTF8 –D ../data –locale=zh_CN.UTF-8
  initdb -E GB18030 -D ../data -locale=zh_CN.GB18030
  initdb -E GB18030_2022 -D ../data -locale=zh_CN.GB18030
  initdb –E GBK –D ../data –locale=zh_CN.GBK
  initdb –E ZHS16GBK –D ../data –locale=zh_CN.GBK
  ```

- **LIMIT clause**

  Consists of two independent sub-clauses:

  LIMIT { count | ALL } limits the number of rows to be returned. **count** specifies the number of rows to be returned. The effect of **LIMIT ALL** is the same as that of omitting the LIMIT clause.

  OFFSET start count specifies the maximum number of rows to be returned. **count** specifies the number of rows, and **start** specifies the number of rows to be ignored before the first row is returned. If both parameters are specified, the **count** of returned rows starts being calculated after the **start** row.

  ROWNUM cannot be used as count or offset in the LIMIT clause.

- **OFFSET clause**

  The SQL: 2008 standard has introduced a different clause:

  ```
  OFFSET start { ROW | ROWS }
  ```

  start specifies the number of rows to be ignored before starting to return rows.

- **FETCH { FIRST | NEXT } [count] { ROW | ROWS } ONLY [OFFSET offset_count]**

  If **count** is omitted in a **FETCH** clause, it defaults to **1**.

- **FOR UPDATE | SHARE clause**
  - FOR UPDATE: adds an exclusive lock to the rows retrieved by SELECT to prevent the retrieved rows from being modified or deleted by other transactions before the current transaction ends. This blocks other UPDATE, DELETE, and SELECT FOR UPDATE operations until the current transaction ends.
  - FOR SHARE: adds a shared lock to the rows retrieved by SELECT to prevent them from being modified or deleted by other transactions before the current transaction ends. This blocks other UPDATE, DELETE, and SELECT operations (except for SELECT FOR SHARE), until the current transaction ends.
  - **[OF table_name [, ...]]**: object to which the lock is added. If a table name is explicitly specified, only the specified table is locked, while others used in SELECT remain unlocked; otherwise, all tables employed in the command will be locked. If applied to a view or subquery, it locks all specified tables used in the view or subquery.

  To prevent the operation from waiting for the commit of other transactions, you can set the following options:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **NOWAIT**: If the selected row cannot be locked immediately, an error is reported immediately after **SELECT FOR UPDATE NOWAIT** is executed.
- **WAIT** *n*: If the selected row cannot be locked immediately, wait for *n* seconds (*n* is of the int type and the value range is $0 \leq n \leq 2147483$). If the lock is obtained within *n* seconds, the operation is performed normally. Otherwise, an error is reported.
- **SKIP LOCKED**: skips locked rows when adding locks to a table. **SKIP LOCKED** skips only row locks and does not skip scenarios where locks do not block each other in different transactions, such as in scenario of SELECT FOR SHARE - SELECT FOR SHARE SKIP LOCKED.

NOTICE

- Multiple FOR UPDATE and FOR SHARE clauses can be written if it is necessary to specify different locking behaviors for different tables.
- If the same table is mentioned (or implicitly affected) by both FOR UPDATE and FOR SHARE clauses, it is processed as FOR UPDATE. Similarly, a table is processed as **NOWAIT** if that is specified in any of the clauses affecting it.
- For SQL statements containing FOR UPDATE or FOR SHARE, their execution plans will be pushed down to DNs. If the pushdown fails, an error will be reported.
- The query of row number contained in the projection column or WHERE conditions does not support FOR UPDATE or FOR SHARE.
- For the FOR UPDATE or FOR SHARE operation whose subquery is a stream plan, the same locked row cannot be concurrently updated.
- For the ORDER BY FOR UPDATE or ORDER BY FOR SHARE operation, the execution order of the sort operator and lock operator in the stream plan differs from that in other plans. In the stream plan, the lock operation is performed before the sort operation. In other plans, the sort operation is performed before the lock operation. The reason is that if the data in the stream plan is not on the current DN, the data needs to be redistributed and locked on the original DN. After redistribution, data becomes disordered. Therefore, the SORT operator needs to be added. If SORT is performed before LOCK, the original ordered data becomes disordered again. In this case, the SORT operator is meaningless and can be eliminated. The final plan execution sequence is changed from **sort > lock > sort** to **lock > sort**.
- When FOR UPDATE or FOR SHARE operations are performed concurrently, adding ORDER BY to sort data can help prevent issues like no response. However, this approach is inappropriate in distributed systems because the locking order of DNs cannot be determined by ORDER BY, and specifying ORDER BY also leads to performance overhead. You are advised not to use ORDER BY to address this issue.
- The DATABASE LINK function does not support the SKIP LOCKED syntax.
- In distributed scenarios, FOR UPDATE/SHARE cannot be performed on multiple tables.
- The hierarchical query statement cannot be used together with this clause.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- NLS_SORT

  Sorts data according to the specified mode.

  Value range:

  - **SCHINESE_PINYIN_M**, sorted by Pinyin order.
  - **generic_m_ci**: sorted in case-insensitive order (optional; only English characters are supported in the case-insensitive order.)

  NOTICE

  Currently, only Chinese Pinyin and case-insensitive sorting are supported. When creating a database, you need to specify the encoding format as **UTF8**, **GB18030**, **GB18030_2022**, **GBK**, or **ZHS16GBK**. If you specify another encoding format, such as **SQL_ASCII**, an error may occur or the sorting may be invalid.

- **PARTITION clause**

  Queries data in a partition of a partitioned table.

1.13.19.3.1 Simple Queries

A simple query retrieves one or more columns of data from one or more tables or views.

Example:

```
-- Create a table and insert data into the table.
gaussdb=# CREATE TABLE student(
    sid INT PRIMARY KEY,
    class INT,
    name  VARCHAR(50),
    gender INT CHECK(gender = 0 OR gender = 1) -- Gender. 1: male; 0: female
);
gaussdb=# INSERT INTO student (sid, class, name, gender) VALUES (1, 1, 'michael', 0);
gaussdb=# INSERT INTO student (sid, class, name, gender) VALUES (2, 2, 'bob', 1);
gaussdb=# INSERT INTO student (sid, class, name, gender) VALUES (3, 2, 'gary', 0);

-- Query some columns.
gaussdb=# SELECT sid, name FROM student;
 sid |  name
-----+---------
   1 | michael
   2 | bob
   3 | gary
(3 rows)

-- Query all columns.
gaussdb=# SELECT * FROM student;
 sid | class |  name   | gender
-----+-------+---------+-----
   1 |     1 | michael |   0
   2 |     2 | bob     |   1
   3 |     2 | gary    |   0
(3 rows)

-- Specify the column alias.
gaussdb=# SELECT sid student_id, name FROM student;
 student_id |  name
------------+---------
          1 | michael
          2 | bob
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
        3 | gary
(3 rows)

-- Drop the table.
gaussdb=# DROP TABLE student;
```

1.13.19.3.2 Conditional Queries

A conditional query retrieves data that meets the conditions.

Example:

```
-- Create a table and insert data into the table.
gaussdb=# CREATE TABLE test_grade(
    id INT,
    name VARCHAR(20),
    score FLOAT
);
gaussdb=# INSERT INTO test_grade VALUES (1,'Scott',90),(2,'Jack',87.5),(3,'Ben',48);

-- Query information about students who fail to pass the test.
gaussdb=# SELECT * FROM test_grade WHERE score < 60;
 id | name | score
----+------+-------
  3 | Ben  |    48
(1 row)

-- Drop the table.
gaussdb=# DROP TABLE test_grade;
```

1.13.19.3.3 Group Queries

A group query is usually used together with aggregate functions to query category statistics. Common aggregate functions include count(), sum(), avg(), min(), and max(). GROUP BY is often used in group queries.

```
-- Create a table and insert data into the table.
gaussdb=# CREATE TABLE student (id INT,name VARCHAR(20),class INT);
gaussdb=# INSERT INTO student VALUES (1, 'Scott', 1), (2, 'Ben', 1);
gaussdb=# INSERT INTO student VALUES (3, 'Jack', 2),(4, 'Anna', 2),(5, 'Judy', 2);
gaussdb=# INSERT INTO student VALUES (6, 'Sally', 3), (7, 'Jordan', 3);

-- Use the aggregate function COUNT() to count the number of people in each class.
gaussdb=# SELECT class, count(*) AS cnt FROM student GROUP BY class;
 class | cnt
-------+-----
     2 |   3
     1 |   2
     3 |   2
(3 rows)

-- Use the HAVING clause to retrieve data of classes with fewer than three people.
gaussdb=# SELECT class, COUNT(*) AS num FROM student GROUP BY class HAVING COUNT(*) < 3;
 class | num
-------+-----
     1 |   2
     3 |   2
(2 rows)

-- Drop the table.
gaussdb=# DROP TABLE student;
```

sql_mode contains the **ONLY_FULL_GROUP_BY** option, which is used to verify the GROUP BY list and SELECT list.

```
-- Create a table and insert data into the table.
gaussdb=# CREATE TABLE test (
        id int  primary key NOT NULL,
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
        id_2 int unique NOT NULL,
        s1 varchar(10),
        s2 int,
        s3 varchar(12)
      );
gaussdb=# INSERT INTO test value(1,101,'a',1000,'aa');
gaussdb=# INSERT INTO test value(2,102,'b',2000,'aaa');
gaussdb=# INSERT INTO test value(3,103,'c',3000,'aaaa');
gaussdb=# INSERT INTO test value(4,104,'b',4000,'aaa');
gaussdb=# INSERT INTO test value(5,105,'c',5000,'aaaaa');
gaussdb=# CREATE TABLE tb1(a int, b int, c int);
gaussdb=# INSERT INTO tb1 VALUES(1, 4, 11);
gaussdb=# INSERT INTO tb1 VALUES(2, 5, 12);
gaussdb=# INSERT INTO tb1 VALUES(2, 6, 13);
gaussdb=# INSERT INTO tb1 VALUES(2, 2, 13);
gaussdb=# CREATE TABLE tb2(a int, b int);
gaussdb=# INSERT INTO tb2 VALUES(2, 7);
gaussdb=# INSERT INTO tb2 VALUES(2, 8);
gaussdb=# INSERT INTO tb2 VALUES(3, 9);

-- Set <b>sql_mode</b>.
gaussdb=# SET sql_mode =
'ONLY_FULL_GROUP_BY,STRICT_TRANS_TABLES,NO_ZERO_IN_DATE,NO_ZERO_DATE,ERROR_FOR_DIVISION_
BY_ZERO,NO_AUTO_CREATE_USER,NO_ENGINE_SUBSTITUTION';

-- If the non-aggregate function column in the SELECT list is consistent with the column for GROUP BY, no
error is reported.
gaussdb=# SELECT s1, s3 FROM test GROUP BY s1,s3 ORDER BY s1,s3;
 s1 |  s3
----+-------
 a  | aa
 b  | aaa
 c  | aaaa
 c  | aaaaa
(4 rows)

gaussdb=# SELECT s1, s3 FROM test GROUP BY s3 ORDER BY s3;
ERROR:  Column "test.s1" must be used in the GROUP BY clause or aggregate function.
LINE 1: SELECT s1, s3 FROM test GROUP BY s3 ORDER BY s3;
               ^
-- If the non-aggregate function column in the SELECT list is inconsistent with the column for GROUP BY,
the following two cases exist:
-- Situation 1: If the GROUP BY list contains a primary key or a unique not-null key, the SQL statement does
not report an error.
gaussdb=# SELECT s1, MAX(LENGTH(s3)) FROM test GROUP BY id ORDER BY id;
 s1 | max

 c  |   4
 b  |   3
 c  |   5
(5 rows)

-- Situation 2: All non-aggregate function columns in the SELECT list are displayed in the GROUP BY or WHERE list. Columns in the WHERE clause must be equal to a constant.
gaussdb=# SELECT s1, SUM(s2) FROM test WHERE s1 = 'b' GROUP BY s1;
 s1 | sum
----+------
 b  | 6000
(1 row)

-- Drop.
gaussdb=# DROP TABLE test, tb1, tb2;
```

1.13.19.3.4 Pagination Queries

The syntax is as follows:

```
SELECT query_list FROM table_name [ LIMIT { [offset,] count | ALL } ]
SELECT query_list FROM table_name [ FETCH { FIRST | NEXT } [ count ] { ROW | ROWS } ONLY [OFFSET offset_count]]
```

- **offset**: indicates the number of rows to skip before starting to return rows.
- **count**: indicates the number of data records to be retrieved after the skipped rows.
- **ALL**: indicates that all data after the skipped rows is retrieved.
- **FIRST**: queries data from the beginning of the result set. It can be used together with **OFFSET** to start the query from the offset specified by **offset_count**.
- **NEXT**: It can be used together with **OFFSET** to start the query from the offset specified by **offset_count**. If **OFFSET** is not specified, data is queried from the beginning of the result set.
- **offset_count**: offset, indicating that data is queried after the specified offset.

```
-- Create a table and insert 100 data records into the table.
gaussdb=# CREATE TABLE testl(id int PRIMARY KEY, flag varchar(10));
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gaussdb=# INSERT INTO testl (id, flag) VALUES (generate_series(1,100),'flag'||generate_series(1,100));

-- Query the first five data records.
gaussdb=# SELECT * FROM testl ORDER BY 1  LIMIT 5;
 id | flag
----+-------
  1 | flag1
  2 | flag2
  3 | flag3
  4 | flag4
  5 | flag5
(5 rows)

gaussdb=# SELECT * FROM testl ORDER BY 1 FETCH FIRST 5 ROWS ONLY;

gaussdb=# SELECT * FROM testl ORDER BY 1 LIMIT 96,ALL;
 id  |  flag
-----+---------
  97 | flag97
  98 | flag98
  99 | flag99
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
 100 | flag100
(4 rows)

-- Drop the table.
gaussdb=# DROP TABLE testl;
```

1.13.19.3.5 Partition Queries

Queries data in a specified partition.

Example:

```
-- Create a range partitioned table.
gaussdb=# CREATE TABLE test_range1(
    id INT,
    info VARCHAR(20)
) PARTITION BY RANGE (id) (
    PARTITION p1 VALUES LESS THAN (200),
    PARTITION p2 VALUES LESS THAN (400),
    PARTITION p3 VALUES LESS THAN (600),
    PARTITION p4 VALUES LESS THAN (800),
    PARTITION pmax VALUES LESS THAN (MAXVALUE)
);

-- Insert 1000 data records.
gaussdb=# INSERT INTO test_range1 VALUES(GENERATE_SERIES(1,1000),'abcd');

-- Query the number of data records in the p1 partition.
gaussdb=# SELECT COUNT(*) FROM test_range1 PARTITION (p1);
 count
-------
   199
(1 row)

-- Drop the table.
gaussdb=# DROP TABLE test_range1;
```

1.13.19.3.6 Join Queries

A join query may also be referred to as a cross-table query, where multiple tables need to be joined.

```
-- Create a table and insert data into the table.
gaussdb=# CREATE TABLE emp(
    id int,         -- Employee ID.
    name varchar,   -- Employee name.
    deptno int      -- Department ID.
);

gaussdb=# CREATE TABLE dept(
    deptno int,     -- Department ID.
    depname varchar -- Department name.
);

gaussdb=# INSERT INTO emp VALUES (1, 'Joe', 10), (2, 'Scott', 20), (3, 'Ben', 999);   -- The department of Ben has not been confirmed yet. Therefore, the department ID is 999.
gaussdb=# INSERT INTO dept VALUES (10, 'hr'), (20, 'it'), (30, 'sal');                -- There is no employee in the sal department.
```

- INNER JOIN

  ```
  gaussdb=# SELECT t1.id,t1.name,t2.depname FROM emp t1 JOIN dept t2 ON t1.deptno = t2.deptno;
   id | name  | depname
  ----+-------+---------
    1 | Joe   | hr
    2 | Scott | it
  (2 rows)
  ```

- LEFT JOIN

  ```
  gaussdb=# SELECT t1.id,t1.name,t2.depname FROM emp t1 LEFT JOIN dept t2 ON t1.deptno =
  t2.deptno;
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
 id | name  | depname
----+-------+---------
  1 | Joe   | hr
  2 | Scott | it
  3 | Ben   |
(3 rows)
```

- RIGHT JOIN

```
gaussdb=# SELECT t1.id,t1.name,t2.depname FROM emp t1 RIGHT JOIN dept t2 ON t1.deptno =
t2.deptno;
 id | name  | depname
----+-------+---------
  1 | Joe   | hr
  2 | Scott | it
    |       | sal
(3 rows)
```

- FULL JOIN

```
gaussdb=# SELECT t1.id,t1.name,t2.depname FROM emp t1 FULL JOIN dept t2 ON t1.deptno =
t2.deptno;
 id | name  | depname
----+-------+---------
  1 | Joe   | hr
  2 | Scott | it
    |       | sal
  3 | Ben   |
(4 rows)

-- Drop the table.
gaussdb=# DROP TABLE emp,dept;
```

- Multi-table join

```
gaussdb=# CREATE TABLE t1(a int, b int, c int);
gaussdb=# CREATE TABLE t2(a int, b int, c int);
gaussdb=# CREATE TABLE t3(a int, b int, c int);

gaussdb=# INSERT INTO t1 VALUES(1,generate_series(1,10),generate_series(1,20));
gaussdb=# INSERT INTO t2 VALUES(generate_series(1,5),generate_series(1,10),generate_series(1,20));
gaussdb=# INSERT INTO t3
VALUES(generate_series(6,10),generate_series(1,20),generate_series(1,10));

gaussdb=# SELECT * FROM t1 LEFT JOIN t2 ON t1.a =t2.a INNER JOIN t3 ON t1.b = t3.b AND t2.c =
t3.c;
 a | b | c  | a | b | c | a | b | c

(4 rows)

gaussdb=# DROP TABLE t1,t2,t3;
```

1.13.19.3.7 Subqueries

A query can be nested in another query, and its result is used as the data source or condition of the other query. Outer queries are also called parent queries, and inner queries are also called subqueries.

- Subqueries can be classified into single-row subqueries and multi-row subqueries based on the number of records returned.
- Subqueries can be classified into correlated subqueries and non-correlated subqueries based on whether a subquery is executed for multiple times.

Single-Row Subqueries

Single-row subquery operators include >=, >, <=, <, and <>.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
-- Create a student table and insert data into the table.
gaussdb=# CREATE TABLE student(
    sid VARCHAR(5),      -- Student ID
    grade INT,           -- Grade
    name VARCHAR(20),    -- Name
    height INT           -- Height
);
gaussdb=# INSERT INTO student VALUES ('00001',1,'Scott',135),('00002',1,'Jack',95),('00003',1,'Ben',100);
gaussdb=# INSERT INTO student VALUES ('00004',2,'Henry',115),('00005',2,'Jordan',130),
('00006',2,'Bob',126);
gaussdb=# INSERT INTO student VALUES ('00007',3,'Bella',128),('00008',3,'Alicia',136);
-- Create a teacher table and insert data into the table.
gaussdb=# CREATE TABLE teacher (
    name VARCHAR(20),    -- Teacher name
    grade INT            -- Class
);
-- Insert data.
gaussdb=# INSERT INTO teacher VALUES ('Bill',1),('Sally',2),('Luke',3);

-- Query the students who are taller than Bella.
gaussdb=# SELECT * FROM student
WHERE height > (SELECT height FROM student WHERE name = 'Bella');
  sid  | grade |  name  | height
-------+-------+--------+--------
 00001 |     1 | Scott  |    135
 00005 |     2 | Jordan |    130
 00008 |     3 | Alicia |    136
(3 rows)
```

Multi-Row Subqueries

Multi-row subquery operators are as follows:

- IN: equal to any value in the list.
- ANY: used together with single-row comparison operators to compare with any value returned by the subquery.
- ALL: used together with single-row comparison operators to compare with all values returned by the subquery.
- SOME: another name for ANY and both operators have the same effect.

Example: Query the students of Sally and Luke.

```
gaussdb=# SELECT * FROM student t1 WHERE t1.grade IN (
    SELECT grade FROM teacher WHERE name = 'Sally' OR name = 'Luke'
);
  sid  | grade |  name  | height
-------+-------+--------+--------
 00004 |     2 | Henry  |    115
 00005 |     2 | Jordan |    130
 00006 |     2 | Bob    |    126
 00007 |     3 | Bella  |    128
 00008 |     3 | Alicia |    136
(5 rows)
```

Example: Query the students in grade 2 who are taller than any students in grade 3.

```
gaussdb=# SELECT * FROM student
WHERE grade = 2 AND
      height > ANY (SELECT height FROM student WHERE grade = 3);
  sid  | grade |  name  | height
-------+-------+--------+--------
 00005 |     2 | Jordan |    130
(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
-- The query result is equivalent to that of the following query:
gaussdb=# SELECT * FROM student
WHERE grade = 2 AND
    height > (SELECT MIN(height) FROM student WHERE grade = 3);
```

Example: Query the students in grade 1 who are taller than all students in grade 2.

```
gaussdb=# SELECT * FROM student
WHERE grade = 1 AND
    height > ALL (SELECT height FROM student WHERE grade = 2);
 sid  | grade | name  | height
-------+-------+-------+--------
 00001 |     1 | Scott |    135
(1 row)

-- The query result is equivalent to that of the following query:
gaussdb=# SELECT * FROM student
WHERE grade = 1 AND
    height > (SELECT MAX(height) FROM student WHERE grade = 2);
```

Correlated Subqueries

Characteristics: Subqueries cannot run independently and are related to parent queries. Execute parent queries and then subqueries. Each time a parent query is executed, its subquery is recalculated.

Example: Query the students whose height is greater than the average height of the students in the class.

```
gaussdb=# SELECT * FROM student out
WHERE height > (SELECT AVG(height) FROM student
              WHERE grade = out.grade);
 sid  | grade |  name  | height
-------+-------+--------+--------
 00001 |     1 | Scott  |    135
 00005 |     2 | Jordan |    130
 00006 |     2 | Bob    |    126
 00008 |     3 | Alicia |    136
(4 rows)
```

Non-Correlated Subqueries

Characteristics: A subquery queries the value and then returns the result to the outer layer for query.

Example: Query the students whose height is greater than the average height of the students in the class.

```
gaussdb=# SELECT t1.*
FROM student t1,
    (SELECT grade, AVG(height) avg_hei FROM student GROUP BY grade) t2
WHERE t1.grade = t2.grade AND
    t1.height > t2.avg_hei;
 sid  | grade |  name  | height
-------+-------+--------+--------
 00001 |     1 | Scott  |    135
 00005 |     2 | Jordan |    130
 00006 |     2 | Bob    |    126
 00008 |     3 | Alicia |    136
(4 rows)

-- Drop the table.
gaussdb=# DROP TABLE student;
gaussdb=# DROP TABLE teacher;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

1.13.19.3.8 Hierarchical Queries

Syntax

```
SELECT { { column | LEVEL | CONNECT_BY_ISLEAF | CONNECT_BY_ISCYCLE | SYS_CONNECT_BY_PATH(col,
separator) | CONNECT_BY_ROOT(col) } [, ...] }
 FROM table
START WITH condition
CONNECT BY [NOCYCLE] [PRIOR column1 = column2|column1 = prior column2]
[ORDER SIBLINGS BY expression] [ORDER BY expression]
```

Parameters

- **LEVEL**: pseudocolumn that returns the query level.
- **CONNECT_BY_ISLEAF**: pseudocolumn that returns whether the current node is a leaf node.
- **CONNECT_BY_ISCYCLE**: pseudocolumn that returns whether a row in the current node causes a cycle, which means it has a child which is also its parent.
- **NOCYCLE**: specifies whether to stop recursion when a cycle is detected. If it is not specified, an error is reported when a cycle is detected.
- **SYS_CONNECT_BY_PATH(col, separator)**: function used for hierarchical queries. It returns the connection path from the root node to the current row. The **col** parameter indicates the name of the column displayed in the path, and the **separator** parameter indicates the connector.
- **CONNECT_BY_ROOT(col)**: function used for hierarchical queries. It displays the top node above the current node. The **col** parameter indicates the name of the output column.
- **START WITH**: specifies the hierarchy, that is, the root row of the query.
- **CONNECT BY**: specifies the relationship between parent rows and child rows.
- **PRIOR**: specifies the parent level.
- **ORDER SIBLINGS BY**: specifies the sequence in the same level.

Examples

```
-- Create a table and insert data into the table.
gaussdb=# CREATE TABLE area (id INT,name VARCHAR(25),parent_id INT);
gaussdb=# INSERT INTO area VALUES (1,'China',NULL);
gaussdb=# INSERT INTO area VALUES (2,'Beijing',1);
gaussdb=# INSERT INTO area VALUES(3,'Chaoyang',2);
gaussdb=# INSERT INTO area VALUES(4,'Shaanxi',1);
gaussdb=# INSERT INTO area VALUES(5,'Xi'an',4);
gaussdb=# INSERT INTO area VALUES(6,'Yanta',5);
gaussdb=# INSERT INTO area VALUES(7,'Weiyang',5);

-- Query the hierarchy.
gaussdb=# SELECT level,
    name,
    connect_by_isleaf,
    connect_by_iscycle,
    connect_by_root(name),
    sys_connect_by_path(name, '->')
FROM area START WITH (id = 1) CONNECT BY PRIOR id = parent_id;
 level |  name  | connect_by_isleaf | connect_by_iscycle | connect_by_root |      sys_connect_by_path
-------+--------+-------------------+--------------------+-----------------+--------------------------------
     1 | China  |                 0 |                  0 | China           | -> China
     2 | Shaanxi |                0 |                  0 | China           | -> China -> Shaanxi
     3 | Xi'an  |                 0 |                  0 | China           | -> China -> Shaanxi -> Xi'an
```

```
-- Drop the table.
gaussdb=# DROP TABLE area;
```

1.13.19.3.9 Compound Queries

A query that contains a compound operator is a compound query. All compound queries have the same priority. The number of columns and expressions in each query result in a set operation must be the same, and the types must be compatible.

Common set operations include:

- UNION: a union set of the two query result sets where duplicates are removed.
- UNION ALL: a union set of the two queries where the results of the two queries are simply combined.
- INTERSECT: intersection of two queries (only duplicated data is displayed).
- MINUS: difference of two query result sets. Only the data that exists in the first result set but does not exist in the second result set is displayed, and the data is sorted based on the results in the first column.

Examples

```
-- Create a table and insert data into the table.
gaussdb=# CREATE TABLE test1(c11 INT, c12 VARCHAR);
gaussdb=# INSERT INTO test1 VALUES (1,'a'),(2,'b'),(4,'d');

gaussdb=# CREATE TABLE test2(c21 INT, c22 VARCHAR);
gaussdb=# INSERT INTO test2 VALUES (1,'a'),(3,'c');
```

- UNION

```
gaussdb=# SELECT * FROM test1 UNION SELECT * FROM test2;
 c11 | c12
-----+-----
   1 | a
   4 | d
   2 | b
   3 | c
(4 rows)
```

- UNION ALL

```
gaussdb=# SELECT * FROM test1 UNION ALL SELECT * FROM test2;
 c11 | c12
-----+-----
   1 | a
   2 | b
   4 | d
   1 | a
   3 | c
(5 rows)
```

- INTERSECT

```
gaussdb=# SELECT * FROM test1 INTERSECT SELECT * FROM test2;
 c11 | c12
-----+-----
   1 | a
(1 row)
```

- MINUS

```
gaussdb=# SELECT * FROM test1 MINUS SELECT * FROM test2;
 c11 | c12
-----+-----
   4 | d
   2 | b
(2 rows)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
-- Drop the table.
gaussdb=# DROP TABLE test1,test2;
```

1.13.19.3.10 Rows to Columns and Columns to Rows

- Rows to columns

```
-- Create a table and insert data into the table.
gaussdb=# CREATE TABLE test_p2(id INT, class VARCHAR(20), score INT);
gaussdb=# INSERT INTO test_p2 VALUES (1,'math',64), (1,'english',78);
gaussdb=# INSERT INTO test_p2 VALUES (2,'math',98), (2,'english',82);
gaussdb=# INSERT INTO test_p2 VALUES (3,'math',68), (3,'english',59);
gaussdb=# SELECT * FROM test_p2;
 id |  class  | score
----+---------+-------
  3 | math    |    68
  3 | english |    59
  1 | math    |    64
  1 | english |    78
  2 | math    |    98
  2 | english |    82
(6 rows)

-- Convert rows to columns.
gaussdb=# SELECT * FROM test_p2 PIVOT(MAX(score) FOR class IN('math','english'));
 id | 'math' | 'english'
----+--------+-----------
  3 |     68 |        59
  1 |     64 |        78
  2 |     98 |        82
(3 rows)

-- Drop the table.
gaussdb=# DROP TABLE test_p2;
```

- Columns to rows

```
-- Create a table and insert data into the table.
gaussdb=# CREATE TABLE test_p1(id INT, math INT, english INT);
gaussdb=# INSERT INTO test_p1 VALUES (1,84,78), (2,98,82), (3,68,59);
gaussdb=# SELECT * FROM test_p1;
 id | math | english
----+------+---------
  3 |   68 |      59
  1 |   84 |      78
  2 |   98 |      82
(3 rows)

-- Convert columns to rows.
gaussdb=# SELECT * FROM test_p1 UNPIVOT(score FOR class IN(math, english));
 id |  class  | score
----+---------+-------
  3 | MATH    |    68
  3 | ENGLISH |    59
  1 | MATH    |    84
  1 | ENGLISH |    78
  2 | MATH    |    98
  2 | ENGLISH |    82
(6 rows)

-- Drop the table.
gaussdb=# DROP TABLE test_p1;
```

1.13.19.3.11 Window Function Queries

The window function performs a calculation on the related row set in the data set and returns a result set. Compared with the calculation performed by the aggregate function, the window function does not aggregate multiple rows into a single output row.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Example:

```
-- Create a table and insert data into the table.
gaussdb=# CREATE TABLE fruit_sale (
  "statistical_date" date,
  "product" varchar(255),
  "year" varchar(5),
  "sales_quantity" numeric(8),
  "amount" numeric(8)
);

gaussdb=# INSERT INTO fruit_sale VALUES ('2024-01-01', 'Watermelon', '2024', 1721, 253541);
gaussdb=# INSERT INTO fruit_sale VALUES ('2024-01-01', 'Apple', '2024', 5559, 269419);
gaussdb=# INSERT INTO fruit_sale VALUES ('2024-02-01', 'Watermelon', '2024', 4711, 129644);

-- Collect statistics on the sales volume of all fruits.
gaussdb=# SELECT *,SUM(sales_quantity) OVER (PARTITION by null) total_qty FROM fruit_sale;
 statistical_date | product | year | sales_quantity | amount | total_qty
------------------+---------+------+----------------+--------+-----------
 2024-01-01       | Watermelon    | 2024 |          1721 | 253541 |     11991
 2024-01-01       | Apple    | 2024 |          5559 | 269419 |     11991
 2024-02-01       | Watermelon    | 2024 |          4711 | 129644 |     11991
(3 rows)

-- Drop the table.
gaussdb=# DROP TABLE fruit_sale;
```

1.13.19.3.12 Simplified Queries

Simplified queries can be performed on tables without the SELECT keyword.

Example:

```
-- Create a table.
gaussdb=# CREATE TABLE t1(c1 int, c2 int, c3 int);

-- Insert data.
gaussdb=# INSERT INTO t1 VALUES (1,2,3);
 c1 | c2 | c3
----+----+----
  1 |  2 |  3
(1 row)

-- Query data in the table.
gaussdb=# TABLE t1;
 c1 | c2 | c3
----+----+----
  1 |  2 |  3
(1 row)

-- Drop the table.
gaussdb=# DROP TABLE t1;
```

1.13.19.3.13 Queries Using Hints

Hints can be used to modify the SQL execution plan.

Example:

```
-- Create a table.
gaussdb=# CREATE TABLE t1(c1 int, c2 int, c3 int);
gaussdb=# CREATE TABLE t2(c1 int, c2 int, c3 int);
gaussdb=# CREATE INDEX it1 ON t1(c1,c2);

-- Specify the scanning mode using a hint.
gaussdb=# EXPLAIN SELECT /*+ indexscan(t1 it1)*/* from t1,t2 WHERE t1.c1=t2.c2;
 id |                operation                 | E-rows | E-width | E-costs
----+------------------------------------------+--------+---------+---------
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
 1 | ->  Streaming (type: GATHER)               |     30 |      24 | 61.51
 2 |    ->  Hash Join (3,4)                     |     30 |      24 | 60.26
 3 |       ->  Index Scan using it1 on t1       |     30 |      12 | 44.46
 4 |       ->  Hash                             |     29 |      12 | 15.49
 5 |         ->  Streaming(type: REDISTRIBUTE) |     30 |      12 | 15.49
 6 |           ->  Seq Scan on t2               |     30 |      12 | 14.14
(6 rows)

 Predicate Information (identified by plan id)
-----------------------------------------------
   2 --Hash Join (3,4)
         Hash Cond: (t1.c1 = t2.c2)
(2 rows)

-- Specify the number of rows using a hint.
gaussdb=# EXPLAIN SELECT /*+ rows(t1 t2 #5)*/* FROM t1,t2;
 id |             operation              | E-rows | E-width | E-costs
----+------------------------------------+--------+---------+---------
 1 | ->  Streaming (type: GATHER)        |      5 |      24 | 37.60
 2 |    ->  Nested Loop (3,5)            |      5 |      24 | 37.35
 3 |       ->  Streaming(type: BROADCAST) |     90 |      12 | 17.93
 4 |         ->  Seq Scan on t1          |     30 |      12 | 14.14
 5 |       ->  Materialize               |     30 |      12 | 14.21
 6 |         ->  Seq Scan on t2          |     30 |      12 | 14.14
(6 rows)

-- Drop the table.
gaussdb=# DROP TABLE t1;
gaussdb=# DROP TABLE t2;
```

1.13.19.4 SELECT INTO

Description

SELECT INTO creates a table based on the query result and inserts data retrieved by the query into the new table. Different from common SELECT, SELECT INTO does not return data to the client. The columns of the new table have the same names and data types as the output columns of SELECT.

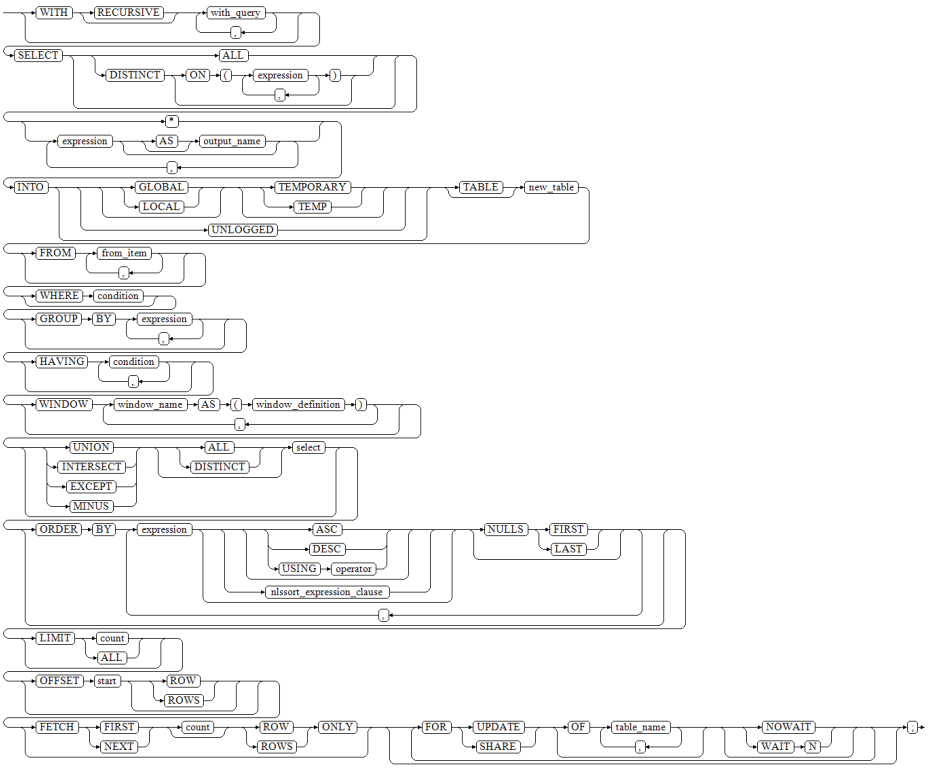
Precautions

CREATE TABLE AS provides functions similar to SELECT INTO in functions and provides a superset of functions provided by SELECT INTO. You are advised to use CREATE TABLE AS because SELECT INTO cannot be used in a stored procedure.

Syntax

```
[ WITH [ RECURSIVE ] with_query [, ...] ]
SELECT [ ALL | DISTINCT [ ON ( expression [, ...] ) ] ]
   { * | {expression [ [ AS ] output_name ]} [, ...] }
   INTO [ [ GLOBAL | LOCAL ] [ TEMPORARY | TEMP ] | UNLOGGED ] [ TABLE ] new_table
   [ FROM from_item [, ...] ]
   [ WHERE condition ]
   [ GROUP BY expression [, ...] ]
   [ HAVING condition [, ...] ]
   [ WINDOW {window_name AS ( window_definition )} [, ...] ]
   [ { UNION | INTERSECT | EXCEPT | MINUS } [ ALL | DISTINCT ] select ]
   [ ORDER BY {expression [ [ ASC | DESC | USING operator ] | nlssort_expression_clause ] [ NULLS { FIRST |
LAST } ]} [, ...] ]
   [ LIMIT { count | ALL } ]
   [ OFFSET start [ ROW | ROWS ] ]
   [ FETCH { FIRST | NEXT } [ count ] { ROW | ROWS } ONLY ]
   [ {FOR { UPDATE | SHARE } [ OF table_name [, ...] ] [ NOWAIT | WAIT N]} [...] ];
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.



Parameters

- **new_table**

  Specifies the name of the new table.

- **UNLOGGED**

  Specifies that the table is created as an unlogged table. Data written to unlogged tables is not written to the WALs, which makes them considerably faster than ordinary tables. However, in the event of a conflict, OS restart, database restart, primary/standby switchover, power supply interruption, or unclean shutdown, unlogged tables will be cleared, posing a risk of data loss. The contents of an unlogged table are also not replicated to standby servers. The indexes created in unlogged tables are not automatically recorded.

  - Usage scenario: Unlogged tables do not ensure data security. Users can back up data before using unlogged tables; for example, users should back up the data before a system upgrade.
  - Troubleshooting: If data is missing in the indexes of unlogged tables due to some unexpected operations such as an unclean shutdown, users should rebuild the indexes with errors.

NOTE

For details about other parameters of SELECT INTO, see **Parameters**.

Examples

```
-- Create a table and insert data into the table.
gaussdb=# CREATE TABLE tbl_person (
  id     integer,
  name   varchar(20),
  gender varchar(5) CHECK(gender = 'Male' or gender = 'Female')
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
);
gaussdb=# INSERT INTO tbl_person VALUES (1, 'Bob', 'Male'),(2, 'Anne', 'Female'),(3, 'Jack', 'Male'),(4,
'Danny', 'Male'),(5, 'Alice', 'Female'),(6, 'Susan', 'Female');

-- Add information about all persons whose gender is male in the person table to the new table.
gaussdb=# SELECT * INTO tbl_man FROM tbl_person WHERE gender =' Male'

-- Query data in the tbl_man table.
gaussdb=# SELECT * FROM tbl_man;
 id | name  | gender
----+-------+-----
  1 | Bob   | Male
  3 | Jack  | Male
  4 | Danny | Male
(3 rows)

-- Drop the table.
gaussdb=# DROP TABLE tbl_person, tbl_man;
```

Helpful Links

SELECT

1.13.19.5 SET

Description

Modifies GUC parameters.

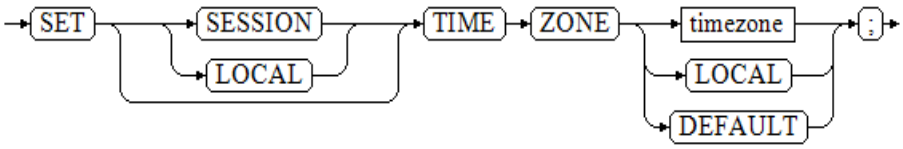
Precautions

Most GUC parameters can be modified at runtime by using SET, but some parameters cannot be modified after a service or session starts.

Syntax

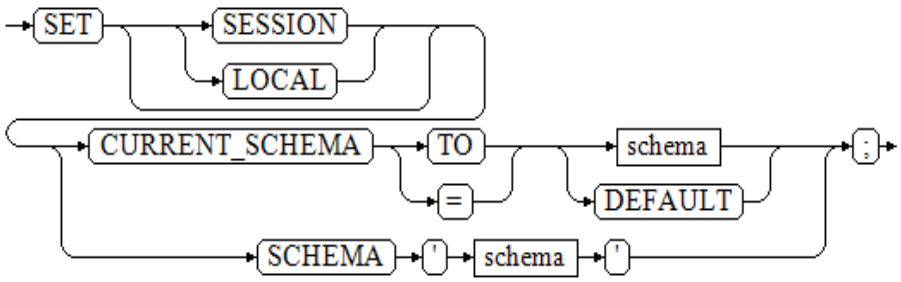
- Set the time zone.

```
SET [ SESSION | LOCAL ] TIME ZONE { timezone | LOCAL | DEFAULT };
```



- Set the schema.

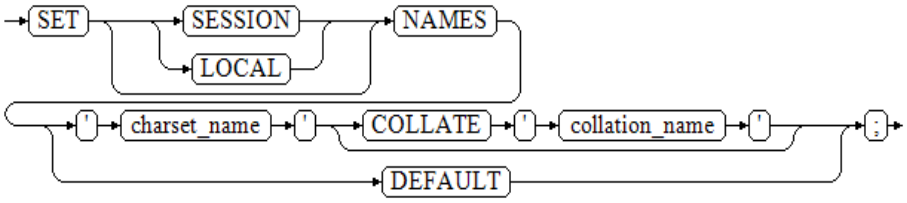
```
SET [ SESSION | LOCAL ]
    {CURRENT_SCHEMA { TO | = } { schema | DEFAULT }
    | SCHEMA 'schema'};
```



- Set the client character set.

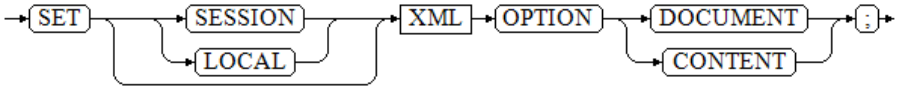
 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
SET [ SESSION | LOCAL ] NAMES {'charset_name' [COLLATE 'collation_name'] | DEFAULT};
```



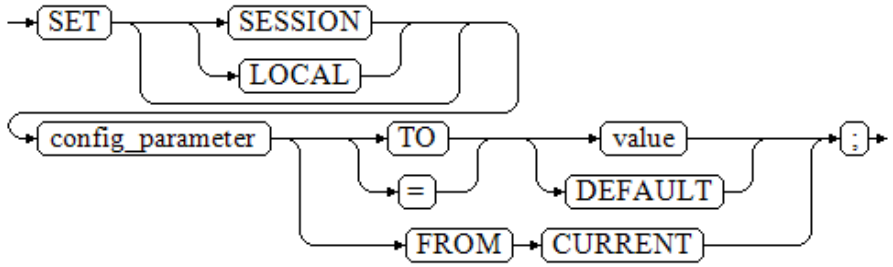
- Set XML parsing mode.

```
SET [ SESSION | LOCAL ] XML OPTION { DOCUMENT | CONTENT };
```



- Set other GUC parameters.

```
SET [ SESSION | LOCAL ]
   {config_parameter { { TO | = } { value | DEFAULT }
                     | FROM CURRENT }};
```



Parameters

- **SESSION**

  Specifies that the specified parameters take effect only for the current session. If neither **SESSION** nor **LOCAL** appears, **SESSION** is the default value.

  If this command is executed in a transaction, the effect of the command disappears after the transaction is rolled back. Once the surrounding transaction is committed, the effect will persist until the end of the session, unless the parameters are reset by another SET statement.

- **LOCAL**

  Specifies that the specified parameters take effect only for the current transaction. After COMMIT or ROLLBACK, session-level settings will take effect again.

  The effect of this command lasts only until the end of the current transaction, whether the transaction is committed or not. A special case is where SET is followed by SET LOCAL within a single transaction. In this case, SET LOCAL will take effect until the end of the transaction, but after the transaction is committed, SET will take effect.

- **TIME ZONE timezone**

  Specifies the local time zone for the current session.

  Value range: valid local time zones. The corresponding GUC parameter is **TimeZone**. The default value is **PRC**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

> NOTE
>
> SET TIME ZONE cannot write a time zone in hours and minutes, such as "-12:30", but can write a time zone in English or decimal, for example, "EST", "America/New_York", and "-12.5".

- **CURRENT_SCHEMA schema**

  Specifies the current schema.

  Value range: existing schema names.

- **SCHEMA schema**

  Same as **CURRENT_SCHEMA**. The schema here is a string.

  Example: **set schema 'public';**

- **NAMES {'charset_name' [COLLATE 'collation_name'] | DEFAULT};**
  - The COLLATE clause can be specified when **sql_compatibility** is set to **'MYSQL'**, **b_format_version** set to **'5.7'**, and **b_format_dev_version** set to **'s2'**.

    Sets the client character encoding, character set of a constant string, collation, and character set of the returned result.

    It is equivalent to:

    ```
    SET client_encoding = charset_name;
    SET character_set_connection = charset_name;
    SET collation_connection = collation_name;
    SET character_set_results = charset_name;
    ```

    Value range: character sets and collations supported in MYSQL-compatible mode. Currently, **charset_name** must be one of the character sets specified for the database.
  - The COLLATE clause cannot be specified in other scenarios.

    Specifies the client character encoding.

    It is equivalent to:

    ```
    SET client_encoding TO charset_name;
    ```

    Value range: a valid character encoding name. The default value is **UTF8**.

- **XML OPTION option**

  Specifies the XML parsing mode.

  Value range: **CONTENT** (default) and **DOCUMENT**

- **config_parameter**

  Specifies the name of the configurable GUC parameter. You can use SHOW ALL to view the available GUC parameters. For details about the setting rules, see **Setting Parameters**.

  > NOTE
  >
  > Some parameters viewed by SHOW ALL cannot be set by using SET. For example, **max_datanodes**.

- **value**

  Specifies the new value of **config_parameter**. You can specify the parameter as a string constant, identifier, number, or comma-separated list. When **DEFAULT** is specified, the parameter is set to its default value.

- **FROM CURRENT**

  Uses the value of **config_parameter** of the current session.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Examples

```
-- Set the time zone.
gaussdb=# SET TIME ZONE 'PST8PDT';

-- Set the schema search path.
gaussdb=# SET search_path TO tpcds, public;

-- Set client-side encoding.
gaussdb=# SET client_encoding TO utf8;

-- Set XML parsing mode.
gaussdb=# SET XML OPTION DOCUMENT;

-- Set the date style to the traditional POSTGRES style (date placed before month).
gaussdb=# SET datestyle TO postgres;
```

RESET and **SHOW**

1.13.19.6 SET CONSTRAINTS

Description

SET CONSTRAINTS sets the behavior of constraint checking within the current transaction.

IMMEDIATE constraints are checked at the end of each statement. DEFERRED constraints are not checked until transaction commit. Each constraint has its own mode.

Upon creation, a constraint is given one of three characteristics **DEFERRABLE INITIALLY DEFERRED**, **DEFERRABLE INITIALLY IMMEDIATE**, or **NOT DEFERRABLE**. The third class is always **IMMEDIATE** and is not affected by the **SET CONSTRAINTS** statement. The first two classes start every transaction in specified modes, but its behaviors can be changed within a transaction by SET CONSTRAINTS.

SET CONSTRAINTS with a list of constraint names changes the mode of just those constraints (which must all be deferrable). If multiple constraints match a name, the name is affected by all of these constraints. **SET CONSTRAINTS ALL** changes the modes of all deferrable constraints.

When **SET CONSTRAINTS** changes the mode of a constraint from **DEFERRED** to **IMMEDIATE**, any data that is modified at the end of the transaction is checked during the execution of the **SET CONSTRAINTS** statement. If any such constraint is violated, the **SET CONSTRAINTS** fails (and does not change the constraint mode). Therefore, **SET CONSTRAINTS** can be used to force checking of constraints to occur at a specific point in a transaction. Check and unique constraints are always checked immediately when a row is inserted or modified.

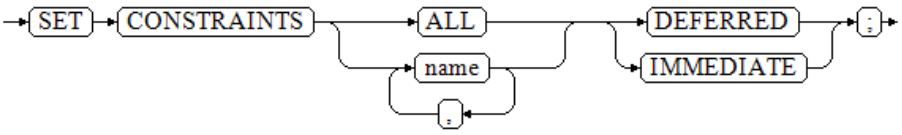
Precautions

SET CONSTRAINTS sets the behavior of constraint checking only within the current transaction. Therefore, if you execute this statement outside of a transaction block (START TRANSACTION/COMMIT pair), it will not appear to have any effect.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Syntax

```
SET CONSTRAINTS { ALL | { name  } [, ...] } { DEFERRED | IMMEDIATE };
```



Parameters

- **name**

  Specifies the constraint name.

  Value range: an existing table name, which can be found in the system catalog pg_constraint.

- **ALL**

  Specifies all constraints.

- **DEFERRED**

  Specifies that constraints are not checked until transaction commit.

- **IMMEDIATE**

  Specifies that constraints are checked at the end of each statement.

Examples

```
-- Set that constraints are checked when a transaction is committed.
gaussdb=# SET CONSTRAINTS ALL DEFERRED;

-- Set that constraints are checked at the end of each statement.
gaussdb=# SET CONSTRAINTS ALL IMMEDIATE;
```

1.13.19.7 SET ROLE

Description

Sets the current user identifier for the current session.

Precautions

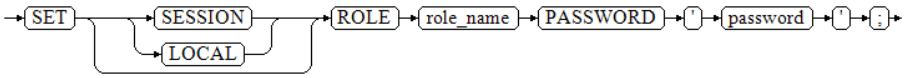
- Users of the current session must be members of specified **rolename**, but the system administrator can choose any roles when separation of duties is disabled.
- This statement may add permissions to or restrict permissions of a user. If the role of a session user has the INHERITS attribute, then the user is automatically granted all permissions of the roles that SET ROLE enables the user to be. In this case, SET ROLE deletes all permissions directly granted to the session user, as well as the permissions of the role it belongs to, that is, the user is left with the permissions of only the specified role. On the other hand, if the role of a session user has the NOINHERITS attribute, SET ROLE deletes permissions directly granted to the session user and obtains permissions of the specified role.
- If a user is configured to use LDAP for login authentication, the user identifier cannot be set to this user by performing this operation.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Syntax

- Set the current user identifier of the current session.

```
SET [ SESSION | LOCAL ] ROLE role_name PASSWORD 'password';
```



- Reset the current user identifier to that of the current session.

```
RESET ROLE;
```

Parameters

- **SESSION**

  Specifies that the command takes effect only for the current session. This parameter is used by default.

- **LOCAL**

  Specifies that the command takes effect only for the current transaction.

- **role_name**

  Indicates the role name.

  Value range: a string. It must be an existing username in the database.

- **password**

  Specifies the password for the role. It must comply with the password convention.

  NOTE

  - The restrictions on using a ciphertext password are as follows:
    - An administrator cannot use a ciphertext password to switch to another administrator but to a user with lower permissions.
  - Ciphertext passwords are usually used in gs_dump and gs_dumpall export scenarios. In other scenarios, you are advised not to use ciphertext passwords directly.

- **RESET ROLE**

  Resets the current user identifier.

Examples

```
-- Query the current session user and the current user.
gaussdb=# SELECT SESSION_USER, CURRENT_USER;
 session_user | current_user
--------------+--------------
 omm          | omm
(1 row)

-- Create a role named paul.
gaussdb=# CREATE ROLE paul PASSWORD '********';

-- Set the current user to paul.
gaussdb=# SET ROLE paul PASSWORD '********';

-- View the current session user and the current user.
gaussdb=> SELECT SESSION_USER, CURRENT_USER;
 session_user | current_user
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
--------------+--------------
 omm          | paul
(1 row)

-- Reset the current user.
gaussdb=> RESET ROLE;

-- Drop the user.
gaussdb=# DROP USER paul;
```

Helpful Links

SET SESSION AUTHORIZATION

1.13.19.8 SET SESSION AUTHORIZATION

Description

Sets the session user identifier and the current user identifier of the current session to the specified user.

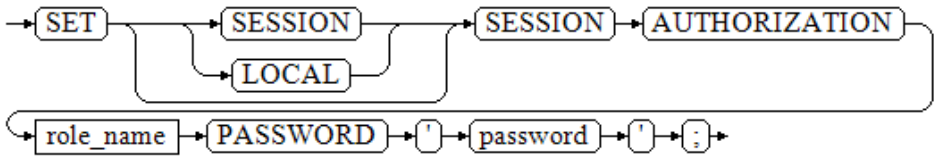
Precautions

- The session identifier can be changed only when the initial session user has the SYSADMIN permission. Otherwise, the system executes the command only when an authenticated username is specified.
- If a user is configured to use LDAP for login authentication, the user identifier cannot be set to this user by performing this operation.

Syntax

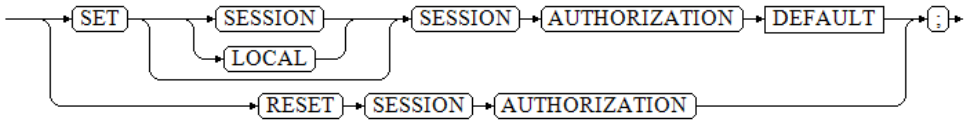
- Set the session user identifier and current user identifier for the current session.

```
SET [ SESSION | LOCAL ] SESSION AUTHORIZATION role_name PASSWORD 'password';
```



- Reset the session and current user identifiers to the originally authenticated username.

```
{SET [ SESSION | LOCAL ] SESSION AUTHORIZATION DEFAULT
   | RESET SESSION AUTHORIZATION};
```



Parameters

- **SESSION**

  Specifies that the command takes effect only for the current session.
- **LOCAL**

  Specifies that the command takes effect only for the current transaction.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **role_name**

  Specifies the username.

  Value range: a string. It must be an existing username in the database.

- **password**

  Specifies the password for the role. The password must comply with the password convention.

  NOTE

  The restrictions on using a ciphertext password are as follows:

  - An administrator cannot use a ciphertext password to switch to another administrator but to a user with lower permissions.

  Ciphertext passwords are usually used in gs_dump and gs_dumpall export scenarios. In other scenarios, you are advised not to use ciphertext passwords directly.

- **DEFAULT**

  Resets the identifiers of the session and current users to the initially authenticated usernames.

Examples

```
-- Query the session user and the current user.
gaussdb=# SELECT SESSION_USER, CURRENT_USER;
 session_user | current_user
--------------+--------------
 omm          | omm
(1 row)

-- Create a role named paul.
gaussdb=# CREATE ROLE paul PASSWORD '********';

-- Set the current user and session user to paul, and query the session user and current user.
gaussdb=# SET SESSION AUTHORIZATION paul PASSWORD '********';
gaussdb=> SELECT SESSION_USER, CURRENT_USER;
 session_user | current_user
--------------+--------------
 paul         | paul
(1 row)

-- Reset the session user and the current user.
gaussdb=> RESET SESSION AUTHORIZATION;
gaussdb=# SELECT SESSION_USER, CURRENT_USER;
 session_user | current_user
--------------+--------------
 omm          | omm
(1 row)

-- Drop the user.
gaussdb=# DROP USER paul;
```

SET ROLE

1.13.19.9 SET TRANSACTION

Description

Sets the transaction characteristics. Transaction characteristics include transaction isolation level and transaction access mode (read/write or read-only). You can set

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

the current transaction characteristics using LOCAL or the default transaction characteristics of a session using SESSION.

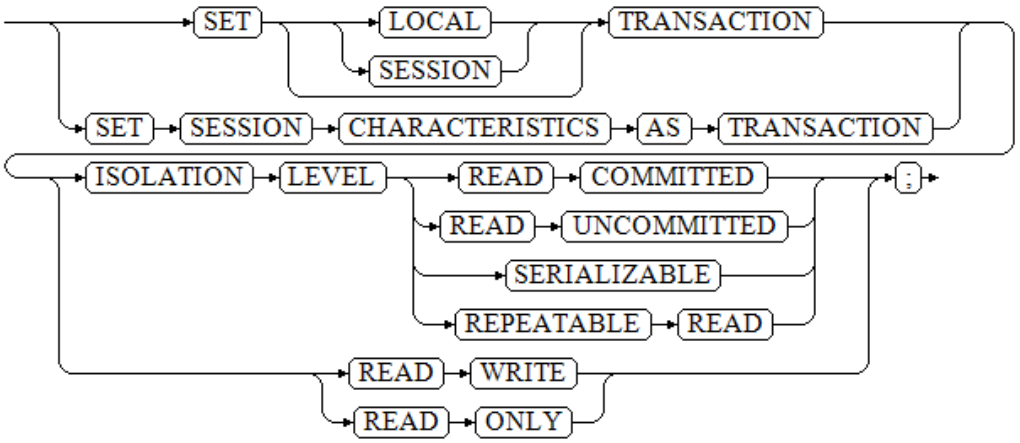
Precautions

The current transaction characteristics must be set in a transaction, that is, **START TRANSACTION** or **BEGIN** must be executed before **SET TRANSACTION** is executed. Otherwise, the setting does not take effect.

Syntax

Set the transaction isolation level and access mode.

```
{ SET [ LOCAL | SESSION ] TRANSACTION | SET SESSION CHARACTERISTICS AS TRANSACTION }
  { ISOLATION LEVEL { READ COMMITTED | READ UNCOMMITTED | SERIALIZABLE | REPEATABLE READ }
  | { READ WRITE | READ ONLY }
  };
```



Parameters

- **LOCAL**

  Specifies that the specified statement takes effect only for the current transaction.

- **SESSION**

  Specifies that the command takes effect only for the current session.

- **SESSION CHARACTERISTICS**

  Specifies that the command takes effect only for the current session.

- **ISOLATION LEVEL**

  Specifies the transaction isolation level. It determines what data a transaction can read when other concurrent transactions are in progress.

  NOTE

  - The isolation level cannot be changed after data is modified using INSERT, DELETE, UPDATE, FETCH, or COPY in the current transaction.

  Value range:

  – **READ COMMITTED**: Only committed data can be read; uncommitted data remains invisible. This is the default.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

  - **READ UNCOMMITTED**: This isolation level behaves identically to **READ COMMITTED**.
  - **REPEATABLE READ**: The transaction can only read data that was committed before the transaction began. It cannot read uncommitted data or changes committed by other concurrent transactions during its execution.
  - **SERIALIZABLE**: Currently, this isolation level is not supported in GaussDB. It is equivalent to **REPEATABLE READ**.
- **READ WRITE | READ ONLY**

  Specifies the transaction access mode (**READ WRITE** or **READ ONLY**).

Examples

```
-- Start a transaction.
gaussdb=# START TRANSACTION;

-- Set the isolation level of the transaction to READ COMMITTED and the access mode to READ ONLY.
gaussdb=# SET LOCAL TRANSACTION ISOLATION LEVEL READ COMMITTED READ ONLY;

-- Query the current transaction isolation level.
gaussdb=# SHOW transaction_isolation;
 transaction_isolation
-----------------------
 read committed
(1 row)

-- Commit the transaction.

gaussdb=# COMMIT;
```

1.13.19.10 SHOW

Description

SHOW shows the current value of a GUC parameter.

Syntax

```
SHOW
 {
   [VARIABLES LIKE] configuration_parameter |
   CURRENT_SCHEMA |
   TIME ZONE |
   TRANSACTION ISOLATION LEVEL |
   SESSION AUTHORIZATION |
   ALL
 };
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameters

- **configuration_parameter**

  Specifies the name of the GUC parameter.

  Value range: GUC parameters. You can view the GUC parameters by using the SHOW ALL statement.

  NOTE

  Some parameters viewed by running **SHOW ALL** cannot be set by running **SET**, for example, **max_datanodes**.

- **CURRENT_SCHEMA**

  Specifies the current schema.

- **TIME ZONE**

  Specifies the time zone.

- **TRANSACTION ISOLATION LEVEL**

  Specifies the transaction isolation level.

- **SESSION AUTHORIZATION**

  Specifies the user identifier of the current session.

- **ALL**

  Specifies all GUC parameters.

Examples

```
-- Show the value of timezone.
gaussdb=# SHOW timezone;
TimeZone
----------
 PRC
(1 row)

-- Show the current schema.
gaussdb=# SHOW CURRENT_SCHEMA;
 current_schema
----------------
 "$user",public
(1 row)

-- Show the isolation level of a transaction.
gaussdb=# SHOW TRANSACTION ISOLATION LEVEL;
 transaction_isolation
-----------------------
 read committed
(1 row)

-- Show the user identifier of the current session.
gaussdb=# SHOW SESSION AUTHORIZATION;
 session_authorization
-----------------------
 omm1
(1 row)

-- Show all parameters.
gaussdb=# SHOW ALL;

-- Show all parameters whose names contain var.
gaussdb=# SHOW VARIABLES LIKE var;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Helpful Links

SET and **RESET**

1.13.19.11 SHUTDOWN

Description

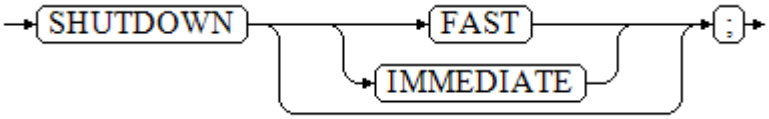
SHUTDOWN shuts down the currently connected database node.

Precautions

- Only the administrator can run this command.
- The distributed database does not support the **SHUTDOWN** command.

Syntax

```
SHUTDOWN [FAST | IMMEDIATE];
```



Parameters

FAST | IMMEDIATE

FAST: Rolls back all active transactions, forcibly disconnects the client, and shuts down the database node without waiting for the client to disconnect.

IMMEDIATE: Shuts down the server forcibly. Fault recovery will occur on the next startup.

If the shutdown mode is not specified, the default value **FAST** is used.

Examples

```
-- Shut down the current database node.
gaussdb=# SHUTDOWN;

-- Shut down the current database node in fast mode.
gaussdb=# SHUTDOWN FAST;
```

1.13.19.12 START TRANSACTION

Description

START TRANSACTION starts a transaction. If the isolation level or read/write mode is specified, a new transaction will have those characteristics. You can also specify them using **SET TRANSACTION**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

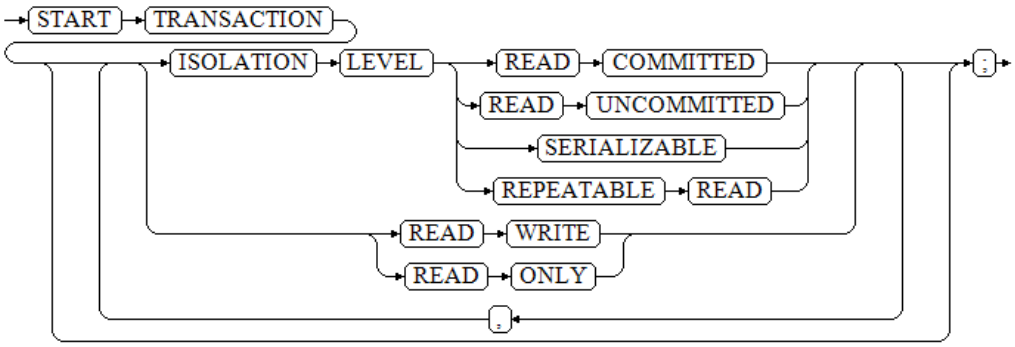
Precautions

When START TRANSACTION is used, **autocommit** remains disabled and is not restored to the initial state until you run COMMIT or ROLLBACK to end a transaction.

Syntax

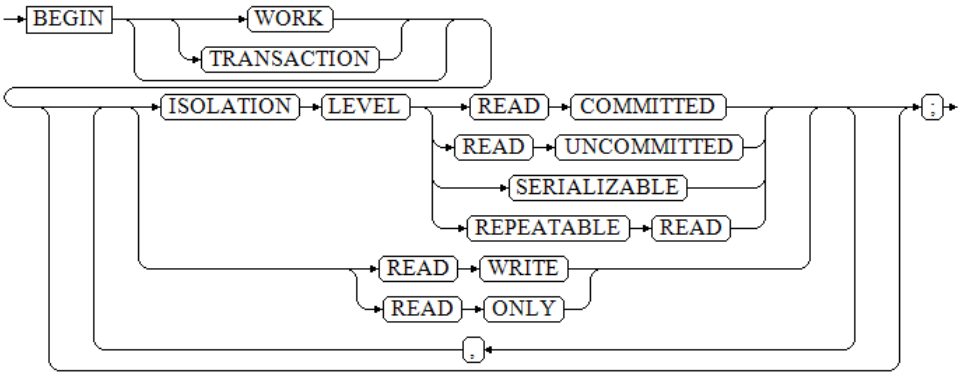
Format 1: START TRANSACTION

```
START TRANSACTION
 [
  {
    ISOLATION LEVEL { READ COMMITTED | READ UNCOMMITTED | SERIALIZABLE | REPEATABLE READ }
    | { READ WRITE | READ ONLY }
  } [, ...]
];
```



Format 2: BEGIN

```
BEGIN [ WORK | TRANSACTION ]
 [
  {
    ISOLATION LEVEL { READ COMMITTED | READ UNCOMMITTED | SERIALIZABLE | REPEATABLE READ }
    | { READ WRITE | READ ONLY }
  } [, ...]
];
```



Parameters

- **WORK | TRANSACTION**

  Serve as optional keywords in the BEGIN statement. However, these keywords currently have no practical effect.

- **ISOLATION LEVEL**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Specifies the transaction isolation level. It determines what data a transaction can read when other concurrent transactions are in progress.

> **NOTE**
>
> The isolation level of a transaction cannot be changed after the first clause (INSERT, DELETE, UPDATE, FETCH, COPY) for modifying data is executed in the transaction.

Value range:

- **READ COMMITTED**: Only committed data can be read; uncommitted data remains invisible. This is the default.
- **READ UNCOMMITTED**: This isolation level behaves identically to **READ COMMITTED**.
- **REPEATABLE READ**: The transaction can only read data that was committed before the transaction began. It cannot read uncommitted data or changes committed by other concurrent transactions during its execution.
- **SERIALIZABLE**: Currently, GaussDB does not support this isolation level. Setting this isolation level is equivalent to **REPEATABLE READ**.

- **READ WRITE | READ ONLY**

  Specifies the transaction access mode (**READ WRITE** or **READ ONLY**).

Examples

```
-- Create a schema.
gaussdb=# CREATE SCHEMA tpcds;

-- Create the tpcds.reason table.
gaussdb=# CREATE TABLE tpcds.reason (c1 int, c2 int);

-- Start a transaction in default mode.
gaussdb=# START TRANSACTION;
gaussdb=# SELECT * FROM tpcds.reason;
gaussdb=# END;

-- Start a transaction in default mode.
gaussdb=# BEGIN;
gaussdb=# SELECT * FROM tpcds.reason;
gaussdb=# END;

-- Start a transaction with the isolation level being READ COMMITTED and access mode being READ WRITE.
gaussdb=# START TRANSACTION ISOLATION LEVEL READ COMMITTED READ WRITE;
gaussdb=# SELECT * FROM tpcds.reason;
gaussdb=# COMMIT;

-- Drop the table.
gaussdb=# DROP TABLE tpcds.reason;

-- Drop the schema.
gaussdb=# DROP SCHEMA tpcds CASCADE;
```

Helpful Links

COMMIT | END, **ROLLBACK**, and **SET TRANSACTION**

1.13.20 T

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

1.13.20.1 TIMECAPSULE TABLE

Description

The TIMECAPSULE TABLE statement restores a table to an earlier state in the event of human or application errors.

The table can flash back to a past point in time, depending on the source version of the data stored in the system. In addition, GaussDB cannot restore a table to an earlier state through DDL operations that has changed the structure of the table.

Precautions

- The TIMECAPSULE TABLE statement can be used to flash back the data of the source version or the data from the recycle bin.
  - TO TIMESTAMP and TO CSN can flash a table back to an earlier version. Currently, only Ustore is supported.
  - The recycle bin records the objects dropped or truncated by running DROP and TRUNCATE. TO BEFORE DROP and TO BEFORE TRUNCATE can flash data back from the recycle bin. Currently, the Ustore and Astore are supported.
- The following object types do not support flashback: system catalogs, DFS tables, global temporary tables, local temporary tables, unlogged tables, sequence tables, and encrypted tables.
- Flashback is not supported for tables that contain user-defined types.
- After flashback is enabled, tables in the recycle bin can be backed up but cannot be restored.
- If a statement (DDL, DCL, or VACUUM FULL) that modifies the table definition or affects physical storage is executed between the flashback point and the current point, the flashback fails.
- To run DROP, you must have the CREATE or USAGE permission on the schema to which the junk object belongs, and you must be the owner of the schema or the owner of the junk object.

  To run TRUNCATE, you must have the CREATE or USAGE permission on the schema to which the junk object belongs, and you must be the owner of the schema or the junk object. In addition, you must have the TRUNCATE permission on the junk object.
- Scenarios or tables that do not support DROP or TRUNCATE:
  - Scenario where the recycle bin is disabled (**enable_recyclebin** is set to **off**)
  - The system is in the maintenance state (**xc_maintenance_mode** is set to **on**).
  - The version is upgraded from an unsupported baseline version to a supported version and is in the upgrade observation period.
  - Scenario where multiple objects are deleted (The **DROP** or **TRUNCATE TABLE** command is executed to delete multiple objects at the same time.)
  - System catalogs, DFS tables, global temporary tables, local temporary tables, unlogged tables, sequence tables, and encrypted tables

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

  - Objects in the recycle bin are cleared and do not support DROP or TRUNCATE FLASHBACK. The **recyclebin_retention_time** parameter specifies the retention period of objects in the recycle bin.
  - Scaling is not supported. During scale-out and redistribution, data in the recycle bin is forcibly dropped. During scale-out, dropped objects are not moved to the recycle bin.
  - The recycle bin does not support write operations such as DML, DCL, and DDL, and does not support DQL query operations.
  - If a statement (such as DDL, DCL, VACUUM FULL, and partition adding/deleting/splitting/merging) that modifies the table definition or affects physical files are executed between the TRUNCATE TABLE and TRUNCATE flashback operations, the flashback fails.
  - When a table is entirely deleted or truncated, partitions are moved to the recycle bin along with the entire table. A single deleted partition cannot be moved to the recycle bin. This avoids data consistency damage.
  - If there are residual online indexes (a node that is not created exists and the index cannot be found on the node), an error is reported when a table is dropped. You need to clear the residual data to successfully drop the table and place the object in the recycle bin.
  - If the object on which the table depends is an external object (for example, a composite object or a user-defined object), the table is physically deleted and is not moved to the recycle bin.

- DROP FLASHBACK constraints

  You can specify either the original user-defined name of the table or the system-generated name assigned to the object when it was dropped.

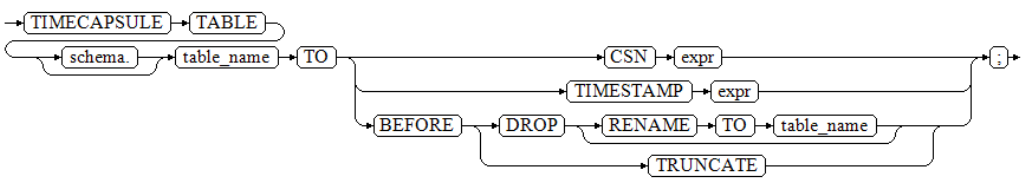
  - System-generated recycle bin object names are unique. Therefore, if you specify the system-generated name, the database retrieves that specified object. To see the content in your recycle bin, run **SELECT * FROM gs_recyclebin;**.
  - If you specify a user-specified name and the recycle bin contains more than one object of that name, the database retrieves the object that was moved to the recycle bin most recently. To retrieve a table of an earlier version, perform the following steps:
    - Specify the system-generated recycle bin name of the table you want to retrieve.
    - Run the **TIMECAPSULE TABLE ... TO BEFORE DROP** statement until you retrieve the table you want.
  - During table restoration, the dropped table along with its original base table name is restored. The subobject names of the table remain the same as those in the recycle bin. You can run the DDL command to manually change the names of subobjects as required.
  - If a table has default values that reference sequences and user-defined functions, flashing back the dropped table will succeed, but the default values will not be restored.
  - Similarly, if a table is referenced by views, dropping the table will cascadingly delete the views. Therefore, flashing back the dropped table will succeed, but the views will not be restored.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

  - The recycle bin does not support write operations such as DML, DCL, and DDL, and does not support DQL query operations (supported in later versions).
  - The **recyclebin_retention_time** parameter specifies the retention period of objects in the recycle bin. The objects will be automatically deleted after the retention period expires.
- TRUNCATE FLASHBACK constraints
  - After TRUNCATE FLASHBACK is performed, the statistics remain unchanged and are still displayed as **0**. You can modify the statistics by manual ANALYZE during off-peak hours (to reduce the impact on performance).
  - RENAME TO supports only the DROP FLASHBACK operation to specify a new name for the retrieval table, but does not support TRUNCATE FLASHBACK.
  - TRUNCATE FLASHBACK cannot span statements that affect the table definition or physical storage. Otherwise, an error is reported. If a statement (such as DDL, DCL, VACUUM FULL, and partition adding/deleting/splitting/merging) that modifies the table definition or affects physical storages are executed between the flashback point and current point, the flashback fails. The error message "ERROR: The table definition of %s has been modified." is displayed when flashback is performed on a table where DDL operations have been performed. The error message "ERROR: recycle object %s desired does not exist" is displayed when flashback is performed on a table where DDL operations, such as changing namespaces and table names, have been performed.
- When VACUUM is used to update database-level **frozenXid**, the value of **rcyfrozenxid64** in the recycle bin is referenced. If there are tables that are not cleared for a long time in the recycle bin, **frozenXid** may fail to be updated, affecting Clog recycling (Clog files occupy a small amount of storage space and have little impact in actual scenarios). You can clear the tables that do not need to be flashed back in the recycle bin to update **frozenXid**.
- If the recycle bin has been enabled before the upgrade from a version earlier than 503.0 to the latest version, ensure that no partitioned table object exists in the recycle bin before the upgrade. Otherwise, the upgrade will fail.
- During the upgrade from a version earlier than 503.0 to the latest version, no matter whether a partitioned table is in the upgrade uncommitted or upgrade committed state, an error is reported when a flashback table or flashback query operation is performed, indicating that the table structure is changed.

Syntax

```
TIMECAPSULE TABLE
   [schema.]table_name TO { CSN expr | TIMESTAMP expr | BEFORE { DROP [RENAME TO table_name] |
TRUNCATE } };
```



Parameters

- **schema**

  Specifies a schema containing the table to be flashed back. If this parameter is not specified, the current schema is used.

- **table_name**

  Specifies a table name.

- **TO CSN**

  Specifies the CSN corresponding to the time point when the table is to be flashed back. *expr* must be a number representing a valid CSN.

  Note: In the GTM-free scenario, each node uses the local CSN and does not have a globally unified CSN. Therefore, flashback in TO CSN mode is not supported.

- **TO TIMESTAMP**

  Specifies a timestamp value corresponding to the point in time to which you want to flash back the table. The result of *expr* must be a valid past timestamp (convert a string to a time type using the **TO_TIMESTAMP** function). The table will be flashed back to a time within approximately 3 seconds of the specified timestamp.

  Note: When the flashback point is too old, the source version cannot be obtained because it is recycled. As a result, the flashback fails and the error message "Restore point too old" is displayed.

- **TO BEFORE DROP**

  Retrieves dropped tables and their subobjects from the recycle bin.

- **RENAME TO**

  Specifies a new name for the table retrieved from the recycle bin.

- **TO BEFORE TRUNCATE**

  Flashes back to the point in time before the TRUNCATE operation.

Examples

- **Flashing data back to a specified time**

  You need to set the **undo_retention_time** parameter to set the retention period of old undo logs.

  For details about how to use the parameters, contact an administrator.

```
-- Create a table and insert data into the table.
gaussdb=# CREATE TABLE tbl_test(c1 int, c2 int) with(storage_type = ustore) DISTRIBUTE BY
REPLICATION;
gaussdb=# INSERT INTO tbl_test VALUES (1,1),(2,2),(3,3);

-- Query the current time and next_csn on all global nodes.
gaussdb=# SELECT now();
              now
-------------------------------
 2023-11-27 17:06:34.840698+08
(1 row)

gaussdb=# SELECT int8in(xidout(next_csn)) FROM gs_get_next_xid_csn();
 int8in
--------
  25391
  25391
  25391
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
 25391
 25391
 25391
(6 rows)

-- Modify data.
gaussdb=# UPDATE tbl_test SET c1=111, c2=222 WHERE c1=1;

-- Query data and flash the data back to the state before UPDATE.
gaussdb=# SELECT * FROM tbl_test;
 c1  | c2
-----+-----
 111 | 222
   2 |   2
   3 |   3
(3 rows)
gaussdb=# TIMECAPSULE table tbl_test TO TIMESTAMP to_timestamp('2023-11-27
17:06:34.840698','YYYY-MM-DD HH24:MI:SS.FF');

-- You can also use the following SQL statements:
gaussdb=# TIMECAPSULE table tbl_test TO CSN 25391;

gaussdb=# SELECT * FROM tbl_test;
 c1 | c2
----+----
  2 |  2
  3 |  3
  1 |  1
(3 rows)

-- Drop.
gaussdb=# DROP TABLE tbl_test PURGE;
```

- **Flashing back data from the recycle bin**

  Prerequisites:

  – The **enable_recyclebin** parameter has been set to enable the recycle bin. For details about how to use the parameter, contact an administrator.

  – The **recyclebin_retention_time** parameter has been set to specify how long objects will remain in the recycle bin before being automatically deleted. Contact an administrator for the parameter usage.

```
-- Create a table and insert data into the table.
gaussdb=# CREATE TABLE tbl_test1(c1 int, c2 varchar(10))with(storage_type = ustore);
gaussdb=# INSERT INTO tbl_test1 VALUES (1,'AAA'),(2,'BBB');

-- Drop the table.
gaussdb=# DROP TABLE tbl_test1;

-- Flash back to the time before the table is deleted.
gaussdb=# TIMECAPSULE TABLE tbl_test1 TO BEFORE DROP;

-- Query data.
gaussdb=# SELECT * FROM tbl_test1;
 c1 | c2
----+-----
  1 | AAA
  2 | BBB
(2 rows)

-- Drop a table. (The PURGE parameter is added to delete the table data from the recycle bin.)
gaussdb=# DROP TABLE tbl_test1 PURGE;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

1.13.20.2 TRUNCATE

Description

TRUNCATE quickly removes all rows from a database table.

It has the same effect as an unqualified DELETE on each table, but TRUNCATE is faster because it does not actually scan the tables. This is most useful on large tables.

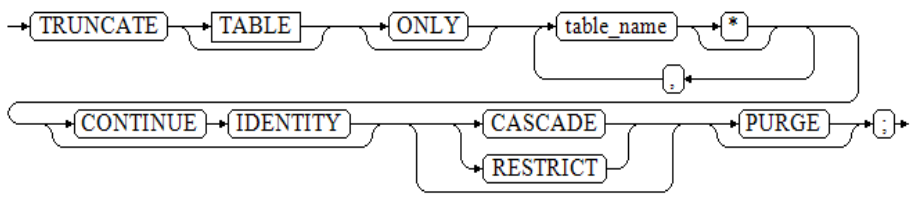
Precautions

- The owner of a table, users granted the TRUNCATE permission on the table, or users granted the TRUNCATE ANY TABLE permission can truncate the specified table. When separation of duties is disabled, system administrators have this permission by default.
- TRUNCATE TABLE has the same function as a DELETE statement with no WHERE clause, emptying a table.
- TRUNCATE TABLE uses less system and transaction log resources as compared with DELETE.
  - DELETE deletes a row each time, and records the deletion of each row in the transaction log.
  - TRUNCATE TABLE deletes all rows in a table by releasing the data page storing the table data, and records the releasing of the data page only in the transaction log.
- The differences between TRUNCATE, DELETE, and DROP are as follows:
  - TRUNCATE TABLE deletes content, releases space, but does not delete definitions.
  - DELETE TABLE deletes content, but does not delete definitions nor release space.
  - DROP TABLE deletes content and definitions, and releases space.

Syntax

- Truncate the data in a table.

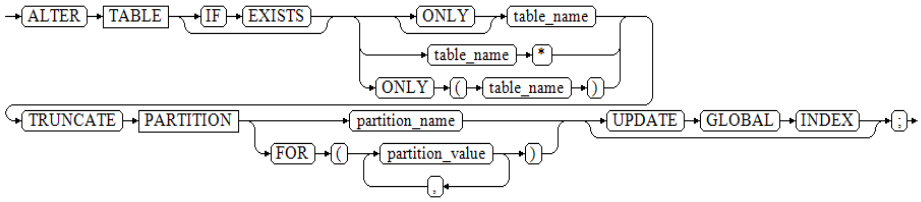
```
TRUNCATE [ TABLE ] [ ONLY ] {table_name [ * ]} [, ... ]
    [ CONTINUE IDENTITY ] [ CASCADE | RESTRICT ] [ PURGE ];
```



- Truncate the data in a partition.

```
ALTER TABLE [ IF EXISTS  ] { [ ONLY  ] table_name
                           | table_name *
                           | ONLY ( table_name )  }
    TRUNCATE PARTITION { partition_name
                       | FOR (  partition_value  [, ...] )  } [ UPDATE GLOBAL INDEX ];
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.



Parameters

- **ONLY**

  If **ONLY** is specified, only the specified table is cleared. If **ONLY** is not specified, the table and all its subtables (if any) are cleared.

- **table_name**

  Specifies the name (optionally schema-qualified) of the target table.

  Value range: an existing table name

- **CONTINUE IDENTITY**

  Does not change the values of sequences. This is the default action.

- **CASCADE | RESTRICT**
  - **CASCADE**: cascadingly truncates all tables added to a group due to CASCADE.
  - **RESTRICT** (default): refuses to truncate if any of the tables have foreign-key references from tables that are not listed in the statement (not supported in distributed scenarios).

- **PURGE**

  Purges table data in the recycle bin by default.

- **partition_name**

  Specifies the partition in the target partitioned table.

  Value range: an existing table name

- **partition_value**

  Specifies the partition key value.

  The value specified by **PARTITION FOR** can uniquely identify a partition.

  Value range: value range of the partition key for the partition to be renamed

  NOTICE

  When the PARTITION FOR clause is used, the entire partition where **partition_value** is located is cleared.

- **UPDATE GLOBAL INDEX**

  Updates all global indexes in the partitioned table to ensure that correct data can be queried using global indexes.

  If this parameter is not used and the GUC parameters **enable_gpi_auto_update** and **enable_drop_truncate_partition_keep_gpi** are set to **off**, all global indexes in the partitioned table will become invalid.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Examples

- Clear table data.

```
-- Create the reason table.
gaussdb=# CREATE TABLE reason (r_reason_sk int,r_reason_id varchar(16),r_reason_desc
varchar(100));

-- Insert multiple records into the table.
gaussdb=# INSERT INTO reason values(1,'AAAAAAAABAAAAAAA','reason 1'),
(5,'AAAAAAAABAAAAAAA','reason 2'),
                                  (15,'AAAAAAAABAAAAAAA','reason 3'), (25,'AAAAAAAABAAAAAAA','reason
4'),
                                  (35,'AAAAAAAABAAAAAAA','reason 5'), (45,'AAAAAAAACAAAAAAA','reason
6');

-- Check the table information. The table size is about 16 KB.
gaussdb=# \d+
                                  List of relations
 Schema |  Name  | Type  | Owner | Size  |             Storage              | Description
--------+--------+-------+-------+-------+----------------------------------+-------------
 public | reason | table | omm   | 16 kB | {orientation=row,compression=no} |
(1 row)

-- Run the DELETE statement without the WHERE condition to clear data in the table and check the
table size.
gaussdb=# DELETE FROM reason;
gaussdb=# \d+
                                  List of relations
 Schema |  Name  | Type  | Owner | Size  |             Storage              | Description
--------+--------+-------+-------+-------+----------------------------------+-------------
 public | reason | table | omm   | 16 kB | {orientation=row,compression=no} |
(1 row)

-- Run the TRUNCATE statement to clear the reason table and check the table size.
gaussdb=# TRUNCATE TABLE reason;
gaussdb=# \d+
                                  List of relations
 Schema |  Name  | Type  | Owner |  Size   |             Storage              | Description
--------+--------+-------+-------+---------+----------------------------------+-------------
 public | reason | table | omm   | 0 bytes | {orientation=row,compression=no} |
(1 row)

-- Drop the table.
gaussdb=# DROP TABLE reason;
```

- Clear data of a partitioned table.

```
-- Create a partitioned table.
gaussdb=# CREATE TABLE reason_p(
    r_reason_sk integer,
    r_reason_id character(16),
    r_reason_desc character(100)
)PARTITION BY RANGE (r_reason_sk)(
    partition p_05_before values less than (05),
    partition p_15 values less than (15),
    partition p_25 values less than (25),
    partition p_35 values less than (35),
    partition p_45_after values less than (MAXVALUE)
);

-- Insert data.
gaussdb=# INSERT INTO reason_p values(1,'AAAAAAAABAAAAAAA','reason 1'),
(5,'AAAAAAAABAAAAAAA','reason 2'),
                                   (15,'AAAAAAAABAAAAAAA','reason 3'), (25,'AAAAAAAABAAAAAAA','reason
4'),
                                   (35,'AAAAAAAABAAAAAAA','reason 5'), (45,'AAAAAAAACAAAAAAA','reason
6');

-- Clear the p_05_before partition.
gaussdb=# ALTER TABLE reason_p TRUNCATE PARTITION p_05_before UPDATE GLOBAL INDEX;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
-- Clear the partitioned table.
gaussdb=# TRUNCATE TABLE reason_p;

-- Delete the reason_p table.
gaussdb=# DROP TABLE reason_p;
```

1.13.21 U

1.13.21.1 UPDATE

Description

Updates specified columns in all rows that meet the specified conditions. You can use WHERE to declare conditions. All columns specified by the SET clause will be updated. Other columns retain their original values.

Precautions

- The owner of a table, users with the UPDATE permission on the table, or users with the UPDATE ANY TABLE permission can update data in the table. When separation of duties is disabled, system administrators have this permission by default.
- UPDATE..... LIMIT row_count supports only some scenarios of execution plan pushdown. (Table replication is not supported.) The prerequisites are that the filter criteria must contain the equivalent distribution key and the filter criteria should be relatively simple. Do not use forcible type conversion. If the command fails to be executed, simplify the filter criteria.
- You must have the SELECT permission on all tables involved in the expressions or conditions.
- The distribution keys can be updated only when **enable_update_distkey** is set to **on** and constraints are met. Otherwise, distribution keys do not support the UPDATE operation.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

The constraints on updating distribution keys are as follows:

- Distribution keys can be updated only when **enable_update_distkey** is set to **on**.
- The UPDATE statement cannot be pushed down to DNs for execution. The PGXC plan is directly generated and is not changed based on the values before and after the distribution key is updated.
- Tables with row-level UPDATE TRIGGER are not supported. Otherwise, the execution fails and an error message is displayed. The row-level INSERT/DELETE TRIGGER does not take effect, and the update-statement-level TRIGGER is executed normally.
- Concurrent update of the same row is not supported. You need to obtain a lock first. The result (returning **0** or reporting an error) of obtaining a lock on DNs depends on the setting of the GUC parameter **concurrent_dml_mode**. An error will be reported in the following cases: (1) The error message "update distribute column conflict" is displayed. (2) When the time spent for obtaining a lock exceeds the threshold, an error message is displayed, indicating that the lock times out.
- Tables with global secondary indexes (GSIs) are not supported. Otherwise, an error is reported.
- Only hash distribution is supported. LIST/RANGE distributed tables are not supported. Otherwise, an error is reported.
- MERGE INTO and UPSERT cannot be used to update distribution keys. Otherwise, an error is reported.
- GTM_FREE is not supported. Otherwise, an error is reported.
- UPDATE RETURNING is not supported. Otherwise, an error is reported.
- Statements with joined tables are not supported. Otherwise, an error is reported.
- UPDATE+LIMIT is not supported. Otherwise, an error is reported.
- In ORA-compatible and MYSQL-compatible modes, multiple partitions cannot be deleted at a time. Therefore, when the DELETE statements are reversely parsed during distribution key update, multiple partitions are not involved. Data consistency is ensured by the condition **tableoid**.

- For row-store replication tables, UPDATE can be performed only in the following two scenarios:
  - Scenarios with PRIMARY KEY constraints.
  - Scenarios where the execution plan can be pushed down.
- For the UPDATE statement whose subquery is a STREAM plan, the same row cannot be concurrently updated.
- You cannot modify the database character encoding by updating a system catalog. Such operation will cause exceptions in existing data or other operations. If you need to change the character encoding of a database, follow the database switching process to migrate data.
- In high-concurrency scenarios, when a large number of UPDATE operations are performed on an ultra-wide table, if frequent DDL operations are performed in seconds, the UPDATE operation may take hours. Minute-level DDL operations do not significantly affect performance.

Syntax

```
[ WITH [ RECURSIVE ] with_query [, ...] ]
UPDATE [/*+ plan_hint */] [ ONLY ] {table_name [ partition_clause ] | subquery | view_name} [ * ] [ [ AS ] alias ]
SET {column_name = { expression | DEFAULT }
    |( column_name [, ...] ) = {( { expression | DEFAULT } [, ...] ) |sub_query }}[, ...]
```

```
   [ FROM from_list] [ WHERE condition | WHERE CURRENT OF cursor_name ]
   [ ORDER BY {expression [ [ ASC | DESC | USING operator ]
[ LIMIT { count } ]
   [ RETURNING {*
            | {output_expression [ [ AS ] output_name ]} [, ...] }];

where sub_query can be:
SELECT [ ALL | DISTINCT [ ON ( expression [, ...] ) ] ]
{ * | {expression [ [ AS ] output_name ]} [, ...] }
[ FROM from_item [, ...] ]
[ WHERE condition  ]
[ GROUP BY grouping_element [, ...] ]
[ HAVING condition [, ...] ]
[ ORDER BY {expression [ [ ASC | DESC | USING operator ] | nlssort_expression_clause ] [ NULLS { FIRST |
LAST } ]} [, ...] ]
[ LIMIT { [offset,] count | ALL } ]
```

- The subquery **with_query** is as follows:

  ```
  with_query_name [ ( column_name [, ...] ) ] AS [ [ NOT ] MATERIALIZED ] ( {select | values | insert |
  update | delete} )
  ```

- For subquery:

  ```
  [ WITH [ RECURSIVE ] with_query [, ...] ]
  SELECT [/*+ plan_hint */] [ ALL ]
  { * | {expression [ [ AS ] output_name ]} [, ...] }
  [ into_option ]
  [ FROM from_item [, ...] ]
  [ WHERE condition ]
  [ [ START WITH condition ] CONNECT BY [NOCYCLE] condition [ ORDER SIBLINGS BY expression ] ]
  [ ORDER BY {expression [ [ ASC | DESC | USING operator ] | nlssort_expression_clause ] [ NULLS
  { FIRST | LAST } ]} [, ...] ]
  [ FETCH { FIRST | NEXT } [ count ] { ROW | ROWS } ONLY ]
  [ into_option ];
  ```

- The specified subquery source **from_item** is as follows:

  ```
  {[ ONLY ] {table_name | view_name} [ * ] [ partition_clause ] [ [ AS ] alias [ ( column_alias [, ...] ) ] ]
  |( select ) [ AS ] alias [ ( column_alias [, ...] ) ]
  |with_query_name [ [ AS ] alias [ ( column_alias [, ...] ) ] ]
  |from_item [ NATURAL ] join_type from_item [ ON join_condition | USING ( join_column [, ...] ) ]}
  ```

- For partition_clause:

  ```
  PARTITION { ( partition_name [, ...] ) | FOR ( partition_value [, ...] ) }
  ```

Parameters

- **WITH [RECURSIVE] with_query [, ...]**

  Specifies one or more subqueries that can be referenced by name in the main query, which is equivalent to a temporary table. This subquery statement structure is called the common table expression (CTE) structure. When this structure is used, the execution plan contains the CTE SCAN content.

  If **RECURSIVE** is specified, it allows a SELECT subquery to reference itself by name.

  with_query:

  - **with_query_name** specifies the name of the result set generated by a subquery. Such names can be used to access the result sets of subqueries in a query.
  - **column_name** specifies the column name displayed in the subquery result set.
  - Each subquery can be a SELECT, VALUES, INSERT, UPDATE, or DELETE statement.
  - You can use MATERIALIZED or NOT MATERIALIZED to modify the CTE.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

  - If **MATERIALIZED** is specified, the WITH query will be materialized, and a copy of the subquery result set is generated. The copy is directly queried at the reference point. Therefore, the WITH subquery cannot be jointly optimized with the SELECT statement trunk (for example, predicate pushdown and equivalence class transfer). In this scenario, you can use **NOT MATERIALIZED** for modification. If the WITH query can be executed as a subquery inline, the preceding optimization can be performed.
  - If the user does not explicitly declare the materialized attribute, comply with the following rules: If the CTE is referenced only once in the SELECT statement trunk to which it belongs and semantically supports inline execution, it will be rewritten as subquery inline execution. Otherwise, the materialized execution will be performed in CTE Scan mode.

- **plan_hint**

  Follows the UPDATE keyword in the /*+ */ format. It is used to optimize the plan of a UPDATE statement block using hints. For details, see "Hint-based Optimization" in *SQL Optimization Guide*. In each statement, only the first **/*+ plan_hint */** comment block takes effect as a hint. Multiple hints can be written.

- **table_name**

  Specifies the name (optionally schema-qualified) of the table to be updated. If **ONLY** is specified before the table name, only matching rows in the specified table are updated. If it is not specified, any matching rows inherited from the table are also updated.

  Value range: existing table names.

  NOTE

  You can use database links to perform operations on remote tables. For details, see "Feature Usage Guidelines > Database Links" in *Developer Guide*.

- **subquery**

  Specifies the subquery to be updated. When a subquery is updated, the subquery is regarded as a temporary view. The **CHECK OPTION** option can be added to the end of the subquery.

  If a subquery contains only one table, data is updated into the table. If a subquery contains multiple tables or has nested relationships, check whether a key-preserved table exists to determine whether data can be updated. For details about key-preserved tables and **WITH CHECK OPTION**, see **CREATE VIEW**.

- **view_name**

  Specifies the target view to be updated.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

> **NOTE**
>
> Pay attention to the following limitations when updating a view or subquery:
>
> - The UPDATE operation can be performed only on columns that directly reference user columns in the base table.
> - The view or subquery must contain at least one updatable column. For details about updatable columns, see **CREATE VIEW**.
> - The view or subquery must not contain the DISTINCT, GROUP BY, HAVING, LIMIT, or OFFSET clause at the top layer.
> - Views and subqueries that contain set operations (UNION, INTERSECT, EXCEPT, and MINUS) at the top layer are not supported.
> - The view or subquery must not contain aggregate functions, window functions, or return set functions (such as array_agg, json_agg, and generate_series) in the target list.
> - Views with BEFORE or AFTER triggers but without INSTEAD OF triggers or INSTEAD rules are not supported.
> - The view or subquery uses only the following types of tables: ordinary tables, temporary tables, global temporary tables, partitioned tables, subpartitioned tables, Ustore tables, and Astore tables.
> - Only one base table can be updated at a time in a multi-table join view or join subquery.
> - Join views or subqueries can update only key-preserved tables. If **CHECK OPTION** is specified, join columns cannot be updated. For details about key-preserved tables, see **CREATE VIEW**.
> - System views cannot be updated.

- **partition_clause**

  Updates a specified partition.

  > **NOTE**
  >
  > If PARTITION specifies multiple partition names, the partition names can be the same. The union set of the partition ranges is used.

- **alias**

  Specifies the alias of the target table.

  Value range: character strings complying with **Identifier Naming Conventions**.

- **column_name**

  Specifies the name of the column to be modified.

  You can reference this column by using the target table alias and column name. Example: **UPDATE foo AS f SET f.col_name = 'namecol'**

  Value range: existing column names.

- **expression**

  Specifies the expression or value to be assigned to the column.

- **DEFAULT**

  Specifies the default value of a column.

  The value is **NULL** if there is no default value.

- **sub_query**

  Specifies a subquery.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

This statement can be executed to update a table with information for other tables in the same database. For details about clauses in the SELECT statement, see **SELECT**.

When a single column is updated, the ORDER BY and LIMIT clauses can be used. When multiple columns are updated, the ORDER BY and LIMIT clauses cannot be used.

NOTE

- When multiple columns are updated using a subquery, if the GUC parameter **enable_shared_set_update** is disabled, the optimizer generates a subplan for each updated column. If the parameter is enabled, multiple columns can share one subplan to improve query efficiency and reduce query optimization and execution overhead. For details about the GUC parameter setting, contact an administrator.
- When a subquery is used to update multiple columns, you are advised not to use asterisks (*) to replace specific column names in the targetlist of the subquery. Instead, specify the names to be updated clearly.
- If the WHERE clause of a subquery in the SET clause uses the + operator, the configuration item **enable_ora_joinop_in_updatestmt** must be added to the compatibility parameter **behavior_compat_options** for the setting to take effect.

- **from_list**

  Specifies a list of table expressions. You can use columns of other tables in the WHERE condition. It is similar to specifying a table list in a FROM clause of a SELECT statement.

  NOTICE

  Note that the target table cannot appear in **from_list**, unless you intend a self-join (in which case it must appear with an alias in **from_list**).

- **condition**

  Specifies an expression that returns a value of the Boolean type. Only rows for which this expression returns **true** are updated. You are advised not to use numeric types such as int for **condition** because such types can be implicitly converted to Boolean values (non-zero values are implicitly converted to **true** and **0** is implicitly converted to **false**), which may cause unexpected results.

- **WHERE CURRENT OF cursor_name**

  When the cursor points to a row in a table, you can use this syntax to update the row.

  cursor_name: specifies the name of a cursor.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTICE

- This syntax is not supported by the database in MYSQL-compatible mode.
- This syntax supports only ordinary tables instead of partitioned tables or hash bucket tables.
- This syntax can be used only in stored procedures.
- This syntax cannot be used together with other WHERE conditions.
- This syntax cannot be used together with WITH, USING, ORDER BY, or FROM.
- The SELECT statement corresponding to the CURSOR must be declared as FOR UPDATE.
- The SELECT statement corresponding to the CURSOR supports only a single table. It does not support LIMIT/OFFSET, subqueries, or sublinks.
- The CURSOR declared as FOR UPDATE in a stored procedure cannot be used after being committed or rolled back.
- If the row to which the CURSOR points does not exist, an error is reported (only when UPDATE is used instead of DELETE) in the ORA-compatible mode, indicating that the specified row does not exist. In other compatibility modes, no error is reported.
- When this syntax is used in a replication table, pushdown is not supported. A primary key is required.

- **ORDER BY**

  For details about the keywords, see **SELECT**.

- **LIMIT**

  For details about the keywords, see **SELECT**.

- **RETURNING output_expression**

  Specifies an expression to be computed and returned by the UPDATE statement after each row is updated.

  Value range: any table and table columns listed in FROM. Write * to return all columns.

- **output_name**

  Specifies a name to use for a returned column.

Examples

- Modify all data in the table.

```
-- Create a table named tbl_test1 and insert data into the table.
gaussdb=# CREATE TABLE tbl_test1(id int, info varchar(10));
gaussdb=# INSERT INTO tbl_test1 VALUES (1, 'A'), (2, 'B');

-- Query.
gaussdb=# SELECT * FROM tbl_test1;
 id | info
----+------
  1 | A
  2 | B
(2 rows)

-- Modify the info column of all data in the tbl_test1 table.
gaussdb=# UPDATE tbl_test1 SET info = 'aa';
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
-- Query the tbl_test1 table.
gaussdb=# SELECT * FROM tbl_test1;
 id | info
----+------
  1 | aa
  2 | aa
(2 rows)
```

- Modify some data in the table.

```
-- Modify the data whose id is 2 in the tbl_test1 table.
gaussdb=# UPDATE tbl_test1 SET info = 'bb' WHERE id = 2;

-- Query the tbl_test1 table.
gaussdb=# SELECT * FROM tbl_test1;
 id | info
----+------
  1 | aa
  2 | bb
(2 rows)
```

- Modify the data and return the modified data.

```
-- Modify the data whose id is 1 in the tbl_test1 table and specify that the info column should be
returned.
gaussdb=# UPDATE tbl_test1 SET info = 'ABC' WHERE id = 1 RETURNING info;
 info
------
 ABC
(1 row)

UPDATE 1

-- Drop the tbl_test1 table.
gaussdb=# DROP TABLE tbl_test1;
```

- Use a subquery to insert new data based on the existing data when modifying data.

```
-- Create a table.
gaussdb=# CREATE TABLE test_grade (
    sid int,                -- Student ID
    name varchar(50),       -- Name
    score char,             -- Score
    examtime date,          -- Exam time
    last_exam boolean       -- The last exam or not
);

-- Insert data.
gaussdb=# INSERT INTO test_grade VALUES (1,'Scott','A','2008-07-08',1),(2,'Ben','D','2008-07-08',1),
(3,'Jack','D','2008-07-08',1);

-- Query.
gaussdb=# SELECT * FROM test_grade;
 sid | name  | score |  examtime  | last_exam
-----+-------+-------+------------+-----------
   3 | Jack  | D     | 2008-07-08 | t
   1 | Scott | A     | 2008-07-08 | t
   2 | Ben   | D     | 2008-07-08 | t
(3 rows)

-- On August 25, 2008, Ben took a make-up exam and the score is B. You need to change the value of
last_exam to No, and then insert the score of August 25, 2008.
gaussdb=# WITH old_exa AS ( UPDATE test_grade SET last_exam = 0 WHERE sid = 2 AND examtime
= '2008-07-08' RETURNING sid, name )
        INSERT INTO test_grade VALUES ( ( SELECT sid FROM old_exa ), (SELECT name FROM old_exa),
'B', '2008-08-25', 1 );

-- Query.
gaussdb=# SELECT * FROM test_grade;
 sid | name  | score |  examtime  | last_exam
-----+-------+-------+------------+-----------
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
  3 | Jack  | D     | 2008-07-08 | t
  1 | Scott | A     | 2008-07-08 | t
  2 | Ben   | D     | 2008-07-08 | f
  2 | Ben   | B     | 2008-08-25 | t

1.13.21.1.1 Pseudo-update of Distribution Keys

Description

When the UPDATE statement is executed to update a distribution key, GaussDB checks the equivalent distribution keys and eliminates the distribution key information that is not actually updated through the query rewriting mechanism. This prevents the SELECT FOR UPDATE syntax visibility error caused by the deletion or rebuild of distribution keys that are not actually updated. This function is controlled by the GUC parameter **enable_remove_redundant_update_col**. This function is enabled when the parameter is set to **on**.

After this function is enabled, the actual effect is as follows:

Original user statement:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
UPDATE TABLE SET distkey=value,amount=10000 WHERE distkey=value;
```

Statement after query rewriting:

```
UPDATE TABLE SET amount=10000 WHERE distkey=value;
```

NOTE

Before this function is enabled, the following error message is displayed for the pseudo-update of distribution keys (no additional error information is displayed):

```
ERROR:  Distributed key cannot be updated in the current version.
```

Limitations

- Only ORA compatibility is supported.
- Only hash distributed tables are supported.
- Syntax constraints on pseudo-update of distribution keys:
  - Only the UPDATE syntax is supported. The MERGE INTO, REPLACE INTO, or UPSERT syntax is not supported.
  - Only scenarios where actual values can be calculated during query rewriting are supported, including:
    - Common constants: data passed by values such as numbers and strings.
    - Parameter types: constant values (such as numbers and strings) passed in PBE packets.
    - Function types: immutable functions (stable and volatile functions are not supported).
    - Operator types: common operators (such as + - * /), with constant inputs.
    - Boolean expression types: OR, AND, and NOT, with constant inputs.
    - Explicit type conversion: explicit type conversion of constants ('1.23'::numeric).
    - Condition expression types: CASE WHEN, with constant parameters. NVL/COALESCE, with constant parameters.
    - NULL value.
  - Only equality expressions are supported. Ranges specified by greater than, less than, between, and in are not supported.
  - Subquery scenarios are not supported.
  - The combination of UPDATE and CTE is not supported.
  - Views cannot be updated.
- In scenarios where pseudo-update of distribution keys can be eliminated, the distribution keys do not need to be updated after elimination. In this case, constraints listed in **NOTE** do not need to be followed.
- Pseudo-update of distribution keys forcibly selects a Cplan. The priorities of plan selection are as follows:

  /*+ use_gplan*/ > Pseudo-update of distribution keys > **plan_cache_mode**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Examples

- Example 1: Pseudo-update a distribution key of the nvarchar2 type.

```
-- Create a test database.
gaussdb=# CREATE DATABASE ora_db DBCOMPATIBILITY = 'ORA';
gaussdb=# \c ora_db

-- Create a hash distributed table.
ora_db=# CREATE TABLE test_hash(
    id       nvarchar2(10),
    name     VARCHAR(20),
    province VARCHAR(60),                    -- Province
    country   VARCHAR(30) DEFAULT 'Country1'        -- Country
)DISTRIBUTE BY HASH(id);
ora_db=# INSERT INTO test_hash VALUES ('0000001', 'Bob',   'City1', 'Country1'),
    ('0000002', 'Jack',  'City2',  'Country1'),
    ('0000003', 'Scott', 'City2',  'Country1');

-- An error is reported in the original scenario.
ora_db=# UPDATE test_hash SET id = '0000001', name = 'bob1' WHERE id = '0000001';
ERROR:  Distributed key cannot be updated in the current version.

-- No error is reported after the function is enabled.
ora_db=# SET enable_remove_redundant_update_col=on;
ora_db=# UPDATE test_hash SET id = '0000001', name = 'bob1' WHERE id = '0000001';
UPDATE 1

-- Display the plan (the projected column id = '0000001' in the SET clause is successfully eliminated).
ora_db=# EXPLAIN VERBOSE UPDATE test_hash SET id = '0000001', name = 'bob1' WHERE id =
'0000001';
                                        QUERY PLAN
-----------------------------------------------------------------------------------------------------------------
 Data Node Scan on "__REMOTE_FQS_QUERY__"  (cost=0.00..0.00 rows=0 width=0)
   Node/s: datanode1
   Remote query: UPDATE public.test_hash SET name = 'bob1'::character varying WHERE id::text =
'0000001'::text
(3 rows)

-- Delete the test database. Replace postgres with the actual initial database name.
ora_db=# \c postgres
gaussdb=# DROP DATABASE ora_db;
```

- Example 2: Pseudo-update multiple distribution keys.

```
-- Create a test database.
gaussdb=# CREATE DATABASE ora_db DBCOMPATIBILITY = 'ORA';
gaussdb=# \c ora_db

-- Enable the function.
ora_db=# SET enable_remove_redundant_update_col=on;

-- Create a hash distributed table.
ora_db=# CREATE TABLE test_hash_multi_distcol(
    id       int,
    name     VARCHAR(20),
    province VARCHAR(60),                    -- Province
    country   VARCHAR(30) DEFAULT 'Country1'        -- Country
)DISTRIBUTE BY HASH(id,name);
ora_db=# INSERT INTO test_hash_multi_distcol VALUES (1, 'Bob',   'City1', 'Country1'),
    (2, 'Jack',  'City1',  'Country1'),
    (3, 'Scott', 'City2',  'Country1');

-- No error is reported after the function is enabled.
ora_db=# UPDATE test_hash_multi_distcol SET id = 1,name='Bob', province = 'City1' WHERE id = 1
and name='Bob';
UPDATE 1

-- Display the plan.
ora_db=# EXPLAIN VERBOSE UPDATE test_hash_multi_distcol SET id = 1,name='Bob', province =
'City1' WHERE id = 1 AND name='Bob';
                                            QUERY PLAN
```

NOTE

In the example, the forcible conversion of the varchar2 type is affected by the GUC parameter **modify_function_property_json**.

- Set the GUC parameter to an empty value, or set **property_value** from **s** to **i** for the object whose **property_name** is **provolatile** in the configuration item with OID **4186** in the GUC parameter, and restart the database. The result is returned normally.
- If the **modify_function_property_json** parameter is not modified, an error is reported, as expected. This happens because the function variability is stable, similar to the forcible conversion of the text type. The error message is as follows:

```
ora_db=# EXPLAIN VERBOSE UPDATE distcol_update_timestamp SET c1 = '2026-03-05
09:25:20.411077+08',c2 = -3 WHERE c1 = '2026-03-05 09:25:20.411077+08'::varchar2;
ERROR:  Distributed key cannot be updated in the current version.
```

- Example 5: System functions such as NVL and implicit type conversion are not supported.

```
-- Create a test database.
gaussdb=# CREATE DATABASE ora_db DBCOMPATIBILITY = 'ORA';
gaussdb=# \c ora_db

-- Enable the function.
ora_db=# SET enable_remove_redundant_update_col=on;

-- Create a hash distributed table.
ora_db=# CREATE TABLE distcol_update_timestamp(c1 timestamp(6),c2 int,c3 text) DISTRIBUTE BY
HASH(c1);
ora_db=# INSERT INTO distcol_update_timestamp VALUES ('2026-03-05
09:25:19.411077+08',1,'gaussdb'),
    ('2026-03-05 09:25:19.411077+08',2,'gaussdb'),
    ('2026-03-05 09:25:20.411077+08',3,'gaussdb'),
    ('2026-03-05 09:25:21.411077+08',4,'gaussdb'),

    ('2026-03-06 09:25:22.411077+08',6,'gaussdb'),
    ('2026-03-07 09:25:22',7,'gaussdb');
ora_db=# CREATE INDEX ON distcol_update_timestamp(c1);

-- Run the UPDATE statement.
ora_db=# UPDATE distcol_update_timestamp SET c1 = '2026-03-05 09:25:20.411077+08',c2 = -3
WHERE c1 = nvl('2026-03-05 09:25:20.411077+08','2026-03-05 09:25:21.411077+08');
ERROR:  Distributed key cannot be updated in the current version.

-- Delete the test database. Replace postgres with the actual initial database name.
ora_db=# \c postgres
gaussdb=# DROP DATABASE ora_db;
```

- **Example 6**: An error is reported when a distribution key of the bigint or int type is pseudo-updated using the statement SET a = null,b = 1 WHERE a = null.

```
-- Create a test database.
gaussdb=# CREATE DATABASE ora_db DBCOMPATIBILITY = 'ORA';
gaussdb=# \c ora_db

-- Create a hash distributed table.
ora_db=# CREATE TABLE distcol_update_bigint(c1 bigint,c2 int,c3 text) DISTRIBUTE BY hash(c1);
ora_db=# INSERT INTO distcol_update_bigint VALUES(null,9,'gaussdb');

-- Set parameters and run the UPDATE statement.
ora_db=# SET enable_remove_redundant_update_col=on;
ora_db=# SET a_format_version = '10c';
ora_db=# SET a_format_dev_version = 's6';
ora_db=# UPDATE distcol_update_bigint SET c1 = null,c3 = 'update4' WHERE c1 = null;
ERROR:  Distributed key cannot be updated in the current version.

-- Delete the test database. Replace postgres with the actual initial database name.
ora_db=# \c postgres
gaussdb=# DROP DATABASE ora_db;
```

1.13.22 V

1.13.22.1 VACUUM

Description

VACUUM recycles storage space occupied by deleted rows in tables or B-Tree indexes. In normal database operation, rows that have been deleted are not physically removed from their table; they remain present until a VACUUM is done. Therefore, it is necessary to execute VACUUM periodically, especially on frequently-updated tables.

Precautions

- If no table is specified, VACUUM processes the tables on which the user has the corresponding permission in the current database. If a table is specified, VACUUM processes only the specified table.
- To vacuum a table, you must be the table owner or a user with the VACUUM permission on the table. When separation of duties is disabled, system administrators have this authorization by default. However, database owners are allowed to perform VACUUM on all tables in their databases, except shared catalogs. (The restriction for shared catalogs means that a true database-wide VACUUM can only be executed by system administrators). VACUUM skips over any tables that the calling user does not have permission to vacuum.
- VACUUM cannot be executed inside a transaction block.
- It is recommended that production databases be vacuumed frequently (at least nightly) to ensure that dead rows are removed. It might be a good idea to always perform VACUUM ANALYZE on the affected table after adding or deleting a large number of rows. This will update the system catalogs with the results of all recent changes, and allow the query planner to make better choices in planning queries.
- FULL is recommended only in special scenarios. For example, you want to physically narrow the table to decrease the occupied disk space after deleting most rows of a table. VACUUM FULL usually shrinks a table more than VACUUM does. If the occupied physical space does not decrease after you run the statement, check whether there are other active transactions (that started before the data deleting transaction and has not finished before you run VACUUM FULL). If there are such transactions, wait for them to finish and run the statement again.
- VACUUM FULL returns the free space in the table to the tablespace by rebuilding the table. During the rebuild, extra storage space equivalent to the valid data size in the table is required. If the storage space is insufficient, the cluster may become read-only when you run VACUUM FULL. For a non-segment-page table, after VACUUM FULL is executed, the physical files occupied by the source table are deleted, and the physical file space occupied by the source table is returned to the OS. For a segment-page table, after VACUUM FULL is executed, the physical space occupied by the source table is returned to the segment-page data file instead of the OS.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- VACUUM causes a significant increase in I/O traffic, which may affect the performance of other active sessions. Therefore, it is sometimes advisable to use the cost-based VACUUM delay feature.
- When **VERBOSE** is specified, VACUUM prints progress messages to indicate which table is currently being processed. Various statistics about the tables are printed as well.
- When the option list is surrounded by parentheses, the options can be written in any order. Without parentheses, the options must be specified in the order given in the syntax.
- During VACUUM and VACUUM FULL operations, the cleanup of row-store table records is deferred based on the **vacuum_defer_cleanup_age** parameter, which means recently deleted tuples are not cleaned up immediately.
- VACUUM ANALYZE executes a VACUUM operation and then an ANALYZE operation for each selected table. This is a handy combination form for routine maintenance scripts.
- Plain VACUUM (without FULL) simply recycles space and makes it available for reuse. This form of statement can operate in parallel with normal reading and writing of the table, as an exclusive lock is not obtained. VACUUM FULL executes wider processing, including moving rows across blocks to compress tables so they occupy the minimum number of disk blocks. This form is much slower and requires an exclusive lock on each table while it is being processed.
- If the **xc_maintenance_mode** parameter is not enabled, VACUUM FULL skips all system catalogs.
- VACUUM HDFSDIRECTORY is a reserved syntax.
- If you run **VACUUM FULL** immediately after running **DELETE**, the space will not be recycled. After running **DELETE**, execute 1000 non-SELECT transactions, or wait for 1s and then execute one transaction. Then, run **VACUUM FULL** to recycle the space.
- During VACUUM FULL, an exclusive lock is added to the table. Therefore, you are advised not to run **VACUUM FULL** during peak hours. Otherwise, the lock waiting time is too long or a deadlock occurs.
- To ensure performance and statistics accuracy, do not run ANALYZE-related commands, such as VACUUM ANALYZE, AUTOANALYZE, and manual ANALYZE, at the same time or frequently.
- For Ustore, the behavior of manual VACUUM is the same as that in Astore. Locks are obtained to clear heap tables and indexes. In Ustore, AUTOVACUUM only clears GPIs of partitioned tables, updates FSMs of heap tables, and recycles index pages.
- When **VACUUM FULL** is executed, partitions are traversed for clearance and GPIs are rebuilt after partition clearance. Therefore, if there are a large number of partitions, you are advised to delete GPIs first and rebuild indexes after **VACUUM FULL** is executed. In this way, the execution time of **VACUUM FULL** is reduced. For online VACUUM FULL, if the object is a partitioned table, the GPI is rebuilt when the partition is cleared. The GPI is rebuilt after the partition is cleared only when the object is a single partition. Therefore, you do not need to delete the GPI before using VACUUM FULL.
- Online VACUUM FULL cannot be performed on database-level, index-level, segment-page, hash bucket, temporary, or unlogged tables. If an object

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

involves the preceding unsupported types, the ONLINE keyword does not take effect. By default, VACUUM FULL is executed offline, and a message is displayed indicating that the VACUUM FULL statement cannot be executed online.

- When performing online VACUUM FULL operations, reserve sufficient disk space, at least equal to the total size of the tables to be operated and the accessories such as indexes on the tables.
- If the online VACUUM FULL execution is canceled, the residual data clearance process starts first. If the execution is also canceled again, the clearance process ends and residual data remains.
- Resource contention exists between online VACUUM FULL operations and user services. Therefore, online VACUUM FULL operations are not suitable for heavy-traffic scenarios. In scenarios where resources are limited, fine-grained resource control is recommended. Parallel acceleration is not recommended.
- Online VACUUM FULL is not supported in M-compatible mode.
- Online VACUUM FULL execution does not support the FREEZE keyword. If both FREEZE and ONLINE keywords are specified, VACUUM FULL is executed offline by default, and a message is displayed indicating that the VACUUM FULL statement cannot be executed online.
- Online VACUUM FULL cannot be executed within a transaction or a stored procedure. If you use the JDBC driver to run multiple SQL statements, a transaction is implicitly started, and these SQL statements cannot be executed together.
- If online VACUUM FULL fails, significant table space bloat may occur. The bloat degree is proportional to the online VACUUM FULL execution duration and the number of concurrent write operations. Long transactions may block online VACUUM FULL. You are advised not to perform online VACUUM FULL when long transactions exist.
- DQL and DML operations will be blocked after online VACUUM FULL is executed.
- During online VACUUM FULL execution, do not execute DDL statements concurrently with other DDL statements. Otherwise, deadlocks or errors may occur. In this case, reconnect to the client and try again.
- A schema named **online$$ddl$$[hash value]** is generated during online VACUUM FULL execution.
  - By default, the owner of the schema is the initial user. You are advised not to perform the operations on the schema during online VACUUM FULL execution. Otherwise, the online VACUUM FULL execution may be terminated and an unknown error may occur. You are advised not to query tables in this schema. By default, this schema is not exported when gs_dump is used for data export.
  - You cannot create a schema whose prefix is **online$$**. Otherwise, an error notice is displayed. If schemas with the same name conflict with each other, online VACUUM FULL execution does not take effect. By default, VACUUM FULL is executed offline, and a message is displayed indicating that the VACUUM FULL statement cannot be executed online due to the schema name conflict.
- If a GSI exists in the object table, the ONLINE keyword does not take effect. By default, VACUUM FULL is executed offline, and a message is displayed indicating that VACUUM FULL cannot be executed online.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- Avoid performing online VACUUM FULL operations and scaling concurrently. Otherwise, online VACUUM FULL operations or the scaling may fail.
- Except the VACUUM ANALYZE statement, other VACUUM operations do not report the **relpages**/**reltuples** information of the main table of a partitioned table in the statistics if the original behavior remains unchanged.
- In the **reloptions** column of the PG_PARTITION system catalog, **wait_clean_gpi** specifies whether to wait for the global partitioned index to be cleared. If a tuple whose **wait_clean_gpi** is **y** exists, the tuple cannot be directly cleared and can be cleared only after the global partitioned index is cleared.

Syntax

- Recycle space and update statistics. The keyword order does not matter.

```
VACUUM [ ( { FULL | FREEZE | VERBOSE | { ANALYZE | ANALYSE } } [, ... ] ) ]
    [ table_name [ (column_name [, ...] ) ] [ PARTITION ( partition_name ) | SUBPARTITION
( subpartition_name ) ] ]
    [ OFFLINE | [ ONLINE [ WITH ( { online_parameter = value } [, ... ] ) ] ] ];
```

- Recycle space, without updating statistics information.

```
VACUUM [ FULL ] [ FREEZE ] [ VERBOSE ] [ table_name [ PARTITION ( partition_name ) |
SUBPARTITION ( subpartition_name ) ] ]
    [ OFFLINE | [ ONLINE [ WITH ( { online_parameter = value } [, ... ] ) ] ] ];
```

- Recycle space and update statistics. The keywords need to be in order.

```
VACUUM [ FULL ] [ FREEZE ] [ VERBOSE ] { ANALYZE | ANALYSE } [ VERBOSE ]
    [ table_name [ ( column_name [, ...] ) ] ] [ PARTITION ( partition_name ) ]
    [ OFFLINE | [ ONLINE [ WITH ( { online_parameter = value } [, ... ] ) ] ] ];
```

- Recycle the space of a specified bucket and update the **bucketxid** column in the pg_hashbucket system catalog. Statistics are not updated. It can be called by administrators only during scale-out.

```
VACUUM FREEZE BUCKETS (bucketid [, ...]);
```

Parameters

- **FULL**

  Selects "FULL" vacuum, which can recycle more space, but takes much longer and exclusively locks the table.

  NOTE

  Using FULL will cause statistics information missing. To collect statistics information, add the keyword ANALYZE to the VACUUM FULL statement.

- **FREEZE**

  Specifying FREEZE is equivalent to running **VACUUM** with the **vacuum_freeze_min_age** parameter set to **0**.

- **VERBOSE**

  Prints a detailed vacuum activity report for each table.

- **ANALYZE | ANALYSE**

  Updates statistics used by the planner to determine the most efficient way to execute a query.

- **table_name**

  Specifies the name (optionally schema-qualified) of a specific table to vacuum.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Value range: name of a specific table to vacuum. The default value indicates all tables in the current database.

- **column_name**

  Specifies the name of the column to be analyzed. This parameter must be used together with ANALYZE.

  Value range: name of a specific column to analyze. The default value indicates all columns.

  NOTE

  The mechanism of the VACUUM ANALYZE statement is to execute VACUUM and ANALYZE in sequence. Therefore, if **column_name** is incorrect, VACUUM may be successfully executed but ANALYZE may fail to be executed. For a partitioned table, ANALYZE may fail to be executed after VACUUM is successfully executed on a partition.

- **partition_name**

  Specifies the partition name of the table to be cleared. The default value indicates all partitions.

- **ONLINE | OFFLINE**

  Executes VACUUM online or offline. This parameter is used to execute VACUUM FULL online and therefore the read and write services are not blocked for a long time during VACUUM FULL.

  The keywords ONLINE and OFFLINE are used.

  – ONLINE: executes online. If the VACUUM FULL statement contains scenarios (such as the FREEZE keyword) that are not supported by the current feature, the statement is executed offline and a NOTICE is displayed, indicating that the ONLINE keyword is ignored.

  – OFFLINE: executes offline.

  Value range: **OFFLINE** or **ONLINE**, which indicates offline execution and online execution respectively. The value is **OFFLINE** by default.

  NOTE

  If VACUUM FULL fails to be executed online due to user instruction termination commands, lock timeout, or database faults, the system automatically clears residual objects. Automatic cleanup may fail due to reasons such as lock timeout. In this case, manual cleanup is required. In the case of severe faults, such as FATAL, PANIC, and database faults, temporary schema objects may remain, affecting the execution of subsequent online VACUUM FULL and online DDL operations. In this case, you can use the **online_ddl_cleanup()** function to manually clear the objects or choose to automatically clear them when the next online VACUUM FULL or online DDL operation is performed. If no residual data exists, you are advised not to use the online_ddl_cleanup() function. Otherwise, online VACUUM FULL may be terminated and an unknown error may occur.

- **online_parameter**

  Specifies the online VACUUM FULL option when the **ONLINE** keyword is specified. This parameter does not take effect if the **ONLINE** keyword is not specified or conditions for online VACUUM FULL execution are not met.

  Value range:

  – **parallel_threads**: controls multi-thread parallel operations to achieve higher performance when resources are sufficient. Value range: an integer ranging from 1 to 32. The default value is **1**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- When a user enables resource control, for example, I/O resource control (for example, **io_limits** > **0** or **io_priority** = **high**/**medium**/**low**), **parallel_threads** ignores resource control under the user or session. In addition, a message is displayed, indicating that the current resource control is invalid and multi-thread acceleration is enabled. The online VACUUM FULL multi-thread execution complies with the resource control of the initial user.
- This parameter can take effect together with the index parallel parameter **parallel_workers**. **parallel_workers** controls the degree of parallelism for index building during VACUUM FULL, and **parallel_threads** controls the degree of parallelism for catchups during VACUUM FULL.

– **max_catchup_times**: controls the maximum number of catchups. This parameter is used to prevent the execution of VACUUM FULL from taking a long time. The value is an integer from 1 to *INT_MAX*, with **50** being the default.

- Online VACUUM FULL execution records the IUD incremental data generated during data reconstruction to a temporary table and reconstructs the incremental data in multiple rounds of catchups. To prevent VACUUM FULL catchup failures due to a large amount of concurrent IUD data, you can set this parameter to limit the number of catchups.

– **last_catchup_threshold**: specifies the upper limit of the time for triggering the last catchup. After a catchup round is complete, if the duration of this round is less than the threshold, the last round of catchup and switchover is triggered. Value range: [1000,1200000] (unit: ms). The default value is **5000**.

– **online_ddl_lockwait_timeout**: specifies the lock wait timeout interval for online DDL operations. If the thread waiting for the lock fails to obtain the lock within the specified time, a lock timeout error is reported. When the **CANCEL** mode is used to obtain the lock, the actual timeout interval is twice the value of this parameter. Value range: [1,1200000] (unit: ms). The default value is **10000**.

– **lockwait_interval**: indicates the lock wait increment, that is, the retry interval after the lock wait times out. If the lock wait times out in the current round, the system waits for the period specified by this parameter and then attempts to obtain the lock in the next round. Value range: [0,300] (unit: seconds). The default value is **5**.

– **trylock_threshold**: indicates the maximum number of lock wait attempts. It must be used together with **enable_cancel**. If the lock cannot be obtained due to lock wait timeout after the maximum number of attempts is reached, the **CANCEL** mode will be used for the next attempt. If **enable_cancel** is not enabled, the lock fails to be obtained and an error is reported after the maximum number of attempts is reached. Value range: [1,*INT_MAX*] or **-1** (indicating that there is no upper limit). The default value is **-1**.

– **enable_cancel**: specifies whether services can be canceled. That is, when the number of lock attempts reaches the upper limit or the level-8 lock of the user table is obtained during the table switching transaction, user

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

services are quickly terminated to ensure that the online DDL operation can successfully obtain the lock. The value can be **false** or **true**. The default value is **false**.

Examples

- VACUUM

```
-- Create the table tbl_test and insert data into the tables.
gaussdb=# CREATE TABLE tbl_test(c1 int);
gaussdb=# INSERT INTO tbl_test VALUES (1);

-- View the data and the CTID of the data.
gaussdb=# SELECT ctid,* FROM tbl_test;
 ctid  | c1
-------+----
 (0,1) |  1
(1 row)

-- Delete the data record.
gaussdb=# DELETE FROM tbl_test;

-- Insert a data record again. It is found that a new ctid is used.
gaussdb=# INSERT INTO tbl_test VALUES (2);
gaussdb=# SELECT ctid,* FROM tbl_test;
 ctid  | c1
-------+----
 (0,2) |  2
(1 row)

-- After the VACUUM statement is executed, the old space is reused when data is inserted.
gaussdb=# VACUUM ANALYZE tbl_test;
gaussdb=# INSERT INTO tbl_test VALUES (3);
gaussdb=# SELECT ctid,* FROM tbl_test;
 ctid  | c1
-------+----
 (0,1) |  3
 (0,2) |  2
(2 rows)

-- Drop the table.
gaussdb=# DROP TABLE tbl_test;
```

- VACUUM FULL

```
-- Create a table.
gaussdb=# CREATE TABLE tbl_test2(c1 int);

-- Insert 100,000 data records and check the table size.
gaussdb=# INSERT INTO tbl_test2 VALUES (generate_series(1,100000));
gaussdb=# SELECT 'tbl_test2' AS tablename, pg_size_pretty(pg_relation_size('tbl_test2')) AS size;
 tablename |  size
-----------+---------
 tbl_test2 | 3048 kB
(1 row)

-- Delete data and check the table size.
gaussdb=# DELETE FROM tbl_test2;
gaussdb=# SELECT 'tbl_test2' AS tablename, pg_size_pretty(pg_relation_size('tbl_test2')) AS size;
 tablename |  size
-----------+---------
 tbl_test2 | 3048 kB
(1 row)

-- Run the SELECT statement to obtain the ID of the current transaction.
gaussdb=# SELECT TXID_CURRENT();
txid_current
-------------
       55196
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
-- Use VACUUM FULL to recycle space, update statistics, and check the table size.
gaussdb=# VACUUM FULL ANALYZE tbl_test2;
gaussdb=# SELECT 'tbl_test2' AS tablename, pg_size_pretty(pg_relation_size('tbl_test2')) AS size;
 tablename |  size
-----------+---------
 tbl_test2 | 0 bytes
(1 row)

-- Use online VACUUM FULL to recycle space and update statistics.
gaussdb=# VACUUM FULL ANALYZE tbl_test2 ONLINE;
VACUUM

-- Use online VACUUM FULL to recycle space, update statistics, and set online_parameter.
gaussdb=# VACUUM FULL ANALYZE tbl_test2 ONLINE with(parallel_threads=10,
max_catchup_times=20, last_catchup_threshold=3000, online_ddl_lockwait_timeout=10,
lockwait_interval=10, trylock_threshold=1, enable_cancel=true);
VACUUM

-- Drop.
gaussdb=# DROP TABLE tbl_test2;
```

Suggestions

- vacuum
  - VACUUM cannot be executed inside a transaction block.
  - It is recommended that production databases be vacuumed frequently (at least nightly) to ensure that dead rows are removed. It is strongly recommended that you perform VACUUM ANALYZE on corresponding tables after adding or deleting a large number of records.
  - FULL is recommended only in special scenarios. For example, you wish to physically narrow the table to decrease the occupied disk space after deleting most rows of a table.

1.13.22.2 VALUES

Description

Computes a row or a set of rows based on given values. It is most commonly used to generate a constant table within a large statement.

Precautions

- VALUES lists with large numbers of rows should be avoided, as you might encounter out-of-memory failures or poor performance. VALUES appearing within INSERT is a special case because the desired column types are known from the INSERT's target table, and need not be inferred by scanning the VALUES list. In this case, a large number of result rows can be processed.
- If more than one row is specified, all the rows must have the same number of elements.
- When the IN expression is used for multi-column query, IN LIST and IN VALUES LIST have similar functions but different internal processing mechanisms. To ensure query performance and data accuracy, pay special attention to the following key differences during replacement:
  - Logical structure difference: IN LIST parses multiple columns of conditions into a combination of multiple OR conditions. For example, (a, b) IN ((1, 2), (2, 3)) is converted into (a = 1 AND b = 2) OR (a = 2 AND b = 3).

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

When the list after IN is too long, the generated OR condition chain is extremely long, the query optimizer needs to traverse the entire condition chain, which may cause the query performance to deteriorate significantly.

- Query optimization mechanism: IN VALUES LIST considers the VALUES clause as a derived table, parses the IN expression to an ANY subquery, and converts the IN expression to a JOIN operation in the query rewriting phase. This mechanism effectively avoids the performance overhead of processing long OR condition chains.
- Difference in type processing: IN LIST performs type check and implicit conversion on each group of data separately, while IN VALUES LIST deduces the common data type for each column in the VALUES clause, and then performs type check and conversion. This unified type processing method is stricter, requiring that the data types of the same column in the VALUES clause be consistent to ensure the accuracy of the query result.

Syntax

```
VALUES {( expression [, ...] )} [, ...]
    [ ORDER BY { sort_expression [ ASC | DESC | USING operator ] } [, ...] ]
    [ LIMIT { count | ALL } ]
    [ OFFSET start [ ROW | ROWS ] ]
    [ FETCH { FIRST | NEXT } [ count ] { ROW | ROWS } ONLY ];
```

Parameters

- **expression**

  Specifies a constant or expression to compute and insert at the indicated place in the resulting table or set of rows.

  In a **VALUES** list appearing at the top level of an **INSERT**, an expression can be replaced by **DEFAULT** to indicate that the destination column's default value should be inserted. **DEFAULT** cannot be used when **VALUES** appears in other contexts.

- **sort_expression**

  Specifies an expression or integer constant indicating how to sort the result rows.

- **ASC**

  Specifies an ascending sort order.

- **DESC**

  Specifies a descending sort order.

- **operator**

  Specifies a sorting operator.

- **count**

  Specifies the maximum number of rows to return.

- **OFFSET start [ROW | ROWS]**

  Specifies the maximum number of returned rows, whereas **start** specifies the number of rows to skip before starting to return rows.

- **FETCH { FIRST | NEXT } [count] { ROW | ROWS } ONLY**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

The **FETCH** clause restricts the total number of rows starting from the first row of the return query result, and the default value of **count** is **1**.

Examples

```
-- Create a table.
gaussdb=# CREATE TABLE test_t2(col1 INT,col2 VARCHAR);
gaussdb=# CREATE TABLE test_t3(col1 INT,col2 VARCHAR);

-- Insert multiple data records.
gaussdb=# INSERT INTO test_t2 (col1, col2) VALUES (10,'AA'),(20,'BB'),(30,'CC');

-- Perform a pagination query and return to the first page. Display one row of data on each page.
gaussdb=# SELECT * FROM test_t2 ORDER BY col1 ASC LIMIT 1 OFFSET 0;
col1 | col2
------+------
   10 | AA
(1 row)

-- Insert data in test_t2 into test_t3.
gaussdb=# INSERT INTO test_t3 SELECT * FROM test_t2;

-- Perform a query using FETCH and return to the first page. Display one row of data on each page.
gaussdb=# SELECT * FROM test_t3 ORDER BY col1 ASC OFFSET 0 FETCH FIRST 1 ROWS ONLY;
 col1 | col2
------+------
   10 | AA
(1 row)

-- Delete tables test_t2 and test_t3.
gaussdb=# DROP TABLE test_t2;
gaussdb=# DROP TABLE test_t3;
```

1.14 Appendix

1.14.1 Extended Functions

The following table lists the extended functions supported by GaussDB and they are for reference only.

Type	Name	Description
Trigger function	pg_get_triggerdef(trigger_oid)	Gets **CREATE** [**CONSTRAINT**] **TRIGGER** command for triggers.
	pg_get_triggerdef(trigger_oid, pretty_bool)	Gets **CREATE** [**CONSTRAINT**] **TRIGGER** command for triggers.

1.14.2 Dollar-Quoted String Constants

If a string sequence contains a single quotation mark ('), double the single quotation mark (') to two single quotation marks (''). Otherwise, the SQL statement may fail to be executed.

If a string contains many single quotation marks (') or backslashes (\), the string may be difficult to understand and error-prone because all the single quotation marks (') are doubled.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

To make the query more readable in such situations, dollar quoting is provided to write string constants. A dollar-quoted string constant consists of a dollar sign ($), a "tag" of zero or more characters, another dollar sign, an arbitrary sequence of characters that make up the string content, a dollar sign, another tag the same as the previous one, and a dollar sign.

```
gaussdb=# SELECT $$it's an example$$;
   ?column?
-----------------
 it's an example
(1 row)
```

2 Stored Procedures

2.1 Overview

In GaussDB, business rules and logics are saved as stored procedures.

A stored procedure is a combination of SQL, PL/SQL, and Java statements. With stored procedures, the code for executing business rules can be migrated from the application layer to the database layer, thereby reusing the code. That is, the code, once stored, can be called by multiple programs.

For details about how to create and call a stored procedure, see **CREATE PROCEDURE**.

The application methods for PL/SQL functions mentioned in "User-defined Functions > PL/SQL Functions" in *Developer Guide* are the same as those for stored procedures. Unless otherwise specified, the following sections apply to stored procedures and PL/SQL functions.

2.2 Data Types

A data type refers to a value set and an operation set defined on the value set. GaussDB consists of tables, each of which is defined by its own columns. Each column corresponds to a data type. GaussDB provides corresponding functions to perform operations on data based on data types. For example, GaussDB can perform operations such as addition, subtraction, multiplication, and division on numeric data.

XML data can be used as input parameters, output parameters, user-defined variables, and return values of stored procedures. Stored procedures in autonomous transactions are supported.

2.3 Data Type Conversion

In the database system, some data types support implicit type conversion (such as assignment and function call parameters), while some data types (such as INT and composite types) do not support implicit type conversion. You can use the type conversion function provided by GaussDB to forcibly convert the data type.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 2-1 lists common implicit data type conversions in GaussDB.

NOTICE

The valid value range of **DATE** supported by GaussDB is from 4713 B.C. to 294276 A.D.

Table 2-1 Implicit data type conversions

Raw Data Type	Target Data Type	Remarks
CHAR	VARCHAR2	-
CHAR	NUMBER	Raw data must consist of digits.
CHAR	DATE	Raw data cannot exceed the valid date range.
CHAR	RAW	-

2.4 Arrays, Collections, and Records

2.4.1 Arrays

2.4.1.1 Use of Array Types

Before the use of arrays, an array type needs to be defined:

Syntax

Define an array type immediately after the AS keyword in a stored procedure. The definition method is as follows:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
TYPE array_type IS VARRAY(size) OF data_type;
```

Figure 2-1 shows the syntax diagram.

Figure 2-1 Syntax for defining an array type

In the preceding information:

- **array_type**: name of the array type to be defined.
- **size**: maximum number of members in the array type to be defined. The value is a positive integer.
- **data_type**: type of members in the array type to be created.

Precautions

- GaussDB supports access to array elements using index syntax (enclosed by parentheses) and provides various dedicated functions (such as EXTEND, COUNT, FIRST, LAST, PRIOR, EXISTS, TRIM, NEXT, and DELETE) for flexible array operations and management.
- In GaussDB, an array is auto-incremental. If out-of-bounds access occurs, a **NULL** value will be returned, and no error message will be reported.
- The scope of an array type defined in a stored procedure is only limited to this stored procedure.
- **size** is used only for syntax compatibility and has no actual meaning.
- **data_type** can also be the record type defined in a stored procedure (anonymous blocks are not supported) or collection type, but cannot be the array or cursor type defined in a stored procedure.
- When **data_type** is defined as a collection, multi-dimensional arrays are not supported.
- Constructors of the array type can be used only in ORA-compatible mode.
- A constructor of the array type cannot be used as the default value of a function or stored procedure parameter.
- If the elements of an array are of the collection type and **data_type** of the array is set to **VARCHAR** or **NUMERIC** that can define the length and precision, you need to enable the **tableof_elem_constraints** option for GUC parameter **behavior_compat_options** to verify the element length of the array or convert the element to the corresponding precision.
- After **enable_recordtype_check_strict** is set to **on**, if the elements are of the record type and a column of the record type has the NOT NULL or DEFAULT attribute, an error will be reported during stored procedure or package compilation.
- If the stored procedure contains DML statements (SELECT, UPDATE, INSERT, or DELETE), DML statements can access array elements only by using brackets, so as to differentiate it from a function expression.
- The NOT NULL syntax is not supported.
- Elements of varray variables cannot be accessed by DML statements.
- Custom array types cannot be pushed down. In pushdown scenarios, variables are used to carry array elements.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- When you access an array member using an index, the parser preferentially interprets the array variable as a table column name. If the table column name is ambiguous, for example, two tables have columns with the same name, an error will occur.

Examples

```
-- Perform array operations in a stored procedure.
gaussdb=# CREATE OR REPLACE PROCEDURE array_proc AS
DECLARE
    TYPE ARRAY_INTEGER IS VARRAY(1024) OF INTEGER;-- Define an array type.
    ARRINT ARRAY_INTEGER: = ARRAY_INTEGER(); -- Declare the variable of the array type.
BEGIN
    ARRINT.EXTEND(10);
    FOR I IN 1..10 LOOP
        ARRINT(I) := I;
    END LOOP;
    DBE_OUTPUT.PRINT_LINE(ARRINT.COUNT);
    DBE_OUTPUT.PRINT_LINE(ARRINT(1));
    DBE_OUTPUT.PRINT_LINE(ARRINT(10));
    DBE_OUTPUT.PRINT_LINE(ARRINT(ARRINT.FIRST));
    DBE_OUTPUT.PRINT_LINE(ARRINT(ARRINT.LAST));
    DBE_OUTPUT.PRINT_LINE(ARRINT(ARRINT.NEXT(ARRINT.FIRST)));
    DBE_OUTPUT.PRINT_LINE(ARRINT(ARRINT.PRIOR(ARRINT.LAST)));
    ARRINT.TRIM();
    IF ARRINT.EXISTS(10) THEN
       DBE_OUTPUT.PRINT_LINE('Exist 10th element');
    ELSE
       DBE_OUTPUT.PRINT_LINE('Not exist 10th element');
    END IF;
    DBE_OUTPUT.PRINT_LINE(ARRINT.COUNT);
    DBE_OUTPUT.PRINT_LINE(ARRINT(ARRINT.FIRST));
    DBE_OUTPUT.PRINT_LINE(ARRINT(ARRINT.LAST));
    ARRINT.DELETE();
END;
/

-- Call a stored procedure.
gaussdb=# CALL array_proc();
10
1
10
1
10
2
9
Not exist 10th element
9
1

2.4.1.2 Array Functions

NOTE

- The following examples are applicable in ORA-compatible mode. In the function definition, the content in [] is optional. For example, count[()] can be written as count or count().
- Currently, the following errors are not supported: "An uninitialized collection is referenced" (array uninitialized), "Subscript beyond count" (array index out-of-bounds), and "Subscript outside of limit" (array index out-of-limit).
- In an inner expression, functions of the array type cannot be called in nesting mode.
- The extend(count), delete(idx), and trim(n) functions support only a single constant or variable and do not support parameters in other forms, such as function calls and expressions.
- When types are nested and the array type is used as the internal type, the extend, delete, and trim functions without parameters can only be called as extend, delete, and trim, but not as extend(), delete(), or trim().

- extend[(count)]

  Parameter: *count* of the int4 type.

  Return value: none.

  Description: Extends one or *count* elements at the end of a varray variable. The default value is **NULL**.

  Example 1: Extend one element. The default value is **NULL**.

```
gaussdb=# DECLARE
gaussdb-#     TYPE array_integer IS VARRAY(10) OF INTEGER;
gaussdb-#     arrint array_integer := array_integer();
gaussdb-# BEGIN
gaussdb$#     DBE_OUTPUT.PRINT_LINE(arrint.COUNT);
gaussdb$#     arrint.EXTEND;
gaussdb$#     DBE_OUTPUT.PRINT_LINE(arrint.COUNT);
gaussdb$# END;
gaussdb$# /
0
1
ANONYMOUS BLOCK EXECUTE
```

  Example 2: Extend *count* elements. The default value is **NULL**.

```
gaussdb=# DECLARE
gaussdb-#     TYPE array_integer IS VARRAY(10) OF INTEGER;
gaussdb-#     arrint array_integer := array_integer();
gaussdb-# BEGIN
gaussdb$#     DBE_OUTPUT.PRINT_LINE(arrint.COUNT);
gaussdb$#     arrint.EXTEND(3);
gaussdb$#     DBE_OUTPUT.PRINT_LINE(arrint.COUNT);
gaussdb$# END;
gaussdb$# /
0
3
ANONYMOUS BLOCK EXECUTE
```

- extend(count, idx)

  Parameters: *idx* and *count* are of the INT4 type.

  Return value: none.

  Description: Extends *count* elements at the end of a varray variable, with the values of the extended elements equal to the value of the element at the *idx* position.

  Example: Extend *count* elements at the *idx* position.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gaussdb=# SET a_format_version='10c';
SET
gaussdb=# SET a_format_dev_version='s1';
SET
gaussdb=# DECLARE
gaussdb-#     TYPE array_integer IS VARRAY(10) OF INTEGER;
gaussdb-#     arrint array_integer := array_integer(1,2);
gaussdb-# BEGIN
gaussdb$#     arrint.EXTEND(2, 1);
gaussdb$#     DBE_OUTPUT.PRINT_LINE(arrint.COUNT);
gaussdb$#     FOR i IN 1..arrint.COUNT LOOP
gaussdb$#         DBE_OUTPUT.PRINT_LINE(arrint(i));
gaussdb$#     END LOOP;
gaussdb$# END;
gaussdb$# /
4
1
2
1
1
ANONYMOUS BLOCK EXECUTE
```

- count[()]

  Parameter: none.

  Return value: INT4 type.

  Description: Returns the number of elements in an array.

  Example: View the number of initialized array elements.

```
gaussdb=# DECLARE
gaussdb-#     TYPE array_integer IS VARRAY(10) OF INTEGER;
gaussdb-#     arrint array_integer;
gaussdb-#     len INT;
gaussdb-# BEGIN
gaussdb$#     arrint := array_integer(1, 2, 3);
gaussdb$#     len := arrint.COUNT();
gaussdb$#     DBE_OUTPUT.PRINT_LINE(len);
gaussdb$# END;
gaussdb$# /
3
ANONYMOUS BLOCK EXECUTE
```

- trim[(n)]

  Parameter: *n* is of the INT4 type.

  Return value: none.

  Description: Deletes an element at the end of the array if there is no parameter. Alternatively, deletes a specified number of elements at the end of the array if the input parameter *n* is specified.

  Example: Delete *n* elements from an array.

```
gaussdb=# DECLARE
gaussdb-#     TYPE array_integer IS VARRAY(10) OF INTEGER;
gaussdb-#     arrint array_integer := array_integer(1,2,3);
gaussdb-# BEGIN
gaussdb$#     DBE_OUTPUT.PRINT_LINE(arrint.COUNT);
gaussdb$#     arrint.TRIM(1);
gaussdb$#     DBE_OUTPUT.PRINT_LINE(arrint.COUNT);
gaussdb$# END;
gaussdb$# /
3

gaussdb$#     DBE_OUTPUT.PRINT_LINE(arrint.COUNT);
gaussdb$# END;
gaussdb$# /
3
0
ANONYMOUS BLOCK EXECUTE
```

- delete[()]

  Parameter: none.

  Return value: No value is returned.

  Description: Clears elements in an array.

  Example: Clear elements in an array.

```
gaussdb=# DECLARE
gaussdb-#     TYPE array_integer IS VARRAY(10) OF INTEGER;
gaussdb-#     arrint array_integer := array_integer(1,2,3);
gaussdb-# BEGIN
gaussdb$#     DBE_OUTPUT.PRINT_LINE(arrint.COUNT);
gaussdb$#     arrint.DELETE();
gaussdb$#     DBE_OUTPUT.PRINT_LINE(arrint.COUNT);
gaussdb$# END;
gaussdb$# /
3
0
ANONYMOUS BLOCK EXECUTE. All array elements are NULL.
-- The array is not initialized.

gaussdb-# BEGIN
gaussdb$#     arrint.DELETE();
gaussdb$# END;
gaussdb$# /
ANONYMOUS BLOCK EXECUTE
```

- delete(idx)

  Parameter: INT4 type.

  Return value: none.

  Description: Deletes the element with the specified index *idx* from an array if the specified index *idx* is within the array range.

  Example 1: The given index *idx* is within the array range.

```
gaussdb=# DECLARE
gaussdb-#     TYPE array_integer IS VARRAY(10) OF INTEGER;
gaussdb-#     arrint array_integer := array_integer(1, 2, 3);
gaussdb-# BEGIN
gaussdb$#     DBE_OUTPUT.PRINT_LINE(arrint.COUNT);
gaussdb$#     arrint.DELETE(2);
gaussdb$#     DBE_OUTPUT.PRINT_LINE(arrint.COUNT);
gaussdb$#     FOR i IN 1..arrint.COUNT LOOP

- first[()]

  Parameter: none.

  Return value: INT4 type.

  Description: Returns the index of the first element in an array. If there is no first element, **NULL** is returned.

  Example:

```
gaussdb=# DECLARE
gaussdb-#     TYPE varr IS VARRAY(10) OF VARCHAR(3);
gaussdb-#     v varr := varr('asd','zxc');
gaussdb-# BEGIN
gaussdb$#     RAISE INFO 'first is %',v.FIRST();
gaussdb$# END;
gaussdb$# /
INFO:  first is 1
ANONYMOUS BLOCK EXECUTE
-- If the array is not initialized, NULL is returned.

gaussdb$#     RAISE INFO 'first is %',v.FIRST;
gaussdb$# END;
gaussdb$# /
INFO:  first is <NULL>
ANONYMOUS BLOCK EXECUTE
```

- last[()]

  Parameter: none.

  Return value: INT4 type.

  Description: Returns the index of the last element in an array. If there is no last element, **NULL** is returned.

  Example:

```
gaussdb=# DECLARE
gaussdb-#     TYPE varr IS VARRAY(10) OF VARCHAR(3);
gaussdb-#     v varr := varr('asd','zxc');
gaussdb-# BEGIN
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gaussdb$#     RAISE INFO 'last is %',v.LAST();
gaussdb$# END;
gaussdb$# /

gaussdb-# BEGIN
gaussdb$#     RAISE INFO 'last is %',v.LAST;
gaussdb$# END;
gaussdb$# /
INFO:  last is <NULL>
ANONYMOUS BLOCK EXECUTE
```

- prior(idx)

  Parameter: INT4 type.

  Return value: INT4 type.

  Description: Returns the index of the element before the specified index in an array. If the index of the element cannot be found, **NULL** is returned.

  Example:

```
gaussdb=# DECLARE
gaussdb-#     TYPE varr IS VARRAY(10) OF VARCHAR(3);
gaussdb-#     v varr := varr('asd','zxc');
gaussdb-# BEGIN
gaussdb$#     RAISE INFO 'prior is %',v.PRIOR(2);
gaussdb$# END;
gaussdb$# /
INFO:  prior is 1
ANONYMOUS BLOCK EXECUTE
-- If the array is not initialized, NULL is returned.
gaussdb=# DECLARE
gaussdb-#     TYPE varr IS VARRAY(10) OF VARCHAR(3);
gaussdb-#     v varr;
gaussdb-# BEGIN
gaussdb$#     RAISE INFO 'prior is %',v.PRIOR(2);
gaussdb$# END;
gaussdb$# /
INFO:  prior is <NULL>
ANONYMOUS BLOCK EXECUTE
-- The index is out of range and is greater than the array range.
gaussdb=# DECLARE
gaussdb-#     TYPE varr IS VARRAY(10) OF VARCHAR(3);
gaussdb-#     v varr := varr('asd','zxc','qwe');
gaussdb-# BEGIN
gaussdb$#     RAISE INFO 'prior is %',v.PRIOR(10);
gaussdb$# END;
gaussdb$# /
INFO:  prior is 3
ANONYMOUS BLOCK EXECUTE
```

- next(idx)

  Parameter: int4 type.

  Return value: INT4 type.

  Description: Returns the index of the element following the specified index in an array. If the index of an element cannot be found, **NULL** is returned.

  Example:

```
gaussdb=# DECLARE
gaussdb-#     TYPE varr IS VARRAY(10) OF VARCHAR(3);
gaussdb-#     v varr := varr('asd','zxc');
gaussdb-# BEGIN
gaussdb$#     RAISE INFO 'next is %',v.NEXT(1);
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gaussdb$# END;
gaussdb$# /
INFO:  next is 2
ANONYMOUS BLOCK EXECUTE
-- If the array is not initialized, NULL is returned.
gaussdb=# DECLARE
gaussdb-#     TYPE varr IS VARRAY(10) OF VARCHAR(3);
gaussdb-#     v varr;
gaussdb-# BEGIN
gaussdb$#     RAISE INFO 'next  is %',v.NEXT(1);
gaussdb$# END;
gaussdb$# /
INFO:  next  is <NULL>
ANONYMOUS BLOCK EXECUTE
-- The index is out of range and is greater than the array range.
gaussdb=# DECLARE
gaussdb-#     TYPE varr IS VARRAY(10) OF VARCHAR(3);
gaussdb-#     v varr := varr('asd','zxc','qwe');
gaussdb-# BEGIN
gaussdb$#     RAISE INFO 'next  is %',v.NEXT(10);
gaussdb$# END;
gaussdb$# /
INFO:  next  is <NULL>
ANONYMOUS BLOCK EXECUTE
```

- exists(idx)

  Parameter: INT4 type.

  Return value: **TRUE** or **FALSE**, of the Boolean type.

  Function: Checks whether an element exists in a specified position.

  Example:

```
gaussdb=# DECLARE
gaussdb-#     TYPE varr IS VARRAY(10) OF VARCHAR(3);
gaussdb-#     v varr := varr('asd','zxc');
gaussdb-#     flag BOOL;
gaussdb-# BEGIN
gaussdb$#     flag := v.EXISTS(1);
gaussdb$#     RAISE INFO '%',flag;
gaussdb$#     flag := v.EXISTS(3);
gaussdb$#     RAISE INFO '%',flag;
gaussdb$#     flag := v.EXISTS(7);
gaussdb$#     RAISE INFO '%',flag;
gaussdb$# END;
gaussdb$# /
INFO:  t

2.4.2 Collections

2.4.2.1 Use of Collection Types

Before the use of collections, a collection type must be defined.

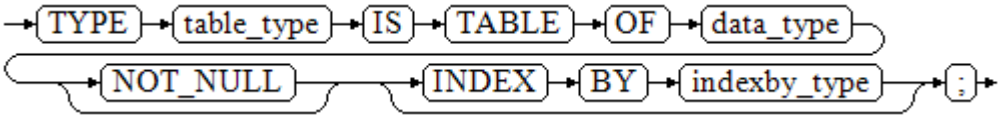
Syntax

Define a collection type immediately after the AS keyword in a stored procedure. The definition method is as follows:

```
TYPE table_type IS TABLE OF data_type [ [NOT_NULL] [INDEX BY indexby_type]];
```

Figure 2-2 shows the syntax diagram.

Figure 2-2 Syntax for defining a collection type



In the preceding information:

- **table_type**: name of the collection type to be defined.
- **data_type**: type of members in the collection to be created.
- **indexby_type**: type of the index set to be created.

Nest-Table Collection Type

- Type definition

  After a collection type is defined, use **table_type** as the type name to declare the variable.

- Variable declaration and initialization

  You can use a type constructor to initialize the variable during or after declaration. If the variable is not initialized, the value of **var_name** is **NULL**.

  This collection type stores indexes and member values of a specified data type in a variable-length array. You can use the extend function to expand the storage space and use the trim function to release the storage space. For example, if a collection variable *x* has 10 storage units and the member type is int, members are stored as shown in Figure 2-3.

  Figure 2-3 Storage model

  
  Members x(2), x(5), and x(8) are invalid, but their storage space is still reserved. You can assign values to them later without re-allocating space.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

When a nest-table collection is used as the return value of a function or an input parameter of an autonomous transaction, invalid members will be deleted from the storage space, and the index sets of all members change accordingly.

- Variable assignment

  After the variable is declared and initialized, you can access collection members through an index set or assign values to members. The index set range is [1,*upper*]. The value of *upper* is the size of the current space. If you attempt to access a deleted member, the error message "no data found" will be returned.

- Variable value

  After the variable is declared and initialized, you can access collection members through an index set to obtain the values of member variables. The index set range is [1,*upper*]. The value of *upper* is the size of the current space. If you attempt to access a deleted member, the error message "no data found" will be returned.

Limitations

- GaussDB supports access to collection elements by using parentheses, and it also supports the extend, count, first, last, prior, next, and delete functions. Collection functions multiset union, intersect, except all, and distinct are supported.
- Collection types can be created only in ORA-compatible mode (**sql_compatibility** is set to **ORA**).
- In GaussDB, a nest-table collection does not automatically increment, and an error is reported when you attempt to access the index set out of the specified range.
- Collections can be defined in schemas, anonymous blocks, stored procedures, packages, and user-defined functions, among which the scopes of the collection types vary.
- **NOT NULL** has no function but only takes effect in the syntax.
- When **data_type** is set to a type that can define the length and precision, such as varchar and numeric, you need to enable the **tableof_elem_constraints** parameter (**behavior_compat_options** must be set to **tableof_elem_constraints**) to validate the length of elements in the collection or convert elements to the corresponding precision.
- If **data_type** is of the array type, the element length validation or precision conversion of the array type is also affected by whether the **tableof_elem_constraints** parameter is enabled.
- The value of the collection type converted from the array type does not support element length validation or precision conversion.
- The value of **data_type** can be a basic data type or a record type, collection type, or array type defined in a stored procedure. The ref cursor type is not supported.
- Variables of a collection type cannot be assigned a value of another collection type, even if their member types are the same. For example, *t1* and *t2* are of different collection types defined by **TYPE** *t1* **IS TABLE OF** *int* and **TYPE** *t2* **IS TABLE OF** *int*, respectively. A value of the collection type defined by **TYPE** *t1* **IS TABLE OF** *int* cannot be assigned to *t2*, and vice versa. (This limitation may

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

not take effect when the variables are of the member types because the value assignment logic of variables is affected by the parent type.)

- Only the equal (=) and non-equal operations (<> or !=) between collections are supported. Other relational and arithmetic operations are not supported.
- Use IS [NOT] NULL to compare a collection type with **NULL**. The result of comparison with **NULL** using the equal operator (=) is inaccurate.
- Variables of the collection type can be used as parameters and return values of functions. In this case, the type of the parameters or return values must have been defined in a schema.
- When a nest-table collection is used as the input parameter of a function, an array with elements of the same type can be specified as the input parameter. Multi-dimensional arrays are not supported, and the array index set must start from 1. (This function is outdated and not recommended.) You can run the **SET behavior_compat_options = 'disable_rewrite_nesttable';** command to disable the function.
- Operations on XML data are not supported.
- When creating a table, do not use the collection type or any type containing a collection as a column in the table.
- Constructors of the collection type do not support floating-point numbers or expressions as indexes.
- For a collection type defined in an anonymous block, after **ROLLBACK** is executed or "EXCEPTION" is thrown in an anonymous block, the collection type cannot be used.
- If the GUC parameter **enable_recordtype_check_strict** is set to **on** and the member is of the record type and a column of the record type has the NOT NULL or DEFAULT attribute, an error will be reported during stored procedure or package compilation.
- DML statements cannot be used to access elements of the collection type if the elements are not defined in schemas.
- User-defined collections cannot be pushed down. In pushdown scenarios, variables are used to carry collection elements.
- When you access a collection member using an index, the parser preferentially interprets the collection variable as a table column name. If the table column name is ambiguous, for example, two tables have columns with the same name, an error will occur.

Index-By Table Collection Type

This collection type stores the index set and corresponding member values in a hash table as key-value pairs. All operations on variables of this type are actually operations on the hash table. Users do not need to expand or release storage space, but only need to assign values or delete members. The operations related to the collection type are described as follows:

1. Type definition

   When defining the index-by table collection type, specify both the member type **data_type** and index set type **indexby_type**. The index set type can only be INTEGER or VARCHAR.

2. Variable declaration and initialization

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

After the index-by table collection type is declared, it can be initialized. There are three initialization scenarios: uninitialized, initialized to null, and initialized to specified index and member values. The effect of uninitialized variables is the same as that of initializing variables to null. If a variable is not initialized or is initialized to null, the variable is not **NULL**. You can assign a value to the variable later. Initializing a variable to specified index set and member values will save the specified index set and member values to the variable as key-value pairs.

3. Variable assignment

   Assignment to variables of the index-by table collection type is classified into member assignment and group assignment. Member assignment can assign a value to a member by specifying the index set. If the member does not exist, the value is assigned after the member is inserted. If the member has a value, the member value is updated. Group assignment will clear the original members in the variable and save the new member values. In the group assignment scenario, **NULL** cannot be assigned to variables. Otherwise, an error is reported.

4. Variable value

   You can specify an index set to obtain the member value of the corresponding index in the variable. If the member cannot be found based on the index set, the error message "no data found" is returned.

Limitations

- Index-by table collection types can be created only in ORA-compatible mode (**sql_compatibility** is set to **ORA**).
- Index-by table collection types can be defined in anonymous blocks, stored procedures, user-defined functions, and packages, among which the scopes of the collection types vary. Index-by table collection types cannot be defined in schemas.
- **NOT NULL** has no function but only takes effect in the syntax.
- When **data_type** is set to a type that can define the length and precision, such as varchar and numeric, you need to enable the **tableof_elem_constraints** parameter (**behavior_compat_options** must be set to **tableof_elem_constraints**) to validate the length of elements in the collection or convert elements to the corresponding precision.
- If **data_type** is of the array type, the element length validation or precision conversion of the array type is also affected by whether the **tableof_elem_constraints** parameter is enabled.
- The value of the collection type converted from the array type does not support element length validation or precision conversion.
- The value of **data_type** can be a basic data type or a record type, collection type, or array type defined in a stored procedure. The ref cursor type is not supported.
- The value of **indexby_type** can only be **INTEGER** or **VARCHAR**.
- When **indexby_type** is set to **VARCHAR** and **tableof_elem_constraints** is enabled, the length of the index value is validated when a value is assigned to an index-by table collection type. The validation behavior is not affected by whether **char_coerce_compat** is enabled. If the index length is greater than the defined length, an error is reported. If the **tableof_elem_constraints** parameter is disabled, the index value length is not validated.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- An uninitialized variable of the index-by table collection type is not **NULL**.
- **NULL** cannot be assigned to a variable of the index-by table collection type. Otherwise, an error is reported.
- **NULL** and single quotation marks ('') cannot be assigned to a variable of the index-by table collection type.
- Variables of the index-by table collection type cannot be assigned values of another index-by table collection type, even if their member type and index set type are the same. For example, **t1** and **t2** are different collection types defined by running **TYPE t1 IS TABLE OF int index by int;** and **TYPE t2 IS TABLE OF int index by int;**. Variables defined by them cannot be assigned values to each other. (This constraint may not take effect when the variables are used as member types because the assignment logic is affected by their parent type.)
- An index-by table collection type does not support relational and arithmetic operations.
- When a variable of the index-by table collection type is assigned by running **SELECT ... bulk collect INTO**, the index set must be of the integer type. The index set type cannot be varchar.
- Variables of the index-by table collection type can be used as the parameters and return values of functions. In this case, the type of the parameters or return values must be a collection type defined in the package.
- When an index-by table collection is used as the input parameter of a function, an array with elements of the same type can be passed as the input parameter. Multi-dimensional arrays are not supported, and the index type cannot be VARCHAR. (This function is outdated and not recommended. You can run the **SET behavior_compat_options = 'disable_rewrite_nesttable';** command to disable the function.)
- Currently, the type constructor supports only the collection type and the maximum number of parameters is the same as that of user-defined function parameters. For the index-by table collection type, the index value can only be a constant when the constructor is used.
- Operations on XML data are not supported.
- When creating a table, do not use the collection type or any type containing a collection as a column in the table.
- Constructors of the collection type do not support floating-point numbers or expressions as indexes.
- For a collection type defined in an anonymous block, after **ROLLBACK** is executed or "EXCEPTION" is thrown in an anonymous block, the collection type cannot be used.
- If the GUC parameter **enable_recordtype_check_strict** is set to **on** and the member is of the record type and a column of the record type has the NOT NULL or DEFAULT attribute, an error is reported during stored procedure or package compilation.
- DML statements cannot be used to access elements of the collection type if the elements are not defined in schemas.
- User-defined collections cannot be pushed down. In pushdown scenarios, variables are used to carry collection elements.
- When you access a collection member using an index, the parser preferentially interprets the collection variable as a table column name. If the

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

table column name is ambiguous, for example, two tables have columns with the same name, an error will occur.

Examples

Example 1: nest-table collection type

```
-- Perform operations on a collection in a stored procedure.
gaussdb=# CREATE OR REPLACE PROCEDURE table_proc AS
DECLARE
    TYPE TABLE_INTEGER IS TABLE OF INTEGER;-- Define a collection type.
    TABLEINT TABLE_INTEGER := TABLE_INTEGER();  -- Declare the variable of the collection type.
BEGIN
    TABLEINT.extend(10);
    FOR I IN 1..10 LOOP
        TABLEINT(I) := I;
    END LOOP;
    DBE_OUTPUT.PRINT_LINE(TABLEINT.COUNT);
    DBE_OUTPUT.PRINT_LINE(TABLEINT(1));
    DBE_OUTPUT.PRINT_LINE(TABLEINT(10));
END;
/
CREATE PROCEDURE
-- Call the stored procedure.
gaussdb=# CALL table_proc();
10
1
10
 table_proc
------------

(1 row)

-- Drop the stored procedure.
gaussdb=# DROP PROCEDURE table_proc;
DROP PROCEDURE
-- Perform operations on a nest-table collection in the stored procedure.
gaussdb=# CREATE OR REPLACE PROCEDURE nest_table_proc AS
DECLARE
    TYPE TABLE_INTEGER IS TABLE OF INTEGER;-- Define a collection type.
    TYPE NEST_TABLE_INTEGER IS TABLE OF TABLE_INTEGER;-- Define a collection type.
    NEST_TABLE_VAR NEST_TABLE_INTEGER := NEST_TABLE_INTEGER(); -- Declare a variable of the nest-table collection type.
BEGIN
    NEST_TABLE_VAR.extend(10);
    FOR I IN 1..10 LOOP
        NEST_TABLE_VAR(I) := TABLE_INTEGER();
        NEST_TABLE_VAR(I).extend(10);
        NEST_TABLE_VAR(I)(I) := I;
    END LOOP;
    DBE_OUTPUT.PRINT_LINE(NEST_TABLE_VAR.COUNT);
    DBE_OUTPUT.PRINT_LINE(NEST_TABLE_VAR(1)(1));
    DBE_OUTPUT.PRINT_LINE(NEST_TABLE_VAR(10)(10));
END;
/
CREATE PROCEDURE
-- Call the stored procedure.
gaussdb=# CALL nest_table_proc();

```

Example 2: index-by table collection type

```
-- Perform operations on an index-by table collection in a stored procedure.
gaussdb=# CREATE OR REPLACE PROCEDURE index_table_proc AS
DECLARE
    TYPE TABLE_INTEGER IS TABLE OF INTEGER INDEX BY INTEGER; -- Define a collection type.
    TYPE TABLE_VARCHAR IS TABLE OF INTEGER INDEX BY VARCHAR; -- Define a collection type.
    TABLEINT_01 TABLE_INTEGER;                              -- Declare a variable of the collection type, which is
not initialized.
    TABLEINT_02 TABLE_INTEGER := TABLE_INTEGER();           -- Declare a variable of the collection type.
The initial value is null.
    TABLEINT_03 TABLE_INTEGER := TABLE_INTEGER(2=>3,3=>4);   -- Declare a variable of the collection
type and initialize it to the specified value.
    RES INTEGER;
BEGIN
    FOR I IN 1..10 LOOP
        TABLEINT_01(I) := I;     -- Assign values to members.
        TABLEINT_02(I) := I + 1; -- Assign values to members.
    END LOOP;
    TABLEINT_01 := TABLEINT_02;  -- Group assignment
    RES := TABLEINT_03(2);       -- Return values.
    DBE_OUTPUT.PRINT_LINE(RES);
    DBE_OUTPUT.PRINT_LINE(TABLEINT_01(1));
    DBE_OUTPUT.PRINT_LINE(TABLEINT_01(10));
END;
/
CREATE PROCEDURE
-- Call the stored procedure.
gaussdb=# CALL index_table_proc();

2.4.2.2 Collection Functions

Collection Operators

- =

  Parameter: nesttable type.

  Return value: **TRUE** or **FALSE**, of the Boolean type.

  Description: Checks whether two collections are equal.

  Example:

```
gaussdb=# DECLARE
 TYPE nest IS TABLE OF INT
 a nest := nest(1,2);
 b nest := nest(1,2);
 flag BOOL;
 BEGIN
    flag := a = b;
    RAISE INFO '%', flag;
END;
 /
INFO:  t
ANONYMOUS BLOCK EXECUTE
```

- <>

  Parameter: nesttable type.

  Return value: **TRUE** or **FALSE**, of the Boolean type.

  Description: Checks whether two collections are not equal.

  Example:

```
gaussdb=# DECLARE
  TYPE nest IS TABLE OF INT;
  a nest := nest(1,2);
  b nest := nest(1,2);
  flag BOOL;
 BEGIN
   flag := a <> b;
   RAISE INFO '%', flag;
END;
/
INFO:  f
ANONYMOUS BLOCK EXECUTE
```

- IS [NOT] NULL

  Parameter: nesttable type.

  Return value: **TRUE** or **FALSE**, of the Boolean type.

  Description: IS NULL determines whether a collection is NULL, and IS NOT NULL determines whether a collection is not NULL.

  Example:

```
gaussdb=# DECLARE
   TYPE nest IS TABLE OF INT;
   a nest;
   b nest := NULL;
   c nest := nest(1,2);
   flag BOOL;
BEGIN
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
   flag := a IS NULL;
   RAISE INFO '%', flag;
   flag := b IS NULL;
   RAISE INFO '%', flag;
   flag := c IS NULL;
   RAISE INFO '%', flag;
 END;
 /
INFO:  t
INFO:  t
INFO:  f
ANONYMOUS BLOCK EXECUTE

gaussdb=# DECLARE
   TYPE nest IS TABLE OF INT;
   a nest;
   b nest := NULL;
   c nest := nest(1,2);
   flag BOOL;
BEGIN
   flag := a IS NOT NULL;
   RAISE INFO '%', flag;
   flag := b IS NOT NULL;
   RAISE INFO '%', flag;
   flag := c IS NOT NULL;
   RAISE INFO '%', flag;
 END;
 /
INFO:  f
INFO:  f
INFO:  t
ANONYMOUS BLOCK EXECUTE
```

- ^=

  Parameter: nesttable type.

  Return value: **TRUE** or **FALSE**, of the Boolean type.

  Description: Checks whether two collections are not equal.

  Example:

```
gaussdb=# DECLARE
   TYPE nest IS TABLE OF INT;
   a nest := nest(1,2);
   b nest := nest(1,2);
   flag BOOL;
 BEGIN
   flag := a ^= b;
   RAISE INFO '%', flag;
 END;
 /
INFO:  f
ANONYMOUS BLOCK EXECUTE
```

- [NOT] IN

  Parameter: nesttable type.

  Return value: **TRUE** or **FALSE**, of the Boolean type.

  Description: Determines whether a collection is in the collection list.

  Example:

```
gaussdb=# DECLARE
   TYPE tab IS TABLE OF VARCHAR(10);
   tmp1 tab := tab('a', 'b');
   tmp2 tab := tab('a', 'b');
   flag BOOL;
 BEGIN
   flag := tmp2 in (tmp1);
   RAISE INFO '%', flag;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
 END;
 /
INFO:  t
ANONYMOUS BLOCK EXECUTE
```

MULTISET

- MULTISET UNION [ALL | DISTINCT]

  Parameter: nesttable type.

  Return value: nesttable type.

  Description: Union of two collection variables. The default value **ALL** indicates that duplicate elements are not removed, and **DISTINCT** indicates that duplicate elements are removed.

  Example 1: Calculate the union of two collection variables and do not remove duplicate elements. That is, MULTISET UNION ALL.

  ```
  gaussdb=# DECLARE
    TYPE nest IS TABLE OF INT;
    a nest := nest(1,2);
    b nest := nest(2,3);
  BEGIN
    a := a MULTISET UNION ALL b;
    RAISE INFO '%', a;
  end;
  /
  INFO:  {1,2,2,3}
  ANONYMOUS BLOCK EXECUTE
  ```

  Example 2: Calculate the union of two collection variables and remove duplicate elements. That is, MULTISET UNION DISTINCT.

  ```
  gaussdb=# DECLARE
     TYPE nest IS TABLE OF INT;
     a nest := nest(1,2);
     b nest := nest(2,3);
  BEGIN
     a := a MULTISET UNION DISTINCT b;
     RAISE INFO '%', a;
  END;
  /
  INFO:  {1,2,3}
  ANONYMOUS BLOCK EXECUTE
  ```

- MULTISET EXCEPT [ALL | DISTINCT]

  Parameter: nesttable type.

  Return value: nesttable type.

  Description: Difference of two collection variables. Take A MULTISET EXCEPT B as an example. **ALL** indicates that elements that both A and B have in A are removed and returned. The number of elements to be removed is calculated. For a specific element, if A appears *m* times and B appears *n* times (m > n), the number of elements removed from A is *m* minus *n*. If m ≤ n, *m* elements are removed from A. **DISTINCT** indicates that elements that both A and B have in A are removed and returned. The number of elements to be removed is not calculated. If specific elements appear in A and B, all such elements in A are removed. **ALL** is the default value.

  Example 1: Calculate a difference set of two collection variables, remove elements that both A and B have in A, and return the result. The number of elements to be removed is calculated. That is, MULTISET EXCEPT ALL.

  ```
  gaussdb=# DECLARE
    TYPE nest IS TABLE OF INT;
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
  a nest := nest(1,2,2);
  b nest := nest(2,3);
 BEGIN
  a := a MULTISET EXCEPT ALL b;
  RAISE INFO '%', a;
 END;
 /
INFO:  {1,2}
ANONYMOUS BLOCK EXECUTE
```

Example 2: Calculate a difference set of two collection variables, remove elements that both A and B have in A, and return the result. The number of elements to be removed is not calculated. That is, MULTISET EXCEPT DISTINCT.

```
gaussdb=# DECLARE
  TYPE nest IS TABLE OF INT;
  a nest := nest(1,2,2);
  b nest := nest(2,3);
 BEGIN
  a := a MULTISET EXCEPT DISTINCT b;
  RAISE INFO '%', a;
 END;
 /
INFO:  {1}
ANONYMOUS BLOCK EXECUTE
```

- MULTISET INTERSECT [ALL | DISTINCT]

  Parameter: nesttable type.

  Return value: nesttable type.

  Description: Intersection of two collection variables. Take A MULTISET INTERSECT B as an example. **ALL** indicates that all duplicate elements (including elements that repeat for multiple times) are retained. **DISTINCT** indicates that the intersection of distinct values is returned and duplicate elements are removed. **ALL** is the default value.

  Example 1: Calculate the intersection of two collection variables and do not remove duplicate elements. That is, MULTISET INTERSECT ALL.

```
gaussdb=# DECLARE
  TYPE nest IS TABLE OF INT;
  a nest := nest(1,2,2);
  b nest := nest(2,2,3);
 BEGIN
  a := a MULTISET INTERSECT ALL b;
  RAISE INFO '%', a;
 END;
 /
INFO:  {2,2}
ANONYMOUS BLOCK EXECUTE
```

  Example 2: Calculate the intersection of two collection variables and remove duplicate elements. That is, MULTISET INTERSECT DISTINCT.

```
gaussdb=# DECLARE
  TYPE nest IS TABLE OF INT;
  a nest := nest(1,2,2);
  b nest := nest(2,2,3);
 BEGIN
  a := a MULTISET INTERSECT DISTINCT b;
  RAISE INFO '%', a;
 END;
 /
INFO:  {2}
ANONYMOUS BLOCK EXECUTE
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Functions of the Collection Type

NOTE

- In the following function definition description, the content in [] is optional. For example, count[()] can be written as count or count().
- In an inner expression, functions of the collection type cannot be called in nesting mode.
- When types are nested and the collection type is used as the internal type, the extend, delete, and trim functions without parameters can be called extend, delete, and trim, but not extend(), delete(), or trim().

- exists(idx)

  Parameter: *idx* is of the INT4 or VARCHAR type.

  Return value: **TRUE** or **FALSE**, of the Boolean type.

  Description: Checks whether a valid element exists in a specified position.

  Example:

```
gaussdb=# DECLARE
  TYPE nest IS TABLE OF VARCHAR2;
  a nest := nest('happy','?');
  flag BOOL;
 BEGIN
  flag := a.EXISTS(1);
  RAISE INFO '%', flag;
  flag := a.EXISTS(10);
  RAISE INFO '%', flag;
 END;
 /
INFO:  t
INFO:  f
ANONYMOUS BLOCK EXECUTE
gaussdb=# DECLARE
  TYPE nest IS TABLE OF VARCHAR2 INDEX BY VARCHAR2;
  a nest;
  flag BOOL;
 BEGIN
  a('1') := 'Be';
  a('2') := 'happy';
  a('3') := '.';
  flag := a.EXISTS('1');
  RAISE INFO '%', flag;
  flag := a.EXISTS('ddd');
  RAISE INFO '%', flag;
 END;
 /
INFO:  t
INFO:  f
ANONYMOUS BLOCK EXECUTE
```

- extend[(count[, idx])]

  Parameter: *idx* and *count* are of the INT4 type. If no parameter is passed, one element is extended and the value is **NULL**.

  Return value: No value is returned.

  Description: Supports only variables of the nest-table type. One or *count* elements are extended at the end of the nest-table variable. If the element indexed by *idx* exists, *count* elements are copied to the end of the variable.

  Example 1: A nest-table variable extends one element and the extended element value is **NULL**.

```
gaussdb=# DECLARE
  TYPE nest IS TABLE OF INT;
  a nest := nest(1);
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
 BEGIN
   RAISE INFO '%', a;
   a.EXTEND;
   RAISE INFO '%', a;
   a.EXTEND;
   RAISE INFO '%', a;
 END;
 /
INFO:  {1}
INFO:  {1,NULL}
INFO:  {1,NULL,NULL}
ANONYMOUS BLOCK EXECUTE
```

Example 2: A nest-table variable extends *n* elements and the extended element value is **NULL**.

```
gaussdb=# DECLARE
   TYPE nest IS TABLE OF INT;
   a nest := nest(1);
 BEGIN
   RAISE INFO '%', a;
   a.EXTEND(2);
   RAISE INFO '%', a;
 END;
 /
INFO:  {1}
INFO:  {1,NULL,NULL}
ANONYMOUS BLOCK EXECUTE
```

Example 3: A nest-table variable extends *n* elements and the extended element value is the value of the element with the specified index.

```
gaussdb=# DECLARE
   TYPE nest IS TABLE OF INT;
   a nest := nest(9);
 BEGIN
   RAISE INFO '%', a;
   a.EXTEND(2,1);
   RAISE INFO '%', a;
 END;
 /
INFO:  {9}
INFO:  {9,9,9}
ANONYMOUS BLOCK EXECUTE
```

- delete[(idx1[, idx2])]

  Parameter: *idx1* and *idx2* are of the INT4 or VARCHAR2 type.

  Return value: No value is returned.

  Description: If there is no parameter, the variable of the nest-table type deletes all elements of the collection type and the space. If the space is used later, the space needs to be expanded. If there is no parameter, the variable of the index-by table type deletes all elements. If there is one parameter, the element at the specified position is deleted (the space is not deleted). If there are two parameters, all elements in the index range are deleted (the space is not deleted).

  Limitation: For the nest-table collection type, if an element is deleted but it is not removed from the storage space, the space is invalid and can be assigned a value. Note: When a collection is used as the return value of a function or an input parameter of an autonomous transaction, invalid members will be deleted from the storage space, and the index set of all members changes accordingly.

  Example 1: Delete all elements and spaces of the collection type from the variable of the nest-table collection type.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gaussdb=# DECLARE
  TYPE nest IS TABLE OF INT;
  a nest := nest(1,2,3,4,5);
 BEGIN
  RAISE INFO '%', a;
  a.DELETE();
  RAISE INFO '%', a;
 END;
 /
INFO:  {1,2,3,4,5}
INFO:  {}
ANONYMOUS BLOCK EXECUTE
```

Example 2: Delete an element at a specified position from the variable of the nest-table collection type.

```
gaussdb=# DECLARE
  TYPE nest IS TABLE OF INT;
  a nest := nest(1,2,3,4,5);
 BEGIN
  RAISE INFO '%', a;
  a.DELETE(3);
  RAISE INFO '%', a;
  a(3) := 3;
  RAISE INFO '%', a;
 END;
 /
INFO:  {1,2,3,4,5}
INFO:  {1,2,4,5}
INFO:  {1,2,3,4,5}
ANONYMOUS BLOCK EXECUTE
```

Example 3: Delete elements in a specified interval from the variable of the nest-table collection type.

```
gaussdb=# DECLARE
  TYPE nest IS TABLE OF INT;
  a nest := nest(1,2,3,4,5);
 BEGIN
  RAISE INFO '%', a;
  a.DELETE(2,4);
  RAISE INFO '%', a(1);
  RAISE INFO '%', a(5);
  RAISE INFO '%', a;
 END;
 /
INFO:  {1,2,3,4,5}
INFO:  1
INFO:  5
INFO:  {1,5}
ANONYMOUS BLOCK EXECUTE
```

Example 4: Delete all elements and spaces of the collection type from the variable of the index-by table collection type.

```
gaussdb=# DECLARE
  TYPE t1 IS TABLE OF INT INDEX BY VARCHAR;
  v t1 := t1('a' => 1, 'b' => 2, 'c' => 3, 'd' => 4);
 BEGIN
  v.DELETE();
  RAISE INFO '%', v.COUNT();
 END;
 /
INFO:  0
ANONYMOUS BLOCK EXECUTE
```

Example 5: Delete an element at a specified position from the variable of the index-by table collection type.

```
gaussdb=# declare
  type t1 is table of int index by varchar;
  v t1 := t1('a' => 1, 'b' => 2, 'c' => 3, 'd' => 4);
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
 begin
   raise info '%', v('a');
   v.delete('a');
   raise info '%', v('a');
 end;
 /
INFO:  1
ERROR:  no data found
CONTEXT:  PL/pgSQL function inline_code_block line 6 at RAISE
```

Example 6: Delete elements in a specified interval from the variable of the index-by table collection type.

```
gaussdb=# declare
   type t1 is table of int index by varchar;
   v t1 := t1('a' => 1, 'b' => 2, 'c' => 3, 'd' => 4);
 begin
   raise info '%', v('b');
   v.delete('a', 'c');
   raise info '%', v('b');
 end;
 /
INFO:  2
ERROR:  no data found
CONTEXT:  PL/pgSQL function inline_code_block line 6 at RAISE
```

- trim[(n)]

  Parameter: *n* is of the INT4 type.

  Return value: No value is returned.

  Description: Supports only variables of the nest-table type. If no parameter is specified, the last element space is deleted. If the input parameter is valid, the specified number of element spaces are deleted.

  Example:

```
gaussdb=# DECLARE
   TYPE nest IS TABLE OF INT;
   aa nest := nest(11,22,33,44,55);
 BEGIN
   RAISE INFO 'aa:%' ,aa;
   aa.TRIM;  -- No parameter
   RAISE INFO 'aa:%' ,aa;
   aa.TRIM();  -- No parameter
   RAISE INFO 'aa:%' ,aa;
   aa.TRIM(2);  -- Valid parameter
   RAISE INFO 'aa:%' ,aa;
   aa.TRIM(2);  -- The collection element space is less than 2. An error is reported when the parameter
is invalid.
 END;
 /
INFO:  aa:{11,22,33,44,55}
INFO:  aa:{11,22,33,44}
INFO:  aa:{11,22,33}
INFO:  aa:{11}
ERROR:  Subscript beyond count
CONTEXT:  PL/pgSQL function inline_code_block line 11 at assignment
```

- count[()]

  Parameter: none.

  Return value: INT type.

  Description: Returns the number of valid elements in a collection.

  Example 1: Use the count function for the variable of the nest-table collection type.

```
gaussdb=# DECLARE
 TYPE nest IS TABLE OF INT;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
 aa nest:=nest(11,22,33,44,55);
 BEGIN
 RAISE INFO 'count:%' ,aa.COUNT;
 aa.DELETE(3);  -- Delete an element. The element whose index is 3 is invalid.
 RAISE INFO 'count:%' ,aa.COUNT();
 END;
 /
INFO:  count:5
INFO:  count:4
ANONYMOUS BLOCK EXECUTE
```

Example 2: Use the count function for the variable of the index-by table collection type.

```
gaussdb=# DECLARE
 TYPE t1 IS TABLE OF INT INDEX BY INT;
 aa t1;
 BEGIN
 aa(1) := 111;
 aa(2) := 222;
 aa(3) := 333;
 RAISE INFO 'count:%' ,aa.COUNT();
 END;
 /

```

- first[()]

  Parameter: none.

  Return value: INT or VARCHAR type.

  Description: Returns the index of the first valid element in a collection.

  Example 1: Use the first function for the variable of the nest-table collection type.

```
gaussdb=# DECLARE
 TYPE nest IS TABLE OF INT;
 aa nest:=nest(11,22,33,44,55);
 BEGIN
 RAISE INFO 'first:%' ,aa.FIRST();
 aa.DELETE(1);

 RAISE INFO 'first:%' ,aa.FIRST;
 END;
 /
INFO:  first:aaa
ANONYMOUS BLOCK EXECUTE
```

- last[()]

  Parameter: none.

  Return value: INT or VARCHAR type.

  Description: Returns the index of the last valid element in a collection.

  Example 1: Use the last function for the variable of the nest-table collection type.

```
gaussdb=# DECLARE
 TYPE nest IS TABLE OF INT;
 aa nest:=nest(11,22,33,44,55);
 BEGIN
 RAISE INFO 'last:%' ,aa.LAST;
 aa.DELETE(5);

 RAISE INFO 'last:%' ,aa.LAST();
 END;
 /
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
INFO:  last:ccc
ANONYMOUS BLOCK EXECUTE
```

- prior(idx)

  Parameter: *idx* is of the INT or VARCHAR type.

  Return value: INT or VARCHAR type.

  Description: Returns the index of the valid element before the given index in a collection. If the index does not exist, the last element in the collection is returned.

  Example 1: Use the prior function for the variable of the nest-table collection type.

```
gaussdb=# DECLARE
 TYPE nest IS TABLE OF INT;
 aa nest:=nest(11,22,33,44,55);
 BEGIN
 RAISE INFO 'prior:%' ,aa.PRIOR(3);
 END;
 /
INFO:  prior:2
ANONYMOUS BLOCK EXECUTE
```

  Example 2: Use the prior function for the variable of the index-by table collection type.

```
gaussdb=# DECLARE
 TYPE t1 IS TABLE OF INT INDEX BY VARCHAR;
 aa t1;
 BEGIN
 aa('ccc') := 111;
 aa('bbb') := 222;
 aa('aaa') := 333;
 RAISE INFO 'prior:%' ,aa.PRIOR('bbb');
 RAISE INFO 'prior:%' ,aa.PRIOR('ddd');
 END;
 /
INFO:  prior:aaa
INFO:  prior:ccc
ANONYMOUS BLOCK EXECUTE
```

- next(idx)

  Parameter: *idx* is of the INT or VARCHAR type. If the index does not exist, the first element in the collection is returned.

  Return value: INT or VARCHAR type.

  Description: Returns the index of a valid element following the given index in a collection.

  Example 1: Use the next function for the variable of the nest-table collection type.

```
gaussdb=# DECLARE
 TYPE nest IS TABLE OF INT;
 aa nest:=nest(11,22,33,44,55);
 BEGIN
 RAISE INFO 'next:%' ,aa.NEXT(3);
 END;
 /
INFO:  next:4
ANONYMOUS BLOCK EXECUTE
```

  Example 2: Use the next function for the variable of the index-by table collection type.

```
gaussdb=# DECLARE
 TYPE t1 IS TABLE OF INT INDEX BY INT;
 aa t1;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
BEGIN
 aa(3) := 111;
 aa(2) := 222;
 aa(1) := 333;

 RAISE INFO 'next:%' ,aa.NEXT(-999);
 END;
 /
INFO:  next:3
INFO:  next:1
ANONYMOUS BLOCK EXECUTE
```

- limit

  Parameter: none.

  Return value: **NULL**.

  Description: Applies only to variables of the nest-table type. The return value is **NULL**.

  Example:

```
gaussdb=# DECLARE
 TYPE nest IS TABLE OF INT;
 aa nest:=nest(11,22,33,44,55);
 BEGIN
 RAISE INFO 'limit:%' ,aa.LIMIT;
 END;
 /
INFO:  limit:<NULL>
ANONYMOUS BLOCK EXECUTE
```

Collection-related Functions

- unnest_table (anynesttable) or unnest (anynesttable)

  Parameter: any nest-table collection type.

  Description: Returns the result set of all valid elements in a given nest-table. Multiple rows of data are returned.

  Return type: setof anyelement.

  Example:

```
If the element type of the collection is record and any element is NULL, the element is not returned. Instead, a non-null record value is returned. All columns of the record are NULL.
gaussdb=# CREATE OR REPLACE p1()
gaussdb-# AS
gaussdb$#     TYPE t1 IS TABLE OF INT;

2.4.3 Records

Record Variables

Define a record type and use this type to declare a variable, which is a record variable.

Syntax

The syntax for defining the record type is as follows:

```
TYPE type_name IS_RECORD (field_declaration [,...] );
```

Figure 2-4 shows the syntax diagram.

Figure 2-4 Syntax for defining a record type

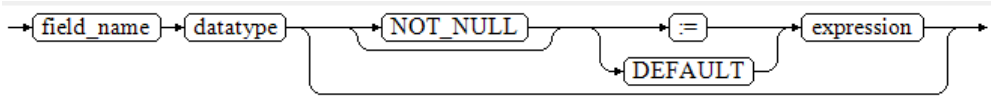
 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

field_declaration is as follows:

```
field_name datatype [ [NOT_NULL] { := | DEFAULT } expression]
```

Figure 2-5 shows the syntax diagram of field_declaration.

Figure 2-5 field_declaration



The syntax is described as follows:

- *type_name*: record type.
- *field_name*: member variables of this type.
- *datatype*: data type of the member variables.
- *expression*: expression for setting a default value.

Limitations

In GaussDB:

- When assigning values to record variables, you can:
  - Declare a record type and define member variables of this type when you declare a function or stored procedure.
  - Assign the value of a record variable to another record variable.
  - Use SELECT INTO or FETCH to assign values to a record variable.
  - Assign the **NULL** value to a record variable.
- The constructor of the record type can use => to assign values. The limitations are as follows:
  - The constructor of the record type can assign values using => only when an ORA-compatible database is used (**sql_compatibility** is set to **'ORA'**).
  - The record type can be defined in a package.
  - The constructor of the record type uses => to assign values only when => is consecutively used to assign values to input parameters, for example, **record_name(elename1 => val1, elename2 => val2, elename3 => val3)** or **record_name(val1, elename2 => val2, elename3 => val3)**. Discontinuous use of => is not supported. For example, **record_name(elename1 => val1, elename2 => val2, val3)** or **record_name(val1, elename2 => val2, val3)**, where the last input parameter is not assigned a value using =>.
- The INSERT and UPDATE statements cannot use a record variable to insert or update data.
- The constructor of the record type cannot be used as the default value of a function or stored procedure parameter.
- Just like a variable declared, a member of the composite type does not have a default value when it is declared.
- For members of the record type, the default value of the inner record type cannot be passed to the outer record type.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- If the GUC parameter **enable_recordtype_check_strict** is set to **on** and members are of the record type and a column of the record type has the NOT NULL or DEFAULT attribute, an error will be reported during stored procedure or package compilation.
- If the GUC parameter **enable_recordtype_check_strict** is set to **on**, a package contains the record type, and a column of the record type has the NOT NULL or DEFAULT attribute, an error will be reported during creation or compilation.
- If the GUC parameter **enable_recordtype_check_strict** is set to **on**, the NOT NULL attribute of the record type in the stored procedure takes effect.
- After the **proc_outparam_override** option is enabled for the GUC parameter **behavior_compat_options**:
  - Functions that contain the **out** parameter and returns data of the record type can be called using SELECT and CALL in external SQL statements, and can be called using PERFORM and expressions in stored procedures.
  - If the function returns data of the undefined record type, at least one **out** parameter is required. If the function returns data of the defined record type, the **out** parameter is optional. For details, see **Examples**.
  - Functions that contain the **out** output parameter and return data of the composite or record type, ensure that the expected return type of the function is the same as the actual return type.
- In the INSERT INTO *table_name* VALUES *record_var* syntax, *record_var* supports only record variables and record variables nested in a single-layer array, but does not support record variables nested in a multi-layer array.
- Static DDL statements in PL/SQL do not support variables or members of the record type.
- When a record variable is assigned as a whole, values are assigned to columns in the declaration order. If an exception occurs during the assignment of a column, the columns that have been assigned values will not be rolled back.

Examples

```
-- Create a table and insert data into the table.
gaussdb=# CREATE TABLE emp_rec(
gaussdb(#     empno NUMERIC(4,0) NOT NULL,
gaussdb(#     ename VARCHAR(10)
gaussdb(# );
NOTICE:  The 'DISTRIBUTE BY' clause is not specified. Using 'empno' as the distribution column by default.
HINT:  Please use 'DISTRIBUTE BY' clause to specify suitable data distribution column.
CREATE TABLE
gaussdb=# INSERT INTO emp_rec VALUES(111, 'aaa'), (222, 'bbb'), (333, 'ccc');
INSERT 0 3
-- The table is defined as follows:
gaussdb=# \d emp_rec
          Table "public.emp_rec"
 Column |         Type          | Modifiers
--------+-----------------------+-----------
 empno  | numeric(4,0)          | not null
 ename  | character varying(10) |

-- Perform record operations in the function.
gaussdb=# CREATE OR REPLACE FUNCTION regress_record(p_w VARCHAR2) RETURNS VARCHAR2 AS $$

2.5 DECLARE Syntax

2.5.1 Basic Structure

Structure

A PL/SQL block can contain a sub-block which can be placed in any section. The following describes the architecture of a PL/SQL block:

- Declaration section: declares variables, types, cursors, and local stored procedures and functions used in the PL/SQL block.
  ```
  DECLARE
  ```

  NOTE

  This section is optional if no variables need to be declared.
  - An anonymous block may omit the DECLARE keyword if no variable needs to be declared.
  - For a stored procedure, if the DECLARE keyword is not used, the AS keyword is equivalent to the DECLARE keyword. The AS keyword must be retained in the syntax structure even if there is no explicit variable declaration.
- Execution section: specifies procedure and SQL statements. It is the main section of a program. It is required.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
BEGIN
```

- Exception-handling section: processes errors. It is optional.

```
EXCEPTION
```

- End section: It is required.

```
END;
/
```

NOTICE

You are not allowed to use consecutive tabs in the PL/SQL block because they may result in an exception when the gsql tool is executed with the **-r** parameter specified.

Types

PL/SQL blocks are classified into the following types:

- Anonymous block: a dynamic block that can be executed only for once. For details about the syntax, see **Figure 2-6**.
- Subprogram: a stored procedure, function, operator, or advanced package stored in a database. A subprogram can be called in other programs after it is created.

2.5.2 Anonymous Blocks

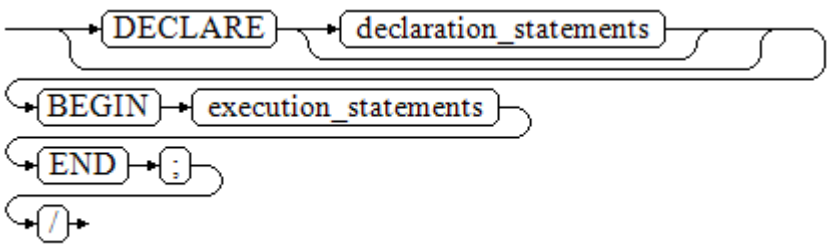
An anonymous block applies to a script infrequently executed or a one-off activity. An anonymous block is executed in a session and is not stored.

Syntax

```
[ DECLARE [ declaration_statements ] ]
BEGIN execution_statements
END ;
/
```

Figure 2-6 shows the syntax diagram of an anonymous block.

Figure 2-6 anonymous_block::=



- The execute part of an anonymous block starts with a BEGIN statement, has a break with an END statement, and ends with a semicolon (;). Type a slash (/) and press **Enter** to execute the statement.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTICE

The terminator "/" must be written in an independent row.

- The declaration section includes the variable definition, type, and cursor definition.
- A simplest anonymous block does not execute any commands. However, at least one statement, even a **NULL** statement, must be presented in any implementation blocks.

Examples

The following lists basic anonymous block programs:

```
-- Null statement block
gaussdb=# BEGIN
    NULL;
END;
/

-- Display information on the console.
gaussdb=# BEGIN
    dbe_output.print_line('hello world!');
END;
/
hello world!
ANONYMOUS BLOCK EXECUTE
-- Display variable content on the console.
gaussdb=# DECLARE
    my_var VARCHAR2(30);
BEGIN
    my_var :='world';
    dbe_output.print_line('hello'||my_var);
END;
/
helloworld
ANONYMOUS BLOCK EXECUTE
```

Using the JDBC Driver to Bind Parameters in an Anonymous Block

NOTICE

- This function supports only ORA-compatible databases and only Oracle Database-style anonymous blocks.
- In the full encryption scenario:
  - When **enable_ce** is set to **1** for JDBC connections, parameters cannot be bound to anonymous blocks.
- If the variables (including the explicitly defined variables or types) defined in an anonymous block conflict with bind variables ($1, $2...) in names, an error will be reported.
- An anonymous block declared as an autonomous transaction does not support bind parameters.
- The maximum number of parameters that can be bound to an anonymous block is 32767, and the maximum number of output parameters that can be bound is 1664.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Prerequisites: You have connected to the database using the connection object **conn**.

To use the JDBC driver to bind parameters to an anonymous block, perform the following steps:

Step 1 Create the call statement object cstmt by calling the prepareCall method of Connection.

```
CallableStatement cstmt = conn.prepareCall("DECLARE var int; BEGIN var := ?; ? := 50; END;");
```

Step 2 Set parameters by calling the setInt method of CallableStatement.

```
cstmt.setInt(1, 20);
```

Step 3 Register an output parameter by calling the registerOutParameter method in CallableStatement.

```
cstmt.registerOutParameter(2, Types.INTEGER);  // Register an out parameter of the integer type.
```

Step 4 Call the execute method of CallableStatement to execute the anonymous block statement.

```
cstmt.execute();
```

Step 5 Obtain the out parameter by calling the getInt method of CallableStatement.

```
int out = cstmt.getInt(2);
```

Step 6 Close the call statement object cstmt by calling the close method of CallableStatement.

```
cstmt.close();
```

----End

NOTE

- When the JDBC driver for 507.0.0 is used to connect to a database of an earlier version (503.1.0 or later), the JDBC driver cannot be used to bind parameters to anonymous blocks. When the JDBC driver for 503.1.0 or later is used to connect to a database of version 507.0.0, the JDBC driver can be used to bind input parameters to anonymous blocks, but cannot be used to bind output parameters to anonymous blocks.
- During the upgrade observation period after the upgrade from a version earlier than 507.0.0 to 507.0.0 or later, if the JDBC driver for the target version is used to connect to the database, the JDBC driver can be used to bind parameters to anonymous blocks. If the JDBC driver for the source version (503.1.0 or later) is used to connect to the database of version 507.0.0, the JDBC driver can be used to bind input parameters to anonymous blocks, but cannot be used to bind output parameters to anonymous blocks.

2.5.3 Subprograms

Subprograms are objects stored in a database, including stored procedures, functions, operators, and advanced packages.

After a subprogram is created in the database, it can be called by other programs.

2.5.3.1 Standalone Subprograms

Standalone subprograms include stored procedures, functions, and packages created in a schema.

For details, see:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **CREATE PACKAGE**
- **CREATE FUNCTION**
- **CREATE PROCEDURE**

2.5.3.2 Package Subprograms

A subprogram created inside a package is a package subprogram. You can declare and create a stored procedure or function in the package body.

For details, see **CREATE PACKAGE**.

2.5.3.3 Nested Subprograms

A subprogram created inside a PL/SQL block is a nested subprogram. You can declare and create a stored procedure or function inside an anonymous block, stored procedure, function, or a stored procedure/function inside a package.

Precautions

- It is used in ORA-compatible databases.
- The maximum number of nesting layers is specified by the GUC parameter **max_subpro_nested_layers**. The default value is **3**, and the value range is 0 to 100. If a subprogram is nested under an anonymous block, the layer of the anonymous block is not counted in the total number of layers.
- Nested subprograms do not support overloading or SETOF.
- Nested subprograms cannot be defined as autonomous transactions. They can call stored procedures or functions that contain autonomous transactions.
- Nested functions cannot be directly called and must have return values. Nested stored procedures cannot be called in expressions.
- Nested subprograms cannot be called by PERFORM. Dynamic statements cannot contain nested subprograms.
- Currently, only the following modifiers are supported for nested subprograms:
  ```
  {IMMUTABLE  | STABLE  | VOLATILE }
  {CALLED ON NULL INPUT | RETURNS NULL ON NULL INPUT | STRICT }
  ```
- Only one qualifier can reference a nested subprogram or a variable of a nested subprogram.
- When the return value type of a nested function is the record type customized by the function, subfunc().col cannot be used to access the column attribute of the return value of the nested function. As a result, an error is reported during execution.
- The declaration of a nested subprogram must be at the end of the declarative part (declaring the nested subprogram after the declaration of variables, cursors, and types is complete).
- Nested subprograms can be called only inside declared functions or stored procedures and cannot be used externally.
- Nested subprograms do not support debugger breakpoints, but support step-by-step debugging.
- Other precautions are the same as those for stored procedures and functions.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Syntax

- Syntax format for creating a nested stored procedure:

```
PROCEDURE procedure_name [ (parameters) ]
    [{IMMUTABLE  | STABLE  | VOLATILE }
     | {CALLED ON NULL INPUT | RETURNS NULL ON NULL INPUT | STRICT }]
    { IS | AS }
    [ declarations ]
BEGIN
    plsql_body
END;
```

- Syntax for creating a nested function:

```
FUNCTION function_name  [ (parameters) ] RETURN rettype
    [{IMMUTABLE  | STABLE  | VOLATILE }
     | {CALLED ON NULL INPUT | RETURNS NULL ON NULL INPUT | STRICT }]
    { IS | AS }
    [ declarations ]
BEGIN
    plsql_body
END;
```

  In the **declarations** part, you can define the nested subprograms of the lower layer.

- Example:

```
-- Create a stored procedure.
CREATE OR REPLACE PROCEDURE proc_test() AS
    -- Declare and define a nested stored procedure.
    PROCEDURE proc_sub() IS
    BEGIN
        dbe_output.put_line('this is subprogram');
    END;
BEGIN
    dbe_output.put_line('this is a procedure');
    -- Call the nested stored procedure inside an execution block.
    proc_sub();
END;
/
    -- Call a stored procedure externally.
BEGIN
    proc_test;
END;
/
-- Output the result.
this is a procedure
this is subprogram
ANONYMOUS BLOCK EXECUTE
```

Declaration and Definition Rules of Nested Subprograms

- Nested subprograms cannot be declared or defined repeatedly. Overloading is not supported.
- The identifier of a nested subprogram cannot be the same as the variable name or keyword.
- You can declare a subprogram before defining it. All declared subprograms must be defined in the subsequent declaration blocks.

Calling Rules of Nested Subprograms

- Nested subprograms can call themselves to implement recursive calls.
- Nested subprograms can call subprograms declared in the upper scope.
- Nested subprograms can call locally declared lower-layer subprograms, but cannot access nested subprograms in lower-layer subprograms.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- Nested subprograms can call subprograms declared before themselves in the same scope.

Example:

```
-- Call itself.
CREATE OR REPLACE PROCEDURE proc_test(var1 int) AS
    PROCEDURE proc_sub(var2 int) IS
    BEGIN
        dbe_output.put_line('var = ' || var2);
        IF var2 > 1 THEN
            proc_sub(var2 - 1);
        END IF;
    END;
BEGIN
    proc_sub(var1);
END;
/
BEGIN
    proc_test(3);
END;
/
-- Output the result.
var = 3
var = 2
var = 1

-- Call the upper-layer subprogram.
CREATE OR REPLACE PROCEDURE proc_test(var1 int) AS
    PROCEDURE procsub_1(var2 int) IS
    BEGIN
 proc_test(var2 - 1);
    END;
BEGIN
    dbe_output.put_line('proc_test var1 = ' || var1);
 IF var1 > 1 THEN
       procsub_1(var1);
 END IF;
END;
/
BEGIN
    proc_test(3);
END;
/
-- Output the result.
proc_test var1 = 3
proc_test var1 = 2
proc_test var1 = 1

-- Call the lower-layer subprogram declared locally.
CREATE OR REPLACE PROCEDURE proc_test() AS
    PROCEDURE proc_sub1 IS
        procedure proc_sub2 IS
        BEGIN
            dbe_output.put_line('--this is subprogram2 begin');
            dbe_output.put_line('--this is subprogram2 end');
        END;
    BEGIN
 dbe_output.put_line('this is subprogram1 begin');
 proc_sub2();
 dbe_output.put_line('this is subprogram1 end');
    END;
BEGIN
    dbe_output.put_line('this is a procedure begin');
    proc_sub1();
    dbe_output.put_line('this is a procedure end');
END;
/
BEGIN
    proc_test;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
END;
/
-- Output the result.
this is a procedure begin
this is subprogram1 begin
--this is subprogram2 begin
--this is subprogram2 end
this is subprogram1 end
this is a procedure end
```

Variables of Nested Subprograms

Variable types include basic types, record types, TABLE OF types, cursor types, and varray types supported by PL/SQL.

- Accessible variables:
  - Variable declared by itself.
  - Variable declared by the upper-layer subprogram.
- Variable access rules:
  - If a variable does not have a qualifier, it is searched in the current program. If the variable name does not exist, the variable is searched at the upper layer, and so on.
  - If a variable has a qualifier, it is searched in the area of the qualifier. Currently, only one qualifier can be used.

2.6 Basic Statements

In PL/SQL programming, you need to define variables, assign values, and call stored procedures. This section describes basic PL/SQL statements, including variable definition statements, value assignment statements, call statements, and return statements.

NOTE

Do not call the SQL statements containing passwords in the stored procedures because authorized users may view the stored procedure file in the database, causing password leakage. If the stored procedure contains other sensitive information, you are advised to configure the access permission for the stored procedure to ensure the security of sensitive data.

2.6.1 Variable Definition Statements

This section describes the declaration of variables in the PL/SQL and the scope of this variable in code.

Variable Declaration

Figure 2-7 shows the variable declaration syntax.

Figure 2-7 declare_variable::=

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

The syntax is described as follows:

- **variable_name** indicates the name of a variable.
- **type** indicates the type of a variable.
- **value** indicates the initial value of the variable. (If the initial value is not given, **NULL** is taken as the initial value.) **value** can also be an expression.

Examples

```
gaussdb=# DECLARE
    emp_id  INTEGER := 7788; -- Define a variable and assign a value to it.
BEGIN
    emp_id := 5*7784; -- Assign a value to the variable.
END;
/
```

In addition to the declaration of basic variable types, **%TYPE** and **%ROWTYPE** can be used to declare variables related to table columns or table definitions.

%TYPE Attribute

%TYPE declares a variable to be of the same data type as a previously declared variable (for example, a column in a table). For example, if you want to define the *my_name* variable whose data type is the same as the data type of the **firstname** column in the **employee** table, you can define the variable as follows:

```
my_name employee.firstname%TYPE
-- Example
DROP TABLE IF EXISTS employee;
CREATE TABLE employee(firstname varchar,secondname varchar);
DECLARE
    my_name employee.firstname%TYPE;
BEGIN
    my_name = 'abc';
    DBE_OUTPUT.PRINT_LINE(my_name);
END;
/
```

In this way, you do not need to know the data type of the **firstname** column in the **employee** table. In addition, you do not need to modify the type definition of **my_name** when the data type of the **firstname** column changes.

%ROWTYPE Attribute

%ROWTYPE declares data types of a set of data. It stores a row of table data or obtains results from a cursor. If you want to define a set of data with the same column names and column types as the **employee** table, you can define the data as follows:

```
my_employee employee%ROWTYPE
DROP TABLE IF EXISTS employee;
CREATE TABLE employee(firstname varchar,secondname varchar);
DECLARE
    my_employee employee%ROWTYPE;
BEGIN
    my_employee.firstname := 'ab1';
    my_employee.secondname := 'ab2';
    DBE_OUTPUT.PRINT_LINE(my_employee.firstname);
    DBE_OUTPUT.PRINT_LINE(my_employee.secondname);
END;
/
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- In the environment with multiple CNs, the **%ROWTYPE** and **%TYPE** attributes of the temporary table cannot be declared in a stored procedure. The temporary table is valid only in the current session. During compilation, other CNs cannot view the temporary table of the current CN. Therefore, if there are multiple CNs, the system displays a message indicating that the temporary table does not exist.
- **%TYPE** cannot reference the record variables that are not across packages or the cursor variables of a column type.
- **%ROWTYPE** cannot reference the type of a composite variable or a record variable.
- The non-PACKAGE *record%TYPE* cannot be used as the variable type or input/output parameter type.
- *View%ROWTYPE* or **SCHEMA.***view%ROWTYPE* cannot be used as the input/output parameter type.
- The **PACKAGE.***record%TYPE* or **SCHEMA.PACKAGE.***record%TYPE* cannot be used as the input/output parameter type.
- *Table/View*.**column.***column%TYPE* or **SCHEMA.***Table/View*.**column.***column%TYPE* cannot be nested with one or more layers as variable types or the input/output parameter type.
- *Record*.**column.***column%TYPE* and **PACKAGE.***record*.**column.***column%TYPE* cannot be nested with a column type of records at one or more layers as the variable type or input/output parameter type.
- A cursor variable of more layers, such as **PACKAGE.***cursor%ROWTYPE* and **SCHEMA.PACKAGE.***cursor%ROWTYPE*, cannot be used as the parameter type or input/output parameter type.
- In an anonymous block, *cursor_name%ROWTYPE* does not contain column information. When it is used as the base type of a collection element, for example, BULK COLLECT INTO, an exception may occur.

Scope of a Variable

The scope of a variable defines the accessibility and availability of the variable in a code block. A variable is valid only within its scope.

- A variable must be declared in the DECLARE part, that is, the BEGIN-……END block structure must be established. The structure requires that a variable must be declared before being used. That is, a variable has different scopes and lifetimes during a process.
- A variable can be defined repeatedly in different scopes. The definition of the inner scope overwrites that of the outer scope.
- Variables defined in an outer block can be used in nested blocks, but variables defined in nested blocks cannot be accessed by the outer block.

Example

```
gaussdb=# DECLARE
    emp_id  INTEGER :=7788; -- Define a variable and assign a value to it.
    outer_var  INTEGER :=6688; -- Define a variable and assign a value to it.
BEGIN
    DECLARE
        emp_id INTEGER :=7799; -- Define a variable and assign a value to it.
        inner_var  INTEGER :=6688; -- Define a variable and assign a value to it.
    BEGIN
        dbe_output.print_line('inner emp_id ='||emp_id); -- Display the value 7799.
        dbe_output.print_line('outer_var ='||outer_var); -- Reference a variable of an outer block.
    END;
    dbe_output.print_line('outer emp_id ='||emp_id); -- Display the value 7788.
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
END;
/
```

2.6.2 Assignment Statements

Variable Syntax

Figure 2-8 shows the syntax for assigning a value to a variable.

Figure 2-8 assignment_value::=

The syntax is described as follows:

- **variable_name** indicates the name of a variable.
- **value** can be a value or an expression. The type of **value** must be compatible with the type of **variable_name**.

Variable Value Assignment Example

```
DECLARE
    emp_id  INTEGER := 7788; -- Assign a value.
BEGIN
    emp_id := 5; -- Assign a value.
    DBE_OUTPUT.PRINT_LINE(emp_id);
    emp_id := 5*7784;
    DBE_OUTPUT.PRINT_LINE(emp_id);
END;
/
-- The result is as follows:
5
38920
ANONYMOUS BLOCK EXECUTE
```

NOTE

After the GUC parameter is enabled (by running **SET behavior_compat_options = 'proc_outparam_override';**), the **value** of an assignment statement cannot call an overloaded function whose return type is composite or array type in the form of a reference column (for example, func(x).a or func(x)[1]).

INTO/BULK COLLECT INTO

Values returned by statements in a stored procedure are stored in variables. BULK COLLECT INTO allows some or all returned values to be temporarily stored in an array.

Syntax

```
SELECT select_expressions INTO [STRICT] target FROM ...
SELECT INTO [STRICT] target [FROM ..]
EXECUTE [IMMEDIATE] select_expressions BULK COLLECT INTO target ...
```

The syntax is described as follows:

- **select_expressions**: SQL statement for query. You can use basic SQL commands and INTO clauses to assign the result of a single row or multiple columns to a variable (such as record, row, or scalar variable list).

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **target**: target variable, which can be a record variable, a row variable, or a comma-separated list of simple variables and record/row fields.
- **STRICT** (Optional): If **behavior_compat_options** is set to **'select_into_return_null'** (the parameter is disabled by default) and this option is specified, the query result must contain a row of result set that is not empty. Otherwise, an error is reported. The error information may be NO_DATA_FOUND (no row), TOO_MANY_ROWS (more than one row), or QUERY_RETURNED_NO_ROWS (no data is returned). If the option is not specified, the empty result set can be returned.

NOTE

- BULK COLLECT INTO can assign values to arrays or collections in batches. Use the LIMIT clause properly to prevent performance deterioration caused by excessive data operations.
- INTO and BULK COLLECT INTO support only direct nesting of record values with less than four layers.
- To return an empty result set, you need to enable PG-compatible mode during database initialization. Set the GUC parameter **behavior_compat_options** to **'select_into_return_null'**. The compatibility mode is enabled. If the GUC parameter **behavior_compat_options** is not set, the compatibility mode is disabled.
- For array variables, elements in parentheses (()) are preferentially identified as index sets. Therefore, expressions with parentheses cannot be written after array variables. For example, **SELECT (1+3) INTO va(5)** cannot be written as **SELECT INTO va(5) (1+3)** or **SELECT INTO va[5] (1+3)**.
- BULK COLLECT INTO can be used only in an ORA-compatible database.
- The IMMEDIATE keyword is used only for syntax compatibility and has no actual meaning.
- The SELECT INTO data in a stored procedure is stored in the specified output variables. If the number of output variables is greater than the number of data columns in the actual query result set, null values are assigned to the extra variables, and no error is reported. If the number of output variables is less than the number of data columns in the actual cursor query result set, the extra columns are silently discarded, and no error is reported.

Examples

```
gaussdb=# DROP TABLE IF EXISTS customers;
gaussdb=# CREATE TABLE customers(id int,name varchar);
gaussdb=# INSERT INTO customers VALUES(1,'ab');
gaussdb=# DECLARE
    my_id integer;
BEGIN
    select id into my_id from customers limit 1; -- Assign a value.
END;
/
ANONYMOUS BLOCK EXECUTE
gaussdb=# DECLARE
    type id_list is varray(6) of customers.id%type;
    id_arr id_list;
BEGIN
    select id bulk collect into id_arr from customers order by id DESC limit 20; -- Assign values in batches.
END;
/
ANONYMOUS BLOCK EXECUTE
gaussdb=#  DECLARE
    TYPE id_list IS varray(6) OF customers.id%type;
    id_arr id_list;
    sql_qry varchar2(150);
BEGIN
    sql_qry := 'SELECT id FROM customers ORDER BY id DESC LIMIT 20';
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

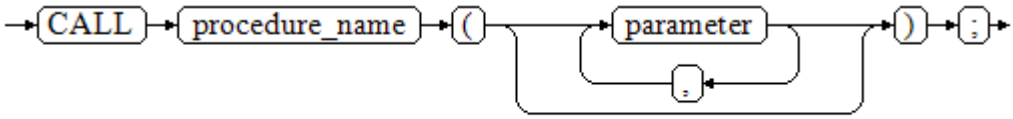
```
   EXECUTE IMMEDIATE sql_qry BULK COLLECT INTO id_arr; -- Assign values in batches.
END;
/
ANONYMOUS BLOCK EXECUTE
```

2.6.3 Call Statements

Syntax

Figure 2-9 shows the syntax diagram for a call statement.

Figure 2-9 call_clause::=



The syntax is described as follows:

- **procedure_name** specifies the name of a stored procedure.
- **parameter** specifies the parameters for the stored procedure. You can set no parameter or multiple parameters.

Examples

```
-- Create a table.
gaussdb=# CREATE SCHEMA hr;
gaussdb=# SET CURRENT_SCHEMA = hr;
gaussdb=# CREATE TABLE staffs
(
  section_id INTEGER,
  salary INTEGER
);
gaussdb=# INSERT INTO staffs VALUES (30, 10);
gaussdb=# INSERT INTO staffs VALUES (30, 20);

-- Create the stored procedure proc_staffs.
gaussdb=# CREATE OR REPLACE PROCEDURE proc_staffs
(
section     NUMBER(6),
salary_sum out NUMBER(8,2),
staffs_count out INTEGER
)
IS
BEGIN
SELECT sum(salary), count(*) INTO salary_sum, staffs_count FROM hr.staffs where section_id = section;
END;
/
CREATE PROCEDURE
-- Create the stored procedure proc_return.
gaussdb=# CREATE OR REPLACE PROCEDURE proc_return
AS
v_num NUMBER(8,2);
v_sum INTEGER;
BEGIN
proc_staffs(30, v_sum, v_num);  -- Call statement.
dbe_output.print_line(v_sum||'#'||v_num);
RETURN;  -- Return statement.
END;
/
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
CREATE PROCEDURE
-- Call the stored procedure proc_return.
gaussdb=# CALL proc_return();
30#2.00
 proc_return
-------------

(1 row)

-- Drop the stored procedures.
gaussdb=# DROP PROCEDURE proc_staffs;
gaussdb=# DROP PROCEDURE proc_return;

-- Create the function func_return.
gaussdb=# CREATE OR REPLACE FUNCTION func_return returns void
language plpgsql
AS $$
DECLARE
v_num INTEGER := 1;
BEGIN
dbe_output.print_line(v_num);
RETURN;  -- Return statement.
END $$;
CREATE FUNCTION

-- Call the function func_return.
gaussdb=# CALL func_return();
1
 func_return
-------------

(1 row)

-- Drop the function.
gaussdb=# DROP FUNCTION func_return;

-- Drop the current schema.
gaussdb=# DROP SCHEMA hr CASCADE;
```

2.7 Dynamic Statements

2.7.1 Dynamically Executing Query Statements

This section describes dynamic query statements and their execution examples. GaussDB supports dynamic query using EXECUTE IMMEDIATE and OPEN FOR. The former dynamically executes SELECT statements while the latter uses the cursor. If you need to store query results in a data set, use OPEN FOR.

EXECUTE IMMEDIATE

Figure 2-10 shows the syntax diagram.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Figure 2-10 EXECUTE IMMEDIATE dynamic_select_clause::=

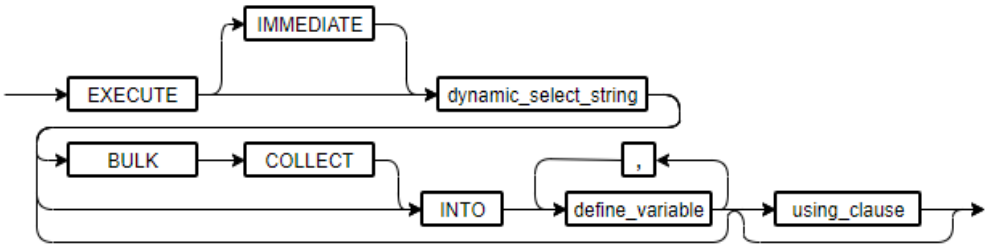


Figure 2-11 shows the syntax diagram for the USING clause.

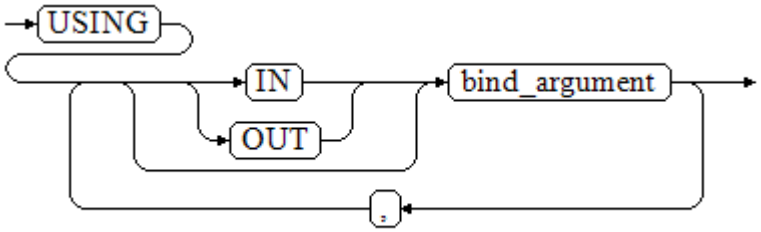
Figure 2-11 using_clause::=



The syntax is described as follows:

- **define_variable**: specifies a variable to store query results.
- **USING IN** *bind_argument*: specifies a variable whose value is passed to a dynamic SQL statement. The variable is used when a dynamic placeholder exists in *dynamic_select_string*.
- **USING OUT** *bind_argument*: specifies a variable that stores a value returned by the dynamic SQL statement.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTICE

- In query statements, INTO and OUT cannot coexist.
- A placeholder name starts with a colon (:) and can be followed by digits, characters, or character strings (excluding quoted digits, characters, or character strings). A placeholder name corresponds to *bind_argument* in the USING clause.
- *bind_argument* can only be a value, variable, or expression. It cannot be a database object such as a table name, column name, and data type. That is, *bind_argument* cannot be used to specify schema objects for dynamic SQL statements. If a stored procedure needs to specify database objects by declaring parameters to construct dynamic SQL statements (generally, DDL statements), you are advised to use double vertical bars (||) to concatenate *dynamic_select_clause* with a database object.
- A dynamic PL/SQL block allows duplicate placeholders. That is, a placeholder can correspond to only one *bind_argument* in the USING clause. When the GUC parameter **behavior_compat_options** is set to **dynamic_sql_compat**, the bind arguments in the USING clause are matched in sequence based on the placeholder sequence. Duplicate placeholders will not be identified as the same placeholder.
- The IMMEDIATE keyword is used only for syntax compatibility and has no actual meaning.

Example:

```
gaussdb=# DROP SCHEMA IF EXISTS hr CASCADE;
gaussdb=# CREATE SCHEMA hr;
gaussdb=# SET CURRENT_SCHEMA = hr;
gaussdb=# CREATE TABLE staffs
(
  staff_id NUMBER,
  first_name VARCHAR2,
  salary NUMBER
);
gaussdb=# INSERT INTO staffs VALUES (200, 'mike', 5800);
gaussdb=# INSERT INTO staffs VALUES (201, 'lily', 3000);
gaussdb=# INSERT INTO staffs VALUES (202, 'john', 4400);

-- Retrieve values from dynamic statements (INTO clause).
gaussdb=# DECLARE
   staff_count  VARCHAR2(20);
BEGIN
   EXECUTE IMMEDIATE 'select count(*) from hr.staffs'
      INTO staff_count;
   dbe_output.print_line(staff_count);
END;
/
3
ANONYMOUS BLOCK EXECUTE
-- Pass and retrieve values (the INTO clause is used before the USING clause).
gaussdb=# CREATE OR REPLACE PROCEDURE dynamic_proc
AS
   staff_id     NUMBER(6) := 200;
   first_name   VARCHAR2(20);
   salary       NUMBER(8,2);
BEGIN
   EXECUTE IMMEDIATE 'select first_name, salary from hr.staffs where staff_id = :1'
      INTO first_name, salary
      USING IN staff_id;
   dbe_output.print_line(first_name || ' ' || salary);
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
END;
/
CREATE PROCEDURE
-- Call a stored procedure.
gaussdb=# CALL dynamic_proc();
mike 5800.00
 dynamic_proc
--------------

(1 row)

-- Drop a stored procedure.
gaussdb=# DROP PROCEDURE dynamic_proc;

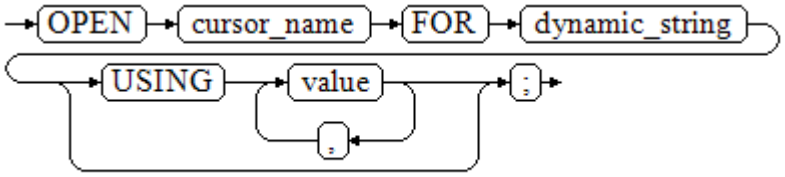
-- Drop the current schema.
gaussdb=# DROP SCHEMA hr CASCADE;
```

OPEN FOR

Dynamic query statements can be executed by using OPEN FOR to open dynamic cursors.

Figure 2-12 shows the syntax diagram.

Figure 2-12 open_for::=



Parameters:

- *cursor_name*: specifies the name of the cursor to be opened.
- *dynamic_string*: specifies the dynamic query statement.
- **USING** *value*: applies when a placeholder exists in *dynamic_string*.

For details about use of cursors, see **Cursors**.

Example:

```
gaussdb=# CREATE SCHEMA hr;
gaussdb=# SET CURRENT_SCHEMA = hr;
gaussdb=# DROP TABLE IF EXISTS staffs;
gaussdb=# CREATE TABLE staffs
(
  section_id NUMBER,
  first_name VARCHAR2,
  phone_number VARCHAR2,
  salary NUMBER
  );
gaussdb=# INSERT INTO staffs VALUES (30, 'mike', '13567829252', 5800);
gaussdb=# INSERT INTO staffs VALUES (40, 'john', '17896354637', 4000);

gaussdb=# DECLARE
    name          VARCHAR2(20);
    phone_number  VARCHAR2(20);
    salary        NUMBER(8,2);
    sqlstr        VARCHAR2(1024);

    TYPE app_ref_cur_type IS REF CURSOR; -- Define the cursor type.
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
    my_cur app_ref_cur_type; -- Define the cursor variable.

BEGIN
    sqlstr := 'select first_name,phone_number,salary from hr.staffs
        where section_id = :1';
    OPEN my_cur FOR sqlstr USING '30'; -- Open the cursor. USING is optional.
    FETCH my_cur INTO name, phone_number, salary; -- Retrieve the data.
    WHILE my_cur%FOUND LOOP

        FETCH my_cur INTO name, phone_number, salary;
    END LOOP;
    CLOSE my_cur; -- Close the cursor.
END;
/
mike#13567829252#5800.00
ANONYMOUS BLOCK EXECUTE
gaussdb=# DROP TABLE staffs;
```

2.7.2 Dynamically Executing Non-Query Statements

Syntax

Figure 2-13 shows the syntax diagram.

Figure 2-13 noselect::=

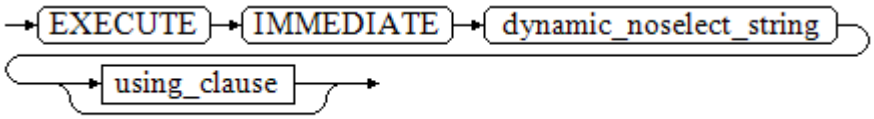

Figure 2-14 shows the syntax diagram for the USING clause.

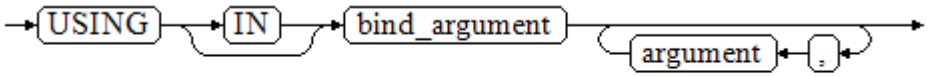
Figure 2-14 using_clause::=



The above syntax diagram is explained as follows:

USING IN *bind_argument* is used to specify the variable whose value is passed to the dynamic SQL statement. The variable is used when a placeholder exists in *dynamic_noselect_string*. That is, a placeholder is replaced by the corresponding *bind_argument* when a dynamic SQL statement is executed.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTICE

- *bind_argument* can only be a value, variable, or expression, and cannot be a database object such as a table name, column name, and data type. If a stored procedure needs to specify database objects by declaring parameters to construct dynamic SQL statements (generally, DDL statements), you are advised to use double vertical bars (||) to concatenate *dynamic_select_clause* with a database object.
- In addition, duplicate placeholders are allowed in dynamic statements. A placeholder can correspond to only one *bind_argument* by position. When the GUC parameter **behavior_compat_options** is set to **dynamic_sql_compat**, the *bind_argument* in the USING clause is matched in the placeholder sequence. Duplicate placeholders will not be identified as the same placeholder (placeholder names cannot contain quoted digits, characters, or strings).

Examples

```
-- Create a table.
gaussdb=# CREATE TABLE sections_t1
(
   section       NUMBER(4) ,
   section_name  VARCHAR2(30),
   manager_id    NUMBER(6),
   place_id      NUMBER(4)
)
DISTRIBUTE BY hash(manager_id);

-- Declare a variable.
gaussdb=# DECLARE
   section       NUMBER(4) := 280;
   section_name  VARCHAR2(30) := 'Info support';
   manager_id    NUMBER(6) := 103;
   place_id      NUMBER(4) := 1400;
   new_colname   VARCHAR2(10) := 'sec_name';
BEGIN
-- Execute the query.
    EXECUTE IMMEDIATE 'insert into sections_t1 values(:1, :2, :3, :4)'
       USING section, section_name, manager_id,place_id;
-- Execute the query (duplicate placeholders).
    EXECUTE IMMEDIATE 'insert into sections_t1 values(:1, :2, :3, :1)'
       USING section, section_name, manager_id;
-- Run the ALTER statement. You are advised to use double vertical bars (||) to concatenate the dynamic
DDL statement with a database object.
    EXECUTE IMMEDIATE 'alter table sections_t1 rename section_name to ' || new_colname;
END;
/
ANONYMOUS BLOCK EXECUTE
-- Query data.
gaussdb=# SELECT * FROM sections_t1;
 section |   sec_name   | manager_id | place_id
---------+--------------+------------+----------
     280 | Info support |        103 |     1400
     280 | Info support |        103 |      280
(2 rows)

-- Drop a table.
gaussdb=# DROP TABLE sections_t1;
```

2.7.3 Dynamically Calling Stored Procedures

When dynamically calling a stored procedure, you must use an anonymous statement block to wrap the stored procedure or statement block. The EXECUTE

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

IMMEDIATE...USING statement is used together with IN and OUT to implement parameter input and output.

Syntax

Figure 2-15 shows the syntax diagram.

Figure 2-15 call_procedure::=

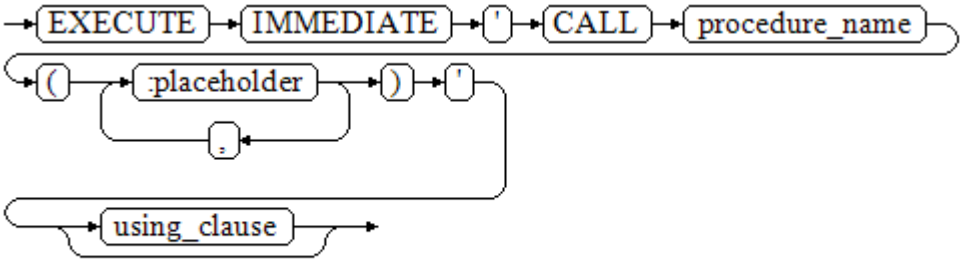


Figure 2-16 shows the syntax diagram for the USING clause.

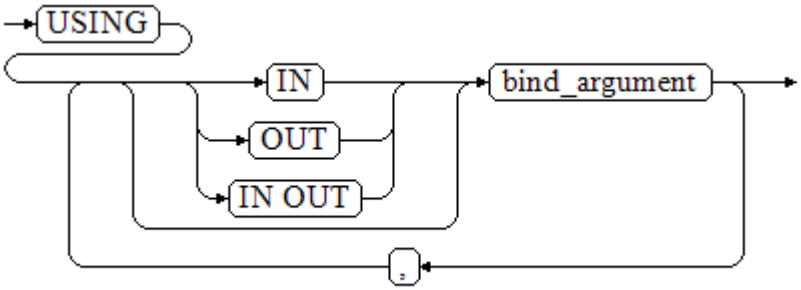
Figure 2-16 using_clause::=



The above syntax diagram is explained as follows:

- **CALL** *procedure_name*: calls a stored procedure.
- **[:placeholder1,:placeholder2, ...]**: indicates the list of placeholders for stored procedure parameters. Placeholder names cannot contain quoted digits, characters, or character strings. The numbers of the placeholders and parameters are the same.
- **USING [IN|OUT|IN OUT]** *bind_argument*: specifies where the variable passed to the stored procedure parameter value is stored. The modifiers in front of *bind_argument* and of the corresponding parameter are the same.

When a stored procedure is called, => cannot be used to skip parameters.

Examples

```
-- Create the stored procedure proc_add.
gaussdb=# CREATE OR REPLACE PROCEDURE proc_add
(
    param1    in   INTEGER,
    param2    out  INTEGER,
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
    param3    in   INTEGER
)
AS
BEGIN
   param2:= param1 + param3;
END;
/

gaussdb=# DECLARE
    input1 INTEGER:=1;
    input2 INTEGER:=2;
    statement  VARCHAR2(200);
    param2     INTEGER;
BEGIN
   -- Declare the call statement.
    statement := 'call proc_add(:col_1, :col_2, :col_3)';
   -- Execute the statement.
    EXECUTE IMMEDIATE statement
        USING IN input1, OUT param2, IN input2;
    dbe_output.print_line('result is: '||to_char(param2));
END;
/
result is: 3
ANONYMOUS BLOCK EXECUTE
-- Drop the stored procedure.
gaussdb=# DROP PROCEDURE proc_add;
```

2.7.4 Dynamically Calling Anonymous Blocks

Dynamically calling anonymous blocks refers to executing anonymous blocks in dynamic statements. The EXECUTE IMMEDIATE...USING statement is used together with IN and OUT to implement parameter input and output.

Syntax

Figure 2-17 shows the syntax for dynamically calling an anonymous block.

Figure 2-17 call_anonymous_block::=

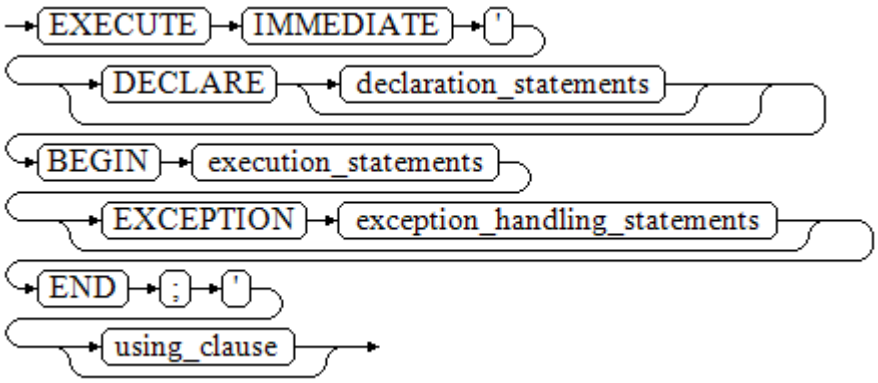


Figure 2-18 shows the syntax diagram for the USING clause.

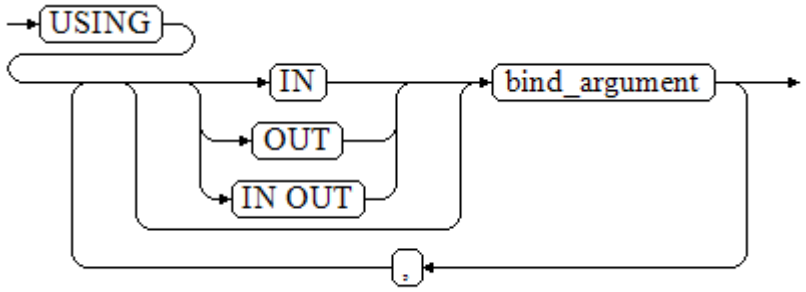
 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Figure 2-18 using_clause::=



The above syntax diagram is explained as follows:

- The execute part of an anonymous block starts with a BEGIN statement, has a break with an END statement, and ends with a semicolon (;).
- **USING [IN|OUT|IN OUT]** *bind_argument*: specifies where the variable passed to the stored procedure parameter value is stored. The modifiers in front of *bind_argument* and of the corresponding parameter are the same.
- The INOUT parameters in the middle of an anonymous block are designated by placeholders. The numbers of the placeholders and parameters are the same. The sequences of the parameters corresponding to the placeholders and the USING parameters are the same.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTICE

- Parameters can be bound only when SQL statements and stored procedures are called in anonymous blocks. For example, expressions and cursors are used in anonymous blocks, and dynamic statements are called in nested mode in anonymous blocks.
- Output parameters cannot be bound when the SELECT INTO statement in an anonymous block calls FUNCTION/PROCEDURE that contains output parameters.
- Output parameters of the composite type cannot be bound to an anonymous block.
- Variables declared in an anonymous block and bind variables cannot be used in the same statement at the same time.
- The PERFORM keyword cannot be used to call a stored procedure when bind variables are used.
- When a stored procedure is called, only bind variables can be used as INOUT parameters. Expressions (for example, 1+:va) cannot be used as INOUT parameters. In addition, placeholder names cannot contain quoted digits, characters, or character strings.
- The IMMEDIATE keyword is used only for syntax compatibility and has no actual meaning.
- When the bound input parameter type is refcursor, the modification in the stored procedure is isolated from the input parameter.
- When the **dynamic_sql_check** parameter is enabled and the number of placeholders is the same as the number of parameters, an error will be reported if placeholders with the same name are used as anonymous block parameters. In this case, you need to rename the placeholders. For details, see **Examples**.

Examples

```
gaussdb=# DROP SCHEMA IF EXISTS hr CASCADE;
gaussdb=# CREATE SCHEMA hr;
CREATE SCHEMA
gaussdb=# SET CURRENT_SCHEMA = hr;
SET
gaussdb=# CREATE TABLE staffs
(
  staff_id NUMBER,
  first_name VARCHAR2,
  salary NUMBER
);
CREATE TABLE
gaussdb=# INSERT INTO staffs VALUES (200, 'mike', 5800);

```

2.8 Control Statements

2.8.1 RETURN Statements

In GaussDB, data can be returned in either of the following ways: **RETURN** or **RETURN NEXT**/**RETURN QUERY**. **RETURN NEXT**/**RETURN QUERY** is used only for functions and cannot be used for stored procedures.

2.8.1.1 RETURN

Syntax

Figure 2-19 shows the syntax diagram for a RETURN statement.

Figure 2-19 return_clause::=

The above syntax diagram is explained as follows:

Assign the result returned by a stored procedure or function to the caller.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Examples

See **Examples** for call statement examples.

2.8.1.2 RETURN NEXT/RETURN QUERY

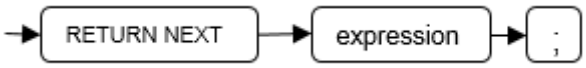
Syntax

When creating a function, specify **SETOF** *datatype* for the return values.

- return_next_clause::=

  Figure 2-20 shows the return_next_clause::= statement.

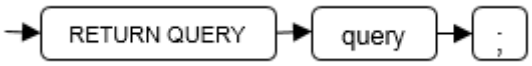
  Figure 2-20 return_next_clause::=

- return_query_clause::=

  Figure 2-21 shows the return_query_clause::= statement.

  Figure 2-21 return_query_clause::=

If a function needs to return a result set, use RETURN NEXT or RETURN QUERY to add results to the result set, and then continue to execute the next statement of the function. As the RETURN NEXT or RETURN QUERY statement is executed repeatedly, more and more results will be added to the result set. After the function is executed, all results are returned.

RETURN NEXT can be used for scalar and compound data types.

RETURN QUERY has a variant RETURN QUERY EXECUTE. You can add dynamic queries and add parameters to the queries by USING.

Examples

```
gaussdb=# DROP TABLE t1;
gaussdb=# CREATE TABLE t1(a int);
gaussdb=# INSERT INTO t1 VALUES(1),(10);

--RETURN NEXT
gaussdb=# CREATE OR REPLACE FUNCTION fun_for_return_next() RETURNS SETOF t1 AS $$
DECLARE
  r t1%ROWTYPE;
BEGIN
  FOR r IN select * from t1
  LOOP
    RETURN NEXT r;
  END LOOP;
  RETURN;
END;
$$ LANGUAGE plpgsql;
gaussdb=# call fun_for_return_next();
 a
---
 1
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
 10
(2 rows)
-- RETURN QUERY
gaussdb=# CREATE OR REPLACE FUNCTION fun_for_return_query() RETURNS SETOF t1 AS $$
DECLARE
  r t1%ROWTYPE;
BEGIN
  RETURN QUERY select * from t1;
END;
$$
language plpgsql;
gaussdb=# call fun_for_return_query();
 a
---
 1
 10
(2 rows)
```

2.8.2 Conditional Statements

Conditional statements are used to decide whether given conditions are met. Operations are executed based on the decisions made.

GaussDB supports five usages of IF:

- IF_THEN

  Figure 2-22 shows the IF_THEN::= statement.

  Figure 2-22 IF_THEN::=

  
  IF_THEN is the simplest form of IF. If the condition is true, statements are executed. If it is false, they are skipped.

  Example:

  ```
  gaussdb=# DECLARE
      v_user_id integer default 1;
  BEGIN
  IF v_user_id <> 0 THEN
      raise info 'v_user_id is NOT 0';
  END IF;
  END;
  /
  INFO:  v_user_id is NOT 0
  ```

- IF_THEN_ELSE

  Figure 2-23 shows the IF_THEN_ELSE::= statement.

  Figure 2-23 IF_THEN_ELSE::=

  
 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

IF_THEN_ELSE has an ELSE branch and can be executed if the condition is false.

Example:

```
gaussdb=# DECLARE
    v_user_id integer default 0;
BEGIN
    IF v_user_id <> 0 THEN
        raise info 'v_user_id is NOT 0';
    ELSE
        raise info 'v_user_id is 0';
    END IF;
END;
/
INFO:  v_user_id is 0
```

- IF_THEN_ELSE IF

  IF statements can be nested in the following way:

```
gaussdb=# DECLARE
    v_user_id integer default 1;
BEGIN
    IF v_user_id = 0 THEN
        raise info 'v_user_id is  0';
    ELSE
        IF v_user_id > 0 THEN
            raise info 'v_user_id > 0';
        END IF;
    END IF;
END;
/
INFO:  v_user_id > 0
```

  Actually, this is a way of an IF statement nesting in the ELSE part of another IF statement. Therefore, an END IF statement is required for each nesting IF statement and another END IF statement is required to end the parent IF-ELSE statement. To set multiple options, use the following form:

- IF_THEN_ELSIF_ELSE

  Figure 2-24 shows the IF_THEN_ELSIF_ELSE::= statement.

  Figure 2-24 IF_THEN_ELSIF_ELSE::=

  Example:

```
gaussdb=# DECLARE
    v_user_id integer default NULL;
BEGIN
    IF v_user_id = 0 THEN
        raise info 'v_user_id is  0';
    ELSIF v_user_id > 0 THEN
        raise info 'v_user_id > 0';
    ELSIF v_user_id < 0 THEN
        raise info 'v_user_id < 0';
    ELSE
        raise info 'v_user_id is NULL';
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
    END IF;
END;
/
INFO:  v_user_id is NULL
```

- IF_THEN_ELSEIF_ELSE

  ELSEIF is an alias of ELSIF.

  Example:

```
gaussdb=# CREATE OR REPLACE PROCEDURE proc_control_structure(i in integer)
AS
    BEGIN
        IF i > 0 THEN
            raise info 'i:% is greater than 0. ',i;
        ELSIF i < 0 THEN
            raise info 'i:% is smaller than 0. ',i;
        ELSE
            raise info 'i:% is equal to 0. ',i;
        END IF;
        RETURN;
    END;
/
CREATE PROCEDURE

gaussdb=# CALL proc_control_structure(3);
INFO:  i:3 is greater than 0.
 proc_control_structure
------------------------

(1 row)

-- Drop a stored procedure.
gaussdb=# DROP PROCEDURE proc_control_structure;
DROP PROCEDURE
```

2.8.3 Loop Statements

Simple Loop Statements

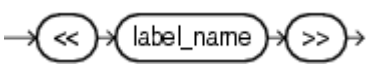
Syntax diagram

Figure 2-25 shows the loop::= statement.

Figure 2-25 loop::=

Figure 2-26 shows the label declaration ::= statement.

Figure 2-26 label declaration ::=



Example:

```
gaussdb=# CREATE OR REPLACE PROCEDURE proc_loop(i in integer, count out integer)
AS
```

```
    BEGIN
        count:=0;
        LOOP
        IF count > i THEN
            raise info 'count is %. ', count;
            EXIT;
        ELSE
            count:=count+1;
        END IF;
        END LOOP;
    END;
/
CREATE PROCEDURE

gaussdb=# CALL proc_loop(10,5);
INFO:  count is 11.
 count
-------
    11
(1 row)
```

NOTICE

The loop must be exploited together with EXIT; otherwise, a dead loop occurs.

WHILE_LOOP

Syntax diagram

Figure 2-27 shows the while_loop::= statement.

Figure 2-27 while_loop::=

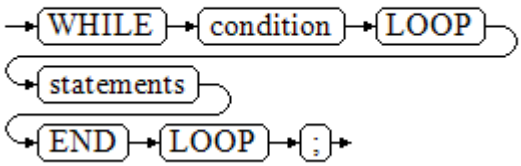


Figure 2-28 shows the label declaration ::= statement.

Figure 2-28 label declaration ::=

If the conditional expression is true, a series of statements in the WHILE statement are repeatedly executed and the condition is decided each time the loop body is executed.

Example:

```
gaussdb=# CREATE TABLE integertable(c1 integer) DISTRIBUTE BY hash(c1);
CREATE TABLE
gaussdb=# CREATE OR REPLACE PROCEDURE proc_while_loop(maxval in integer)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
AS
    DECLARE
    i int :=1;
    BEGIN
        WHILE i < maxval LOOP
            INSERT INTO integertable VALUES(i);
            i:=i+1;
        END LOOP;
    END;
/
CREATE PROCEDURE

-- Call a stored procedure.
gaussdb=# CALL proc_while_loop(10);
 proc_while_loop
-----------------

(1 row)

-- Drop a stored procedure and a table.
gaussdb=# DROP PROCEDURE proc_while_loop;
DROP PROCEDURE

gaussdb=# DROP TABLE integertable;
DROP TABLE
```

FOR_LOOP (*Integer variable*) *Statement*

Syntax diagram

Figure 2-29 shows the for_loop::= statement.

Figure 2-29 for_loop::=

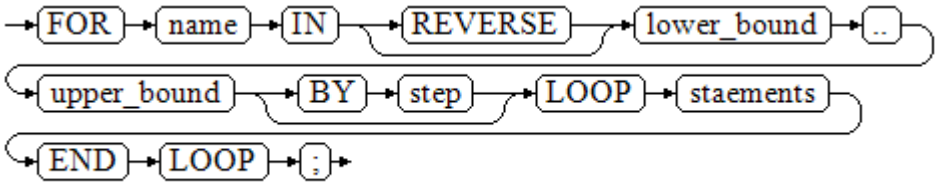

Figure 2-30 shows the label declaration ::= statement.

Figure 2-30 label declaration ::=

NOTE

- The variable *name* is automatically defined as the integer type and exists only in this loop. The variable name falls between lower_bound and upper_bound.
- When the keyword REVERSE is used, the lower bound must be greater than or equal to the upper bound; otherwise, the loop body is not executed.
- When FORALL is used together with BULK COLLECT INTO, the INTO variable returns only the execution result of a single DML statement.

Example:

```
-- Loop from 0 to 5.
gaussdb=# CREATE OR REPLACE PROCEDURE proc_for_loop()
```

```
AS
    BEGIN
    FOR I IN 0..5 LOOP
        DBE_OUTPUT.PRINT_LINE('It is '||to_char(I) || ' time;') ;
    END LOOP;
END;
/
CREATE PROCEDURE

-- Call a stored procedure.
gaussdb=# CALL proc_for_loop();
It is 0 time;
It is 1 time;
It is 2 time;
It is 3 time;
It is 4 time;
It is 5 time;
 proc_for_loop
---------------

(1 row)

-- Drop a stored procedure.
gaussdb=# DROP PROCEDURE proc_for_loop;
DROP PROCEDURE
```

FOR_LOOP

Syntax diagram

Figure 2-31 shows the for_loop_query::= statement.

Figure 2-31 for_loop_query::=

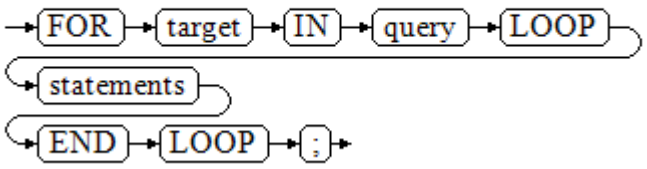

Figure 2-32 shows the label declaration ::= statement.

Figure 2-32 label declaration ::=

NOTE

- The variable *target* is automatically defined, its type is the same as that in the query result, and it is valid only in this loop. The target value is the query result.
- You can use EXECUTE to add a dynamic query and use USING to insert parameters to the query. For details, see the dynamic query content in **Example**.

Example:

```
-- Display the query result from the loop.
gaussdb=# CREATE OR REPLACE PROCEDURE proc_for_loop_query()
```

```
AS
    record VARCHAR2(50);
BEGIN
    FOR record IN SELECT spcname FROM pg_tablespace LOOP
    dbe_output.print_line(record);
    END LOOP;
END;
/
CREATE PROCEDURE

-- Call a stored procedure.
gaussdb=# CALL proc_for_loop_query();
pg_default
pg_global
 proc_for_loop_query
---------------------

(1 row)

-- Drop a stored procedure.
gaussdb=# DROP PROCEDURE proc_for_loop_query;
DROP PROCEDURE

-- Perform dynamic query.
gaussdb=# CREATE TABLE t1(id int);
gaussdb=# INSERT INTO t1 VALUES(1);
gaussdb=#
DECLARE
a int := 1;
item t1%rowtype;
BEGIN
    FOR item IN EXECUTE 'SELECT * FROM t1 WHERE id = :1' USING a LOOP
        RAISE INFO '%', item;
    END LOOP;
END;
/
INFO:  (1)
ANONYMOUS BLOCK EXECUTE
gaussdb=# DROP TABLE t1;
```

FORALL

Syntax diagram

Figure 2-33 shows the forall::= statement.

Figure 2-33 forall::=

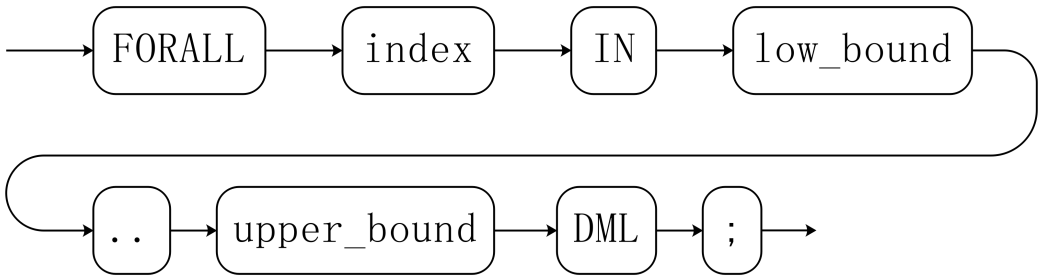

Figure 2-34 shows the label declaration:: statement.

Figure 2-34 label declaration ::=

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- The variable *index* is automatically defined as the integer type and exists only in this loop. The index value falls between low_bound and upper_bound.
- The FORALL loop body can contain only DML statements.

Example:

```
gaussdb=# CREATE TABLE TEST_t1 (
  title NUMBER(6),
  did VARCHAR2(20),
  data_period VARCHAR2(25),
  kind VARCHAR2(25),
  interval VARCHAR2(20),
  time DATE,
  isModified VARCHAR2(10)
)
DISTRIBUTE BY hash(did);
CREATE TABLE

gaussdb=# INSERT INTO TEST_t1 VALUES( 8, 'Donald', 'OConnell', 'DOCONNEL', '650.507.9833',
to_date('21-06-1999', 'dd-mm-yyyy'), 'SH_CLERK' );
INSERT 0 1
gaussdb=# CREATE OR REPLACE PROCEDURE proc_forall()
AS
BEGIN
    FORALL i IN 100..120
        update TEST_t1 set title = title + 100*i;
END;
/
CREATE PROCEDURE

-- Call a stored procedure.
gaussdb=# CALL proc_forall();
 proc_forall
-------------

(1 row)

-- Query the calling result of the stored procedure.
gaussdb=# SELECT * FROM TEST_t1;
 title  |  did   | data_period |   kind   |   interval   |        time         | ismodified
--------+--------+-------------+----------+--------------+---------------------+------------
 231008 | Donald | OConnell    | DOCONNEL | 650.507.9833 | 1999-06-21 00:00:00 | SH_CLERK
(1 row)

-- Drop a stored procedure and a table.
gaussdb=# DROP PROCEDURE proc_forall;
DROP PROCEDURE

gaussdb=# DROP TABLE TEST_t1;
DROP TABLE
```

2.8.4 Branching Statements

Syntax

Figure 2-35 shows the syntax diagram for a branching statement.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Figure 2-35 case_when::=

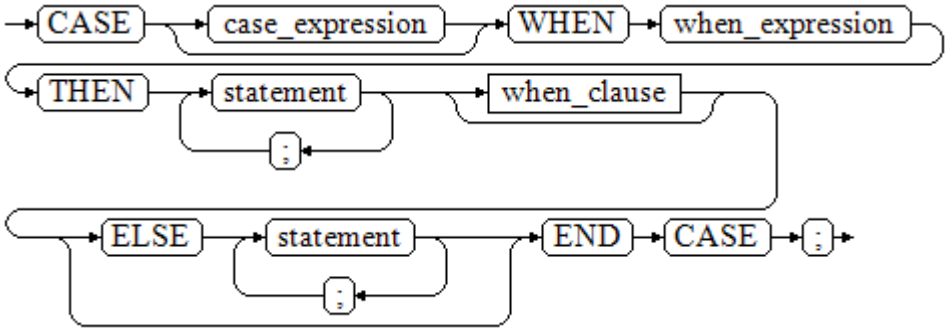

Figure 2-36 shows the syntax diagram for the WHEN clause.

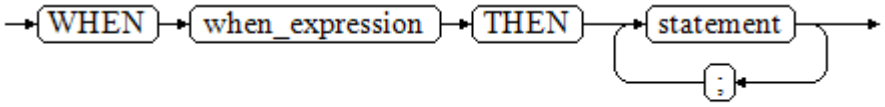
Figure 2-36 when_clause::=



Parameters:

- *case_expression*: specifies a variable or an expression.
- *when_expression*: specifies a constant or conditional expression.
- *statement*: specifies the statement to be executed.

Examples

```
gaussdb=# CREATE OR REPLACE PROCEDURE proc_case_branch(pi_result in integer, pi_return out integer)
AS
   BEGIN
      CASE pi_result
         WHEN 1 THEN
            pi_return := 111;
         WHEN 2 THEN
            pi_return := 222;
         WHEN 3 THEN
            pi_return := 333;
         WHEN 6 THEN
            pi_return := 444;
         WHEN 7 THEN
            pi_return := 555;
         WHEN 8 THEN
            pi_return := 666;
         WHEN 9 THEN
            pi_return := 777;
         WHEN 10 THEN
            pi_return := 888;
         ELSE
            pi_return := 999;
      END CASE;
      raise info 'pi_return : %',pi_return ;
END;
/
CREATE PROCEDURE

gaussdb=# CALL proc_case_branch(3,0);
```

gaussdb=# DROP PROCEDURE proc_case_branch;
DROP PROCEDURE
```

2.8.5 NULL Statements

In PL/SQL programs, NULL statements are used to indicate "nothing should be done", equal to placeholders. They grant meanings to some statements and improve program readability.

Syntax

The following shows example use of NULL statements:

```
DECLARE
   ...
BEGIN
   ...
   IF v_num IS NULL THEN
      NULL; -- No data needs to be processed.
   END IF;
END;
/
```

Parameters:

- *v_num*: specifies a variable or expression.

Example

```
gaussdb=# DECLARE
   v_num integer default NULL;
BEGIN
   IF v_num IS NOT NULL THEN
      raise info 'v_num is NULL';
   ELSE
      NULL; -- No data needs to be processed.
   END IF;
END;
/
ANONYMOUS BLOCK EXECUTE
```

2.8.6 Error Trapping Statements

By default, any error occurring in a PL/SQL function aborts execution of the function, and indeed of the surrounding transaction as well. You can trap errors and restore from them by using a BEGIN block with an EXCEPTION clause. The syntax is an extension of the normal syntax for a BEGIN block:

```
[<<label>>]
[DECLARE
   declarations]
BEGIN
   statements
EXCEPTION
   WHEN condition [OR condition ...] THEN
      handler_statements
   [WHEN condition [OR condition ...] THEN
      handler_statements
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
    ...]
END;
```

If no error occurs, this form of block simply executes all the statements, and then control passes to the next statement after END. But if an error occurs within the statements, further processing of the statements is abandoned and the statements will be rolled back, and then the control passes to the EXCEPTION list. The list is searched for the first condition matching the error that occurred. If a match is found, the corresponding **handler_statements** are executed, and then the control passes to the next statement after END. If no match is found, the error propagates out as if the EXCEPTION clause was not there at all: Error codes can be used to catch other error codes of the same type.

The error can be caught by an enclosing block with EXCEPTION, or if there is none it aborts processing of the function.

The condition name can be any value listed as an SQL standard error code description. The special condition name **OTHERS** matches every error type except **QUERY_CANCELED**.

If a new error occurs within the selected **handler_statements**, it cannot be caught by this EXCEPTION clause, but is propagated out. A surrounding EXCEPTION clause could catch it.

When an error is caught by an EXCEPTION clause, the local variables of the PL/SQL function remain as they were when the error occurred, but all changes to persistent database state within the block are rolled back.

Example:

```
gaussdb=# CREATE TABLE mytab(id INT,firstname VARCHAR(20),lastname VARCHAR(20)) DISTRIBUTE BY
hash(id);
CREATE TABLE

gaussdb=# INSERT INTO mytab(firstname, lastname) VALUES('Tom', 'Jones');
INSERT 0 1

gaussdb=# CREATE FUNCTION fun_exp() RETURNS INT
AS $$
DECLARE
    x INT :=0;
    y INT;
BEGIN
    UPDATE mytab SET firstname = 'Joe' WHERE lastname = 'Jones';
    x := x + 1;
    y := x / 0;
EXCEPTION
    WHEN division_by_zero THEN
        RAISE NOTICE 'caught division_by_zero';
        RETURN x;
END;$$
LANGUAGE plpgsql;
CREATE FUNCTION

gaussdb=# call fun_exp();
NOTICE:  caught division_by_zero
 fun_exp
---------
       1
(1 row)

gaussdb=# select * from mytab;
 id | firstname | lastname
----+-----------+----------
    | Tom       | Jones
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
(1 row)

gaussdb=# DROP FUNCTION fun_exp();
DROP FUNCTION

gaussdb=# DROP TABLE mytab;
DROP TABLE
```

When the control reaches the assignment to **y**, it will fail with a **division_by_zero** error. This will be caught by the EXCEPTION clause. The value returned from the RETURN statement will be the incremented value of **x**.

NOTE

- A block containing an EXCEPTION clause is more expensive to enter and exit than a block without one. Therefore, do not use EXCEPTION unless necessary.
- The following exceptions cannot be captured and the entire stored procedure is rolled back: 1. The node is faulty. 2. The thread of the node involved in the stored procedure exits due to a network fault. In addition, the definition of the source table is inconsistent with that of the target table in the COPY FROM operation. 3. An exception occurs during subtransaction clearing. (For a stored procedure that contains the EXCEPTION statement, an implicit subtransaction is started when the statement is executed. After the statement is executed, the subtransaction is automatically cleared. During the clearing, an exception may occur due to memory control.)

Example: UPDATE/INSERT exception

This example explains how to perform either UPDATE or INSERT appropriately with exception handler:

```
gaussdb=# CREATE TABLE db (a INT, b TEXT);
NOTICE:  The 'DISTRIBUTE BY' clause is not specified. Using 'a' as the distribution column by default.
HINT:  Please use 'DISTRIBUTE BY' clause to specify suitable data distribution column.
CREATE TABLE
gaussdb=# CREATE FUNCTION merge_db(key INT, data TEXT) RETURNS VOID AS
$$
BEGIN
    LOOP

-- First try to update the key
        UPDATE db SET b = data WHERE a = key;
        IF found THEN
            RETURN;
        END IF;
-- The key does not exist. Therefore, try to insert one. If someone else inserts the same key concurrently, the
unique key may fail to be obtained.
        BEGIN
            INSERT INTO db(a,b) VALUES (key, data);
            RETURN;
        EXCEPTION WHEN unique_violation THEN
        -- Do nothing, and loop to try the UPDATE operation again.
        END;
    END LOOP;
END;
$$
LANGUAGE plpgsql;
CREATE FUNCTION

gaussdb=# SELECT merge_db(1, 'david');
 merge_db
----------

(1 row)

gaussdb=# SELECT merge_db(1, 'dennis');
 merge_db
----------
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
(1 row)

-- Drop the function and table.
gaussdb=# DROP FUNCTION merge_db;
DROP FUNCTION

gaussdb=# DROP TABLE db ;
DROP TABLE
```

In ORA-compatible mode, if the **'on(PLSQL_RETURN_EXCEPTION)'** option is enabled for the GUC parameter **exec_behavior_knob**, the error returned during statement type conversion is captured by the EXCEPTION clause. If the option is disabled, the error is not captured by the EXCEPTION clause. For details, see **exec_behavior_knob**.

```
gaussdb=# CREATE OR REPLACE FUNCTION func RETURN INT AS
BEGIN
    RETURN 'abc';
    EXCEPTION WHEN OTHERS THEN
    RETURN 123;
END;
/
CREATE FUNCTION
gaussdb=# set exec_behavior_knob='on(PLSQL_RETURN_EXCEPTION)';
SET
gaussdb=# SELECT func();
 func

referenced column: func
gaussdb=# DROP FUNCTION IF EXISTS func;
DROP FUNCTION
```

2.8.6.1 Obtaining Exception Information

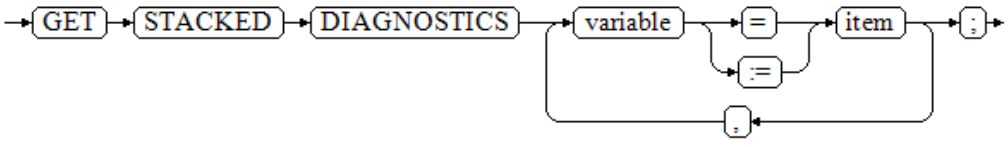
You can use the GET STACKED DIAGNOSTICS statement to query the exception information during the execution of the current PL/SQL function.

Syntax

```
GET STACKED DIAGNOSTICS {{variable { = | := } item }[ , ... ]};
```

Figure 2-37 shows the syntax diagram.

Figure 2-37 Syntax for obtaining error information



In the preceding information, **item** indicates the diagnosis item dedicated to exceptions. Currently, the following diagnosis items are available:

- **PG_EXCEPTION_DETAIL**: error details.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **PG_EXCEPTION_HINT**: error prompt.
- **PG_EXCEPTION_CONTEXT**: call stack information about the exception.
- **MESSAGE_TEXT**: main error information.
- **RETURNED_SQLSTATE**: SQLSTATE error code of the exception.

Examples

```
gaussdb=# CREATE TABLE diag_table(int_col int, str_col varchar2);
CREATE TABLE
gaussdb=# CREATE OR REPLACE PROCEDURE get_diag_proc() AS
DECLARE
    sql_state text;
    message_text text;
    pg_exception_detail text;
    pg_exception_hint text;
    pg_exception_context text;
BEGIN
    UPDATE diag_table set int_col = 'aaa';
    EXCEPTION WHEN others THEN
        GET STACKED DIAGNOSTICS sql_state = returned_sqlstate;
        GET STACKED DIAGNOSTICS message_text = message_text;
        GET STACKED DIAGNOSTICS pg_exception_detail = pg_exception_detail;
        GET STACKED DIAGNOSTICS pg_exception_hint = pg_exception_hint;
        GET STACKED DIAGNOSTICS pg_exception_context = pg_exception_context;
        raise info 'sql_state: %, message_text: %', sql_state, message_text;
END;
/
CREATE PROCEDURE
gaussdb=# CALL get_diag_proc();
INFO:  sql_state: 22P02, message_text: invalid input syntax for integer: "aaa"
 get_diag_proc
---------------

(1 row)

gaussdb=# DROP TABLE diag_table;
DROP TABLE
gaussdb=# DROP PROCEDURE get_diag_proc();
DROP PROCEDURE
```

2.8.6.2 Obtaining Current Execution Information

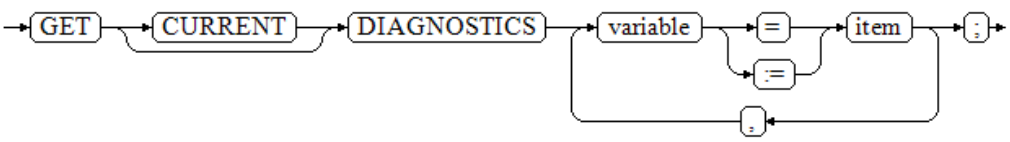
You can use the GET [CURRENT] DIAGNOSTICS statement to query the status information during the execution of the current PL/SQL function.

Syntax

```
GET [ CURRENT ] DIAGNOSTICS {{variable { = | := } item }[ , ... ]};
```

Figure 2-38 shows the syntax diagram.

Figure 2-38 Syntax for obtaining current execution information



In the preceding information, **item** indicates the diagnosis item in the execute state. Currently, the following diagnosis items are available:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **ROW_COUNT**: number of rows processed by the previous SQL statement.
- **RESULT_OID**: OID of the previous INSERT statement.

Examples

```
gaussdb=# CREATE TABLE diag_table(int_col int, str_col varchar2);
CREATE TABLE
gaussdb=# CREATE OR REPLACE PROCEDURE get_diag_proc() AS
DECLARE
    nrows INT;
    result_oid oid;
BEGIN
    INSERT INTO diag_table values(1, 'aaa');
    GET CURRENT DIAGNOSTICS nrows = row_count;
    GET CURRENT DIAGNOSTICS result_oid = result_oid;
    raise info 'row_count: %, result_oid: %', nrows, result_oid;
END;
/
CREATE PROCEDURE
gaussdb=# CALL get_diag_proc();
INFO:  row_count: 1, result_oid: 0
 get_diag_proc
---------------

(1 row)

gaussdb=# DROP TABLE diag_table;
DROP TABLE
gaussdb=# DROP PROCEDURE get_diag_proc();
DROP PROCEDURE
```

2.8.7 GOTO Statements

A GOTO statement unconditionally transfers the control from the current statement to a labeled statement. The GOTO statement changes the execution logic. Therefore, use this statement only when necessary. Alternatively, you can use the EXCEPTION statement to handle issues in special scenarios. To execute a GOTO statement, the labeled statement must be unique.

Syntax

Figure 2-39 shows the label declaration ::= statement.

Figure 2-39 label declaration ::

Figure 2-40 shows the goto statement ::= statement.

Figure 2-40 goto statement ::

Examples

```
gaussdb=# CREATE OR REPLACE PROCEDURE GOTO_test()
AS
DECLARE
   v1  int;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
BEGIN
   v1  := 0;
      LOOP
      EXIT WHEN v1 > 100;
            v1 := v1 + 2;
            if v1 > 25 THEN
                  GOTO pos1;
            END IF;
      END LOOP;
<<pos1>>
v1 := v1 + 10;
raise info 'v1 is %. ', v1;
END;
/
CREATE PROCEDURE
gaussdb=# call GOTO_test();
INFO:  v1 is 36.
 goto_test
-----------

(1 row)
```

Limitations

Using GOTO statements has the following limitations:

- Do not use multiple GOTO statements with the same label even if the statements are in different blocks.

  ```
  BEGIN
    GOTO pos1;
    <<pos1>>
    SELECT * FROM ...
    <<pos1>>
    UPDATE t1 SET ...
  END;
  ```

- A GOTO statement cannot transfer control to the IF, CASE, or LOOP statement.

  ```
  BEGIN
    GOTO pos1;
    IF valid THEN
      <<pos1>>
      SELECT * FROM ...
    END IF;
  END;
  ```

- A GOTO statement cannot transfer control from one IF clause to another, or from one WHEN clause in the CASE statement to another.

  ```
  BEGIN
    IF valid THEN
      GOTO pos1;
      SELECT * FROM ...
    ELSE
      <<pos1>>
      UPDATE t1 SET ...
    END IF;
  END;
  ```

- Transferring control from an outer block to an inner BEGIN-END block is not supported.

  ```
  BEGIN
    GOTO pos1;
    BEGIN
      <<pos1>>
      UPDATE t1 SET ...
    END;
  END;
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- Transferring control from an exception handler to the current BEGIN-END block is not supported. However, transferring control to the upper-layer BEGIN-END block is supported.

```
BEGIN
  <<pos1>>
  UPDATE t1 SET ...
  EXCEPTION
    WHEN condition THEN
      GOTO pos1;
END;
```

- To branch to a position that does not have an executable statement, you need to add the NULL statement.

```
DECLARE
  done  BOOLEAN;
BEGIN
  FOR i IN 1..50 LOOP
    IF done THEN
      GOTO end_loop;
    END IF;
    <<end_loop>>  -- You cannot run the GOTO statement to go here unless there is an executable
statement following it.
    NULL; -- The statement added here is used to avoid errors.
  END LOOP;  -- If the previous sentence NULL does not exist, an error will be reported.
END;
/
```

2.9 Transaction Statements

A stored procedure itself is automatically in a transaction. A transaction is automatically started when the outmost stored procedure is called. In addition, the transaction is automatically committed when the calling ends, or is rolled back when an exception occurs during calling. In addition to automatic transaction control, you can also use COMMIT/ROLLBACK to control transactions in stored procedures. Running the COMMIT/ROLLBACK commands in a stored procedure will commit or roll back the current transaction and automatically starts a new transaction. All subsequent operations will be performed in the new transaction.

A savepoint is a special mark inside a transaction. It allows all commands that are executed after it was established to be rolled back, restoring the transaction state to what it was at the time of the savepoint. In a stored procedure, you can use savepoints to manage transactions. Currently, you can create, roll back, and release savepoints. If a savepoint for rollback is used in a stored procedure, only the modification of the current transaction is rolled back. The execution process of the stored procedure is not changed, and the values of local variables in the stored procedure are not rolled back.

Syntax

```
Define a savepoint.
   SAVEPOINT savepoint_name;
Roll back a savepoint.
   ROLLBACK TO [SAVEPOINT] savepoint_name;
Release a savepoint.
   RELEASE [SAVEPOINT] savepoint_name;
```

Application Scenarios

The applicable contexts are as follows:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- COMMIT, ROLLBACK, and SAVEPOINT can be used in PL/SQL stored procedures/functions.
- COMMIT, ROLLBACK, and SAVEPOINT can be used in stored procedures and functions that contain EXCEPTION.
- COMMIT, ROLLBACK, and SAVEPOINT can be used in EXCEPTION statements of stored procedures.
- A stored procedure that contains COMMIT, ROLLBACK, or SAVEPOINT (which means the stored procedure is controlled by BEGIN, START, or END) can be called in a transaction block.
- A stored procedure that contains savepoints can be called in a subtransaction and an externally defined savepoint is used to roll back the transaction to the savepoint defined outside the stored procedure.
- A savepoint defined in the stored procedure can be viewed outside the stored procedure. That is, the modification of the transaction can be rolled back to the savepoint defined in the stored procedure.
- COMMIT, ROLLBACK, and SAVEPOINT, as well as IF, FOR, CURSOR LOOP, and WHILE, can be called in most PL/SQL contexts and statements.

The following content can be committed or rolled back:

- DDL statements after COMMIT or ROLLBACK can be committed or rolled back.
- DML statements after COMMIT or ROLLBACK can be committed.
- GUC parameters in stored procedures can be committed or rolled back.

Limitations

The following contexts are not applicable:

- COMMIT, ROLLBACK, and SAVEPOINT cannot be called in stored procedures other than PL/SQL, such as PL/Python.
- After SAVEPOINT is called in a transaction block, stored procedures that contain COMMIT/ROLLBACK cannot be called.
- Stored procedures that contain COMMIT, ROLLBACK, or SAVEPOINT cannot be called in TRIGGER.
- COMMIT, ROLLBACK, and SAVEPOINT cannot be called in EXECUTE statements.
- Stored procedures that contain COMMIT, ROLLBACK, or SAVEPOINT cannot be called in CURSOR statements.
- Stored procedures that contain IMMUTABLE or SHIPPABLE cannot call COMMIT, ROLLBACK, SAVEPOINT or another stored procedure that contains COMMIT, ROLLBACK, or SAVEPOINT.
- Stored procedures that contain COMMIT, ROLLBACK, or SAVEPOINT cannot be called in SQL statements other than SELECT PROC and CALL PROC.
- COMMIT, ROLLBACK, or SAVEPOINT cannot be called in a stored procedure whose header contains GUC parameters.
- COMMIT, ROLLBACK, or SAVEPOINT cannot be called in expressions or CURSOR and EXECUTE statements.
- Stored procedures that contain COMMIT, ROLLBACK, or SAVEPOINT cannot be called in the return values and expression calculation of stored procedures.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- Savepoints defined outside a stored procedure cannot be released in the stored procedure.
- A stored procedure transaction and its autonomous transaction are two independent transactions and cannot use savepoints defined in each other's transaction.
- Advanced packages cannot call stored procedures that contain COMMIT, ROLLBACK, or SAVEPOINT statements through DBE_SQL.

The following content cannot be committed or rolled back:

- Variables declared or imported in stored procedures cannot be committed or rolled back.
- In stored procedures, GUC parameters that take effect only after a restart cannot be committed or rolled back.

NOTE

Executing the **COMMIT** or **ROLLBACK** statement in a stored procedure, function, or anonymous block does not update the statistics records in the PG_STAT-related system catalogs immediately. The statistics are updated only after the outermost transaction is complete. Therefore, when a large amount of data is updated through stored procedures, functions, or anonymous blocks, related statistics may not be updated in a timely manner.

Examples

- Example 1: COMMIT and ROLLBACK can be used in PL/SQL stored procedures. Subsequent examples depend on this case.

```
gaussdb=# DROP TABLE IF EXISTS EXAMPLE1;
gaussdb=# CREATE TABLE EXAMPLE1(COL1 INT);

gaussdb=# CREATE OR REPLACE PROCEDURE TRANSACTION_EXAMPLE()
AS
BEGIN
    FOR i IN 0..20 LOOP
        INSERT INTO EXAMPLE1(COL1) VALUES (i);
        IF i % 2 = 0 THEN
            COMMIT;
        ELSE
            ROLLBACK;
        END IF;
    END LOOP;
END;
/
gaussdb=# call TRANSACTION_EXAMPLE();
 transaction_example
---------------------

(1 row)
```

- Example 2:

  COMMIT and ROLLBACK can be used in stored procedures that contain EXCEPTION.

  COMMIT and ROLLBACK can be used in EXCEPTION statements of stored procedures.

  DDL statements after COMMIT or ROLLBACK can be committed or rolled back.

```
gaussdb=# DROP TABLE IF EXISTS EXAMPLE1;
gaussdb=# CREATE TABLE EXAMPLE1(COL1 INT);
gaussdb=# CREATE OR REPLACE PROCEDURE TEST_COMMIT_INSERT_EXCEPTION_ROLLBACK()
AS
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

2.10 Other Statements

2.10.1 Lock Operations

GaussDB provides multiple lock modes to control concurrent access to table data.

These modes are used when Multi-Version Concurrency Control (MVCC) cannot deliver expected behaviors.

Most GaussDB commands automatically apply appropriate locks to ensure that referenced tables are not deleted or modified in an incompatible manner during command execution. For example, when concurrent operations exist, ALTER TABLE cannot be executed on the same table.

2.10.2 Cursor Operations

GaussDB provides cursors as a data buffer for users to store execution results of SQL statements. Each cursor area has a name. Users can use SQL statements to fetch records one by one from cursors and grant the records to host variables, then being processed further by the host language.

Cursor operations include cursor definition, opening, fetching, and closing.

For the complete example of cursor operations, see **Explicit Cursors**.

2.11 Cursors

2.11.1 Overview

To process SQL statements, the stored procedure process assigns a memory segment to store context information. Cursors are handles or pointers pointing to context areas. With cursors, stored procedures can control alterations in context areas.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTICE

- When a stored procedure uses returns to return a cursor, if JDBC is used to call the stored procedure, the returned cursor is unavailable. Using the **out** parameters is not affected.
- In distributed mode, if the parameter of the stored procedure called in the SQL statement is of the refcursor type or the return value is of the refcursor type, pushdown is not supported.
- When a stored procedure contains COMMIT/ROLLBACK, an explicit cursor caches all data of the cursor to ensure that the cursor is still available after COMMIT/ROLLBACK. If the cursor data volume is large, this process may take a long time.
- The FETCH cursor data in a stored procedure is stored in the specified output variables. If the number of output variables is greater than the number of data columns in the actual cursor query result set, null values are assigned to the extra variables, and no error is reported. If the number of output variables is less than the number of data columns in the actual cursor query result set, the extra columns are silently discarded, and no error is reported.
- When the GUC parameter **forbid_hold_cursor_with_forupdate** is enabled, if a cursor has the FOR UPDATE or FOR SHARE feature and is used in a cursor loop or FOR loop query statement, an error will be reported when the cursor is accessed in the next loop after a transaction is committed or rolled back.
- When the **plstmt_implicit_savepoint** option of the GUC parameter **behavior_compat_options** is enabled, if an error is reported when a cursor executes an SQL statement pushed down to a DN, the transaction will be abnormal and cannot be captured by EXCEPTION.

Cursors are classified into explicit cursors and implicit cursors. **Table 2-2** shows the usage conditions of explicit and implicit cursors for different SQL statements.

Table 2-2 Cursor usage conditions

SQL Statement	Cursor
Non-query statements	Implicit
Query statements with single-line results	Implicit or explicit
Query statements with multi-line results	Explicit

2.11.2 Explicit Cursors

An explicit cursor is used to process query statements, particularly when the query result contains multiple records.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

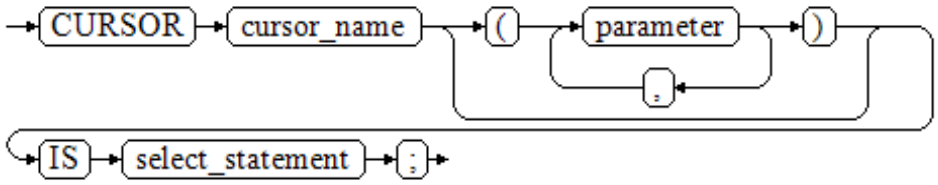
Procedure

An explicit cursor performs the following six PL/SQL steps to process query statements:

Step 1 Define a static cursor: Define a cursor name and its SELECT statement.

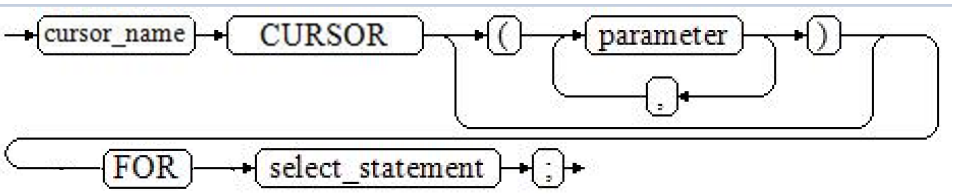
Figure 2-41 and **Figure 2-42** show the syntax diagrams for defining a static cursor.

Figure 2-41 static_cursor_define::=



or

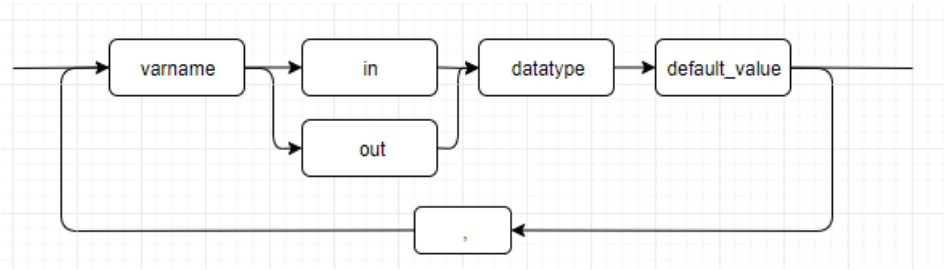
Figure 2-42 static_cursor_define::=



Parameters:

- **cursor_name**: defines a cursor name.
- **parameter**: cursor parameter, which can only be an input parameter. The default value can be defined by **:=**, **=**, or **default**. For details about the format, see **Figure 2-43**.

  Figure 2-43 Reference diagram for using the parameter format

- *select_statement*: specifies a query statement.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- The system automatically determines whether the cursor can be used for backward fetching based on the execution plan.
- In syntax, **parameter** can be an output parameter, but its behavior is the same as that of an input parameter.
- It is automatically disabled in the exception.
- For a cursor with parameters created in a package, the cursor parameters can be used as variables.

Define a dynamic cursor: Define a ref cursor, which means that the cursor can be opened dynamically by a set of static SQL statements. Define the type of the ref cursor first, and then the cursor variable of this cursor type. Dynamically bind a SELECT statement through OPEN FOR when the cursor is opened.

Figure 2-44 and **Figure 2-45** show the syntax diagrams for defining a dynamic cursor.

Figure 2-44 cursor_typename::=

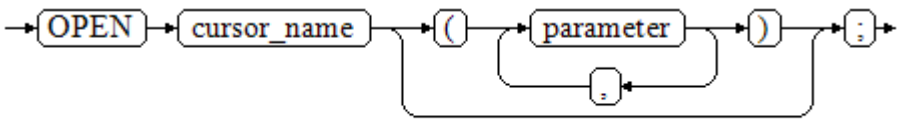
GaussDB supports the dynamic cursor type **sys_refcursor**. A function or stored procedure can use the **sys_refcursor** parameter to pass on or pass out the cursor result set. A function can return **sys_refcursor** to return the cursor result set.

Figure 2-45 dynamic_cursor_define::=

Step 2 Open the static cursor: Execute the SELECT statement corresponding to the cursor. After that, the query result will be placed in the workspace and the pointer directs to the head of the workspace to identify the cursor result set. If the cursor query statement carries the **FOR UPDATE** option, the OPEN statement locks the data rows corresponding to the cursor result set in the database table.

Figure 2-46 shows the syntax diagram for opening a static cursor.

Figure 2-46 open_static_cursor::=

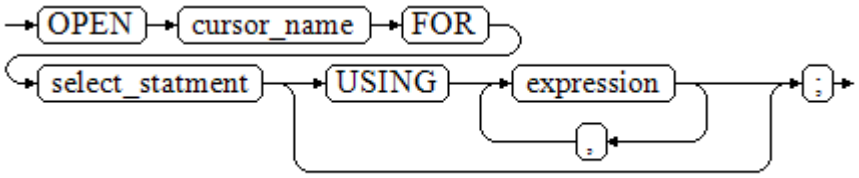


Open the dynamic cursor: Use the OPEN FOR statement to open the dynamic cursor, so that the SQL statement is dynamically bound.

Figure 2-47 shows the syntax diagram for opening a dynamic cursor.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Figure 2-47 open_dynamic_cursor::=

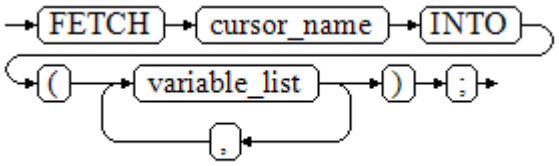


A PL/SQL program cannot use the OPEN statement to repeatedly open a cursor.

Step 3 Fetch cursor data: Retrieve data rows in the result set and place them in specified output variables.

Figure 2-48 shows the syntax diagram for fetching cursor data.

Figure 2-48 fetch_cursor::=



Step 4 Process the record.

Step 5 Continue to process until the active set has no record.

Step 6 Close the cursor: After you fetch and process the data in the cursor result set, close the cursor in time to release system resources used by the cursor and invalidate the workspace of the cursor so that the FETCH statement cannot be used to fetch data anymore. A closed cursor can be reopened by an OPEN statement.

Figure 2-49 shows the syntax diagram for closing a cursor.

Figure 2-49 close_cursor::=

----End

Attributes

Cursor attributes are used to control program procedures or learn about program status. When a DML statement is executed, the PL/SQL opens a built-in cursor and processes its result. A cursor is a memory segment for maintaining query results. It is opened when a DML statement is executed and closed when the execution is finished. An explicit cursor has the following attributes:

- **%FOUND**: Boolean attribute, which returns **TRUE** if the last fetch returns a row.
- **%NOTFOUND**: Boolean attribute, which returns **TRUE** if the last fetch fails to return a row.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **%ISOPEN**: Boolean attribute, which returns **TRUE** if the cursor has been opened.
- **%ROWCOUNT**: numeric attribute, which returns the number of records fetched from the cursor.

Examples

DDL and DML statements are prepared. Subsequent examples in this section depend on this case.

```
gaussdb=# drop schema if exists hr cascade;

1
1
ANONYMOUS BLOCK EXECUTE
-- Drop a stored procedure.
gaussdb=# DROP PROCEDURE proc_sys_ref;
```

2.11.3 Implicit Cursors

Implicit cursors are automatically set by the system for non-query statements such as modification and deletion operations, along with their workspace. Implicit cursors are named **SQL**, which is defined by the system.

Overview

Implicit cursor operations, such as definition, opening, data fetching, and closing, are automatically performed by the system and do not need to be processed by users. Users can use only attributes related to implicit cursors to complete operations. In workspace of implicit cursors, the data of the latest SQL statement is stored and is not related to explicit cursors defined by users.

Format call: **SQL%**

NOTE

- INSERT, UPDATE, DELETE, and SELECT statements do not need defined cursors.
- Implicit cursor attributes are not affected by the commit or rollback operation.
- If an exception is triggered by a DML statement in a stored procedure, the implicit cursor attribute value is not affected by the execution of the DML statement and retains the value before the DML statement is executed.

Attributes

An implicit cursor has the following attributes:

- **SQL%FOUND**: Boolean attribute, which returns **TRUE** if the last fetch returns a row.
- **SQL%NOTFOUND**: Boolean attribute, which returns **TRUE** if the last fetch fails to return a row.
- **SQL%ROWCOUNT**: numeric attribute, which returns the number of records fetched from the cursor.
- **SQL%ISOPEN**: Boolean attribute, whose value is always **FALSE**. Close implicit cursors immediately after an SQL statement is run.

Examples

```
-- Delete all employees in a department from the hr.staffs table. If the department has no employees, delete the department from the hr.department table.

gaussdb=# CREATE OR REPLACE PROCEDURE proc_cursor3()
AS
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
    DECLARE
    V_DEPTNO NUMBER(4) := 100;
    BEGIN
        DELETE FROM hr.staffs WHERE section_id = V_DEPTNO;
        -- Proceed based on cursor status.
        IF SQL%NOTFOUND THEN
        DELETE FROM hr.department WHERE section_id = V_DEPTNO;
        END IF;
    END;
/

gaussdb=# CALL proc_cursor3();
 proc_cursor3
--------------

(1 row)

-- Drop the stored procedure and the temporary table.
gaussdb=# DROP PROCEDURE proc_cursor3;
```

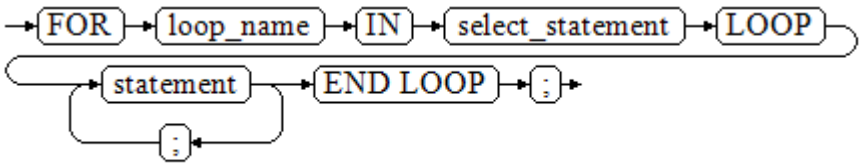
2.11.4 Cursor Loop

Use of cursors in WHILE and LOOP statements is called a cursor loop. Generally, OPEN, FETCH, and CLOSE statements are called in this kind of loop. The following describes a loop that simplifies a cursor loop without the need for these operations. This mode is applicable to a static cursor loop, without executing four steps about a static cursor.

Syntax

Figure 2-50 shows the syntax diagram of a FOR AS loop.

Figure 2-50 FOR_AS_loop::=



Precautions

- The UPDATE operation for the queried table is not allowed in the loop statement.
- The variable *loop_name* is automatically defined and is valid only in this loop. Its type is the same as that in the query result of *select_statement*. The value of *loop_name* is the query result of *select_statement*.
- The specific type of the **loop_name** variable is not parsed during compilation. If the specific type needs to be parsed (for example, **loop_name** is used as the INOUT parameters of an overloaded function or stored procedure), a compilation error is reported.

Examples

```
gaussdb=# DROP SCHEMA IF EXISTS hr CASCADE;
gaussdb=# CREATE SCHEMA hr;
gaussdb=# SET current_schema = hr;
-- Create an employee table.
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gaussdb=# CREATE TABLE staffs(
    staff_id number(6),
    salary number(8,2),
    section_id int,
    first_name varchar(20)
);
gaussdb=# INSERT INTO staffs VALUES (1,100,1,'Tom');
gaussdb=# BEGIN
FOR ROW_TRANS IN
        SELECT first_name FROM hr.staffs
    LOOP
        DBE_OUTPUT.PRINT_LINE (ROW_TRANS.first_name );
    END LOOP;
END;
/
-- Execution result.
gaussdb=# Tom
ANONYMOUS BLOCK EXECUTE
```

2.12 Advanced Packages

Advanced packages are classified into two sets of APIs: basic APIs and secondary encapsulation APIs which are used to improve usability. The second set is recommended.

2.12.1 Basic APIs

2.12.1.1 PKG_SERVICE

Table 2-3 lists APIs supported by PKG_SERVICE.

Table 2-3 PKG_SERVICE

API	Description
PKG_SERVICE.SQL_IS_CONTEXT_ACTIVE	Checks whether a context is registered.
PKG_SERVICE.SQL_CLEAN_ALL_CONTEXTS	Deregisters all contexts.
PKG_SERVICE.SQL_REGISTER_CONTEXT	Registers a context.
PKG_SERVICE.SQL_UNREGISTER_CONTEXT	Deregisters a context.
PKG_SERVICE.SQL_SET_SQL	Sets an SQL statement for a context. Currently, only the SELECT statement is supported.
PKG_SERVICE.SQL_RUN	Executes the SQL statement configured for a context.
PKG_SERVICE.SQL_NEXT_ROW	Reads the next row of data in a context.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

API	Description
PKG_SERVICE.SQL_GET_VALUE	Reads a dynamically defined column value in a context.
PKG_SERVICE.SQL_SET_RESULT_TYPE	Dynamically defines a column of a context based on the type OID.
PKG_SERVICE.JOB_CANCEL	Removes a scheduled task by task ID.
PKG_SERVICE.JOB_FINISH	Disables or enables scheduled job execution.
PKG_SERVICE.JOB_SUBMIT	Submits a scheduled job. Job ID can be automatically generated by the system or specified manually.
PKG_SERVICE.JOB_UPDATE	Modifies attributes of a scheduled job, including the job content, next-execution time, and execution interval.
PKG_SERVICE.SUBMIT_ON_NODES	Submits a job to all nodes. The job ID is automatically generated by the system.
PKG_SERVICE.ISUBMIT_ON_NODES	Submits a job to all nodes. The job ID is specified by the user.
PKG_SERVICE.SQL_GET_ARRAY_RESULT	Obtains the array value returned from the context.
PKG_SERVICE.SQL_GET_VARIABLE_RESULT	Obtains the column value returned from the context.

NOTE

When the EXECUTE DIRECT ON syntax is used to execute functions in the PKG_SERVICE package, if the GUC parameter **enable_udf_execute_direct** is set to **on**, the functions can be executed; if the parameter is set to **off**, the functions cannot be executed.

- PKG_SERVICE.SQL_IS_CONTEXT_ACTIVE

  Checks whether a context is registered. This function passes the ID of the context to be queried. If the context exists, **true** is returned. Otherwise, **false** is returned.

  The prototype of PKG_SERVICE.SQL_IS_CONTEXT_ACTIVE is as follows:

```
PKG_SERVICE.SQL_IS_CONTEXT_ACTIVE(
 context_id     IN INTEGER
)
RETURN BOOLEAN;
```

Table 2-4 PKG_SERVICE.SQL_IS_CONTEXT_ACTIVE API parameters

Parameter	Description
context_id	ID of the context to be queried.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- PKG_SERVICE.SQL_CLEAN_ALL_CONTEXTS

  Deregisters all contexts.

  The prototype of PKG_SERVICE.SQL_CLEAN_ALL_CONTEXTS is as follows:

  ```
  PKG_SERVICE.SQL_CLEAN_ALL_CONTEXTS(
  )
  RETURN VOID;
  ```

- PKG_SERVICE.SQL_REGISTER_CONTEXT

  Registers a context. Registering a context is the prerequisite for performing operations on the context. This function does not require any input parameter. It automatically generates a context ID in ascending order and assigns the context ID as a return value to an integer variable.

  The prototype of PKG_SERVICE.SQL_REGISTER_CONTEXT is as follows:

  ```
  DBE_SQL.REGISTER_CONTEXT(
  )
  RETURN INTEGER;
  ```

- PKG_SERVICE.SQL_UNREGISTER_CONTEXT

  Deregisters a context. Deregistering a context is the end of all operations on the context. If this function is not called when a stored procedure ends, the memory occupied by the context will not be released. Therefore, remember to deregister the context. If an exception occurs, the stored procedure may exit prematurely, resulting in the context not being deregistered. You are advised to include this API in the exception handling of the stored procedure.

  The prototype of PKG_SERVICE.SQL_UNREGISTER_CONTEXT is as follows:

  ```
  PKG_SERVICE.SQL_UNREGISTER_CONTEXT(
   context_id     IN INTEGER
  )
  RETURN INTEGER;
  ```

  Table 2-5 PKG_SERVICE.SQL_UNREGISTER_CONTEXT API parameters

Parameter	Description
context_id	ID of the context to be deregistered.

- PKG_SERVICE.SQL_SET_SQL

  This function parses the query statement of a specified cursor. The passed query statement is executed immediately. Currently, only the SELECT query statement can be parsed. The statement parameters can be specified only through the TEXT type. The length cannot exceed 1 GB.

  The prototype of PKG_SERVICE.SQL_SET_SQL is as follows:

  ```
  PKG_SERVICE.SQL_SET_SQL(
  context_id     IN INTEGER,
  query_string   IN TEXT,
  language_flag  IN INTEGER
  )
  RETURN BOOLEAN;
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 2-6 PKG_SERVICE.SQL_SET_SQL API parameters

Parameter	Description
context_id	ID of the context whose query statement is to be parsed.
query_string	Query statement to be parsed.
language_flag	Version language number, which specifies the behavior of different versions. ● **1**: incompatible version. ● **2**: ORA-compatible version.

- PKG_SERVICE.SQL_RUN

  Executes the SQL statement configured for a context. It receives a context ID first, and the data obtained after execution is used for subsequent operations. Currently, only the SELECT query statement can be executed.

  The prototype of PKG_SERVICE.SQL_RUN is as follows:

```
PKG_SERVICE.SQL_RUN(
context_id     IN INTEGER,
)
RETURN INTEGER;
```

Table 2-7 PKG_SERVICE.SQL_RUN API parameters

Parameter	Description
context_id	ID of the context whose query statement is to be parsed.

- PKG_SERVICE.SQL_NEXT_ROW

  Returns the number of data rows returned from the SQL statement executed. Each time the API is called, the system reads the next row of data until all data is read.

  The prototype of PKG_SERVICE.SQL_NEXT_ROW is as follows:

```
PKG_SERVICE.SQL_NEXT_ROW(
context_id     IN INTEGER,
)
RETURN INTEGER;
```

Table 2-8 PKG_SERVICE.SQL_NEXT_ROW API parameters

Parameter	Description
context_id	ID of the context to be executed.

- PKG_SERVICE.SQL_GET_VALUE

  Returns the value of the element at the specified position in the specified context. This API accesses the data obtained by PKG_SERVICE.SQL_NEXT_ROW.

  The prototype of PKG_SERVICE.SQL_GET_VALUE is as follows:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
PKG_SERVICE.SQL_GET_VALUE(
context_id          IN    INTEGER,
pos                 IN    INTEGER,
col_type            IN    ANYELEMENT
)
RETURN ANYELEMENT;
```

Table 2-9 PKG_SERVICE.SQL_GET_VALUE API parameters

Parameter	Description
context_id	ID of the context to be executed.
pos	Position of a dynamically defined column in the query.
col_type	Variable of any type, which defines the return value type of columns.

- PKG_SERVICE.SQL_SET_RESULT_TYPE

  Defines columns returned from the specified context. This API applies only to the context defined by SELECT. The defined columns are identified by the relative positions in the query list. The prototype of PKG_SERVICE.SQL_SET_RESULT_TYPE is as follows:

  ```
  PKG_SERVICE.SQL_SET_RESULT_TYPE(
  context_id     IN INTEGER,
  pos            IN INTEGER,
  coltype_oid    IN ANYELEMENT,
  maxsize        IN INTEGER
  )
  RETURN INTEGER;
  ```

  Table 2-10 PKG_SERVICE.SQL_SET_RESULT_TYPE API parameters

Parameter	Description
context_id	ID of the context to be executed.
pos	Position of a dynamically defined column in the query.
coltype_oid	Variable of any type. The OID of the corresponding type can be obtained based on the variable type.
maxsize	Length of a defined column.

- PKG_SERVICE.JOB_CANCEL

  Removes a specified scheduled job.

  The prototype of PKG_SERVICE.JOB_CANCEL is as follows:

  ```
  PKG_SERVICE.JOB_CANCEL(
  id  IN  INTEGER);
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 2-11 PKG_SERVICE.JOB_CANCEL API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
id	INTEGER	IN	No	ID of the scheduled job to be deleted.

- PKG_SERVICE.JOB_FINISH

  Disables or enables a scheduled job.

  The prototype of PKG_SERVICE.JOB_FINISH is as follows:

```
PKG_SERVICE.JOB_FINISH(
id          IN   INTEGER,
broken      IN   BOOLEAN,
next_time   IN   TIMESTAMP  DEFAULT  sysdate);
```

Table 2-12 PKG_SERVICE.JOB_FINISH API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
id	INTEGER	IN	No	ID of the scheduled job to be disabled or enabled.
broken	BOOLEAN	IN	No	Status flag: **true** for broken and **false** for not broken. The job status is updated based on the parameter value **true** or **false**. If it is null, the job status remains unchanged.
next_time	TIMESTAMP	IN	Yes	Next execution time. The default value is the current system time. This parameter can be omitted, and its default value will be used in this case. ● If the value of **broken** is **true**, the value of this parameter is updated to **'4000-1-1'**. ● If the parameter **broken** is set to **false** and the parameter **next_time** is not null, the **next_time** value of a specified job is updated. If the parameter **next_time** is null, the **next_time** value is not updated.

- PKG_SERVICE.JOB_SUBMIT

  Submits a system scheduled job.

  The prototype of PKG_SERVICE.JOB_SUBMIT is as follows:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
PKG_SERVICE.JOB_SUBMIT(
id            IN   BIGINT,
content       IN   TEXT,
next_time     IN   TIMESTAMP DEFAULT sysdate,
interval_time IN   TEXT  DEFAULT 'null',
job           OUT  INTEGER);
```

NOTE

- When a scheduled job is created, the system binds the current database and the username to the job by default.
- This function can be called by using the CALL or SELECT statement. If you call this function by using the SELECT statement, there is no need to specify output parameters. To call this function within a stored procedure, use the PERFORM statement.
- If the submitted SQL statement job accesses a non-**PUBLIC** schema, specify the schema where a table or a function resides, or add **SET current_schema =** *xxx***;** before the SQL statement.

Table 2-13 PKG_SERVICE.JOB_SUBMIT API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
id	BIGINT	IN	No	ID of a scheduled job. If the input ID is **NULL**, a job ID is generated internally.
content	TEXT	IN	No	SQL statement to be executed. One or multiple DML statements, anonymous blocks, and statements for calling stored procedures, or all three combined are supported.
next_time	TIMESTAMP	IN	No	Next time the job will be executed. The default value is the current system time (**sysdate**). If the specified time has past, the job is executed immediately after being submitted.
interval_time	TEXT	IN	Yes	Expression for calculating the next time the job will be executed. It can be an interval expression, or **sysdate** followed by a NUMERIC value, for example, **sysdate+1.0/24**. If the value is left empty or set to **"null"**, the job will be executed only once, and the job status will change to **'d'** afterward, indicating that the job is no longer executed.
job	INTEGER	OUT	No	Job ID. The value ranges from 1 to 3000000. When pkg_service.job_submit is called using the SELECT statement, this parameter can be omitted.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- PKG_SERVICE.JOB_UPDATE

  Modifies attributes of a scheduled job, including the job content, next-execution time, and execution interval.

  The prototype of PKG_SERVICE.JOB_UPDATE is as follows:

```
PKG_SERVICE.JOB_UPDATE(
id            IN   BIGINT,
next_time     IN   TIMESTAMP,
interval_time IN   TEXT,
content       IN   TEXT);
```

Table 2-14 PKG_SERVICE.JOB_UPDATE API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
id	INTEGER	IN	No	ID of a specified scheduled job.
next_time	TIMESTAMP	IN	Yes	Next execution time. If this parameter is null, the system does not update the **next_time** parameter for the specified job. Otherwise, the system updates the **next_time** parameter for the specified job.
interval_time	TEXT	IN	Yes	Expression for calculating the next time the job will be executed. ● If this parameter is null, the **interval_time** value of the specified job is not updated. ● If this parameter is not null, the system checks whether **interval_time** is a valid time type or interval type. If it is valid, the **interval_time** value of the specified job is updated. ● If the value is set to **"null"**, the job will be executed only once, and the job status will change to **'d'** afterward, indicating that the job is no longer executed.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Type	Input/Output Parameter	Can Be Null	Description
content	TEXT	IN	Yes	Name of the stored procedure or SQL statement block that is executed. If this parameter is null, the system does not update the **content** parameter for the specified job. Otherwise, the system updates the **content** parameter for the specified job.

Example:

```
CREATE TABLE test_table(a int);
CREATE TABLE

CREATE OR REPLACE PROCEDURE test_job(a in int) IS
BEGIN
INSERT INTO test_table VALUES(a);
COMMIT;
END;
/
CREATE PROCEDURE

--PKG_SERVICE.JOB_SUBMIT
SELECT PKG_SERVICE.JOB_SUBMIT(NULL, 'call test_job(1);', to_date('20180101','yyyymmdd'),'sysdate
+1');
 job_submit
------------
      28269
(1 row)

SELECT PKG_SERVICE.JOB_SUBMIT(NULL, 'call test_job(1);', to_date('20180101','yyyymmdd'),'sysdate
+1.0/24');
 job_submit
------------
       1506
(1 row)

CALL PKG_SERVICE.JOB_SUBMIT(NULL, 'INSERT INTO test_table VALUES(1);  call test_job(1); call
test_job(1);', add_months(to_date('201701','yyyymm'),1), 'date_trunc(''day'',SYSDATE) + 1
+(8*60+30.0)/(24*60)' ,:jobid);
  job
-------
 14131
(1 row)

SELECT PKG_SERVICE.JOB_SUBMIT (101, 'insert_msg_statistic1;', sysdate, 'sysdate+3.0/24');
 job_submit
------------
       101
(1 row)

--PKG_SERVICE.JOB_UPDATE
CALL PKG_SERVICE.JOB_UPDATE(101, sysdate, 'sysdate + 1.0/1440', 'call test_job(1);');
 job_update
------------
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
(1 row)

CALL PKG_SERVICE.JOB_UPDATE(101, sysdate, 'sysdate + 1.0/1440', 'insert into test_table values(1);');
 job_update
------------

(1 row)

--PKG_SERVICE.JOB_FINISH
CALL PKG_SERVICE.JOB_FINISH(101,true);
 job_finish
------------

(1 row)

--PKG_SERVICE.JOB_CANCEL
CALL PKG_SERVICE.JOB_CANCEL(101);
 job_cancel
------------

(1 row)

DROP TABLE test_table;
DROP TABLE
```

- PKG_SERVICE.SUBMIT_ON_NODES

  Creates a scheduled job on all CNs and DNs. Only users with the SYSADMIN or MONADMIN permission can call this function.

  The prototype of PKG_SERVICE.SUBMIT_ON_NODES is as follows:

```
PKG_SERVICE.SUBMIT_ON_NODES(
node_name    IN   NAME,
database     IN   NAME,
what         IN   TEXT,
next_date    IN   TIMESTAMP WITHOUT TIME ZONE,
job_interval IN   TEXT,
job          OUT  INTEGER);
```

Table 2-15 PKG_SERVICE.SUBMIT_ON_NODES API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
node_name	TEXT	IN	No	Job execution node. Currently, the value can only be **ALL_NODE** (indicating that the job is executed on all nodes) or **CCN** (indicating that the job is executed on the CCN).
database	TEXT	IN	No	Database used by a cluster job. When the node type is **ALL_NODE**, the value can only be **postgres**.
what	TEXT	IN	No	SQL statement to be executed. One or multiple DML statements, anonymous blocks, and statements for calling stored procedures, or all three combined are supported.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Type	Input/Output Parameter	Can Be Null	Description
nextdate	TIMESTAMP	IN	No	Next time the job will be executed. The default value is the current system time (**sysdate**). If the specified time has past, the job is executed immediately after being submitted.
job_interval	TEXT	IN	No	Expression for calculating the next time the job will be executed. It can be an interval expression, or **sysdate** followed by a NUMERIC value, for example, **sysdate+1.0/24**. If the value is left empty or set to **"null"**, the job will be executed only once, and the job status will change to **'d'** afterward, indicating that the job is no longer executed.
job	INTEGER	OUT	No	Job ID. The value ranges from 1 to 3000000. When DBMS.SUBMIT_ON_NODES is called using the SELECT statement, this parameter can be omitted.

Example:

```
SELECT pkg_service.submit_on_nodes('ALL_NODE', 'postgres', 'select
capture_view_to_json(''dbe_perf.statement'', 0);', sysdate, 'interval ''60 second''');
 submit_on_nodes
-----------------
           12068
(1 row)

SELECT pkg_service.submit_on_nodes('CCN', 'postgres', 'select
capture_view_to_json(''dbe_perf.statement'', 0);', sysdate, 'interval ''60 second''');
 submit_on_nodes
-----------------
            9027
(1 row)
```

- PKG_SERVICE.ISUBMIT_ON_NODES

  ISUBMIT_ON_NODES has the same syntax function as **SUBMIT_ON_NODES**, but the first parameter of **ISUBMIT_ON_NODES** is an input parameter, that is, a specified job ID. In contrast, the last parameter of **ISUBMIT_ON_NODES** is an output parameter, indicating the job ID automatically generated by the system. Only users with the SYSADMIN or MONADMIN permission can call this function.

- PKG_SERVICE.SQL_GET_ARRAY_RESULT

  Returns the value of the bound **OUT** parameter of the array type and obtains the **OUT** parameter in a stored procedure.

  The prototype of PKG_SERVICE.SQL_GET_ARRAY_RESULT is as follows:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
PKG_SERVICE.SQL_GET_ARRAY_RESULT(
    context_id in int,
    pos in VARCHAR2,
    column_value inout anyarray,
    result_type in anyelement
);
```

Table 2-16 PKG_SERVICE.SQL_GET_ARRAY_RESULT API parameters

Parameter	Description
context_id	ID of the context to be queried.
pos	Name of the bound parameter.
column_value	Return value.
result_type	Return type.

- PKG_SERVICE.SQL_GET_VARIABLE_RESULT

  Returns the value of the bound **OUT** parameter of the non-array type and obtains the **OUT** parameter in a stored procedure.

  The prototype of PKG_SERVICE.SQL_GET_VARIABLE_RESULT is as follows:

```
PKG_SERVICE.SQL_GET_VARIABLE_RESULT(
    context_id in int,
    pos in VARCHAR2,
    result_type in anyelement
)
RETURNS anyelement;
```

Table 2-17 PKG_SERVICE.SQL_GET_VARIABLE_RESULT API parameters

Parameter	Description
context_id	ID of the context to be queried.
pos	Name of the bound parameter.
result_type	Return type.

2.12.1.2 PKG_UTIL

Table 2-18 lists all APIs supported by the PKG_UTIL package.

NOTE

LOB update APIs (such as LOB_WRITE_HUGE, LOB_COPY_HUGE, LOB_CONVERTTOBLOB_HUGE, and LOADBLOBFROMFILE) in the PKG_UTIL package update only LOB variables in memory and do not automatically update the associated physical table data. Even if the target row has been locked using SELECT ... FOR UPDATE, LOB data changes are not automatically persisted to the database table. To save the update result, you must explicitly execute the UPDATE statement.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 2-18 PKG_UTIL

API	Description
PKG_UTIL.LOB_READ	Reads a part of a LOB.
PKG_UTIL.LOB_WRITE	Writes the source object to the target object in the specified format.
PKG_UTIL.LOB_APPEND	Appends the source LOB to the target LOB.
PKG_UTIL.LOB_COMPARE	Compares two LOBs based on the specified length.
PKG_UTIL.LOB_MATCH	Returns the position of the *N*th occurrence of a character string in a LOB.
PKG_UTIL.LOB_RESET	Sets a segment of data in a BLOB to the specified value and returns the processed BLOB and the actually processed length.
PKG_UTIL.LOB_GET_LENGTH	Obtains and returns the specified length of a LOB.
PKG_UTIL.LOB_READ_HUGE	Reads a part of the LOB content based on the specified length and initial position offset, and returns the read LOB and length.
PKG_UTIL.LOB_WRITEAPPEND_HUGE	Reads the content of a specified length from the source BLOB or CLOB, appends the content to the target BLOB or CLOB, and returns the target object.
PKG_UTIL.LOB_APPEND_HUGE	Appends the source BLOB/CLOB to the target BLOB/CLOB and returns the target object.
PKG_UTIL.READ_BFILE_TO_BLOB	Loads the source BFILE file to the target BLOB and returns the target object.
PKG_UTIL.LOB_COPY_HUGE	Reads the content of a specified length from the specified offset position of the source BLOB or CLOB, writes the content to the specified offset position of the target BLOB or CLOB, and returns the target object.
PKG_UTIL.BLOB_RESET	Sets a segment of data in a BLOB to the specified value and returns the processed BLOB and the actually processed length.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

API	Description
PKG_UTIL.CLOB_RESET	Sets a segment of data in a CLOB to spaces and returns the processed CLOB and the actually processed length.
PKG_UTIL.LOADBLOBFROMFILE	Reads the content of a specified length from the specified offset position of the source BFILE object, writes the content to the specified offset position of the target BLOB, and returns the target object, read position, and write position.
PKG_UTIL.LOADCLOBFROMFILE	Reads the content of a specified length from the specified offset position of the source BFILE object, writes the content to the specified offset position of the target CLOB, and returns the target object, read position, and write position.
PKG_UTIL.LOB_CONVERTTOBLOB_HUGE	Reads the content of a specified length from the specified offset position of the source CLOB, converts the content to a BLOB, and writes the BLOB to the specified position of target LOB. *amount* indicates the length to be converted.
PKG_UTIL.LOB_CONVERTTOCLOB_HUGE	Reads the content of a specified length from the specified offset position of the source CLOB, converts the content to a CLOB, and writes the CLOB to the specified position of target LOB. *amount* indicates the length to be converted.
PKG_UTIL.BFILE_GET_LENGTH	Obtains and returns the specified length of a BFILE file.
PKG_UTIL.BFILE_OPEN	Opens a BFILE file and returns its file descriptor.
PKG_UTIL.BFILE_CLOSE	Closes a BFILE file.
PKG_UTIL.LOB_WRITE_HUGE	Reads the specified length of the source object from the start position, writes the content to the specified offset position of the target LOB, overrides the original content, and returns the target LOB.
PKG_UTIL.IO_PRINT	Displays character strings.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

API	Description
PKG_UTIL.RAW_GET_LENGTH	Obtains the length of RAW data.
PKG_UTIL.RAW_CAST_FROM_VARCHAR2	Converts VARCHAR2 data to RAW data.
PKG_UTIL.RAW_CAST_FROM_BINARY_INTEGER	Converts binary integers to RAW data.
PKG_UTIL.RAW_CAST_TO_BINARY_INTEGER	Converts RAW data to binary integer data.
PKG_UTIL.RANDOM_SET_SEED	Sets a random seed.
PKG_UTIL.RANDOM_GET_VALUE	Returns a random value.
PKG_UTIL.FILE_SET_DIRNAME	Sets the directory to be operated.
PKG_UTIL.FILE_OPEN	Opens a file based on the specified file name and directory.
PKG_UTIL.FILE_SET_MAX_LINE_SIZE	Sets the maximum length of a line to be written to a file.
PKG_UTIL.FILE_IS_CLOSE	Checks whether a file handle is closed.
PKG_UTIL.FILE_READ	Reads data of a specified length from an open file handle.
PKG_UTIL.FILE_READLINE	Reads a line of data from an open file handle.
PKG_UTIL.FILE_WRITE	Writes the data specified in the buffer to a file.
PKG_UTIL.FILE_WRITELINE	Writes the buffer to a file and adds newline characters.
PKG_UTIL.FILE_NEWLINE	Adds a line.
PKG_UTIL.FILE_READ_RAW	Reads binary data of a specified length from an open file handle.
PKG_UTIL.FILE_WRITE_RAW	Writes binary data to a file.
PKG_UTIL.FILE_FLUSH	Writes data from a file handle to a physical file.
PKG_UTIL.FILE_CLOSE	Closes a file handle.
PKG_UTIL.FILE_REMOVE	Removes a physical file. To do so, you must have the corresponding permission.
PKG_UTIL.FILE_RENAME	Renames a file on the disk, similar to **mv** in Unix.
PKG_UTIL.FILE_SIZE	Returns the size of a file.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

API	Description
PKG_UTIL.FILE_BLOCK_SIZE	Returns the number of blocks contained in a file.
PKG_UTIL.FILE_EXISTS	Checks whether a file exists.
PKG_UTIL.FILE_GETPOS	Specifies the offset of a returned file, in bytes.
PKG_UTIL.FILE_SEEK	Sets the offset for determining the file position.
PKG_UTIL.FILE_CLOSE_ALL	Closes all file handles opened in a session.
PKG_UTIL.EXCEPTION_REPORT_ERROR	Throws an exception.
PKG_UTIL.APP_READ_CLIENT_INFO	Reads the client information.
PKG_UTIL.APP_SET_CLIENT_INFO	Sets the client information.
PKG_UTIL.LOB_CONVERTTOBLOB	Converts the CLOB type to the BLOB type.
PKG_UTIL.LOB_CONVERTTOCLOB	Converts the BLOB type to the CLOB type.
PKG_UTIL.LOB_RAWTOTEXT	Converts the input BLOB into a hexadecimal text output, automatically prefixing a leading zero for odd-length inputs. The input must consist of valid hexadecimal digits (0-9, A-F, a-f). If any invalid characters are included, an error will be reported.
PKG_UTIL.LOB_TEXTTORAW	Converts the input CLOB text into a RAW output, automatically prefixing a leading zero for odd-length inputs. The input text must consist of valid hexadecimal digits (0-9, A-F, a-f). If any invalid characters are included, an error will be reported.
PKG_UTIL.MATCH_EDIT_DISTANCE_SIMILARITY	Calculates the difference between two character strings.
PKG_UTIL.RAW_CAST_TO_VARCHAR2	Converts the RAW type to the VARCHAR2 type.
PKG_UTIL.SESSION_CLEAR_CONTEXT	Clears the attribute values in **session_context**.
PKG_UTIL.SESSION_SEARCH_CONTEXT	Searches for an attribute value.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

API	Description
PKG_UTIL.SESSION_SET_CONTEXT	Sets an attribute value.
PKG_UTIL.UTILITY_FORMAT_CALL_STACK	Displays the call stack of a stored procedure.
PKG_UTIL.UTILITY_FORMAT_ERROR_BACKTRACE	Displays the error stack of a stored procedure.
PKG_UTIL.UTILITY_FORMAT_ERROR_STACK	Displays the error information about a stored procedure.
PKG_UTIL.UTILITY_GET_TIME	Displays the Unix timestamp of the system.
PKG_UTIL.UTILITY_COMPILE_SCHEMA	Recompiles specified schemas, packages, functions, and stored procedures. If an error is reported when you compile a PL/SQL object, the PL/SQL object is returned and the recompilation stops. This API is not recommended. You are advised to use pkg_util.gs_compile_schema.
PKG_UTIL.GS_COMPILE_SCHEMA	Recompiles specified schemas, packages, functions, and stored procedures. If an error is reported when you compile a PL/SQL object, the exception is captured and the recompilation continues until all objects are compiled or the number of recompilation attempts reaches the upper limit. When the advanced package is executed through JDBC, **SQLSTATE** will return error code "00000", which indicates that the operation is successful..
PKG_UTIL.APP_SET_MODULE	Sets the value of a module.
PKG_UTIL.APP_READ_MODULE	Reads the value of a module.
PKG_UTIL.APP_SET_ACTION	Sets the value of an action.
PKG_UTIL.APP_READ_ACTION	Reads the value of an action.
PKG_UTIL.MODIFY_PACKAGE_STATE	Modifies the PL/SQL status of the current session.

- PKG_UTIL.LOB_READ

  Reads an object and returns the specified part.

  The prototype of the PKG_UTIL.LOB_READ function is as follows:

  ```
  PKG_UTIL.LOB_READ(
  lob       IN   ANYELEMENT,
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
len       IN   INT,
start     IN   INT,
mode      IN   INT
)
RETURN ANYELEMENT
```

Table 2-19 PKG_UTIL.LOB_READ API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
lob	CLOB / BLOB	IN	No	CLOB or BLOB data.
len	INT	IN	No	Length of the returned result.
start	INT	IN	No	Offset to the first character.
mode	INT	IN	No	Type of the read operation. **0** indicates **READ**, **1** indicates **TRIM**, and **2** indicates **SUBSTR**.

- PKG_UTIL.LOB_WRITE

  Writes the source object to the target object based on the specified parameters and returns the target object.

  The prototype of the PKG_UTIL.LOB_WRITE function is as follows:

```
PKG_UTIL.LOB_WRITE(
dest_lob    INOUT   BLOB,
src_lob     IN      RAW
len         IN      INT,
start_pos   IN      BIGINT
)
RETURN BLOB;
PKG_UTIL.LOB_WRITE(
dest_lob    INOUT   CLOB,
src_lob     IN      VARCHAR2
len         IN      INT,
start_pos   IN      BIGINT
)
RETURN CLOB;
```

Table 2-20 PKG_UTIL.LOB_WRITE API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
dest_lob	CLOB / BLOB	INOUT	No	Target object to which data will be written.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Type	Input/Output Parameter	Can Be Null	Description
src_lob	CLOB / BLOB	IN	No	Source object to be written.
len	INT	IN	No	Write length of the source object.
start_pos	BIGINT	IN	No	Write start position of the target object.

- PKG_UTIL.LOB_APPEND

  Appends the source BLOB/CLOB to the target BLOB/CLOB and returns the target object.

  The prototype of the PKG_UTIL.LOB_APPEND function is as follows:

```
PKG_UTIL.LOB_APPEND(
dest_lob    INOUT   BLOB,
src_lob     IN      BLOB,
len         IN      INT DEFAULT NULL
)
RETURN BLOB;

PKG_UTIL.LOB_APPEND(
dest_lob    INOUT   CLOB,
src_lob     IN      CLOB,
len         IN      INT DEFAULT NULL
)
RETURN CLOB;
```

Table 2-21 PKG_UTIL.LOB_APPEND API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
dest_lob	BLOB/CLOB	INOUT	No	Target BLOB/CLOB to which data will be written.
src_lob	BLOB/CLOB	IN	No	BLOB/CLOB from which data is to be written.
len	INT	IN	Yes	Length read from *src* and appended to *dest*. The default value is **NULL**, indicating that all content of *src* is read and appended to *dest*.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- PKG_UTIL.LOB_COMPARE

  Checks whether objects are the same based on the specified start position and size. If **lob1** is larger, **1** is returned. If **lob2** is larger, **-1** is returned. If **lob1** is equal to **lob2**, **0** is returned.

  The prototype of the PKG_UTIL.LOB_COMPARE function is as follows:

```
PKG_UTIL.LOB_COMPARE(
lob1        IN   ANYELEMENT,
lob2        IN   ANYELEMENT,
len         IN   INT DEFAULT 1073741771,
start_pos1      IN   INT DEFAULT 1,
start_pos2      IN   INT DEFAULT 1
)
RETURN INTEGER;
```

  Table 2-22 PKG_UTIL.LOB_COMPARE API parameters

Parameter	Type	Input / Output Parameter	Can Be Null	Description
lob1	CLOB/ BLOB	IN	No	Character string for comparison.
lob2	CLOB/ BLOB	IN	No	Character string for comparison.
len	INT	IN	No	Length to be compared.
start_pos1	INT	IN	No	Start offset of **lob1**.
start_pos2	INT	IN	No	Start offset of **lob2**.

- PKG_UTIL.LOB_MATCH

  Returns the position where a pattern is displayed in a LOB for the *match_n*th time.

  The prototype of the PKG_UTIL.LOB_MATCH function is as follows:

```
PKG_UTIL.LOB_MATCH(
lob         IN   ANYELEMENT,
pattern      IN   ANYELEMENT,
start       IN   INT,
match_nth    IN   INT DEFAULT 1
)
RETURN INTEGER;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 2-23 PKG_UTIL.LOB_MATCH API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
lob	CLOB/BLOB	IN	No	Character string for comparison.
pattern	CLOB/BLOB	IN	No	Pattern to be matched.
start	INT	IN	No	Start position for LOB comparison.
match_nth	INT	IN	No	Number of matching times when the matching succeeds.

- PKG_UTIL.LOB_RESET

  Sets a segment of data in a BLOB to the specified value and returns the processed BLOB and the actually processed length.

  The prototype of the PKG_UTIL.LOB_RESET function is as follows:

```
PKG_UTIL.LOB_RESET(
lob         INOUT   BLOB,
len         INOUT   INT,
start       IN   INT DEFAULT 1,
value        IN   INT DEFAULT 0
)
RETURN RECORD;
```

Table 2-24 PKG_UTIL.LOB_RESET API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
lob	BLOB	INOUT	No	Character string for resetting. **NOTE** This function does not reset the content of the LOB parameter. The processed result is returned by the function.
len	INT	INOUT	No	Length of the string to be reset.
start	INT	IN	Yes	Start position for resetting. Default value: **'1'**.
value	INT	IN	Yes	Character to be set. Default value: **'0'**.

- PKG_UTIL.LOB_GET_LENGTH

  Obtains and returns the specified length of a LOB.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

The prototype of the PKG_UTIL.LOB_GET_LENGTH function is as follows:

```
PKG_UTIL.LOB_GET_LENGTH(
   lob IN BLOB)
RETURN BIGINT;

PKG_UTIL.LOB_GET_LENGTH(
   lob IN CLOB)
RETURN BIGINT;
```

Table 2-25 PKG_UTIL.LOB_GET_LENGTH API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
lob	BLOB/CLOB	IN	No	LOB type.

- PKG_UTIL.LOB_READ_HUGE

  Reads a part of the LOB content based on the specified length and initial position offset, and returns the read LOB and length.

  The prototype of the PKG_UTIL.LOB_READ_HUGE function is as follows:

```
PKG_UTIL.LOB_READ_HUGE(
   lob       IN CLOB,
   len       IN BIGINT,
   start_pos IN BIGINT,
   mode      IN INTEGER)
RETURN RECORD;

PKG_UTIL.LOB_READ_HUGE(
   lob       IN BLOB,
   len       IN BIGINT,
   start_pos IN BIGINT,
   mode      IN INTEGER)
RETURN RECORD;

PKG_UTIL.LOB_READ_HUGE(
   fd        IN INTEGER,
   len       IN BIGINT,
   start_pos IN BIGINT,
   mode      IN INTEGER)
RETURN RECORD;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 2-26 PKG_UTIL.LOB_READ_HUGE API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
lob/fd	BLOB/CLOB/INTEGER	IN	No	File descriptor of the specified LOB or BFILE file.
len	BIGINT	IN	No	Length to read.
start_pos	BIGINT	IN	No	Offset position from which read starts.
mode	INTEGER	IN	No	Read mode (**0**: read, **1**: trim, **2**: substr).

- PKG_UTIL.LOB_WRITEAPPEND_HUGE

  Reads the content of a specified length from the source BLOB or CLOB, appends the content to the target BLOB or CLOB, and returns the target object.

  The prototype of the PKG_UTIL.LOB_WRITEAPPEND_HUGE function is as follows:

```
PKG_UTIL.LOB_WRITEAPPEND_HUGE(
   dest_lob INOUT CLOB,
   len      IN    INTEGER,
   src_lob  IN    VARCHAR2
)RETURN CLOB;

PKG_UTIL.LOB_WRITEAPPEND_HUGE(
   dest_lob INOUT BLOB,
   len      IN    INTEGER,
   src_lob  IN    RAW
)RETURN BLOB;
```

Table 2-27 PKG_UTIL.LOB_WRITEAPPEND_HUGE API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
dest_lob	BLOB/CLOB	INOUT	No	Target BLOB/CLOB to which data will be written.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Type	Input/Output Parameter	Can Be Null	Description
len	INTEGER	IN	Yes	Length of the source object to be written. If the value is **NULL**, the entire source object is written by default.
src_lob	VARCHAR2/RAW	IN	No	BLOB/CLOB from which data is to be written.

- PKG_UTIL.LOB_APPEND_HUGE

  Appends the source BLOB/CLOB to the target BLOB/CLOB and returns the target object.

  The prototype of the PKG_UTIL.LOB_APPEND_HUGE function is as follows:

```
PKG_UTIL.LOB_APPEND_HUGE(
   dest_lob INOUT BLOB,
   src_lob  IN    BLOB)
RETURN BLOB;
PKG_UTIL.LOB_APPEND_HUGE(
   dest_lob INOUT CLOB,
   src_lob  IN    CLOB)
RETURN CLOB;
```

  Table 2-28 PKG_UTIL.LOB_APPEND_HUGE API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
dest_lob	BLOB/CLOB	INOUT	No	Target BLOB/CLOB to which data will be written.
src_lob	BLOB/CLOB	IN	No	BLOB/CLOB from which data is to be written.

- PKG_UTIL.READ_BFILE_TO_BLOB

  Loads the source BFILE file to the target BLOB and returns the target object.

  The prototype of the PKG_UTIL.READ_BFILE_TO_BLOB function is as follows:

```
PKG_UTIL.READ_BFILE_TO_BLOB(
   fd IN INTEGER
)RETURN BLOB;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 2-29 PKG_UTIL.READ_BFILE_TO_BLOB API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
fd	INTEGER	IN	No	Source BFILE file to be read.

- PKG_UTIL.LOB_COPY_HUGE

  Reads the content of a specified length from the specified offset position of the source BLOB or CLOB, writes the content to the specified offset position of the target BLOB or CLOB, and returns the target object.

  The prototype of the PKG_UTIL.LOB_COPY_HUGE function is as follows:

```
PKG_UTIL.LOB_COPY_HUGE(
   lob_obj    INOUT BLOB,
   source_obj  IN    BLOB,
   amount      IN    BIGINT,
   dest_offset IN    BIGINT DEFAULT 1,
   src_offset  IN    BIGINT DEFAULT 1
)RETURN BLOB;

PKG_UTIL.LOB_COPY_HUGE(
   lob_obj    INOUT CLOB,
   source_obj  IN    CLOB,
   amount      IN    BIGINT,
   dest_offset IN    BIGINT DEFAULT 1,
   src_offset  IN    BIGINT DEFAULT 1
)RETURN CLOB;
```

Table 2-30 PKG_UTIL.LOB_COPY_HUGE API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
lob_obj	BLOB/CLOB	INOUT	No	Target BLOB/CLOB.
source_obj	BLOB/CLOB	IN	No	Source BLOB/CLOB.
amount	BIGINT	IN	No	Length of the data to be copied (in bytes for BLOBs or in characters for CLOBs).
dest_offset	BIGINT	IN	No	Offset position of the target LOB to which the data is loaded.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Type	Input/Output Parameter	Can Be Null	Description
src_offset	BIGINT	IN	No	Offset position of the source LOB from which the data is read.

- PKG_UTIL.BLOB_RESET

  Sets a segment of data in a BLOB to the specified value and returns the processed BLOB and the actually processed length.

  The prototype of the PKG_UTIL.BLOB_RESET function is as follows:

```
PKG_UTIL.BLOB_RESET(
   lob       INOUT BLOB,
   len       INOUT BIGINT,
   start_pos IN    BIGINT DEFAULT 1,
   value     IN    INTEGER DEFAULT 0
)RETURN RECORD;
```

  Table 2-31 PKG_UTIL.BLOB_RESET API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
lob	BLOB	INOUT	No	LOB to be reset. **NOTE** This function does not reset the content of the LOB parameter. The processed result is returned by the function.
len	BIGINT	INOUT	No	Length to reset, in bytes.
start	BIGINT	IN	Yes	Start position for resetting. Default value: **'1'**.
value	INTEGER	IN	Yes	Character to be set. Default value: **'0'**.

- PKG_UTIL.CLOB_RESET

  Sets a piece of data to spaces.

  The prototype of the PKG_UTIL.CLOB_RESET function is as follows:

```
PKG_UTIL.CLOB_RESET(
   lob       INOUT CLOB,
   len       INOUT BIGINT,
   start_pos IN    BIGINT DEFAULT 1
)RETURN RECORD;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 2-32 PKG_UTIL.CLOB_RESET API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
lob	CLOB	INOUT	No	LOB to be reset.
len	BIGINT	INOUT	No	Length to reset, in characters.
start	BIGINT	IN	Yes	Reset start position. The default value is **1**.

- PKG_UTIL.LOADBLOBFROMFILE

  Reads the content of a specified length from the specified offset position of the source BFILE object, writes the content to the specified offset position of the target BLOB, and returns the target object, read position, and write position.

  The prototype of the PKG_UTIL.LOADBLOBFROMFILE function is as follows:

```
PKG_UTIL.LOADBLOBFROMFILE(
   dest_lob     INOUT  BLOB,
   fd           IN     INTEGER,
   amount       IN     BIGINT,
   dest_offset  INOUT  BIGINT,
   file_offset  INOUT  BIGINT
)RETURN RECORD;
```

Table 2-33 PKG_UTIL.LOADBLOBFROMFILE API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
dest_lob	BLOB	INOUT	No	Target BLOB as the INOUT parameter.
fd	INTEGER	IN	No	File descriptor of the source BFILE object.
amount	BIGINT	IN	No	Length of the data to be copied (in bytes for BLOBs or in characters for CLOBs).
dest_offset	BIGINT	INOUT	No	Offset position of the target LOB to which the data is written as the INOUT parameter.
src_offset	BIGINT	INOUT	No	Offset position of the source BFILE file from which the data is read as the INOUT parameter.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- PKG_UTIL.LOADCLOBFROMFILE

  Reads the content of a specified length from the specified offset position of the source BFILE object, writes the content to the specified offset position of the target CLOB, and returns the target object, read position, and write position.

  The prototype of the PKG_UTIL.LOADCLOBFROMFILE function is as follows:

```
PKG_UTIL.LOADCLOBFROMFILE(
   dest_lob     INOUT  CLOB,
   fd           IN     INTEGER,
   amount       IN     BIGINT,
   dest_offset  INOUT  BIGINT,
   file_offset  INOUT  BIGINT
)RETURN RECORD;
```

  Table 2-34 PKG_UTIL.LOADCLOBFROMFILE API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
dest_lob	CLOB	INOUT	No	Target CLOB as the INOUT parameter.
fd	INTEGER	IN	No	File descriptor of the source BFILE object.
amount	BIGINT	IN	No	Length to copy (in characters for CLOBs).
dest_offset	BIGINT	INOUT	No	Offset position of the target LOB to which the data is written as the INOUT parameter.
src_offset	BIGINT	INOUT	No	Offset position of the source BFILE file from which the data is read as the INOUT parameter.

- PKG_UTIL.LOB_CONVERTTOBLOB_HUGE

  Reads the content of a specified length from the specified offset position of the source CLOB, converts the content to a BLOB, and writes the BLOB to the specified position of target LOB. *amount* indicates the length to be converted.

  The prototype of the PKG_UTIL.LOB_CONVERTTOBLOB_HUGE function is as follows:

```
PKG_UTIL.LOB_CONVERTTOBLOB_HUGE(
   dest_lob    INOUT  BLOB,
   src_clob    IN     CLOB,
   amount      IN     BIGINT,
   dest_offset INOUT  BIGINT,
   src_offset  INOUT  BIGINT)
)RETURN RECORD;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 2-35 PKG_UTIL.LOB_CONVERTTOBLOB_HUGE API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
dest_lob	BLOB	INOUT	No	Target LOB.
src_clob	CLOB	IN	No	CLOB to be converted.
amount	BIGINT	IN	No	Length to convert, in characters.
dest_offset	BIGINT	INOUT	No	Offset position of the target LOB to which the data is written as the INOUT parameter.
src_offset	BIGINT	INOUT	No	Offset position of the source CLOB from which the data is read as the INOUT parameter.

- PKG_UTIL.LOB_CONVERTTOCLOB_HUGE

  Reads the content of a specified length from the specified offset position of the source CLOB, converts the content to a CLOB, and writes the CLOB to the specified position of target LOB. *amount* indicates the length to be converted.

  The prototype of the PKG_UTIL.LOB_CONVERTTOCLOB_HUGE function is as follows:

```
PKG_UTIL.LOB_CONVERTTOCLOB_HUGE(
   dest_lob    INOUT  CLOB,
   src_blob    IN     BLOB,
   amount      IN     BIGINT,
   dest_offset INOUT  BIGINT,
   src_offset  INOUT  BIGINT)
)RETURN RECORD;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 2-36 PKG_UTIL.LOB_CONVERTTOCLOB_HUGE API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
dest_lob	CLOB	INOUT	No	Target LOB.
src_blob	BLOB	IN	No	BLOB to be converted.
amount	BIGINT	IN	No	Length to convert, in bytes.
dest_offset	BIGINT	INOUT	No	Offset position of the target LOB to which the data is written as the INOUT parameter.
src_offset	BIGINT	INOUT	No	Offset position of the source CLOB from which the data is read as the INOUT parameter.

- PKG_UTIL.BFILE_GET_LENGTH

  Obtains and returns the specified length of a BFILE file.

  The prototype of the PKG_UTIL.BFILE_GET_LENGTH function is as follows:

```
PKG_UTIL.BFILE_GET_LENGTH(
    fd INTEGER
)RETURN BIGINT;
```

Table 2-37 PKG_UTIL.LOB_GET_LENGTH API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
fd	INTEGER	IN	No	File descriptor of the specified BFILE file.

- PKG_UTIL.BFILE_OPEN

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Opens a BFILE file and returns its file descriptor.

The prototype of the PKG_UTIL.BFILE_OPEN function is as follows:

```
PKG_UTIL.BFILE_OPEN(
   file_name TEXT,
   open_mode TEXT)
RETURN INTEGER;
```

Table 2-38 PKG_UTIL.BFILE_OPEN API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
file_name	TEXT	IN	No	Name of the specified BFILE file.
open_mode	TEXT	IN	No	Open mode, which can only be set to **r**, that is, the read mode.

- PKG_UTIL.BFILE_CLOSE

  Closes a BFILE file.

  The prototype of the PKG_UTIL.BFILE_CLOSE function is as follows:

  ```
  PKG_UTIL.BFILE_CLOSE(
     fd INTEGER)
  RETURN BOOL;
  ```

  Table 2-39 PKG_UTIL.BFILE_CLOSE API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
fd	INTEGER	IN	No	File descriptor of the specified BFILE file.

- PKG_UTIL.LOB_WRITE_HUGE

  Reads the specified length of the source object from the start position, writes the content to the specified offset position of the target LOB, overrides the original content, and returns the target LOB.

  The prototype of the PKG_UTIL.LOB_WRITE_HUGE function is as follows:

  ```
  PKG_UTIL.LOB_WRITE_HUGE(
     dest_lob  INOUT BLOB,
     len       IN INTEGER,
     start_pos IN BIGINT,
     src_lob   IN RAW
  )RETURN BLOB;

  PKG_UTIL.LOB_WRITE_HUGE(
     dest_lob  INOUT CLOB,
     len       IN INTEGER,
     start_pos IN BIGINT,
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
  src_lob   IN VARCHAR2
)RETURN CLOB;
```

Table 2-40 PKG_UTIL.LOB_WRITE_HUGE API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
dest_lob	BLOB/CLOB	INOUT	No	Target LOB as the INOUT parameter, to which the content is to be written.
len	INTEGER	IN	No	Length of the data to be written (in bytes for BLOBs or in characters for CLOBs).
start_pos	BIGINT	IN	No	Offset position for writing data to *dest_lob*.
src_lob	RAW/VARCHAR2	IN	No	Source LOB.

- PKG_UTIL.IO_PRINT

  Prints a string.

  The prototype of the PKG_UTIL.IO_PRINT function is as follows:

```
PKG_UTIL.IO_PRINT(
format      IN   TEXT,
is_one_line  IN   BOOLEAN
)
RETURN VOID;
```

Table 2-41 PKG_UTIL.IO_PRINT API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
format	TEXT	IN	No	String to be printed.
is_one_line	BOOLEAN	IN	No	Specifies whether to print the string as a line.

- PKG_UTIL.RAW_GET_LENGTH

  Obtains the length of RAW data.

  The prototype of the PKG_UTIL.RAW_GET_LENGTH function is as follows:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
PKG_UTIL.RAW_GET_LENGTH(
value       IN   RAW
)
RETURN INTEGER;
```

Table 2-42 PKG_UTIL.RAW_GET_LENGTH API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
raw	RAW	IN	No	Object whose length is to be obtained.

- PKG_UTIL.RAW_CAST_FROM_VARCHAR2

  Converts VARCHAR2 data to RAW data.

  The prototype of the PKG_UTIL.RAW_CAST_FROM_VARCHAR2 function is as follows:

```
PKG_UTIL.RAW_CAST_FROM_VARCHAR2(
str       IN   VARCHAR2
)
RETURN RAW;
```

Table 2-43 PKG_UTIL.RAW_CAST_FROM_VARCHAR2 API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
str	VARCHAR2	IN	No	Source data to be converted

- PKG_UTIL.RAW_CAST_FROM_BINARY_INTEGER

  Converts BIGINT data to RAW data.

  The prototype of the PKG_UTIL.RAW_CAST_FROM_BINARY_INTEGER function is as follows:

```
PKG_UTIL.RAW_CAST_FROM_BINARY_INTEGER(
value       IN   BIGINT,
endianess   IN   INTEGER
)
RETURN RAW;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 2-44 PKG_UTIL.RAW_CAST_FROM_BINARY_INTEGER API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
value	BIGINT	IN	No	Source data to be converted.
endianess	INTEGER	IN	No	Endianness, which is an integer. Currently, the value can be **1** (BIG_ENDIAN), **2** (LITTLE_ENDIAN), or **3** (MACHINE_ENDIAN).

- PKG_UTIL.RAW_CAST_TO_BINARY_INTEGER

  Converts RAW data into BINARY_INTEGER.

  The prototype of the PKG_UTIL.RAW_CAST_TO_BINARY_INTEGER function is as follows:

```
PKG_UTIL.RAW_CAST_TO_BINARY_INTEGER(
value       IN   RAW,
endianess   IN   INTEGER
)
RETURN INTEGER;
```

Table 2-45 PKG_UTIL.RAW_CAST_TO_BINARY_INTEGER API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
value	RAW	IN	No	Source data to be converted.
endianess	INTEGER	IN	No	Endianness, which is an integer. Currently, the value can be **1** (BIG_ENDIAN), **2** (LITTLE_ENDIAN), or **3** (MACHINE_ENDIAN).

- PKG_UTIL.RANDOM_SET_SEED

  Sets a random seed.

  The prototype of the PKG_UTIL.RANDOM_SET_SEED function is as follows:

```
PKG_UTIL.RANDOM_SET_SEED(
seed        IN   INT
)
RETURN INTEGER;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 2-46 PKG_UTIL.RANDOM_SET_SEED API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
seed	INT	IN	No	Random seed.

- PKG_UTIL.RANDOM_GET_VALUE

  Returns a 15-digit random number ranging from 0 to 1.

  The prototype of the PKG_UTIL.RANDOM_GET_VALUE function is as follows:

```
PKG_UTIL.RANDOM_GET_VALUE(
)
RETURN NUMERIC;
```

  NOTE

  You are advised not to use the PKG_UTIL.RANDOM_SET_SEED and PKG_UTIL.RANDOM_GET_VALUE functions in security scenarios.

- PKG_UTIL.FILE_SET_DIRNAME

  Sets the directory to be operated. It must be called to set a directory for each operation involving a single directory.

  The prototype of the PKG_UTIL.FILE_SET_DIRNAME function is as follows:

```
PKG_UTIL.FILE_SET_DIRNAME(
dir  IN  TEXT
)
RETURN BOOL
```

Table 2-47 PKG_UTIL.FILE_SET_DIRNAME API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
dir	TEXT	IN	No	Directory of a file. It is a string, indicating an object name. **NOTE** File directories need to be added to the system catalog **PG_DIRECTORY**. If the input path does not match the path in **PG_DIRECTORY**, an error indicating that the path does not exist will be reported. Functions that take **location** as parameters also comply with this rule.

- PKG_UTIL.FILE_OPEN

  Opens a file. A maximum of 50 files can be opened at a time. This function returns a handle of the INTEGER type.

  The prototype of the PKG_UTIL.FILE_OPEN function is as follows:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
PKG_UTIL.FILE_OPEN(
file_name    IN  TEXT,
open_mode    IN  INTEGER)
```

Table 2-48 PKG_UTIL.FILE_OPEN API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
file_name	TEXT	IN	No	File name with an extension (file type), excluding the path name. A path contained in a file name is ignored in the OPEN function. In Unix, the file name cannot end with the combination of a slash and a dot (/.).
open_mode	INTEGER	IN	No	File opening mode, including **r** (read text), **w** (write text), and **a** (append text). **NOTE** For the write operation, the system checks the file type. If the ELF file is written, an error will be reported and the system exits.

- PKG_UTIL.FILE_SET_MAX_LINE_SIZE

  Sets the maximum length of a line to be written to a file.

  The prototype of the PKG_UTIL.FILE_SET_MAX_LINE_SIZE function is as follows:

  ```
  PKG_UTIL.FILE_SET_MAX_LINE_SIZE(
  max_line_size IN INTEGER)
  RETURN BOOL
  ```

  Table 2-49 PKG_UTIL.FILE_SET_MAX_LINE_SIZE API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
max_line_size	INTEGER	IN	Yes	Maximum number of characters in each line, including newline characters. The minimum value is **1** and the maximum value is **32767**. If this parameter is not specified, the default value **1024** is used.

- PKG_UTIL.FILE_IS_CLOSE

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Checks whether a file handle is closed.

The prototype of the PKG_UTIL.FILE_IS_CLOSE function is as follows:

```
PKG_UTIL.FILE_IS_CLOSE(
file IN INTEGER
)
RETURN BOOL
```

Table 2-50 PKG_UTIL.FILE_IS_CLOSE API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
file	INTEGER	IN	No	Opened file handle.

- PKG_UTIL.FILE_READ

  Reads a line of data from an open file handle based on the specified length.

  The prototype of the PKG_UTIL.FILE_READ function is as follows:

  ```
  PKG_UTIL.FILE_READ(
  file     IN   INTEGER,
  buffer   OUT  TEXT,
  len      IN   BIGINT DEFAULT 1024)
  ```

  Table 2-51 PKG_UTIL.FILE_READ API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
file	INTEGER	IN	No	File handle opened by calling the OPEN function. The file must be opened in read mode. Otherwise, the INVALID_OPERATION exception is thrown.
buffer	TEXT	OUT	No	Buffer used to receive data.
len	BIGINT	IN	No	Number of bytes read from a file.

- PKG_UTIL.FILE_READLINE

  Reads a line of data from an open file handle based on the specified length.

  The prototype of the PKG_UTIL.FILE_READLINE function is as follows:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
PKG_UTIL.FILE_READLINE(
file    IN  INTEGER,
buffer  OUT TEXT,
len     IN  INTEGER DEFAULT NULL)
```

Table 2-52 PKG_UTIL.FILE_READLINE API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
file	INTEGER	IN	No	File handle opened by calling the OPEN function. The file must be opened in read mode. Otherwise, the INVALID_OPERATION exception is thrown.
buffer	TEXT	OUT	No	Buffer used to receive data.
len	INTEGER	IN	Yes	Number of bytes read from a file. The default value is **NULL**. If the default value **NULL** is used, **max_line_size** is used to specify the line size.

- PKG_UTIL.FILE_WRITE

  Writes the data specified in the buffer to a file.

  The prototype of the PKG_UTIL.FILE_WRITE function is as follows:

  ```
  PKG_UTIL.FILE_WRITE(
  file IN INTEGER,
  buffer IN TEXT
  )
  RETURN BOOL
  ```

  Table 2-53 PKG_UTIL.FILE_WRITE API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
file	INTEGER	IN	No	Opened file handle.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Type	Input/Output Parameter	Can Be Null	Description
buffer	TEXT	IN	No	Text data to be written to a file. The maximum buffer size is 32767 bytes. If no value is specified, the default value is 1024 bytes. Before the writing is performed, the buffer occupied by PUT operations cannot exceed 32767 bytes. **NOTE** For the write operation, the system checks the file type. If the ELF file is written, an error will be reported and the system exits.

- PKG_UTIL.FILE_NEWLINE

  Writes a line terminator to an open file. The line terminator is related to the platform.

  The prototype of the PKG_UTIL.FILE_NEWLINE function is as follows:

  ```
  PKG_UTIL.FILE_NEWLINE(
  file IN INTEGER
  )
  RETURN BOOL
  ```

  Table 2-54 PKG_UTIL.FILE_NEWLINE API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
file	INTEGER	IN	No	Opened file handle.

- PKG_UTIL.FILE_WRITELINE

  Writes a line to a file.

  The prototype of the PKG_UTIL.FILE_WRITELINE function is as follows:

  ```
  PKG_UTIL.FILE_WRITELINE(
  file IN INTEGER,
  buffer IN TEXT
  )
  RETURN BOOL
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 2-55 PKG_UTIL.FILE_WRITELINE API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
file	INTEGER	IN	No	Opened file handle.
buffer	TEXT	IN	No	Content to be written.

- PKG_UTIL.FILE_READ_RAW

  Reads binary data of a specified length from an open file handle and returns the read binary data of the RAW type.

  The prototype of the PKG_UTIL.FILE_READ_RAW function is as follows:

```
PKG_UTIL.FILE_READ_RAW(
file      IN INTEGER,
length    IN INTEGER DEFAULT NULL
)
RETURN RAW
```

Table 2-56 PKG_UTIL.FILE_READ_RAW API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
file	INTEGER	IN	No	Opened file handle.
length	INTEGER	IN	Yes	Length of the data to be read. The default value is **NULL**. By default, all data in the file is read. The maximum size is 1 GB.

- PKG_UTIL.FILE_WRITE_RAW

  Writes the input binary object of the RAW type to an open file. If the insertion is successful, **true** is returned.

  The prototype of the PKG_UTIL.FILE_WRITE_RAW function is as follows:

```
PKG_UTIL.FILE_WRITE_RAW(
file IN INTEGER,
r    IN RAW
)
RETURN BOOL
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 2-57 PKG_UTIL.FILE_WRITE_RAW API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
file	INTEGER	IN	No	Opened file handle.
r	RAW	IN	No	Data to be written to the file. **NOTE** For the write operation, the system checks the file type. If the ELF file is written, an error will be reported and the system exits.

- PKG_UTIL.FILE_FLUSH

  Adds a line terminator to data in the buffer to write data in a file handle into a physical file. You can flush data if a file can only be read when it is opened. For example, debugging information can be flushed to a file so that it can be read immediately.

  The prototype of the PKG_UTIL.FILE_FLUSH function is as follows:

  ```
  PKG_UTIL.FILE_FLUSH(
  file IN INTEGER
  )
  RETURN VOID
  ```

  Table 2-58 PKG_UTIL.FILE_FLUSH API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
file	INTEGER	IN	No	Opened file handle.

- PKG_UTIL.FILE_CLOSE

  Closes a file handle.

  The prototype of the PKG_UTIL.FILE_CLOSE function is as follows:

  ```
  PKG_UTIL.FILE_CLOSE(
  file IN INTEGER
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
)
RETURN BOOL
```

Table 2-59 PKG_UTIL.FILE_CLOSE API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
file	INTEGER	IN	No	Opened file handle.

- PKG_UTIL.FILE_REMOVE

  Removes a disk file. To perform this operation, you must have required permissions.

  The prototype of the PKG_UTIL.FILE_REMOVE function is as follows:

  ```
  PKG_UTIL.FILE_REMOVE(
  file_name IN TEXT
  )
  RETURN VOID
  ```

  Table 2-60 PKG_UTIL.FILE_REMOVE API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
file_name	TEXT	IN	No	Name of the file to be removed.

- PKG_UTIL.FILE_RENAME

  Renames a file on the disk, similar to **mv** in Unix.

  The prototype of the PKG_UTIL.FILE_RENAME function is as follows:

  ```
  PKG_UTIL.FILE_RENAME(
  src_dir IN TEXT,
  src_file_name IN TEXT,
  dest_dir IN TEXT,
  dest_file_name IN TEXT,
  overwrite BOOLEAN DEFAULT false)
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 2-61 PKG_UTIL.FILE_RENAME API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
src_dir	TEXT	IN	No	Source file directory (case-sensitive). **NOTE** • Location of the file directory, which needs to be added to system catalog **PG_DIRECTORY**. If the input path does not match the path in **PG_DIRECTORY**, an error indicating that the path does not exist will be reported. • When the GUC parameter **safe_data_path** is enabled, you can only use an advanced package to operate files in the file path specified by **safe_data_path**.
src_file_name	TEXT	IN	No	Source file name.
dest_dir	TEXT	IN	No	Target file directory (case-sensitive). **NOTE** • Location of the file directory, which needs to be added to system catalog **PG_DIRECTORY**. If the input path does not match the path in **PG_DIRECTORY**, an error indicating that the path does not exist will be reported. • When the GUC parameter **safe_data_path** is enabled, you can only use an advanced package to operate files in the file path specified by **safe_data_path**.
dest_file_name	TEXT	IN	No	Target file name.
overwrite	BOOLEAN	IN	Yes	If a file with the same name exists in the destination directory, the file will not be rewritten. The default value is **false**.

- PKG_UTIL.FILE_SIZE

  Returns the size of a specified file.

  The prototype of the PKG_UTIL.FILE_SIZE function is as follows:

```
bigint PKG_UTIL.FILE_SIZE(
file_name IN TEXT
)return BIGINT
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 2-62 PKG_UTIL.FILE_SIZE API parameters

Parameter	Type	Input/ Output Parameter	Can Be Null	Description
file_name	TEXT	IN	No	File name.

- PKG_UTIL.FILE_BLOCK_SIZE

  Returns the number of blocks contained in a specified file.

  The prototype of the PKG_UTIL.FILE_BLOCK_SIZE function is as follows:

  ```
  bigint PKG_UTIL.FILE_BLOCK_SIZE(
  file_name IN TEXT
  )return BIGINT
  ```

  Table 2-63 PKG_UTIL.FILE_BLOCK_SIZE API parameters

Parameter	Type	Input/ Output Parameter	Can Be Null	Description
file_name	TEXT	IN	No	File name.

- PKG_UTIL.FILE_EXISTS

  Checks whether a file exists.

  The prototype of the PKG_UTIL.FILE_EXISTS function is as follows:

  ```
  PKG_UTIL.FILE_EXISTS(
  file_name IN TEXT
  )
  RETURN BOOL
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 2-64 PKG_UTIL.FILE_EXISTS API parameters

Parameter	Type	Input/ Output Parameter	Can Be Null	Description
file_name	TEXT	IN	No	File name.

- PKG_UTIL.FILE_GETPOS

  Specifies the offset of a returned file, in bytes.

  The prototype of the PKG_UTIL.FILE_GETPOS function is as follows:

```
PKG_UTIL.FILE_GETPOS(
file IN INTEGER
)
RETURN BIGINT
```

Table 2-65 PKG_UTIL.FILE_GETPOS API parameters

Parameter	Type	Input/ Output Parameter	Can Be Null	Description
file	INTEGER	IN	No	Opened file handle.

- PKG_UTIL.FILE_SEEK

  Adjusts the position of a file pointer forward or backward based on the specified number of bytes.

  The prototype of the PKG_UTIL.FILE_SEEK function is as follows:

```
void PKG_UTIL.FILE_SEEK(
file IN INTEGER,
start IN BIGINT
)
RETURN VOID
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 2-66 PKG_UTIL.FILE_SEEK API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
file	INTEGER	IN	No	Opened file handle.
start	BIGINT	IN	No	File offset, in bytes.

- PKG_UTIL.FILE_CLOSE_ALL

  Closes all file handles opened in a session. This function does not have input or output parameters.

  The prototype of the PKG_UTIL.FILE_CLOSE_ALL function is as follows:

  ```
  PKG_UTIL.FILE_CLOSE_ALL(
  )
  RETURN VOID
  ```

- PKG_UTIL.EXCEPTION_REPORT_ERROR

  Throws an exception.

  The prototype of the PKG_UTIL.EXCEPTION_REPORT_ERROR function is as follows:

  ```
  PKG_UTIL.EXCEPTION_REPORT_ERROR(
  code INTEGER,
  log TEXT,
  flag BOOLEAN DEFAULT FALSE
  )
  RETURN INTEGER
  ```

Table 2-67 PKG_UTIL.EXCEPTION_REPORT_ERROR API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
code	Integer	IN	No	Error code displayed when a running exception occurs.
log	TEXT	IN	No	Log displayed when a running exception occurs.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Type	Input/Output Parameter	Can Be Null	Description
flag	BOOLEAN	IN	Yes	Reserved. The default value is **FALSE**.

- PKG_UTIL.APP_READ_CLIENT_INFO

  Reads the client information.

  The prototype of the PKG_UTIL.APP_READ_CLIENT_INFO function is as follows:

  ```
  PKG_UTIL.APP_READ_CLIENT_INFO(
  OUT buffer TEXT
  )return TEXT
  ```

  Table 2-68 PKG_UTIL.APP_READ_CLIENT_INFO API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
buffer	TEXT	OUT	No	Client information returned.

- PKG_UTIL.APP_SET_CLIENT_INFO

  Sets the client information.

  The prototype of the PKG_UTIL.APP_SET_CLIENT_INFO function is as follows:

  ```
  PKG_UTIL.APP_SET_CLIENT_INFO(
  str TEXT
  )
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 2-69 PKG_UTIL.APP_SET_CLIENT_INFO API parameters

Parameter	Type	Input/ Output Parameter	Can Be Null	Description
str	TEXT	IN	No	Client information to be set.

- PKG_UTIL.LOB_CONVERTTOBLOB

  Converts a CLOB to a BLOB. *amount* indicates the conversion length.

  The prototype of the PKG_UTIL.LOB_CONVERTTOBLOB function is as follows:

```
PKG_UTIL.LOB_CONVERTTOBLOB(
dest_lob BLOB,
src_clob CLOB,
amount INTEGER,
dest_offset INTEGER,
src_offset INTEGER
)return RAW
```

Table 2-70 PKG_UTIL.LOB_CONVERTTOBLOB API parameters

Parameter	Type	Input/ Output Parameter	Can Be Null	Description
dest_lob	BLOB	IN	No	Target LOB.
src_clob	CLOB	IN	No	CLOB to be converted.
amount	INTEGER	IN	No	Length to be converted. If the length is less than 1 or greater than 32767, an error is reported.
dest_offset	INTEGER	IN	No	Start position of the target LOB. If the offset is less than 1 or greater than 1073741312, an error is reported.
src_offset	INTEGER	IN	No	Start position of the source CLOB. If the offset is less than 1 or greater than 1073741312, an error is reported.

- PKG_UTIL.LOB_CONVERTTOCLOB

  Converts a BLOB to a CLOB. *amount* indicates the conversion length.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

The prototype of the PKG_UTIL.LOB_CONVERTTOCLOB function is as follows:

```
PKG_UTIL.LOB_CONVERTTOCLOB(
dest_lob CLOB,
src_blob BLOB,
amount INTEGER,
dest_offset INTEGER,
src_offset INTEGER
)return TEXT
```

Table 2-71 PKG_UTIL.LOB_CONVERTTOCLOB API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
dest_lob	CLOB	IN	No	Target LOB.
src_blob	BLOB	IN	No	BLOB to be converted.
amount	INTEGER	IN	No	Length to be converted. If the length is less than 1 or greater than 32767, an error is reported.
dest_offset	INTEGER	IN	No	Start position of the target LOB. If the offset is less than 1 or greater than 1073741312, an error is reported.
src_offset	INTEGER	IN	No	Start position of the source CLOB. If the offset is less than 1 or greater than 1073741312, an error is reported.

- PKG_UTIL.LOB_TEXTTORAW

  Converts the input CLOB text into a RAW output, automatically prefixing a leading zero for odd-length inputs. The input text must consist of valid hexadecimal digits (0-9, A-F, a-f). If any invalid characters are included, an error will be reported.

  The prototype of the PKG_UTIL.LOB_TEXTTORAW function is as follows:

  ```
  PKG_UTIL.LOB_TEXTTORAW(
  src_lob CLOB
  )
  RETURN RAW
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 2-72 PKG_UTIL.LOB_TEXTTORAW API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
src_lob	CLOB	IN	No	LOB to be converted.

- PKG_UTIL.LOB_RAWTOTEXT

  Converts the input BLOB into a hexadecimal text output, automatically prefixing a leading zero for odd-length inputs. The input must consist of valid hexadecimal digits (0-9, A-F, a-f). If any invalid characters are included, an error will be reported.

  The prototype of the PKG_UTIL.LOB_RAWTOTEXT function is as follows:

```
PKG_UTIL.LOB_RAWTOTEXT(
src_lob IN BLOB
)
RETURN TEXT
```

Table 2-73 PKG_UTIL.LOB_RAWTOTEXT API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
src_lob	BLOB	IN	No	LOB to be converted.

- PKG_UTIL.MATCH_EDIT_DISTANCE_SIMILARITY

  Calculates the difference between two character strings.

  The prototype of the PKG_UTIL.MATCH_EDIT_DISTANCE_SIMILARITY function is as follows:

```
PKG_UTIL.MATCH_EDIT_DISTANCE_SIMILARITY(
str1 TEXT,
str2 TEXT
)
RETURN INTEGER
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 2-74 PKG_UTIL.MATCH_EDIT_DISTANCE_SIMILARITY API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
str1	TEXT	IN	No	First character string.
str2	TEXT	IN	No	Second character string.

- PKG_UTIL.RAW_CAST_TO_VARCHAR2

  Converts the raw type to the varchar2 type.

  The prototype of the PKG_UTIL.RAW_CAST_TO_VARCHAR2 function is as follows:

```
PKG_UTIL.RAW_CAST_TO_VARCHAR2(
str RAW
)
RETURN VARCHAR2
```

Table 2-75 PKG_UTIL.RAW_CAST_TO_VARCHAR2 API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
str	RAW	IN	No	Hexadecimal string.

- PKG_UTIL.SESSION_CLEAR_CONTEXT

  Clears the session context.

  The prototype of the PKG_UTIL.SESSION_CLEAR_CONTEXT function is as follows:

```
PKG_UTIL.SESSION_CLEAR_CONTEXT(
namespace TEXT,
client_identifier TEXT,
attribute TEXT
)
RETURN INTEGER
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 2-76 PKG_UTIL.SESSION_CLEAR_CONTEXT API parameters

Parameter	Type	Input/ Output Parameter	Can Be Null	Description
namespace	TEXT	IN	No	Namespace of an attribute.
client_identifier	TEXT	IN	Yes	Usually same as the value of **namespace**. If this parameter is set to **null**, all namespaces are modified by default.
attribute	TEXT	IN	No	Attribute value to be cleared.

- PKG_UTIL.SESSION_SEARCH_CONTEXT

  Searches for an attribute value.

  The prototype of the PKG_UTIL.SESSION_SEARCH_CONTEXT function is as follows:

```
PKG_UTIL.SESSION_SEARCH_CONTEXT(
namespace TEXT,
attribute TEXT
)
RETURN INTEGER
```

Table 2-77 PKG_UTIL.SESSION_SEARCH_CONTEXT API parameters

Parameter	Type	Input/ Output Parameter	Can Be Null	Description
namespace	TEXT	IN	No	Namespace of an attribute.
attribute	TEXT	IN	No	Attribute value to be searched for.

- PKG_UTIL.SESSION_SET_CONTEXT

  Sets an attribute value.

  The prototype of the PKG_UTIL.SESSION_SET_CONTEXT function is as follows:

```
PKG_UTIL.SESSION_SET_CONTEXT(
namespace TEXT,
attribute TEXT,
value TEXT
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
)
RETURN INTEGER
```

Table 2-78 PKG_UTIL.SESSION_SET_CONTEXT API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
namespace	TEXT	IN	No	Namespace of an attribute.
attribute	TEXT	IN	No	Attribute to be set.
value	TEXT	IN	No	Attribute value.

- PKG_UTIL.UTILITY_GET_TIME

  Prints the Unix timestamp.

  The prototype of the PKG_UTIL.UTILITY_GET_TIME function is as follows:

  ```
  PKG_UTIL.UTILITY_GET_TIME()
  RETURN BIGINT
  ```

- PKG_UTIL.UTILITY_FORMAT_ERROR_BACKTRACE

  Displays the error stack of a stored procedure.

  The prototype of the PKG_UTIL.UTILITY_FORMAT_ERROR_BACKTRACE function is as follows:

  ```
  PKG_UTIL.UTILITY_FORMAT_ERROR_BACKTRACE()
  RETURN TEXT
  ```

- PKG_UTIL.UTILITY_FORMAT_ERROR_STACK

  Displays the error information about a stored procedure.

  The prototype of the PKG_UTIL.UTILITY_FORMAT_ERROR_STACK function is as follows:

  ```
  PKG_UTIL.UTILITY_FORMAT_ERROR_STACK()
  RETURN TEXT
  ```

- PKG_UTIL.UTILITY_FORMAT_CALL_STACK

  Displays the call stack of a stored procedure.

  The prototype of the PKG_UTIL.UTILITY_FORMAT_CALL_STACK function is as follows:

  ```
  PKG_UTIL.UTILITY_FORMAT_CALL_STACK()
  RETURN TEXT
  ```

- PKG_UTIL.UTILITY_COMPILE_SCHEMA

  Recompiles packages, functions, and stored procedures in the specified schema.

  The prototype of the PKG_UTIL.UTILITY_COMPILE_SCHEMA function is as follows:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
PKG_UTIL.UTILITY_COMPILE_SCHEMA (
schema IN VARCHAR2,
compile_all IN BOOLEAN DEFAULT TRUE,
reuse_settings IN BOOLEAN DEFAULT FALSE
)
RETURNS VOID
```

- PKG_UTIL.GS_COMPILE_SCHEMA

  Recompiles packages, functions, and stored procedures in the specified schema.

  The prototype of the PKG_UTIL.GS_COMPILE_SCHEMA stored procedure is as follows:

  ```
  pkg_util.GS_COMPILE_SCHEMA (
  schema_name IN VARCHAR2 DEFAULT NULL,
  compile_all IN BOOLEAN DEFAULT FALSE,
  retry_times IN INT DEFAULT 10
  )
  ```

  Table 2-79 PKG_UTIL.GS_COMPILE_SCHEMA API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
schema_name	VARCHAR2	IN	Yes	Schema name.
compile_all	Boolean	IN	Yes	Specifies whether all objects are compiled. ● **false**: The packages, functions, and stored procedures whose status is **false** in the pg_object table are compiled. ● **true**: All packages, functions, and stored procedures in the pg_object table are compiled. ● **retry_times**: number of retry times.

- PKG_UTIL.APP_SET_MODULE

  Sets the value of a module.

  The prototype of the PKG_UTIL.APP_SET_MODULE stored procedure is as follows:

  ```
  PKG_UTIL.APP_SET_MODULE (
     str TEXT)
  returns VOID
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 2-80 PKG_UTIL.APP_SET_MODULE API parameters

Parameter	Type	Input/ Output Parameter	Can Be Null	Description
text	Text	IN	No	Value of the module to be set.

Example:

```
CALL PKG_UTIL.APP_SET_MODULE('set module');
 app_set_module
----------------

(1 row)
```

- PKG_UTIL.APP_READ_MODULE

  Reads the value of a module.

  The prototype of the PKG_UTIL.APP_READ_MODULE stored procedure is as follows:

```
PKG_UTIL.APP_READ_MODULE(
OUT buffer TEXT
)
```

Table 2-81 PKG_UTIL.APP_READ_MODULE API parameters

Parameter	Type	Input/ Output Parameter	Can Be Null	Description
buffer	TEXT	OUT	No	Value of the module to be returned.

Example:

```
CALL PKG_UTIL.APP_SET_MODULE('set module');
 app_set_module
----------------

(1 row)

DECLARE
    module VARCHAR2(64);
BEGINPKG_UTIL.APP_READ_MODULE(module);
    dbe_output.print_line(module);
END;
/
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
set module
ANONYMOUS BLOCK EXECUTE
```

- PKG_UTIL.APP_SET_ACTION

  Sets the value of an action.

  The prototype of the PKG_UTIL.APP_SET_ACTION stored procedure is as follows:

```
PKG_UTIL.APP_SET_ACTION (
    str TEXT)
returns VOID
```

Table 2-82 PKG_UTIL.APP_SET_ACTION API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
text	Text	IN	No	Value of the action to be set.

Example:

```
CALL PKG_UTIL.APP_SET_ACTION('set action');
 app_set_action
----------------

(1 row)
```

- PKG_UTIL.APP_READ_ACTION

  Reads the value of an action.

  The prototype of the PKG_UTIL.APP_READ_ACTION stored procedure is as follows:

```
PKG_UTIL.APP_READ_ACTION(
OUT buffer TEXT
)
```

Table 2-83 PKG_UTIL.APP_READ_ACTION API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
buffer	TEXT	OUT	No	Value of the action to be returned.

Example:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
CALL PKG_UTIL.APP_SET_ACTION('set action');
 app_set_action
----------------

(1 row)

DECLARE
       action VARCHAR2(64);
BEGINPKG_UTIL.APP_READ_ACTION(action);
      dbe_output.print_line(action);
END;
/
set action
ANONYMOUS BLOCK EXECUTE
```

- PKG_UTIL.MODIFY_PACKAGE_STATE

  Modifies the PL/SQL status of the current session.

  The prototype of the PKG_UTIL.MODIFY_PACKAGE_STATE stored procedure is as follows:

```
PKG_UTIL.MODIFY_PACKAGE_STATE (
    flags INT)
returns VOID
```

Table 2-84 PKG_UTIL.MODIFY_PACKAGE_STATE API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
flags	INT	IN	No	Bit flag of the operation performed on the PL/SQL. When **flags** is set to **1**, the session cache of the PL/SQL that is currently running in the session is released after the top-level PL/SQL is executed. The current value of any package is cleared globally and the cached cursor is closed. On subsequent use, PL/SQL re-instantiates and re-initializes the package globally. Other bit flags are not supported.

Example:

```
CALL PKG_UTIL.MODIFY_PACKAGE_STATE(1);
 modify_package_state
----------------------

(1 row)
```

2.12.1.3 DBE_XML

Table 2-85 lists all APIs supported by DBE_XML.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 2-85 DBE_XML API parameters

API	Description
DBE_XML.XML_FREE_PARSER	Frees a parser.
DBE_XML.XML_PARSER_GET_DOC	Obtains the parsed document node.
DBE_XML.XML_GET_VALIDATION_MODE	Obtains the validation attribute.
DBE_XML.XML_NEW_PARSER	Creates a parser instance.
DBE_XML.XML_PARSE_BUFFER	Parses the VARCHAR string.
DBE_XML.XML_PARSE_CLOB	Parses the CLOB string.
DBE_XML.XML_SET_VALIDATION_MODE	Sets the validation attribute.
DBE_XML.XML_DOM_APPEND_CHILD	Adds the newchild node to the end of the parent(n) node and returns the newly added node.
DBE_XML.XML_DOM_CREATE_ELEMENT	Returns the DOMElement object with the specified name.
DBE_XML.XML_DOM_CREATE_ELEMENT_NS	Returns the DOMElement object with the specified name and namespace.
DBE_XML.XML_DOM_CREATE_TEXT_NODE	Creates and returns a DOMText object.
DBE_XML.XML_DOM_FREE_DOCUMENT	Frees a specified XML DOM object.
DBE_XML.XML_DOM_FREE_ELEMENT	Frees a specified XML DOM object.
DBE_XML.XML_DOM_FREE_NODE	Frees a DOMNode node.
DBE_XML.XML_DOM_FREE_NODELIST	Frees a DOMNodeList node.
DBE_XML.XML_DOM_GET_ATTRIBUTE	Obtains the attributes of a specified XML DOM object.
DBE_XML.XML_DOM_GET_ATTRIBUTES	Returns the attribute values of a DOMNode node as a map.
DBE_XML.XML_DOM_GET_CHILD_NODES	Converts several subnodes under a node into a node list.
DBE_XML.XML_DOM_GET_CHILDREN_BY_TAGNAME	Obtains the list of specified subnodes of a specified XML DOM object.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

API	Description
DBE_XML.XML_DOM_GET_CHILDREN_BY_TAGNAME_NS	Obtains the list of subnodes in the specified namespace of a specified XML DOM object.
DBE_XML.XML_DOM_GET_DOCUMENT_ELEMENT	Returns the first subnode of the specified document.
DBE_XML.XML_DOM_GET_FIRST_CHILD	Returns the first subnode of a node.
DBE_XML.XML_DOM_GET_LAST_CHILD	Returns the last subnode of a node.
DBE_XML.XML_DOM_GET_LENGTH	Returns the number of nodes based on the content in the node of the specified type.
DBE_XML.XML_DOM_GET_LOCALNAME	Returns the local name of the given object.
DBE_XML.XML_DOM_GET_NAMED_ITEM	Returns the node specified by name.
DBE_XML.XML_DOM_GET_NAMED_ITEM_NS	Returns the node specified by name and namespace.
DBE_XML.XML_DOM_GET_NEXT_SIBLING	Returns the next node of the specified node.
DBE_XML.XML_DOM_GET_NODE_NAME	Returns the name of a node.
DBE_XML.XML_DOM_GET_NODE_TYPE	Returns the type of a node.
DBE_XML.XML_DOM_GET_NODE_VALUE	Returns the value of a node.
DBE_XML.XML_DOM_GET_PARENT_NODE	Returns the parent node of the given node.
DBE_XML.XML_DOM_GET_TAGNAME	Obtains the tag name of a specified XML DOM object.
DBE_XML.XML_DOM_HAS_CHILD_NODES	Checks whether the DOMNode object has any subnode.
DBE_XML.XML_DOM_IMPORT_NODE	Copies a node to another node and mounts the copied node to a specified document.
DBE_XML.XML_DOM_IS_NULL	Checks whether the given object is null.
DBE_XML.XML_DOM_ITEM	Returns the element corresponding to the index in a list or map based on the index.
DBE_XML.XML_DOM_MAKE_ELEMENT	Returns the DOMElement object after conversion.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

API	Description
DBE_XML.XML_DOM_MAKENODE	Converts the given object to the DOMNode type.
DBE_XML.XML_DOM_NEW_DOM_DOCUMENT_EMPTY	Returns a new DOMDocument object.
DBE_XML.XML_DOM_NEW_DOM_DOCUMENT_CLOB	Returns a new DOMDocument instance object created from the specified CLOB type.
DBE_XML.XML_DOM_NEW_DOCUMENT_XMLTYPE	Returns a new DOMDocument instance object created from the specified XMLType type.
DBE_XML.XML_DOM_SET_ATTRIBUTE	Sets the attributes of a specified XML DOM object.
DBE_XML.XML_DOM_SET_CHARSET	Sets the character set for a DOMDocument object.
DBE_XML.XML_DOM_SET_DOCTYPE	Sets the external DTD of a DOMDocument object.
DBE_XML.XML_DOM_SET_NODE_VALUE	Sets the value of a node in the DOMNode object.
DBE_XML.XML_DOM_WRITE_TO_BUFFER_DOC	Writes the given DOMDocument object to the buffer.
DBE_XML.XML_DOM_WRITE_TO_BUFFER_NODE	Writes the given DOMNode object to the buffer.
DBE_XML.XML_DOM_WRITE_TO_CLOB_DOC	Writes the given DOMDocument object to a CLOB.
DBE_XML.XML_DOM_WRITE_TO_CLOB_NODE	Writes the given DOMNode object to a CLOB.
DBE_XML.XML_DOM_WRITE_TO_FILE_DOC	Writes an XML node to a specified file using the database character set.
DBE_XML.XML_DOM_WRITE_TO_FILE_NODE	Writes an XML node to a specified file using the database character set.
DBE_XML.XML_DOM_GET_SESSION_TREE_NUM	Displays the number of DOM trees of all types in the current session.
DBE_XML.XML_DOM_GET_DOC_TREES_INFO	Displays statistics such as the memory usage and number of nodes of the DOM tree of the document type.
DBE_XML.XML_DOM_GET_DETAIL_DOC_TREE_INFO	Displays the number of nodes of each type for a specific document variable.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- DBE_XML.XML_FREE_PARSER

  Frees a given parser object.

  The prototype of the DBE_XML.XML_FREE_PARSER stored procedure is as follows:

  ```
  DBE_XML.XML_FREE_PARSER(
  id IN RAW(13))
  returns VOID;
  ```

  Table 2-86 DBE_XML.XML_FREE_PARSER API parameters

Parameter	Type	Input/ Output Parameter	Can Be Null	Description
id	RAW(13)	IN	Yes	Parser object.

- DBE_XML.XML_PARSER_GET_DOC

  Returns the root node of the DOM tree document constructed by the parser.

  The prototype of the DBE_XML.XML_PARSER_GET_DOC function is as follows:

  ```
  DBE_XML.XML_PARSER_GET_DOC(
  id IN RAW(13))
  returns RAW(13);
  ```

  Table 2-87 DBE_XML.XML_PARSER_GET_DOC API parameters

Parameter	Type	Input/ Output Parameter	Can Be Null	Description
id	RAW(13)	IN	Yes	Parser object.

  NOTE

  - If the DBE_XML.XML_PARSER_GET_DOC function is empty, **NULL** is returned.
  - If the parser input by the DBE_XML.XML_PARSER_GET_DOC function has not parsed any document, **NULL** is returned.

- DBE_XML.XML_GET_VALIDATION_MODE

  Obtains the parsing validation mode of a specified parser. If DTD validation is enabled, **TRUE** is returned. Otherwise, **FALSE** is returned.

  The prototype of the DBE_XML.XML_GET_VALIDATION_MODE function is as follows:

  ```
  DBE_XML.XML_GET_VALIDATION_MODE(
  id RAW(13))
  returns BOOL;
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 2-88 DBE_XML.XML_GET_VALIDATION_MODE API parameters

Parameter	Type	Input/ Output Parameter	Can Be Null	Description
id	RAW(13)	IN	Yes	Parser object.

- DBE_XML.XML_NEW_PARSER

  Creates a parser object and returns a new parser instance.

  The prototype of the DBE_XML.XML_NEW_PARSER function is as follows:

  ```
  DBE_XML.XML_NEW_PARSER()
  RETURNS RAW(13);
  ```

- DBE_XML.XML_PARSE_BUFFER

  Parses XML documents stored in strings.

  The prototype of the DBE_XML.XML_PARSE_BUFFER stored procedure is as follows:

  ```
  DBE_XML.XML_PARSE_BUFFER(
  id RAW(13),
  xmlstr VARCHAR2)
  RETURNS VOID;
  ```

Table 2-89 DBE_XML.XML_PARSE_BUFFER API parameters

Parameter	Type	Input/ Output Parameter	Can Be Null	Description
id	RAW(13)	IN	Yes	Parser object.
xmlstr	VARCHAR2	IN	No	A string that stores XML documents.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- The maximum length of a character string that can be parsed by the xml_parse_buffer function is 32767. If the length exceeds the maximum, an error is reported.
- Different from the ORA database, this database supports only UTF-8 in terms of character encoding, and **version** can only be set to **1.0**. If versions 1.0 to 1.9 are parsed, the execution is normal but a warning appears. For versions later than 1.9, an error is reported.
- DTD validation differences:
  - **!ATTLIST to type (CHECK|check|Check) "Ch..."** reports an error because the default value **"Ch..."** is not an enumerated value in the brackets. However, the ORA database does not report this error.
  - **<!ENTITY baidu "www.baidu.com">..... &Baidu;&writer** reports an error because the letters are case-sensitive. **Baidu** cannot correspond to **baidu**. However, the ORA database does not report this error.
- Namespace validation difference: Undeclared namespace tags are parsed. However, the ORA database reports an error.
- Difference in parsing XML predefined entities: **'** and **"** are parsed and escaped to ' and ". However, predefined entities in database ORA are not escaped to characters.

- DBE_XML.XML_PARSE_CLOB

  Parses XML documents stored in XML_PARSE_CLOB.

  The prototype of the DBE_XML.XML_PARSE_CLOB stored procedure is as follows:

```
DBE_XML.XML_PARSE_CLOB(
id IN RAW(13),
doc IN CLOB)
returns VOID;
```

Table 2-90 DBE_XML.XML_PARSE_CLOB API parameters

Parameter	Type	Input/ Output Parameter	Can Be Null	Description
id	RAW(13)	IN	Yes	Parser object.
doc	CLOB	IN	No	A string that stores XML documents.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- xml_parse_clob cannot parse CLOBs larger than 1 GB.
- Different from the ORA database, this database supports only UTF-8 in terms of character encoding, and **version** can only be set to **1.0**. If versions 1.0 to 1.9 are parsed, the execution is normal but a warning appears. For versions later than 1.9, an error is reported.
- DTD validation differences:
  - **!ATTLIST to type (CHECK|check|Check) "Ch..."** reports an error because the default value **"Ch..."** is not an enumerated value in the brackets. However, the ORA database does not report this error.
  - **<!ENTITY baidu "www.baidu.com">..... &Baidu;&writer** reports an error because the letters are case-sensitive. **Baidu** cannot correspond to **baidu**. However, the ORA database does not report this error.
- Namespace validation difference: Undeclared namespace tags are parsed. However, the ORA database reports an error.
- Difference in parsing XML predefined entities: **'** and **"** are parsed and escaped to ' and ". However, predefined entities in database ORA are not escaped to characters.

- DBE_XML.XML_SET_VALIDATION_MODE

  Sets the parsing validation mode of a specified parser.

  The stored procedure prototype of DBE_XML.XML_SET_VALIDATION_MODE is as follows:

```
DBE_XML.XML_SET_VALIDATION_MODE(
id RAW(13),
validate BOOLEAN)
returns VOID;
```

Table 2-91 DBE_XML.XML_SET_VALIDATION_MODE API parameters

Parameter	Type	Input/ Output Parameter	Can Be Null	Description
id	RAW(13)	IN	Yes	Parser object.
validate	BOOLEAN	IN	Yes	Mode to be set: • **TRUE**: DTD validation is enabled. • **FALSE**: DTD validation is disabled.

NOTE

- If the input parameter **validate** of the DBE_XML.XML_SET_VALIDATION_MODE function is null, the parsing validation mode of the parser is not changed.
- By default, the DTD validation is enabled during parser initialization.

- DBE_XML.XML_DOM_APPEND_CHILD

  Adds the newchild node to the end of the parent(n) node and returns the newly added node.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

The prototype of the DBE_XML.XML_DOM_APPEND_CHILD stored procedure is as follows:

```
DBE_XML.XML_DOM_APPEND_CHILD(
   parentId IN RAW(13),
   childId IN RAW(13)
)
RETURNS RAW(13);
```

Table 2-92 DBE_XML.XML_DOM_APPEND_CHILD API parameters

Parameter	Type	Input/ Output Parameter	Can Be Null	Description
parentId	RAW(13)	IN	No	XML DOM object.
childId	RAW(13)	IN	No	XML DOM object.

- DBE_XML.XML_DOM_CREATE_ELEMENT

  Returns the DOMElement object with the specified name.

  The prototype of the DBE_XML.XML_DOM_CREATE_ELEMENT function is as follows:

```
DBE_XML.XML_DOM_CREATE_ELEMENT(
   id IN RAW(13),
   tagname IN VARCHAR2
)
RETURNS RAW(13);
```

Table 2-93 DBE_XML.XML_DOM_CREATE_ELEMENT API parameters

Parameter	Type	Input/ Output Parameter	Can Be Null	Description
id	RAW(13)	IN	No	XML DOM object.
tagname	VARCHAR2	IN	No	Name of the new DOMElement object.

- DBE_XML.XML_DOM_CREATE_ELEMENT_NS

  Returns the DOMElement object with the specified name and namespace.

  The prototype of the DBE_XML.XML_DOM_CREATE_ELEMENT_NS function is as follows:

```
DBE_XML.XML_DOM_CREATE_ELEMENT_NS(
   id IN RAW(13),
   tagname IN VARCHAR2,
   ns IN VARCHAR2
)
RETURNS RAW(13);
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 2-94 DBE_XML.XML_DOM_CREATE_ELEMENT_NS API parameters

Parameter	Type	Input/ Output Parameter	Can Be Null	Description
id	RAW(13)	IN	No	XML DOM object.
tagname	VARCHAR2	IN	No	Name of the new DOMElement object.
ns	VARCHAR2	IN	No	Namespace.

- DBE_XML.XML_DOM_CREATE_TEXT_NODE

  Creates and returns a DOMText object.

  The prototype of the DBE_XML.XML_DOM_CREATE_TEXT_NODE function is as follows:

```
DBE_XML.XML_DOM_CREATE_TEXT_NODE(
   id IN RAW(13),
   data IN VARCHAR2
)
RETURNS RAW(13);
```

  Table 2-95 DBE_XML.XML_DOM_CREATE_TEXT_NODE API parameters

Parameter	Type	Input/ Output Parameter	Can Be Null	Description
id	RAW(13)	IN	No	XML DOM object.
data	VARCHAR2	IN	No	Content of the new DOMText node.

- DBE_XML.XML_DOM_FREE_DOCUMENT

  Frees a specified XML DOM object.

  The prototype of the DBE_XML.XML_DOM_FREE_DOCUMENT stored procedure is as follows:

```
DBE_XML.XML_DOM_FREE_DOCUMENT(
   id RAW(13)
)
RETURNS VOID;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 2-96 DBE_XML.XML_DOM_FREE_DOCUMENT API parameters

Parameter	Type	Input/ Output Parameter	Can Be Null	Description
id	RAW(13)	IN	No	XML DOM object.

- DBE_XML.XML_DOM_FREE_ELEMENT

  Frees a specified XML DOM object.

  The prototype of the DBE_XML.XML_DOM_FREE_ELEMENT stored procedure is as follows:

```
DBE_XML.XML_DOM_FREE_ELEMENT (
    id RAW(13)
)
RETURNS VOID;
```

Table 2-97 DBE_XML.XML_DOM_FREE_ELEMENT API parameters

Parameter	Type	Input/ Output Parameter	Can Be Null	Description
id	RAW(13)	IN	No	XML DOM object.

- DBE_XML.XML_DOM_FREE_NODE

  Frees a DOMNode node.

  The prototype of the DBE_XML.XML_DOM_FREE_NODE function is as follows:

```
DBE_XML.XML_DOM_FREE_NODE (
    id RAW(13)
)
RETURNS VOID;
```

Table 2-98 DBE_XML.XML_DOM_FREE_NODE API parameters

Parameter	Type	Input/ Output Parameter	Can Be Null	Description
id	RAW(13)	IN	No	XML DOM object.

- DBE_XML.XML_DOM_FREE_NODELIST

  Frees a DOMNodeList node.

  The prototype of the DBE_XML.XML_DOM_FREE_NODELIST stored procedure is as follows:

```
DBE_XML.XML_DOM_FREE_NODELIST(
    id IN RAW(13)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
)
RETURNS VOID
```

Table 2-99 DBE_XML.XML_DOM_FREE_NODELIST API parameters

Parameter	Type	Input/ Output Parameter	Can Be Null	Description
id	RAW(13)	IN	No	XML DOM object.

- DBE_XML.XML_DOM_GET_ATTRIBUTE

  Obtains the attributes of a specified XML DOM object.

  The prototype of the DBE_XML.XML_DOM_GET_ATTRIBUTE stored procedure is as follows:

```
DBE_XML.XML_DOM_GET_ATTRIBUTE (
   docid   IN  RAW(13),
   name    IN  VARCHAR2
)
RETURNS VARCHAR2;
```

Table 2-100 DBE_XML.XML_DOM_GET_ATTRIBUTE API parameters

Parameter	Type	Input/ Output Parameter	Can Be Null	Description
docid	RAW(13)	IN	No	XML DOM object.
name	VARCHAR2	IN	No	A string.

- DBE_XML.XML_DOM_GET_ATTRIBUTES

  Returns the attribute values of a DOMNode node as a map.

  The prototype of the DBE_XML.XML_DOM_GET_ATTRIBUTES function is as follows:

```
DBE_XML.XML_DOM_GET_ATTRIBUTES (
   id RAW(13)
)
RETURNS RAW(13);
```

Table 2-101 DBE_XML.XML_DOM_GET_ATTRIBUTES API parameters

Parameter	Type	Input/ Output Parameter	Can Be Null	Description
id	RAW(13)	IN	No	XML DOM object.

- DBE_XML.XML_DOM_GET_CHILD_NODES

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Converts several subnodes under a node into a node list.

The prototype of the DBE_XML.XML_DOM_GET_CHILD_NODES function is as follows:

```
DBE_XML.XML_DOM_GET_CHILD_NODES(
   id IN RAW(13)
)
RETURNS RAW(13);
```

Table 2-102 DBE_XML.XML_DOM_GET_CHILD_NODES API parameters

Parameter	Type	Input/ Output Parameter	Can Be Null	Description
id	RAW(13)	IN	No	XML DOM object.

- DBE_XML.XML_DOM_GET_CHILDREN_BY_TAGNAME

  Obtains the list of specified subnodes of a specified XML DOM object.

  The prototype of the DBE_XML.XML_DOM_GET_CHILDREN_BY_TAGNAME stored procedure is as follows:

  ```
  DBE_XML.XML_DOM_GET_CHILDREN_BY_TAGNAME (
     docid   IN  RAW(13),
     name    IN  VARCHAR2
  )
  RETURNS RAW(13);
  ```

  Table 2-103 DBE_XML.XML_DOM_GET_CHILDREN_BY_TAGNAME API parameters

Parameter	Type	Input/ Output Parameter	Can Be Null	Description
docid	RAW(13)	IN	No	XML DOM object.
name	VARCHAR2	IN	No	A string.

- DBE_XML.XML_DOM_GET_CHILDREN_BY_TAGNAME_NS

  Obtains the list of subnodes in the specified namespace of a specified XML DOM object.

  The prototype of the DBE_XML.XML_DOM_GET_CHILDREN_BY_TAGNAME_NS stored procedure is as follows:

  ```
  DBE_XML.XML_DOM_GET_CHILDREN_BY_TAGNAME_NS (
     docid   IN  RAW(13),
     name    IN  VARCHAR2,
     ns      IN  VARCHAR2
  )
  RETURNS RAW(13);
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 2-104 DBE_XML.XML_DOM_GET_CHILDREN_BY_TAGNAME_NS API parameters

Parameter	Type	Input/ Output Parameter	Can Be Null	Description
docid	RAW(13)	IN	No	XML DOM object.
name	VARCHAR2	IN	No	A string.
ns	VARCHAR2	IN	Yes	A string.

- DBE_XML.XML_DOM_GET_DOCUMENT_ELEMENT

  Returns the first subnode of the specified document.

  The prototype of the DBE_XML.XML_DOM_GET_DOCUMENT_ELEMENT stored procedure is as follows:

```
DBE_XML.XML_DOM_GET_DOCUMENT_ELEMENT(
   id  RAW(13)
)
RETURNS RAW(13);
```

  Table 2-105 DBE_XML.XML_DOM_GET_DOCUMENT_ELEMENT API parameters

Parameter	Type	Input/ Output Parameter	Can Be Null	Description
id	RAW(13)	IN	No	XML DOM object.

- DBE_XML.XML_DOM_GET_FIRST_CHILD

  Returns the first subnode of a node.

  The prototype of the DBE_XML.XML_DOM_GET_FIRST_CHILD function is as follows:

```
DBE_XML.XML_DOM_GET_FIRST_CHILD(
   id IN RAW(13)
)
RETURNS RAW(13);
```

  Table 2-106 DBE_XML.XML_DOM_GET_FIRST_CHILD API parameters

Parameter	Type	Input/ Output Parameter	Can Be Null	Description
id	RAW(13)	IN	No	XML DOM object.

- DBE_XML.XML_DOM_GET_LAST_CHILD

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Returns the last subnode of a node.

The prototype of the DBE_XML.XML_DOM_GET_LAST_CHILD function is as follows:

```
DBE_XML.XML_DOM_GET_LAST_CHILD(
    id IN RAW(13)
)
RETURNS RAW(13);
```

Table 2-107 DBE_XML.XML_DOM_GET_LAST_CHILD API parameters

Parameter	Type	Input/ Output Parameter	Can Be Null	Description
id	RAW(13)	IN	No	XML DOM object.

- DBE_XML.XML_DOM_GET_LENGTH

  Returns the number of nodes based on the content in the node of the specified type.

  The prototype of the DBE_XML.XML_DOM_GET_LENGTH stored procedure is as follows:

  ```
  DBE_XML.XML_DOM_GET_LENGTH(
      id RAW(13)
  )
  RETURNS VOID;
  ```

  Table 2-108 DBE_XML.XML_DOM_GET_LENGTH API parameters

Parameter	Type	Input/ Output Parameter	Can Be Null	Description
id	RAW(13)	IN	Yes	XML DOM object.

- DBE_XML.XML_DOM_GET_LOCALNAME

  Returns the local name of the given object.

  The prototype of the DBE_XML.XML_DOM_GET_LOCALNAME stored procedure is as follows:

  ```
  DBE_XML.XML_DOM_GET_LOCALNAME (
      id  RAW(13)
  )
  RETURNS VARCHAR2;
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 2-109 DBE_XML.XML_DOM_GET_LOCALNAME API parameters

Parameter	Type	Input/ Output Parameter	Can Be Null	Description
id	RAW(13)	IN	Yes	XML DOM object.

- DBE_XML.XML_DOM_GET_NAMED_ITEM

  Returns the node specified by name.

  The prototype of the DBE_XML.XML_DOM_GET_NAMED_ITEM function is as follows:

```
DBE_XML.XML_DOM_GET_NAMED_ITEM(
   id IN RAW(13),
   nodeName IN VARCHAR2
)
RETURNS RAW(13);
```

Table 2-110 DBE_XML.XML_DOM_GET_NAMED_ITEM API parameters

Parameter	Type	Input/ Output Parameter	Can Be Null	Description
id	RAW(13)	IN	No	XML DOM object.
nodeName	VARCHAR2	IN	No	Name of the element to be retrieved.

- DBE_XML.XML_DOM_GET_NAMED_ITEM_NS

  Returns the node specified by name and namespace.

  The prototype of the DBE_XML.XML_DOM_GET_NAMED_ITEM_NS function is as follows:

```
DBE_XML.XML_DOM_GET_NAMED_ITEM_NS(
   id  RAW(13),
   nodeName IN VARCHAR2,
   ns IN VARCHAR2
)
RETURNS RAW(13);
```

Table 2-111 DBE_XML.XML_DOM_GET_NAMED_ITEM_NS API parameters

Parameter	Type	Input/ Output Parameter	Can Be Null	Description
id	RAW(13)	IN	No	XML DOM object.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Type	Input/ Output Parameter	Can Be Null	Description
nodeName	VARCHAR2	IN	No	Name of the element to be retrieved.
ns	VARCHAR2	IN	Yes	Namespace.

- DBE_XML.XML_DOM_GET_NEXT_SIBLING

  Returns the next node of the specified node.

  The prototype of the DBE_XML.XML_DOM_GET_NEXT_SIBLING function is as follows:

```
DBE_XML.XML_DOM_GET_NEXT_SIBLING(
    id IN RAW(13)
)
RETURNS RAW(13);
```

  Table 2-112 DBE_XML.XML_DOM_GET_NEXT_SIBLING API parameters

Parameter	Type	Input/ Output Parameter	Can Be Null	Description
id	RAW(13)	IN	No	XML DOM object.

- DBE_XML.XML_DOM_GET_NODE_NAME

  Returns the name of a node.

  The prototype of the DBE_XML.XML_DOM_GET_NODE_NAME function is as follows:

```
DBE_XML.XML_DOM_GET_NODE_NAME(
    id IN RAW(13)
)
RETURNS VARCHAR2;
```

  Table 2-113 DBE_XML.XML_DOM_GET_NODE_NAME API parameters

Parameter	Type	Input/ Output Parameter	Can Be Null	Description
id	RAW(13)	IN	No	XML DOM object.

- DBE_XML.XML_DOM_GET_NODE_TYPE

  Returns the type of a node.

  The prototype of the DBE_XML.XML_DOM_GET_NODE_TYPE function is as follows:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
DBE_XML.XML_DOM_GET_NODE_TYPE(
   id IN RAW(13)
)
RETURNS INTEGER;
```

Table 2-114 DBE_XML.XML_DOM_GET_NODE_TYPE API parameters

Parameter	Type	Input/ Output Parameter	Can Be Null	Description
id	RAW(13)	IN	No	XML DOM object.

- DBE_XML.XML_DOM_GET_NODE_VALUE

  Returns the value of a node.

  The prototype of the DBE_XML.XML_DOM_GET_NODE_VALUE stored procedure is as follows:

  ```
  DBE_XML.XML_DOM_GET_NODE_VALUE(
  id IN RAW(13))
  RETURNS VARCHAR2;
  ```

  Table 2-115 DBE_XML.XML_DOM_GET_NODE_VALUE API parameters

Parameter	Type	Input/ Output Parameter	Can Be Null	Description
id	RAW(13)	IN	Yes	XML DOM object.

- DBE_XML.XML_DOM_GET_PARENT_NODE

  Returns the parent node of the given node.

  The prototype of the DBE_XML.XML_DOM_GET_PARENT_NODE stored procedure is as follows:

  ```
  DBE_XML.XML_DOM_GET_PARENT_NODE(
  id IN RAW(13))
  RETURNS RAW(13);
  ```

  Table 2-116 DBE_XML.XML_DOM_GET_PARENT_NODE API parameters

Parameter	Type	Input/ Output Parameter	Can Be Null	Description
id	RAW(13)	IN	Yes	XML DOM object.

- DBE_XML.XML_DOM_GET_TAGNAME

  Obtains the tag name of a specified XML DOM object.

  The prototype of the DBE_XML.XML_DOM_GET_TAGNAME stored procedure is as follows:

```
DBE_XML.XML_DOM_GET_TAGNAME (
   docid RAW(13)
)
RETURNS VARCHAR2;
```

Table 2-117 DBE_XML.XML_DOM_GET_TAGNAME API parameters

Parameter	Type	Input/ Output Parameter	Can Be Null	Description
docid	RAW(13)	IN	Yes	XML DOM object.

- DBE_XML.XML_DOM_HAS_CHILD_NODES

  Checks whether the DOMNode object has any subnode.

  The prototype of the DBE_XML.XML_DOM_HAS_CHILD_NODES stored procedure is as follows:

  ```
  DBE_XML.XML_DOM_HAS_CHILD_NODES(
  id IN RAW(13))
  RETURNS BOOLEAN
  ```

  Table 2-118 DBE_XML.XML_DOM_HAS_CHILD_NODES API parameters

Parameter	Type	Input/ Output Parameter	Can Be Null	Description
id	RAW(13)	IN	Yes	XML DOM object.

- DBE_XML.XML_DOM_IMPORT_NODE

  Copies a node to another node and mounts the copied node to a specified document. If the type of the copied node does not belong to the 12 types specified by constants of XML DOM, an exception indicating that the type is not supported will be thrown.

  The prototype of the DBE_XML.XML_DOM_IMPORT_NODE function is as follows:

  ```
  DBE_XML.XML_DOM_IMPORT_NODE(
     doc_id IN RAW(13),
     node_id IN RAW(13),
     deep IN BOOLEAN
  )
  RETURNS RAW(13);
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 2-119 DBE_XML.XML_DOM_IMPORT_NODE API parameters

Parameter	Type	Input/ Output Parameter	Can Be Null	Description
doc_id	RAW(13)	IN	No	Document to which the node is mounted.
node_id	RAW(13)	IN	No	Node to be imported.
deep	BOOLEAN	IN	No	Specifies whether to perform recursive import. • If the value is **TRUE**, the node and all its subnodes are imported. • If the value is **FALSE**, the node itself is imported.

- DBE_XML.XML_DOM_IS_NULL

  Checks whether the given object is null. If it is null, **TRUE** is returned. Otherwise, **FALSE** is returned.

  The prototype of the DBE_XML.XML_DOM_IS_NULL function is as follows:

```
DBE_XML.XML_DOM_IS_NULL (
   id  RAW(13)
)
RETURNS BOOLEAN;
```

Table 2-120 DBE_XML.XML_DOM_IS_NULL API parameters

Parameter	Type	Input/ Output Parameter	Can Be Null	Description
id	RAW(13)	IN	Yes	XML DOM object.

- DBE_XML.XML_DOM_ITEM

  Returns the element corresponding to the index in a list or map based on the index.

  The prototype of the DBE_XML.XML_DOM_ITEM function is as follows:

```
DBE_XML.XML_DOM_ITEM (
   id IN RAW(13),
   index IN INTEGER
)
RETURNS RAW(13);
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 2-121 DBE_XML.XML_DOM_ITEM API parameters

Parameter	Type	Input/ Output Parameter	Can Be Null	Description
id	RAW(13)	IN	No	XML DOM object.
index	INTEGER	IN	No	Index of the element to be retrieved.

- DBE_XML.XML_DOM_MAKE_ELEMENT

  Returns the DOMElement object after conversion.

  The prototype of the DBE_XML.XML_DOM_MAKE_ELEMENT stored procedure is as follows:

```
DBE_XML.XML_DOM_MAKE_ELEMENT(
id IN RAW(13))
RETURNS RAW(13)
```

Table 2-122 DBE_XML.XML_DOM_MAKE_ELEMENT API parameters

Parameter	Type	Input/ Output Parameter	Can Be Null	Description
id	RAW(13)	IN	No	XML DOM object.

- DBE_XML.XML_DOM_MAKENODE

  Converts the given object to the DOMNode type.

  The prototype of the DBE_XML.XML_DOM_MAKENODE stored procedure is as follows:

```
DBE_XML.XML_DOM_MAKENODE(
  id    RAW(13)
)
RETURNS DOMNODE;
```

Table 2-123 DBE_XML.XML_DOM_MAKENODE API parameters

Parameter	Type	Input/ Output Parameter	Can Be Null	Description
id	RAW(13)	IN	Yes	XML DOM object.

- DBE_XML.XML_DOM_NEW_DOM_DOCUMENT_EMPTY

  Returns a new DOMDocument object.

  The prototype of the DBE_XML.XML_DOM_NEW_DOM_DOCUMENT_EMPTY function is as follows:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
DBE_XML.XML_DOM_NEW_DOM_DOCUMENT_EMPTY()
RETURNS RAW(13);
```

- DBE_XML.XML_DOM_NEW_DOM_DOCUMENT_CLOB

  Returns a new DOMDocument instance object created from the specified CLOB type.

  The prototype of the DBE_XML.XML_DOM_NEW_DOM_DOCUMENT_CLOB function is:

```
DBE_XML.XML_DOM_NEW_DOM_DOCUMENT_CLOB(
   content IN  CLOB
)
RETURNS RAW(13);
```

  Table 2-124 xml_dom_new_dom_document_clob API parameters

Parameter	Type	Input/ Output Parameter	Can Be Null	Description
content	CLOB	IN	No	Specified CLOB type.

- DBE_XML.XML_DOM_NEW_DOCUMENT_XMLTYPE

  Returns a new DOMDocument instance object created from the specified XMLType type.

  The prototype of the DBE_XML.XML_DOM_NEW_DOCUMENT_XMLTYPE function is as follows:

```
DBE_XML.XML_DOM_NEW_DOCUMENT_XMLTYPE(
   content IN  CLOB
)
RETURNS RAW(13);
```

  Table 2-125 DBE_XML.XML_DOM_NEW_DOCUMENT_XMLTYPE API parameters

Parameter	Type	Input/ Output Parameter	Can Be Null	Description
content	CLOB	IN	No	Specified CLOB type.

- DBE_XML.XML_DOM_SET_ATTRIBUTE

  Sets the attributes of a specified XML DOM object.

  The prototype of the DBE_XML.XML_DOM_SET_ATTRIBUTE stored procedure is as follows:

```
DBE_XML.XML_DOM_SET_ATTRIBUTE(
   docid   IN  RAW(13),
   name    IN  VARCHAR2,
   value   IN  VARCHAR2
)
RETURNS void;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 2-126 DBE_XML.XML_DOM_SET_ATTRIBUTE API parameters

Parameter	Type	Input/ Output Parameter	Can Be Null	Description
docid	RAW(13)	IN	No	XML DOM object.
name	VARCHAR2	IN	No	A string.
value	VARCHAR2	IN	No	A string.

- DBE_XML.XML_DOM_SET_CHARSET

  Sets the character set for a DOMDocument object.

  The prototype of the DBE_XML.XML_DOM_SET_CHARSET function is as follows:

```
DBE_XML.XML_DOM_SET_CHARSET(
   id      IN RAW(13),
   charset IN VARCHAR2
)
RETURNS void;
```

Table 2-127 DBE_XML.XML_DOM_SET_CHARSET API parameters

Parameter	Type	Input/ Output Parameter	Can Be Null	Description
id	RAW(13)	IN	No	XML DOM object.
charset	VARCHAR2	IN	No	Character set.

- DBE_XML.XML_DOM_SET_DOCTYPE

  Sets the external DTD of a DOMDocument object.

  The prototype of the DBE_XML.XML_DOM_SET_DOCTYPE function is as follows:

```
DBE_XML.XML_DOM_SET_DOCTYPE(
   id          IN  RAW(13),
   dtd_name    IN  VARCHAR2,
   system_id   IN  VARCHAR2,
   public_id   IN  VARCHAR2
)
RETURNS void;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 2-128 DBE_XML.XML_DOM_SET_DOCTYPE API parameters

Parameter	Type	Input/ Output Parameter	Can Be Null	Description
id	RAW(13)	IN	No	XML DOM object.
dtd_name	VARCHAR2	IN	No	Name of the DOCType to be initialized.
system_id	VARCHAR2	IN	No	ID of the system whose DOCType needs to be initialized.
public_id	VARCHAR2	IN	No	Public ID of the DOCType to be initialized.

- DBE_XML.XML_DOM_SET_NODE_VALUE

  Sets the value of a node in the DOMNode object.

  The prototype of the DBE_XML.XML_DOM_SET_NODE_VALUE stored procedure is as follows:

  ```
  DBE_XML.XML_DOM_SET_NODE_VALUE(
  id IN RAW(13),
  node_value IN VARCHAR2)
  RETURNS VOID
  ```

  Table 2-129 DBE_XML.XML_DOM_SET_NODE_VALUE API parameters

Parameter	Type	Input/ Output Parameter	Can Be Null	Description
id	RAW(13)	IN	No	XML DOM object.
node_value	VARCHAR2	IN	No	String to be set in the DOMNode object.

- DBE_XML.XML_DOM_WRITE_TO_BUFFER_DOC

  Writes the given DOMDocument object to the buffer.

  The prototype of the DBE_XML.XML_DOM_WRITE_TO_BUFFER_DOC stored procedure is as follows:

  ```
  DBE_XML.XML_DOM_WRITE_TO_BUFFER_DOC(
  id IN RAW(13))
  RETURNS VARCHAR2;
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 2-130 DBE_XML.XML_DOM_WRITE_TO_BUFFER_DOC API parameters

Parameter	Type	Input/ Output Parameter	Can Be Null	Description
id	RAW(13)	IN	Yes	XML DOM object.

- DBE_XML.XML_DOM_WRITE_TO_BUFFER_NODE

  Writes the given DOMNode object to the buffer.

  The prototype of the DBE_XML.XML_DOM_WRITE_TO_BUFFER_NODE stored procedure is as follows:

  ```
  DBE_XML.XML_DOM_WRITE_TO_BUFFER_NODE(
  id IN RAW(13))
  RETURNS VARCHAR2;
  ```

  Table 2-131 DBE_XML.XML_DOM_WRITE_TO_BUFFER_NODE API parameters

Parameter	Type	Input/ Output Parameter	Can Be Null	Description
id	RAW(13)	IN	Yes	XML DOM object.

- DBE_XML.XML_DOM_WRITE_TO_CLOB_DOC

  Writes the given DOMDocument object to a CLOB.

  The prototype of the DBE_XML.XML_DOM_WRITE_TO_CLOB_DOC stored procedure is as follows:

  ```
  DBE_XML.XML_DOM_WRITE_TO_CLOB_DOC(
      id IN RAW(13)
  )
  RETURNS VARCHAR2;
  ```

  Table 2-132 DBE_XML.XML_DOM_WRITE_TO_CLOB_DOC API parameters

Parameter	Type	Input/ Output Parameter	Can Be Null	Description
id	RAW(13)	IN	Yes	XML DOM object.

- DBE_XML.XML_DOM_WRITE_TO_CLOB_NODE

  Writes the given DOMNode object to a CLOB.

  The prototype of the DBE_XML.XML_DOM_WRITE_TO_CLOB_NODE stored procedure is as follows:

  ```
  DBE_XML.XML_DOM_WRITE_TO_CLOB_NODE(
      id          IN  RAW(13)
  )
  RETURNS CLOB;
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 2-133 DBE_XML.XML_DOM_WRITE_TO_CLOB_NODE API parameters

Parameter	Type	Input/ Output Parameter	Can Be Null	Description
id	RAW(13)	IN	Yes	XML DOM object.

- DBE_XML.XML_DOM_WRITE_TO_FILE_DOC

  Writes an XML node to a specified file using the database character set.

  The prototype of the DBE_XML.XML_DOM_WRITE_TO_FILE_DOC stored procedure is as follows:

```
DBE_XML.XML_DOM_WRITE_TO_FILE_DOC(
id IN  RAW(13),
file_dir IN  VARCHAR2)
RETURNS VOID

DBE_XML.XML_DOM_WRITE_TO_FILE_DOC(
id IN  RAW(13),
file_dir IN  VARCHAR2,
charset  IN  VARCHAR2)
RETURNS VOID PACKAGE
```

Table 2-134 DBE_XML.XML_DOM_WRITE_TO_FILE_DOC API parameters

Parameter	Type	Input/ Output Parameter	Can Be Null	Description
id	RAW(13)	IN	Yes	XML DOM object.
file_dir	VARCHAR2	IN	No	File to be written.
charset	VARCHAR2	IN	No	Specified character set.

- DBE_XML.XML_DOM_WRITE_TO_FILE_NODE

  Writes an XML node to a specified file using the database character set.

  The prototype of the DBE_XML.XML_DOM_WRITE_TO_FILE_NODE stored procedure is as follows:

```
DBE_XML.XML_DOM_WRITE_TO_FILE_NODE(
id IN  RAW(13),
filename IN  VARCHAR2)
RETURNS VOID
```

Table 2-135 DBE_XML.XML_DOM_WRITE_TO_FILE_NODE API parameters

Parameter	Type	Input/ Output Parameter	Can Be Null	Description
id	RAW(13)	IN	No	XML DOM object.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Type	Input/ Output Parameter	Can Be Null	Description
filename	VARCHAR2	IN	No	Specified file address.

- DBE_XML.XML_DOM_GET_SESSION_TREE_NUM

  Queries the number of DOM trees of all types in the current session.

  The prototype of the DBE_XML.XML_DOM_GET_SESSION_TREE_NUM function is as follows:

  ```
  DBE_XML.XML_DOM_GET_SESSION_TREE_NUM()
  RETURNS INTEGER
  ```

- DBE_XML.XML_DOM_GET_DOC_TREES_INFO

  Queries the DOM tree information of the document type in the current session, such as the memory usage.

  The prototype of the DBE_XML.XML_DOM_GET_DOC_TREES_INFO function is as follows:

  ```
  DBE_XML.XML_DOM_GET_DOC_TREES_INFO()
  RETURNS VARCHAR2
  ```

- DBE_XML.XML_DOM_GET_DETAIL_DOC_TREE_INFO

  Queries the number of subnodes of each type in the specified document.

  The prototype of the DBE_XML.XML_DOM_GET_DETAIL_DOC_TREE_INFO function is as follows:

  ```
  dbe_xml.xml_dom_get_detail_doc_tree_info(
  id IN  RAW(13))
  RETURNS VARCHAR2
  ```

  Table 2-136 DBE_XML.XML_DOM_GET_DETAIL_DOC_TREE_INFO API parameters

Parameter	Type	Input/ Output Parameter	Can Be Null	Description
id	RAW(13)	IN	No	XML DOM object.

2.12.2 Secondary Encapsulation APIs

2.12.2.1 DBE_APPLICATION_INFO

APIs

Table 2-137 provides all APIs supported by the DBE_APPLICATION_INFO package. DBE_APPLICATION_INFO applies to the current session.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 2-137 DBE_APPLICATION_INFO

API	Description
DBE_APPLICATION_INFO.SET_CLIENT_INFO	Writes client information.
DBE_APPLICATION_INFO.READ_CLIENT_INFO	Reads client information.
DBE_APPLICATION_INFO.SET_MODULE	Sets the name of the currently running module to the new module. You can set the module and action.
DBE_APPLICATION_INFO.READ_MODULE	Reads the values of the module and action columns of the current session.
DBE_APPLICATION_INFO.SET_ACTION	Sets the name of the current action in the current module.

- DBE_APPLICATION_INFO.SET_CLIENT_INFO

  Writes client information.

  The prototype of DBE_APPLICATION_INFO.SET_CLIENT_INFO is as follows:

  ```
  DBE_APPLICATION_INFO.SET_CLIENT_INFO(
      str text
  )returns void;
  ```

  Table 2-138 DBE_APPLICATION_INFO.SET_CLIENT_INFO API parameter

Parameter	Description
str	Client information to be written. The maximum length is 64 bytes. If the length exceeds 64 bytes, it will be truncated.

- DBE_APPLICATION_INFO.READ_CLIENT_INFO

  Reads client information.

  The prototype of DBE_APPLICATION_INFO.READ_CLIENT_INFO is as follows:

  ```
  DBE_APPLICATION_INFO.READ_CLIENT_INFO(
   OUT client_info text);
  ```

  Table 2-139 DBE_APPLICATION_INFO.READ_CLIENT_INFO API parameter

Parameter	Description
client_info	Client information

- DBE_APPLICATION_INFO.SET_MODULE

  Sets the name of the currently running module to the new module.

  The prototype of DBE_APPLICATION_INFO.SET_MODULE is as follows:

  ```
  DBE_APPLICATION_INFO.SET_MODULE(
      IN module_name text,
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
    IN action_name text
);
```

Table 2-140 DBE_APPLICATION_INFO.SET_MODULE API parameters

Parameter	Description
module_name	Name of the running module. The maximum length is 64 bytes. If the length exceeds 64 bytes, it will be truncated.
action_name	Name of the current action in the current module. The maximum length is 64 bytes. If the length exceeds 64 bytes, it will be truncated.

Example:

```
CALL dbe_application_info.set_module('module_name','action_name');
 set_module
------------

(1 row)
```

- DBE_APPLICATION_INFO.READ_MODULE

  Reads the values of the module and action columns of the current session.

  The prototype of DBE_APPLICATION_INFO.READ_MODULE is as follows:

```
DBE_APPLICATION_INFO.READ_MODULE(
    OUT module_name text,
    OUT action_name text
);
```

Table 2-141 DBE_APPLICATION_INFO.READ_MODULE API parameters

Parameter	Description
module_name	Name of the running module.
action_name	Name of the current action in the current module.

Example:

```
DECLARE
 module varchar2(64);
 action varchar2(64);
BEGIN
 dbe_application_info.read_module(module,action);
 dbe_output.print_line(module);
 dbe_output.print_line(action);
END;
/
module_name
action_name
ANONYMOUS BLOCK EXECUTE
```

- DBE_APPLICATION_INFO.SET_ACTION

  Sets the name of the current action in the current module.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

The prototype of DBE_APPLICATION_INFO.SET_ACTION is as follows:

```
DBE_APPLICATION_INFO.SET_ACTION(
      IN action_name text
);
```

Table 2-142 DBE_APPLICATION_INFO.SET_ACTION API parameters

Parameter	Description
action_name	Name of the current action in the current module. The maximum length is 64 bytes. If the length exceeds 64 bytes, it will be truncated.

Example:

```
CALL dbe_application_info.set_action('action_name');
 set_action
------------

(1 row)
```

2.12.2.2 DBE_COMPRESSION

APIs

Evaluate the sampling compression speed of a specified data object or obtain the compression type of a specified row of data based on the input parameters. **Table 2-143** lists APIs supported by DBE_COMPRESSION.

Table 2-143 DBE_COMPRESSION

API	Description
DBE_COMPRESSION.GET_COMPRESSION_RATIO	Evaluates the sampling compression ratio of a specified data object based on input parameters.
DBE_COMPRESSION.GET_COMPRESSION_TYPE	Obtains the compression type of data in a specified row based on input parameters.
DBE_COMPRESSION.GET_ACTUAL_COMPRESSION_RATIO	Evaluates the actual compression ratio of a specified data object based on input parameters.
DBE_COMPRESSION.GET_HOLE_RATIO	Evaluates the sampling hole rate of a specified cross-page transparent compression data object based on input parameters.
DBE_COMPRESSION.TURBO_COMPRESS_BUFFER_STATS	Outputs the usage of turbo_compress_shared_buffers.
DBE_COMPRESSION.GET_INDEX_COMPRESSION_TYPE	Obtains the compression type of data in a specified index page based on input parameters.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

The GET_COMPRESSION_TYPE API supports only DNs in the distributed database.

- DBE_COMPRESSION.GET_COMPRESSION_RATIO

  Evaluates the sampling compression ratio of a specified data object based on input parameters.

  The prototype of DBE_COMPRESSION.GET_COMPRESSION_RATIO is as follows:

```
DBE_COMPRESSION.GET_COMPRESSION_RATIO(
SCRATCHTBSNAME IN VARCHAR2,
OWNNAME        IN VARCHAR2,
OBJNAME        IN VARCHAR2,
SUBOBJNAME     IN VARCHAR2,
COMPTYPE       IN NUMBER,
BLKCNT_CMP     OUT INTEGER,
BLKCNT_UNCMP   OUT INTEGER,
ROW_CMP        OUT INTEGER,
ROW_UNCMP      OUT INTEGER,
CMP_RATIO      OUT NUMBER,
COMPTYPE_STR   OUT VARCHAR2,
SAMPLE_RATIO   IN NUMBER DEFAULT 20,
OBJTYPE        IN INTEGER DEFAULT 1);
```

  NOTE

  - For a cross-page transparently compressed table, the partition name must be passed if it is a partitioned table and the subpartition name must be passed if it is a subpartitioned table; otherwise, the error message "no data found." will be displayed. For an advanced compressed table, the partition name must be passed if it is a partitioned table (or a subpartitioned table); otherwise, the error message "no data found." will be displayed.
  - The compression ratio of cross-page transparent compression cannot be evaluated on an advanced compressed table. If you directly use this API on such a table, the error message "The ilm turbo policy is not supported here." will be displayed.

Table 2-144 DBE_COMPRESSION.GET_COMPRESSION_RATIO API parameters

Parameter	Description
SCRATCHTBSNAME	Tablespace to which a data object belongs.
OWNNAME	Data object owner (schema to which the data object belongs).
OBJNAME	Data object name.
SUBOBJNAME	Data subobject name.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Description
COMPTYPE	Compression type. The options are as follows: ● **1**: uncompressed. ● **2**: advanced compression. ● **3**: cross-page transparent compression (low). ● **4**: cross-page transparent compression (medium). ● **5**: cross-page transparent compression (high). ● **6**: advanced compression (high).
BLKCNT_CMP	Number of blocks occupied by compressed samples.
BLKCNT_UNCMP	Number of blocks occupied by uncompressed samples.
ROW_CMP	Number of rows that can be contained in a single block after samples are compressed. The value is **0** for cross-page transparent compression.
ROW_UNCMP	Number of rows that can be contained in a single data block when samples are not compressed. The value is **0** for cross-page transparent compression.
CMP_RATIO	Compression ratio, that is, **blkcnt_uncmp** divided by **blkcnt_cmp**.
COMPTYPE_STR	Character string that describes the compression type.
SAMPLE_RATIO	Sampling ratio. The value is an integer or floating-point number ranging from 0 to 100, corresponding to the sampling ratio of *N* percent. The default value is **20**, indicating that 20% of the rows are sampled.
OBJTYPE	Object type. The options are as follows: ● **1**: table object.

- DBE_COMPRESSION.GET_COMPRESSION_TYPE

  This API is used to obtain the compression status (**1** for uncompressed and **2** for compressed) of a specified row based on input parameters. It is an O&M API and does not check the visibility. That is, if the input CTID is a deleted row, this API still returns the latest status of the current row on the page. Cross-page transparent compression does not support this advanced package. The default value **1** is returned, which is meaningless.

  The prototype of DBE_COMPRESSION.GET_COMPRESSION_TYPE is as follows:

```
DBE_COMPRESSION.GET_COMPRESSION_TYPE(
OWNNAME    IN VARCHAR2,
TABNAME    IN VARCHAR2,
CTID       IN TEXT,
SUBOBJNAME IN VARCHAR2 DEFAULT NULL,
BUCKETID   IN pg_catalog.int2 DEFAULT NULL))
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 2-145 DBE_COMPRESSION.GET_COMPRESSION_TYPE API parameters

Parameter	Description
OWNNAME	Data object owner (schema to which the data object belongs).
TABNAME	Data object name.
CTID	CTID of the target row.
SUBOBJNAME	Data subobject name.
BUCKETID	Table bucket ID of the target row.

- DBE_COMPRESSION.GET_ACTUAL_COMPRESSION_RATIO

  Evaluates the actual compression ratio of a specified data object based on input parameters. Only cross-page transparently compressed tables are supported.

  The prototype of DBE_COMPRESSION.GET_ACTUAL_COMPRESSION_RATIO is as follows:

```
DBE_COMPRESSION.GET_ACTUAL_COMPRESSION_RATIO(
OWNER_NAME       IN VARCHAR2,
OBJNAME          IN VARCHAR2,
FILEPATH         OUT VARCHAR2,
IS_COMPRESS      OUT BOOL,
FILE_COUNT       OUT INTEGER,
LOGIC_SIZE       OUT BIGINT,
PHYSIC_SIZE      OUT BIGINT,
COMPRESS_RATIO   OUT VARCHAR2);
```

Table 2-146 DBE_COMPRESSION.GET_ACTUAL_COMPRESSION_RATIO API parameters

Parameter	Description
OWNER_NAME	Data object owner (schema to which the data object belongs).
OBJNAME	Data object name.
FILEPATH	Data object path.
IS_COMPRESS	Compression type.
FILE_COUNT	Number of files, including data files and CMAP files.
LOGIC_SIZE	Logical size.
PHYSIC_SIZE	Physical size.
COMPRESS_RATIO	Compression ratio. In small table scenarios, the compression ratio may be less than 1, which is normal.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

In small table scenarios, the compression ratio may be less than 1, which is normal.

For example, create a **table_test** table, insert a data record, and use an advanced package for query. The output shows that the compression ratio is less than 1.

```
gaussdb=# CREATE TABLE table_test(a int) ILM ADD POLICY ROW STORE COMPRESS TURBO
HIGH UNIT AFTER 1 days OF NO MODIFICATION;
gaussdb=# INSERT INTO table_test VALUES(1);
gaussdb=# CALL DBE_COMPRESSION.GET_ACTUAL_COMPRESSION_RATIO('public', 'table_test',
NULL,NULL,NULL,NULL,NULL,NULL);
```

- DBE_COMPRESSION.GET_HOLE_RATIO

  Evaluates the sampling hole rate of a specified cross-page transparent compression data object based on input parameters. Only cross-page transparent compression tables are supported.

  The prototype of DBE_COMPRESSION.GET_HOLE_RATIO is as follows:

```
DBE_COMPRESSION.GET_HOLE_RATIO(
OWNER_NAME       IN VARCHAR2,
OBJNAME          IN VARCHAR2,
FILE_COUNT       OUT INTEGER,
PHYSIC_SIZE      OUT BIGINT,
HOLE_SIZE        OUT BIGINT,
HOLE_RATIO       OUT VARCHAR2,
SAMPLE_RATIO     IN NUMBER DEFAULT 20);
```

Table 2-147 DBE_COMPRESSION.GET_HOLE_RATIO API parameters

Parameter	Description
OWNER_NAME	Data object owner (schema to which the data object belongs).
OBJNAME	Data object name.
FILE_COUNT	Number of data object files, including only data files.
PHYSIC_SIZE	Physical size.
HOLE_SIZE	Hole size.
HOLE_RATIO	Hole rate.
SAMPLE_RATIO	Sampling rate.

- DBE_COMPRESSION.TURBO_COMPRESS_BUFFER_STATS

  Outputs the usage of turbo_compress_shared_buffers.

  The prototype of DBE_COMPRESSION.TURBO_COMPRESS_BUFFER_STATS is as follows:

```
DBE_COMPRESSION.TURBO_COMPRESS_BUFFER_STATS(
CAPACITY        OUT BIGINT,
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
MAIN_LEN        OUT BIGINT,
FREE_LEN        OUT BIGINT,
BUFFER_ACCESS   OUT BIGINT,
BUFFER_NOREADS  OUT BIGINT,
DISK_READS      OUT BIGINT,
RECYCLE_TIMES   OUT BIGINT,
RECYCLE_STEP    OUT BIGINT,
RECYCLE_WAITS   OUT BIGINT,
HIT_RATIO       OUT VARCHAR2);
```

Table 2-148 DBE_COMPRESSION.TURBO_COMPRESS_BUFFER_STATS API parameters

Parameter	Description
CAPACITY	Capacity of turbo_compress_shared_buffers.
MAIN_LEN	Length of main_list in the LRU list.
FREE_LEN	Length of free_list in the LRU list.
BUFFER_ACCESS	Number of logical reads.
BUFFER_NOREADS	Number of new blocks.
DISK_READS	Number of physical reads.
RECYCLE_TIMES	Number of recycling times.
RECYCLE_STEP	Recycling step size.
RECYCLE_WAITS	Number of wait times during the execution of **alloc buf ctrl**.
HIT_RATIO	Hit ratio in the memory.

- DBE_COMPRESSION.GET_INDEX_COMPRESSION_TYPE

  Checks whether the index page has been compressed. This advanced package can only query the status of advanced compression, but cannot query the status of cross-page transparent compression.

  The prototype of DBE_COMPRESSION.GET_INDEX_COMPRESSION_TYPE is as follows:

  ```
  DBE_COMPRESSION.GET_INDEX_COMPRESSION_TYPE(
  IDXOID          IN OID,
  IDXTYPE         IN TEXT,
  BUCKET_ID       IN INT2 DEFAULT NULL,
  BLOCK_ID        IN INT8);
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 2-149 DBE_COMPRESSION.GET_INDEX_COMPRESSION_TYPE API parameters

Parameter	Description
IDXOID	Index OID.
IDXTYPE	Index type. Ordinary index ('i'), global index ('I'), and partitioned index ('x') are supported.
BUCKET_ID	If the index is stored in a bucket, the corresponding bucket ID is passed. The default value is **NULL**.
BLOCK_ID	Block ID of the index to be queried. If the value is a decimal, the value is rounded off.

2.12.2.3 DBE_DESCRIBE

Data Types

The advanced package DBE_DESCRIBE has two built-in data types. The two data types are created using user-defined types and are used for the return values of the DESCRIBE_PROCEDURE API.

- DBE_DESCRIBE.NUMBER_TABLE

  This type is the TABLE type of NUMBER and is implemented through the TABLE OF syntax.

  The prototype of DBE_DESCRIBE.NUMBER_TABLE is as follows:

  ```
  CREATE TYPE DBE_DESCRIBE.NUMBER_TABLE AS TABLE OF NUMBER INDEX BY INTEGER;
  ```

- DBE_DESCRIBE.VARCHAR2_TABLE

  This type is the TABLE type of VARCHAR2 and is implemented through the TABLE OF syntax.

  The prototype of DBE_DESCRIBE.VARCHAR2_TABLE is as follows:

  ```
  CREATE TYPE DBE_DESCRIBE.VARCHAR2_TABLE AS TABLE OF VARCHAR2(30) INDEX BY INTEGER;
  ```

API

The advanced package DBE_DESCRIBE provides the DBE_DESCRIBE.DESCRIBE_PROCEDURE API. For details about the API description, see **Table 2-150**.

Table 2-150 DBE_DESCRIBE

API	Description
DBE_DESCRIBE.DESCRIBE_PROCEDURE	Displays the parameters of a stored procedure or function.

- DBE_DESCRIBE.DESCRIBE_PROCEDURE

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

The stored procedure DESCRIBE_PROCEDURE is used to display the parameter information of a stored procedure or function, such as the parameter name, parameter mode, and parameter position. The parameter information of a function or stored procedure is returned in a list.

The prototype of DBE_DESCRIBE.DESCRIBE_PROCEDURE is as follows:

```
DBE_DESCRIBE.DESCRIBE_PROCEDURE(
  object_name               IN  VARCHAR2,
  reserved1                 IN  VARCHAR2,
  reserved2                 IN  VARCHAR2,
  overload                  OUT DBE_DESCRIBE.NUMBER_TABLE,
  dataposition               OUT DBE_DESCRIBE.NUMBER_TABLE,
  datalevel                 OUT DBE_DESCRIBE.NUMBER_TABLE,
  argument_name                OUT DBE_DESCRIBE.VARCHAR2_TABLE,
  datatype                  OUT DBE_DESCRIBE.NUMBER_TABLE,
  default_value              OUT DBE_DESCRIBE.NUMBER_TABLE,
  in_out                    OUT DBE_DESCRIBE.NUMBER_TABLE,
  datalength                 OUT DBE_DESCRIBE.NUMBER_TABLE,
  dataprecision              OUT DBE_DESCRIBE.NUMBER_TABLE,
  scale                     OUT DBE_DESCRIBE.NUMBER_TABLE,
  radix                     OUT DBE_DESCRIBE.NUMBER_TABLE,
  spare                     OUT DBE_DESCRIBE.NUMBER_TABLE,
  include_string_constraints OUT BOOLEAN
);
```

Table 2-151 DBE_DESCRIBE.DESCRIBE_PROCEDURE API parameters

Parameter	Type	Can Be Null	Description
object_name	varchar2	No	Stored procedure name. The syntax format of this parameter is [[*schema*.]*package*.]*function*[@*dblink*], in which: • *schema* (optional): schema name. • *package* (optional): package name. • *function* (required): function or stored procedure name. • *dblink* (optional): remote connection name.
reserved1	varchar2	Yes	Reserved parameter.
reserved2	varchar2	Yes	Reserved parameter.
overload	number_table	Yes	Unique ID assigned to a stored procedure or function. If a stored procedure or function is overloaded, each overloading of the stored procedure or function is counted and numbered from 1 in ascending order. If a stored procedure or function is not overloaded, **overload** is set to **0**.
dataposition	number_table	Yes	Position of a specified parameter in the parameter list.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Type	Can Be Null	Description
datalevel	number_table	Yes	It is set to **0**.
argument_name	varchar2_table	Yes	Name of the parameter associated with the specified stored procedure.
datatype	number_table	Yes	Data type OID of the specified parameter.
default_value	number_table	Yes	If the specified parameter has a default value, the value is **1**. Otherwise, the value is **0**.
in_out	number_table	Yes	Parameter mode. The options are as follows: • **0**: IN. • **1**: OUT. • **2**: IN OUT.
datalength	number_table	Yes	Not supported. It is set to **0** by default.
dataprecision	number_table	Yes	Not supported. It is set to **0** by default.
scale	number_table	Yes	Not supported. It is set to **0** by default.
radix	number_table	Yes	If the value is of the numeric type (such as NUMBER and INTEGER), **10** is returned. Otherwise, **0** is returned. For details about the numeric type, see **Numeric Types**.
spare	number_table	Yes	Reserved parameter. It is set to **0** by default.
include_string_constraints	Boolean	Yes	Reserved parameter. It is set to **FALSE** by default.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- The data type of the **datatype** parameter is different from that of the ORA-compatible database. GaussDB returns the OID of the data type, and the ORA-compatible database returns the number of the data type in the ORA-compatible database.
- **include_string_constraints** is a reserved parameter. Its value does not change and does not affect the return values of other parameters.
- The OIDs of the data types created by the CREATE TYPE operation are uncertain. Therefore, do not use these OIDs for sure.
- For the **dataposition** parameter, if a stored procedure is specified, the return value starts from **1**. If a function is specified, the return value starts from **0**. **0** indicates the position sequence number of the return value of the function.
- For the **argument_name** parameter, if a function is specified, the first position of the return value is empty. This position indicates the name of the return value of the described function (that is, the empty name).
- Do not directly specify a package. Otherwise, an error is reported.
- If you do not have the execute permission on a stored procedure, function, or package, the system considers that the stored procedure, function, or package does not exist and reports an error.
- The input parameters **reserved1** and **reserved2** are not involved in internal processing. Entering any character string does not affect the returned result.
- The advanced package cannot specify the stored procedures or functions obtained through database links.
- You are advised to add the schema prefix before the specified stored procedure or function. If the schema prefix is omitted, the advanced package searches for its owning entity in the schema of the current session. (If the owning entity does not exist in the schema of the current session, the mechanism specified by **bind_procedure_searchpath** in **behavior_compat_options** is followed.)
- If the %type operation is used to obtain the data type from a table column, the constraint on the data type (such as NUMBER(3) and VARCHAR2(10)) is not retained.

Example:

```
-- Create a stored procedure to encapsulate the advanced package for printing return values.
gaussdb=# CREATE PROCEDURE PRINT_DESCRIBE (obj_name IN VARCHAR2)
AS
  a_overload      DBE_DESCRIBE.NUMBER_TABLE;

2.12.2.4 DBE_FILE

DBE_FILE provides the capabilities of reading and writing OS text files for stored procedures.

Precautions

- DBE_FILE requires that files opened using DBE_FILE.FOPEN be encoded using the database character set. If the opened files are not encoded using the expected character set, an encoding verification error occurs when DBE_FILE.READ_LINE is used to read files. DBE_FILE requires that files opened using DBE_FILE.FOPEN_NCHAR be encoded using the UTF-8 character set. If the opened files are not encoded using the expected character set, an encoding verification error occurs when DBE_FILE.READ_LINE_NCHAR is used to read files.
- When DBE_OUTPUT.PUT_LINE is used to print the DBE_FILE.READ_LINE_NCHAR API result, ensure that the UTF-8 character set encoding can be converted to the current database character set encoding. If the preceding conditions are met, the result can be properly output. DBE_OUTPUT.PRINT_LINE does not support this function.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- DBE_FILE requires that the character set encoding of the client be the same as that of the database.
- Assume that the database character set is ASCII, the client character set supports Chinese, and the client calls DBE_FILE.WRITE_NCHAR or DBE_FILE.WRITE_LINE_NCHAR to write Chinese content. If the entered content is in UTF-8 encoding format, the written content may not be encoded in UTF-8 format. An error may be reported when the DBE_FILE.READ_LINE_NCHAR is used.

Data Types

DBE_FILE.FILE_TYPE

Defines the representation of files in the DBE_FILE package. The columns in DBE_FILE.FILE_TYPE are private columns of the DBE_FILE package. Do not change the column values in DBE_FILE.FILE_TYPE.

The prototype of DBE_FILE.FILE_TYPE is as follows:

```
CREATE TYPE DBE_FILE.FILE_TYPE AS(
    id INTEGER,
    datatype INTEGER,
    byte_mode BOOLEAN
);
```

Table 2-152 DBE_FILE.FILE_TYPE columns

Parameter	Description
id	File handle.
datatype	File data type (CHAR, NCHAR, or binary). Currently, CHAR and NCHAR files are supported. For a CHAR file, **1** is returned. For an NCHAR file, **2** is returned.
byte_mode	Specifies whether the file is opened in binary mode (**TRUE**) or text mode (**FALSE**).

APIs

Table 2-153 lists APIs supported by the DBE_FILE package.

Table 2-153 DBE_FILE

API	Description
DBE_FILE.OPEN/ DBE_FILE.FOPEN	Opens a file based on the specified directory and file name. The corresponding file handle or the DBE_FILE.FILE_TYPE object encapsulated with the handle is returned.
DBE_FILE.IS_CLOSE	Checks whether a specified file handle is closed.
DBE_FILE.IS_OPEN	Checks whether a specified file handle is opened.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

API	Description
DBE_FILE.READ_LINE	Reads a line of a specified length from an open file handle.
DBE_FILE.WRITE	Writes data to the buffer of an open file.
DBE_FILE.NEW_LINE	Writes one or more line terminators to the buffer of an open file.
DBE_FILE.WRITE_LINE	Writes data to the buffer of an open file and automatically appends a line terminator.
DBE_FILE.FORMAT_WRITE	Writes data in a specified format to the buffer of an open file.
DBE_FILE.GET_RAW	Reads RAW data of a specified number of bytes from an open file.
DBE_FILE.PUT_RAW	Writes RAW data to the buffer of an open file.
DBE_FILE.FLUSH	Writes data in the buffer to a physical file.
DBE_FILE.CLOSE	Closes an open file handle.
DBE_FILE.CLOSE_ALL	Closes all file handles opened in a session.
DBE_FILE.REMOVE	Removes a disk file based on the specified directory and file name. You must have sufficient permissions to perform this operation.
DBE_FILE.RENAME	Renames a disk file. This function is similar to the **mv** command of Unix.
DBE_FILE.COPY	Copies data in a continuous area to a new file. If **start_line** and **end_line** are not specified, the entire file is copied.
DBE_FILE.GET_ATTR	Reads and returns the attributes of a disk file.
DBE_FILE.SEEK	Adjusts the position of a file pointer forward or backward based on the specified number of bytes.
DBE_FILE.GET_POS	Returns the current offset of a file, in bytes.
DBE_FILE.FOPEN_NCHAR	Opens a file of the NCHAR type based on the specified directory and file name.
DBE_FILE.WRITE_NCHAR	Writes data of the NVARCHAR2 type to the buffer of an open file of the NCHAR type.
DBE_FILE.WRITE_LINE_NCHAR	Writes data of the NVARCHAR2 type to the buffer of an open file of the NCHAR type and automatically appends a line terminator.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

API	Description
DBE_FILE.FORMAT_WRITE_NCHAR	Writes data of the NVARCHAR2 type to the buffer of an open file of the NCHAR type in a specified format. It is a DBE_FILE.WRITE_NCHAR API that allows formatting.
DBE_FILE.READ_LINE_NCHAR	Reads a line of a specified length from an open file of the NCHAR type.

- DBE_FILE.OPEN/DBE_FILE.FOPEN

  Opens a file. You can specify the maximum line size. A maximum of 50 files can be opened in a session. This function returns a file handle of the INTEGER type. The function of DBE_FILE.FOPEN is similar to that of DBE_FILE.OPEN. The difference is that DBE_FILE.FOPEN returns a DBE_FILE.FILE_TYPE object.

  The prototypes of DBE_FILE.OPEN and DBE_FILE.FOPEN are as follows:

  ```
  DBE_FILE.OPEN (
  dir             IN    TEXT,
  file_name       IN    TEXT,
  open_mode       IN    TEXT,
  max_line_size   IN    INTEGER DEFAULT 1024)
  RETURN INTEGER;

  DBE_FILE.FOPEN(
     dir          IN TEXT,
     file_name    IN TEXT,
     open_mode    IN TEXT,
     max_line_size IN INTEGER DEFAULT 1024)
  RETURN DBE_FILE.FILE_TYPE;
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 2-154 DBE_FILE.OPEN/DBE_FILE.FOPEN API parameters

Parameter	Type	Input/OutputParameter	CanBeNull	Description
dir	TEXT	IN	No	Directory of a file. The string indicates the name of a directory object. **NOTE** • Location of the file directory, which needs to be added to system catalog **PG_DIRECTORY**. If the input path does not match the path in **PG_DIRECTORY**, an error indicating that the path does not exist will be reported. • When the GUC parameter **safe_data_path** is enabled, you can only use an advanced package to read and write files in the file path specified by **safe_data_path**.
file_name	TEXT	IN	No	File name with an extension (file type), excluding the path name. A path contained in a file name is ignored in the OPEN function. In Unix, the file name cannot end with the combination of a slash and a dot (/.).
open_mode	TEXT	IN	No	Open mode of a specified file, including: • **r**: read text. • **w**: write text. • **a**: append text. • **rb**: read byte. • **wb**: write byte. • **ab**: append byte. **NOTE** For the write operation, the system checks the file type. If the ELF file is written, an error is reported and the system exits.
max_line_size	INTEGER	IN	Yes	Maximum number of bytes in each line, including newline characters. The minimum value is **1** and the maximum value is **32767**. If this parameter is not specified, the default value **1024** is used.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- DBE_FILE.IS_CLOSE

  Checks whether a specified file handle is closed. A Boolean value is returned. If an invalid file handle is detected, the INVALID_FILEHANDLE exception will be thrown.

  The prototype of DBE_FILE.IS_CLOSE is as follows:

```
DBE_FILE.IS_CLOSE (
   file IN INTEGER)
RETURN BOOLEAN;

DBE_FILE.IS_CLOSE(
   file IN DBE_FILE.FILE_TYPE)
RETURN BOOLEAN;
```

  Table 2-155 DBE_FILE.IS_CLOSE API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
file	INTEGER or DBE_FILE.FILE_TYPE	IN	Yes	File handle or DBE_FILE.FILE_TYPE object to be checked. If it is left empty, the DBE_FILE.IS_CLOSE API returns null.

- DBE_FILE.IS_OPEN

  Checks whether a specified file handle is opened. A Boolean value is returned. If an invalid file handle is detected, the INVALID_FILEHANDLE exception will be thrown.

  The prototype of DBE_FILE.IS_OPEN is as follows:

```
DBE_FILE.IS_OPEN(
   file IN INTEGER)
RETURN BOOLEAN;

DBE_FILE.IS_OPEN(
   file IN DBE_FILE.FILE_TYPE)
RETURN BOOLEAN;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 2-156 DBE_FILE.IS_OPEN API parameters

Parameter	Type	Input/OutputParameter	Can Be Null	Description
file	INTEGER or DBE_FILE.FILE_TYPE	IN	Yes	File handle or DBE_FILE.FILE_TYPE object to be checked. If it is left empty, the DBE_FILE.IS_OPEN API returns **false**.

- DBE_FILE.READ_LINE

  Reads data from an open file and stores the read result to the buffer. It reads data to the end of each line excluding the line terminator, to the end of the file, or to the size specified by the **len** parameter. The length of the data to be read cannot exceed the value of **max_line_size** specified when the file is opened.

  The prototype of DBE_FILE.READ_LINE is as follows:

```
DBE_FILE.READ_LINE(
   file   IN  INTEGER,
   buffer OUT TEXT,
   len    IN  INTEGER DEFAULT NULL)
RETURN TEXT;

DBE_FILE.READ_LINE(
   file   IN  DBE_FILE.FILE_TYPE,
   buffer OUT TEXT,
   len    IN  INTEGER DEFAULT NULL)
RETURN TEXT;
```

Table 2-157 DBE_FILE.READ_LINE API parameters

Parameter	Type	Input/OutputParameter	Can Be Null	Description
file	INTEGER or DBE_FILE.FILE_TYPE	IN	No	File handle opened using OPEN or object of the DBE_FILE.FILE_TYPE type opened using FOPEN. The file must be opened in read mode. Otherwise, the INVALID_OPERATION exception is thrown.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Type	Input/Output Parameter	Can Be Null	Description
buffer	TEXT	OUT	No	Buffer for receiving data.
len	INTEGER	IN	Yes	Number of bytes read from a file. The default value is **NULL**. If the default value **NULL** is used, **max_linesize** is used to specify the line size.

- DBE_FILE.WRITE

  Writes buffer data to the buffer corresponding to a file. The file must be opened in write mode. This operation does not write a line terminator.

  The prototype of DBE_FILE.WRITE is as follows:

```
DBE_FILE.WRITE(
   file   IN INTEGER,
   buffer IN TEXT)
RETURN BOOLEAN;

DBE_FILE.WRITE(
   file   IN DBE_FILE.FILE_TYPE,
   buffer IN TEXT)
RETURN VOID;
```

Table 2-158 DBE_FILE.WRITE API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
file	INTEGER or DBE_FILE.FILE_TYPE	IN	No	File handle opened using OPEN or object of the DBE_FILE.FILE_TYPE type opened using FOPEN. The file must be opened in write mode. This operation does not write line terminators.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Type	Input/Output Parameter	Can Be Null	Description
buffer	TEXT	IN	Yes	Text data to be written to the file. The accumulated write length of each line cannot be greater than or equal to the value of **max_line_size** specified when OPEN or FOPEN is used. Otherwise, an error is reported when the file is flushed. If this parameter is left empty, the API directly returns an empty value. **NOTE** For the write operation, the system checks the file type. If the ELF file is written, an error is reported and the system exits.

- DBE_FILE.NEW_LINE

  Writes one or more line terminators to the buffer corresponding to a file. The line terminators are related to the platform used.

  The prototype of DBE_FILE.NEW_LINE is as follows:

```
DBE_FILE.NEW_LINE(
   file      IN INTEGER,
   line_nums IN INTEGER DEFAULT 1)
RETURN BOOLEAN;

DBE_FILE.NEW_LINE(
   file      IN DBE_FILE.FILE_TYPE,
   line_nums IN INTEGER DEFAULT 1)
RETURN VOID;
```

Table 2-159 DBE_FILE.NEW_LINE API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
file	INTEGER or DBE_FILE.FILE_TYPE	IN	No	File handle opened using OPEN or object of the DBE_FILE.FILE_TYPE type opened using FOPEN. The file must be opened in write mode. This operation does not write line terminators.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Type	Input/Output Parameter	Can Be Null	Description
line_nums	INTEGER	IN	Yes	Number of line terminators written to a file. The default value is **1**. If this parameter is left blank, line terminators are not written.

- DBE_FILE.WRITE_LINE

  Writes buffer data to the buffer corresponding to a file. The file must be opened in write mode. This operation automatically adds a line terminator.

  The prototype of DBE_FILE.WRITE_LINE is as follows:

```
DBE_FILE.WRITE_LINE(
   file   IN INTEGER,
   buffer IN TEXT,
   flush  IN BOOLEAN DEFAULT FALSE)
RETURN BOOLEAN;

DBE_FILE.WRITE_LINE(
   file   IN DBE_FILE.FILE_TYPE,
   buffer IN TEXT,
   flush  IN BOOLEAN DEFAULT FALSE)
RETURN VOID;
```

Table 2-160 DBE_FILE.WRITE_LINE API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
file	INTEGER or DBE_FILE.FILE_TYPE	IN	No	File handle opened using OPEN or object of the DBE_FILE.FILE_TYPE type opened using FOPEN.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Type	Input/Output Parameter	Can Be Null	Description
buffer	TEXT	IN	Yes	Text data to be written to the file. The length of each line (including the newline character) cannot be greater than the value of **max_line_size** specified when OPEN or FOPEN is executed or the default value. Otherwise, an error is reported when the file is flushed. **NOTE** For the write operation, the system checks the file type. If the ELF file is written, an error is reported and the system exits.
flush	BOOLEAN	IN	Yes	Specifies whether to flush data to disks after WRITE_LINE. The default value is **FALSE**.

- DBE_FILE.FORMAT_WRITE

  The DBE_FILE.FORMAT_WRITE function writes formatted data to the buffer corresponding to an open file. It is a DBE_FILE.WRITE API that allows formatting.

  The prototype of DBE_FILE.FORMAT_WRITE is as follows:

```
DBE_FILE.FORMAT_WRITE(
   file   IN INTEGER,
   format IN TEXT,
   arg1   IN TEXT DEFAULT NULL,
   . . .
   arg6   IN TEXT DEFAULT NULL)
RETURN BOOLEAN;

DBE_FILE.FORMAT_WRITE(
   file   IN DBE_FILE.FILE_TYPE,
   format IN TEXT,
   arg1   IN TEXT DEFAULT NULL,
   . . .
   arg6   IN TEXT DEFAULT NULL)
RETURN VOID;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 2-161 DBE_FILE.FORMAT_WRITE API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
file	INTEGER or DBE_FILE.FILE_TYPE	IN	No	File handle opened using OPEN or object of the DBE_FILE.FILE_TYPE type opened using FOPEN.
format	TEXT	IN	Yes	Formatted string, containing the text and format characters \n and %s. If this parameter is left blank, no data is written.
[arg1. . .arg6]	TEXT	IN	Yes	Six optional parameters. The parameters and the positions of characters to be formatted are in one-to-one correspondence. If the parameter corresponding to a character to be formatted is not provided or the parameter is empty, an empty string is used to replace %s.

- DBE_FILE.GET_RAW

  Reads RAW data from an open file, stores the read result in the buffer, and returns the result from *r*.

  The prototype of DBE_FILE.GET_RAW is as follows:

```
DBE_FILE.GET_RAW(
   file   IN  INTEGER,
   r      OUT RAW,
   length IN  INTEGER DEFAULT NULL)
RETURN RAW;

DBE_FILE.GET_RAW(
   file   IN  DBE_FILE.FILE_TYPE,
   r      OUT RAW,
   length IN  INTEGER DEFAULT NULL)
RETURN RAW;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 2-162 DBE_FILE.GET_RAW API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
file	INTEGER or DBE_FILE.FILE_TYPE	IN	No	File handle opened using OPEN or object of the DBE_FILE.FILE_TYPE type opened using FOPEN.
r	RAW	OUT	No	Buffer for receiving RAW data.
length	INTEGER	IN	Yes	Number of bytes read from the file. The default value is **NULL**. If the value is **NULL**, the maximum length of the RAW type is used to specify the size.

- DBE_FILE.PUT_RAW

  Writes raw data to the buffer corresponding to a file.

  The prototype of DBE_FILE.PUT_RAW is as follows:

```
DBE_FILE.PUT_RAW (
   file  IN INTEGER,
   r     IN RAW,
   flush IN BOOLEAN DEFAULT FALSE)
RETURN BOOLEAN;

DBE_FILE.PUT_RAW (
   file  IN DBE_FILE.FILE_TYPE,
   r     IN RAW,
   flush IN BOOLEAN DEFAULT FALSE)
RETURN VOID;
```

Table 2-163 DBE_FILE.PUT_RAW API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
file	INTEGER or DBE_FILE.FILE_TYPE	IN	No	File handle opened using OPEN or object of the DBE_FILE.FILE_TYPE type opened using FOPEN.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Type	Input/Output Parameter	Can Be Null	Description
r	RAW	IN	Yes	RAW data to be written to a file. If this parameter is set to **NULL**, no data is written. **NOTE** For the write operation, the system checks the file type. If the ELF file is written, an error is reported and the system exits.
flush	BOOLEAN	IN	Yes	Determines whether to flush data to disks after PUT_RAW. The default value is **FALSE**.

- DBE_FILE.FLUSH

  Writes cached data to a physical file. The cached data must have a line terminator.

  The prototype of DBE_FILE.FLUSH is as follows:

```
DBE_FILE.FLUSH(
   file IN INTEGER)
RETURN VOID;

DBE_FILE.FLUSH(
   file IN DBE_FILE.FILE_TYPE)
RETURN VOID;
```

  Table 2-164 DBE_FILE.FLUSH API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
file	INTEGER or DBE_FILE.FILE_TYPE	IN	No	File handle opened using OPEN or object of the DBE_FILE.FILE_TYPE type opened using FOPEN.

- DBE_FILE.CLOSE

  Closes an open file. When this function is called, if there is cached data to be written, exception information may be received and the return value is always **TRUE**.

  The prototype of DBE_FILE.CLOSE is as follows:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
DBE_FILE.CLOSE(
   file IN INTEGER)
RETURN BOOLEAN;

DBE_FILE.CLOSE(
   file IN DBE_FILE.FILE_TYPE)
RETURN BOOLEAN;
```

Table 2-165 DBE_FILE.CLOSE API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
file	INTEGER or DBE_FILE.FILE_TYPE	IN	No	File handle opened using OPEN or object of the DBE_FILE.FILE_TYPE type opened using FOPEN.

- DBE_FILE.CLOSE_ALL

  Closes all file handles opened in a session. This function can be used for emergency cleanup.

  The prototype of DBE_FILE.CLOSE_ALL is as follows:

  ```
  DBE_FILE.CLOSE_ALL()
  RETURN VOID;
  ```

- DBE_FILE.REMOVE

  Removes a disk file. Only users with the required permission can execute this function.

  The prototype of DBE_FILE.REMOVE is as follows:

  ```
  DBE_FILE.REMOVE(
     dir       IN TEXT,
     file_name IN TEXT)
  RETURN VOID;
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 2-166 DBE_FILE.REMOVE API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
dir	TEXT	IN	No	Directory of a file. It is a string, indicating an object name. **NOTE** • Location of the file directory, which needs to be added to system catalog **PG_DIRECTORY**. If the input path does not match the path in **PG_DIRECTORY**, an error indicating that the path does not exist will be reported. • When the GUC parameter **safe_data_path** is enabled, you can only use an advanced package to operate files in the file path specified by **safe_data_path**.
file_name	TEXT	IN	No	File name.

- DBE_FILE.RENAME

  Renames a disk file. This function is similar to the **mv** command of Unix.

  The prototype of DBE_FILE.RENAME is as follows:

```
DBE_FILE.RENAME(
   dir        IN TEXT,
   src_file_name  IN TEXT,
   dest_dir       IN TEXT,
   dest_file_name IN TEXT,
   overwrite      IN BOOLEAN DEFAULT FALSE)
RETURN VOID;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 2-167 DBE_FILE.RENAME API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
dir	TEXT	IN	No	Directory of the source file (case-sensitive). **NOTE** • Location of the file directory, which needs to be added to system catalog **PG_DIRECTORY**. If the input path does not match the path in **PG_DIRECTORY**, an error indicating that the path does not exist will be reported. • When the GUC parameter **safe_data_path** is enabled, you can only use an advanced package to operate files in the file path specified by **safe_data_path**.
src_file_name	TEXT	IN	No	Source file to be renamed.
dest_dir	TEXT	IN	No	Target directory (case-sensitive). **NOTE** • Location of the file directory, which needs to be added to system catalog **PG_DIRECTORY**. If the input path does not match the path in **PG_DIRECTORY**, an error indicating that the path does not exist will be reported. • When the GUC parameter **safe_data_path** is enabled, you can only use an advanced package to operate files in the file path specified by **safe_data_path**.
dest_file_name	TEXT	IN	No	New file name.
overwrite	BOOLEAN	IN	Yes	Specifies whether to overwrite the file. If the parameter is left empty or not specified, the parameter is not overwritten. If no overwriting is performed and a file with the same name already exists in the destination directory, an error is reported.

- DBE_FILE.COPY

  Copies data in a continuous area to a new file. If **start_line** and **end_line** are omitted, the entire file is copied.

  The prototype of DBE_FILE.COPY is as follows:

```
DBE_FILE.COPY (
src_dir         IN     TEXT,
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
src_file_name     IN     TEXT,
dest_dir          IN     TEXT,
dest_file_name    IN     TEXT,
start_line        IN     INTEGER DEFAULT 1,
end_line          IN     INTEGER DEFAULT NULL)
RETURN VOID;
```

Table 2-168 DBE_FILE.COPY API parameters

Parameter	Type	Input/OutputParameter	CanBeNull	Description
src_dir	TEXT	IN	No	Directory of the source file. **NOTE** • Location of the file directory, which needs to be added to system catalog **PG_DIRECTORY**. If the input path does not match the path in **PG_DIRECTORY**, an error indicating that the path does not exist will be reported. • When the GUC parameter **safe_data_path** is enabled, you can only use an advanced package to operate files in the file path specified by **safe_data_path**.
src_file_name	TEXT	IN	No	Name of the source file to be copied.
dest_dir	TEXT	IN	No	Directory of the target file. **NOTE** • Location of the file directory, which needs to be added to system catalog **PG_DIRECTORY**. If the input path does not match the path in **PG_DIRECTORY**, an error indicating that the path does not exist will be reported. • When the GUC parameter **safe_data_path** is enabled, you can only use an advanced package to operate files in the file path specified by **safe_data_path**.
dest_file_name	TEXT	IN	No	Target file name. **NOTE** For the write operation, the system checks the file type. If the ELF file is written, an error is reported and the system exits.
start_line	INTEGER	IN	No	Number of the line where the copy starts. The default value is **1**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Type	Input/OutputParameter	CanBeNull	Description
end_line	INTEGER	IN	Yes	Number of the line where the copy ends. The default value is **NULL**, indicating the end of the file.

- DBE_FILE.GET_ATTR

  Reads and returns the attributes of a disk file.

  The prototype of DBE_FILE.GET_ATTR is as follows:

```
DBE_FILE.GET_ATTR(
   location    IN  TEXT,
   filename    IN  TEXT,
   fexists     OUT BOOLEAN,
   file_length OUT BIGINT,
   block_size  OUT INTEGER)
RETURN RECORD;
```

Table 2-169 DBE_FILE.GET_ATTR API parameters

Parameter	Type	Input/OutputParameter	CanBeNull	Description
location	TEXT	IN	No	File directory. **NOTE** • Location of the file directory, which needs to be added to system catalog **PG_DIRECTORY**. If the input path does not match the path in **PG_DIRECTORY**, an error indicating that the path does not exist will be reported. • When the GUC parameter **safe_data_path** is enabled, you can only use an advanced package to operate files in the file path specified by **safe_data_path**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Type	Input/OutputParameter	CanBeNull	Description
filename	TEXT	IN	No	File name.
fexists	BOOLEAN	OUT	No	Specifies whether the file exists.
file_length	BIGINT	OUT	No	File length (unit: bytes). If the file does not exist, **NULL** is returned.
block_size	INTEGER	OUT	No	Block size of the file system (unit: bytes). If the file does not exist, **NULL** is returned.

- DBE_FILE.SEEK

  Adjusts the position of a file pointer forward or backward based on the specified number of bytes.

  The prototype of DBE_FILE.SEEK is as follows:

```
DBE_FILE.SEEK(
   file          IN INTEGER,
   absolute_start IN BIGINT DEFAULT NULL,
   relative_start IN BIGINT DEFAULT NULL)
RETURN VOID;

DBE_FILE.SEEK(
   file          IN DBE_FILE.FILE_TYPE,
   absolute_start IN INTEGER DEFAULT NULL,
   relative_start IN INTEGER DEFAULT NULL)
RETURN VOID;
```

Table 2-170 DBE_FILE.SEEK API parameters

Parameter	Type	Input/OutputParameter	Can Be Null	Description
file	INTEGER or DBE_FILE.FILE_TYPE	IN	No	File handle opened using OPEN or object of the DBE_FILE.FILE_TYPE type opened using FOPEN.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Type	Input/Output Parameter	Can Be Null	Description
absolute_start	BIGINT or INTEGER	IN	Yes	Absolute offset of a file. The default value is **NULL**.
relative_start	BIGINT or INTEGER	IN	Yes	Relative offset of a file. A positive number indicates forward offset and a negative number indicates backward offset. The default value is **NULL**. If both **absolute_start** and this parameter are specified, the **absolute_start** parameter is used.

- DBE_FILE.GET_POS

  Returns the current offset of a file, in bytes.

  The prototype of DBE_FILE.GET_POS is as follows:

```
DBE_FILE.GET_POS(
    file IN INTEGER)
RETURN BIGINT;

DBE_FILE.GET_POS(
    file IN DBE_FILE.FILE_TYPE)
RETURN BIGINT;
```

  Table 2-171 DBE_FILE.GET_POS API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
file	INTEGER or DBE_FILE.FILE_TYPE	IN	No	File handle opened using OPEN or object of the DBE_FILE.FILE_TYPE type opened using FOPEN.

- DBE_FILE.FOPEN_NCHAR

  Opens a file. You can specify the maximum line size. A maximum of 50 files can be opened in a session. This function returns a DBE_FILE.FILE_TYPE type object that encapsulates a file handle. This function opens a file in national character set mode for input or output.

  The prototype of DBE_FILE.FOPEN_NCHAR is as follows:

```
DBE_FILE.FOPEN_NCHAR(
    dir         IN TEXT,
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
  file_name     IN TEXT,
  open_mode     IN TEXT,
  max_line_size IN INTEGER DEFAULT 1024)
RETURN DBE_FILE.FILE_TYPE;
```

Table 2-172 DBE_FILE.FOPEN_NCHAR API parameters

Parameter	Type	Input/ Output Parameter	Can Be Null	Description
dir	TEXT	IN	No	Directory of a file. The string indicates the name of a directory object. **NOTE** • Location of the file directory, which needs to be added to system catalog **PG_DIRECTORY**. If the input path does not match the path in **PG_DIRECTORY**, an error indicating that the path does not exist will be reported. • When the GUC parameter **safe_data_path** is enabled, you can only use an advanced package to read and write files in the file path specified by **safe_data_path**.
file_name	TEXT	IN	No	File name with an extension (file type), excluding the path name. A path contained in a file name is ignored in the FOPEN_NCHAR function. In Unix, the file name cannot end with the combination of a slash and a dot (/.).
open_mode	TEXT	IN	No	Open mode of a specified file, including: • **r**: read text. • **w**: write text. • **a**: append text. • **rb**: read byte. • **wb**: write byte. • **ab**: append byte. **NOTE** For the write operation, the system checks the file type. If the ELF file is written, an error is reported and the system exits.
max_line_size	INTEGER	IN	Yes	Maximum number of bytes in each line, including newline characters. The minimum value is **1** and the maximum value is **32767**. If this parameter is not specified, the default value **1024** is used.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- DBE_FILE.WRITE_NCHAR

  Writes buffer data to the buffer of a file. The file must be opened in national character set or write mode. This operation does not write a line terminator. The text string is written in the UTF-8 character set format.

  The prototype of DBE_FILE.WRITE_NCHAR is as follows:

```
DBE_FILE.WRITE_NCHAR(
   file   IN DBE_FILE.FILE_TYPE,
   buffer IN NVARCHAR2)
RETURN VOID;
```

  Table 2-173 DBE_FILE.WRITE_NCHAR API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
file	DBE_FILE.FILE_TYPE	IN	No	Object of the DBE_FILE.FILE_TYPE type opened using FOPEN_NCHAR. The file must be opened in write mode. This operation does not write line terminators.
buffer	VARCHAR2	IN	Yes	Text data to be written to the file. The accumulated write length of each line cannot be greater than or equal to the value of **max_line_size** specified by **FOPEN_NCHAR**. Otherwise, an error is reported when the file is flushed. **NOTE** For the write operation, the system checks the file type. If the ELF file is written, an error is reported and the system exits.

- DBE_FILE.WRITE_LINE_NCHAR

  Writes buffer data to the buffer of a file. The file must be opened in national character set or write mode. This operation automatically adds a line terminator. The text string is written in the UTF-8 character set format.

  The prototype of DBE_FILE.WRITE_LINE_NCHAR is as follows:

```
DBE_FILE.WRITE_LINE_NCHAR(
   file   IN DBE_FILE.FILE_TYPE,
   buffer IN NVARCHAR2)
RETURN VOID;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 2-174 DBE_FILE.WRITE_LINE_NCHAR API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
file	DBE_FILE.FILE_TYPE	IN	No	Object of the DBE_FILE.FILE_TYPE type opened using FOPEN_NCHAR.
buffer	VARCHAR2	IN	Yes	Text data to be written to the file. The length of each line (including the newline character) cannot be greater than the value of **max_line_size** specified by **FOPEN_NCHAR** or the default value. Otherwise, an error is reported when the file is flushed. **NOTE** For the write operation, the system checks the file type. If the ELF file is written, an error is reported and the system exits.

- DBE_FILE.FORMAT_WRITE_NCHAR

  Writes formatted data to the buffer of an open file. It is a DBE_FILE.WRITE_NCHAR API that allows formatting.

  The prototype of DBE_FILE.FORMAT_WRITE_NCHAR is as follows:

```
DBE_FILE.FORMAT_WRITE_NCHAR(
   file   IN DBE_FILE.FILE_TYPE,
   format IN NVARCHAR2,
   arg1   IN NVARCHAR2 DEFAULT NULL,
   . . .
   arg5   IN NVARCHAR2 DEFAULT NULL)
RETURN VOID;
```

Table 2-175 DBE_FILE.FORMAT_WRITE_NCHAR API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
file	DBE_FILE.FILE_TYPE	IN	No	Object of the DBE_FILE.FILE_TYPE type opened using FOPEN_NCHAR.
format	VARCHAR2	IN	Yes	Formatted string, containing the text and format characters \n and %s.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Type	Input/Output Parameter	Can Be Null	Description
[arg1. . .arg5]	VARCHAR2	IN	Yes	Five optional parameters. The parameters and the positions of characters to be formatted are in one-to-one correspondence. If the parameter corresponding to a character to be formatted is not provided, an empty string is used to replace %s.

- DBE_FILE.READ_LINE_NCHAR

  Reads data from an open file and stores the read result to the buffer. It reads data to the end of each line excluding the line terminator, to the end of the file, or to the size specified by the **len** parameter. The length of the data to be read cannot exceed the value of **max_line_size** specified by **FOPEN_NCHAR**.

  The prototype of DBE_FILE.READ_LINE_NCHAR is as follows:

```
DBE_FILE.READ_LINE_NCHAR(
   file   IN  DBE_FILE.FILE_TYPE,
   buffer OUT NVARCHAR2,
   len    IN  INTEGER DEFAULT NULL)
RETURN NVARCHAR2;
```

Table 2-176 DBE_FILE.READ_LINE_NCHAR API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
file	DBE_FILE.FILE_TYPE	IN	No	Object of the DBE_FILE.FILE_TYPE type opened using FOPEN_NCHAR. The file must be opened in read mode. Otherwise, the INVALID_OPERATION exception is thrown.
buffer	VARCHAR2	OUT	No	Buffer for receiving data.
len	INTEGER	IN	Yes	Number of bytes read from the file. The default value is **NULL**. If the default value **NULL** is used, **max_line_size** is used to specify the line size.

2.12.2.5 DBE_HEAT_MAP

API

DBE_HEAT_MAP returns information such as the last modification time of a row in the target data block based on the input parameters. The information is used to browse the basis for determining cold and hot rows. This API is an O&M API and has no visibility check. That is, if the input CTID is a deleted row, this API still returns the latest status of the current row on the page. **Table 2-177** lists APIs supported by DBE_HEAT_MAP. Cross-page transparent compression does not support this advanced package. In the query result of a cross-page transparently compressed table, the last modification time of rows is empty.

Table 2-177 DBE_HEAT_MAP

API	Description
DBE_HEAT_MAP.ROW_HEAT_MAP	Obtains information such as the last modification time of a row based on the schema to which the object belongs, data object name, data object partition name, and CTID.

- DBE_HEAT_MAP.ROW_HEAT_MAP

  Obtains information such as the last modification time of a row based on the schema to which the object belongs, data object name, data object partition name, and CTID.

  The prototype of DBE_HEAT_MAP.ROW_HEAT_MAP is as follows:

```
BE_HEAT_MAP.ROW_HEAT_MAP(
OWNER           IN VARCHAR2,
SEGMENT_NAME    IN VARCHAR2,
PARTITION_NAME  IN VARCHAR2     DEFAULT NULL,
CTID            IN TEXT,
V_DEBUG         IN BOOL         DEFAULT FALSE,
BUCKETID        IN pg_catalog.int2 DEFAULT NULL))
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 2-178 DBE_HEAT_MAP.ROW_HEAT_MAP API parameters

Parameter	Description
OWNER	Schema to which a data object belongs.
SEGMENT_NAME	Data object name.
PARTITION_NAME	Data object partition name. This parameter is optional. The default value is **NULL**.
CTID	**ctid** of the target row, that is, **block_id** or **row_id**.
V_DEBUG	Debugging. Debug logs are recorded.
BUCKETID	Table bucket ID of the target row.

Table 2-179 Output parameters of DBE_HEAT_MAP.ROW_HEAT_MAP

Parameter	Description
OWNER	Data object owner.
SEGMENT_NAME	Data object name.
PARTITION_NAME	Data object partition name. This parameter is optional.
TABLESPACE_NAME	Name of the tablespace to which data belongs.
FILE_ID	ID of the absolute file to which a row belongs.
RELATIVE_FNO	ID of the relative file to which a row belongs. (GaussDB does not have this logic. Therefore, the value is the same as the preceding value.)
CTID	**ctid** of a row, that is, **block_id** or **row_id**.
WRITETIME	Last modification time of a row.

NOTE

The DBE_HEAT_MAP.ROW_HEAT_MAP API supports only DNs in the distributed database.

Example:

```
gaussdb=# ALTER DATABASE set ilm = on;
gaussdb=# CREATE SCHEMA HEAT_MAP_DATA;
gaussdb=# SET current_schema=HEAT_MAP_DATA;

gaussdb=# CREATE TABLESPACE example1 RELATIVE LOCATION 'tablespace1';
gaussdb=# CREATE TABLE HEAT_MAP_DATA.heat_map_table(id INT, value TEXT) TABLESPACE
example1;
gaussdb=# INSERT INTO HEAT_MAP_DATA.heat_map_table VALUES (1, 'test_data_row_1');
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gaussdb=# SELECT * FROM DBE_HEAT_MAP.ROW_HEAT_MAP(
    owner          =>  'heat_map_data',
    segment_name   =>  'heat_map_table',
    partition_name  => NULL,
    ctid           =>  '(0,1)');
     owner     |  segment_name  | partition_name | tablespace_name | file_id | relative_fno | ctid  |
writetime
---------------+----------------+----------------+-----------------+---------+--------------+-------+-----------
 heat_map_data | heat_map_table |                | example1        |   17291 |        17291 | (0,1) |
(1 row)
```

2.12.2.6 DBE_ILM

APIs

Implements ILM policies and APIs for manually triggering and stopping ADO tasks. **Table 2-180** lists APIs supported by DBE_ILM.

Table 2-180 DBE_ILM

API	Description
DBE_ILM.EXECUTE_ILM	Evaluates the specified data and ILM policy based on parameters. If the evaluation is passed, the corresponding compression job is generated.
DBE_ILM.STOP_ILM	Stops a compression job that is being executed based on parameters.

- DBE_ILM.EXECUTE_ILM

  Evaluates the specified data and ILM policy based on parameters. If the evaluation is passed, the corresponding compression job is generated.

  The prototype of DBE_ILM.EXECUTE_ILM is as follows:

```
DBE_ILM.EXECUTE_ILM(
OWNER          IN VARCHAR2,
OBJECT_NAME    IN VARCHAR2,
TASK_ID        IN OUT NUMBER,
SUBOBJECT_NAME IN VARCHAR2 DEFAULT NULL,
POLICY_NAME    IN VARCHAR2 DEFAULT 'ALL POLICIES',
EXECUTION_MODE IN NUMBER DEFAULT 2,
TURBO_FORCE    IN BOOLEAN DEFAULT FALSE,
TURBO_BLKSTART IN INTEGER DEFAULT -1,
TURBO_BLKEND   IN INTEGER DEFAULT -1)
```

Table 2-181 DBE_ILM.EXECUTE_ILM API parameters

Parameter	Description
OWNER	Schema to which an object belongs.
OBJECT_NAME	Object name.
TASK_ID	Descriptor ID of the generated ADO task.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Description
SUBOBJECT_NAME	Subobject name.
POLICY_NAME	Policy name. You can query the **GS_ADM_ILMOBJECTS** view to obtain the policy name. The default value of **DBE_ILM.ILM_ALL_POLICIES** is **'ALL POLICIES'**, indicating all policies on the object. Lowercase letters are not supported.
EXECUTION_MOD	Execution mode. This parameter is not supported in the current version and is reserved.
TURBO_FORCE	Specifies whether to enable forcible compression that ignores cold and hot data management. This function takes effect only for cross-page transparent compression. The value can be **TRUE** (enabled) or **FALSE** (disabled).
TURBO_BLKSTART	Number of the block from which forcible compression starts. This parameter takes effect only for cross-page transparent compression.
TURBO_BLKEND	Number of the block at which forcible compression stops. This parameter takes effect only for cross-page transparent compression.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- DBE_ILM.EXECUTE_ILM generates a job name in the format of *Database name_Table name_Partition name_Number* based on the current database name and table name, and then creates a job with the corresponding name by using DBE_SCHEDULER.Create_job. If the table name contains special characters, an error message "Invalid program name" will be displayed when this API is called.
- When DBE_ILM.EXECUTE_ILM and DBE_ILM.STOP_ILM are executed concurrently, there is a low probability that the job fails, and "tuple concurrently updated" is displayed in the **comments** column in the gs_adm_ilmresults view.
- When performing compression operations (either automatically or manually), you are advised not to perform DDL operations on the tables that are being compressed. In particular, executing DDL operations in a long transaction may cause deadlocks or lock waiting. If DDL operations are necessary, you are advised to call the DBE_ILM.STOP_ILM API to stop the compression jobs of the related tables, and then perform the DDL operations.
- To execute DBE_ILM.EXECUTE_ILM, you must have the CREATE JOB permission. You can grant the permissions using DBE_SCHEDULER.GRANT_USER_AUTHORIZATION. If you are not a SYSADMIN user, you must have the table owner permission.
- To compress a subpartition, the **SUBOBJECT_NAME** column cannot be set to the name of the partition. Instead, the name of the subpartition must be passed. (Alternatively, pass **NULL** to compress all subpartitions.)
- If this API is called within a transaction, the compression operation takes effect only after the transaction ends or is committed. If the DBE_ILM.EXECUTE_ILM API is called by multiple transactions in sequence and the first transaction is not committed, the subsequent transactions may encounter lock timeout.
- The value of the **TURBO_FORCE** parameter influences the gs_adm_ilmresults view as follows:
  - If this parameter is set to **FALSE**, the **statistics** field in the gs_adm_ilmresults view is meaningless for cross-page transparent compression. Therefore, the default value is displayed for cross-page transparent compression objects in this field.
  - If this parameter is set to **TRUE**, the current compression task runs independently of the original task division mechanism of ILM and does not collect statistics on the object. Therefore, the **statistics** field in the gs_adm_ilmresults view is empty.

- DBE_ILM.STOP_ILM

  Stops an ILM policy that is being executed based on parameters.

  The prototype of DBE_ILM.STOP_ILM is as follows:

```
DBE_ILM.STOP_ILM (
TASK_ID               IN NUMBER DEFAULT -1,
P_DROP_RUNNING_JOBS     IN BOOLEAN DEFAULT FALSE,
P_JOBNAME               IN VARCHAR2 DEFAULT NULL);
```

Table 2-182 DBE_ILM.STOP_ILM API parameters

Parameter	Description
TASK_ID	Specifies the descriptor ID of the ADO task to be stopped.
P_DROP_RUNNING_JOBS	Determines whether to stop a task that is being executed. The value **TRUE** indicates that the task is forcibly stopped, and the value **FALSE** indicates that the task is not stopped.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Description
P_JOBNAME	Specifies the name of the job to be stopped, which can be queried in the **GS_MY_ILMEVALUATIONDETAILS** view.

> **NOTE**
>
> When there are a large number of concurrent requests, the system may display the following message when you execute DBE_ILM.STOP_ILM: "Resources are busy, please try again later." In this case, try again later.

Examples

```
gaussdb=# CREATE DATABASE ilmtabledb with dbcompatibility = 'ORA';
gaussdb=# \c ilmtabledb
gaussdb=# ALTER DATABASE set ilm = on;
gaussdb=# CREATE Schema ILM_DATA;
gaussdb=# SET current_schema=ILM_DATA;
gaussdb=# CREATE SEQUENCE ILM_DATA.ORDER_TABLE_SE_ORDER_ID MINVALUE 1;
gaussdb=# CREATE OR REPLACE PROCEDURE ILM_DATA.ORDER_TABLE_CREATE_DATA(NUM INTEGER) IS
BEGIN
    FOR X IN 1..NUM
        LOOP
            INSERT INTO ORDER_TABLE VALUES(ORDER_TABLE_SE_ORDER_ID.nextval, 'Snack gift basket A',
NOW());
        END LOOP;
    COMMIT;
END;
/
gaussdb=# CREATE TABLE ILM_DATA.ORDER_TABLE (ORDER_ID INT, GOODS_NAME TEXT, CREATE_TIME
TIMESTAMP) WITH (STORAGE_TYPE=ASTORE) ILM ADD POLICY ROW STORE COMPRESS ADVANCED ROW
AFTER 1 DAYS OF NO MODIFICATION;
NOTICE:  The 'DISTRIBUTE BY' clause is not specified. Using 'order_id' as the distribution column by default.
HINT:  Please use 'DISTRIBUTE BY' clause to specify suitable data distribution column.
BEGIN
    ILM_DATA.ORDER_TABLE_CREATE_DATA(100);
    PERFORM PG_SLEEP(2);
END;
/
DECLARE
    v_taskid number;
BEGIN
    DBE_ILM.EXECUTE_ILM(OWNER        => 'ilm_data',
                        OBJECT_NAME    => 'order_table',
                        TASK_ID        => v_taskid,
                        SUBOBJECT_NAME => NULL,
                        POLICY_NAME    => 'ALL POLICIES',
                        EXECUTION_MODE => 2);
    RAISE INFO 'Task ID is:%', v_taskid;
END;
/
INFO:  Task ID is:1

```

2.12.2.7 DBE_ILM_ADMIN

APIs

Implement ILM policies, and control ADO background scheduling and concurrency control parameters. **Table 2-183** lists APIs supported by DBE_ILM_ADMIN.

Table 2-183 DBE_ILM_ADMIN

API	Description
DBE_ILM_ADMIN.CUSTOMIZE_ILM	Customizes ILM policy attributes based on input parameters.
DBE_ILM_ADMIN.DISABLE_ILM	Disables background scheduling.
DBE_ILM_ADMIN.ENABLE_ILM	Enables background scheduling.
DBE_ILM_ADMIN.CREATE_ILM_DB_POLICY	Creates a database-level compression policy.
DBE_ILM_ADMIN.DELETE_ILM_DB_POLICY	Deletes a database-level compression policy.

NOTE

When there are a large number of concurrent requests and you run DBE_ILM_ADMIN.DISABLE_ILM or DBE_ILM_ADMIN.ENABLE_ILM, the system may display the message "Resources are busy, please try again later." In this case, try again later.

- DBE_ILM_ADMIN.CUSTOMIZE_ILM

  Customizes ILM policy attributes based on input parameters.

  The prototype of DBE_ILM_ADMIN.CUSTOMIZE_ILM is as follows:

  ```
  DBE_ILM_ADMIN.CUSTOMIZE_ILM(
  PARAM    IN    NUMBER,
  VAL      IN    NUMBER);
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 2-184 DBE_ILM_ADMIN.CUSTOMIZE_ILM API parameters

Parameter	Description
PARAM	Sequence number of a parameter.
VAL	Parameter value.

NOTE

In MYSQL- or M-compatible mode, if the input **VAL** is a non-numeric character when DBE_ILM_ADMIN.CUSTOMIZE_ILM() is called, for example, DBE_ILM_ADMIN.CUSTOMIZE_ILM(13, '*'), the input **VAL** is set to **0** by default.

Table 2-185 DBE_ILM_ADMIN.CUSTOMIZE_ILM API parameters

No.	Parameter Value	Description
1	EXECUTION_INTERVAL	Specifies the frequency of executing an ADO task, in minutes. The default value is **15**. The value is an integer or floating-point number greater than or equal to 1 and less than or equal to 2147483647. The value is rounded down.
2	RETENTION_TIME	Specifies the retention period of ADO-related history records, in days. The default value is **30**. The value is an integer or floating-point number greater than or equal to 1 and less than or equal to 2147483647. The value is rounded down.
7	ENABLE	Status of background scheduling. This parameter cannot be modified using DBE_ILM_ADMIN.CUSTOMIZE_ILM. Use DBE_ILM_ADMIN.DISABLE_ILM or DBE_ILM_ADMIN.ENABLE_ILM to modify it.
11	POLICY_TIME	Specifies whether the time unit of ADO is day or second. The time unit second is used only for testing. Possible values are: ● **0**: ILM_POLICY_IN_DAYS (default value) ● **1**: ILM_POLICY_IN_SECONDS
12	ABS_JOBLIMIT	Maximum number of ADO jobs generated by an ADO task. The value is an integer or floating-point number greater than or equal to 0 and less than or equal to 2147483647. The value is rounded down.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

No.	Parameter Value	Description
13	JOB_SIZELIMIT	Maximum number of bytes that can be processed by a single ADO job. The unit is MB. The value is an integer or floating-point number greater than or equal to 0 and less than or equal to 2147483647. The value is rounded down. When the value of **JOB_SIZELIMIT** is **0**, a warning is reported and no compression is performed when a compression task is manually executed. In addition, the automatic background scheduling job does not perform compression.
14	WIND_DURATION	Duration of the maintenance window, in minutes. The default value is **240** (4 hours). The value is an integer greater than or equal to 0 and less than 1440 (24 hours).
15	BLOCK_LIMITS	Upper limit of the instance-level row-store compression speed. The default value is **40**. The unit is blocks/ms, indicating the maximum number of blocks that can be compressed per millisecond. The value ranges from 0 to 10000. The value **0** indicates no limit. Cross-page transparent compression does not support this parameter.
16	ENABLE_META_COMPRESSION	Specifies whether to enable header compression. The default value is **0**. The value can be **0** (disabled) or **1** (enabled). Cross-page transparent compression does not support this parameter. **NOTE** If this parameter is set to **1**, the compression ratio is improved for tables with short rows (less data in a single row), but the performance of accessing compressed rows greatly deteriorates. If most tables in the database have long rows, you are advised not to enable this parameter.
17	SAMPLE_MIN	Minimum sampling step for constant encoding and equivalent encoding. The default value is **10**. The value range is [1,100]. Decimals can be entered and will be automatically rounded down. Cross-page transparent compression does not support this parameter.
18	SAMPLE_MAX	Maximum sampling step for constant encoding and equivalent encoding. The default value is **10**. The value range is [1,100]. Decimals can be entered and will be automatically rounded down. Cross-page transparent compression does not support this parameter.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

No.	Parameter Value	Description
19	CONST_PRIO	Constant encoding priority. The default value is **40**. The value range is [0,100]. The value **100** indicates that constant encoding is disabled. Decimals can be entered and will be automatically rounded down. Cross-page transparent compression does not support this parameter.
20	CONST_THRESHOLD	Constant encoding threshold. The default value is **90**. The value range is [1,100], indicating that constant encoding is performed when the proportion of constant values in a column exceeds the threshold. Decimals can be entered and will be automatically rounded down. Cross-page transparent compression does not support this parameter.
21	EQVALUE_PRIO	Equivalent encoding priority. The default value is **60**. The value range is [0,100]. The value **100** indicates that equivalent encoding is disabled. Decimals can be entered and will be automatically rounded down. Cross-page transparent compression does not support this parameter.
22	EQVALUE_THRESHOLD	Equivalent encoding threshold. The default value is **80**. The value range is [1,100], indicating that equivalent encoding is performed when the ratio of equal values in two columns exceeds the threshold. Decimals can be entered and will be automatically rounded down. Cross-page transparent compression does not support this parameter.
23	ENABLE_DELTA_ENCODE_SWITCH	Specifies whether to enable difference encoding. The default value is **1**. Value range: [0, 1]. The value **0** indicates that the function is disabled and **1** indicates that the function is enabled. Decimals are supported and will be automatically rounded down. Cross-page transparent compression does not support this parameter.
24	LZ4_COMPRESSION_LEVEL	LZ4 compression level. The default value is **0**. The value range is [0,16]. Decimals can be entered and will be automatically rounded down. Cross-page transparent compression does not support this parameter.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

No.	Parameter Value	Description
25	ENABLE_LZ4_PARTIAL_DECOMPRESSION	Specifies whether to enable partial decompression. The default value is **1**. Value range: [0,1]. The value **0** indicates that the function is disabled and **1** indicates that the function is enabled. Decimals are supported and will be automatically rounded down. Cross-page transparent compression does not support this parameter.
26	INDEXJOB_SIZELIMIT	Maximum number of bytes that can be processed by a single ADO job during index compression. The unit is MB. The default value is **1024**. The value is an integer or floating-point number greater than or equal to 0 and less than or equal to 2147483647. The value is rounded down. When the value of this parameter is **0**, a warning is reported and no compression is performed when a compression task is manually executed. In addition, the automatic background scheduling job does not perform compression.
27	ENABLE_INDEX_COMPRESS	Specifies whether to enable index compression. The value **0** (default value) indicates that index compression is disabled, and the value **1** indicates that index compression is enabled.

Example:

```
gaussdb=# CALL DBE_ILM_ADMIN.CUSTOMIZE_ILM(1, 15);
 customize_ilm
---------------

(1 row)
gaussdb=# SELECT * FROM gs_adm_ilmparameters;
              name               | value
---------------------------------+-------
 EXECUTION_INTERVAL              |    15
 RETENTION_TIME                  |    30
 ENABLED                         |     1
 POLICY_TIME                     |     0
 ABS_JOBLIMIT                    |    10
 JOB_SIZELIMIT                   |  1024
 WIND_DURATION                   |   240
 BLOCK_LIMITS                    |    40
 ENABLE_META_COMPRESSION         |     0
 SAMPLE_MIN                      |    10
 SAMPLE_MAX                      |    10
 CONST_PRIO                      |    40
 CONST_THRESHOLD                 |    90
 EQVALUE_PRIO                    |    60
 EQVALUE_THRESHOLD               |    80
 ENABLE_DELTA_ENCODE_SWITCH      |     1
 LZ4_COMPRESSION_LEVEL           |     0
 ENABLE_LZ4_PARTIAL_DECOMPRESSION |     1
 INDEXJOB_SIZELIMIT              |  1024
 ENABLE_INDEX_COMPRESS           |     0
(20 rows)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- DBE_ILM_ADMIN.DISABLE_ILM

  Disables background scheduling.

  The prototype of DBE_ILM_ADMIN.DISABLE_ILM is as follows:

  ```
  CALL DBE_ILM_ADMIN.DISABLE_ILM();
  ```

- DBE_ILM_ADMIN.ENABLE_ILM

  Enables background scheduling.

  The prototype of DBE_ILM_ADMIN.ENABLE_ILM is as follows:

  ```
  CALL DBE_ILM_ADMIN.ENABLE_ILM();
  ```

  NOTE

  To make background scheduling take effect, you need to set the GUC parameter **enable_ilm** to **on** on the database O&M platform.

- DBE_ILM_ADMIN.CREATE_ILM_DB_POLICY

  Creates a database-level compression policy based on input parameters. The policy performs the following operations:

  – Automatically overwriting existing tables: This policy is added to all user tables that are not bound to a compression policy in the current database.

  – Default inheritance for new tables: If no compression policy is explicitly specified for a new table, the table automatically inherits the database-level policy.

  The prototype of DBE_ILM_ADMIN.CREATE_ILM_DB_POLICY is as follows:

  ```
  DBE_ILM_ADMIN.CREATE_ILM_DB_POLICY(
  DAYS IN INT,
  COMPRESSION_LEVEL IN TEXT DEFAULT 'MEDIUM');
  ```

  Table 2-186 DBE_ILM_ADMIN.CREATE_ILM_DB_POLICY API parameters

Parameter	Description
DAYS	Number of days of the compression policy.
COMPRESSION_LEVEL	Compression policy level. Only **HIGH** and **MEDIUM** are supported. The default value is **MEDIUM**.

- DBE_ILM_ADMIN.DELETE_ILM_DB_POLICY

  Deletes a database-level compression policy and the compression policies inherited from the database-level compression policy on all tables.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- Only advanced database-level compression policies are supported.
- Database-level policies do not support expressions.
- When using gs_dump to export the database-level policy definition, ensure that the entire database is exported and you have the system administrator permission. If the preceding conditions are not met, the related policies are exported as independent policies at the table, partition, or subpartition level instead of being processed as database-level policies.
- If the DBE_ILM_ADMIN.CREATE_ILM_DB_POLICY, DBE_ILM_ADMIN.DELETE_ILM_DB_POLICY, and DBE_ILM.EXECUTE_ILM APIs are called by multiple transactions concurrently and the first transaction is not committed, the subsequent transactions may encounter lock timeout.

Example of a database-level policy:

- Create a compression policy that takes effect for 10 days.

```
gaussdb=# CALL DBE_ILM_ADMIN.CREATE_ILM_DB_POLICY(10);
 create_ilm_db_policy
----------------------

(1 row)
```

- Delete a database-level policy.

```
gaussdb=# CALL DBE_ILM_ADMIN.DELETE_ILM_DB_POLICY();
 delete_ilm_db_policy
----------------------

(1 row)
```

- Create a high-level compression policy that takes effect for 10 days.

```
gaussdb=# CALL DBE_ILM_ADMIN.CREATE_ILM_DB_POLICY(10, 'high');
 create_ilm_db_policy
----------------------

(1 row)
```

2.12.2.8 DBE_LICENSE

NOTE

Only SYSADMIN or OPRADMIN can call the APIs in the advanced package.

APIs

The advanced package DBE_LICENSE is used to activate, view, and revoke licenses. For details about the supported APIs, see **Table DBE_LICENSE**.

Table 2-187 DBE_LICENSE

API	Description
DBE_LICENSE.ACTIVATE	Activates a license.
DBE_LICENSE.DEACTIVATE	Revokes the current license.
DBE_LICENSE.GET_ESN	Queries the ESN of a node.
DBE_LICENSE.GET_LICENSE_INFO	Queries the license status of the current node.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

API	Description
DBE_LICENSE.GET_ALL_NODE_LICENSE_ACTIVATE	Queries the license activation status of the database cluster.

- DBE_LICENSE.ACTIVATE

  Activates a license based on the license type and the corresponding file.

  Currently, only the token file or ESDP license file can be activated.

  The prototype of DBE_LICENSE.ACTIVATE is as follows:

```
DBE_LICENSE.ACTIVATE(
    license_type IN VARCHAR2,
    token_file IN VARCHAR2)
RETURN BOOLEAN;

DBE_LICENSE.ACTIVATE(
    license_type IN VARCHAR2,
    license_file IN VARCHAR2,
    key_file IN VARCHAR2)
RETURN BOOLEAN;
```

  Table 2-188 DBE_LICENSE.ACTIVATE API parameters

Parameter	Description
license_type	Type of the license to be activated. The value can be **OnCloud** or **OffCloud**. • **OnCloud**: The license is activated using a token file. • **OffCloud**: The license is activated using an ESDP license file.
token_file	Name of the token file. The following requirements must be met: • The name cannot be **license.json** or **license.xml**. • The name cannot contain slashes (/) or backslashes (\).
license_file	Name of the license file in ESDP format.
key_file	Public key file name.

- DBE_LICENSE.DEACTIVATE

  Deactivates the license of the current node.

  If the input parameter is **false**, the function throws an error when the license is deactivated. If the input parameter is **true**, the function returns **true** when the license is deactivated.

  If no parameter is passed, the default value **false** is used.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTICE

- After the license is deactivated, it becomes invalid. The system will generate a new ESN for the current database node and the ESN is not activated. To protect your rights and interests, exercise caution when performing this operation.
- When you use an ESDP license file to activate the license, the revocation code file **RevoTicket.txt** is generated in the **gs_esn** folder in the data directory. You can use this file to update the ESN of the license on the ESDP platform and activate the node license again.

The prototype of DBE_LICENSE.DEACTIVATE is as follows:

```
DBE_LICENSE.DEACTIVATE(
    idempotent    IN BOOLEAN DEFAULT FALSE)
RETURN BOOLEAN;
```

- DBE_LICENSE.GET_ESN

  Queries the ESN of the current database node. The ESN is the unique identifier of the database node. The database ensures that the ESN of each node is unique.

  The prototype of DBE_LICENSE.GET_ESN is as follows:

  ```
  DBE_LICENSE.GET_ESN()
  RETURN VARCHAR2;
  ```

- DBE_LICENSE.GET_LICENSE_INFO

  Queries the license information of a node.

  The prototype of DBE_LICENSE.GET_LICENSE_INFO is as follows:

  ```
  DBE_LICENSE.GET_LICENSE_INFO()
  ```

  Return type: setof record

  Examples:

  ```
  gaussdb=# SELECT * FROM  dbe_license.get_license_info();
       create_time       |     activate_time      |      expire_time       |  type   | license_version | customer |
  state   |       lsn       |                                 feature_list
                                  | dn_capacity | cn_capacity
  ------------------------+------------------------+------------------------+---------+-----------------+----------
  +-----------+-----------------+-------------------------------------------------------------
  ----------------------------------+-------------+-------------
   2024-10-20 14:30:45+08 | 2026-01-22 12:02:17+08 | 2026-01-22 12:03:45+08 | OnCloud |               1 |
  Test     | Activated | lsntesttesttest | enable_ilm,enable_tde,enable_ledger,enable
  _security_policy |           1 |           1

  ```

Table 2-189 DBE_LICENSE.GET_LICENSE_INFO API return columns

Name	Type	Description
create_time	timestamptz(0)	Time when a license is created.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Name	Type	Description
activate_time	timestamptz(0)	License activation time. • For an activated commercial license, the activation time is the time when the license is activated by calling the API. • For a trial license, the activation time is the time when the trial mode is enabled.
expire_time	timestamptz(0)	Time when the license expires. • For an activated license, the expiration time is the time when the token file or ESDP license file expires. • For a trial license, the expiration time is the 90th day after the trial mode is enabled.
type	text	License deployment type. • **OnCloud**: with a console deployed. • **OffCloud**: without a console deployed. • Others: illegal deployment mode.
license_version	bigint	License version. • In the case of deployment with a console, this parameter is used to distinguish the signature algorithm and license structure. • **0** for deployment without a console.
customer	text	Purchaser of a license.
state	text	License status. • **Activated**: The license has been activated. • **Deactivated**: The license has been deactivated. • **Expired**: The license has expired. • **Trial**: The license is in trial state. • **Error**: The license is abnormal.
lsn	text	License identifier.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Name	Type	Description
feature_list	text	List of advanced features contained in the license, which is a list of GUC parameter names separated by commas (,). For example, "enable_tde,enable_ledger".
dn_capacity	bigint	Reserved.
cn_capacity	bigint	Reserved.

- DBE_LICENSE.GET_ALL_NODE_LICENSE_ACTIVATE

  Queries the license activation status of the current database cluster. If the licenses of all CNs and primary DNs in the cluster are activated or in trial state, **true** is returned. Otherwise, **false** is returned.

  The prototype of DBE_LICENSE.GET_ALL_NODE_LICENSE_ACTIVATE is as follows:

```
DBE_LICENSE.GET_ALL_NODE_LICENSE_ACTIVATE()
RETURN BOOLEAN;
```

2.12.2.9 DBE_LOB

APIs

Table 2-190 lists APIs supported by the DBE_LOB package.

NOTE

- In database ORA, the byte content of the space is 00. However, in GaussDB, the byte content corresponding to the space is ASCII code 32.
- In a distributed environment, the maximum size of a CLOB, BLOB, or BFILE is 1 GB.
- LOBMAXSIZE supports a maximum of 1073741771 bytes.
- LOB update APIs (such as LOB_WRITE, LOB_COPY, CONVERTTOBLOB, LOB_CONVERTTOBLOB, and LOADBLOBFROMBFILE) in the DBE_LOB package update only LOB variables in memory and do not automatically update the associated physical table data. Even if the target row has been locked using SELECT ... FOR UPDATE, LOB data changes are not automatically persisted to the database table. To save the update result, you must explicitly execute the UPDATE statement.

Table 2-190 DBE_LOB

API	Description
DBE_LOB.GET_LENGTH	Obtains and returns the length of a specified LOB. The object cannot be greater than 2 GB.
DBE_LOB.LOB_GET_LENGTH	Obtains and returns the length of a specified LOB or BFILE.
DBE_LOB.OPEN	Opens a LOB and returns a LOB descriptor.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

API	Description
DBE_LOB.READ	Loads a part of LOB content to the buffer based on the specified length and initial position offset.
DBE_LOB.LOB_READ	Reads a part of LOB (including BFILE) content to the buffer based on the specified length and initial position offset.
DBE_LOB.WRITE	Copies content in the buffer to a LOB based on the specified length and initial position offset.
DBE_LOB.WRITE_APPEND	Copies content in the buffer to the end part of a LOB based on the specified length.
DBE_LOB.LOB_WRITE_APPEND	Copies content in the buffer to the end part of a LOB based on the specified length.
DBE_LOB.COPY	Copies content in a LOB to another LOB based on the specified length and initial position offset.
DBE_LOB.LOB_COPY	Copies content in a LOB to another LOB based on the specified length and initial position offset.
DBE_LOB.ERASE	Deletes content in a LOB (less than or equal to 1 GB) based on the specified length and initial position offset.
DBE_LOB.LOB_ERASE	Deletes content in a LOB based on the specified length and initial position offset.
DBE_LOB.CLOSE	Closes a LOB descriptor.
DBE_LOB.MATCH	Returns the position of the *N*th occurrence of a character string in a LOB.
DBE_LOB.COMPARE	Compares two LOBs (including BFILE objects) or a certain part of two LOBs.
DBE_LOB.SUBSTR	Reads a LOB substring and returns the read substring.
DBE_LOB.LOB_SUBSTR	Reads a LOB or BFILE substring and returns the read substring.
DBE_LOB.STRIP	Truncates the LOB of a specified length. After the execution is complete, the length of the LOB is set to the length specified by the **newlen** parameter.
DBE_LOB.LOB_STRIP	Truncates the LOB of a specified length. After the execution is complete, the length of the LOB is set to the length specified by the **newlen** parameter.
DBE_LOB.CREATE_TEMPORARY	Creates a temporary BLOB or CLOB.
DBE_LOB.APPEND	Adds the content of a LOB to another LOB.
DBE_LOB.LOB_APPEND	Adds the content of a LOB to another LOB.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

API	Description
DBE_LOB.FREETEMPORARY	Deletes a temporary BLOB or CLOB.
DBE_LOB.FILEOPEN	Opens a database BFILE and returns its file descriptor.
DBE_LOB.FILECLOSE	Closes a BFILE that is opened by FILEOPEN.
DBE_LOB.BFILEOPEN	Opens a database BFILE.
DBE_LOB.BFILECLOSE	Closes a BFILE that is opened by BFILEOPEN.
DBE_LOB.LOADFROMFILE	Loads the database BFILE of the specified length in the specified location to the BLOB in the specified location.
DBE_LOB.LOADFROMBFILE	Loads the database BFILE of the specified length in the specified location to the LOB in the specified location.
DBE_LOB.LOADBLOBFROMFILE	Loads an external database file of the specified length in the specified location to a BLOB (less than or equal to 1 GB) in a specified location.
DBE_LOB.LOADBLOBFROMBFILE	Loads the database BFILE of the specified length in the specified location to the BLOB in the specified location.
DBE_LOB.LOADCLOBFROMFILE	Loads an external database file of the specified length in the specified location to a CLOB (less than or equal to 1 GB) in a specified location.
DBE_LOB.LOADCLOBFROMBFILE	Loads the database BFILE of the specified length in the specified location to the CLOB in the specified location.
DBE_LOB.CONVERTTOBLOB	Converts a CLOB to a BLOB (less than or equal to 1 GB).
DBE_LOB.CONVERTTOCLOB	Converts a BLOB to a CLOB (less than or equal to 1 GB).
DBE_LOB.LOB_CONVERTTOBLOB	Converts a CLOB to a BLOB.
DBE_LOB.LOB_CONVERTTOCLOB	Converts a BLOB to a CLOB.
DBE_LOB.GETCHUNKSIZE	Obtains the maximum size of LOB data that can be stored in the chunk structure in the database.
DBE_LOB.LOB_WRITE	Reads the specified length of the source object from the start position, writes the content to the specified offset position of the target LOB, overrides the original content, and returns the target LOB.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

API	Description
DBE_LOB.BFILENAME	Constructs and returns the DBE_LOB.BFILE based on the directory and file name.

- DBE_LOB.GET_LENGTH

  Obtains and returns the size of a specified LOB. The maximum size of the object is 2 GB.

  The prototype of DBE_LOB.GET_LENGTH is as follows:

```
DBE_LOB.GET_LENGTH (
   blob_obj IN BLOB)
RETURN INTEGER;

DBE_LOB.GET_LENGTH (
   clob_obj IN CLOB)
RETURN INTEGER;
```

  Table 2-191 DBE_LOB.GET_LENGTH API parameters

Parameter	Description
blob_obj/ clob_obj	BLOB/CLOB whose length is to be obtained.

- DBE_LOB.LOB_GET_LENGTH

  Obtains and returns the length of a specified LOB or BFILE file. The maximum size of the object is 32 TB.

  The prototype of DBE_LOB.LOB_GET_LENGTH is as follows:

```
DBE_LOB.LOB_GET_LENGTH (
   blob_obj IN BLOB)
RETURN BIGINT;

DBE_LOB.LOB_GET_LENGTH (
   clob_obj IN CLOB)
RETURN BIGINT;

DBE_LOB.LOB_GET_LENGTH (
   bfile IN DBE_LOB.BFILE)
RETURN BIGINT;
```

  Table 2-192 DBE_LOB.LOB_GET_LENGTH API parameters

Parameter	Description
blob_obj/ clob_obj/bfile	BLOB/CLOB/BFILE whose length is to be obtained.

- DBE_LOB.OPEN

  The stored procedure opens a LOB and returns a LOB descriptor. This procedure is meaningless and is used only for compatibility.

  The prototype of DBE_LOB.OPEN is as follows:

```
DBE_LOB.OPEN (
   lob INOUT BLOB);
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
DBE_LOB.OPEN (
   lob INOUT CLOB);

DBE_LOB.OPEN (
   bfile     INOUT DBE_LOB.BFILE,
   open_mode IN    TEXT DEFAULT 'null');
```

Table 2-193 DBE_LOB.OPEN API parameters

Parameter	Description
lob/bfile	Opened BLOB/CLOB/BFILE.
open_mode	Operation mode. Currently, the range is [R,W,A,RB,WB,AB].

- DBE_LOB.READ

  Reads a part of LOB to the output buffer based on the specified length and initial position offset.

  The prototype of DBE_LOB.READ is as follows:

```
DBE_LOB.READ (
   blob_obj IN  BLOB,
   amount   IN  INTEGER,
   off_set  IN  INTEGER,
   out_put  OUT RAW);

DBE_LOB.READ (
   clob_obj IN  CLOB,
   amount   IN  INTEGER,
   off_set  IN  INTEGER,
   out_put  OUT VARCHAR2);
```

Table 2-194 DBE_LOB.READ API parameters

Parameter	Description
blob_obj/ clob_obj	BLOB/CLOB to be read.
amount	Length of read content. **NOTE** If the length to read is less than 1 or greater than 32767, an error is reported.
off_set	Start position for reading the LOB, that is, the offset bytes to initial position of the LOB content. If the offset is less than 1 or greater than the LOB length, an error is reported. The initial position is 1.
out_put	Target buffer for storing the read LOB.

- DBE_LOB.LOB_READ

  Reads a part of LOB/BFILE to the output buffer based on the specified length and initial position offset.

  The prototype of DBE_LOB.LOB_READ is as follows:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
DBE_LOB.LOB_READ(
   blob_obj IN    BLOB,
   amount   INOUT BIGINT,
   off_set  IN    BIGINT,
   out_put  OUT   RAW);

DBE_LOB.LOB_READ(
   clob_obj IN    CLOB,
   amount   INOUT BIGINT,
   off_set  IN    BIGINT,
   out_put  OUT   VARCHAR2);

DBE_LOB.LOB_READ(
   bfile   IN    DBE_LOB.BFILE,
   amount  INOUT BIGINT,
   off_set IN    BIGINT,
   out_put OUT   RAW);
```

Table 2-195 DBE_LOB.LOB_READ API parameters

Parameter	Description
blob_obj/ clob_obj/bfile	BLOB/CLOB/BFILE to be read (which can be greater than 1 GB).
amount	Length to read as the IN parameter, or actual read length as the OUT parameter. **NOTE** If the length to read is less than 1 or greater than 32767, an error is reported.
off_set	Start position for reading the LOB/BFILE, that is, the offset bytes to initial position of the LOB content. If the offset is less than 1 or greater than the LOB/BFILE length, an error is reported. The initial position is 1.
out_put	Target buffer for storing the read LOB/BFILE.

- DBE_LOB.WRITE

  Writes content in the source to a LOB based on the specified length and initial position.

  The prototype of DBE_LOB.WRITE is as follows:

```
DBE_LOB.WRITE (
   blob_obj INOUT BLOB,
   amount   IN    INTEGER,
   off_set  IN    INTEGER,
   source   IN    RAW);

DBE_LOB.WRITE (
   clob_obj INOUT CLOB,
   amount   IN    INTEGER,
   off_set  IN    INTEGER,
   source   IN    VARCHAR2);
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 2-196 DBE_LOB.WRITE API parameters

Parameter	Description
blob_obj/ clob_obj	BLOB/CLOB to be written.
amount	Write size. A maximum of 32767 bytes are supported. **NOTE** If the length of written content is shorter than 1 or longer than the length of content to be written, an error is reported.
off_set	Start position for writing content to the target BLOB/ CLOB, that is, the offset bytes to the initial position of LOB content. **NOTE** If the offset is less than 1 or greater than the value of **LOBMAXSIZE**, an error is reported. The initial position is 1, and the maximum value is the maximum LOB length.
source	Content to be written.

- DBE_LOB.WRITE_APPEND

  Writes content in the source object to the end part of a LOB based on the specified length.

  The prototype of DBE_LOB.WRITE_APPEND is as follows:

```
DBE_LOB.WRITE_APPEND (
   blob_obj   INOUT BLOB,
   amount     IN    INTEGER,
   source_obj IN    RAW);

DBE_LOB.WRITE_APPEND (
   clob_obj   INOUT CLOB,
   amount     IN    INTEGER,
   source_obj IN    VARCHAR2);
```

Table 2-197 DBE_LOB.WRITE_APPEND API parameters

Parameter	Description
blob_obj/ clob_obj	BLOB/CLOB to be written.
amount	Write size. A maximum of 32767 bytes are supported. **NOTE** If the length of written content is shorter than 1 or longer than the length of content to be written, an error is reported.
source_obj	Content to be written.

- DBE_LOB.LOB_WRITE_APPEND

  Writes content in the source object to the end part of a LOB based on the specified length.

  The prototype of DBE_LOB.LOB_WRITE_APPEND is as follows:

```
DBE_LOB.LOB_WRITE_APPEND(
   blob_obj    INOUT BLOB,
```

```
  amount      IN    INTEGER,
  source_obj  IN    RAW);

DBE_LOB.LOB_WRITE_APPEND (
  clob_obj    INOUT CLOB,
  amount      IN    INTEGER,
  source_obj  IN    VARCHAR2);
```

Table 2-198 DBE_LOB.LOB_WRITE_APPEND API parameters

Parameter	Description
blob_obj/ clob_obj	BLOB/CLOB to be written.
amount	Write size. A maximum of 32767 bytes are supported. **NOTE** If the length of written content is shorter than 1 or longer than the length of content to be written, an error is reported.
source_obj	Content to be written.

- DBE_LOB.COPY

  Copies content in a LOB to another LOB based on the specified length and initial position offset.

  The prototype of DBE_LOB.COPY is as follows:

```
DBE_LOB.COPY (
  dest_lob   INOUT BLOB,
  src_lob    IN    BLOB,
  len        IN    INTEGER,
  dest_start IN    INTEGER DEFAULT 1,
  src_start  IN    INTEGER DEFAULT 1);
```

Table 2-199 DBE_LOB.COPY API parameters

Parameter	Description
dest_lob	LOB to which the buffer content is to be pasted.
src_lob	LOB from which the buffer content is to be copied.
len	Length of the copied data.
dest_start	Start position for pasting the buffer content to the target LOB (**dest_lob**), that is, the offset bytes to the initial position of LOB content.
src_start	Start position for copying the buffer content from the source LOB (**src_lob**), that is, the offset bytes to the initial position of LOB content.

- DBE_LOB.LOB_COPY

  Copies content in a LOB to another LOB based on the specified length and initial position offset.

  The prototype of DBE_LOB.LOB_COPY is as follows:

```
DBE_LOB.LOB_COPY(
  blob_obj    INOUT BLOB,
```

```
  source_obj  IN    BLOB,
  amount      IN    BIGINT,
  dest_offset IN    BIGINT DEFAULT 1,
  src_offset  IN    BIGINT DEFAULT 1);

DBE_LOB.LOB_COPY(
  clob_obj    INOUT CLOB,
  source_obj  IN    CLOB,
  amount      IN    BIGINT,
  dest_offset IN    BIGINT DEFAULT 1,
  src_offset  IN    BIGINT DEFAULT 1);
```

Table 2-200 DBE_LOB.LOB_COPY API parameters

Parameter	Description
blob_obj/ clob_obj	LOB to which the buffer content is to be pasted.
source_obj	LOB from which the buffer content is to be copied.
amount	Length of the copied data. **NOTE** If the length to copy is less than 1 or greater than the value of **LOBMAXSIZE**, an error is reported.
dest_offset	Start position for pasting the buffer content to the target LOB, that is, the offset bytes/characters to the initial position of LOB content. The unit is byte for BLOB and character for CLOB. **NOTE** If the offset is less than 1 or greater than the value of **LOBMAXSIZE**, an error is reported.
src_offset	Start position for copying the content from the source object, that is, the offset bytes to the initial position of LOB content. The unit is byte for BLOB and character for CLOB. **NOTE** If the offset is less than 1, an error is reported.

- DBE_LOB.ERASE

  Deletes the content in a BLOB (not greater than 1 GB) based on the specified length and initial position offset. The bytes of the deleted part in the BLOB are filled with 0.

  The prototype of DBE_LOB.ERASE is as follows:

```
DBE_LOB.ERASE (
  blob_obj INOUT BLOB,
  amount   INOUT INTEGER,
  off_set  IN    INTEGER DEFAULT 1);
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 2-201 DBE_LOB.ERASE API parameters

Parameter	Description
blob_obj	LOB whose content is to be deleted as the IN parameter, or LOB with specified content deleted as the OUT parameter. If this parameter is left empty, an error is reported.
amount	Length (in bytes for BLOBs) to delete as the IN parameter, or actual length deleted as the OUT parameter. **NOTE** If the length to delete is less than 1 or this parameter is left empty, an error is reported.
off_set	Start position from which LOB is to be deleted, that is, the number of offset bytes to the initial position of LOB content. The value cannot be greater than 1 GB. **NOTE** If the offset is less than 1 or this parameter is left empty, an error is reported.

- DBE_LOB.LOB_ERASE

  Deletes the content in the LOB based on the specified length and initial position offset. The bytes of the deleted part in the BLOB are filled with 0, and the characters of the deleted part in the CLOB are filled with spaces. The LOB can be greater than 1 GB and the maximum size is 32 TB.

  The prototype of DBE_LOB.LOB_ERASE is as follows:

```
DBE_LOB.LOB_ERASE (
   blob_obj INOUT BLOB,
   amount   INOUT BIGINT,
   off_set  IN    BIGINT DEFAULT 1);

DBE_LOB.LOB_ERASE (
   clob_obj INOUT CLOB,
   amount   INOUT BIGINT,
   off_set  IN    BIGINT DEFAULT 1);
```

Table 2-202 DBE_LOB.LOB_ERASE API parameters

Parameter	Description
blob_obj/ clob_obj	LOB whose content is to be deleted as the IN parameter, or LOB with specified content deleted as the OUT parameter. If this parameter is left empty, an error is reported.
amount	Length (BLOB in bytes and CLOB in characters) to delete as the IN parameter, or actual length deleted as the OUT parameter. **NOTE** If the length to delete is less than 1 or this parameter is left empty, an error is reported.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Description
off_set	Start position from which the LOB content is to be deleted, that is, the number of bytes relative to the start position of the BLOB content or the number of characters relative to the start position of the CLOB content. **NOTE** If the offset is less than 1 or this parameter is left empty, an error is reported.

- DBE_LOB.CLOSE

  Closes the LOB descriptor that has been opened.

  The prototype of DBE_LOB.CLOSE is as follows:

```
DBE_LOB.CLOSE(
   lob IN BLOB);

DBE_LOB.CLOSE (
   lob IN CLOB);

DBE_LOB.CLOSE (
   file IN INTEGER);
```

  Table 2-203 DBE_LOB.CLOSE API parameters

Parameter	Description
lob/file	BLOB/CLOB/BFILE to be closed.

- DBE_LOB.MATCH

  The function returns the *N*th occurrence position of a string in a LOB or BFILE. **NULL** is returned for an invalid input. The LOB or BFILE can be greater than 1 GB, up to 32 TB.

  The prototype of DBE_LOB.MATCH is as follows:

```
DBE_LOB.MATCH(
   blob_obj    IN BLOB,
   blob_obj2   IN RAW,
   beg_index   IN BIGINT DEFAULT 1,
   occur_index IN BIGINT DEFAULT 1)
RETURN BIGINT;

DBE_LOB.MATCH(
   clob_obj    IN CLOB,
   clob_obj2   IN VARCHAR2,
   beg_index   IN BIGINT DEFAULT 1,
   occur_index IN BIGINT DEFAULT 1)
RETURN BIGINT;

DBE_LOB.MATCH(
   bfile       IN DBE_LOB.BFILE,
   blob_obj2     IN RAW,
   beg_index   IN BIGINT DEFAULT 1,
   occur_index IN BIGINT DEFAULT 1)
RETURN BIGINT;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 2-204 DBE_LOB.MATCH API parameters

Parameter	Description
blob_obj/ clob_obj/ bfile	BLOB/CLOB descriptor to be searched for, or BFILE (which must be opened by DBE_LOB.BFILEOPEN first). If this parameter is left blank, **NULL** is returned.
blob_obj2/ clob_obj2	Pattern to match. It is RAW for BLOB/BFILE objects and VARCHAR2 for CLOBs. If this parameter is left empty, **NULL** is returned.
beg_index	Absolute offset (in bytes) for BLOB/BFILE objects, or offset (in characters) for CLOBs. The start position for matching is 1. **NOTE** The value ranges from 1 to *LOBMAXSIZE*. If a value out of the range is input, **NULL** is returned.
occur_index	Number of pattern matching times. The minimum value is 1. **NOTE** If the value is greater than the maximum number of times that the pattern string can be matched in the LOB, **0** is returned. If the value is out of the range from 1 to *LOBMAXSIZE*, **NULL** is returned.

- DBE_LOB.COMPARE

  Compares some or all LOBs or BFILEs.

  - If the two parts are equal, **0** is returned. Otherwise, a non-zero value is returned.
  - If the first LOB is smaller than the second, **-1** is returned. If the first LOB is larger than the second, **1** is returned.
  - If any of the *len*, *start1*, and *start2* parameters is invalid, **NULL** is returned. The valid offset range is 1 to *LOBMAXSIZE*.
  - If both the values of **start_pos1** and **start_pos2** exceed the LOB/BFILE length, **0** is returned.

  The prototype of DBE_LOB.COMPARE is as follows:

```
DBE_LOB.COMPARE (
   lob1       IN BLOB,
   lob2       IN BLOB,
   len        IN BIGINT DEFAULT 1073741312,
   start_pos1 IN BIGINT DEFAULT 1,
   start_pos2 IN BIGINT DEFAULT 1)
RETURN INTEGER;

DBE_LOB.COMPARE (
   lob1       IN CLOB,
   lob2       IN CLOB,
   len        IN BIGINT DEFAULT 1073741312,
   start_pos1 IN BIGINT DEFAULT 1,
   start_pos2 IN BIGINT DEFAULT 1)
RETURN INTEGER;

DBE_LOB.COMPARE (
   file1      IN DBE_LOB.BFILE,
   file2      IN DBE_LOB.BFILE,
   len        IN BIGINT DEFAULT 1073741312,
   start_pos1 IN BIGINT DEFAULT 1,
   start_pos2 IN BIGINT DEFAULT 1)
RETURN INTEGER;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 2-205 DBE_LOB.COMPARE API parameters

Parameter	Description
lob1/file1	First BLOB/CLOB/BFILE to be compared (which must be opened by DBE_LOB.BFILEOPEN first.)
lob2/file2	Second BLOB/CLOB/BFILE to be compared (which must be opened by DBE_LOB.BFILEOPEN first.)
len	Number of characters or bytes to be compared. The default value is **1073741312**.
start_pos1	Offset of the first LOB descriptor. The initial position is 1, and the maximum value is the maximum LOB length.
start_pos2	Offset of the second LOB descriptor. The initial position is 1, and the maximum value is the maximum LOB length.

- DBE_LOB.SUBSTR

  Reads a LOB substring and returns the read substring.

  The prototype of DBE_LOB.SUBSTR is as follows:

```
DBE_LOB.SUBSTR(
   lob_loc IN BLOB,
   amount  IN INTEGER DEFAULT 32767,
   off_set IN INTEGER  DEFAULT 1)
RETURN RAW;

DBE_LOB.SUBSTR(
   lob_loc IN CLOB,
   amount  IN INTEGER DEFAULT 32767,
   off_set IN INTEGER  DEFAULT 1)
RETURN VARCHAR2;
```

Table 2-206 DBE_LOB.SUBSTR API parameters

Parameter	Description
lob_loc	LOB descriptor whose substring is to be read. For BLOBs, the return value is of the RAW type. For CLOBs, the return value is of the VARCHAR2 type.
amount	Number of bytes or characters to be read. **NOTE** The value ranges from 1 to 32767. If the value exceeds the range, **NULL** is returned.
off_set	Number of characters or bytes offset from the start position. **NOTE** The value ranges from 1 to *LOBMAXSIZE*. If the value exceeds the range, **NULL** is returned.

- DBE_LOB.LOB_SUBSTR

  Reads a LOB or BFILE substring and returns the read substring. The LOB or BFILE can be up to 32 TB.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

The prototype of DBE_LOB.LOB_SUBSTR is as follows:

```
DBE_LOB.LOB_SUBSTR(
   lob_loc IN BLOB,
   amount  IN INTEGER DEFAULT 32767,
   off_set IN BIGINT  DEFAULT 1)
RETURN RAW;

DBE_LOB.LOB_SUBSTR(
   lob_loc IN CLOB,
   amount  IN INTEGER DEFAULT 32767,
   off_set IN BIGINT  DEFAULT 1)
RETURN VARCHAR2;

DBE_LOB.LOB_SUBSTR(
   bfile   IN DBE_LOB.BFILE,
   amount  IN INTEGER DEFAULT 32767,
   off_set IN BIGINT  DEFAULT 1)
RETURN RAW;
```

Table 2-207 DBE_LOB.LOB_SUBSTR API parameters

Parameter	Description
lob_loc/ bfile	LOB descriptor or BFILE whose substring is to be read. The file must be opened by DBE_LOB.BFILEOPEN first. For BLOBs/ BFILE files, the return value is of the RAW type. For CLOBs, the return value is of the VARCHAR2 type.
amount	Number of bytes or characters to be read. **NOTE** The value ranges from 1 to 32767. If the value exceeds the range, **NULL** is returned.
off_set	Number of characters or bytes offset from the start position. **NOTE** The value ranges from 1 to *LOBMAXSIZE*. If the value exceeds the range, **NULL** is returned.

- DBE_LOB.STRIP

  Truncates the LOB of a specified length. After STRIP is executed, the LOB length is set to the length specified by **newlen**.

  The prototype of DBE_LOB.STRIP is as follows:

```
DBE_LOB.STRIP(
   lob_loc INOUT BLOB,
   newlen  IN INTEGER);

DBE_LOB.STRIP(
   lob_loc INOUT CLOB,
   newlen  IN INTEGER);
```

Table 2-208 DBE_LOB.STRIP API parameters

Parameter	Description
lob_loc	LOB to read as the IN parameter, or truncated object as the OUT parameter. If this parameter is left empty, an error is reported.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Description
newlen	New length after truncation, in bytes for BLOBs or in characters for CLOBs.

- DBE_LOB.LOB_STRIP

  Truncates the LOB of a specified length. After LOB_STRIP is executed, the LOB length is set to the length specified by **newlen**. The LOB can be greater than 1 GB, up to 32 TB.

  The prototype of DBE_LOB.LOB_STRIP is as follows:

```
DBE_LOB.LOB_STRIP(
   lob_loc INOUT BLOB,
   newlen  IN    BIGINT);

DBE_LOB.LOB_STRIP(
   lob_loc INOUT CLOB,
   newlen  IN    BIGINT);
```

  Table 2-209 DBE_LOB.LOB_STRIP API parameters

Parameter	Description
lob_loc	LOB to read as the IN parameter, or truncated object as the OUT parameter. If this parameter is left empty, an error is reported.
newlen	New length after truncation, in bytes for BLOBs or in characters for CLOBs. **NOTE** If the value is less than 1, **NULL** is returned. If the value is greater than the LOB length, an error is reported.

- DBE_LOB.CREATE_TEMPORARY

  Creates a temporary BLOB or CLOB. CREATE_TEMPORARY is used only for syntax compatibility.

  The prototype of DBE_LOB.CREATE_TEMPORARY is as follows:

```
DBE_LOB.CREATE_TEMPORARY (
   lob_loc INOUT BLOB,
   cache   IN    BOOLEAN,
   dur     IN    INTEGER DEFAULT 10);

DBE_LOB.CREATE_TEMPORARY (
   lob_loc INOUT CLOB,
   cache   IN    BOOLEAN,
   dur     IN    INTEGER DEFAULT 10);
```

  Table 2-210 DBE_LOB.CREATE_TEMPORARY API parameters

Parameter	Description
lob_loc	LOB descriptor.
cache	Used only for syntax compatibility.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Description
dur	Used only for syntax compatibility.

- DBE_LOB.APPEND

  Appends **source_obj** to the end of the target LOB.

  The prototype of DBE_LOB.APPEND is as follows:

```
DBE_LOB.APPEND (
   blob_obj INOUT BLOB,
   source_obj  IN    BLOB);

DBE_LOB.APPEND (
   clob_obj INOUT CLOB,
   source_obj  IN    CLOB);
```

  Table 2-211 DBE_LOB.APPEND API parameters

Parameter	Description
blob_obj/ clob_obj	BLOB/CLOB to be written.
source_obj	BLOB/CLOB to be read.

- DBE_LOB.LOB_APPEND

  Appends **source_obj** to the end of the target LOB.

  The prototype of DBE_LOB.LOB_APPEND is as follows:

```
DBE_LOB.LOB_APPEND(
   blob_obj   INOUT BLOB,
   source_obj IN    BLOB);

DBE_LOB.LOB_APPEND(
   clob_obj   INOUT CLOB,
   source_obj IN    CLOB);
```

  Table 2-212 DBE_LOB.LOB_APPEND API parameters

Parameter	Description
blob_obj/ clob_obj	BLOB/CLOB to be written.
source_obj	BLOB/CLOB to be read.

- DBE_LOB.FREETEMPORARY

  Frees LOBs created by CREATE_TEMPORARY.

  The prototype of DBE_LOB.FREETEMPORARY is as follows:

```
DBE_LOB.FREETEMPORARY (
   blob INOUT BLOB);

DBE_LOB.FREETEMPORARY (
   clob INOUT CLOB);
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 2-213 DBE_LOB.FREETEMPORARY API parameters

Parameter	Description
blob/clob	BLOB/CLOB to be released.

- DBE_LOB.FILEOPEN

  Opens an external database BFILE and returns its file descriptor. A maximum of 10 BFILEs can be opened in a session.

  The BFILE type is defined as follows:

```
DBE_LOB.BFILE (
   directory TEXT,
   filename  TEXT,
   fd        INTEGER);
```

  The prototype of DBE_LOB.FILEOPEN is as follows:

```
DBE_LOB.FILEOPEN (
   bfile     IN DBE_LOB.BFILE,
   open_mode IN TEXT)
RETURN INTEGER;
```

Table 2-214 DBE_LOB.FILEOPEN API parameters

Parameter	Description
bfile	External database file to be opened. For a BFILE, it specifies the file path, file name, and file descriptor. **NOTE** The variable contains the file directory and the file name. • Location of the file directory, which needs to be added to system catalog **PG_DIRECTORY**. If the input path does not match the path in **PG_DIRECTORY**, an error indicating that the path does not exist will be reported. • When the GUC parameter **safe_data_path** is enabled, you can only use an advanced package to read and write files in the file path specified by **safe_data_path**. • File name with an extension (file type), excluding the path name. The path contained in the file name will be ignored by OPEN. In Unix, the file name cannot end with the combination of a slash and a dot (/.).
open_mode	File open mode, which can only be **r** (that is, read). An error is reported in other modes.

- DBE_LOB.FILECLOSE

  Closes an external BFILE.

  The prototype of DBE_LOB.FILECLOSE is as follows:

```
DBE_LOB.FILECLOSE (
   file IN INTEGER);
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 2-215 DBE_LOB.FILECLOSE API parameters

Parameter	Description
file	External file to be closed (the file descriptor is returned by FILEOPEN).

- DBE_LOB.BFILEOPEN

  Opens an external BFILE. A maximum of 10 BFILE files can be opened in a session.

  The prototype of DBE_LOB.BFILEOPEN is as follows:

```
DBE_LOB.BFILEOPEN (
    bfile     INOUT DBE_LOB.BFILE,
    open_mode IN    TEXT DEFAULT 'R');
```

Table 2-216 DBE_LOB.BFILEOPEN API parameters

Parameter	Description
bfile	Opened database BFILE file as the INOUT parameter. **NOTE** The variable contains the file directory and the file name. • Location of the file directory, which needs to be added to system catalog **PG_DIRECTORY**. If the input path does not match the path in **PG_DIRECTORY**, an error indicating that the path does not exist will be reported. • When the GUC parameter **safe_data_path** is enabled, you can only use an advanced package to read and write files in the file path specified by **safe_data_path**. • File name with an extension (file type), excluding the path name. The path contained in the file name will be ignored by OPEN. In Unix, the file name cannot end with the combination of a slash and a dot (/.).
open_mode	File open mode, which can only be **r** (that is, read). An error is reported in other modes.

  Example:

```
-- Obtain the substring of the BFILE (the file content is ABCD).
DECLARE
bfile dbe_lob.bfile;
BEGIN
bfile = DBE_LOB.BFILENAME(dir_name, file_name); -- Obtain the corresponding BFILE.
DBE_LOB.bfileopen(bfile, 'r'); -- Open the BFILE.
RAISE NOTICE 'res:%', DBE_LOB.lob_substr(bfile, 10, 1); -- Obtain and print the substring.
DBE_LOB.bfileclose(bfile);-- Close the BFILE.
END;
/
NOTICE:  res:41
ANONYMOUS BLOCK EXECUTE
```

- DBE_LOB.BFILECLOSE

  Closes an external BFILE.

  The prototype of DBE_LOB.BFILECLOSE is as follows:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
DBE_LOB.BFILECLOSE (
   bfile INOUT DBE_LOB.BFILE);
```

Table 2-217 DBE_LOB.BFILECLOSE API parameters

Parameter	Description
bfile	Closed BFILE file as the INOUT parameter.

- DBE_LOB.LOADFROMFILE

  Loads an external BFILE to a BLOB and returns the object of the RAW type.

  The prototype of DBE_LOB.LOADFROMFILE is as follows:

```
DBE_LOB.LOADFROMFILE (
   dest_lob    IN BLOB,
   src_file    IN INTEGER,
   amount      IN INTEGER,
   dest_offset IN INTEGER,
   src_offset  IN INTEGER)
RETURN RAW;
```

Table 2-218 DBE_LOB.LOADFROMFILE API parameters

Parameter	Description
dest_lob	Target BLOB. The BFILE will be loaded to the specified offset position of the BLOB.
src_bfile	Source BFILE file to be read.
amount	Length of the content to be read from the BFILE file. **NOTE** If the length is less than 1 or greater than 32767, an error is reported.
dest_offset	Offset length of the BLOB. **NOTE** If the offset is less than 1 or greater than the value of *LOBMAXSIZE*, an error is reported.
src_offset	Offset length of the BFILE file. **NOTE** • If the offset is less than 1 or greater than the value of *LOBMAXSIZE*, an error is reported. • If the sum of *amount* and *src_offset* is greater than the length of *src_bfile* plus 1, an error is reported.

- DBE_LOB.LOADFROMBFILE

  Loads an external BFILE to a LOB.

  The prototype of DBE_LOB.LOADFROMBFILE is as follows:

```
DBE_LOB.LOADFROMBFILE (
   dest_lob    INOUT BLOB,
   src_file    IN    DBE_LOB.BFILE,
   amount      IN    BIGINT,
   dest_offset IN    BIGINT DEFAULT 1,
   src_offset  IN    BIGINT DEFAULT 1)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
RETURN BLOB;

DBE_LOB.LOADFROMBFILE (
   dest_lob    INOUT CLOB,
   src_file    IN    DBE_LOB.BFILE,
   amount      IN    BIGINT,
   dest_offset IN    BIGINT DEFAULT 1,
   src_offset  IN    BIGINT DEFAULT 1)
RETURN CLOB;
```

Table 2-219 DBE_LOB.LOADFROMBFILE API parameters

Parameter	Description
dest_lob	Target LOB as the INOUT parameter, to which the BFILE will be loaded. The file must be opened by DBE_LOB.BFILEOPEN first. The LOB can be greater than 1 GB, up to 32 TB.
src_file	Source BFILE file to be read. The BFILE file can be greater than 1 GB, up to 32 TB.
amount	Length of the content to be read from the BFILE and to be written to the LOB. **NOTE** If the length is less than 1 or greater than the value of *LOBMAXSIZE*, an error is reported.
dest_offset	Offset length of the LOB. **NOTE** If the offset is less than 1 or greater than the value of *LOBMAXSIZE*, an error is reported.
src_offset	Offset length of the BFILE file. **NOTE** • If the offset is less than 1 or greater than the value of *LOBMAXSIZE*, an error is reported. • If the sum of *amount* and *src_offset* is greater than the length of *src_bfile* plus 1, an error is reported.

- DBE_LOB.LOADBLOBFROMFILE

  Loads an external BFILE to a BLOB and returns the object of the RAW type.

  The prototype of DBE_LOB.LOADBLOBFROMFILE is as follows:

```
DBE_LOB.LOADBLOBFROMFILE (
   dest_lob    IN BLOB,
   src_file    IN INTEGER,
   amount      IN INTEGER,
   dest_offset IN INTEGER,
   src_offset  IN INTEGER)
RETURN RAW;
```

Table 2-220 DBE_LOB.LOADBLOBFROMFILE API parameters

Parameter	Description
dest_lob	Target BLOB, to which the BFILE will be loaded.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Description
src_file	Source BFILE file to be read.
amount	Length of the target BLOB. If the length of a file exceeds this threshold, the file will not be saved to the BLOB. **NOTE** If the length is less than 1 or greater than 32767, an error is reported.
dest_offset	Offset length of the BLOB. **NOTE** If the offset is less than 1 or greater than the value of *LOBMAXSIZE*, an error is reported.
src_offset	Offset length of the BFILE file. **NOTE** • If the offset is less than 1 or greater than the value of *LOBMAXSIZE*, an error is reported. • If the sum of *amount* and *src_offset* is greater than the length of *src_bfile* plus 1, an error is reported.

- DBE_LOB.LOADBLOBFROMBFILE

  Loads an external BFILE to a BLOB.

  The prototype of DBE_LOB.LOADBLOBFROMBFILE is as follows:

```
DBE_LOB.LOADBLOBFROMFILE (
   dest_lob    INOUT BLOB,
   src_file    IN    DBE_LOB.BFILE,
   amount      IN    BIGINT,
   dest_offset INOUT BIGINT,
   src_offset  INOUT BIGINT)
```

Table 2-221 DBE_LOB.LOADBLOBFROMBFILE API parameters

Parameter	Description
dest_lob	Target BLOB as the INOUT parameter, to which the BFILE (which must be opened by DBE_LOB.BFILEOPEN first) is loaded. The BFILE file can be greater than 1 GB, up to 32 TB.
src_file	Source BFILE file to be read. The BFILE file can be greater than 1 GB, up to 32 TB.
amount	Length of the target BLOB. If the length of a file exceeds this threshold, the file will not be saved to the BLOB. **NOTE** If the length is less than 1 or greater than the value of *LOBMAXSIZE*, an error is reported.
dest_offset	Offset length of the BLOB. **NOTE** If the offset is less than 1 or greater than the value of *LOBMAXSIZE*, an error is reported.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Description
src_offset	Offset length of the BFILE file. **NOTE** • If the offset is less than 1 or greater than the value of *LOBMAXSIZE*, an error is reported. • If the sum of *amount* and *src_offset* is greater than the length of *src_bfile* plus 1, an error is reported.

- DBE_LOB.LOADCLOBFROMFILE

  Loads an external BFILE to a CLOB and returns the object of the RAW type.

  The prototype of DBE_LOB.LOADCLOBFROMFILE is as follows:

```
DBE_LOB.LOADCLOBFROMFILE (
   dest_lob    IN CLOB,
   src_file    IN INTEGER,
   amount      IN INTEGER,
   dest_offset IN INTEGER,
   src_offset  IN INTEGER)
RETURN RAW;
```

  Table 2-222 DBE_LOB.LOADCLOBFROMFILE API parameters

Parameter	Description
dest_lob	Target CLOB, to which the BFILE will be loaded.
src_file	Source BFILE file to be read.
amount	Length of the CLOB. **NOTE** If the length is less than 1 or greater than 32767, an error is reported.
dest_offset	Offset length of the CLOB. **NOTE** If the offset is less than 1 or greater than the value of *LOBMAXSIZE*, an error is reported.
src_offset	Offset length of the BFILE file. **NOTE** • If the offset is less than 1 or greater than the value of *LOBMAXSIZE*, an error is reported. • If the sum of *amount* and *src_offset* is greater than the length of *src_bfile* plus 1, an error is reported.

- DBE_LOB.LOADCLOBFROMBFILE

  Loads an external BFILE to a CLOB.

  The prototype of DBE_LOB.LOADCLOBFROMBFILE is as follows:

```
DBE_LOB.LOADCLOBFROMBFILE (
   dest_lob    INOUT CLOB,
   src_file    IN    DBE_LOB.BFILE,
   amount      IN    BIGINT,
   dest_offset INOUT BIGINT,
   src_offset  INOUT BIGINT)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 2-223 DBE_LOB.LOADCLOBFROMBFILE API parameters

Parameter	Description
dest_lob	Target CLOB as the INOUT parameter, to which the BFILE (which must be opened by DBE_LOB.BFILEOPEN first) is loaded. The BFILE file can be greater than 1 GB, up to 32 TB.
src_file	Source BFILE file to be read. The BFILE file can be greater than 1 GB, up to 32 TB.
amount	Length of the target CLOB. If the length of a file exceeds this threshold, the file will not be saved to the CLOB. **NOTE** If the length is less than 1 or greater than the value of *LOBMAXSIZE*, an error is reported.
dest_offset	Offset length of the CLOB. **NOTE** If the offset is less than 1 or greater than the value of *LOBMAXSIZE*, an error is reported.
src_offset	Offset length of the BFILE file. **NOTE** • If the offset is less than 1 or greater than the value of *LOBMAXSIZE*, an error is reported. • If the sum of *amount* and *src_offset* is greater than the length of *src_bfile* plus 1, an error is reported.

- DBE_LOB.CONVERTTOBLOB

  Converts a CLOB to a BLOB. The CLOB cannot be greater than 1 GB.

  The prototype of DBE_LOB.CONVERTTOBLOB is as follows:

```
DBE_LOB.CONVERTTOBLOB(
   dest_blob   IN BLOB,
   src_clob    IN CLOB,
   amount      IN INTEGER DEFAULT 32767,
   dest_offset IN INTEGER DEFAULT 1,
   src_offset  IN INTEGER DEFAULT 1)
RETURN RAW;
```

Table 2-224 DBE_LOB.CONVERTTOBLOB API parameters

Parameter	Description
dest_blob	Target BLOB, which is converted from a CLOB.
src_clob	Source CLOB to be read.
amount	Length of the target CLOB. If the length of a file exceeds this threshold, the file will not be saved to the BLOB. If the length is less than 1 or greater than the value of *LOBMAXSIZE*, an error is reported.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Description
dest_offset	Offset length of the BLOB. If **dest_offset** is set to **1**, data is loaded from the start position of the file. The rest may be deduced by analogy.
src_offset	Offset length of the CLOB. If **src_offset** is set to **1**, data is read from the start position of the file. The rest may be deduced by analogy.

- DBE_LOB.LOB_CONVERTTOBLOB

  Converts a CLOB to a BLOB. The size of a LOB can be greater than 1 GB.

  The prototype of DBE_LOB.LOB_CONVERTTOBLOB is as follows:

```
DBE_LOB.LOB_CONVERTTOBLOB(
   dest_blob   INOUT BLOB,
   src_clob    IN    CLOB,
   amount      IN    BIGINT,
   dest_offset INOUT BIGINT,
   src_offset  INOUT BIGINT)
```

  Table 2-225 DBE_LOB.LOB_CONVERTTOBLOB API parameters

Parameter	Description
dest_blob	Target BLOB, which is converted from a CLOB.
src_clob	Source CLOB to be read.
amount	Length of the target CLOB. If the length of a file exceeds this threshold, the file will not be saved to the BLOB. If the length is less than 1 or greater than the value of *LOBMAXSIZE*, an error is reported.
dest_offset	Offset length of the BLOB. If **dest_offset** is set to **1**, data is loaded from the start position of the file. The rest may be deduced by analogy. If the offset is less than 1 or greater than the value of *LOBMAXSIZE*, an error is reported.
src_offset	Offset length of the CLOB. If **src_offset** is set to **1**, data is read from the start position of the file. The rest may be deduced by analogy. If the offset is less than 1 or greater than the value of *LOBMAXSIZE*, an error is reported.

- DBE_LOB.CONVERTTOCLOB

  Converts a BLOB to a CLOB. The BLOB cannot be greater than 1 GB.

  The prototype of DBE_LOB.CONVERTTOCLOB is as follows:

```
DBE_LOB.CONVERTTOCLOB(
   dest_clob   IN CLOB,
   src_blob    IN BLOB,
   amount      IN INTEGER DEFAULT 32767,
   dest_offset IN INTEGER DEFAULT 1,
   src_offset  IN INTEGER DEFAULT 1)
RETURN text;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 2-226 DBE_LOB.CONVERTTOCLOB API parameters

Parameter	Description
dest_clob	Target CLOB, which is converted from a BLOB.
src_blob	Source BLOB to be read.
amount	Length of the target BLOB. If the length of a file exceeds this threshold, the file will not be saved to the CLOB.
dest_offset	Offset length of the CLOB. If **dest_offset** is set to **1**, data is loaded from the start position of the file. The rest may be deduced by analogy.
src_offset	Offset length of the BLOB. If **src_offset** is set to **1**, data is read from the start position of the file. The rest may be deduced by analogy.

- DBE_LOB.LOB_CONVERTTOCLOB

  Converts a BLOB to a CLOB. The size of a LOB can be greater than 1 GB.

  The prototype of DBE_LOB.LOB_CONVERTTOCLOB is as follows:

```
DBE_LOB.LOB_CONVERTTOCLOB(
   dest_clob    INOUT CLOB,
   src_blob    IN    BLOB,
   amount      IN    BIGINT,
   dest_offset INOUT BIGINT,
   src_offset  INOUT BIGINT)
```

Table 2-227 DBE_LOB.LOB_CONVERTTOCLOB API parameters

Parameter	Description
dest_clob	Target CLOB, which is converted from a BLOB.
src_blob	Source BLOB to be read.
amount	Length of the target BLOB. If the length of a file exceeds this threshold, the file will not be saved to the CLOB.
dest_offset	Offset length of the CLOB. If **dest_offset** is set to **1**, data is loaded from the start position of the file. The rest may be deduced by analogy. If the offset is less than 1 or greater than the value of *LOBMAXSIZE*, an error is reported.
src_offset	Offset length of the BLOB. If **src_offset** is set to **1**, data is read from the start position of the file. The rest may be deduced by analogy. If the offset is less than 1 or greater than the value of *LOBMAXSIZE*, an error is reported.

- DBE_LOB.GETCHUNKSIZE

  Returns *TOAST_MAX_CHUNK_SIZE*. When LOB is stored in the database, TOAST is used internally.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

The prototype of DBE_LOB.GETCHUNKSIZE is as follows:

```
DBE_LOB.GETCHUNKSIZE(
   lob_loc IN CLOB
)RETURN INTEGER

DBE_LOB.GETCHUNKSIZE(
   lob_loc IN BLOB
)RETURN INTEGER
```

Table 2-228 DBE_LOB.GETCHUNKSIZE API parameters

Parameter	Description
lob_loc	Target CLOB/BLOB.

- DBE_LOB.LOB_WRITE

  Reads the specified length of the source object from the start position, writes the content to the specified offset position of the target LOB, overrides the original content, and returns the target LOB.

  The prototype of DBE_LOB.LOB_WRITE is as follows:

```
DBE_LOB.LOB_WRITE(
   clob_obj INOUT CLOB,
   amount   IN    INTEGER,
   off_set  IN    BIGINT,
   source   IN    VARCHAR2
)
RETURN CLOB;

DBE_LOB.LOB_WRITE(
   blob_obj INOUT BLOB,
   amount   IN    INTEGER,
   off_set  IN    BIGINT,
   source   IN    RAW
)
RETURN BLOB;
```

Table 2-229 DBE_LOB.LOB_WRITE API parameters

Parameter	Type	Input/ Output Parameter	Can Be Null	Description
blob_obj / clob_obj	BLOB/ CLOB	INOUT	No	Target LOB as the INOUT parameter, to which the content is to be written.
amount	INTEGER	IN	No	Length of the data to be written (in bytes for BLOBs or in characters for CLOBs).
off_set	BIGINT	IN	No	Offset position for writing data to *blob_obj/clob_obj*

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Type	Input/Output Parameter	Can Be Null	Description
source	RAW/VARCHAR2	IN	No	Source object

- DBE_LOB.BFILENAME

  Constructs a BFILE based on the directory and file name.

  The prototype of DBE_LOB.BFILENAME is as follows:

```
DBE_LOB.BFILENAME(
    directory IN TEXT,
    filename  IN TEXT)
RETURN DBE_LOB.BFILE;
```

Table 2-230 DBE_LOB.BFILENAME API parameters

Parameter	Description
directory	File directory. **NOTE** Location of the file directory, which needs to be added to system catalog **PG_DIRECTORY**. If the input path does not match the path in **PG_DIRECTORY**, an error indicating that the path does not exist will be reported. • When the GUC parameter **safe_data_path** is enabled, you can only use an advanced package to read and write files in the file path specified by **safe_data_path**. • File name with an extension (file type), excluding the path name. The path contained in the file name will be ignored by OPEN. In Unix, the file name cannot end with the combination of a slash and a dot (/.).
filename	File name.

Examples

```
-- Obtain the length of a string.
SELECT DBE_LOB.GET_LENGTH('12345678');
 get_length
------------
          8
(1 row)

-- DBE_LOB.READ API.
DECLARE
myraw  RAW(100);
amount INTEGER :=2;
buffer INTEGER :=1;
begin
DBE_LOB.READ('123456789012345',amount,buffer,myraw);
dbe_output.print_line(myraw);

2.12.2.10 DBE_MATCH

APIs

Table 2-231 lists APIs supported by the DBE_MATCH package.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 2-231 DBE_MATCH

API	Description
DBE_MATCH.EDIT_DISTANCE_SIMILARITY	Compares the difference between two character strings (minimum steps of deletion, addition, and conversion) and normalizes the difference to a value ranging from 0 to 100. The value **100** indicates that the two character strings are the same, and the value **0** indicates that the two character strings are different.

- DBE_MATCH.EDIT_DISTANCE_SIMILARITY

  Compares the difference between two character strings (minimum steps of deletion, addition, and conversion) and normalizes the difference to a value ranging from 0 to 100. The value **100** indicates that the two character strings are the same, and the value **0** indicates that the two character strings are different.

  The prototype of DBE_MATCH.EDIT_DISTANCE_SIMILARITY is as follows:

```
DBE_MATCH.EDIT_DISTANCE_SIMILARITY(
    str1 IN text,
    str2 IN text
)returns integer ;
```

Table 2-232 DBE_MATCH.EDIT_DISTANCE_SIMILARITY API parameters

Parameter	Description
str1	First character string. If the value is **null**, **0** is returned.
str2	Second character string. If the value is **null**, **0** is returned.

2.12.2.11 DBE_OBFUSCATION_TOOLKIT

APIs

NOTICE

The DES, DES3, and MD5 hash algorithms have security risks. Exercise caution when using DBE_OBFUSCATION_TOOLKIT for encryption and decryption.

DBE_OBFUSCATION_TOOLKIT is a compatibility function package provided by GaussDB to support APIs of the DES, DES3, and MD5 hash algorithms, ensuring compatibility with the original service logic. **Table 2-233** lists APIs supported by DBE_OBFUSCATION_TOOLKIT.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 2-233 DBE_OBFUSCATION_TOOLKIT

API	Description
DBE_OBFUSCATION_TOOLKIT.DESGETKEY	Generates a key using the DES algorithm.
DBE_OBFUSCATION_TOOLKIT.DESENCRYPT	Encrypts data using the DES algorithm.
DBE_OBFUSCATION_TOOLKIT.DESDECRYPT	Decrypts data using the DES algorithm.
DBE_OBFUSCATION_TOOLKIT.DES3GETKEY	Generates a key using the DES3 algorithm.
DBE_OBFUSCATION_TOOLKIT.DES3ENCRYPT	Encrypts data using the DES3 algorithm.
DBE_OBFUSCATION_TOOLKIT.DES3DECRYPT	Decrypts data using the DES3 algorithm.
DBE_OBFUSCATION_TOOLKIT.MD5	Calculates the MD5 hash value of data.

- DBE_OBFUSCATION_TOOLKIT.DESGETKEY

  Description: Generates a key using the DES algorithm.

  DBE_OBFUSCATION_TOOLKIT.DESGETKEY has two prototypes:

```
-- Prototype 1: The input parameter is of the VARCHAR2 type.
DBE_OBFUSCATION_TOOLKIT.DESGETKEY(
seed_string IN VARCHAR2
) RETURN VARCHAR2;

-- Prototype 2: The input parameter is of the RAW type.
DBE_OBFUSCATION_TOOLKIT.DESGETKEY(
seed IN RAW
) RETURN RAW;
```

  Table 2-234 DBE_OBFUSCATION_TOOLKIT.DESGETKEY API parameters

Parameter	Type	Can Be Null	Description
seed_string	VARCHAR2	No	Seed value used to generate a key. The value must contain at least 80 bytes.
seed	RAW	No	

  Example:

```
-- Create a database in ORA-compatible mode.
gaussdb=# CREATE DATABASE ora_db dbcompatibility = 'ORA' encoding = 'utf8';
gaussdb=# \c ora_db
-- Generate a random key.
ora_db=# SELECT
```

```

NOTE

The key generated by DBE_OBFUSCATION_TOOLKIT.DESGETKEY is a random key.

- DBE_OBFUSCATION_TOOLKIT.DESENCRYPT

  Description: Encrypts data using the DES algorithm.

  DBE_OBFUSCATION_TOOLKIT.DESENCRYPT has two prototypes:

```
-- Prototype 1: The input parameter is of the VARCHAR2 type.
DBE_OBFUSCATION_TOOLKIT.DESENCRYPT(
input_string IN VARCHAR2,
key_string   IN VARCHAR2
) RETURN VARCHAR2;

-- Prototype 2: The input parameter is of the RAW type.
DBE_OBFUSCATION_TOOLKIT.DESENCRYPT(
input IN RAW,
key   IN RAW
) RETURN RAW;
```

Table 2-235 DBE_OBFUSCATION_TOOLKIT.DESENCRYPT API parameters

Parameter	Type	Can Be Null	Description
input_string	VARCHAR2	No	Data to be encrypted. The length must be a multiple of 8 bytes.
input	RAW	No	
key_string	VARCHAR2	No	Encryption key. The length must be at least 8 bytes. If the length exceeds 8 bytes, the encryption result is not affected.
key	RAW	No	

Example:

```
ora_db=# SELECT
rawtohex(dbe_raw.cast_from_varchar2_to_raw(dbe_obfuscation_toolkit.desencrypt(input_string =>
'12345678', key_string => '12345678')));

NOTE

A password is required for executing this function. For security purposes, the gsql tool does not record the SQL statements containing this function in the execution history. That is, the execution history of this function cannot be found with gsql by paging up and down.

- DBE_OBFUSCATION_TOOLKIT.DESDECRYPT

  Description: Decrypts data using the DES algorithm.

  DBE_OBFUSCATION_TOOLKIT.DESDECRYPT has two prototypes:

```
-- Prototype 1: The input parameter is of the VARCHAR2 type.
DBE_OBFUSCATION_TOOLKIT.DESDECRYPT(
input_string IN VARCHAR2,
key_string   IN VARCHAR2
) RETURN VARCHAR2;

-- Prototype 2: The input parameter is of the RAW type.
DBE_OBFUSCATION_TOOLKIT.DESDECRYPT(
input IN RAW,
key   IN RAW
) RETURN RAW;
```

Table 2-236 DBE_OBFUSCATION_TOOLKIT.DESDECRYPT API parameters

Parameter	Type	Can Be Null	Description
input_string	VARCHAR2	No	Data to be decrypted. The length of the data must be a multiple of 8 bytes.
input	RAW	No	
key_string	VARCHAR2	No	Decryption key. The length of the key must be at least 8 bytes. If the length exceeds 8 bytes, the decryption result is not affected.
key	RAW	No	

Example:

```
ora_db=# SELECT
rawtohex(dbe_raw.cast_from_varchar2_to_raw(dbe_obfuscation_toolkit.desdecrypt(input_string =>
'12345678', key_string => '12345678')));

NOTE

A password is required for executing this function. For security purposes, the gsql tool does not record the SQL statements containing this function in the execution history. That is, the execution history of this function cannot be found with gsql by paging up and down.

- DBE_OBFUSCATION_TOOLKIT.DES3GETKEY

  Description: Generates a key using the DES3 algorithm.

  DBE_OBFUSCATION_TOOLKIT.DES3GETKEY has two prototypes:

```
-- Prototype 1: The input parameter is of the VARCHAR2 type.
DBE_OBFUSCATION_TOOLKIT.DES3GETKEY(
which       IN INTEGER DEFAULT 0,
seed_string IN VARCHAR2
) RETURN VARCHAR2;

-- Prototype 2: The input parameter is of the RAW type.
DBE_OBFUSCATION_TOOLKIT.DES3GETKEY(
which IN INTEGER DEFAULT 0,
seed  IN RAW
) RETURN RAW;
```

Table 2-237 DBE_OBFUSCATION_TOOLKIT.DES3GETKEY API parameters

Parameter	Type	Can Be Null	Description
which	INTEGER	No	Key mode. Value range: **0** or **1**. • **0**: A 16-byte key (that is, two keys) is returned. • **1**: A 24-byte key (that is, three keys) is returned. Default value: **0**.
seed_string	VARCHAR2	No	Seed value used to generate a key. The value must contain at least 80 bytes.
seed	RAW	No	

Example:

```
-- Generate a random key.
ora_db=# SELECT
rawtohex(dbe_raw.cast_from_varchar2_to_raw(dbe_obfuscation_toolkit.des3getkey(seed_string =>
'00000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000')));
WARNING:  The DES3 algorithm is an insecure algorithm, please use it with caution.

NOTE

A password is required for executing this function. For security purposes, the gsql tool does not record the SQL statements containing this function in the execution history. That is, the execution history of this function cannot be found with gsql by paging up and down.

- DBE_OBFUSCATION_TOOLKIT.DES3DECRYPT

  Description: Decrypts data using the DES3 algorithm.

  DBE_OBFUSCATION_TOOLKIT.DES3DECRYPT has two prototypes:

```
-- Prototype 1: The input parameter is of the VARCHAR2 type.
DBE_OBFUSCATION_TOOLKIT.DES3DECRYPT(
input_string IN VARCHAR2,
key_string   IN VARCHAR2,
which        IN INTEGER DEFAIULT 0,
iv_string    IN VARCHAR2 DEFAULT NULL
) RETURN VARCHAR2;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
-- Prototype 2: The input parameter is of the RAW type.
DBE_OBFUSCATION_TOOLKIT.DES3DECRYPT(
input IN RAW,
key   IN RAW,
which IN INTEGER DEFAIULT 0,
iv    IN RAW DEFAULT NULL
) RETURN RAW;
```

Table 2-239 DBE_OBFUSCATION_TOOLKIT.DES3DECRYPT API parameters

Parameter	Type	Can Be Null	Description
input_string	VARCHAR2	No	Data to be decrypted. The length of the data must be a multiple of 8 bytes.
input	RAW	No	
key_string	VARCHAR2	No	Decryption key. The length of the key depends on the value of **which**. • If the value of **which** is **0**, the length of the decryption key must be at least 16 bytes. If the length exceeds 16 bytes, the decryption result is not affected. • If the value of **which** is **1**, the length of the decryption key must be at least 24 bytes. If the length exceeds 24 bytes, the decryption result is not affected.
key	RAW	No	
which	INTEGER	No	Key mode. Value range: **0** or **1**. • **0**: A 16-byte key (that is, two keys) is used for decryption. • **1**: A 24-byte key (that is, three keys) is used for decryption. Default value: **0**.
iv_string	VARCHAR2	Yes	Initial vector. When this parameter is not set to **NULL**, the length of the initial vector must be a multiple of 8 bytes. The excess part will not affect the decryption result. Default value: **NULL**.
iv	RAW	Yes	

Example:

```
ora_db=# SELECT
rawtohex(dbe_raw.cast_from_varchar2_to_raw(dbe_obfuscation_toolkit.des3decrypt(input_string =>
'12345678', key_string => '1234567823456789', iv_string => '12345678')));

- DBE_OBFUSCATION_TOOLKIT.MD5

  Description: Calculates the MD5 hash value of data.

  DBE_OBFUSCATION_TOOLKIT.MD5 has two prototypes:

```
-- Prototype 1: The input parameter is of the VARCHAR2 type.
DBE_OBFUSCATION_TOOLKIT.MD5(
input_string IN VARCHAR2
) RETURN VARCHAR2;

-- Prototype 2: The input parameter is of the RAW type.
DBE_OBFUSCATION_TOOLKIT.MD5(
input IN RAW
) RETURN RAW;
```

Table 2-240 DBE_OBFUSCATION_TOOLKIT.MD5 API parameters

Parameter	Type	Can Be Null	Description
input_string	VARCHAR2	No	Data to be hashed.
input	RAW	No	

Example:

```
ora_db=# SELECT
rawtohex(dbe_raw.cast_from_varchar2_to_raw(dbe_obfuscation_toolkit.md5(input_string =>
'1234567890')));

```

2.12.2.12 DBE_OUTPUT

NOTE

When DBE_OUTPUT.PUT_LINE is used to print the result obtained by the DBE_FILE.READ_LINE_NCHAR API, ensure that the UTF-8 character set encoding can be converted to the current database character set encoding. If the preceding conditions are met, the result can be properly output. DBE_OUTPUT.PRINT_LINE does not support this function.

APIs

Table 2-241 lists the APIs supported by the DBE_OUTPUT package.

Table 2-241 DBE_OUTPUT

API	Description
DBE_OUTPUT.PRINT_LINE	Outputs the specified text with newline characters.
DBE_OUTPUT.PRINT	Outputs the specified text without newline characters.
DBE_OUTPUT.SET_BUFFER_SIZE	Sets the size of the output buffer. If the size is not specified, the buffer can contain a maximum of 20000 bytes. If the size is set to a value less than or equal to 2000 bytes, the buffer can contain a maximum of 2000 bytes.
DBE_OUTPUT.DISABLE	Disables the calling of PUT, PUT_LINE, NEW_LINE, GET_LINE, and GET_LINES, and clears the output buffer.
DBE_OUTPUT.ENABLE	Enables the buffer, allows the calling of PUT, PUT_LINE, NEW_LINE, GET_LINE, and GET_LINES, and sets the buffer size.
DBE_OUTPUT.GET_LINE	Obtains a line of data from the buffer with a newline character as the boundary. The obtained data is not output to the client.
DBE_OUTPUT.GET_LINES	Obtains the character string of a specified number of lines in the buffer as a VARCHAR array. The obtained content is cleared from the buffer and is not output to the client.
DBE_OUTPUT.NEW_LINE	Places a line at the end of the buffer, places an end-of-line marker, and leaves a new line empty.
DBE_OUTPUT.PUT	Places an input string in the buffer without a newline character at the end. When the stored procedure ends, the line ending with the newline character is displayed.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

API	Description
DBE_OUTPUT.PUT_LINE	Places an input string in the buffer with a newline character at the end. When the stored procedure ends, the line ending with the newline character is displayed.

- DBE_OUTPUT.PRINT_LINE

  Outputs the specified text and adds newline characters.

  The prototype of DBE_OUTPUT.PRINT_LINE is as follows:

  ```
  DBE_OUTPUT.PRINT_LINE (
  format IN VARCHAR2);
  ```

  Table 2-242 DBE_OUTPUT.PRINT_LINE API parameters

Parameter	Description
format	Output text.

- DBE_OUTPUT.PRINT

  Outputs the specified text without adding newline characters.

  The prototype of DBE_OUTPUT.PRINT is as follows:

  ```
  DBE_OUTPUT.PRINT (
  format IN VARCHAR2);
  ```

  Table 2-243 DBE_OUTPUT.PRINT API parameters

Parameter	Description
format	Output text.

- DBE_OUTPUT.SET_BUFFER_SIZE

  Sets the output buffer size. If the size is not specified, it contains a maximum of 20000 bytes.

  The prototype of DBE_OUTPUT.SET_BUFFER_SIZE is as follows:

  ```
  DBE_OUTPUT.SET_BUFFER_SIZE (
  size IN INTEGER default 20000);
  ```

  Table 2-244 DBE_OUTPUT.SET_BUFFER_SIZE API parameters

Parameter	Description
size	Sets the output buffer size. The value ranges from 2000 to 1000000 bytes. If the passed value is less than 2000, it is automatically adjusted to 2000. If the passed value is greater than 1000000, it is automatically adjusted to 1000000.

- DBE_OUTPUT.DISABLE

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Disables the calling of PUT, PUT_LINE, NEW_LINE, GET_LINE, and GET_LINES, and clears the output buffer.

The prototype of DBE_OUTPUT.DISABLE is as follows:

```
DBE_OUTPUT.DISABLE;
```

- DBE_OUTPUT.ENABLE

  Enables the buffer, allows the calling of PUT, PUT_LINE, NEW_LINE, GET_LINE, and GET_LINES, and sets the buffer size. If the buffer size is not specified, 20,000 bytes are allowed by default.

  The prototype of DBE_OUTPUT.ENABLE is as follows:

  ```
  DBE_OUTPUT.ENABLE (
      buffer_size IN INTEGER DEFAULT 20000
  );
  ```

  Table 2-245 DBE_OUTPUT.ENABLE API parameters

Parameter	Description
buffer_size	Upper limit of the buffer size, in bytes. If **buffer_size** is set to **NULL**, the default value (20000 bytes) is used.

- DBE_OUTPUT.GET_LINE

  Obtains a line of data from the buffer with a newline character as the boundary. The obtained data is not output to the client.

  The prototype of DBE_OUTPUT.GET_LINE is as follows:

  ```
  DBE_OUTPUT.GET_LINE (
      line   OUT VARCHAR2,
      status OUT INTEGER
  );
  ```

  Table 2-246 DBE_OUTPUT.GET_LINE API parameters

Parameter	Description
line	Obtained character string.
status	Specifies whether the calling is normal. If a character string is obtained, the value is **0**. Otherwise, the value is **1**.

- DBE_OUTPUT.GET_LINES

  Obtains the character string of a specified number of lines in the buffer as a VARCHAR array. The obtained content is cleared from the buffer and is not output to the client.

  The prototype of DBE_OUTPUT.GET_LINES is as follows:

  ```
  DBE_OUTPUT.GET_LINES (
      lines    OUT   VARCHAR[],
      numlines IN OUT INTEGER
  );
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 2-247 DBE_OUTPUT.GET_LINES API parameters

Parameter	Description
lines	Outputs an array of multi-line strings read from the buffer.
numlines	Inputs the number of lines to be retrieved from the buffer. The output value is the number of rows actually retrieved. The value must be greater than 0 and cannot be **NULL**. If the output value is less than the input value, it indicates that the number of rows in the buffer is less than the input value.

- DBE_OUTPUT.NEW_LINE

  Places a line at the end of the buffer, places an end-of-line marker, and leaves a new line empty.

  The prototype of DBE_OUTPUT.NEW_LINE is as follows:

  ```
  DBE_OUTPUT.NEW_LINE;
  ```

- DBE_OUTPUT.PUT

  Places an input string in the buffer without a newline character at the end. After the anonymous block is executed, the line ending with the newline character is displayed.

  The prototype of DBE_OUTPUT.PUT is as follows:

  ```
  DBE_OUTPUT.PUT (
     item IN VARCHAR2);
  ```

  Table 2-248 DBE_OUTPUT.PUT API parameters

Parameter	Description
item	Character or string item to be placed in the buffer. The value can contain up to 32767 bytes.

- DBE_OUTPUT.PUT_LINE

  Places an input string in the buffer with a newline character at the end. After the anonymous block is executed, the line ending with the newline character is displayed.

  The prototype of DBE_OUTPUT.PUT_LINE is as follows:

  ```
  DBE_OUTPUT.PUT_LINE (
     item IN VARCHAR2);
  ```

  Table 2-249 DBE_OUTPUT.PUT_LINE API parameters

Parameter	Description
item	Character or string item to be placed in the buffer. The value can contain up to 32767 bytes.

Examples

```
BEGIN
   DBE_OUTPUT.SET_BUFFER_SIZE(50);
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
    DBE_OUTPUT.PRINT('hello, ');
    DBE_OUTPUT.PRINT_LINE('database!'); -- Output "hello, database!"
END;

END;
/
-- The expected result is as follows:
num: 3
line 1
line 2
line 3
ANONYMOUS BLOCK EXECUTE
```

NOTE

When the character encoding type **server_encoding** of the server is not UTF-8, if the character encoding in the data is valid UTF-8 encoding, when processing the character encoding, the DBE_OUTPUT.PUT_LINE and DBE_OUTPUT.PUT functions convert the character encoding into the **server_encoding** encoding format based on the UTF-8 encoding logic before performing subsequent operations; as a result, the return values of the functions may not meet the expectation or an error may be reported. After the GUC parameter **enable_convert_illegal_char** is set to **on**, the DBE_OUTPUT.PUT_LINE and DBE_OUTPUT.PUT functions process such codes in the same way as when the parameter is disabled. Special characters are not output as placeholders; therefore, you are advised not to use the DBE_OUTPUT.PUT_LINE and DBE_OUTPUT.PUT functions for data containing special characters.

2.12.2.13 DBE_RANDOM

APIs

Table 2-250 lists APIs supported by the DBE_RANDOM package.

Table 2-250 DBE_RANDOM

API	Description
DBE_RANDOM.SET_SEED	Sets a seed for a random number.
DBE_RANDOM.GET_VALUE	Generates a random number between a specified **low** and a specified **high**.

- DBE_RANDOM.SET_SEED

  Sets a seed for a random number.

  The prototype of DBE_RANDOM.SET_SEED is as follows:

  ```
  DBE_RANDOM.SET_SEED (seed  IN  INTEGER);
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 2-251 DBE_RANDOM.SET_SEED API parameter

Parameter	Description
seed	Generates a seed for a random number.

- DBE_RANDOM.GET_VALUE

  Generates a random number between a specified **low** and a specified **high**.

  The prototype of DBE_RANDOM.GET_VALUE is as follows:

```
DBE_RANDOM.GET_VALUE(
min  IN  NUMBER default 0,
max  IN  NUMBER default 1)
RETURN NUMBER;
```

Table 2-252 DBE_RANDOM.GET_VALUE API parameter

Parameter	Description
min	Sets the low bound for a random number. The generated random number is greater than or equal to **min**.
max	Sets the high bound for a random number. The generated random number is less than **max**.

NOTE

- DBE_RANDOM.GET_VALUE requires that the parameter type be NUMERIC. There is no requirement on the size of the left and right bound values.
- DBE_RANDOM implements pseudo-random numbers. Therefore, if the initial value (seed) remains unchanged, the sequence of the pseudo-random numbers also remains unchanged. You are advised not to use DBE_RANDOM in security scenarios.
- The generated random number contains 15 valid digits.

Example:

```
-- Generate a random number between 0 and 1.
SELECT DBE_RANDOM.GET_VALUE(0,1);
    get_value
------------------
 .917468812743886
(1 row)

-- For integers within a specified range, add the arguments min and max, and truncate the decimals from the result (the maximum value is not included as a possible value). Therefore, for integers from 0 to 99, you can use the following code:
SELECT TRUNC(DBE_RANDOM.GET_VALUE(0,100));
 trunc
-------
    26
(1 row)
```

2.12.2.14 DBE_RAW

The DBE_RAW package provides APIs for operating RAW types.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

RAW data is represented as hexadecimal characters externally, and stored as binary characters internally. For example, one byte of RAW data with bits **11001011** is displayed and entered as **'CB'**.

Permissions

The DBE_RAW schema is a system catalog. Only a system administrator has the permission to create the DBE_RAW schema during database initialization. All users have the permission to use the schema and APIs under the schema.

APIs

Table 2-253 lists APIs supported by the DBE_RAW package.

Table 2-253 DBE_RAW

API	Description
DBE_RAW.CAST_FROM_BINARY_INTEGER_TO_RAW	Converts a value of the INTEGER type to a binary representation (RAW type).
DBE_RAW.CAST_FROM_RAW_TO_BINARY_INTEGER	Converts a RAW value to an INTEGER value.
DBE_RAW.GET_LENGTH	Obtains the length of a RAW object.
DBE_RAW.CAST_FROM_VARCHAR2_TO_RAW	Converts a VARCHAR2 value to a RAW value.
DBE_RAW.CAST_TO_VARCHAR2	Converts a value of the RAW type to a value of the VARCHAR2 type.
DBE_RAW.BIT_OR	Returns a RAW value after bitwise OR calculation.
DBE_RAW.SUBSTR	Returns the substring of a RAW value.
DBE_RAW.BIT_AND	Returns a RAW value after bitwise AND calculation.
DBE_RAW.BIT_COMPLEMENT	Returns a RAW value after bitwise NOT calculation.
DBE_RAW.BIT_XOR	Returns a RAW value after bitwise XOR calculation.
DBE_RAW.CAST_FROM_BINARY_DOUBLE_TO_RAW	Converts a BINARY_DOUBLE value to a RAW value.
DBE_RAW.CAST_FROM_RAW_TO_BINARY_DOUBLE	Converts a RAW value to a BINARY_DOUBLE value.
DBE_RAW.CAST_FROM_RAW_TO_BINARY_FLOAT	Converts a RAW value to a FLOAT4 value.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

API	Description
DBE_RAW.CAST_FROM_BINARY_FLOAT_TO_RAW	Converts a FLOAT4 value to a RAW value.
DBE_RAW.CAST_FROM_RAW_TO_NUMBER	Converts a RAW value to a NUMERIC value.
DBE_RAW.CAST_FROM_NUMBER_TO_RAW	Converts a NUMERIC value to a RAW value.
DBE_RAW.CAST_FROM_RAW_TO_NVARCHAR2	Converts a RAW value to an NVARCHAR2 value.
DBE_RAW.COMPARE	Returns the first different position of two RAW values.
DBE_RAW.CONCAT	Concatenates a maximum of 12 RAW values into a new RAW value and returns the result.
DBE_RAW.CONVERT	Converts a RAW value from the source encoding mode **from_charset** to the target encoding mode **to_charset**.
DBE_RAW.COPIES	Copies a RAW value for *n* times, concatenates the values, and returns the concatenated result.
DBE_RAW.OVERLAY	Overlays one RAW data with another RAW data by specifying the start position and length to be overlaid.
DBE_RAW.REVERSE	Reverses RAW data by byte.
DBE_RAW.TRANSLATE	Converts or discards a specified byte of a RAW value.
DBE_RAW.TRANSLITERATE	Converts a specified byte of a RAW value.
DBE_RAW.XRANGE	Returns a value containing the succession of one-byte encodings beginning and ending with the specified byte-code.

- DBE_RAW.CAST_FROM_BINARY_INTEGER_TO_RAW

  Converts an INTEGER value to a RAW value.

  The prototype of DBE_RAW.CAST_FROM_BINARY_INTEGER_TO_RAW is as follows:

  ```
  DBE_RAW.CAST_FROM_BINARY_INTEGER_TO_RAW (
  value          IN  BIGINT,
  endianess      IN  INTEGER DEFAULT 1)
  RETURN RAW;
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 2-254 DBE_RAW.CAST_FROM_BINARY_INTEGER_TO_RAW API parameters

Parameter	Description
value	INTEGER value to be converted. **NOTE** DBE_RAW.CAST_FROM_BINARY_INTEGER_TO_RAW expects to process values of the INTEGER type. For compatibility purposes, this parameter is defined as the BIGINT type. The BIGINT type has a larger range than the INTEGER type, which does not affect the API use.
endianess	Specifies the endianness. ● **1**: BIG_ENDIAN. This is the default value. ● **2**: LITTLE-ENDIAN.

- DBE_RAW.CAST_FROM_RAW_TO_BINARY_INTEGER

  Converts a RAW value to an INTEGER value.

  The prototype of DBE_RAW.CAST_FROM_RAW_TO_BINARY_INTEGER is as follows:

```
DBE_RAW.CAST_FROM_RAW_TO_BINARY_INTEGER (
value          IN  RAW,
endianess      IN  INTEGER DEFAULT 1)
RETURN INTEGER;
```

Table 2-255 DBE_RAW.CAST_FROM_RAW_TO_BINARY_INTEGER API parameters

Parameter	Description
value	RAW value to be converted to the INTEGER type.
endianess	Endianness. The options are as follows: ● **1** (default value): BIG_ENDIAN. This is the default value. ● **2**: LITTLE_ENDIAN. ● **3**: MACHINE_ENDIAN. If BIG_ENDIAN is used on the host where the function is executed, the function execution result using MACHINE_ENDIAN is the same as that using BIG_ENDIAN. If LITTLE_ENDIAN is used on the host where the function is executed, the function execution result using MACHINE_ENDIAN is the same as that using LITTLE_ENDIAN.

- DBE_RAW.GET_LENGTH

  Returns the length of a RAW value.

  The prototype of DBE_RAW.GET_LENGTH is as follows:

```
DBE_RAW.GET_LENGTH(
value     IN    RAW)
RETURN INTEGER;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 2-256 DBE_RAW.GET_LENGTH API parameters

Parameter	Description
value	RAW object.

- DBE_RAW.CAST_FROM_VARCHAR2_TO_RAW

  Converts a VARCHAR2 value to a RAW value.

  The prototype of DBE_RAW.CAST_FROM_VARCHAR2_TO_RAW is as follows:

```
DBE_RAW.CAST_TO_RAW(
str     IN    VARCHAR2)
RETURN RAW;
```

Table 2-257 DBE_RAW.CAST_FROM_VARCHAR2_TO_RAW API parameters

Parameter	Description
str	VARCHAR2 value to be converted.

- DBE_RAW.CAST_TO_VARCHAR2

  Converts a RAW value to a VARCHAR2 value.

  The prototype of DBE_RAW.CAST_TO_VARCHAR2 is as follows:

```
DBE_RAW.CAST_TO_VARCHAR2(
str     IN    RAW)
RETURN VARCHAR2;
```

Table 2-258 DBE_RAW.CAST_TO_VARCHAR2 API parameters

Parameter	Description
str	VARCHAR2 value to be converted.

- DBE_RAW.BIT_OR

  Returns two RAW values after bitwise OR calculation.

  The prototype of DBE_RAW.BIT_OR is as follows:

```
DBE_RAW.BIT_OR(
   str1 IN TEXT,
   str2 IN TEXT)
RETURN TEXT;
```

Table 2-259 DBE_RAW.BIT_OR API parameters

Parameter	Description
str1	First character string of the bitwise OR calculation. **NOTE** Due to legacy reasons, this parameter is defined as the TEXT type. However, the DBE_RAW.BIT_OR API expects to process RAW values. Defining this parameter as the TEXT type does not affect the processing of RAW values.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Description
str2	Second character string of the bitwise OR calculation. **NOTE** Due to legacy reasons, this parameter is defined as the TEXT type. However, the DBE_RAW.BIT_OR API expects to process RAW values. Defining this parameter as the TEXT type does not affect the processing of RAW values.

- DBE_RAW.SUBSTR

  Truncates a RAW value based on the start position (*off_set*) and length (*amount*).

  The prototype of DBE_RAW.SUBSTR is as follows:

```
DBE_RAW.SUBSTR(
   IN lob_loc BLOB,
   IN off_set INTEGER DEFAULT 1,
   IN amount INTEGER DEFAULT 32767)
RETURN RAW;
```

  Table 2-260 DBE_RAW.SUBSTR API parameters

Parameter	Description
lob_loc	RAW value to be truncated. **NOTE** Due to legacy reasons, this parameter is defined as the BLOB type. However, the DBE_RAW.SUBSTR API expects to process RAW values. Defining this parameter as the BLOB type does not affect the processing of RAW values.
off_set	Start position of a substring. The default value is **1**.
amount	Length of a substring. The default value is **32767**.

- DBE_RAW.BIT_AND

  Obtains the bitwise AND result of two RAW values.

  The prototype of DBE_RAW.BIT_AND is as follows:

```
DBE_RAW.BIT_AND(
   r1 IN RAW,
   r2 IN RAW)
RETURN RAW;
```

  Table 2-261 DBE_RAW.BIT_AND API parameters

Parameter	Description
r1	The RAW value for the bitwise AND operation with r2. The maximum length is 32767.
r2	The RAW value for the bitwise AND operation with r1. The maximum length is 32767.

- DBE_RAW.BIT_COMPLEMENT

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Obtains the bitwise NOT result of a RAW value.

The prototype of DBE_RAW.BIT_COMPLEMENT is as follows:

```
DBE_RAW.BIT_COMPLEMENT(
   r IN RAW)
RETURN RAW;
```

Table 2-262 DBE_RAW.BIT_COMPLEMENT API parameters

Parameter	Description
r	RAW value for the bitwise NOT operation. The maximum length is 32767.

- DBE_RAW.BIT_XOR

  Obtains the bitwise XOR result of two RAW values.

  The prototype of DBE_RAW.BIT_XOR is as follows:

  ```
  DBE_RAW.BIT_XOR(
     r1 IN RAW,
     r2 IN RAW)
  RETURN RAW;
  ```

  Table 2-263 DBE_RAW.BIT_XOR API parameters

Parameter	Description
r1	RAW value for the bitwise XOR operation with r2. The maximum length is 32767.
r2	RAW value for the bitwise XOR operation with r1. The maximum length is 32767.

- DBE_RAW.CAST_FROM_BINARY_DOUBLE_TO_RAW

  Converts a BINARY_DOUBLE value to a RAW value.

  The prototype of DBE_RAW.CAST_FROM_BINARY_DOUBLE_TO_RAW is as follows:

  ```
  DBE_RAW.CAST_FROM_BINARY_DOUBLE_TO_RAW (
     n         IN BINARY_DOUBLE,
     endianess IN INTEGER DEFAULT 1)
  RETURN RAW;
  ```

  Table 2-264 DBE_RAW.CAST_FROM_BINARY_DOUBLE_TO_RAW API parameters

Parameter	Description
n	BINARY_DOUBLE value to be converted.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Description
endianess	Endianness. The options are as follows: ● **1** (default value): BIG_ENDIAN. This is the default value. ● **2**: LITTLE_ENDIAN. ● **3**: MACHINE_ENDIAN. If BIG_ENDIAN is used on the host where the function is executed, the function execution result using MACHINE_ENDIAN is the same as that using BIG_ENDIAN. If LITTLE_ENDIAN is used on the host where the function is executed, the function execution result using MACHINE_ENDIAN is the same as that using LITTLE_ENDIAN.

- DBE_RAW.CAST_FROM_RAW_TO_BINARY_DOUBLE

  Converts a RAW value to a BINARY_DOUBLE value.

  The prototype of DBE_RAW.CAST_FROM_RAW_TO_BINARY_DOUBLE is as follows:

```
DBE_RAW.CAST_FROM_RAW_TO_BINARY_DOUBLE(
   r         IN RAW,
   endianess IN INTEGER DEFAULT 1)
RETURN BINARY_DOUBLE;
```

  Table 2-265 DBE_RAW.CAST_FROM_RAW_TO_BINARY_DOUBLE API parameters

Parameter	Description
r	RAW value to be converted. The value contains 8 to 32767 characters.
endianess	Endianness. The options are as follows: ● **1** (default value): BIG_ENDIAN. This is the default value. ● **2**: LITTLE_ENDIAN. ● **3**: MACHINE_ENDIAN. If BIG_ENDIAN is used on the host where the function is executed, the function execution result using MACHINE_ENDIAN is the same as that using BIG_ENDIAN. If LITTLE_ENDIAN is used on the host where the function is executed, the function execution result using MACHINE_ENDIAN is the same as that using LITTLE_ENDIAN.

- DBE_RAW.CAST_FROM_RAW_TO_BINARY_FLOAT

  Converts a RAW value to a FLOAT4 value.

  The prototype of DBE_RAW.CAST_FROM_RAW_TO_BINARY_FLOAT is as follows:

```
DBE_RAW.CAST_FROM_RAW_TO_BINARY_FLOAT(
   r         IN RAW,
   endianess IN INTEGER DEFAULT 1)
RETURN FLOAT4;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 2-266 DBE_RAW.CAST_FROM_RAW_TO_BINARY_FLOAT API parameters

Parameter	Description
r	RAW value to be converted. The value contains 4 to 32767 characters.
endianess	Endianness. The options are as follows: ● **1** (default value): BIG_ENDIAN. This is the default value. ● **2**: LITTLE_ENDIAN. ● **3**: MACHINE_ENDIAN. If BIG_ENDIAN is used on the host where the function is executed, the function execution result using MACHINE_ENDIAN is the same as that using BIG_ENDIAN. If LITTLE_ENDIAN is used on the host where the function is executed, the function execution result using MACHINE_ENDIAN is the same as that using LITTLE_ENDIAN.

- DBE_RAW.CAST_FROM_BINARY_FLOAT_TO_RAW

  Converts a FLOAT4 value to a RAW value.

  NOTE

  Before converting a FLOAT4 value *n* to a RAW value, DBE_RAW.CAST_FROM_BINARY_FLOAT_TO_RAW truncates the input value based on its range and precision. The specific rules are as follows:

  - If *n* is greater than the maximum value 3.40282E+38 of FLOAT4, 3.40282E+38 is used.
  - If *n* is less than the minimum value –3.40282E+38 of FLOAT4, –3.40282E+38 is used.
  - If –1.4013E–45 < *n* < 1.4013E–45, **0** is used.

  The final conversion result is generated based on the truncated value.

  The prototype of DBE_RAW.CAST_FROM_BINARY_FLOAT_TO_RAW is as follows:

```
DBE_RAW.CAST_FROM_BINARY_FLOAT_TO_RAW(
   n         IN FLOAT4,
   endianess IN INTEGER DEFAULT 1)
RETURN RAW;
```

Table 2-267 DBE_RAW.CAST_FROM_BINARY_FLOAT_TO_RAW API parameters

Parameter	Description
n	FLOAT4 value to be converted.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Description
endianess	Endianness. The options are as follows: • **1** (default value): BIG_ENDIAN. This is the default value. • **2**: LITTLE_ENDIAN. • **3**: MACHINE_ENDIAN. If BIG_ENDIAN is used on the host where the function is executed, the function execution result using MACHINE_ENDIAN is the same as that using BIG_ENDIAN. If LITTLE_ENDIAN is used on the host where the function is executed, the function execution result using MACHINE_ENDIAN is the same as that using LITTLE_ENDIAN.

- DBE_RAW.CAST_FROM_RAW_TO_NUMBER

  Converts a RAW value to a NUMERIC value.

  NOTE

  The bottom-layer implementation of the number data type in database ORA is different from that in GaussDB, and the RAW data type is the hexadecimal representation of the binary stream implemented at the bottom layer. Therefore, the function in database ORA is different from that in GaussDB. You cannot obtain the same NUMBER-type data from GaussDB based on the RAW data corresponding to the NUMBER-type data in database ORA. For details about the NUMBER-type data in GaussDB, see **Examples**.

  The prototype of DBE_RAW.CAST_FROM_RAW_TO_NUMBER is as follows:

```
DBE_RAW.CAST_FROM_RAW_TO_NUMBER(
    r IN RAW)
RETURN NUMERIC;
```

Table 2-268 DBE_RAW.CAST_FROM_RAW_TO_NUMBER API parameters

Parameter	Description
r	RAW value to be converted. The value contains 4 to 32767 characters.

- DBE_RAW.CAST_FROM_NUMBER_TO_RAW

  Converts a NUMERIC value to a RAW value.

  NOTE

  The bottom-layer implementation of the number data type in database ORA is different from that in GaussDB, and the RAW data type is the hexadecimal representation of the binary stream implemented at the bottom layer. Therefore, the function in database ORA is different from that in GaussDB. You cannot restore the RAW data corresponding to the NUMBER-type data in database ORA in GaussDB. For details about the performance of this function in GaussDB, see **Examples**.

  The prototype of DBE_RAW.CAST_FROM_NUMBER_TO_RAW is as follows:

```
DBE_RAW.CAST_FROM_NUMBER_TO_RAW(
    value IN NUMERIC)
RETURN RAW;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 2-269 DBE_RAW.CAST_FROM_NUMBER_TO_RAW API parameters

Parameter	Description
value	NUMERIC value to be converted.

- DBE_RAW.CAST_FROM_RAW_TO_NVARCHAR2

  Converts a RAW value to an NVARCHAR2 value.

  The prototype of DBE_RAW.CAST_FROM_RAW_TO_NVARCHAR2 is as follows:

```
DBE_RAW.CAST_FROM_RAW_TO_NVARCHAR2(
   r IN RAW)
RETURN NVARCHAR2;
```

Table 2-270 DBE_RAW.CAST_FROM_RAW_TO_NVARCHAR2 API parameters

Parameter	Description
r	RAW value to be converted. The maximum length is 32767.

- DBE_RAW.COMPARE

  Returns the first different position of two RAW values.

  The prototype of DBE_RAW.COMPARE is as follows:

```
DBE_RAW.COMPARE(
   r1  IN RAW,
   r2  IN RAW,
   pad IN RAW DEFAULT NULL)
RETURN INTEGER;
```

Table 2-271 DBE_RAW.COMPARE API parameters

Parameter	Description
r1	First data to be compared. The value can be **NULL** or the length is 0. The maximum length is 32767.
r2	Second data to be compared. The value can be **NULL** or the length is 0. The maximum length is 32767.
pad	The first byte of **pad** is used to extend the shorter one of **r1** or **r2**. The maximum length is 32767. If this parameter is set to **NULL**, the length is 0, or the default value is used, the extended value is **0x00**.

- DBE_RAW.CONCAT

  Concatenates a maximum of 12 RAW values into a new RAW value and returns the value. If the length after concatenation exceeds 32767, an error is reported.

  The prototype of DBE_RAW.CONCAT is as follows:

```
DBE_RAW.CONCAT(
   r1  IN RAW DEFAULT NULL,
   r2  IN RAW DEFAULT NULL,
   r3  IN RAW DEFAULT NULL,
   r4  IN RAW DEFAULT NULL,
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
  r5  IN RAW DEFAULT NULL,
  r6  IN RAW DEFAULT NULL,
  r7  IN RAW DEFAULT NULL,
  r8  IN RAW DEFAULT NULL,
  r9  IN RAW DEFAULT NULL,
  r10 IN RAW DEFAULT NULL,
  r11 IN RAW DEFAULT NULL,
  r12 IN RAW DEFAULT NULL)
RETURN RAW;
```

Table 2-272 DBE_RAW.CONCAT API parameters

Parameter	Description
r1...r12	RAW values to be concatenated.

- DBE_RAW.CONVERT

  Converts a RAW value from the source encoding mode **from_charset** to the target encoding mode **to_charset**.

  If the rule for converting between source and target encoding (for example, GBK and LATIN1) does not exist, the parameter **r** is returned without conversion. See the **PG_CONVERSION** system catalog for details.

  The prototype of DBE_RAW.CONVERT is as follows:

```
DBE_RAW.CONVERT(
  r           IN RAW,
  to_charset   IN NAME,
  from_charset IN NAME)
RETURN RAW;
```

Table 2-273 DBE_RAW.CONVERT API parameters

Parameter	Description
r	RAW value to be converted. The maximum length is 32767.
to_charset	Name of the target character set.
from_charset	Name of the source character set. In this encoding, **r** must be valid.

- DBE_RAW.COPIES

  Copies a RAW value for *n* times, concatenates the values, and returns the concatenated result. If the length after copying exceeds 32767, an error is reported.

  The prototype of DBE_RAW.COPIES is as follows:

```
DBE_RAW.COPIES(
  r IN RAW,
  n IN NUMERIC)
RETURN RAW;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 2-274 DBE_RAW.COPIES API parameters

Parameter	Description
r	RAW values to be copied.
n	Number of replication times. The value must be a positive number. If the value is a decimal, the value is rounded off.

- DBE_RAW.OVERLAY

  Overlays one RAW value with another RAW value by specifying the start position and length to be overlaid.

  The prototype of DBE_RAW.OVERLAY is as follows:

```
DBE_RAW.OVERLAY(
   overlay_str IN RAW,
   target      IN RAW,
   pos         IN BINARY_INTEGER DEFAULT 1,
   len         IN BINARY_INTEGER DEFAULT NULL,
   pad         IN RAW            DEFAULT NULL)
RETURN RAW;
```

Table 2-275 DBE_RAW.OVERLAY API parameters

Parameter	Description
overlay_str	Byte used for overwriting. The value cannot be **NULL**.
target	Overwritten byte string, which is of the RAW type. The length can exceed 32767 bytes. However, due to the constraints of the **pos** and **len** parameters, the overwrite operation can be performed only in the first 32767 bytes and the value cannot be NULL.
pos	Byte from which the overlay starts. The position of the first byte is 1. The value of **pos** must be greater than or equal to 1 and the value of **len** + (**pos** – 1) must be less than or equal to 32767. The default value is **1**.
len	Length to be overlaid. The value of **len** must be greater than or equal to 0 and the value of **len** + (**pos** – 1) must be less than or equal to 32767. The default value is the length of **overlay_str**.
pad	Padding byte. Only the first byte is valid. The default value is **NULL**. If the value is **NULL**, it is regarded as **0x00** by default.

- DBE_RAW.REVERSE

  Reverses RAW values by byte.

  The prototype of DBE_RAW.REVERSE is as follows:

```
DBE_RAW.REVERSE(
   r IN RAW
)
RETURN RAW;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 2-276 DBE_RAW.REVERSE API parameters

Parameter	Description
r	RAW value to be reversed. The maximum length is 32767. If the value is **NULL**, **NULL** is returned.

- DBE_RAW.TRANSLATE

  Converts or discards a specified byte of a RAW value.

  The prototype of DBE_RAW.TRANSLATE is as follows:

```
DBE_RAW.TRANSLATE(
   r        IN RAW,
   from_set IN RAW,
   to_set   IN RAW)
RETURN RAW;
```

Table 2-277 DBE_RAW.TRANSLATE API parameters

Parameter	Description
r	Source byte string to be converted. The value is of the RAW type and contains a maximum of 32767 bytes. The value cannot be **NULL**.
from_set	Bytecode to be converted in the source byte string. The value is of the RAW type. The value cannot be **NULL**. The bytes in **from_set** in the source byte string are replaced with the bytes in the corresponding positions in **to_set**. If **from_set** contains multiple identical bytes, only the first byte corresponding to the byte is replaced. For example, if **r[x]=from_set[n]**, **r[x]** is replaced with **to_set[n]**. If **to_set[n]** corresponding to **from_set[n]** does not exist (that is, the number of bytes of **to_set** does not exceed **n**), **r[x]** will be discarded.
to_set	Byte code converted from the **from_set** byte. The value is of the RAW type. The value cannot be **NULL**.

- DBE_RAW.TRANSLITERATE

  Converts a RAW value to a NUMERIC value.

  The prototype of DBE_RAW.TRANSLITERATE is as follows:

```
DBE_RAW.TRANSLITERATE(
   r        IN RAW,
   to_set   IN RAW DEFAULT NULL,
   from_set IN RAW DEFAULT NULL,
   pad      IN RAW DEFAULT NULL)
RETURN NUMERIC;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 2-278 DBE_RAW.TRANSLITERATE API parameters

Parameter	Description
r	Byte string to be converted. The value is of the RAW type and contains a maximum of 32767 bytes. The value cannot be **NULL**.
to_set	Byte code converted from the **from_set** byte. The value is of the RAW type. The default value is **NULL**. If the value is **NULL**, all bytes in **r** that exist in **from_set** are converted to **pad**.
from_set	Bytecode to be converted in the byte string **r**. The value is of the RAW type. The default value is **NULL**. If **from_set** is **NULL**, all bytes in the byte string **r** are converted into equal-length data filled by **pad**. Otherwise, the bytes in **from_set** in the byte string **r** are replaced with the bytes in the corresponding position in **to_set**. For example, if **r[x]=from_set[n]**, **r[x]** is converted to **to_set[n]**. If **to_set[n]** does not exist, **r[x]** will be converted to **pad**.
pad	Padding byte. Only the first byte is valid. The default value is **NULL**. If the value is **NULL**, it is regarded as **0x00** by default.

- DBE_RAW.XRANGE

  Returns a RAW value containing the succession of one-byte encodings beginning and ending with the specified byte-code.

  The prototype of DBE_RAW.XRANGE is as follows:

```
DBE_RAW.XRANGE(
   start_byte IN RAW,
   end_byte   IN RAW)
RETURN RAW;
```

Table 2-279 DBE_RAW.XRANGE API parameters

Parameter	Description
start_byte	Start byte. Only the first byte is valid. If the value is **NULL**, it is regarded as **0x00** by default.
end_byte	End byte. Only the first byte is valid. If the value is **NULL**, it is regarded as **0xFF** by default. If the value of **end_byte** is less than that of **start_byte**, the function triggers the wraparound mechanism. Starting from the start byte, the value increases to the maximum hexadecimal value FF and then continues to increase from 00 until the end byte is reached.

Examples

```
-- Perform operations on RAW data in a stored procedure.
CREATE OR REPLACE PROCEDURE proc_raw
AS
str varchar2(100) := 'abcdef';
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
source raw(100);
amount integer;
BEGIN
source := dbe_raw.cast_from_varchar2_to_raw(str); -- Convert the type.
amount := dbe_raw.get_length(source); -- Obtain the length.
dbe_output.print_line(amount);
END;
/
CREATE PROCEDURE

-- Call the stored procedure.
CALL proc_raw();
6
 proc_raw
----------

(1 row)
-- Drop the stored procedure.
DROP PROCEDURE proc_raw;
DROP PROCEDURE

DECLARE

2.12.2.15 DBE_SCHEDULER

APIs

The DBE_SCHEDULER advanced package supports more flexible creation of scheduled jobs through scheduling and programing. For details about supported APIs, see **Table 2-280**.

NOTE

- DBE_SCHEDULER supports scheduled jobs for synchronizing data between CNs. Jobs with the same name cannot be created between different CNs.
- The synchronization function is not implemented in versions earlier than 505.0.0. Therefore, all synchronization APIs synchronize data only in 505.0.0 and later versions.
- Before the upgrade, the system checks whether jobs with the same name exist on CNs of the source version. If jobs with the same name exist on CNs of the source version and they are created on different nodes, an error message is displayed, prompting you to delete the jobs and perform the upgrade again.

Table 2-280 DBE_SCHEDULER

API	Description
DBE_SCHEDULER.CREATE_JOB	Creates a scheduled job.
DBE_SCHEDULER.DROP_JOB	Deletes scheduled jobs.
DBE_SCHEDULER.DROP_SINGLE_JOB	Deletes a single scheduled job.
DBE_SCHEDULER.SET_ATTRIBUTE	Sets object attributes.
DBE_SCHEDULER.RUN_JOB	Runs a scheduled job.
DBE_SCHEDULER.RUN_BACKEND_JOB	Runs a scheduled job in the background.
DBE_SCHEDULER.RUN_FOREGROUND_JOB	Runs a scheduled job in the foreground.
DBE_SCHEDULER.STOP_JOB	Stops scheduled jobs.
DBE_SCHEDULER.STOP_SINGLE_JOB	Stops a single scheduled job.
DBE_SCHEDULER.GENERATE_JOB_NAME	Generates a scheduled job name.
DBE_SCHEDULER.CREATE_PROGRAM	Creates a program.
DBE_SCHEDULER.DEFINE_PROGRAM_ARGUMENT	Defines program parameters.
DBE_SCHEDULER.DROP_PROGRAM	Deletes programs.
DBE_SCHEDULER.DROP_SINGLE_PROGRAM	Deletes a single program.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

API	Description
DBE_SCHEDULER.SET_JOB_ARGUMENT_VALUE	Sets scheduled job parameters.
DBE_SCHEDULER.CREATE_SCHEDULE	Creates a schedule.
DBE_SCHEDULER.DROP_SCHEDULE	Deletes schedules.
DBE_SCHEDULER.DROP_SINGLE_SCHEDULE	Deletes a single schedule.
DBE_SCHEDULER.CREATE_JOB_CLASS	Creates a scheduled job class.
DBE_SCHEDULER.DROP_JOB_CLASS	Deletes scheduled job classes.
DBE_SCHEDULER.DROP_SINGLE_JOB_CLASS	Deletes a single scheduled job class.
DBE_SCHEDULER.GRANT_USER_AUTHORIZATION	Grants special permissions to a user.
DBE_SCHEDULER.REVOKE_USER_AUTHORIZATION	Revokes special permissions from a user.
DBE_SCHEDULER.CREATE_CREDENTIAL	Creates a certificate.
DBE_SCHEDULER.DROP_CREDENTIAL	Destroys a certificate.
DBE_SCHEDULER.ENABLE	Enables objects.
DBE_SCHEDULER.ENABLE_SINGLE	Enables a single object.
DBE_SCHEDULER.DISABLE	Disables objects.
DBE_SCHEDULER.DISABLE_SINGLE	Disables a single object.
DBE_SCHEDULER.EVAL_CALENDAR_STRING	Analyzes the scheduled job period.
DBE_SCHEDULER.EVALUATE_CALENDAR_STRING	Analyzes the scheduled job period.

- DBE_SCHEDULER.CREATE_JOB

  Creates a scheduled job and synchronizes it to all CNs.

  The prototypes of DBE_SCHEDULER.CREATE_JOB are as follows:

```
-- Scheduled jobs of an inline schedule and a program.
DBE_SCHEDULER.CREATE_JOB(
job_name TEXT,
job_type TEXT,
job_action TEXT,
number_of_arguments INTEGER             DEFAULT 0,
start_date TIMESTAMP WITH TIME ZONE     DEFAULT NULL,
repeat_interval TEXT                    DEFAULT NULL,
end_date TIMESTAMP WITH TIME ZONE       DEFAULT NULL,
job_class TEXT          DEFAULT 'DEFAULT_JOB_CLASS',
enabled BOOLEAN                         DEFAULT FALSE,
auto_drop BOOLEAN                       DEFAULT TRUE,
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
comments TEXT                       DEFAULT NULL,
credential_name TEXT                DEFAULT NULL,
destination_name TEXT               DEFAULT NULL
)

-- Reference the created scheduled jobs of the schedule and the program.
DBE_SCHEDULER.CREATE_JOB(
job_name TEXT,
program_name TEXT,
schedule_name TEXT,
job_class TEXT          DEFAULT 'DEFAULT_JOB_CLASS',
enabled BOOLEAN                     DEFAULT FALSE,
auto_drop BOOLEAN                   DEFAULT TRUE,
comments TEXT                       DEFAULT NULL,
job_style TEXT                      DEFAULT 'REGULAR',
credential_name TEXT                DEFAULT NULL,
destination_name TEXT               DEFAULT NULL
)

-- Reference the created program and the scheduled job of the inline schedule.
DBE_SCHEDULER.CREATE_JOB(
job_name text,
program_name TEXT,
start_date TIMESTAMP WITH TIME ZONE     DEFAULT NULL,
repeat_interval TEXT                DEFAULT NULL,
end_date TIMESTAMP WITH TIME ZONE       DEFAULT NULL,
job_class TEXT          DEFAULT 'DEFAULT_JOB_CLASS',
enabled BOOLEAN                     DEFAULT FALSE,
auto_drop BOOLEAN                   DEFAULT TRUE,
comments TEXT                       DEFAULT NULL,
job_style TEXT                      DEFAULT 'REGULAR',
credential_name TEXT                DEFAULT NULL,
destination_name TEXT               DEFAULT NULL
)

-- Reference the created schedule and the scheduled job of the inline program.
DBE_SCHEDULER.CREATE_JOB(
job_name TEXT,
schedule_name TEXT,
job_type TEXT,
job_action TEXT,
number_of_arguments INTEGER         DEFAULT 0,
job_class TEXT          DEFAULT 'DEFAULT_JOB_CLASS',
enabled BOOLEAN                     DEFAULT FALSE,
auto_drop BOOLEAN                   DEFAULT TRUE,
comments TEXT                       DEFAULT NULL,
credential_name TEXT                DEFAULT NULL,
destination_name TEXT               DEFAULT NULL
)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- The scheduled job created by DBE_SCHEDULER does not conflict with the scheduled job in DBE_TASK.
- The scheduled job created by DBE_SCHEDULER generates the corresponding **job_id**. However, the **job_id** is meaningless.
- For the CREATE API, the input parameter types are not validated. Successful creation does not mean successful execution. You can query the execution status of the current job in the **PG_JOB** system catalog.
- Common users cannot execute scheduled jobs, unless they are granted the required permission using DBE_SCHEDULER.GRANT_USER_AUTHORIZATION.
- When **job_type** is set to **'PLSQL_BLOCK'**, program parameters are not accepted, and the value of **number_of_arguments** cannot be greater than 0. Otherwise, the scheduled job will fail to be created.
- If the value of **start_date** is greater than that of **end_date**, the job can be created successfully and no error is reported. However, the job cannot be triggered for scheduling.

Table 2-281 DBE_SCHEDULER.CREATE_JOB API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
job_name	TEXT	IN	No	Name of a scheduled job. In non-ILM scheduling scenarios, jobs prefixed with "ilmadowind$_" and "ilmjob$_" cannot be created.
job_type	TEXT	IN	No	Inline program type of a scheduled job. The options are as follows: • **'PLSQL_BLOCK'**: fast anonymous stored procedure. • **'STORED_PROCEDURE'**: stored procedure that is saved. • **'EXTERNAL_SCRIPT'**: external script.
job_action	TEXT	IN	No	Content executed by the inline program of a scheduled job.
number_of_arguments	INTEGER	IN	No	Number of inline program parameters of a scheduled job. The value ranges from 0 to 255.
program_name	TEXT	IN	No	Name of the program referenced by a scheduled job.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Type	Input/Output Parameter	Can Be Null	Description
start_date	TIMESTAMP WITH TIME ZONE	IN	Yes	Inline scheduling start time of a scheduled job.
repeat_interval	TEXT	IN	Yes	Inline scheduling period of a scheduled job.
end_date	TIMESTAMP WITH TIME ZONE	IN	Yes	Inline scheduling expiration time of a scheduled job.
schedule_name	TEXT	IN	No	Name of the schedule referenced by a scheduled job.
job_class	TEXT	IN	No	Class name of a scheduled job.
enabled	BOOLEAN	IN	No	Status of a scheduled job.
auto_drop	BOOLEAN	IN	No	Automatic deletion of a scheduled job.
comments	TEXT	IN	Yes	Comments.
job_style	TEXT	IN	No	Behavior pattern of a scheduled job. Only **'REGULAR'** is supported.
credential_name	TEXT	IN	Yes	Certificate name of a scheduled job.
destination_name	TEXT	IN	Yes	Target name of a scheduled job. Currently, only **'CCN'** (case-insensitive) is supported. Jobs whose **destination_name** is set to **CCN** can be executed only on the central coordinator. Otherwise, the original processing logic is used.

Example:

```
gaussdb=# CALL DBE_SCHEDULER.create_program('program1', 'STORED_PROCEDURE', 'select
pg_sleep(1);', 3, false, 'test');
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
 create_program
----------------

(1 row)

gaussdb=# CALL DBE_SCHEDULER.create_schedule('schedule1', NULL, 'sysdate', NULL, 'test');
 create_schedule
-----------------

(1 row)

gaussdb=# CALL DBE_SCHEDULER.create_job(job_name=>'job1', program_name=>'program1',
schedule_name=>'schedule1');
 create_job
------------

(1 row)

gaussdb=# CALL DBE_SCHEDULER.drop_job('job1', true, false, 'STOP_ON_FIRST_ERROR');
 drop_job
----------

(1 row)

gaussdb=# CALL DBE_SCHEDULER.drop_schedule('schedule1');
 drop_schedule
---------------

(1 row)

gaussdb=# CALL DBE_SCHEDULER.drop_program('program1', false);
 drop_program
--------------

(1 row)
```

NOTE

To create a scheduled job of the EXTERNAL_SCRIPT type, the administrator must grant related permissions and certificates and the user who starts the database must have the read permission on the external script.

- DBE_SCHEDULER.DROP_JOB

  Deletes scheduled jobs. The operation can be performed only when the job has been synchronized.

  The prototype of the DBE_SCHEDULER.DROP_JOB function is as follows:

```
DBE_SCHEDULER.drop_job(
job_name text,
force boolean                   default false,
defer boolean                   default false,
commit_semantics text      default 'STOP_ON_FIRST_ERROR'
)
```

NOTE

DBE_SCHEDULER.DROP_JOB can delete one or more scheduled jobs, or a scheduled job class.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 2-282 DBE_SCHEDULER.DROP_JOB API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
job_name	TEXT	IN	No	One or more scheduled job names or classes. If you specify multiple scheduled jobs, separate them with commas (,).
force	BOOLEAN	IN	No	Specifies how to delete a scheduled job. ● **true**: The current scheduled job is stopped and then deleted. ● **false**: The scheduled job fails to be deleted if it is running.
defer	BOOLEAN	IN	No	Specifies how to delete a scheduled job. ● **true**: A scheduled job can be deleted after it is complete. ● **false**: The scheduled job cannot be executed and is deleted.
commit_semantics	TEXT	IN	No	Commit rules: ● **'STOP_ON_FIRST_ERROR'**: The deletion operation performed before the first error is reported is committed. ● **'TRANSACTIONAL'**: Transaction-level commit. The deletion operation performed before an error is reported will be rolled back. ● **'ABSORB_ERRORS'**: The system attempts to bypass an error and commit the deletion operation that is performed successfully.

Example:

```
gaussdb=# CALL DBE_SCHEDULER.create_program('program1', 'STORED_PROCEDURE', 'SELECT
pg_sleep(1);', 3, false, 'test');
 create_program
----------------

(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gaussdb=# CALL DBE_SCHEDULER.create_schedule('schedule1', NULL, 'sysdate', NULL, 'test');
 create_schedule
-----------------

(1 row)

gaussdb=# CALL DBE_SCHEDULER.create_job(job_name=>'job1', program_name=>'program1',
schedule_name=>'schedule1');
 create_job
------------

(1 row)

gaussdb=# CALL DBE_SCHEDULER.drop_job('job1', true, false, 'STOP_ON_FIRST_ERROR');
 drop_job
----------

(1 row)

gaussdb=# CALL DBE_SCHEDULER.drop_schedule('schedule1');
 drop_schedule
---------------

(1 row)

gaussdb=# CALL DBE_SCHEDULER.drop_program('program1', false);
 drop_program
--------------

(1 row)
```

NOTE

The **TRANSACTIONAL** option in **commit_semantic** takes effect only when **force** is set to **false**.

- DBE_SCHEDULER.DROP_SINGLE_JOB

  Deletes a single scheduled job. The operation can be performed only when the job has been synchronized.

  The prototype of DBE_SCHEDULER.DROP_SINGLE_JOB is as follows:

```
DBE_SCHEDULER.drop_single_job(
job_name text,
force boolean                   default false,
defer boolean                   default false
)
```

Table 2-283 DBE_SCHEDULER.DROP_SINGLE_JOB API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
job_name	TEXT	IN	No	Specifies the name of a scheduled job or scheduled job class.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Type	Input/Output Parameter	Can Be Null	Description
force	BOOLEAN	IN	No	Specifies how to delete a scheduled job. • **true**: The current scheduled job is stopped and then deleted. • **false**: The scheduled job fails to be deleted if it is running.
defer	BOOLEAN	IN	No	Specifies how to delete a scheduled job. • **true**: A scheduled job can be deleted after it is complete. • **false**: The scheduled job cannot be executed and is deleted.

Example:

```
gaussdb=# CALL DBE_SCHEDULER.create_program('program1', 'STORED_PROCEDURE', 'SELECT
pg_sleep(1);', 0, false, 'test');
 create_program
----------------

(1 row)

gaussdb=# CALL DBE_SCHEDULER.create_job('job1', 'program1', '2021-07-20', 'interval ''3 minute''',
'2121-07-20', 'DEFAULT_JOB_CLASS', false, false,'test', 'style', NULL, NULL);
 create_job
------------

(1 row)

gaussdb=# CALL DBE_SCHEDULER.drop_single_job('job1', false, false);
 drop_single_job
-----------------

(1 row)

gaussdb=# CALL DBE_SCHEDULER.drop_program('program1', false);
 drop_program
--------------

(1 row)
```

- DBE_SCHEDULER.SET_ATTRIBUTE

  Modifies the attributes of a scheduled job. The operation can be performed only when the job has been synchronized.

  The prototypes of DBE_SCHEDULER.SET_ATTRIBUTE are as follows:

```
DBE_SCHEDULER.set_attribute(
name                 text,
attribute            text,
value               boolean
)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
DBE_SCHEDULER.set_attribute(
name                 text,
attribute            text,
value                datea
)

DBE_SCHEDULER.set_attribute(
name                 text,
attribute            text,
value                timestamp
)

DBE_SCHEDULER.set_attribute(
name                 text,
attribute            text,
value                timestamp with time zone
)

DBE_SCHEDULER.set_attribute(
name text,
attribute text,
value text,
value2 text                      default NULL
)
```

NOTE

- **name** specifies any object in DBE_SCHEDULER.
- The DBE_SCHEDULER.set_attribute function with **datea** as the input parameter can be used only when **mapping_date_to_datea** is set to **on**.

Table 2-284 DBE_SCHEDULER.SET_ATTRIBUTE API parameters

Parameter	Type	Input / Output Parameter	Can Be Null	Description
name	TEXT	IN	No	Object name.
attribute	TEXT	IN	No	Attribute name.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Type	Input / Output Parameter	Can Be Null	Description
value	BOOLEAN/DATE/TIMESTAMP/TIMESTAMP WITH TIME ZONE/TEXT	IN	No	Attribute value. The options are as follows: ● Scheduled-job-related: **job_type**, **job_action**, **number_of_arguments**, **start_date**, **repeat_interval**, **end_date**, **job_class**, **enabled**, **auto_drop**, **comments**, **credential_name**, **destination_name**, **program_name**, **schedule_name**, and **job_style**. ● Program-related: **program_action**, **program_type**, **number_of_arguments**, and **comments**. ● Scheduling-related: **start_date**, **repeat_interval**, **end_date**, and **comments**.
value2	TEXT	IN	Yes	Additional attribute value. This is a reserved parameter bit. Currently, target attributes with extra attribute values are not supported.

Example:

```
gaussdb=# CALL DBE_SCHEDULER.create_program('program1', 'STORED_PROCEDURE', 'SELECT
pg_sleep(1);', 3, false, 'test');
 create_program
----------------

(1 row)

gaussdb=# CALL DBE_SCHEDULER.set_attribute('program1', 'number_of_arguments', 0);
 set_attribute
---------------

(1 row)

gaussdb=# CALL DBE_SCHEDULER.set_attribute('program1', 'program_type', 'STORED_PROCEDURE');
 set_attribute
---------------

(1 row)

gaussdb=# CALL DBE_SCHEDULER.drop_program('program1', false);
 drop_program
--------------

(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- You are advised not to use DBE_SCHEDULER.SET_ATTRIBUTE to leave the parameters empty.
- The object name cannot be changed using DBE_SCHEDULER.SET_ATTRIBUTE.
- Inline objects cannot be changed by DBE_SCHEDULER.SET_ATTRIBUTE.

- DBE_SCHEDULER.RUN_JOB

  Runs a scheduled job.

  The prototype of DBE_SCHEDULER.RUN_JOB is as follows:

```
DBE_SCHEDULER.run_job(
job_name text,
use_current_session boolean          default true
)
```

NOTE

DBE_SCHEDULER.RUN_JOB is used to run scheduled jobs immediately. It is independent of the scheduling of scheduled jobs and can even run at the same time.

Table 2-285 DBE_SCHEDULER.RUN_JOB API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
job_name	TEXT	IN	No	One or more scheduled job names. If you specify multiple scheduled jobs, separate them with commas (,).
use_current_session	BOOLEAN	IN	No	Specifies whether to run a scheduled job. ● **true**: The current session is used to check whether the scheduled job can run properly. ● **false**: The scheduled job is started in the background. The execution result is recorded in logs.

Example:

```
gaussdb=# SELECT DBE_SCHEDULER.create_job('job1','PLSQL_BLOCK','BEGIN INSERT INTO test1
VALUES(12); end;',0,null,null,null,'DEFAULT_JOB_CLASS',false,false,null,null,null);
 create_job
------------

(1 row)

gaussdb=# CALL DBE_SCHEDULER.run_job('job1', false);
 run_job
```

```
---------

(1 row)

gaussdb=# CALL DBE_SCHEDULER.drop_job('job1', true, false, 'STOP_ON_FIRST_ERROR');
 drop_job
----------

(1 row)
```

NOTE

Currently, **use_current_session** applies only to scheduled jobs whose **job_type** is set to **EXTERNAL_SCRIPT**.

- DBE_SCHEDULER.RUN_BACKEND_JOB

  Runs a scheduled job in the background.

  The prototype of DBE_SCHEDULER.RUN_BACKEND_JOB is as follows:

```
DBE_SCHEDULER.run_backend_job(
job_name text
)
```

Table 2-286 DBE_SCHEDULER.RUN_BACKEND_JOB API parameters

Parameter	Type	Input/ Output Parameter	Can Be Null	Description
job_name	text	IN	No	Name of a scheduled job.

  Example:

```
gaussdb=# SELECT DBE_SCHEDULER.create_job('job1','PLSQL_BLOCK','BEGIN INSERT INTO test1
VALUES(12); end;',0,null,null,null,'DEFAULT_JOB_CLASS',false,false,null,null,null);
 create_job
------------

(1 row)

gaussdb=# CALL DBE_SCHEDULER.run_backend_job('job1');
 run_backend_job
-----------------

(1 row)

gaussdb=# CALL DBE_SCHEDULER.drop_job('job1', true, false, 'STOP_ON_FIRST_ERROR');
 drop_job
----------

(1 row)
```

- DBE_SCHEDULER.RUN_FOREGROUND_JOB

  Runs a scheduled job in the current session. Only external jobs can be executed.

  Return value: text

  The prototype of DBE_SCHEDULER.RUN_FOREGROUND_JOB is as follows:

```
DBE_SCHEDULER.run_foreground_job(
job_name text
)return text
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 2-287 DBE_SCHEDULER.RUN_FOREGROUND_JOB API parameters

Parameter	Type	Input/ Output Parameter	Can Be Null	Description
job_name	TEXT	IN	No	Name of a scheduled job.

Example:

```
gaussdb=# CREATE USER test1 IDENTIFIED BY '*********';
NOTICE:  The encrypted password contains MD5 ciphertext, which is not secure.
CREATE ROLE
gaussdb=# SELECT DBE_SCHEDULER.create_credential('cre_1', 'test1', '*********');
 create_credential
-------------------

(1 row)

gaussdb=# SELECT DBE_SCHEDULER.create_job(job_name=>'job1', job_type=>'EXTERNAL_SCRIPT',
job_action=>'/usr/bin/pwd', enabled=>true, auto_drop=>false, credential_name => 'cre_1');
 create_job
------------

(1 row)

gaussdb=# CALL DBE_SCHEDULER.run_foreground_job('job1');
  run_foreground_job
---------------------------------
 Host key verification failed.\r+

(1 row)

gaussdb=# CALL DBE_SCHEDULER.drop_job('job1', true, false, 'STOP_ON_FIRST_ERROR');
 drop_job
----------

(1 row)

gaussdb=# CALL DBE_SCHEDULER.drop_credential('cre_1', false);
 drop_credential
-----------------

(1 row)

gaussdb=# DROP USER test1;
DROP ROLE
```

- DBE_SCHEDULER.STOP_JOB

  Stops scheduled jobs.

  The prototype of DBE_SCHEDULER.STOP_JOB is as follows:

  ```
  DBE_SCHEDULER.stop_job(
  job_name text,
  force boolean                    default false,
  commit_semantics text                default 'STOP_ON_FIRST_ERROR'
  )
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 2-288 DBE_SCHEDULER.STOP_JOB API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
job_name	TEXT	IN	No	One or more scheduled job names or classes. If you specify multiple scheduled jobs, separate them with commas (,).
force	BOOLEAN	IN	No	Specifies how to delete a scheduled job. • **true**: The scheduler sends a termination signal to end the job thread immediately. • **false**: The scheduler attempts to use the interrupt signal to terminate the scheduled job thread.
commit_semantics	TEXT	IN	No	Commit rules: • **'STOP_ON_FIRST_ERROR'**: The interrupt operation performed before the first error is reported is committed. • **'ABSORB_ERRORS'**: The system attempts to bypass an error and commit the interrupt operation that is performed successfully.

Example:

```
gaussdb=# SELECT dbe_scheduler.create_job('job1','PLSQL_BLOCK','BEGIN INSERT INTO test1
VALUES(12); end;',0,null,null,null,'DEFAULT_JOB_CLASS',false,false,null,null,null);
 create_job
------------

(1 row)

gaussdb=# CALL DBE_SCHEDULER.stop_job('job1', true, 'STOP_ON_FIRST_ERROR');
 stop_job
----------

(1 row)

gaussdb=# CALL DBE_SCHEDULER.drop_job('job1', true, false, 'STOP_ON_FIRST_ERROR');
 drop_job
----------

(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- DBE_SCHEDULER.STOP_SINGLE_JOB

  Stops a single scheduled job.

  The prototype of DBE_SCHEDULER.STOP_SINGLE_JOB is as follows:

```
DBE_SCHEDULER.stop_single_job(
job_name text,
force boolean                    default false
)
```

Table 2-289 DBE_SCHEDULER.STOP_SINGLE_JOB API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
job_name	TEXT	IN	No	Name of a scheduled job or scheduled job class.
force	BOOLEAN	IN	No	Specifies how to delete a scheduled job. ● **true**: The scheduler sends a termination signal to end the job thread immediately. ● **false**: The scheduler attempts to use the interrupt signal to terminate the scheduled job thread.

Example:

```
gaussdb=# SELECT dbe_scheduler.create_job('job1','PLSQL_BLOCK','BEGIN INSERT INTO test1
VALUES(12); end;',0,null,null,null,'DEFAULT_JOB_CLASS',false,false,null,null,null);
 create_job
------------

(1 row)

gaussdb=# CALL DBE_SCHEDULER.stop_single_job('job1', true);
 stop_single_job
-----------------

(1 row)

gaussdb=# CALL DBE_SCHEDULER.drop_job('job1', true, false, 'STOP_ON_FIRST_ERROR');
 drop_job
----------

(1 row)
```

- DBE_SCHEDULER.GENERATE_JOB_NAME

  Generates a scheduled job name.

  The prototype of DBE_SCHEDULER.GENERATE_JOB_NAME is as follows:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
DBE_SCHEDULER.generate_job_name(
prefix text                    default 'JOB$_'
)return text
```

Table 2-290 DBE_SCHEDULER.GENERATE_JOB_NAME API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
prefix	TEXT	IN	No	Prefix of the generated name. The default value is **'JOB$_'**. Scheduled jobs that are repeatedly executed are named as follows: job$_1, job$_2, job$_3 ...

Example:

```
gaussdb=# CALL DBE_SCHEDULER.generate_job_name();
 generate_job_name
-------------------
 JOB$_1
(1 row)

gaussdb=# CALL DBE_SCHEDULER.generate_job_name();
 generate_job_name
-------------------
 JOB$_2
(1 row)

gaussdb=# CALL DBE_SCHEDULER.generate_job_name('job');
 generate_job_name
-------------------
 job3
(1 row)

gaussdb=# CALL DBE_SCHEDULER.generate_job_name('job');
 generate_job_name
-------------------
 job4
(1 row)
```

NOTE

When DBE_SCHEDULER.GENERATE_JOB_NAME is executed for the first time, a temporary sequence is created in **public** to store the sequence number of the current name. Common users do not have the CREATE permission on **public**. Therefore, if a common user calls the function for the first time in the current database, the function fails to be called. In this case, you need to grant the CREATE permission on **public** to the common user or call the API as a user with the CREATE permission to create a temporary sequence.

- DBE_SCHEDULER.CREATE_PROGRAM

  Creates a program and synchronizes it to all CNs.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

The prototype of DBE_SCHEDULER.CREATE_PROGRAM is as follows:

```
DBE_SCHEDULER.create_program(
program_name text,
program_type text,
program_action text,
number_of_arguments integer          default 0,
enabled boolean                    default false,
comments text                      default NULL
)
```

Table 2-291 DBE_SCHEDULER.CREATE_PROGRAM API parameters

Parameter	Type	Input / Output Parameter	Can Be Null	Description
program_name	TEXT	IN	No	Program name.
program_type	TEXT	IN	No	Program type. The options are as follows: • **'PLSQL_BLOCK'**: fast anonymous stored procedure. • **'STORED_PROCEDURE'**: stored procedure that is saved. • **'EXTERNAL_SCRIPT'**: external script.
program_action	TEXT	IN	No	Program operation.
number_of_arguments	INTEGER	IN	No	Number of program parameters. The value ranges from 0 to 255.
enabled	BOOLEAN	IN	No	Specifies whether the program is enabled.
comments	TEXT	IN	Yes	Comments.

Example:

```
gaussdb=# CALL DBE_SCHEDULER.create_program('program1', 'STORED_PROCEDURE', 'SELECT
pg_sleep(1);', 3, false, 'test');
 create_program
----------------

(1 row)

gaussdb=# CALL DBE_SCHEDULER.drop_program('program1', false);
 drop_program
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
--------------

(1 row)
```

- DBE_SCHEDULER.DEFINE_PROGRAM_ARGUMENT

  Defines program parameters. The operation can be performed only when the program has been synchronized. An API with the default value **default_value** will not convert characters to lowercase letters by default. In this version, characters are case-sensitive.

  The prototype of DBE_SCHEDULER.DEFINE_PROGRAM_ARGUMENT is as follows:

```
DBE_SCHEDULER.define_program_argument(
program_name text,
argument_position integer,
argument_name text                  default NULL,
argument_type text,
out_argument boolean                 default false
)

-- With a default value --
DBE_SCHEDULER.define_program_argument(
program_name text,
argument_position integer,
argument_name text                  default NULL,
argument_type text,
default_value text,
out_argument boolean                 default false
)
```

Table 2-292 DBE_SCHEDULER.DEFINE_PROGRAM_ARGUMENT API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
program_name	TEXT	IN	No	Program name.
argument_position	INTEGER	IN	No	Parameter position. The value ranges from 1 to *number_of_arguments*. If the value of **number_of_arguments** of a program is **0**, an error is reported when this API is called.
argument_name	TEXT	IN	No	Parameter name.
argument_type	TEXT	IN	No	Parameter type.
default_value	TEXT	IN	No	Default value.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Type	Input/Output Parameter	Can Be Null	Description
out_argument	BOOLEAN	IN	No	Reserved parameter.

Example:

```
gaussdb=# CALL DBE_SCHEDULER.create_program('program1', 'STORED_PROCEDURE', 'SELECT
pg_sleep(1);', 2, false, 'test');
create_program
----------------

(1 row)

gaussdb=# CALL DBE_SCHEDULER.define_program_argument('program1', 1, 'pa1', 'type1', false);
 define_program_argument
-------------------------

(1 row)

gaussdb=# CALL DBE_SCHEDULER.define_program_argument('program1', 1, 'pa1', 'type1', 'value1',
false);
 define_program_argument
-------------------------

(1 row)

gaussdb=# CALL DBE_SCHEDULER.drop_program('program1', false);
 drop_program
--------------

(1 row)
```

- DBE_SCHEDULER.DROP_PROGRAM

  Deletes a program. The operation can be performed only when the program has been synchronized.

  The prototype of DBE_SCHEDULER.DROP_PROGRAM is as follows:

  ```
  DBE_SCHEDULER.drop_program(
  program_name text,
  force boolean                    default false
  )
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 2-293 DBE_SCHEDULER.DROP_PROGRAM API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
program_name	TEXT	IN	No	Program name.
force	BOOLEAN	IN	No	Specifies how to delete a program. • **true**: Before a program is deleted, all jobs that use the program are disabled. • **false**: The program cannot be referenced by any job. Otherwise, an error is sent.

Example:

```
gaussdb=# CALL DBE_SCHEDULER.create_program('program1', 'STORED_PROCEDURE', 'SELECT
pg_sleep(1);', 2, false, 'test');
create_program
----------------

(1 row)

gaussdb=# CALL DBE_SCHEDULER.drop_program('program1', false);
 drop_program
--------------

(1 row)
```

- DBE_SCHEDULER.DROP_SINGLE_PROGRAM

  Deletes a single program. The operation can be performed only when the program has been synchronized.

  The prototype of DBE_SCHEDULER.DROP_SINGLE_PROGRAM is as follows:

  ```
  DBE_SCHEDULER.drop_single_program(
  program_name text,
  force boolean                    default false
  )
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 2-294 DBE_SCHEDULER.DROP_SINGLE_PROGRAM API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
program_name	TEXT	IN	No	Program name.
force	BOOLEAN	IN	No	Specifies how to delete a program. • **true**: Before a program is deleted, all jobs that use the program are disabled. • **false**: The program cannot be referenced by any job. Otherwise, an error is sent.

Example:

```
gaussdb=# CALL DBE_SCHEDULER.create_program('program1', 'STORED_PROCEDURE', 'SELECT
pg_sleep(1);', 2, false, 'test');
create_program
----------------

(1 row)

gaussdb=# CALL DBE_SCHEDULER.drop_single_program('program1', false);
 drop_single_program
---------------------

(1 row)
```

- DBE_SCHEDULER.SET_JOB_ARGUMENT_VALUE

  Sets scheduled job parameters. The **argument_value** parameter can be left empty. The operation can be performed only when the job has been synchronized.

  The prototype of DBE_SCHEDULER.SET_JOB_ARGUMENT_VALUE is as follows:

```
DBE_SCHEDULER.set_job_argument_value(
job_name text,
argument_position integer,
argument_value text
)

DBE_SCHEDULER.set_job_argument_value(
job_name text,
argument_name text,
argument_value text
)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 2-295 DBE_SCHEDULER.SET_JOB_ARGUMENT_VALUE API parameters

Parameter	Type	Input/ Output Parameter	Can Be Null	Description
job_name	TEXT	IN	No	Name of a scheduled job.
argument_position	INTEGER	IN	No	Parameter position. The value ranges from 1 to *number_of_arguments*. If the value of **number_of_arguments** of an associated program is **0**, an error is reported when this API is called.
argument_name	TEXT	IN	Yes	Parameter name.
argument_value	TEXT	IN	Yes	Parameter value.

Example:

```
gaussdb=# CALL dbe_scheduler.create_job('job1','EXTERNAL_SCRIPT','BEGIN INSERT INTO test1
VALUES(12); end;',2,null,null,null,'DEFAULT_JOB_CLASS',false,false,null,null,null);
 create_job
------------

(1 row)

gaussdb=# CALL DBE_SCHEDULER.set_job_argument_value('job1', 1, 'value1');
 set_job_argument_value
------------------------

(1 row)

gaussdb=# CALL DBE_SCHEDULER.drop_job('job1', true, false, 'STOP_ON_FIRST_ERROR');
 drop_job
----------

(1 row)
```

- DBE_SCHEDULER.CREATE_SCHEDULE

  Creates a schedule. Then, it is synchronized to all CNs.

  The prototype of DBE_SCHEDULER.CREATE_SCHEDULE is as follows:

```
DBE_SCHEDULER.create_schedule(
schedule_name text,
start_date timestamp with time zone     default NULL,
repeat_interval text,
end_date timestamp with time zone       default NULL,
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
comments text                   default NULL
)
```

Table 2-296 DBE_SCHEDULER.CREATE_SCHEDULE API parameters

Parameter	Type	Input/ Output Parameter	Can Be Null	Description
schedule_name	TEXT	IN	No	Schedule name.
start_date	TIMESTAMP WITH TIME ZONE	IN	Yes	Start time of a schedule.
repeat_interval	TEXT	IN	No	Repetition frequency of a schedule.
end_date	TIMESTAMP WITH TIME ZONE	IN	Yes	End time of a schedule.
comments	TEXT	IN	Yes	Comments.

Example:

```
gaussdb=# CALL DBE_SCHEDULER.create_schedule('schedule1', sysdate, 'sysdate + 3 / (24 * 60 * 60)',
null, 'test1');
 create_schedule
-----------------

(1 row)

gaussdb=# CALL DBE_SCHEDULER.create_schedule('schedule2', sysdate, 'FREQ=DAILY; BYHOUR=6;',
null, 'test1');
 create_schedule
-----------------

(1 row)

gaussdb=# CALL DBE_SCHEDULER.create_schedule('schedule3', sysdate, 'FREQ=DAILY; BYHOUR=6;');
 create_schedule
-----------------

(1 row)

gaussdb=# CALL DBE_SCHEDULER.drop_schedule('schedule1');
 drop_single_schedule
----------------------

(1 row)

gaussdb=# CALL DBE_SCHEDULER.drop_schedule('schedule2', false);
 drop_single_schedule
----------------------

(1 row)

gaussdb=# CALL DBE_SCHEDULER.drop_schedule('schedule3', true);
 drop_single_schedule
----------------------
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
(1 row)
```

- DBE_SCHEDULER.DROP_SCHEDULE

  Deletes a schedule. The operation can be performed only when the schedule has been synchronized.

  The prototype of DBE_SCHEDULER.DROP_SCHEDULE is as follows:

```
DBE_SCHEDULER.drop_schedule(
schedule_name text,
force boolean                    default false
)
```

Table 2-297 DBE_SCHEDULER.DROP_SCHEDULE API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
schedule_name	TEXT	IN	No	Schedule name.
force	BOOLEAN	IN	No	Specifies how to delete a schedule. • **true**: Any jobs or windows that use this schedule are disabled before the schedule is deleted. • **false**: The schedule cannot be referenced by any job or window. Otherwise, an error occurs.

Example:

```
gaussdb=# CALL DBE_SCHEDULER.create_schedule('schedule1', sysdate, 'sysdate + 3 / (24 * 60 * 60)',
null, 'test1');
 create_schedule
-----------------

(1 row)

gaussdb=# CALL DBE_SCHEDULER.create_schedule('schedule2', sysdate, 'FREQ=DAILY; BYHOUR=6;',
null, 'test1');
 create_schedule
-----------------

(1 row)

gaussdb=# CALL DBE_SCHEDULER.create_schedule('schedule3', sysdate, 'FREQ=DAILY; BYHOUR=6;');
 create_schedule
-----------------

(1 row)

gaussdb=# CALL DBE_SCHEDULER.drop_schedule('schedule1');
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
 drop_single_schedule
----------------------

(1 row)

gaussdb=# CALL DBE_SCHEDULER.drop_schedule('schedule2', false);
 drop_single_schedule
----------------------

(1 row)

gaussdb=# CALL DBE_SCHEDULER.drop_schedule('schedule3', true);
 drop_single_schedule
----------------------

(1 row)
```

- DBE_SCHEDULER.DROP_SINGLE_SCHEDULE

  Deletes a single schedule. The operation can be performed only when the schedule has been synchronized.

  The prototype of DBE_SCHEDULER.DROP_SINGLE_SCHEDULE is as follows:

```
DBE_SCHEDULER.drop_single_schedule(
schedule_name text,
force boolean                   default false
)
```

Table 2-298 DBE_SCHEDULER.DROP_SINGLE_SCHEDULE API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
schedule_name	TEXT	IN	No	Schedule name.
force	BOOLEAN	IN	No	Specifies how to delete a schedule. • **true**: Any jobs or windows that use this schedule are disabled before the schedule is deleted. • **false**: The schedule cannot be referenced by any job or window. Otherwise, an error occurs.

Example:

```
gaussdb=# CALL DBE_SCHEDULER.create_schedule('schedule1', sysdate, 'sysdate + 3 / (24 * 60 * 60)',
null, 'test1');
 create_schedule
-----------------

(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gaussdb=# CALL DBE_SCHEDULER.create_schedule('schedule2', sysdate, 'FREQ=DAILY; BYHOUR=6;',
null, 'test1');
 create_schedule
-----------------

(1 row)

gaussdb=# CALL DBE_SCHEDULER.create_schedule('schedule3', sysdate, 'FREQ=DAILY; BYHOUR=6;');
 create_schedule
-----------------

(1 row)

gaussdb=# CALL DBE_SCHEDULER.drop_single_schedule('schedule1');
 drop_single_schedule
----------------------

(1 row)

gaussdb=# CALL DBE_SCHEDULER.drop_single_schedule('schedule2', false);
 drop_single_schedule
----------------------

(1 row)

gaussdb=# CALL DBE_SCHEDULER.drop_single_schedule('schedule3', true);
 drop_single_schedule
----------------------

(1 row)
```

- DBE_SCHEDULER.CREATE_JOB_CLASS

  Creates a scheduled job class. Then, it is synchronized to all CNs.

  The prototype of DBE_SCHEDULER.CREATE_JOB_CLASS is as follows:

```
DBE_SCHEDULER.create_job_class(
job_class_name text,
resource_consumer_group text           default NULL,
service text                        default NULL,
logging_level integer                  default 0,
log_history integer                   default NULL,
comments text                          default NULL
)
```

Table 2-299 DBE_SCHEDULER.CREATE_JOB_CLASS API parameters

Parameter	Type	Input/ Output Parameter	Can Be Null	Description
job_class_name	TEXT	IN	No	Name of a scheduled job class.
resource_consumer_group	TEXT	IN	Yes	Inline resource consumer group of a scheduled job class.
service	TEXT	IN	Yes	Inline database service of a scheduled job class.
logging_level	INTEGER	IN	No	Number of scheduled job records.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Type	Input/ Output Parameter	Can Be Null	Description
log_history	INTEGER	IN	Yes	Number of days for storing scheduled job records.
comments	TEXT	IN	Yes	Comments.

Example:

```
gaussdb=# CALL DBE_SCHEDULER.create_job_class(job_class_name => 'jc1', resource_consumer_group
=> '123');
 create_job_class
------------------

(1 row)

gaussdb=# CALL DBE_SCHEDULER.drop_job_class('jc1', false);
 drop_job_class
----------------

(1 row)
```

- DBE_SCHEDULER.DROP_JOB_CLASS

  Deletes scheduled job classes. The operation can be performed only when the scheduled job class has been synchronized.

  The prototype of DBE_SCHEDULER.DROP_JOB_CLASS is as follows:

  ```
  DBE_SCHEDULER.drop_job_class(
  job_class_name text,
  force boolean                    default false
  )
  ```

  Table 2-300 DBE_SCHEDULER.DROP_JOB_CLASS API parameters

Parameter	Type	Input/ Output Parameter	Can Be Null	Description
job_class_name	TEXT	IN	No	Name of a scheduled job class.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Type	Input/Output Parameter	Can Be Null	Description
force	BOOLEAN	IN	No	Specifies how to delete a scheduled job class. ● **true**: Jobs of this class will be disabled, and another class will be set as the default class. Only when such setting is successful, this class can be deleted. ● **false**: The class to be deleted cannot be referenced by any job. Otherwise, an error occurs.

Example:

```
gaussdb=# CALL DBE_SCHEDULER.create_job_class(job_class_name => 'jc1', resource_consumer_group
=> '123');
 create_job_class
------------------

(1 row)

gaussdb=# CALL DBE_SCHEDULER.drop_job_class('jc1', false);
 drop_job_class
----------------

(1 row)
```

- DBE_SCHEDULER.DROP_SINGLE_JOB_CLASS

  Deletes a single scheduled job class. The operation can be performed only when the scheduled job class has been synchronized.

  The prototype of DBE_SCHEDULER.DROP_SINGLE_JOB_CLASS is as follows:

```
DBE_SCHEDULER.drop_single_job_class(
job_class_name text,
force boolean                   default false
)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 2-301 DBE_SCHEDULER.DROP_SINGLE_JOB_CLASS API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
job_class_name	TEXT	IN	No	Name of a scheduled job class.
force	BOOLEAN	IN	No	Specifies how to delete a scheduled job class. • **true**: Jobs of this class will be disabled, and another class will be set as the default class. Only when such setting is successful, this class can be deleted. • **false**: The class to be deleted cannot be referenced by any job. Otherwise, an error occurs.

Example:

```
gaussdb=# CALL DBE_SCHEDULER.create_job_class(job_class_name => 'jc1', resource_consumer_group
=> '123');
 create_job_class
------------------

(1 row)

gaussdb=# CALL DBE_SCHEDULER.drop_single_job_class('jc1', false);
 drop_single_job_class
-----------------------

(1 row)
```

- DBE_SCHEDULER.GRANT_USER_AUTHORIZATION

  Grants the scheduled job permissions to a database user. The user who calls this function must have the SYSADMIN permission. Then, it is synchronized to all CNs.

  The prototype of DBE_SCHEDULER.GRANT_USER_AUTHORIZATION is as follows:

  ```
  DBE_SCHEDULER.grant_user_authorization(
  username              text,
  privilege             text
  )
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 2-302 DBE_SCHEDULER.GRANT_USER_AUTHORIZATION API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
username	TEXT	IN	No	Database username.
privilege	TEXT	IN	No	Scheduled job permission.

Example:

```
gaussdb=# CREATE USER user1 PASSWORD '1*s*****';
NOTICE:  The encrypted password contains MD5 ciphertext, which is not secure.
CREATE ROLE
gaussdb=# CALL DBE_SCHEDULER.grant_user_authorization('user1', 'create job');
 grant_user_authorization
--------------------------

(1 row)
gaussdb=# DROP USER user1;
DROP ROLE
```

- DBE_SCHEDULER.REVOKE_USER_AUTHORIZATION

  Revokes the scheduled job permissions from a database user. The user who calls this function must have the SYSADMIN permission. The operation can be performed only when the permission has been granted.

  The prototype of DBE_SCHEDULER.REVOKE_USER_AUTHORIZATION is as follows:

```
DBE_SCHEDULER.revoke_user_authorization(
username              text,
privilege             text
)
```

Table 2-303 DBE_SCHEDULER.REVOKE_USER_AUTHORIZATION API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
username	TEXT	IN	No	Database username.
privilege	TEXT	IN	No	Scheduled job permission.

Example:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gaussdb=# CREATE USER user1 PASSWORD '1*s*****';
NOTICE:  The encrypted password contains MD5 ciphertext, which is not secure.
CREATE ROLE
gaussdb=# CALL DBE_SCHEDULER.grant_user_authorization('user1', 'create job');
 grant_user_authorization
--------------------------

(1 row)

gaussdb=# CALL DBE_SCHEDULER.revoke_user_authorization('user1', 'create job');
 revoke_user_authorization
---------------------------

(1 row)
gaussdb=# DROP USER user1;
DROP ROLE
```

- DBE_SCHEDULER.CREATE_CREDENTIAL

  Creates an authorization certificate. The user who calls this function must have the SYSADMIN permission. Then, it is synchronized to all CNs.

  The prototype of DBE_SCHEDULER.CREATE_CREDENTIAL is as follows:

```
DBE_SCHEDULER.create_credential(
credential_name         text,
username                text,
password                text            default NULL,
database_role           text            default NULL,
windows_domain          text            default NULL,
comments                text            default NULL
)
```

Table 2-304 DBE_SCHEDULER.CREATE_CREDENTIAL API parameters

Parameter	Type	Input/ Output Parameter	Can Be Null	Description
credential_name	TEXT	IN	No	Name of the authorization certificate.
username	TEXT	IN	No	Database username.
password	TEXT	IN	Yes	User password.
database_role	TEXT	IN	Yes	Database system permission.
windows_domain	TEXT	IN	Yes	Domain to which a Windows user belongs.
comments	TEXT	IN	Yes	Comments.

Example:

```
gaussdb=# CALL DBE_SCHEDULER.create_credential('cre_1', 'user1', '');
 create_credential
-------------------
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
(1 row)

gaussdb=# CALL DBE_SCHEDULER.drop_credential('cre_1', false);
 drop_credential
-----------------

(1 row)
```

NOTE

The **password** parameter of DBE_SCHEDULER.CREATE_CREDENTIAL must be set to **NULL** or **'******'**. This parameter is used only for compatibility processing and does not indicate any actual meaning. Do not use the OS username corresponding to the installation user to create a certificate.

- DBE_SCHEDULER.DROP_CREDENTIAL

  Destroys an authorization certificate. The user who calls this function must have the SYSADMIN permission. The operation can be performed only when the certificate has been synchronized.

  The prototype of DBE_SCHEDULER.DROP_CREDENTIAL is as follows:

```
DBE_SCHEDULER.drop_credential(
credential_name         text,
force boolean default false
)
```

Table 2-305 DBE_SCHEDULER.DROP_CREDENTIAL API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
credential_name	TEXT	IN	No	Name of the authorization certificate.
force	BOOLEAN	IN	No	Specifies how to delete the authorization certificate. • **true**: The certificate will be deleted no matter whether it is referenced by any job. • **false**: No job can reference the certificate. Otherwise, an error occurs.

Example:

```
gaussdb=# CALL DBE_SCHEDULER.create_credential('cre_1', 'user1', '');
 create_credential
-------------------

(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gaussdb=# CALL DBE_SCHEDULER.drop_credential('cre_1', false);
 drop_credential
-----------------

(1 row)
```

- DBE_SCHEDULER.ENABLE

  Enables an object. Then, it is synchronized to all CNs.

  The prototype of DBE_SCHEDULER.ENABLE is as follows:

```
DBE_SCHEDULER.enable(
name text,
commit_semantics text                default 'STOP_ON_FIRST_ERROR'
)
```

Table 2-306 DBE_SCHEDULER.ENABLE API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
name	TEXT	IN	No	Object name. You can specify one or more objects. If you specify multiple objects, separate them with commas (,).
commit_semantics	TEXT	IN	No	Commit rules. The following types are supported: ● **'STOP_ON_FIRST_ERROR'**: The enabling operation performed before the first error is reported is committed. ● **'TRANSACTIONAL'**: Transaction-level commit. The enabling operation performed before an error is reported will be rolled back. ● **'ABSORB_ERRORS'**: The system attempts to bypass an error and commit the enabling operation that is performed successfully.

Example:

```
gaussdb=# CALL dbe_scheduler.create_job('job1','PLSQL_BLOCK','BEGIN INSERT INTO test1
VALUES(12); end;',0,null,null,null,'DEFAULT_JOB_CLASS',false,false,null,null,null);
 create_job
------------

(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gaussdb=# CALL DBE_SCHEDULER.create_program('program1', 'stored_procedure', 'INSERT INTO
tb_job_test(key) VALUES(null);', 0, false, '');
 create_program
----------------

(1 row)

gaussdb=# CALL DBE_SCHEDULER.enable('job1');
 enable
--------

(1 row)

gaussdb=# CALL DBE_SCHEDULER.enable('program1', 'STOP_ON_FIRST_ERROR');
 enable
--------

(1 row)

gaussdb=# CALL DBE_SCHEDULER.drop_job('job1', true, false, 'STOP_ON_FIRST_ERROR');
 drop_job
----------

(1 row)

gaussdb=# CALL DBE_SCHEDULER.drop_program('program1', false);
 drop_program
--------------

(1 row)
```

- DBE_SCHEDULER.ENABLE_SINGLE

  Enables a single object. Then, it is synchronized to all CNs.

  The prototype of DBE_SCHEDULER.ENABLE_SINGLE is as follows:

  ```
  DBE_SCHEDULER.enable_single(
  name text
  )
  ```

  Table 2-307 DBE_SCHEDULER.ENABLE_SINGLE API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
name	TEXT	IN	No	Object name.

  Example:

  ```
  gaussdb=# CALL dbe_scheduler.create_job('job1','PLSQL_BLOCK','BEGIN INSERT INTO test1
  VALUES(12); end;',0,null,null,null,'DEFAULT_JOB_CLASS',false,false,null,null,null);
   create_job
  ------------

  (1 row)

  gaussdb=# CALL DBE_SCHEDULER.enable_single('job1');
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
 enable_single
---------------

(1 row)

gaussdb=# CALL DBE_SCHEDULER.drop_job('job1', true, false, 'STOP_ON_FIRST_ERROR');
 drop_job
----------

(1 row)
```

- DBE_SCHEDULER.DISABLE

  Disables multiple objects. The value of **name** is a character string delimited by commas (,). Each part of the string delimited by commas (,) is an object. This operation can be performed only when enabling has been performed.

  The prototype of DBE_SCHEDULER.DISABLE is as follows:

```
DBE_SCHEDULER.disable(
name text,
force boolean                   default false,
commit_semantics text               default 'STOP_ON_FIRST_ERROR'
)
```

Table 2-308 DBE_SCHEDULER.DISABLE API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
name	TEXT	IN	No	Object name.
force	BOOLEAN	IN	No	Specifies how to disable an object. • **true**: The object is disabled regardless of whether other objects depend on it. • **false**: No object can depend on the object. Otherwise, an error occurs.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Type	Input/Output Parameter	Can Be Null	Description
commit_semantics	TEXT	IN	No	Commit rules. The following types are supported: ● **'STOP_ON_FIRST_ERROR'**: The disabling operation performed before the first error is reported is committed. ● **'TRANSACTIONAL'**: Transaction-level commit. The disabling operation performed before an error is reported will be rolled back. ● **'ABSORB_ERRORS'**: The system attempts to bypass an error and commit the disabling operation that is performed successfully.

Example:

```
gaussdb=# CALL dbe_scheduler.create_job('job1','PLSQL_BLOCK','BEGIN INSERT INTO test1
VALUES(12); end;',0,null,null,null,'DEFAULT_JOB_CLASS',false,false,null,null,null);
 create_job
------------

(1 row)

gaussdb=# CALL DBE_SCHEDULER.create_program('program1', 'stored_procedure', 'INSERT INTO
tb_job_test(key) VALUES(null);', 0, false, '');
 create_program
----------------

(1 row)

gaussdb=# CALL DBE_SCHEDULER.disable('job1');
 disable
---------

(1 row)

gaussdb=# CALL DBE_SCHEDULER.disable('program1', false, 'STOP_ON_FIRST_ERROR');
 disable
---------

(1 row)

gaussdb=# CALL DBE_SCHEDULER.drop_job('job1', true, false, 'STOP_ON_FIRST_ERROR');
 drop_job
----------

(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gaussdb=# CALL DBE_SCHEDULER.drop_program('program1', false);
 drop_program
--------------

(1 row)
```

- DBE_SCHEDULER.DISABLE_SINGLE

  Disables a single object. This operation can be performed only when enabling has been performed.

  The prototype of DBE_SCHEDULER.DISABLE_SINGLE is as follows:

```
DBE_SCHEDULER.disable_single(
name text,
force boolean                    default false
)
```

Table 2-309 DBE_SCHEDULER.DISABLE_SINGLE API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
name	TEXT	IN	No	Object name.
force	BOOLEAN	IN	No	Specifies how to disable an object. • **true**: The object is disabled regardless of whether other objects depend on it. • **false**: No object can depend on the object. Otherwise, an error occurs.

Example:

```
gaussdb=# CALL dbe_scheduler.create_job('job1','PLSQL_BLOCK','BEGIN INSERT INTO test1
VALUES(12); end;',0,null,null,null,'DEFAULT_JOB_CLASS',false,false,null,null,null);
 create_job
------------

(1 row)

gaussdb=# CALL DBE_SCHEDULER.disable_single('job1', false);
 disable_single
----------------

(1 row)

gaussdb=# CALL DBE_SCHEDULER.drop_job('job1', true, false, 'STOP_ON_FIRST_ERROR');
 drop_job
----------

(1 row)
```

- DBE_SCHEDULER.EVAL_CALENDAR_STRING

  Analyzes the scheduled job period.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Return type: timestamp with time zone

The prototype of DBE_SCHEDULER.EVAL_CALENDAR_STRING is as follows:

```
DBE_SCHEDULER.evaluate_calendar_string(
IN calendar_string text,
IN start_date timestamp with time zone,
IN return_date_after timestamp with time zone
)return timestamp with time zone
```

Table 2-310 DBE_SCHEDULER.EVAL_CALENDAR_STRING API parameters

Parameter	Type	Input/ Output Parameter	Can Be Null	Description
calendar_string	TEXT	IN	No	Date string of a scheduled job.
start_date	TIMESTAMP WITH TIME ZONE	IN	No	Start time of a scheduled job.
return_date_after	TIMESTAMP WITH TIME ZONE	IN	No	Date returned by a scheduled job, which is used to filter the first matching scheduling time that comes after this date.

Example:

```
gaussdb=# CALL DBE_SCHEDULER.eval_calendar_string('FREQ=DAILY; BYHOUR=6;', sysdate, sysdate);
  eval_calendar_string
------------------------
 2023-09-15 06:47:24+08
(1 row)
```

- DBE_SCHEDULER.EVALUATE_CALENDAR_STRING

  Analyzes the scheduled job period.

  Return type: timestamp with time zone

  The prototype of DBE_SCHEDULER.EVALUATE_CALENDAR_STRING is as follows:

  ```
  DBE_SCHEDULER.evaluate_calendar_string(
  IN calendar_string text,
  IN start_date timestamp with time zone,
  IN return_date_after timestamp with time zone,
  OUT next_run_date timestamp with time zone
  )return timestamp with time zone
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 2-311 DBE_SCHEDULER.EVALUATE_CALENDAR_STRING API parameters

Parameter	Type	Input/ Output Parameter	Can Be Null	Description
calendar_string	TEXT	IN	No	Date string of a scheduled job.
start_date	TIMESTAMP WITH TIME ZONE	IN	No	Start time of a scheduled job.
return_date_after	TIMESTAMP WITH TIME ZONE	IN	No	Date returned by a scheduled job, which is used to filter the first matching scheduling time that comes after this date.
next_run_date	TIMESTAMP WITH TIME ZONE	OUT	No	Next date when a scheduled job is returned.

Example:

```
gaussdb=# CREATE OR REPLACE PROCEDURE pr1(calendar_str text) as
DECLARE
    start_date        timestamp with time zone;
    return_date_after timestamp with time zone;
    next_run_date     timestamp with time zone;
BEGIN
    start_date := '2003-2-1 10:30:00.111111+8'::timestamp with time zone;
    return_date_after := start_date;
    DBE_SCHEDULER.evaluate_calendar_string(
        calendar_str,
        start_date, return_date_after, next_run_date);
    DBE_OUTPUT.PRINT_LINE('next_run_date: ' || next_run_date);
    return_date_after := next_run_date;
END;
/
CREATE PROCEDURE

gaussdb=# CALL pr1('FREQ=hourly;INTERVAL=2;BYHOUR=6,10;BYMINUTE=0;BYSECOND=0');
next_run_date: 2003-02-02 06:00:00+08
 pr1
-----

(1 row)
```

2.12.2.16 DBE_SESSION

APIs

Table 2-312 lists APIs supported by the DBE_SESSION package. DBE_SESSION takes effect at the session level.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 2-312 DBE_SESSION

API	Description
DBE_SESSION.SET_CONTEXT	Sets the value of an attribute in a specified context.
DBE_SESSION.CLEAR_CONTEXT	Clears the value of an attribute in a specified context.
DBE_SESSION.SEARCH_CONTEXT	Queries the value of an attribute in a specified context.
DBE_SESSION.MODIFY_PACKAGE_STATE	Changes the PL/SQL status of the current session.

- DBE_SESSION.SET_CONTEXT

  Sets the value of an attribute in a specified namespace (context).

  The prototype of DBE_SESSION.SET_CONTEXT is as follows:

```
DBE_SESSION.SET_CONTEXT(
    namespace text,
    attribute text,
    value text
)returns void;
```

  Table 2-313 DBE_SESSION.SET_CONTEXT API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
namespace	TEXT	IN	No	Name of the context to be set. If the context does not exist, create a context. The value contains a maximum of 128 bytes. If the value exceeds 128 bytes, it will be truncated.
attribute	TEXT	IN	No	Attribute name. The value contains a maximum of 1024 bytes. If the value exceeds 1024 bytes, it will be truncated.
value	TEXT	IN	No	Name of the value to be set. The value contains a maximum of 1024 bytes. If the value exceeds 1024 bytes, it will be truncated.

- DBE_SESSION.CLEAR_CONTEXT

  Clears the value of an attribute in a specified namespace (context).

  The prototype of DBE_SESSION.CLEAR_CONTEXT is as follows:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
DBE_SESSION.CLEAR_CONTEXT (
   namespace text,
   client_identifier text default null,
   attribute text default null
)returns void ;
```

Table 2-314 DBE_SESSION.CLEAR_CONTEXT API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
namespace	TEXT	IN	No	Context specified by the user. The value contains a maximum of 128 bytes. If the value exceeds 128 bytes, it will be truncated.
client_identifier	TEXT	IN	Yes	Client authentication. The default value is **null**. Generally, you do not need to manually set this parameter.
attribute	TEXT	IN	Yes	Attribute to be cleared. The default value is **null**, indicating that all attributes of the specified context are cleared. The value contains a maximum of 1024 bytes. If the value exceeds 1024 bytes, it will be truncated. **NOTE** To ensure compatibility with earlier versions, if the parameter value is **'null'**, all attributes of the specified context are cleared.

- DBE_SESSION.SEARCH_CONTEXT

  Queries the value of an attribute in a specified namespace (context).

  The prototype of DBE_SESSION.SEARCH_CONTEXT is as follows:

```
DBE_SESSION.SEARCH_CONTEXT (
   namespace text,
   attribute text
)returns text;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 2-315 DBE_SESSION.SEARCH_CONTEXT API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
namespace	TEXT	IN	No	Context specified by the user. The value contains a maximum of 128 bytes. If the value exceeds 128 bytes, it will be truncated.
attribute	TEXT	IN	No	Attribute to be searched for. The value contains a maximum of 1024 bytes. If the value exceeds 1024 bytes, it will be truncated.

Example:

```
DECLARE
    a text;
BEGIN
    DBE_SESSION.set_context('test', 'gaussdb', 'one');   -- Set the gaussdb attribute in the test context
to one.
    a := DBE_SESSION.search_context('test', 'gaussdb');
    DBE_OUTPUT.PRINT_LINE(a);
    DBE_SESSION.clear_context('test', 'test','gaussdb');
END;
/
-- Expected result:
one
ANONYMOUS BLOCK EXECUTE
```

- DBE_SESSION.MODIFY_PACKAGE_STATE

  Changes the PL/SQL status of the current session.

  The prototype of DBE_SESSION.MODIFY_PACKAGE_STATE is as follows:

  ```
  DBE_SESSION.MODIFY_PACKAGE_STATE (
      flags int);
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 2-316 DBE_SESSION.MODIFY_PACKAGE_STATE API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
flags	INT	IN	No	Bit flag of the operation performed on the PL/SQL. When **flags** is set to **1**, the session cache of the PL/SQL that is currently running in the session is released after the top-level PL/SQL code is executed. The current values of global variables of all packages are cleared and the cached cursors are closed. On subsequent use, PL/SQL re-instantiates and re-initializes the global variables of the packages. Other bit flags are not supported.

Example:

```
CALL dbe_session.modify_package_state(1);
 modify_package_state
----------------------

(1 row)
```

2.12.2.17 DBE_SQL

Data Types

- DBE_SQL.DESC_REC

  This type is a composite type and is used to store the description of the DBE_SQL.SQL_DESCRIBE_COLUMNS API.

  The prototype of the DBE_SQL.DESC_REC type is as follows:

```
CREATE TYPE DBE_SQL.DESC_REC AS (
    col_type            int,
    col_max_len         int,
    col_name            VARCHAR2(32),
    col_name_len        int,
    col_schema_name     VARCHAR2(32),
    col_schema_name_len int,
    col_precision       int,
    col_scale           int,
    col_charsetid       int,
    col_charsetform     int,
    col_null_ok         BOOLEAN
);
```

- DBE_SQL.DESC_TAB

  This type is the TABLE type of DESC_REC and is implemented through the TABLE OF syntax.

  The prototype of the DBE_SQL.DESC_TAB type is as follows:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
CREATE TYPE DBE_SQL.DESC_TAB AS TABLE OF DBE_SQL.DESC_REC;
```

- DBE_SQL.DATE_TABLE

  This type is the TABLE type of DATE and is implemented through the TABLE OF syntax.

  The prototype of the DBE_SQL.DATE_TABLE type is as follows:

  ```
  CREATE TYPE DBE_SQL.DATE_TABLE AS TABLE OF DATE;
  ```

  NOTE

  - When an advanced package is created, if the GUC parameter **mapping_date_to_datea** is set to **on**, DBE_SQL.DATE_TABLE is mapped to the TABLE type of DATEA.
  - When the EXECUTE DIRECT ON syntax is used to execute functions in the DBE_SQL package, if the GUC parameter **enable_udf_execute_direct** is set to **on**, the functions can be executed; if the parameter is set to **off**, the functions cannot be executed.

- DBE_SQL.NUMBER_TABLE

  This type is the TABLE type of NUMBER and is implemented through the TABLE OF syntax.

  The prototype of the DBE_SQL.NUMBER_TABLE type is as follows:

  ```
  CREATE TYPE DBE_SQL.NUMBER_TABLE AS TABLE OF NUMBER;
  ```

- DBE_SQL.VARCHAR2_TABLE

  This type is the TABLE type of VARCHAR2 and is implemented through the TABLE OF syntax.

  The prototype of the DBE_SQL.VARCHAR2_TABLE type is as follows:

  ```
  CREATE TYPE DBE_SQL.VARCHAR2_TABLE AS TABLE OF VARCHAR2(32767);
  ```

- DBE_SQL.BLOB_TABLE

  This type is the TABLE type of BLOB and is implemented through the TABLE OF syntax.

  The prototype of the DBE_SQL.BLOB_TABLE type is as follows:

  ```
  CREATE TYPE DBE_SQL.BLOB_TABLE AS TABLE OF BLOB;
  ```

APIs

Table 2-317 lists APIs supported by the DBE_SQL package.

Table 2-317 DBE_SQL

API	Description
DBE_SQL.REGISTER_CONTEXT	Opens a cursor.
DBE_SQL.SQL_UNREGISTER_CONTEXT	Closes an open cursor.
DBE_SQL.SQL_SET_SQL	Passes a set of SQL statements or anonymous blocks to a cursor.
DBE_SQL.SQL_RUN	Executes SQL statements or anonymous blocks in a given cursor.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

API	Description
DBE_SQL.NEXT_ROW	Reads a row of cursor data.
DBE_SQL.SET_RESULT_TYPE	Dynamically defines a column.
DBE_SQL.SET_RESULT_TYPE_CHAR	Dynamically defines a column of the CHAR type.
DBE_SQL.SET_RESULT_TYPE_INT	Dynamically defines a column of the INT type.
DBE_SQL.SET_RESULT_TYPE_LONG	Dynamically defines a column of the LONG type.
DBE_SQL.SET_RESULT_TYPE_RAW	Dynamically defines a column of the RAW type.
DBE_SQL.SET_RESULT_TYPE_TEXT	Dynamically defines a column of the TEXT type.
DBE_SQL.SET_RESULT_TYPE_UNKNOWN	Dynamically defines a column of an unknown type.
DBE_SQL.GET_RESULT	Reads a dynamically defined column value.
DBE_SQL.GET_RESULT_CHAR	Reads a dynamically defined column value of the CHAR type.
DBE_SQL.GET_RESULT_INT	Reads a dynamically defined column value of the INT type.
DBE_SQL.GET_RESULT_LONG	Reads a dynamically defined column value of the LONG type.
DBE_SQL.GET_RESULT_RAW	Reads a dynamically defined column value of the RAW type.
DBE_SQL.GET_RESULT_TEXT	Reads a dynamically defined column value of the TEXT type.
DBE_SQL.GET_RESULT_UNKNOWN	Reads a dynamically defined column value of an unknown type.
DBE_SQL.DBE_SQL_GET_RESULT_CHAR	Reads a dynamically defined column value of the CHAR type.
DBE_SQL.DBE_SQL_GET_RESULT_LONG	Reads a dynamically defined column value of the LONG type.
DBE_SQL.DBE_SQL_GET_RESULT_LONG2	Reads a dynamically defined column value of the LONG type.
DBE_SQL.DBE_SQL_GET_RESULT_RAW	Reads a dynamically defined column value of the RAW type.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

API	Description
DBE_SQL.IS_ACTIVE	Checks whether a cursor is opened.
DBE_SQL.LAST_ROW_COUNT	Returns the cumulative count of obtained rows.
DBE_SQL.RUN_AND_NEXT	Reads data of a cursor after a set of dynamically defined operations are performed on the cursor.
DBE_SQL.SQL_BIND_VARIABLE	Binds a value to a variable in a statement.
DBE_SQL.SQL_BIND_ARRAY	Binds a group of values to a variable in a statement.
DBE_SQL.SET_RESULT_TYPE_INTS	Dynamically defines a column of the INT array type.
DBE_SQL.SET_RESULT_TYPE_TEXTS	Dynamically defines a column of the TEXT array type.
DBE_SQL.SET_RESULT_TYPE_RAWS	Dynamically defines a column of the RAW array type.
DBE_SQL.SET_RESULT_TYPE_BYTEAS	Dynamically defines a column of the BYTEA array type.
DBE_SQL.SET_RESULT_TYPE_CHARS	Dynamically defines a column of the CHAR array type.
DBE_SQL.SET_RESULTS_TYPE	Dynamically defines a column of the array type.
DBE_SQL.GET_RESULTS_INT	Reads a dynamically defined column value of the INT array type.
DBE_SQL.GET_RESULTS_TEXT	Reads a dynamically defined column value of the TEXT array type.
DBE_SQL.GET_RESULTS_RAW	Reads a dynamically defined column value of the RAW array type.
DBE_SQL.GET_RESULTS_BYTEA	Reads a dynamically defined column value of the BYTEA array type.
DBE_SQL.GET_RESULTS_CHAR	Reads a dynamically defined column value of the CHAR array type.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

API	Description
DBE_SQL.GET_RESULTS	Reads a dynamically defined column value.
DBE_SQL.DESCRIBE_COLUMNS	Describes the column information read by the cursor.
DBE_SQL.SQL_DESCRIBE_COLUMNS	Describes the column information read by the cursor.
DBE_SQL.BIND_VARIABLE	Binds parameters.
DBE_SQL.SQL_SET_RESULTS_TYPE_C	Dynamically defines a column of the array type.
DBE_SQL.SQL_GET_VALUES_C	Reads a dynamically defined column value.
DBE_SQL.GET_VARIABLE_RESULT	Reads the return value of an SQL statement.
DBE_SQL.GET_VARIABLE_RESULT_CHAR	Reads the return value (of the CHAR type) of an SQL statement.
DBE_SQL.GET_VARIABLE_RESULT_RAW	Reads the return value (of the RAW type) of an SQL statement.
DBE_SQL.GET_VARIABLE_RESULT_TEXT	Reads the return value (of the TEXT type) of an SQL statement.
DBE_SQL.GET_VARIABLE_RESULT_INT	Reads the return value (of the INT type) of an SQL statement.
DBE_SQL.GET_ARRAY_RESULT_TEXT	Reads the return value (of the TEXT array type) of an SQL statement.
DBE_SQL.GET_ARRAY_RESULT_RAW	Reads the return value (of the RAW array type) of an SQL statement.
DBE_SQL.GET_ARRAY_RESULT_CHAR	Reads the return value (of the CHAR array type) of an SQL statement.
DBE_SQL.GET_ARRAY_RESULT_INT	Reads the return value (of the INT array type) of an SQL statement.

NOTE

- You are advised to use DBE_SQL.SET_RESULT_TYPE and DBE_SQL.GET_RESULT to define columns.
- When the size of the result set exceeds the value of the GUC parameter **work_mem**, the result set is stored on a temporary disk, but the maximum size of the temporary disk does not exceed 512 MB.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- DBE_SQL.REGISTER_CONTEXT

  Opens a cursor, which is the prerequisite for the subsequent DBE_SQL operations. This function does not pass any parameter. It automatically generates cursor IDs in an ascending order and returns values to integer variables.

  NOTE

  Cursors opened by DBE_SQL are session-level variables. Cross-session calling of opened cursors (such as autonomous transactions) is not supported. If a cross-session cursor is called, the behavior is unpredictable.

  The prototype of DBE_SQL.REGISTER_CONTEXT is as follows:

```
DBE_SQL.REGISTER_CONTEXT(
)
RETURN INTEGER;
```

- DBE_SQL.SQL_UNREGISTER_CONTEXT

  Closes a cursor, which is the end of each DBE_SQL operation. If this function is not called when the stored procedure ends, the memory occupied by the cursor is not released. Therefore, remember to close the cursor. If an exception occurs, the stored procedure may exit in advance and the cursor cannot be closed. It is recommended that this API be included in the exception handling of the stored procedure.

  The prototype of DBE_SQL.SQL_UNREGISTER_CONTEXT is as follows:

```
DBE_SQL.SQL_UNREGISTER_CONTEXT(
    context_id    IN INT
)
RETURN INTEGER;
```

Table 2-318 DBE_SQL.SQL_UNREGISTER_CONTEXT API parameters

Parameter	Type	Input/OutputParameter	CanBeNull	Description
context_id	INT	IN	No	ID of the cursor to be closed.

- DBE_SQL.SQL_SET_SQL

  Parses SQL statements or anonymous blocks in a given cursor. The statement parameters can be passed only through the TEXT type. The length cannot exceed 1 GB.

  The prototype of DBE_SQL.SQL_SET_SQL is as follows:

```
DBE_SQL.SQL_SET_SQL(
   context_id    IN INT,
   query_string  IN TEXT,
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
    language_flag IN INT
)
RETURN BOOLEAN;
```

Table 2-319 DBE_SQL.SQL_SET_SQL API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
context_id	INT	IN	No	ID of the cursor whose query statement is to be parsed.
query_string	TEXT	IN	No	Query statement to be parsed.
language_flag	INT	IN	No	Version language. The value **1** indicates an incompatible version, and the value **2** indicates an ORA-compatible version.

- DBE_SQL.SQL_RUN

  Executes a specified cursor. It receives a cursor ID and executes SQL statements or anonymous blocks in a given cursor.

  The prototype of DBE_SQL.SQL_RUN is as follows:

```
DBE_SQL.SQL_RUN(
    context_id    IN INT,
)
RETURN INTEGER;
```

Table 2-320 DBE_SQL.SQL_RUN API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
context_id	INT	IN	No	ID of the cursor whose query statement is to be parsed.

- DBE_SQL.NEXT_ROW

  Returns the number of data rows that meet query conditions. Each time the function is called, the system obtains a set of new rows until all data is read.

  The prototype of DBE_SQL.NEXT_ROW is as follows:

```
DBE_SQL.NEXT_ROW(
    context_id    IN INT,
)
RETURN INTEGER;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 2-321 DBE_SQL.NEXT_ROW API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
context_id	INT	IN	No	ID of the cursor to be executed.

- DBE_SQL.SET_RESULT_TYPE

  Defines columns returned from a specified cursor. This API applies only to cursors defined by SELECT. The defined columns are identified by the relative positions in the query list. The data type of an input variable determines the corresponding column type.

  The prototype of DBE_SQL.SET_RESULT_TYPE is as follows:

```
DBE_SQL.SET_RESULT_TYPE(
    context_id IN INT,
    pos        IN INT,
    column_ref IN ANYELEMENT,
    maxsize    IN INT default 1024
)
RETURN INTEGER;
```

Table 2-322 DBE_SQL.SET_RESULT_TYPE API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
context_id	INT	IN	No	ID of the cursor to be executed.
pos	INT	IN	No	Relative position of the queried columns in the returned result. The value starts from 1.
column_ref	ANYELEMENT	IN	No	Variable of any type. You can select an appropriate API to dynamically define columns based on variable types.
maxsize	INT	IN	Yes	Length of the defined column return type.

- DBE_SQL.SET_RESULT_TYPE_CHAR

  Defines columns of the CHAR type returned from a specified cursor. This API applies only to cursors defined by SELECT. The defined columns are identified

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

by the relative positions in the query list. The data type of an input variable determines the corresponding column type.

The prototype of DBE_SQL.SET_RESULT_TYPE_CHAR is as follows:

```
DBE_SQL.SET_RESULT_TYPE_CHAR(
   context_id  IN INT,
   pos         IN INT,
   column_ref  IN TEXT,
   column_size IN INT
)
RETURN INTEGER;
```

Table 2-323 DBE_SQL.SET_RESULT_TYPE_CHAR API parameters

Parameter	Type	Input / Output Parameter	Can Be Null	Description
context_id	INT	IN	No	ID of the cursor to be executed.
pos	INT	IN	No	Position of a dynamically defined column in the query.
column_ref	TEXT	IN	No	Parameter to be defined.
column_size	INT	IN	No	Length of a dynamically defined column.

- DBE_SQL.SET_RESULT_TYPE_INT

  Defines columns of the INT type returned from a specified cursor. This API applies only to cursors defined by SELECT. The defined columns are identified by the relative positions in the query list. The data type of an input variable determines the corresponding column type.

  The prototype of DBE_SQL.SET_RESULT_TYPE_INT is as follows:

  ```
  DBE_SQL.SET_RESULT_TYPE_INT(
     context_id IN INT,
     pos        IN INT
  )
  RETURN INTEGER;
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 2-324 DBE_SQL.SET_RESULT_TYPE_INT API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
context_id	INT	IN	No	ID of the cursor to be executed.
pos	INT	IN	No	Position of a dynamically defined column in the query.

- DBE_SQL.SET_RESULT_TYPE_LONG

  Defines columns of the long type (not the long type of data) returned from a specified cursor. This API applies only to cursors defined by SELECT. The defined columns are identified by the relative positions in the query list. The data type of an input variable determines the corresponding column type. The maximum size of a long column is 1 GB.

  The prototype of DBE_SQL.SET_RESULT_TYPE_LONG is as follows:

```
DBE_SQL.SET_RESULT_TYPE_LONG(
   context_id IN INT,
   pos        IN INT
)
RETURN INTEGER;
```

Table 2-325 DBE_SQL.SET_RESULT_TYPE_LONG API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
context_id	INT	IN	No	ID of the cursor to be executed.
pos	INT	IN	No	Position of a dynamically defined column in the query.

- DBE_SQL.SET_RESULT_TYPE_RAW

  Defines columns of the RAW type returned from a specified cursor. This API applies only to cursors defined by SELECT. The defined columns are identified by the relative positions in the query list. The data type of an input variable determines the corresponding column type.

  The prototype of DBE_SQL.SET_RESULT_TYPE_RAW is as follows:

```
DBE_SQL.SET_RESULT_TYPE_RAW(
   context_id  IN INT,
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
  pos         IN INT,
  column_ref  IN BYTEA,
  column_size IN INT
)
RETURN INTEGER;
```

Table 2-326 DBE_SQL.SET_RESULT_TYPE_RAW API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
context_id	INT	IN	No	ID of the cursor to be executed.
pos	INT	IN	No	Position of a dynamically defined column in the query.
column_ref	BYTEA	IN	No	RAW variable.
column_size	INT	IN	No	Column length.

- DBE_SQL.SET_RESULT_TYPE_TEXT

  Defines columns of the TEXT type returned from a specified cursor. This API applies only to cursors defined by SELECT. The defined columns are identified by the relative positions in the query list. The data type of an input variable determines the corresponding column type.

  The prototype of DBE_SQL.SET_RESULT_TYPE_TEXT is as follows:

```
DBE_SQL.SET_RESULT_TYPE_TEXT(
  context_id IN INT,
  pos        IN INT,
  maxsize    IN INT
)
RETURN INTEGER;
```

Table 2-327 DBE_SQL.SET_RESULT_TYPE_TEXT API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
context_id	IN	IN	No	ID of the cursor to be executed.
pos	IN	IN	No	Position of a dynamically defined column in the query.
maxsize	IN	IN	No	Maximum length of the defined TEXT type.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- DBE_SQL.SET_RESULT_TYPE_UNKNOWN

  Processes columns of unknown data types returned from a specified cursor. It is used to report an error and exit only when the data type cannot be identified.

  The prototype of DBE_SQL.SET_RESULT_TYPE_UNKNOWN is as follows:

```
DBE_SQL.SET_RESULT_TYPE_UNKNOWN(
    context_id IN INT,
    pos        IN INT,
    col_type   IN TEXT
)
RETURN INTEGER;
```

  Table 2-328 DBE_SQL.SET_RESULT_TYPE_UNKNOWN API parameters

Parameter	Type	Input / Output Parameter	Can Be Null	Description
context_id	INT	IN	No	ID of the cursor to be executed.
pos	INT	IN	No	Position of a dynamically defined column in the query.
col_type	TEXT	IN	No	Dynamically defined parameter.

- DBE_SQL.GET_RESULT

  Returns the element value of a cursor at a specified position. This API accesses the data obtained by DBE_SQL.NEXT_ROW.

  The prototype of DBE_SQL.GET_RESULT is as follows:

```
DBE_SQL.GET_RESULT(
    context_id   IN INT,
    pos          IN INT,
    column_value INOUT ANYELEMENT
);
```

  Table 2-329 DBE_SQL.GET_RESULT API parameters

Parameter	Type	Input / Output Parameter	Can Be Null	Description
context_id	INT	IN	No	ID of the cursor to be executed.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Type	Input / Output Parameter	Can Be Null	Description
pos	INT	IN	No	Relative position of the queried columns in the returned result. The value starts from 1.
column_value	ANYELEMENT	INOUT	No	Return value of a defined column.

- DBE_SQL.GET_RESULT_CHAR

  Returns a value of the CHAR type at a specified position from a cursor. This API accesses the data obtained by DBE_SQL.NEXT_ROW.

  The prototype of DBE_SQL.GET_RESULT_CHAR is as follows:

```
DBE_SQL.GET_RESULT_CHAR(
    context_id    IN    INT,
    pos           IN    INT,
    tr            INOUT CHAR,
    err           INOUT NUMERIC DEFAULT 0,
    actual_length INOUT INT DEFAULT 1024
);
```

  Table 2-330 DBE_SQL.GET_RESULT_CHAR API parameters

Parameter	Type	Input / Output Parameter	Can Be Null	Description
context_id	INT	IN	No	ID of the cursor to be executed.
pos	INT	IN	No	Position of a dynamically defined column in the query.
tr	CHAR	INOUT	No	Return value.
err	NUMERIC	INOUT	Yes	Error number. It is an output parameter. The input parameter must be a variable. The default value is **0**. Currently, the output value is **-1** regardless of the input parameter.
actual_length	INT	INOUT	Yes	Length of a return value. The default value is **1024**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- DBE_SQL.GET_RESULT_INT

  Returns a value of the INT type at a specified position from a cursor. This API accesses the data obtained by DBE_SQL.NEXT_ROW.

  The prototype of DBE_SQL.GET_RESULT_INT is as follows:

```
DBE_SQL.GET_RESULT_INT(
   context_id IN    INT,
   pos        IN    INT
)
RETURN INTEGER;
```

Table 2-331 DBE_SQL.GET_RESULT_INT API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
context_id	INT	IN	No	ID of the cursor to be executed.
pos	INT	IN	No	Position of a dynamically defined column in the query.

- DBE_SQL.GET_RESULT_LONG

  Returns the value of a long column (not of the long or bigint type) at a specified position from a cursor. This API accesses the data obtained by DBE_SQL.NEXT_ROW.

  The prototype of DBE_SQL.GET_RESULT_LONG is as follows:

```
DBE_SQL.GET_RESULT_LONG(
   context_id IN    INT,
   pos        IN    INT,
   lgth       IN    INT,
   off_set    IN    INT,
   vl         INOUT TEXT,
   vl_length  INOUT INT
);
```

Table 2-332 DBE_SQL.GET_RESULT_LONG API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
context_id	INT	IN	No	ID of the cursor to be executed.
pos	INT	IN	No	Position of a dynamically defined column in the query.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Type	Input / Output Parameter	Can Be Null	Description
lgth	INT	IN	No	Length of a return value.
off_set	INT	IN	No	Start position of a return value.
vl	TEXT	INOUT	No	Return value.
vl_length	INT	INOUT	No	Length of a return value.

- DBE_SQL.GET_RESULT_RAW

  Returns a value of the RAW type at a specified position from a cursor. This API accesses the data obtained by DBE_SQL.NEXT_ROW.

  The prototype of DBE_SQL.GET_RESULT_RAW is as follows:

```
DBE_SQL.GET_RESULT_RAW(
    context_id     IN     INT,
    pos            IN     INT,
    tr             INOUT BYTEA,
    err            INOUT NUMERIC DEFAULT 0,
    actual_length INOUT INT DEFAULT 1024
);
```

Table 2-333 DBE_SQL.GET_RESULT_RAW API parameters

Parameter	Type	Input / Output Parameter	Can Be Null	Description
context_id	INT	IN	No	ID of the cursor to be executed.
pos	INT	IN	No	Position of a dynamically defined column in the query.
tr	BYTEA	INOUT	No	Returned column value.
err	NUMERIC	INOUT	No	Error number. It is an output parameter. The input parameter must be a variable. The default value is **0**. Currently, the output value is **-1** regardless of the input parameter.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Type	Input/Output Parameter	Can Be Null	Description
actual_length	INT	INOUT	No	Length of a return value. The value longer than this length will be truncated. The default value is **1024**.

- DBE_SQL.GET_RESULT_TEXT

  Returns a value of the TEXT type at a specified position from a cursor. This API accesses the data obtained by DBE_SQL.NEXT_ROW.

  The prototype of DBE_SQL.GET_RESULT_TEXT is as follows:

```
DBE_SQL.GET_RESULT_TEXT(
    context_id IN INT,
    pos        IN INT
)
RETURN TEXT;
```

  Table 2-334 DBE_SQL.GET_RESULT_TEXT API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
context_id	INT	IN	No	ID of the cursor to be executed.
pos	INT	IN	No	Position of a dynamically defined column in the query.

- DBE_SQL.GET_RESULT_UNKNOWN

  Returns a value of an unknown type at a specified position from a cursor. It serves as an error handling API when the type is not unknown.

  The prototype of DBE_SQL.GET_RESULT_UNKNOWN is as follows:

```
DBE_SQL.GET_RESULT_UNKNOWN(
    context_id IN INT,
    pos        IN INT,
    col_type   IN TEXT
)
RETURN INTEGER;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 2-335 DBE_SQL.GET_RESULT_UNKNOWN API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
context_id	INT	IN	No	ID of the cursor to be executed.
pos	INT	IN	No	Position of a dynamically defined column in the query.
col_type	TEXT	IN	No	Returned parameter type.

- DBE_SQL.DBE_SQL_GET_RESULT_CHAR

  Returns a value of the CHAR type at a specified position from a cursor. This API accesses the data obtained by DBE_SQL.NEXT_ROW. Different from the DBE_SQL.GET_RESULT_CHAR function, this function does not set the length of the return value but returns the entire string.

  The prototype of DBE_SQL.DBE_SQL_GET_RESULT_CHAR is as follows:

```
DBE_SQL.DBE_SQL_GET_RESULT_CHAR(
    context_id    IN INT,
    pos           IN INT
)
RETURN CHARACTER;
```

Table 2-336 DBE_SQL.DBE_SQL_GET_RESULT_CHAR API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
context_id	INT	IN	No	ID of the cursor to be executed.
pos	INT	IN	No	Position of a dynamically defined column in the query.

- DBE_SQL.DBE_SQL_GET_RESULT_LONG

  Returns the value of a long column (not of the long or bigint type) at a specified position from a cursor. This API accesses the data obtained by DBE_SQL.NEXT_ROW. Different from DBE_SQL.GET_RESULT_LONG, this function does not set the length of the return value but returns the entire BIGINT value.

  The prototype of DBE_SQL.DBE_SQL_GET_RESULT_LONG is as follows:

```
DBE_SQL.DBE_SQL_GET_RESULT_LONG(
    context_id    IN INT,
    pos           IN INT
)
RETURN BIGINT;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 2-337 DBE_SQL.DBE_SQL_GET_RESULT_LONG API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
context_id	INT	IN	No	ID of the cursor to be executed.
pos	INT	IN	No	Position of a dynamically defined column in the query.

NOTE

The return type of this function is different from that of DBE_SQL.SET_RESULT_TYPE_LONG and DBE_SQL.GET_RESULT_LONG. Therefore, you are advised to use DBE_SQL.DBE_SQL_GET_RESULT_LONG2 instead.

- DBE_SQL.DBE_SQL_GET_RESULT_LONG2

  Returns the value of a long column (not of the long or bigint type) at a specified position from a cursor. This API accesses the data obtained by DBE_SQL.NEXT_ROW. Different from DBE_SQL.GET_RESULT_LONG, this function does not set the length of the return value but returns the column value.

  The prototype of DBE_SQL.DBE_SQL_GET_RESULT_LONG2 is as follows:

```
DBE_SQL.DBE_SQL_GET_RESULT_LONG2(
    context_id IN INTEGER,
    pos        IN INTEGER
)
RETURN TEXT;
```

Table 2-338 DBE_SQL.DBE_SQL_GET_RESULT_LONG2 API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
context_id	INTEGER	IN	No	ID of the cursor to be executed.
pos	INTEGER	IN	No	Position of a dynamically defined column in the query.

- DBE_SQL.DBE_SQL_GET_RESULT_RAW

  Returns a value of the RAW type at a specified position from a cursor. This API accesses the data obtained by DBE_SQL.NEXT_ROW.

  Different from the DBE_SQL.GET_RESULT_RAW function, this function does not set the length of the return value but returns the entire string.

  The prototype of DBE_SQL.DBE_SQL_GET_RESULT_RAW is as follows:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
DBE_SQL.DBE_SQL_GET_RESULT_RAW(
   context_id    IN    INT,
   pos           IN    INT
)
RETURN RAW;
```

Table 2-339 DBE_SQL.GET_RESULT_RAW API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
context_id	INT	IN	No	ID of the cursor to be executed.
pos	INT	IN	No	Position of a dynamically defined column in the query.

- DBE_SQL.IS_ACTIVE

  Returns the status of a cursor. When a cursor is opened, parsed, executed, or defined, the value is **true**. When a cursor is closed, the value is **false**. If the status is unknown, an error is reported. In other cases, the cursor is closed by default.

  The prototype of DBE_SQL.IS_ACTIVE is as follows:

  ```
  DBE_SQL.IS_ACTIVE(
     context_id    IN    INT
  )
  RETURN BOOLEAN;
  ```

  Table 2-340 DBE_SQL.IS_ACTIVE API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
context_id	INT	IN	No	ID of the cursor to be queried.

- DBE_SQL.LAST_ROW_COUNT

  Returns the cumulative count of data rows obtained after the latest NEXT_ROW execution.

  The prototype of DBE_SQL.LAST_ROW_COUNT is as follows:

  ```
  DBE_SQL.LAST_ROW_COUNT(
  )
  RETURN INTEGER;
  ```

- DBE_SQL.RUN_AND_NEXT

  Equivalent to calling SQL_RUN and NEXT_ROW in sequence.

  The prototype of DBE_SQL.RUN_AND_NEXT is as follows:

  ```
  DBE_SQL.RUN_AND_NEXT(
     context_id IN INT
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
)
RETURNS INTEGER;
```

Table 2-341 DBE_SQL.RUN_AND_NEXT API parameters

Parameter	Type	Input/ Output Parameter	Can Be Null	Description
context_id	INT	IN	No	ID of the cursor whose query statement is to be parsed.

- DBE_SQL.SQL_BIND_VARIABLE

  Binds a parameter to an SQL statement. When the SQL statement is executed, the SQL statement is executed based on the bound value.

  The prototype of DBE_SQL.SQL_BIND_VARIABLE is as follows:

```
DBE_SQL.SQL_BIND_VARIABLE(
    context_id     IN int,
    query_string   IN text,
    language_flag  IN anyelement,
    out_value_size IN int default null
)
RETURNS void;
```

Table 2-342 DBE_SQL.SQL_BIND_VARIABLE API parameters

Parameter	Type	Input/ Output Parameter	Can Be Null	Description
context_id	INT	IN	No	ID of the cursor to be queried.
query_string	TEXT	IN	No	Name of the bind variable.
language_flag	ANYELEMENT	IN	No	Bound value.
out_value_size	INT	IN	Yes	Size of the return value. Default value: **NULL**.

- DBE_SQL.SQL_BIND_ARRAY

  Binds a group of parameters to an SQL statement. When the SQL statement is executed, the SQL statement is executed based on the bound array.

  The prototype of the **DBE_SQL.SQL_BIND_ARRAY** function is as follows:

```
DBE_SQL.SQL_BIND_ARRAY(
    context_id   IN int,
    query_string IN text,
    value        IN anyarray
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
)
RETURNS void;
DBE_SQL.SQL_BIND_ARRAY(
    context_id   IN int,
    query_string IN text,
    value        IN anyarray,
    lower_index  IN int,
    higher_index IN int
)
RETURNS void;
```

Table 2-343 DBE_SQL.SQL_BIND_ARRAY API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
context_id	INT	IN	No	ID of the cursor to be queried.
query_string	TEXT	IN	No	Name of the bind variable.
value	ANYARRAY	IN	No	Bound array.
lower_index	INT	IN	No	Minimum index of the bound array.
higher_index	INT	IN	No	Maximum index of the bound array.

- DBE_SQL.SET_RESULT_TYPE_INTS

  Defines columns of the INT array type returned from a specified cursor. This API applies only to cursors defined by SELECT. The defined columns are identified by the relative positions in the query list. The data type of an input variable determines the corresponding column type.

  The prototype of DBE_SQL.SET_RESULT_TYPE_INTS is as follows:

```
DBE_SQL.SET_RESULT_TYPE_INTS(
    context_id IN int,
    pos        IN int,
    column_ref IN anyarray,
    cnt        IN int,
    lower_bnd  IN int
)
RETURNS integer;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 2-344 DBE_SQL.SET_RESULT_TYPE_INTS API parameters

Parameter	Type	Input/ Output Parameter	Can Be Null	Description
context_id	INT	IN	No	ID of the cursor to be queried.
pos	INT	IN	No	Position of a dynamically defined column in the query.
column_ref	ANYARRAY	IN	No	Type of the returned array.
cnt	INT	IN	No	Number of values obtained at a time.
lower_bnd	INT	IN	No	Start index when an array is returned.

- DBE_SQL.SET_RESULT_TYPE_TEXTS

  Defines columns of the TEXT array type returned from a specified cursor. This API applies only to cursors defined by SELECT. The defined columns are identified by the relative positions in the query list. The data type of an input variable determines the corresponding column type.

  The prototype of DBE_SQL.SET_RESULT_TYPE_TEXTS is as follows:

```
DBE_SQL.SET_RESULT_TYPE_TEXTS(
    context_id IN int,
    pos        IN int,
    column_ref IN anyarray,
    cnt        IN int,
    lower_bnd  IN int,
    maxsize    IN int
)
RETURNS VOID;
```

Table 2-345 DBE_SQL.SET_RESULT_TYPE_TEXTS API parameters

Parameter	Type	Input/ Output Parameter	Can Be Null	Description
context_id	INT	IN	No	ID of the cursor to be queried.
pos	INT	IN	No	Position of a dynamically defined column in the query.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Type	Input / Output Parameter	Can Be Null	Description
column_ref	ANYARRAY	IN	No	Type of the returned array.
cnt	INT	IN	No	Number of values obtained at a time.
lower_bnd	INT	IN	No	Start index when an array is returned.
maxsize	INT	IN	No	Maximum length of the defined TEXT type.

- DBE_SQL.SET_RESULT_TYPE_RAWS

  Defines columns of the RAW array type returned from a specified cursor. This API applies only to cursors defined by SELECT. The defined columns are identified by the relative positions in the query list. The data type of an input variable determines the corresponding column type.

  The prototype of DBE_SQL.SET_RESULT_TYPE_RAWS is as follows:

```
DBE_SQL.set_result_type_raws(
    context_id  IN int,
    pos         IN int,
    column_ref  IN anyarray,
    cnt         IN int,
    lower_bnd   IN int,
    column_size IN int
)
RETURNS integer;
```

Table 2-346 DBE_SQL.SET_RESULT_TYPE_RAWS API parameters

Parameter	Type	Input / Output Parameter	Can Be Null	Description
context_id	INT	IN	No	ID of the cursor to be queried.
pos	INT	IN	No	Position of a dynamically defined column in the query.
column_ref	ANYARRAY	IN	No	Type of the returned array.
cnt	INT	IN	No	Number of values obtained at a time.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Type	Input / Output Parameter	Can Be Null	Description
lower_bnd	INT	IN	No	Start index when an array is returned.
column_size	INT	IN	No	Column length.

- DBE_SQL.SET_RESULT_TYPE_BYTEAS

  Defines columns of the BYTEA array type returned from a specified cursor. This API applies only to cursors defined by SELECT. The defined columns are identified by the relative positions in the query list. The data type of an input variable determines the corresponding column type.

  The prototype of DBE_SQL.SET_RESULT_TYPE_BYTEAS is as follows:

```
DBE_SQL.set_result_type_byteas(
    context_id  IN int,
    pos         IN int,
    column_ref  IN anyarray,
    cnt         IN int,
    lower_bnd   IN int,
    column_size IN int
)
RETURNS integer;
```

Table 2-347 DBE_SQL.SET_RESULT_TYPE_BYTEAS API parameters

Parameter	Type	Input / Output Parameter	Can Be Null	Description
context_id	INT	IN	No	ID of the cursor to be queried.
pos	INT	IN	No	Position of a dynamically defined column in the query.
column_ref	ANYARRAY	IN	No	Type of the returned array.
cnt	INT	IN	No	Number of values obtained at a time.
lower_bnd	INT	IN	No	Start index when an array is returned.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Type	Input / Output Parameter	Can Be Null	Description
column_size	INT	IN	No	Column length.

- DBE_SQL.SET_RESULT_TYPE_CHARS

  Defines columns of the CHAR array type returned from a specified cursor. This API applies only to cursors defined by SELECT. The defined columns are identified by the relative positions in the query list. The data type of an input variable determines the corresponding column type.

  The prototype of DBE_SQL.SET_RESULT_TYPE_CHARS is as follows:

```
DBE_SQL.SET_RESULT_TYPE_CHARS(
   context_id  IN int,
   pos         IN int,
   column_ref  IN anyarray,
   cnt         IN int,
   lower_bnd   IN int,
   column_size IN int
)
RETURNS integer;
```

  Table 2-348 DBE_SQL.SET_RESULT_TYPE_CHARS API parameters

Parameter	Type	Input / Output Parameter	Can Be Null	Description
context_id	INT	IN	No	ID of the cursor to be queried.
pos	INT	IN	No	Position of a dynamically defined column in the query.
column_ref	ANYARRAY	IN	No	Type of the returned array.
cnt	INT	IN	No	Number of values obtained at a time.
lower_bnd	INT	IN	No	Start index when an array is returned.
column_size	INT	IN	No	Column length.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- DBE_SQL.SET_RESULTS_TYPE

  Defines columns returned from a specified cursor. This API applies only to cursors defined by SELECT. The defined columns are identified by the relative positions in the query list. The data type of an input variable determines the corresponding column type.

  The prototype of DBE_SQL.SET_RESULTS_TYPE is as follows:

```
DBE_SQL.SET_RESULTS_TYPE(
    context_id IN int,
    pos        IN int,
    column_ref IN anyarray,
    cnt        IN int,
    lower_bnd  IN int,
    maxsize    IN int DEFAULT 1024
) returns void;
```

  Table 2-349 DBE_SQL.SET_RESULTS_TYPE API parameters

Parameter	Type	Input / Output Parameter	Can Be Null	Description
context_id	INT	IN	No	ID of the cursor to be queried.
pos	INT	IN	No	Position of a dynamically defined column in the query.
column_ref	ANYARRAY	IN	No	Type of the returned array.
cnt	INT	IN	No	Number of values obtained at a time.
lower_bnd	INT	IN	No	Start index when an array is returned.
maxsize	INT	IN	Yes	Maximum length of the defined type.

- DBE_SQL.GET_RESULTS_INT

  Returns a value of the INT array type at a specified position from a cursor. This API accesses the data obtained by DBE_SQL.NEXT_ROW.

  The prototype of DBE_SQL.GET_RESULTS_INT is as follows:

```
DBE_SQL.GET_RESULTS_INT(
    context_id   IN    int,
    pos          IN    int,
    column_value INOUT anyarray
);
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 2-350 DBE_SQL.GET_RESULTS_INT API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
context_id	INT	IN	No	ID of the cursor to be queried.
pos	INT	IN	No	Position of a dynamically defined column in the query.
column_value	ANYARRAY	INOUT	No	Return value.

- DBE_SQL.GET_RESULTS_TEXT

  Returns a value of the TEXT array type at a specified position from a cursor. This API accesses the data obtained by DBE_SQL.NEXT_ROW.

  The prototype of DBE_SQL.GET_RESULTS_TEXT is as follows:

```
DBE_SQL.GET_RESULTS_TEXT(
    context_id   IN    int,
    pos          IN    int,
    column_value INOUT anyarray
);
```

Table 2-351 DBE_SQL.GET_RESULTS_TEXT API parameters

Parameter	Type	Input / Output Parameter	Can Be Null	Description
context_id	INT	IN	No	ID of the cursor to be queried.
pos	INT	IN	No	Position of a dynamically defined column in the query.
column_value	ANYARRAY	INOUT	No	Return value.

- DBE_SQL.GET_RESULTS_RAW

  Returns a value of the RAW array type at a specified position from a cursor. This API accesses the data obtained by DBE_SQL.NEXT_ROW.

  The prototype of DBE_SQL.GET_RESULTS_RAW is as follows:

```
DBE_SQL.GET_RESULTS_RAW(
    context_id   IN    int,
    pos          IN    int,
    column_value INOUT anyarray
);
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 2-352 DBE_SQL.GET_RESULTS_RAW API parameters

Parameter	Type	Input/ Output Parameter	Can Be Null	Description
context_id	INT	IN	No	ID of the cursor to be queried.
pos	INT	IN	No	Position of a dynamically defined column in the query.
column_value	ANYARRAY	INOUT	No	Return value.

- DBE_SQL.GET_RESULTS_BYTEA

  Returns a value of the BYTEA array type at a specified position from a cursor. This API accesses the data obtained by DBE_SQL.NEXT_ROW.

  The prototype of DBE_SQL.GET_RESULTS_BYTEA is as follows:

```
DBE_SQL.GET_RESULTS_BYTEA(
    context_id   IN    int,
    pos          IN    int,
    column_value INOUT anyarray
);
```

Table 2-353 DBE_SQL.GET_RESULTS_BYTEA API parameters

Parameter	Type	Input/ Output Parameter	Can Be Null	Description
context_id	INT	IN	No	ID of the cursor to be queried.
pos	INT	IN	No	Position of a dynamically defined column in the query.
column_value	ANYARRAY	INOUT	No	Return value.

- DBE_SQL.GET_RESULTS_CHAR

  Returns a value of the CHAR array type at a specified position from a cursor. This API accesses the data obtained by DBE_SQL.NEXT_ROW.

  The prototype of DBE_SQL.GET_RESULTS_CHAR is as follows:

```
DBE_SQL.GET_RESULTS_CHAR(
    context_id   IN    int,
    pos          IN    int,
    column_value INOUT anyarray
);
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 2-354 DBE_SQL.GET_RESULTS_CHAR API parameters

Parameter	Type	Input / Output Parameter	Can Be Null	Description
context_id	INT	IN	No	ID of the cursor to be queried.
pos	INT	IN	No	Position of a dynamically defined column in the query.
column_value	ANYARRAY	INOUT	No	Return value.

- DBE_SQL.GET_RESULTS

  Returns a value of the array type at a specified position from a cursor. This API accesses the data obtained by DBE_SQL.NEXT_ROW.

  NOTE

  The bottom-layer mechanism of DBE_SQL.GET_RESULTS is implemented through arrays. When different arrays are used to obtain the return value of the same column, **NULL** values are filled in the array due to discontinuous internal indexes to ensure the continuity of array indexes. As a result, the length of the returned array is different from that of the ORA Database.

  The prototype of DBE_SQL.GET_RESULTS is as follows:

```
DBE_SQL.GET_RESULTS(
   context_id   IN    int,
   pos          IN    int,
   column_value INOUT anyarray
);
```

Table 2-355 DBE_SQL.GET_RESULTS API parameters

Parameter	Type	Input/ Output Parameter	Can Be Null	Description
context_id	INT	IN	No	ID of the cursor to be queried.
pos	INT	IN	No	Position of a dynamically defined column in the query.
column_value	ANYARRAY	INOUT	No	Return value.

- DBE_SQL.SQL_DESCRIBE_COLUMNS

  Describes column information. This API applies only to cursors defined by SELECT.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

The prototype of DBE_SQL.SQL_DESCRIBE_COLUMNS is as follows:

```
DBE_SQL.SQL_DESCRIBE_COLUMNS(
   context_id IN    int,
   col_cnt    INOUT int,
   desc_t     INOUT dbe_sql.desc_tab
)RETURNS record;
```

Table 2-356 DBE_SQL.SQL_DESCRIBE_COLUMNS API parameters

Parameter	Type	Input/ Output Parameter	Can Be Null	Description
context_id	INT	IN	No	ID of the cursor to be queried.
col_cnt	INT	INOUT	No	Number of columns returned.
desc_t	DBE_SQL.DESC_TAB	INOUT	No	Description of the returned column.

- DBE_SQL.DESCRIBE_COLUMNS

  Describes column information. This API is compatible and can be used only for cursors defined by SELECT.

  The prototype of DBE_SQL.DESCRIBE_COLUMNS is as follows:

  ```
  DBE_SQL.DESCRIBE_COLUMNS(
     context_id IN  int,
     col_cnt    OUT int,
     desc_t     OUT dbe_sql.desc_tab
  )
  ```

  Table 2-357 DBE_SQL.DESCRIBE_COLUMNS API parameters

Parameter	Type	Input/ Output Parameter	Can Be Null	Description
context_id	INT	IN	No	ID of the cursor to be queried.
col_cnt	INT	OUT	No	Number of columns returned.
desc_t	DBE_SQL.DESC_TAB	OUT	No	Description of the returned column.

- DBE_SQL.BIND_VARIABLE

  Binds parameters. You are advised to use DBE_SQL.SQL_BIND_VARIABLE.

- DBE_SQL.SQL_SET_RESULTS_TYPE_C

  Dynamically defines a column of the array type. You are advised not to use it.

  The prototype of DBE_SQL.SQL_SET_RESULTS_TYPE_C is as follows:

```
DBE_SQL.sql_set_results_type_c(
   context_id IN int,
   pos        IN int,
   column_ref IN anyarray,
   cnt        IN int,
   lower_bnd  IN int,
   col_type   IN anyelement,
   maxsize    IN int
)return integer;
```

Table 2-358 DBE_SQL.SQL_SET_RESULTS_TYPE_C API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
context_id	INT	IN	No	ID of the cursor to be queried.
pos	INT	IN	No	Position of a dynamically defined column in the query.
column_ref	ANYARRAY	IN	No	Type of the returned array.
cnt	INT	IN	No	Number of values obtained at a time.
lower_bnd	INT	IN	No	Start index when an array is returned.
col_type	ANYELEMENT	IN	No	Variable type corresponding to the returned array type.
maxsize	INT	IN	No	Maximum length of the defined type.

- DBE_SQL.SQL_GET_VALUES_C

  Reads a dynamically defined column value. You are advised not to use it.

  The prototype of DBE_SQL.SQL_GET_VALUES_C is as follows:

```
DBE_SQL.sql_get_values_c(
   context_id   IN    int,
   pos          IN    int,
   results_type INOUT anyarray,
   result_type  IN    anyelement
)return anyarray;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 2-359 DBE_SQL.SQL_GET_VALUES_C API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
context_id	INT	IN	No	ID of the cursor to be queried.
pos	INT	IN	No	Parameter position.
results_type	ANYARRAY	INOUT	No	Obtained result.
result_type	ANYELEMENT	IN	No	Type of the obtained result.

- DBE_SQL.GET_VARIABLE_RESULT

  Returns the value of the bound OUT parameter and obtains the OUT parameter in a stored procedure.

  The prototype of DBE_SQL.GET_VARIABLE_RESULT is as follows:

```
DBE_SQL.get_variable_result(
    context_id   IN    int,
    pos          IN    VARCHAR2,
    column_value INOUT anyelement
);
```

Table 2-360 DBE_SQL.GET_VARIABLE_RESULT API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
context_id	INT	IN	No	ID of the cursor to be queried.
pos	VARCHAR2	IN	No	Name of the bound parameter.
column_value	ANYELEMENT	INOUT	No	Return value.

- DBE_SQL.GET_VARIABLE_RESULT_CHAR

  Returns the value of the bound OUT parameter of the CHAR type and obtains the OUT parameter in a stored procedure.

  The prototype of DBE_SQL.GET_VARIABLE_RESULT_CHAR is as follows:

```
DBE_SQL.get_variable_result_char(
    context_id IN int,
    pos        IN VARCHAR2
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
)
RETURNS char
```

Table 2-361 DBE_SQL.GET_VARIABLE_RESULT_CHAR API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
context_id	INT	IN	No	ID of the cursor to be queried.
pos	VARCHAR2	IN	No	Name of the bound parameter.

- DBE_SQL.GET_VARIABLE_RESULT_RAW

  Returns the value of the bound OUT parameter of the RAW type and obtains the OUT parameter in a stored procedure.

  The prototype of DBE_SQL.GET_VARIABLE_RESULT_RAW is as follows:

```
DBE_SQL.get_variable_result_raw(
    context_id IN     int,
    pos        IN     VARCHAR2,
    value      INOUT anyelement
);
```

Table 2-362 DBE_SQL.GET_VARIABLE_RESULT_RAW API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
context_id	INT	IN	No	ID of the cursor to be queried.
pos	VARCHAR2	IN	No	Name of the bound parameter.
value	ANYELEMENT	INOUT	No	Return value.

- DBE_SQL.GET_VARIABLE_RESULT_TEXT

  Returns the value of the bound OUT parameter of the TEXT type and obtains the OUT parameter in a stored procedure.

  The prototype of DBE_SQL.GET_VARIABLE_RESULT_TEXT is as follows:

```
CREATE OR REPLACE FUNCTION DBE_SQL.get_variable_result_text(
    context_id IN int,
    pos        IN VARCHAR2
)
RETURNS text
```

Table 2-363 DBE_SQL.GET_VARIABLE_RESULT_TEXT API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
context_id	INT	IN	No	ID of the cursor to be queried.
pos	VARCHAR2	IN	No	Name of the bound parameter.

- DBE_SQL.GET_VARIABLE_RESULT_INT

  Returns the value of the bound OUT parameter of the INT type and obtains the OUT parameter in a stored procedure.

  The prototype of DBE_SQL.GET_VARIABLE_RESULT_INT is as follows:

```
DBE_SQL.get_variable_result_int(
   context_id IN    int,
   pos        IN    VARCHAR2,
   value      INOUT anyelement
);
```

Table 2-364 DBE_SQL.GET_VARIABLE_RESULT_INT API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
context_id	INT	IN	No	ID of the cursor to be queried.
pos	VARCHAR2	IN	No	Name of the bound parameter.
value	ANYELEMENT	INOUT	No	Return value.

- DBE_SQL.GET_ARRAY_RESULT_TEXT

  Returns the value of the bound OUT parameter of the TEXT array type and obtains the OUT parameter in a stored procedure.

  The prototype of DBE_SQL.GET_ARRAY_RESULT_TEXT is as follows:

```
DBE_SQL.get_array_result_text(
   context_id   IN    int,
   pos          IN    VARCHAR2,
   column_value INOUT anyarray
);
```

Table 2-365 DBE_SQL.GET_ARRAY_RESULT_TEXT API parameters

Parameter	Type	Input/ Output Parameter	Can Be Null	Description
context_id	INT	IN	No	ID of the cursor to be queried.
pos	VARCHAR2	IN	No	Name of the bound parameter.
column_value	ANYARRAY	INOUT	No	Return value.

- DBE_SQL.GET_ARRAY_RESULT_RAW

  Returns the value of the bound OUT parameter of the RAW array type and obtains the OUT parameter in a stored procedure.

  The prototype of DBE_SQL.GET_ARRAY_RESULT_RAW is as follows:

```
DBE_SQL.get_array_result_raw(
    context_id   IN    int,
    pos          IN    VARCHAR2,
    column_value INOUT anyarray
);
```

Table 2-366 DBE_SQL.GET_ARRAY_RESULT_RAW API parameters

Parameter	Type	Input/ Output Parameter	Can Be Null	Description
context_id	INT	IN	No	ID of the cursor to be queried.
pos	VARCHAR2	IN	No	Name of the bound parameter.
column_value	ANYARRAY	INOUT	No	Return value.

- DBE_SQL.GET_ARRAY_RESULT_CHAR

  Returns the value of the bound OUT parameter of the CHAR array type and obtains the OUT parameter in a stored procedure.

  The prototype of DBE_SQL.GET_ARRAY_RESULT_CHAR is as follows:

```
DBE_SQL.get_array_result_char(
    context_id   IN    int,
    pos          IN    VARCHAR2,
    column_value INOUT anyarray
);
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 2-367 DBE_SQL.GET_ARRAY_RESULT_CHAR API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
context_id	INT	IN	No	ID of the cursor to be queried.
pos	VARCHAR2	IN	No	Name of the bound parameter.
column_value	ANYARRAY	INOUT	No	Return value.

- DBE_SQL.GET_ARRAY_RESULT_INT

  Returns the value of the bound OUT parameter of the INT array type and obtains the OUT parameter in a stored procedure.

  The prototype of DBE_SQL.GET_ARRAY_RESULT_INT is as follows:

```
DBE_SQL.get_array_result_int(
    context_id   IN    int,
    pos          IN    VARCHAR2,
    column_value INOUT anyarray
);
```

Table 2-368 DBE_SQL.GET_ARRAY_RESULT_INT API parameters

Parameter	Type	Input / Output Parameter	Can Be Null	Description
context_id	INT	IN	No	ID of the cursor to be queried.
pos	VARCHAR2	IN	No	Name of the bound parameter.
column_value	ANYARRAY	INOUT	No	Return value.

Examples

```
-- Example 1
-- Create a table and insert data into the table.

2.12.2.18 DBE_STATS

The advanced package DBE_STATS provides the function of managing statistics information, including locking, unlocking, exporting, importing, setting, and rolling back historical statistics. **Table 2-369** lists APIs supported by DBE_STATS.

NOTE

- DBE_STATS does not support temporary tables.
- The rules for managing DBE_STATS statistics are the same as those for managing existing statistics. Only the functions related to existing statistics in the kernel are supported.
- DBE_STATS and multi-version statistics management do not support the M-compatible mode.
- DBE_STATS does not support the API for deleting statistics.
- The multi-version statistics management function requires that the GUC parameters be consistent on all nodes.
- The values of **stats_history_retention_time** (time for retaining historical statistics) and **stats_history_record_limit** (maximum number of historical statistics records) must be the same for all nodes. If the GUC parameter values are different on different nodes, the historical statistics of the same object on different nodes are inconsistent. During the rollback, the historical statistics of a specified timestamp may not be found on a node, causing the rollback failure.
- After a node is added, if the rollback API is used to specify the timestamp before the scale-out for rollback, the new node reuses the CN metadata. Because the historical statistics are also metadata, the historical statistics of the node are used for rollback.
- Modifying statistics (importing, rolling back, and setting statistics) will invalidate the plan cache. The execution plan in the cache records the version of the statistics on which it depends. If the current statistics version is different from the version recorded in the cached plan, the cached plan is invalid and needs to be regenerated.

APIs

Table 2-369 DBE_STATS

API	Description	Permission Requirement
DBE_STATS.LOCK_TABLE_STATS	Locks table-level statistics.	When using this API, you must have the same permission on the specified table as that of the ANALYZE statement. For permission details, see **ANALYZE | ANALYSE**.
DBE_STATS.LOCK_PARTITION_STATS	Locks partition-level statistics.	
DBE_STATS.LOCK_COLUMN_STATS	Locks column-level statistics.	
DBE_STATS.LOCK_SCHEMA_STATS	Locks statistics about all tables in a specified schema.	• When this API is called, all tables on which the current user has the ANALYZE permission in the schema are locked. Tables on which the current user does not have the ANALYZE permission are skipped. • To call this API, you must have the USAGE permission on the specified schema.
DBE_STATS.UNLOCK_TABLE_STATS	Unlocks table-level statistics.	When using this API, you must have the same permission on the specified table as that of the ANALYZE statement. For permission details, see **ANALYZE | ANALYSE**.
DBE_STATS.UNLOCK_PARTITION_STATS	Unlocks partition-level statistics.	
DBE_STATS.UNLOCK_COLUMN_STATS	Unlocks column-level statistics.	

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

API	Description	Permission Requirement
DBE_STATS.UNLOCK_SCHEMA_STATS	Unlocks statistics about all tables in a specified schema.	• When this API is called, all tables on which the current user has the ANALYZE permission in the schema are unlocked. Tables on which the current user does not have the ANALYZE permission are skipped. • To call this API, you must have the USAGE permission on the specified schema.
DBE_STATS.RESTORE_TABLE_STATS	Rolls back table-level statistics to a specified time point.	When using this API, you must have the same permission on the specified table as that of the ANALYZE statement. For permission details, see ANALYZE | ANALYSE.
DBE_STATS.RESTORE_PARTITION_STATS	Rolls back partition-level statistics to a specified time point.	
DBE_STATS.RESTORE_COLUMN_STATS	Rolls back column-level statistics to a specified time point.	
DBE_STATS.RESTORE_SCHEMA_STATS	Rolls back statistics about all tables in a specified schema to a specified time point.	• When this API is called, all tables on which the current user has the ANALYZE permission in the schema are rolled back. Tables on which the current user does not have the ANALYZE permission are skipped. • To call this API, you must have the USAGE permission on the specified schema.
DBE_STATS.PURGE_STATS	Clears all historical statistics before a specified time point.	Only the initial user can call this API.
DBE_STATS.GET_STATS_HISTORY_RETENTION	Obtains the retention period of historical statistics.	-

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

API	Description	Permission Requirement
DBE_STATS.GET_STATS_HISTORY_AVAILABILITY	Obtains the earliest available time of the current historical statistics.	-
DBE_STATS.CREATE_STAT_TABLE	Creates a statistics table for storing statistics.	To call this procedure to create a statistics table, you must have the permission to create tables and indexes in the specified schema and tablespace.
DBE_STATS.DROP_STAT_TABLE	Deletes a statistics table for storing statistics.	To call this procedure to delete a statistics table, you must have the permission to delete the table and index in the specified schema.
DBE_STATS.EXPORT_INDEX_STATS	Retrieves statistics for the specified index and stores them in the user statistics table.	• When using this API, you must have the same permission on the specified table as that of the ANALYZE statement. For permission details, see ANALYZE | ANALYSE. • To call this procedure to export statistics to a user statistics table, you must have the SELECT, INSERT, DELETE, and UPDATE permissions on the user statistics table.
DBE_STATS.EXPORT_TABLE_STATS	Retrieves statistics for the specified table and stores them in the user statistics table.	
DBE_STATS.EXPORT_COLUMN_STATS	Retrieves statistics for the specified column and stores them in the user statistics table.	
DBE_STATS.EXPORT_SCHEMA_STATS	Retrieves statistics for the specified schema and stores them in the user statistics table.	

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

API	Description	Permission Requirement
DBE_STATS.EXPORT_DATABASE_STATS	Retrieves statistics for the current database and stores them in the user statistics table.	• When this API is called, all tables on which the current user has the ANALYZE permission in the current database are exported. Tables on which the current user does not have the ANALYZE permission are skipped. • To call this procedure to export statistics to a user statistics table, you must have the SELECT, INSERT, DELETE, and UPDATE permissions on the user statistics table.
DBE_STATS.IMPORT_INDEX_STATS	Retrieves statistics for the specified index from the user statistics table and writes it back to the system catalog.	• When using this API, you must have the same permission on the specified table as that of the ANALYZE statement. For permission details, see ANALYZE | ANALYSE. • To call this procedure to import statistics from a user statistics table to a system catalog, you must have the SELECT, INSERT, DELETE, and UPDATE permissions on the user statistics table.
DBE_STATS.IMPORT_TABLE_STATS	Retrieves statistics for the specified table from the user statistics table and writes it back to the system catalog.	
DBE_STATS.IMPORT_COLUMN_STATS	Retrieves statistics for the specified column from the user statistics table and writes it back to the system catalog.	
DBE_STATS.IMPORT_SCHEMA_STATS	Retrieves statistics for the specified schema from the user statistics table and writes it back to the system catalog.	

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

API	Description	Permission Requirement
DBE_STATS.IMPORT_DATABASE_STATS	Retrieves statistics for the specified database from the user statistics table and writes it back to the system catalog.	• When this API is called, all tables on which the current user has the ANALYZE permission in the current database are imported. Tables on which the current user does not have the ANALYZE permission are skipped. • To call this procedure to export statistics to a user statistics table, you must have the SELECT, INSERT, DELETE, and UPDATE permissions on the user statistics table.
DBE_STATS.SET_COLUMN_STATS	Sets column-related statistics, including single-column, multi-column, and expression statistics.	When using this API, you must have the same permission on the specified table as that of the ANALYZE statement. For permission details, see ANALYZE | ANALYSE.
DBE_STATS.SET_INDEX_STATS	Sets index-related statistics.	
DBE_STATS.SET_TABLE_STATS	Sets table-related statistics.	
DBE_STATS.GET_TABLES_BY_SQLID	Obtains all tables involved in the statement corresponding to the unique SQL ID. If multiple tables are involved, multiple rows of records are returned.	When using this function, the user must meet one of the following conditions: • The user is an initial user. • The user has the MONADMIN access permission.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

API	Description	Permission Requirement
DBE_STATS.ANALYZE_SQLID	Obtains all tables involved in the statement corresponding to the unique SQL ID and collects statistics about the tables. If multiple tables are successfully collected, multiple rows of records are returned.	When using this function, the user must meet one of the following conditions: • The user is an initial user. • The user has the MONADMIN access permission and has the same permissions on the corresponding table as the **ANALYZE** command. For permission details, see **ANALYZE | ANALYSE**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

API	Description	Permission Requirement
dbe_stats_tools.py	Exports and imports database-level statistics, and exports the metadata of the statements for which the execution plan is optimized.	• To export statistics, you must have the permission on the corresponding API or command (DBE_STATS.CREATE_STAT_TABLE, DBE_STATS.EXPORT_DATABASE_STATS, \COPY TO or DBE_STATS.DROP_STAT_TABLE) and the read and write permissions on the specified export directory. • To import statistics, you must have the permission on the corresponding API or command (DBE_STATS.CREATE_STAT_TABLE, DBE_STATS.EXPORT_DATABASE_STATS, \COPY FROM or DBE_STATS.DROP_STAT_TABLE) and the read permission on the files in the specified export directory. • To export statement metadata, you must have the system administrator permission on the database and the read and write permissions on the specified directory.

- DBE_STATS.LOCK_TABLE_STATS

  Locks the statistics of a table. After the table is locked, the statistics of the table cannot be updated, and the indexes of the table are locked as well. This API does not return any value.

  The prototype of DBE_STATS.LOCK_TABLE_STATS is as follows:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
DBE_STATS.LOCK_TABLE_STATS(
  ownname   VARCHAR2,
  tabname   VARCHAR2
);
```

Table 2-370 DBE_STATS.LOCK_TABLE_STATS API parameters

Parameter	Type	Can Be Null	Description
ownname	varchar2	Yes	Name of the schema to which the table to be locked belongs. When it is null, the current schema is used by default.
tabname	varchar2	No	Name of the table to be locked.

NOTE

- You can view **stat_state** in **reloptions** of the table to obtain the lock status of the table.
- When a table is locked, its statistics cannot be updated.
- If **ownname** is set to **null**, the current schema is used. In this case, you need to set **behavior_compat_options** to **bind_procedure_searchpath**.

Example:

```
-- Create a table.
gaussdb=# CREATE SCHEMA dbe_stats_lock;
CREATE SCHEMA
gaussdb=# SET CURRENT_SCHEMA=dbe_stats_lock;
SET
gaussdb=# CREATE TABLE t1(a int,b int) distribute by hash(a);
CREATE TABLE

-- Lock the table and check its locking status.
gaussdb=# CALL DBE_STATS.LOCK_TABLE_STATS(ownname=>'dbe_stats_lock',tabname=>'t1');
 lock_table_stats
------------------

(1 row)
gaussdb=# SELECT relname,instr(reloptions::text,'stat_state=locked',1,1) <> 0  AS exist_lock FROM
PG_CLASS WHERE relname='t1' AND relnamespace = (SELECT oid FROM PG_NAMESPACE WHERE
nspname='dbe_stats_lock');
 relname | exist_lock
---------+------------
 t1      | t
(1 row)

-- An error is reported after the ANALYZE operation is performed.
gaussdb=# ANALYZE t1;
ERROR:  The statistics is locked, cannot be updated.

-- Drop the table and namespace.
gaussdb=# DROP TABLE t1;
DROP TABLE
gaussdb=# DROP SCHEMA dbe_stats_lock;
DROP SCHEMA
```

- DBE_STATS.LOCK_PARTITION_STATS

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Locks the statistics of a partition. After the partition is locked, the statistics of the partition cannot be updated, and the indexes of the partition are locked as well. This API does not return any value.

The prototype of DBE_STATS.LOCK_PARTITION_STATS is as follows:

```
DBE_STATS.LOCK_PARTITION_STATS(
   ownname     VARCHAR2,
   tabname     VARCHAR2,
   partname    VARCHAR2
);
```

Table 2-371 DBE_STATS.LOCK_PARTITION_STATS API parameters

Parameter	Type	Can Be Null	Description
ownname	varchar2	Yes	Name of the schema to which the partition to be locked belongs. When it is null, the current schema is used by default.
tabname	varchar2	No	Name of the table to which the partition to be locked belongs.
partname	varchar2	No	Name of the partition to be locked.

NOTE

- You can view **stat_state** in **reloptions** of the partition to obtain the lock status of the table.
- When the partition or the table to which the table belongs is locked, its statistics cannot be updated.
- If **ownname** is set to **null**, the current schema is used. In this case, you need to set **behavior_compat_options** to **bind_procedure_searchpath**.

Example:

```
-- Create a table.
gaussdb=# CREATE SCHEMA dbe_stats_lock;
CREATE SCHEMA
gaussdb=# SET CURRENT_SCHEMA=dbe_stats_lock;
SET
gaussdb=# CREATE TABLE upart_table(a int, b int, c int) distribute by hash(a) PARTITION BY
RANGE(a)
 (
   PARTITION p1 VALUES LESS THAN(1200),
   PARTITION p2 VALUES LESS THAN(2400),
   PARTITION p3 VALUES LESS THAN(MAXVALUE)
 );
CREATE TABLE

-- Lock a partition. Other partitions and tables are not affected.
gaussdb=# CALL
DBE_STATS.LOCK_PARTITION_STATS(ownname=>'dbe_stats_lock',tabname=>'upart_table',partname=>'
p1');
 lock_partition_stats
----------------------

(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gaussdb=# SELECT relname,instr(reloptions::text,'stat_state=locked',1,1) <> 0 AS exist_lock FROM
PG_CLASS WHERE relname='upart_table';
   relname   | exist_lock
-------------+------------
 upart_table | f
(1 row)

gaussdb=# SELECT relname,instr(reloptions::text,'stat_state=locked',1,1) <> 0 AS exist_lock FROM
PG_PARTITION WHERE parentid='upart_table'::REGCLASS ORDER BY oid;
   relname   | exist_lock
-------------+------------
 upart_table | f
 p1          | t
 p2          | f
 p3          | f
(4 rows)
-- Drop the table and namespace.
gaussdb=# DROP TABLE upart_table;
DROP TABLE
gaussdb=# DROP SCHEMA dbe_stats_lock;
DROP SCHEMA
```

- DBE_STATS.LOCK_COLUMN_STATS

  Locks the statistics of a column. After the statistics are locked, they cannot be updated. This API does not return any value.

  The prototype of DBE_STATS.LOCK_COLUMN_STATS is as follows:

```
DBE_STATS.LOCK_COLUMN_STATS(
    ownname     VARCHAR2,
    tabname     VARCHAR2,
    colname     VARCHAR2,
    partname    VARCHAR2 DEFAULT NULL
);
```

Table 2-372 DBE_STATS.LOCK_COLUMN_STATS API parameters

Parameter	Type	Can Be Null	Description
ownname	varchar2	Yes	Name of the schema to which the column to be locked belongs. When it is null, the current schema is used by default.
tabname	varchar2	No	Name of the table to which the column to be locked belongs.
colname	varchar2	No	Name of the column to be locked.
partname	varchar2	Yes	Name of the partition to which the column to be locked belongs. The default value is **NULL**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- If **partname** is **NULL**, the list-level statistics are locked by default.
- If the column-level statistics of the table do not exist, the locking can be executed successfully but does not take effect.
- You can view **stastate** in **PG_STATISTIC** or **PG_STATISTIC_EXT** to obtain the lock status.
- Before locking multiple columns, query the **staextname** column in **PG_STATISTIC_EXT** to obtain the aliases of multiple columns and pass them as the input parameter **colname**.
- If a column is locked or the table or partition to which the column belongs is locked, the statistics cannot be updated. The locked information about the column is not displayed. You need to view the locked information by using logging_module of DBE_STATS at the DEBUG2 level in logs.
- If **ownname** is set to **null**, the current schema is used. In this case, you need to set **behavior_compat_options** to **bind_procedure_searchpath**.

Example:

```
-- Create a table and collect statistics.
gaussdb=# CREATE SCHEMA dbe_stats_lock;
CREATE SCHEMA
gaussdb=# SET CURRENT_SCHEMA=dbe_stats_lock;
SET
gaussdb=# CREATE TABLE t1(a int,b int) distribute by hash(a);
CREATE TABLE
gaussdb=# INSERT INTO t1 VALUES(generate_series(1,100),1);
INSERT 0 100
gaussdb=# ANALYZE t1;
ANALYZE

-- After locking a column, check the locking status of the column.
gaussdb=# CALL
DBE_STATS.LOCK_COLUMN_STATS(ownname=>'dbe_stats_lock',tabname=>'t1',colname=>'a');
 lock_column_stats
-------------------

(1 row)

gaussdb=# SELECT staattnum,stastate FROM PG_STATISTIC WHERE starelid='t1'::REGCLASS ORDER BY
1,2;
 staattnum | stastate
-----------+----------
         1 | l
         2 | u
(2 rows)

-- Drop the table and namespace.
gaussdb=# DROP TABLE t1;
DROP TABLE
gaussdb=# DROP SCHEMA dbe_stats_lock;
DROP SCHEMA
```

- DBE_STATS.LOCK_SCHEMA_STATS

  Locks statistics about all tables and their indexes in a specified schema. This API does not return any value.

  The prototype of DBE_STATS.LOCK_SCHEMA_STATS is as follows:

```
DBE_STATS.LOCK_SCHEMA_STATS(
   ownname    VARCHAR2
);
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 2-373 DBE_STATS.LOCK_SCHEMA_STATS API parameters

Parameter	Type	Can Be Null	Description
ownname	varchar2	Yes	Name of the specified schema. When it is null, the current schema is used by default.

NOTE

If **ownname** is set to **null**, the current schema is used. In this case, you need to set **behavior_compat_options** to **bind_procedure_searchpath**.

Example:

```
gaussdb=# DROP SCHEMA IF EXISTS dbe_stats_lock_schema CASCADE;
NOTICE:  schema "dbe_stats_lock_schema" does not exist, skipping
DROP SCHEMA
gaussdb=# -- Create a table.
gaussdb=# CREATE SCHEMA dbe_stats_lock_schema;
CREATE SCHEMA
gaussdb=# SET CURRENT_SCHEMA = dbe_stats_lock_schema;
SET
gaussdb=# CREATE TABLE t1(a int, b int) distribute by hash(a);
CREATE TABLE
gaussdb=# CREATE TABLE t2(a int, b int) distribute by hash(a);
CREATE TABLE
gaussdb=# -- Lock the schema.
gaussdb=# CALL DBE_STATS.LOCK_SCHEMA_STATS(ownname=>'dbe_stats_lock_schema');
 lock_schema_stats
-------------------

(1 row)

gaussdb=# -- Verification: Both t1 and t2 should be locked (exist_lock set to t).
gaussdb=# SELECT relname, instr(reloptions::text,'stat_state=locked',1,1) <> 0 AS exist_lock
gaussdb-# FROM PG_CLASS
gaussdb-# WHERE relname IN ('t1','t2')

gaussdb=# DROP SCHEMA dbe_stats_lock_schema;
DROP SCHEMA
```

- DBE_STATS.UNLOCK_TABLE_STATS

  Unlocks the statistics of a table. After the statistics are unlocked, they can be updated. The indexes of the table will be unlocked as well. This API does not return any value.

  The prototype of DBE_STATS.UNLOCK_TABLE_STATS is as follows:

```
DBE_STATS.UNLOCK_TABLE_STATS(
   ownname   VARCHAR2,
   tabname   VARCHAR2
);
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 2-374 DBE_STATS.UNLOCK_TABLE_STATS API parameters

Parameter	Type	Can Be Null	Description
ownname	varchar2	Yes	Name of the schema to which the table to be unlocked belongs. When it is null, the current schema is used by default.
tabname	varchar2	No	Name of the table to be unlocked.

NOTE

- You can view **stat_state** in **reloptions** of the table to obtain the lock status of the table.
- If **ownname** is set to **null**, the current schema is used. In this case, you need to set **behavior_compat_options** to **bind_procedure_searchpath**.

Example:

```
gaussdb=# DROP SCHEMA IF EXISTS dbe_stats_lock_unlock_table CASCADE;
NOTICE:  schema "dbe_stats_lock_unlock_table" does not exist, skipping
DROP SCHEMA
gaussdb=# -- Create a table.
gaussdb=# CREATE SCHEMA dbe_stats_lock_unlock_table;
CREATE SCHEMA
gaussdb=# SET CURRENT_SCHEMA = dbe_stats_lock_unlock_table;
SET
gaussdb=# CREATE TABLE t1(a int, b int) distribute by hash(a);

gaussdb=# DROP SCHEMA dbe_stats_lock_unlock_table;
DROP SCHEMA
```

- DBE_STATS.UNLOCK_PARTITION_STATS

  Unlocks the statistics of a partition. After the partition is unlocked, the statistics of the partition can be updated. The indexes of the partition are unlocked as well. This API does not return any value.

  The prototype of DBE_STATS.UNLOCK_PARTITION_STATS is as follows:

```
DBE_STATS.UNLOCK_PARTITION_STATS(
   ownname     VARCHAR2,
   tabname     VARCHAR2,
   partname    VARCHAR2
);
```

Table 2-375 DBE_STATS.UNLOCK_PARTITION_STATS API parameters

Parameter	Type	Can Be Null	Description
ownname	varchar2	Yes	Name of the schema to which the partition to be unlocked belongs. When it is null, the current schema is used by default.
tabname	varchar2	No	Name of the table to which the partition to be unlocked belongs.
partname	varchar2	No	Name of the partition to be unlocked.

NOTE

- You can view **stat_state** in **reloptions** of the partition to obtain the lock status of the table.
- If **ownname** is set to **null**, the current schema is used. In this case, you need to set **behavior_compat_options** to **bind_procedure_searchpath**.

Example:

```
gaussdb=# DROP SCHEMA IF EXISTS dbe_stats_lock_unlock_partition CASCADE;
NOTICE:  schema "dbe_stats_lock_unlock_partition" does not exist, skipping
DROP SCHEMA
gaussdb=# -- Create a partitioned table.
gaussdb=# CREATE SCHEMA dbe_stats_lock_unlock_partition;
CREATE SCHEMA
gaussdb=# SET CURRENT_SCHEMA = dbe_stats_lock_unlock_partition;
SET
gaussdb=# CREATE TABLE upart_table(a int, b int, c int) distribute by hash(a) PARTITION BY
RANGE(a)
gaussdb-# (
gaussdb(#     PARTITION p1 VALUES LESS THAN(1200),

```

- DBE_STATS.UNLOCK_COLUMN_STATS

  Unlocks the statistics of a column. After the column is unlocked, the statistics of the column can be updated. This API does not return any value.

  The prototype of DBE_STATS.UNLOCK_COLUMN_STATS is as follows:

```
DBE_STATS.UNLOCK_COLUMN_STATS(
   ownname     VARCHAR2,
   tabname     VARCHAR2,
   colname     VARCHAR2,
   partname    VARCHAR2 DEFAULT NULL
);
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 2-376 DBE_STATS.UNLOCK_COLUMN_STATS API parameters

Parameter	Type	Can Be Null	Description
ownname	varchar2	Yes	Name of the schema to which the column to be unlocked belongs. When it is null, the current schema is used by default.
tabname	varchar2	No	Name of the table to which the column to be unlocked belongs.
colname	varchar2	No	Name of the column to be unlocked.
partname	varchar2	Yes	Name of the partition to which the column to be unlocked belongs. The default value is **NULL**.

NOTE

- If **partname** is **NULL**, the list-level statistics and column-level statistics of the cascaded partition are unlocked by default.
- You can view **stastate** in **PG_STATISTIC** or **PG_STATISTIC_EXT** to obtain the lock status.
- Before unlocking multiple columns, query the **staextname** column in **PG_STATISTIC_EXT** to obtain the aliases of multiple columns and pass them as the input parameter **colname**.
- If **ownname** is set to **null**, the current schema is used. In this case, you need to set **behavior_compat_options** to **bind_procedure_searchpath**.

Example:

```
gaussdb=# DROP SCHEMA IF EXISTS dbe_stats_lock_unlock_column CASCADE;

```

- DBE_STATS.RESTORE_TABLE_STATS

  Rolls back table statistics to a specified time point. The last statistics collected before the time point are loaded to the system catalog, and the statistics of the lower-level partitions, indexes, and columns that are not locked are cascaded. This API does not return any value.

  The prototype of DBE_STATS.RESTORE_TABLE_STATS is as follows:

```
DBE_STATS.RESTORE_TABLE_STATS(
   ownname                 VARCHAR2,
   tabname                 VARCHAR2,
   as_of_timestamp         TIMESTAMPTZ,
   restore_cluster_index   BOOLEAN DEFAULT NULL,
   force                   BOOLEAN DEFAULT FALSE,
   no_invalidate           BOOLEAN DEFAULT NULL
);
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 2-378 DBE_STATS.RESTORE_TABLE_STATS API parameters

Parameter	Type	Can Be Null	Description
ownname	VARCHAR2	Yes	Name of the schema to which the table to be rolled back belongs. When it is null, the current schema is used by default.
tabname	VARCHAR2	No	Name of the table to be rolled back.
as_of_timestamp	timestamp with time zone	No	Target time point to be rolled back.
restore_cluster_index	BOOLEAN	Yes	Not supported currently.
force	BOOLEAN	Yes	Determines whether to forcibly roll back the statistics when the statistics are locked. The default value is **false**.
no_invalidate	BOOLEAN	Yes	Not supported currently.

NOTE

- When this API is called, the statistics of its lower-level partitions, indexes, and columns are rolled back as well. If the lower-level partitions or columns are locked, the statistics are skipped.
- If **ownname** is set to **null**, the current schema is used. In this case, you need to set **behavior_compat_options** to **bind_procedure_searchpath**.

Example:

```
gaussdb=# DROP SCHEMA IF EXISTS dbe_stats_restore_table CASCADE;

- DBE_STATS.RESTORE_PARTITION_STATS

  Rolls back partition statistics to a specified time point. The last statistics collected before the time point are loaded to the system catalog, and the statistics of the lower-level partitions, indexes, and columns that are not locked are cascaded. This API does not return any value.

  The prototype of DBE_STATS.RESTORE_PARTITION_STATS is as follows:

```
DBE_STATS.RESTORE_PARTITION_STATS(
    ownname                 VARCHAR2,
    tabname                 VARCHAR2,
    partname                VARCHAR2,
    as_of_timestamp           TIMESTAMPTZ,
    force                   BOOLEAN DEFAULT FALSE,
    no_invalidate           BOOLEAN DEFAULT NULL
);
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 2-379 DBE_STATS.RESTORE_PARTITION_STATS API parameters

Parameter	Type	Can Be Null	Description
ownname	VARCHAR2	Yes	Name of the schema to which the partition to be rolled back belongs.
tabname	VARCHAR2	No	Name of the table to which the partition to be rolled back belongs.
partname	VARCHAR2	No	Name of the partition to be rolled back.
as_of_timestamp	timestamp with time zone	No	Target time point to be rolled back.
force	BOOLEAN	Yes	Determines whether to forcibly roll back the statistics when the statistics are locked.
no_invalidate	BOOLEAN	Yes	Not supported currently.

NOTE

- When this API is called, the statistics of its lower-level partitions, indexes, and columns are rolled back.
- If **ownname** is set to **null**, the current schema is used. In this case, you need to set **behavior_compat_options** to **bind_procedure_searchpath**.

Example:

```
gaussdb=# DROP SCHEMA IF EXISTS dbe_stats_restore_partition CASCADE;
NOTICE:  schema "dbe_stats_restore_partition" does not exist, skipping
DROP SCHEMA
gaussdb=# -- Create a partitioned table and collect partition statistics twice.
gaussdb=# CREATE SCHEMA dbe_stats_restore_partition;

DROP SCHEMA
```

- DBE_STATS.RESTORE_COLUMN_STATS

  Rolls back the column statistics to a specified time point. The last statistics collected before the time point to the system catalog are loaded. This API does not return any value.

  The prototype of DBE_STATS.RESTORE_COLUMN_STATS is as follows:

```
DBE_STATS.RESTORE_COLUMN_STATS(
    ownname                 VARCHAR2,
    tabname                 VARCHAR2,
    colname                 VARCHAR2,
    partname                VARCHAR2 DEFAULT NULL,
    as_of_timestamp           TIMESTAMPTZ,
    force                   BOOLEAN DEFAULT FALSE,
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
    no_invalidate           BOOLEAN DEFAULT NULL
);
```

Table 2-380 DBE_STATS.RESTORE_COLUMN_STATS API parameters

Parameter	Type	Can Be Null	Description
ownname	VARCHAR2	Yes	Name of the schema to which the column to be rolled back belongs.
tabname	VARCHAR2	No	Name of the table to which the column to be rolled back belongs.
colname	VARCHAR2	No	Name of the column to be rolled back.
partname	VARCHAR2	Yes	Name of the partition to which the column to be rolled back belongs.
as_of_timestamp	timestamp with time zone	No	Target time point to be rolled back.
force	BOOLEAN	Yes	Determines whether to forcibly roll back the statistics when the statistics are locked.
no_invalidate	BOOLEAN	Yes	Not supported currently.

NOTE

- If **partname** is **NULL**, the list-level statistics are rolled back by default.
- Before rolling back multiple columns, query the **staextname** column in **PG_STATISTIC_EXT** to obtain the aliases of multiple columns and pass them as the input parameter **colname**.
- If **ownname** is set to **null**, the current schema is used. In this case, you need to set **behavior_compat_options** to **bind_procedure_searchpath**.

Example:

```
gaussdb=# DROP SCHEMA IF EXISTS dbe_stats_restore_column CASCADE;
NOTICE:  schema "dbe_stats_restore_column" does not exist, skipping
DROP SCHEMA
gaussdb=# -- Create a table and collect statistics twice.

```

- DBE_STATS.RESTORE_SCHEMA_STATS

  Rolls back statistics of all tables in a specified schema to a specified time point. This API does not return any value.

  The prototype of DBE_STATS.RESTORE_SCHEMA_STATS is as follows:

```
DBE_STATS.RESTORE_SCHEMA_STATS(
   ownname                VARCHAR2,
   as_of_timestamp          TIMESTAMPTZ,
   force                BOOLEAN DEFAULT FALSE,
   no_invalidate            BOOLEAN DEFAULT NULL
);
```

Table 2-381 DBE_STATS.RESTORE_SCHEMA_STATS API parameters

Parameter	Type	Can Be Null	Description
ownname	VARCHAR2	Yes	Specified schema name.
as_of_timestamp	timestamp with time zone	No	Target time point to be rolled back.
force	BOOLEAN	Yes	Determines whether to forcibly roll back the statistics when the statistics are locked.
no_invalidate	BOOLEAN	Yes	Not supported currently.

NOTE

If **ownname** is set to **null**, the current schema is used. In this case, you need to set **behavior_compat_options** to **bind_procedure_searchpath**.

Example:

```
gaussdb=# DROP SCHEMA IF EXISTS dbe_stats_restore_schema CASCADE;
NOTICE:  schema "dbe_stats_restore_schema" does not exist, skipping
DROP SCHEMA
gaussdb=# -- Create a table, insert data, and collect statistics twice.
gaussdb=# CREATE SCHEMA dbe_stats_restore_schema;
CREATE SCHEMA
gaussdb=# SET CURRENT_SCHEMA = dbe_stats_restore_schema;

gaussdb=# DROP SCHEMA dbe_stats_restore_schema;
DROP SCHEMA
```

- DBE_STATS.PURGE_STATS

  Clears all historical statistics before a specified time point. This API does not return any value.

  The prototype of DBE_STATS.PURGE_STATS is as follows:

  ```
  DBE_STATS.PURGE_STATS(
     before_timestamp       TIMESTAMPTZ
  );
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 2-382 DBE_STATS.PURGE_STATS API parameters

Parameter	Type	Can Be Null	Description
before_timestamp	timestamp with time zone	No	Time node for clearing.

Example:

```
-- Create a table and collect statistics twice.
gaussdb=# CREATE SCHEMA dbe_stats_purge;
CREATE SCHEMA
gaussdb=# SET CURRENT_SCHEMA=dbe_stats_purge;
SET
gaussdb=# CREATE TABLE t1(a int, b int) distribute by replication;
CREATE TABLE
gaussdb=# INSERT INTO t1 VALUES(1,1);
INSERT 0 1
gaussdb=# INSERT INTO t1 VALUES(1,1);
INSERT 0 1
gaussdb=# INSERT INTO t1 VALUES(1,1);
INSERT 0 1
gaussdb=# ANALYZE t1;
ANALYZE
gaussdb=# INSERT INTO t1 VALUES(2,2);
INSERT 0 1
gaussdb=# INSERT INTO t1 VALUES(2,2);
INSERT 0 1
gaussdb=# INSERT INTO t1 VALUES(2,2);
INSERT 0 1
gaussdb=# ANALYZE t1;
ANALYZE

-- View history tables.
gaussdb=# SELECT relname,reltuples FROM GS_TABLESTATS_HISTORY WHERE relname='t1' ORDER
BY 1,2;
 relname | reltuples
---------+-----------
 t1      |         3
 t1      |         6
(2 rows)

-- Clear the earlier history statistics and view the history table.
gaussdb=# CALL DBE_STATS.PURGE_STATS(before_timestamp=>((SELECT MIN(reltimestamp) FROM
GS_TABLESTATS_HISTORY WHERE relname='t1') + INTERVAL '1 second'));
 purge_stats
-------------

(1 row)

gaussdb=# SELECT relname,reltuples FROM GS_TABLESTATS_HISTORY WHERE relname='t1';
 relname | reltuples
---------+-----------
 t1      |         6
(1 row)

-- Drop the table and namespace.
gaussdb=# DROP TABLE t1;
DROP TABLE
gaussdb=# DROP SCHEMA dbe_stats_purge;
DROP SCHEMA
```

- DBE_STATS.GET_STATS_HISTORY_RETENTION

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Obtains the retention time of historical statistics. The return value is the value of the GUC parameter **stats_history_retention_time**, indicating the retention time of historical statistics. This API does not have input parameters.

The prototype of DBE_STATS.GET_STATS_HISTORY_RETENTION is as follows:

```
DBE_STATS.GET_STATS_HISTORY_RETENTION()
returns NUMBER;
```

Example:

```
gaussdb=# CALL DBE_STATS.GET_STATS_HISTORY_RETENTION();
 get_stats_history_retention
-----------------------------
                          31
(1 row)
```

- DBE_STATS.GET_STATS_HISTORY_AVAILABILITY

  Obtains the earliest available time of the current historical statistics. The earliest time of all historical statistics in the current database is returned. This API does not have input parameters.

  The prototype of DBE_STATS.GET_STATS_HISTORY_AVAILABILITY is as follows:

```
DBE_STATS.GET_STATS_HISTORY_AVAILABILITY()
returns TIMESTAMPTZ;
```

  Example:

```
gaussdb=# ANALYZE;
ANALYZE
gaussdb=# CALL DBE_STATS.GET_STATS_HISTORY_AVAILABILITY();
 get_stats_history_availability
--------------------------------
 2025-05-07 05:11:43.584349-04
(1 row)
```

  NOTE

  The DBE_STATS advanced package API is valid only for ordinary tables.

- DBE_STATS.CREATE_STAT_TABLE

  Creates a statistics table for storing user statistics. This API does not return any value.

  The prototype of DBE_STATS.CREATE_STAT_TABLE is as follows:

```
DBE_STATS.CREATE_STAT_TABLE (
   ownname          VARCHAR2,
   stattab          VARCHAR2,
   tblspace         VARCHAR2 DEFAULT NULL,
   global_temporary BOOLEAN DEFAULT NULL
);
```

Table 2-383 DBE_STATS.CREATE_STAT_TABLE API parameters

Parameter	Type	Can Be Null	Description
ownname	VARCHAR2	No	Schema where the created statistics table is located. When it is null, the current schema is used by default.
stattab	VARCHAR2	No	Name of a statistics table.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Type	Can Be Null	Description
tblspace	VARCHAR2	Yes	Tablespace where the created statistics table is located. If not specified, the default tablespace is used.
global_temporary	BOOLEAN	Yes	Not supported currently.

NOTE

- To distinguish ordinary tables from statistics tables, the **statstable** column in **reloptions** of a statistics table is not an empty string after the statistics table is created. Considering that the structure of the statistics table may be upgraded in the future, to implement compatibility with earlier versions, **statstable** is assigned the version information of the current statistics table.
- When this table is created, the **gs_stattab_***<name_hash_value>***_statid_type_nameinfo_index** index is automatically generated for index scan. *<name_hash_value>* indicates the hash value of the statistics table name. If the index is deleted, the export and import APIs are unavailable.
- If **ownname** is set to **null**, the current schema is used. In this case, you need to set **behavior_compat_options** to **bind_procedure_searchpath**.

Example:

```
-- Create a stattab statistics table in dbe_stats_create_drop_schema and manually insert a data record. You can query the data record in the new user statistics table.
gaussdb=# CREATE SCHEMA dbe_stats_create_drop_schema;
CREATE SCHEMA
gaussdb=# SET CURRENT_SCHEMA = dbe_stats_create_drop_schema;
SET
gaussdb=# CALL DBE_STATS.CREATE_STAT_TABLE(ownname => 'dbe_stats_create_drop_schema', stattab => 'stat_tab');
 create_stat_table
-------------------

(1 row)
gaussdb=# INSERT INTO stat_tab(nodeid, statid, type, relname) VALUES(0, '123', 't', 't1');
INSERT 0 1
gaussdb=# SELECT statid, type, relname FROM stat_tab;
 statid | type | relname
--------+------+---------
 123    | t    | t1
(1 row)
```

- DBE_STATS.DROP_STAT_TABLE

  Deletes the user statistics table. This API does not return any value.

  The prototype of DBE_STATS.DROP_STAT_TABLE is as follows:

```
DBE_STATS.DROP_STAT_TABLE (
   ownname VARCHAR2,
   stattab VARCHAR2
);
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 2-384 DBE_STATS.DROP_STAT_TABLE API parameters

Parameter	Type	Can Be Null	Description
ownname	VARCHAR2	No	Schema where the statistics table is located. When it is null, the current schema is used by default.
stattab	VARCHAR2	No	Name of a statistics table.

NOTE

- Ordinary tables whose **statstable** attribute is empty cannot be deleted using this function.
- If an index is created on the user statistics table or other objects that depend on the table are created, all objects that depend on the table are deleted when this function is called.
- If **ownname** is set to **null**, the current schema is used. In this case, you need to set **behavior_compat_options** to **bind_procedure_searchpath**.

Example:

```
-- Delete the created user statistics table and the new schema.
gaussdb=# CALL DBE_STATS.DROP_STAT_TABLE(ownname => 'dbe_stats_create_drop_schema',
stattab => 'stat_tab');
 drop_stat_table
-----------------
(1 row)
gaussdb=# DROP SCHEMA dbe_stats_create_drop_schema CASCADE;
DROP SCHEMA
```

- DBE_STATS.EXPORT_INDEX_STATS

  Searches the system catalog for the statistics of the specified index and stores the result in the user statistics table. This API does not return any value.

  The prototype of DBE_STATS.EXPORT_INDEX_STATS is as follows:

```
DBE_STATS.EXPORT_INDEX_STATS (
   ownname  VARCHAR2,
   indname  VARCHAR2,
   partname VARCHAR2 DEFAULT NULL,
   stattab  VARCHAR2,
   statid   VARCHAR2 DEFAULT NULL,
   statown  VARCHAR2 DEFAULT NULL
);
```

Table 2-385 DBE_STATS.EXPORT_INDEX_STATS API parameters

Parameter	Type	Can Be Null	Description
ownname	VARCHAR2	No	Name of the schema where the index is located. When it is null, the current schema is used by default.
indname	VARCHAR2	No	Name of the index whose statistics are to be exported.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Type	Can Be Null	Description
partname	VARCHAR2	Yes	Name of a partitioned index. If the index has been partitioned but **partname** is **null**, global and partitioned index statistics are exported.
stattab	VARCHAR2	No	Name of the user table that stores statistics.
statid	VARCHAR2	Yes	(Optional) Identifier that points to statistics in **stattab**.
statown	VARCHAR2	Yes	Name of the schema where the user table that stores statistics is located. If this parameter is set to **null**, the value of **ownname** is used.

NOTE

- You need to export the reltuples (numrows), relpages (numlblks), and relallvisible (relallvisible) statistics of indexes.
- If **ownname** is set to **null**, the current schema is used. In this case, you need to set **behavior_compat_options** to **bind_procedure_searchpath**.

Example:

```
-- Create a table and collect statistics.
gaussdb=# CREATE SCHEMA dbe_stats_export;
CREATE SCHEMA
gaussdb=# SET CURRENT_SCHEMA = dbe_stats_export;
SET
gaussdb=# CREATE TABLE t2(a int, b int, c int) distribute by replication PARTITION BY RANGE(a)

- DBE_STATS.EXPORT_TABLE_STATS

  Retrieves statistics for the specified table and stores them in the user statistics table. This API does not return any value.

  The prototype of DBE_STATS.EXPORT_TABLE_STATS is as follows:

```
DBE_STATS.EXPORT_TABLE_STATS (
  ownname          VARCHAR2,
  tabname          VARCHAR2,
  partname         VARCHAR2 DEFAULT NULL,
  stattab          VARCHAR2,
  statid           VARCHAR2 DEFAULT NULL,
  cascade          BOOLEAN  DEFAULT TRUE,
  statown          VARCHAR2 DEFAULT NULL,
  stat_category    VARCHAR2 DEFAULT NULL
);
```

Table 2-386 DBE_STATS.EXPORT_TABLE_STATS API parameters

Parameter	Type	Can Be Null	Description
ownname	VARCHAR2	No	Name of the schema. When it is null, the current schema is used by default.
tabname	VARCHAR2	No	Name of the table whose statistics are to be exported.
partname	VARCHAR2	Yes	Table partition name. If the table has been partitioned but **partname** is **null**, global and partitioned table statistics are exported.
stattab	VARCHAR2	No	Name of the user table that stores statistics.
statid	VARCHAR2	Yes	(Optional) Identifier that points to statistics in **stattab**.
cascade	BOOLEAN	Yes	Specifies whether to export statistics about columns, indexes, multiple columns, and index expressions. The default value is **TRUE**.
statown	VARCHAR2	Yes	Name of the schema where the user table that stores statistics is located. If this parameter is set to **null**, the value of **ownname** is used.
stat_category	VARCHAR2	Yes	Not supported currently.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- You need to export the reltuples (numrows), relpages (numblks), and relallvisible (relallvisible) statistics of tables. For details about how to export column-level and index-level statistics in cascading mode, see the statistics of the **EXPORT_INDEX_STATS** and **EXPORT_COLUMN_STATS** APIs.
- If **ownname** is set to **null**, the current schema is used. In this case, you need to set **behavior_compat_options** to **bind_procedure_searchpath**.

Example:

```
gaussdb=# DROP SCHEMA IF EXISTS dbe_stats_export_table CASCADE;
NOTICE:  schema "dbe_stats_export_table" does not exist, skipping
DROP SCHEMA
gaussdb=# -- Create a table and collect statistics.
gaussdb=# CREATE SCHEMA dbe_stats_export_table;
CREATE SCHEMA
gaussdb=# SET CURRENT_SCHEMA = dbe_stats_export_table;
SET
gaussdb=# CREATE TABLE t1(a int, b int, c int) distribute by replication;
CREATE TABLE
gaussdb=# INSERT INTO t1 VALUES (100, 300, 1);
INSERT 0 1
gaussdb=# INSERT INTO t1 VALUES (150, 550, 1);
INSERT 0 1
gaussdb=# INSERT INTO t1 VALUES (250, 150, 1);
INSERT 0 1
gaussdb=# ANALYZE t1;

gaussdb=# DROP SCHEMA dbe_stats_export_table;
DROP SCHEMA
```

- DBE_STATS.EXPORT_COLUMN_STATS

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Retrieves statistics for the specified columns (multiple columns or expressions) and stores them in the user statistics table. This API does not return any value.

The prototype of DBE_STATS.EXPORT_COLUMN_STATS is as follows:

```
DBE_STATS.EXPORT_COLUMN_STATS (
   ownname  VARCHAR2,
   tabname  VARCHAR2,
   colname  VARCHAR2,
   partname VARCHAR2 DEFAULT NULL,
   stattab  VARCHAR2,
   statid   VARCHAR2 DEFAULT NULL,
   statown  VARCHAR2 DEFAULT NULL
);
```

Table 2-387 DBE_STATS.EXPORT_COLUMN_STATS API parameters

Parameter	Type	Can Be Null	Description
ownname	VARCHAR2	No	Name of the schema. When it is null, the current schema is used by default.
tabname	VARCHAR2	No	Name of the table (index name corresponding to the expression) to which the column whose statistics are to be exported belongs.
colname	VARCHAR2	No	Column name or multiple column names (If tabname is an index, **colname** is an expression name.)
partname	VARCHAR2	Yes	Partition name. If the table or index has been partitioned but **partname** is **null**, global and partitioned key, multiple columns, and index statistics are exported.
stattab	VARCHAR2	No	Name of the user table that stores statistics.
statid	VARCHAR2	Yes	(Optional) Identifier that points to statistics in **stattab**.
statown	VARCHAR2	Yes	Name of the schema where the user table that stores statistics is located. If this parameter is set to **null**, the value of **ownname** is used.

NOTE

- You can query **PG_STATISTIC** or **PG_STATISTIC_EXT** to export column-level statistics.
- Before exporting the statistics of multiple columns, query the **staextname** column in **PG_STATISTIC_EXT** to obtain the aliases of multiple columns and pass them as the input parameter **colname**.
- If **ownname** is set to **null**, the current schema is used. In this case, you need to set **behavior_compat_options** to **bind_procedure_searchpath**.

- DBE_STATS.EXPORT_SCHEMA_STATS

  Retrieves statistics for the specified schema and stores them in the user statistics table. This API does not return any value.

  The prototype of DBE_STATS.EXPORT_SCHEMA_STATS is as follows:

```
DBE_STATS.EXPORT_SCHEMA_STATS (
   ownname         VARCHAR2,
   stattab         VARCHAR2,
   statid          VARCHAR2 DEFAULT NULL,
   statown         VARCHAR2 DEFAULT NULL,
   stat_category   VARCHAR2 DEFAULT NULL
);
```

Table 2-388 DBE_STATS.EXPORT_SCHEMA_STATS API parameters

Parameter	Type	Can Be Null	Description
ownname	VARCHAR2	No	Name of the schema. When it is null, the current schema is used by default.
stattab	VARCHAR2	No	Name of the user table that stores statistics.
statid	VARCHAR2	Yes	(Optional) Identifier that points to statistics in **stattab**.
statown	VARCHAR2	Yes	Name of the schema where the user table that stores statistics is located. If this parameter is set to **null**, the value of **ownname** is used.
stat_category	VARCHAR2	Yes	Not supported currently.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- You need to export statistics about all tables on which the current user has permission in the specified schema. Tables on which the current user does not have permission are skipped and no error is reported.
- If **ownname** is set to **null**, the current schema is used. In this case, you need to set **behavior_compat_options** to **bind_procedure_searchpath**.

Example:

```
gaussdb=# DROP SCHEMA IF EXISTS dbe_stats_export_schema CASCADE;
NOTICE:  schema "dbe_stats_export_schema" does not exist, skipping
DROP SCHEMA
gaussdb=# -- Create a table and collect statistics.
gaussdb=# CREATE SCHEMA dbe_stats_export_schema;
CREATE SCHEMA
gaussdb=# SET CURRENT_SCHEMA = dbe_stats_export_schema;
SET
gaussdb=# CREATE TABLE t1(a int, b int) distribute by replication;
CREATE TABLE
gaussdb=# INSERT INTO t1 VALUES (1,1);
INSERT 0 1
gaussdb=# INSERT INTO t1 VALUES (2,2);
INSERT 0 1
gaussdb=# ANALYZE t1;
ANALYZE
gaussdb=# -- Create a user statistics table.
gaussdb=# CALL DBE_STATS.CREATE_STAT_TABLE('dbe_stats_export_schema', 'export_table');
 create_stat_table
-------------------

(1 row)

gaussdb=# -- Export schema statistics.
gaussdb=# CALL DBE_STATS.EXPORT_SCHEMA_STATS(
gaussdb(#     ownname => 'dbe_stats_export_schema',
gaussdb(#     stattab => 'export_table',

```

- DBE_STATS.EXPORT_DATABASE_STATS

  Retrieves statistics for the specified database and stores them in the user statistics table. This API does not return any value.

  The prototype of DBE_STATS.EXPORT_DATABASE_STATS is as follows:

```
DBE_STATS.EXPORT_DATABASE_STATS (
   stattab         VARCHAR2,
   statid          VARCHAR2 DEFAULT NULL,
   statown          VARCHAR2 DEFAULT NULL,
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
  stat_category   VARCHAR2 DEFAULT NULL
);
```

Table 2-389 DBE_STATS.EXPORT_DATABASE_STATS API parameters

Parameter	Type	Can Be Null	Description
stattab	VARCHAR2	No	Name of the user table that stores statistics.
statid	VARCHAR2	Yes	(Optional) Identifier that points to statistics in **stattab**.
statown	VARCHAR2	Yes	Name of the schema where the user table that stores statistics is located. If this parameter is set to **null**, the current schema is used.
stat_category	VARCHAR2	Yes	Not supported currently.

NOTE

- You can export statistics about all tables on which the current user has the ANALYZE permission in the current database. Tables on which the current user does not have permission are skipped and no error is reported.
- If **statown** is set to **null**, the current schema is used. In this case, you need to set **behavior_compat_options** to **bind_procedure_searchpath**.

Example:

```
gaussdb=# DROP SCHEMA IF EXISTS dbe_stats_export_database CASCADE;
NOTICE:  schema "dbe_stats_export_database" does not exist, skipping
DROP SCHEMA
gaussdb=# -- Create a table and collect statistics.
gaussdb=# CREATE SCHEMA dbe_stats_export_database;
CREATE SCHEMA
gaussdb=# SET CURRENT_SCHEMA = dbe_stats_export_database;

```

- DBE_STATS.IMPORT_INDEX_STATS

  Retrieves statistics for the specified index from the user statistics table of the **stattab** identifier and writes it back to the system catalog. This API does not return any value.

  The prototype of DBE_STATS.IMPORT_INDEX_STATS is as follows:

```
DBE_STATS.IMPORT_INDEX_STATS (
   ownname       VARCHAR2,
   indname       VARCHAR2,
   partname      VARCHAR2 DEFAULT NULL,
   stattab       VARCHAR2,
   statid        VARCHAR2 DEFAULT NULL,
   statown       VARCHAR2 DEFAULT NULL,
   no_invalidate BOOLEAN DEFAULT NULL,
   force         BOOLEAN DEFAULT FALSE
);
```

Table 2-390 DBE_STATS.IMPORT_INDEX_STATS API parameters

Parameter	Type	Can Be Null	Description
ownname	VARCHAR2	No	Name of the schema. When it is null, the current schema is used by default.
indname	VARCHAR2	No	Name of the index whose statistics are to be imported.
partname	VARCHAR2	Yes	Name of the index partition. If the index has been partitioned but **partname** is **null**, global and partitioned index statistics are imported.
stattab	VARCHAR2	No	Name of the user table that stores statistics.
statid	VARCHAR2	Yes	(Optional) Identifier that points to statistics in **stattab**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Type	Can Be Null	Description
statown	VARCHAR2	Yes	Name of the schema where the user table that stores statistics is located. If this parameter is set to **null**, the value of **ownname** is used.
no_invalidate	BOOLEAN	Yes	Not supported currently.
force	BOOLEAN	Yes	Specifies whether to forcibly import data. The lock status is ignored. The default value is **false**.

NOTE

- You need to import the reltuples (numrows), relpages (numlblks), and relallvisible (relallvisible) statistics of indexes.
- If **ownname** is set to **null**, the current schema is used. In this case, you need to set **behavior_compat_options** to **bind_procedure_searchpath**.

Example:

```
-- Create a table and collect statistics.
gaussdb=# CREATE SCHEMA dbe_stats_import;
CREATE SCHEMA
gaussdb=# SET CURRENT_SCHEMA = dbe_stats_import;
SET
gaussdb=# CREATE TABLE t2(a int, b int, c int)distribute by replication PARTITION BY RANGE(a)

- DBE_STATS.IMPORT_TABLE_STATS

  Retrieves statistics for the specified table from the user statistics table of the **stattab** identifier and writes it back to the system catalog. This API does not return any value.

  The prototype of DBE_STATS.IMPORT_TABLE_STATS is as follows:

```
DBE_STATS.IMPORT_TABLE_STATS (
   ownname        VARCHAR2,
   tabname        VARCHAR2,
   partname       VARCHAR2 DEFAULT NULL,
   stattab        VARCHAR2,
   statid         VARCHAR2 DEFAULT NULL,
   cascade        BOOLEAN  DEFAULT TRUE,
   statown        VARCHAR2 DEFAULT NULL,
   no_invalidate BOOLEAN  DEFAULT NULL,
   force          BOOLEAN  DEFAULT FALSE,
   stat_category VARCHAR2 DEFAULT NULL
);
```

Table 2-391 DBE_STATS.IMPORT_TABLE_STATS API parameters

Parameter	Type	Can Be Null	Description
ownname	varchar2	No	Name of the schema. When it is null, the current schema is used by default.
tabname	varchar2	No	Name of the table whose statistics are to be imported.
partname	varchar2	Yes	Table partition name. If the table has been partitioned but **partname** is **null**, global and partitioned table statistics are imported.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Type	Can Be Null	Description
stattab	varchar2	No	Name of the user table that stores statistics.
statid	varchar2	Yes	(Optional) Identifier that points to statistics in **stattab**.
cascade	Boolean	Yes	Specifies whether to import statistics about columns, indexes, multiple columns, and index expressions. The default value is **true**.
statown	varchar2	Yes	Name of the schema where the user table that stores statistics is located. If this parameter is set to **null**, the value of **ownname** is used.
no_invalidate	Boolean	Yes	Not supported currently.
force	Boolean	Yes	Specifies whether to forcibly import data. The lock status is ignored. The default value is **false**.
stat_category	varchar2	Yes	Not supported currently.

NOTE

- You need to import the reltuples (numrows), relpages (numblks), and relallvisible (relallvisible) statistics of tables. For details about column-level and index-level statistics imported in cascading mode, see the statistics of the **IMPORT_INDEX_STATS** and **IMPORT_COLUMN_STATS** APIs.
- If **ownname** is set to **null**, the current schema is used. In this case, you need to set **behavior_compat_options** to **bind_procedure_searchpath**.

Example:

```
gaussdb=# DROP SCHEMA IF EXISTS dbe_stats_import_table CASCADE;

- DBE_STATS.IMPORT_COLUMN_STATS

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Retrieves statistics for the specified columns (multiple columns or expressions) from the user statistics table of the **stattab** identifier and writes it back to the system catalog. This API does not return any value.

The prototype of DBE_STATS.IMPORT_COLUMN_STATS is as follows:

```
DBE_STATS.IMPORT_COLUMN_STATS (
   ownname       VARCHAR2,
   tabname       VARCHAR2,
   colname       VARCHAR2,
   partname      VARCHAR2 DEFAULT NULL,
   stattab       VARCHAR2,
   statid        VARCHAR2 DEFAULT NULL,
   statown       VARCHAR2 DEFAULT NULL,
   no_invalidate BOOLEAN DEFAULT NULL,
   force         BOOLEAN DEFAULT FALSE
);
```

Table 2-392 DBE_STATS.IMPORT_COLUMN_STATS API parameters

Parameter	Type	Can Be Null	Description
ownname	VARCHAR2	No	Name of the schema. When it is null, the current schema is used by default.
tabname	VARCHAR2	No	Name of the table (index name corresponding to the expression) to which the column whose statistics are to be imported belongs.
colname	VARCHAR2	No	Column name or multiple column names (If tabname is an index, **colname** is an expression name.)
partname	VARCHAR2	Yes	Partition name. If the table or index has been partitioned but **partname** is **null**, global and partitioned key, multiple columns, and index statistics are imported.
stattab	VARCHAR2	No	Name of the user table that stores statistics.
statid	VARCHAR2	Yes	(Optional) Identifier that points to statistics in **stattab**.
statown	VARCHAR2	Yes	Name of the schema where the user table that stores statistics is located. If this parameter is set to **null**, the value of **ownname** is used.
no_invalidate	BOOLEAN	Yes	Not supported currently.
force	BOOLEAN	Yes	Specifies whether to forcibly import data. The lock status is ignored. The default value is **false**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- You can query **PG_STATISTIC** or **PG_STATISTIC_EXT** to import column-level statistics.
- Before importing multiple columns, query the **staextname** column in **PG_STATISTIC_EXT** to obtain the aliases of multiple columns and pass them as the input parameter **colname**.
- If **ownname** is set to **null**, the current schema is used. In this case, you need to set **behavior_compat_options** to **bind_procedure_searchpath**.

- DBE_STATS.IMPORT_SCHEMA_STATS

  Retrieves statistics for the specified schema from the user statistics table of the **stattab** identifier and writes it back to the system catalog. This API does not return any value.

  The prototype of DBE_STATS.IMPORT_SCHEMA_STATS is as follows:

```
DBE_STATS.IMPORT_SCHEMA_STATS (
   ownname       VARCHAR2,
   stattab       VARCHAR2,
   statid        VARCHAR2 DEFAULT NULL,
   statown       VARCHAR2 DEFAULT NULL,
   no_invalidate BOOLEAN  DEFAULT NULL,
   force         BOOLEAN DEFAULT FALSE,
   stat_category VARCHAR2 DEFAULT NULL
);
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 2-393 DBE_STATS.IMPORT_SCHEMA_STATS API parameters

Parameter	Type	Can Be Null	Description
ownname	VARCHAR2	No	Name of the schema. When it is null, the current schema is used by default.
stattab	VARCHAR2	No	Name of the user table that stores statistics.
statid	VARCHAR2	Yes	(Optional) Identifier that points to statistics in **stattab**.
statown	VARCHAR2	Yes	Name of the schema where the user table that stores statistics is located. If this parameter is set to **null**, the value of **ownname** is used.
no_invalidate	BOOLEAN	Yes	Not supported currently.
force	BOOLEAN	Yes	Specifies whether to forcibly import data. The lock status is ignored. The default value is **false**.
stat_category	VARCHAR2	Yes	Not supported currently.

NOTE

- You need to import statistics about all tables on which the current user has permission in the specified schema. Tables on which the current user does not have permission are skipped and no error is reported.
- If **ownname** is set to **null**, the current schema is used. In this case, you need to set **behavior_compat_options** to **bind_procedure_searchpath**.

Example:

  Sets column-related statistics, including single-column, multi-column, and expression statistics. This API does not return any value.

  The prototype of DBE_STATS.SET_COLUMN_STATS is as follows:

```
DBE_STATS.SET_COLUMN_STATS (
   ownname         VARCHAR2,
   tabname         VARCHAR2,
   colname         VARCHAR2,
   partname        VARCHAR2   DEFAULT NULL,
   stattab         VARCHAR2   DEFAULT NULL,
   statid          VARCHAR2   DEFAULT NULL,
   distcnt         NUMBER     DEFAULT NULL,
   density         NUMBER     DEFAULT NULL,
   nullcnt         NUMBER     DEFAULT NULL,
   srec            VARCHAR2   DEFAULT NULL,
   avgclen         NUMBER     DEFAULT NULL,
   flags           NUMBER     DEFAULT NULL,
   statown         VARCHAR2   DEFAULT NULL,
   no_invalidate   BOOLEAN    DEFAULT NULL,
   force           BOOLEAN    DEFAULT FALSE,
   node_name       VARCHAR2   DEFAULT NULL,
   option          VARCHAR2   DEFAULT NULL
);
```

Table 2-395 DBE_STATS.SET_COLUMN_STATS API parameters

Parameter	Type	Can Be Null	Description
ownname	VARCHAR2	No	Name of the schema where the table is located. When it is null, the current schema is used by default.
tabname	VARCHAR2	No	Table name.
colname	VARCHAR2	No	Column name.
partname	VARCHAR2	Yes	Name of the table partition whose statistics are to be set. If the table has been partitioned and **partname** is null, global column–level statistics are set.
stattab	VARCHAR2	Yes	Not supported currently.
statid	VARCHAR2	Yes	Not supported currently.
distcnt	NUMBER	Yes	Number of NDVs in the column.
density	NUMBER	Yes	Not supported currently.
nullcnt	NUMBER	Yes	Number of null values in the column.
srec	VARCHAR2	Yes	Not supported currently.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Type	Can Be Null	Description
avgclen	NUMBER	Yes	Average length (in bytes) of the fields in the column.
flags	NUMBER	Yes	Not supported currently.
statown	VARCHAR2	Yes	Not supported currently.
no_invalidate	BOOLEAN	Yes	Not supported currently.
force	BOOLEAN	Yes	Behavior when the statistics are locked. If the value is **true**, the procedure sets the value even if the column-level statistics are locked. The default value is **false**.
node_name	VARCHAR2	Yes	If **node_name** is **null**, the statistics of all CNs and DNs are updated. If **node_name** is the DN name, only the statistics of the specified DN are updated. If **node_name** is the name of a CN, statistics of all CNs will be updated.
option	VARCHAR2	Yes	NDV calculation method of the DN. This parameter is valid only when **node_name** is **null**. Currently, only **"p"** and **"s"** are allowed. **"p"**: The NDV of a DN is calculated using Poisson distribution. **"s"**: The DN and CN use the same NDV.

NOTE

- This API can be used to set expression statistics. Expression creation depends on indexes. Therefore, when this API is called to set expression statistics, **tabname** must be set to the index name.
- Currently, only NDV (distcnt), nullfrac (nullcnt) and width (avgclen) statistics of columns can be set.
- After the statistics of a single column or expression are deleted, this API can still be called to set the statistics of the corresponding single column or expression. In this case, new data is inserted into the **PG_STATISTIC** system catalog. After the multi-column statistics are deleted, this API cannot be used to reset the statistics.
- If **ownname** is set to **null**, the current schema is used. In this case, you need to set **behavior_compat_options** to **bind_procedure_searchpath**.
- If the number of rows (**reltuples**) of the current column is **0**, **nullfrac** will be set to **0** and **distcnt** will be set to the input parameter value.

Table 2-396 DBE_STATS.SET_INDEX_STATS API parameters

Parameter	Type	Can Be Null	Description
ownname	VARCHAR2	No	Schema to which the index belongs. When it is null, the current schema is used by default.
indname	VARCHAR2	No	Index name.
partname	VARCHAR2	Yes	Name of the index partition whose statistics are to be set. If the index has been partitioned and **partname** is null, global index–level statistics are set.
stattab	VARCHAR2	Yes	Not supported currently.
statid	VARCHAR2	Yes	Not supported currently.
numrows	NUMBER	Yes	Number of rows in an index.
numlblks	NUMBER	Yes	Number of pages in an index.
relallvisible	NUMBER	Yes	Number of pages marked as all visible in the index.
numdist	NUMBER	Yes	Not supported currently.
avglblk	NUMBER	Yes	Not supported currently.
avgdblk	NUMBER	Yes	Not supported currently.
clstfct	NUMBER	Yes	Not supported currently.
indlevel	NUMBER	Yes	Not supported currently.
flags	NUMBER	Yes	Not supported currently.
statown	VARCHAR2	Yes	Not supported currently.
no_invalidate	BOOLEAN	Yes	Not supported currently.
guessq	NUMBER	Yes	Not supported currently.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Type	Can Be Null	Description
cachedblk	NUMBER	Yes	Not supported currently.
cachehit	NUMBER	Yes	Not supported currently.
force	BOOLEAN	Yes	Behavior when the statistics are locked. If the value is **TRUE**, the procedure sets the value even if the index-level statistics are locked. The default value is **false**.
node_name	VARCHAR2	Yes	If **node_name** is **null**, the statistics of all CNs and DNs are updated. If **node_name** is the DN name, only the statistics of the specified DN are updated. If **node_name** is the name of a CN, statistics of all CNs will be updated.

NOTE

- Currently, only reltuples (numrows), relpages (numlblks) and relallvisible (relallvisible) statistics of indexes can be set.
- If **ownname** is set to **null**, the current schema is used. In this case, you need to set **behavior_compat_options** to **bind_procedure_searchpath**.

Example:

```

```

- DBE_STATS.GET_TABLES_BY_SQLID

  Obtains all tables involved in the statement corresponding to the unique SQL ID. If multiple tables are involved, multiple rows of records are returned.

  The prototype of DBE_STATS.GET_TABLES_BY_SQLID is as follows:

```
DBE_STATS.GET_TABLES_BY_SQLID (
   unique_sqlid    BIGINT
)
RETURNS TABLE (
   nspname         TEXT,
   tabname         TEXT
);
```

Table 2-398 Parameters and return values of the DBE_STATS.GET_TABLES_BY_SQLID API

Column	Data Type	Parameter Type	Can Be Null	Description
unique_sqlid	BIGINT	IN	No	Unique SQL ID, which can be obtained from pg_catalog.pg_stat_activity (view for recording real-time session information), dbe_perf.statement (view for recording normalized SQL statements), or dbe_perf.statement_history (view for recording full or slow SQL statements).
nspname	TEXT	OUT	No	Schema name of the table involved in the statement.
tabname	TEXT	OUT	No	Name of the table involved in the statement.

Example:

- DBE_STATS.ANALYZE_SQLID

  Obtains all tables involved in the statement corresponding to the unique SQL ID and collects statistics about the tables. If multiple tables are successfully collected, multiple rows of records are returned.

  The prototype of DBE_STATS.ANALYZE_SQLID is as follows:

```
DBE_STATS.ANALYZE_SQLID (
    unique_sqlid    BIGINT,
    all_complete    BOOLEAN DEFAULT FALSE,
    node_name       NAME DEFAULT NULL
)
RETURNS TABLE (
    nspname         TEXT,
    tabname         TEXT
);
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 2-399 Parameters and return values of the DBE_STATS.ANALYZE_SQLID API

Column	Data Type	Parameter Type	Can Be Null	Description
unique_sqlid	BIGINT	IN	No	Unique SQL ID, which can be obtained from pg_catalog.pg_stat_activity (view for recording real-time session information), dbe_perf.statement (view for recording normalized SQL statements), or dbe_perf.statement_history (view for recording full or slow SQL statements).
all_complete	BOOLEAN	IN	Yes	Specifies whether to use the **ALL COMPLETE** mode to collect statistics. The behavior is the same as that of **ANALYZE** *tabname* **WITH ALL COMPLETE**. If this parameter is not specified, the default mode is used, which corresponds to **ANALYZE** *tabname*.
node_name	NAME	IN	Yes	CN name, corresponding to **pgxc_node.node_name**. If a CN name is specified, only the SQL statement records on the corresponding CN are queried. If no CN name is specified, the records on all CNs are queried.
nspname	TEXT	OUT	No	Schema name of the table involved in the statement.
tabname	TEXT	OUT	No	Name of the table involved in the statement. Only tables whose statistics are successfully collected are included.

Example:

```
-- The usage of ANALYZE_SQLID is similar to that of GET_TABLES_SQLID. The difference is that this API collects statistics and provides the all_complete option and node_name parameter for filtering.

- dbe_stats_tools.py

  This Python script is used to simplify the process of exporting and importing database-level statistics.

- To export statistics, you must have the permission on the corresponding API or command (DBE_STATS.CREATE_STAT_TABLE, DBE_STATS.EXPORT_DATABASE_STATS, \COPY TO or DBE_STATS.DROP_STAT_TABLE) and the read and write permissions on the specified export directory.
- To import statistics, you must have the permission on the corresponding API or command (DBE_STATS.CREATE_STAT_TABLE, DBE_STATS.EXPORT_DATABASE_STATS, \COPY FROM or DBE_STATS.DROP_STAT_TABLE) and the read permission on the files in the specified export directory.
- When you export statement metadata, the following information must be collected:
  - Input SQL statement text.
  - The information obtained by performing the EXPLAIN operation on the SQL statement when the hint is effective and ineffective.
  - Definitions of all objects in the database.
  - All GUC parameter settings related to plan optimization, excluding the session-level configuration of applications.
  - Current and historical statistics of the table objects referenced by the SQL statement (exported only when the generated plan is of the stream type).

  To export statement metadata, you must have the system administrator permission on the database and the read and write permissions on the specified directory.

NOTE

This tool is not supported in M-compatible mode.

Table 2-400 dbe_stats_tools.py API parameters

Parameter	Can Be Null	Description
--mode/-m	No	Value range: **dump**, **restore**, **explain**, and **explain_analyze**. • **dump**: export. • **restore**: import. • **explain**: Statement metadata is exported without actually executing the statement. • **explain_analyze**: Statement metadata is exported after the statement is actually executed.
--database/-d	No	Name of the target database to be exported or imported.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Can Be Null	Description
--port/-p	No	Port number of the database CN. The value ranges from 1 to 65535.
--user/-U	Yes	Username. If the **-U** parameter is not specified, the current username is used as the input parameter.
--passwd/-W	Yes	User password. If this option is specified, you need to enter the password separately.
--host/-H	Yes	IP address of the target database node to be exported or imported.
--set/-s	Yes	Sets the session-level GUC parameters in statement metadata collection mode. This parameter can be specified for multiple times, corresponding to multiple GUC parameter settings.
--command/-c	No	Specifies the SQL text in statement metadata collection mode. The value must be a single SQL statement that can be executed using **EXPLAIN** and cannot contain the **EXPLAIN** keyword. In **explain_analyze** mode, only the SELECT statement is supported.
--file/-f	No	Specifies the path of the file for storing SQL text in statement metadata collection mode. The value must be a single SQL statement that can be executed using **EXPLAIN** and cannot contain the **EXPLAIN** keyword. In **explain_analyze** mode, only the SELECT statement is supported.
--output/-o	No	Directory for storing exported statistics.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- After the statistics are exported, the **gs_stats.meta** (metadata file) and **gs_stats.csv** (statistics file of the specified database user table) files are generated in the directory specified by the **--output** parameter.
- After the statement metadata is exported, the following directories and files are generated in the directory specified by the **--output** parameter:
  - **query.sql**: stores the entered SQL statement text.
  - **metainfo_nohint**: appears by default and stores information when no hint applies to a statement (the statement lacks a hint, or a tool invalidates the hint).
    - **explain.log**: stores the EXPLAIN result of the SQL statement.
  - **metainfo_hinted**: appears only when a hint takes effect for the statement. The content structure is the same as that of **metainfo_nohint**.
  - **objdefs.sql**: stores the definitions of all objects in the database.
  - **querytuning.conf**: stores all GUC parameter settings related to plan optimization, excluding the session-level configuration of applications.
  - **currstats**: stores the current statistics of the table objects referenced by the SQL statement. The directory structure is the same as that of the output in **dump** mode.
  - **histstats**: stores the historical statistics of the table objects referenced by the SQL statement. Each **histstats**_*<timestamp>* subdirectory in this directory corresponds to a statistics snapshot of a timestamp. The file structure in the subdirectory is the same as that of the output in **dump** mode. **histstats** can store up to 50 historical statistics snapshots. If you query more than 50 snapshots, it returns 50 samples taken at equal intervals.

Example 1: Export and import statistics.

```
# The following is an example of exporting statistics.
[omm@localhost ~]$ python3 dbe_stats_tools.py -m dump -d db1 -p 8000 --output ./stats
export table name: "export_table_1749782634"
execute: "gsql -d db1 -p 8000 -U omm -c "select 1 from pg_catalog.pg_class where relname =
'export_table_1749782634' and relnamespace = 2200;""
execute: "gsql -d db1 -p 8000 -U omm -c "START TRANSACTION;call
dbe_stats.create_stat_table(ownname => 'public', stattab => 'export_table_1749782634');call
dbe_stats.export_database_stats(stattab=>'export_table_1749782634',statown=>'public');\COPY
public.export_table_1749782634TO '/home/omm/stats/gs_stats.csv' WITH (FORMAT CSV,
HEADER);call dbe_stats.drop_stat_table(ownname => 'public', stattab =>
'export_table_1749782634');COMMIT;""
execute: "gsql -d db1 -p 8000 -U omm -c "select pg_catalog.gs_get_current_version() from dual;""
deployment: "M"
execute: "gsql -d db1 -p 8000 -U omm -c "select count(1) from pg_catalog.pgxc_node where
node_type = 'D';""
datanode number: "6"
dump complete!

# After the statistics are exported, the metadata file and dump file of statistics are generated in the
stats directory.
[omm@localhost ~]$ ls stats/
gs_stats.csv  gs_stats.meta

# The following is an example of importing statistics.

Example 2: Reproduce the problem of poor SQL plan using statement metadata. This example contains a typical poor plan. After data changes, statistics are not collected in a timely manner. As a result, the plan with an incorrect index is selected.

Preparations: Create a table, insert data, and reproduce the slow SQL service.

```
# In the example, db1 is an ORA-compatible database. Replace it with the actual database name.
# In the example, the node where the command is executed is the cluster node.
[omm@localhost ~]$ gsql -d db1 -p 8000 -r

-- To prevent cardinality feedback, plan reuse, and statement pushdown from affecting the
reproduction of the slow SQL problem, set the following GUC parameters:
db1=# SET enable_feedback_cardest = OFF;
SET
db1=# SET cursor_sharing = OFF;
SET
db1=# SET enable_fast_query_shipping = OFF;
SET
db1=# SET explain_perf_mode = 'pretty';
SET

-- 2. Preset data. The s table is used only for data generation, and the t table is the service table to be
queried.
db1=# DROP TABLE IF EXISTS s;
NOTICE:  table "s" does not exist, skipping
DROP TABLE
db1=# CREATE TABLE s (
    i INT
) DISTRIBUTE BY HASH (i);
CREATE TABLE
db1=# INSERT INTO s SELECT generate_series(1, 550000);
INSERT 0 550000
db1=# ANALYZE s;

2.12.2.19 DBE_TASK

APIs

Table 2-401 lists APIs supported by the DBE_TASK package.

Table 2-401 DBE_TASK

API	Description
DBE_TASK.SUBMIT	Submits a scheduled job. The job ID is automatically generated by the system.
DBE_TASK.JOB_SUBMIT	Provides the same function as DBE_TASK.SUBMIT, with syntax compatibility parameters.
DBE_TASK.ID_SUBMIT	Submits a scheduled job. The job ID is specified by the user.
DBE_TASK.CANCEL	Deletes a scheduled job by job ID.
DBE_TASK.RUN	Runs a scheduled job.
DBE_TASK.FINISH	Disables or enables scheduled job execution.
DBE_TASK.UPDATE	Modifies attributes of a scheduled job, including the job content, next-execution time, and execution interval.
DBE_TASK.CHANGE	Provides the same function as DBE_TASK.UPDATE, with syntax compatibility parameters.
DBE_TASK.CONTENT	Modifies the content attribute of a scheduled job.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

API	Description
DBE_TASK.NEXT_TIME	Modifies the next-execution time attribute of a scheduled job.
DBE_TASK.INTERVAL	Modifies the execution interval attribute of a scheduled job.

NOTE

- DBE_TASK scheduling in a distributed environment does not ensure high reliability of job execution status information. The execution status of job scheduling can be queried only on the node where the job is submitted. The information queried on other nodes may not be synchronized.
- GaussDB provides a highly available, reliable, and flexible scheduling system using the DBE_SCHEDULER API (recommended in a distributed environment).

- DBE_TASK.SUBMIT

  DBE_TASK.SUBMIT submits a system scheduled job.

  The prototype of DBE_TASK.SUBMIT is as follows:

```
DBE_TASK.SUBMIT(
what          IN   TEXT,
next_time     IN   TIMESTAMP DEFAULT sysdate,
interval_time IN   TEXT  DEFAULT 'null',
id            OUT  INTEGER
)RETURN INTEGER;
```

  NOTE

  - When a scheduled job is created (using DBE_TASK), the system binds the current database and the username to the job by default.
  - The function can be called using the CALL or SELECT statement. If the function is called using the CALL statement, you do not need to set the output parameter. If the function is called using the SELECT statement, you need to set the output parameter. To call this function within a stored procedure, use the PERFORM statement.
  - If the submitted SQL statement job uses a non-**PUBLIC** schema, specify the schema where a table or a function resides, or run **SET current_schema =** *xxx*; before executing the SQL statement.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 2-402 DBE_TASK.SUBMIT API parameters

Parameter	Type	Input/ Output Parameter	Can Be Null	Description
what	Text	IN	No	SQL statement to be executed. One or multiple DDL operations (excluding database-related operations), DML operations, anonymous blocks, and statements for calling stored procedures, or all four combined are supported.
next_time	Timestamp	IN	No	Next time the job will be executed. The default value is the current system time (**sysdate**). If the specified time has past, the job is executed immediately after being submitted.
interval_time	Text	IN	Yes	Expression for calculating the next time the job will be executed. It can be an interval expression, or **sysdate** followed by a numeric value, for example, **sysdate +1.0/24**. If the value is empty or **"null"**, it is executed only once. After execution, the job status is changed to **'d'**, indicating that the job is no longer executed.
id	Integer	OUT	No	Job ID. The value ranges from 1 to 3000000. When the SELECT statement is used for calling, this parameter cannot be added. When the CALL statement is used for calling, this parameter must be added.

NOTE

When you create a user using the **what** parameter, the plaintext password of the user is recorded in the log. Therefore, you are advised not to do so. Jobs created using this API may not be highly available. You are advised to use **PKG_SERVICE.SUBMIT_ON_NODES** to create a job and specify the CCN as the job execution node.

Example:

```
gaussdb=# SELECT DBE_TASK.SUBMIT('call pro_xxx();', to_date('20180101','yyyymmdd'),'sysdate+1');
 submit
--------
  31031
(1 row)

gaussdb=# SELECT DBE_TASK.SUBMIT('call pro_xxx();', to_date('20180101','yyyymmdd'),'sysdate
+1.0/24');
 submit
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
--------
   512
(1 row)

gaussdb=# DECLARE
gaussdb-#     jobid int;
gaussdb-# BEGIN
gaussdb$#     PERFORM DBE_TASK.SUBMIT('call pro_xxx();', sysdate, 'interval ''5 minute''', jobid);
gaussdb$# END;
gaussdb$# /
ANONYMOUS BLOCK EXECUTE
```

- DBE_TASK.JOB_SUBMIT

  Submits a system scheduled job. In addition, it provides additional compatibility parameters.

  The prototype of DBE_TASK.JOB_SUBMIT is as follows:

```
DBE_TASK.JOB_SUBMIT(
job           OUT  INTEGER,
what          IN   TEXT,
next_date     IN   TIMESTAMP  DEFAULT sysdate,
job_interval  IN   TEXT       DEFAULT 'null',
no_parse      IN   BOOLEAN    DEFAULT false,
instance      IN   INTEGER    DEFAULT 0,
force         IN   BOOLEAN    DEFAULT false
)RETURN INTEGER;
```

Table 2-403 DBE_TASK.JOB_SUBMIT API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
job	Integer	OUT	No	Job ID. The value ranges from 1 to 3000000. When DBE_TASK.JOB_SUBMIT is called using the SELECT statement, this parameter can be omitted.
what	Text	IN	No	SQL statement to be executed. One or multiple DDL operations (excluding database-related operations), DML operations, anonymous blocks, and statements for calling stored procedures, or all four combined are supported.
next_date	Timestamp	IN	Yes	Next time the job will be executed. The default value is the current system time (**sysdate**). If the specified time has past, the job is executed immediately after being submitted.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Type	Input/Output Parameter	Can Be Null	Description
job_interval	Text	IN	Yes	Expression for calculating the next time the job will be executed. It can be an interval expression, or **sysdate** followed by a numeric value, for example, **sysdate +1.0/24**. If the value is empty or **"null"**, it is executed only once. After execution, the job status is changed to **'d'**, indicating that the job is no longer executed.
no_parse	Boolean	IN	Yes	The default value is **false**, which is used only for syntax compatibility.
instance	Integer	IN	Yes	The default value is **0**, which is used only for syntax compatibility.
force	Boolean	IN	Yes	The default value is **false**, which is used only for syntax compatibility.

Example:

```
gaussdb=# DECLARE
gaussdb-#     id integer;
gaussdb-# BEGIN
gaussdb$#     id = DBE_TASK.JOB_SUBMIT(
gaussdb$#         what => 'insert into t1 values (1, 2)',
gaussdb$#         job_interval => 'sysdate + 1' --daily
gaussdb$#     );
gaussdb$# END;
gaussdb$# /
ANONYMOUS BLOCK EXECUTE
```

- DBE_TASK.ID_SUBMIT

  DBE_TASK.ID_SUBMIT has the same syntax function as DBE_TASK.SUBMIT. All parameters of DBE_TASK.ID_SUBMIT are input parameters, with the first parameter specifying a job ID. The last parameter of DBE_TASK.SUBMIT is an output parameter, specifying the job ID automatically generated by the system.

  The prototype of DBE_TASK.ID_SUBMIT is as follows:

  ```
  DBE_TASK.ID_SUBMIT(
  id            IN   BIGINT,
  what          IN   TEXT,
  next_time     IN   TIMESTAMP DEFAULT sysdate,
  interval_time IN   TEXT  DEFAULT 'null');
  ```

  Example:

  ```
  gaussdb=# CALL dbe_task.id_submit(101, 'insert_msg_statistic1;', sysdate, 'sysdate+3.0/24');
   id_submit
  -----------

  (1 row)
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- DBE_TASK.CANCEL

  Deletes a specified scheduled job.

  The prototype of DBE_TASK.CANCEL is as follows:

  ```
  CANCEL(id  IN  INTEGER);
  ```

  Table 2-404 DBE_TASK.CANCEL API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
id	Integer	IN	No	Specified job ID.

  Example:

  ```
  gaussdb=# CALL dbe_task.cancel(101);
   cancel
  --------

  (1 row)
  ```

- DBE_TASK.RUN

  Executes a scheduled job.

  The prototype of DBE_TASK.RUN is as follows:

  ```
  DBE_TASK.RUN(
  job          IN   BIGINT,
  force        IN   BOOLEAN DEFAULT FALSE);
  ```

  Table 2-405 DBE_TASK.RUN API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
job	bigint	IN	No	Specified job ID.
force	Boolean	IN	Yes	Used only for syntax compatibility.

  Example:

  ```
  gaussdb=# BEGIN
  gaussdb$#     DBE_TASK.ID_SUBMIT(12345, 'insert_msg_statistic1;', sysdate, 'sysdate+3.0/24');
  gaussdb$#     DBE_TASK.RUN(12345);
  gaussdb$# END;
  gaussdb$# /
  ANONYMOUS BLOCK EXECUTE
  ```

- DBE_TASK.FINISH

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Disables or enables a scheduled job.

The prototype of DBE_TASK.FINISH is as follows:

```
DBE_TASK.FINISH(
id          IN   INTEGER,
broken      IN   BOOLEAN,
next_time   IN   TIMESTAMP  DEFAULT  sysdate);
```

Table 2-406 DBE_TASK.FINISH API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
id	Integer	IN	No	Specified job ID.
broken	Boolean	IN	No	Status flag. **true** means disabled; **false** means enabled. The current job is updated based on the parameter value **true** or **false**. If it is null, the job status remains unchanged.
next_time	Timestamp	IN	Yes	Next execution time. The default value is the current system time. This parameter can be omitted, and its default value will be used in this case. • If the value of **broken** is **true**, the value of this parameter is updated to **'4000-1-1'**. • If the parameter **broken** is set to **false** and the parameter **next_time** is not null, the **next_time** value of a specified job is updated. If the parameter **next_time** is null, the **next_time** value is not updated.

Example:

```
gaussdb=# CALL dbe_task.id_submit(101, 'insert_msg_statistic1;', sysdate, 'sysdate+3.0/24');
 id_submit
-----------

(1 row)

gaussdb=# CALL dbe_task.finish(101, true);
 finish
--------

(1 row)

gaussdb=# CALL dbe_task.finish(101, false, sysdate);
 finish
--------
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
(1 row)
```

- DBE_TASK.UPDATE

  Updates user-defined attributes of a scheduled job, including the job content, next-execution time, and execution interval.

  The prototype of DBE_TASK.UPDATE is as follows:

```
dbe_task.UPDATE(
id             IN     INTEGER,
content        IN     TEXT,
next_time      IN     TIMESTAMP,
interval_time  IN  TEXT);
```

Table 2-407 DBE_TASK.UPDATE API parameters

Parameter	Type	Input / Output Parameter	Can Be Null	Description
id	Integer	IN	No	Specified job ID.
content	Text	IN	Yes	Name of the stored procedure or SQL statement block that is executed. If this parameter is null, the system does not update the **content** parameter for the specified job. Otherwise, the system updates the **content** parameter for the specified job.
next_time	Timestamp	IN	Yes	Next execution time. If this parameter is null, the system does not update the **next_time** parameter for the specified job. Otherwise, the system updates the **next_time** parameter for the specified job.
interval_time	Text	IN	Yes	Expression for calculating the next time the job will be executed. ● If this parameter is null, the **interval_time** value of the specified job is not updated. ● If this parameter is not null, the system checks whether **interval_time** is a valid time type or interval type. If it is valid, the **interval_time** value of the specified job is updated. ● If the value is **"null"**, it is executed only once. After execution, the job status is changed to **'d'**, indicating that the job is no longer executed.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Example:

```
gaussdb=# CALL dbe_task.update(101, 'call userproc();', sysdate, 'sysdate + 1.0/1440');
 update
--------

(1 row)

gaussdb=# CALL dbe_task.update(101, 'insert into tbl_a values(sysdate);', sysdate, 'sysdate +
1.0/1440');
 update
--------

(1 row)
```

- DBE_TASK.CHANGE

  Changes user-defined attributes of a scheduled job, including the job content, next-execution time, and execution interval.

  The prototype of DBE_TASK.CHANGE is as follows:

```
DBE_TASK.CHANGE(
job             IN    INTEGER,
what            IN    TEXT       DEFAULT NULL,
next_date       IN    TIMESTAMP  DEFAULT NULL,
job_interval    IN    TEXT       DEFAULT NULL,
instance        IN    INTEGER    DEFAULT NULL,
force           IN    BOOLEAN    DEFAULT false);
```

Table 2-408 DBE_TASK.CHANGE API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
job	Integer	IN	No	Specified job ID.
what	Text	IN	Yes	Name of the stored procedure or SQL statement block that is executed. If this parameter is null, the system does not update the **what** parameter for the specified job. Otherwise, the system updates the **what** parameter for the specified job.
next_date	Timestamp	IN	Yes	Next execution time. If this parameter is null, the system does not update the **next_time** parameter for the specified job. Otherwise, the system updates the **next_date** parameter for the specified job.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Type	Input/Output Parameter	Can Be Null	Description
job_interval	Text	IN	Yes	Expression for calculating the next time the job will be executed. ● If this parameter is empty, the **job_interval** value of a specified job is not updated. ● If this parameter is not empty, the system checks whether **job_interval** is a valid time type or interval type. If it is valid, the **job_interval** value of a specified job is updated. ● If the value is **"null"**, it is executed only once. After execution, the job status is changed to **'d'**, indicating that the job is no longer executed.
instance	Integer	IN	Yes	Used only for syntax compatibility.
force	Boolean	IN	No	Used only for syntax compatibility.

Example:

```
gaussdb=# BEGIN
gaussdb$#     DBE_TASK.CHANGE(
gaussdb$#         job => 101,
gaussdb$#         what => 'insert into t2 values (2);'
gaussdb$#     );
gaussdb$# END;
gaussdb$# /
ANONYMOUS BLOCK EXECUTE
```

- DBE_TASK.CONTENT

  Modifies the job description for a specified job.

  The prototype of DBE_TASK.CONTENT is as follows:

```
DBE_TASK.CONTENT(
id          IN     INTEGER,
content      IN TEXT);
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 2-409 DBE_TASK.CONTENT API parameters

Parameter	Type	Input/ Output Parameter	Can Be Null	Description
id	Integer	IN	No	Specified job ID.
content	Text	IN	No	Stored procedure call, SQL statement block, or program block that is executed.

NOTE

- If the value specified by the **content** parameter is one or multiple executable SQL statements, program blocks, or stored procedure calls, this function can be executed successfully; otherwise, it will fail to be executed.
- If the value specified by the **content** parameter is a simple statement such as INSERT and UPDATE, a schema name must be added in front of the table name.

Example:

```
gaussdb=# CALL dbe_task.content(101, 'call userproc();');
 content
---------

(1 row)

gaussdb=# CALL dbe_task.content(101, 'insert into tbl_a values(sysdate);');
 content
---------

(1 row)
```

- DBE_TASK.NEXT_TIME

  Modifies the next-execution time attribute of a scheduled job.

  The prototype of DBE_TASK.NEXT_TIME is as follows:

```
DBE_TASK.NEXT_TIME(
id         IN    BIGINT,
next_time  IN    TEXT);
```

Table 2-410 DBE_TASK.NEXT_TIME API parameters

Parameter	Type	Input/ Output Parameter	Can Be Null	Description
id	bigint	IN	No	Specified job ID.
next_time	Text	IN	No	Next execution time.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

If the specified **next_time** value is earlier than the current date, the job is executed once immediately.

Example:

```
gaussdb=# CALL dbe_task.next_time(101, sysdate);
 next_time
-----------

(1 row)
```

- DBE_TASK.INTERVAL

  Modifies the execution interval attribute of a scheduled job.

  The prototype of DBE_TASK.INTERVAL is as follows:

```
DBE_TASK.INTERVAL(
id             IN      INTEGER,
interval_time      IN   TEXT);
```

Table 2-411 DBE_TASK.INTERVAL API parameters

Parameter	Type	Input / Output Parameter	Can Be Null	Description
id	Integer	IN	No	Specified job ID.
interval_time	Text	IN	Yes	Expression for calculating the next time the job will be executed. The job interval must be of a valid time type or interval type. If the value is empty or **"null"**, it is executed only once. After execution, the job status is changed to **'d'**, indicating that the job is no longer executed.

Example:

```
gaussdb=# CALL dbe_task.interval(101, 'sysdate + 1.0/1440');
 interval
----------

(1 row)

gaussdb=# CALL dbe_task.cancel(101);
 cancel
--------

(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

> **NOTE**
>
> For a running job (that is, **job_status** is set to **'r'**), it is not allowed to use the CANCEL, UPDATE, NEXT_TIME, CONTENT, or INTERVAL API to delete or modify job parameters.

Limitations

- After a job is created by using SUMMIT/ID_SUBMIT, the job belongs to the current coordinator (that is, the job is scheduled and executed only on the current coordinator). Other coordinators do not schedule and execute the job. If the coordinator node is faulty, the job cannot be properly executed. You are advised to use the **PKG_SERVICE.SUBMIT_ON_NODES** API to specify the job execution node as CCN to ensure that the job is still available when the node is faulty. Not all coordinators can query, modify, and delete jobs created on other CNs.
- Jobs can be created, updated, and deleted only through the APIs provided by the DBE_TASK advanced package. This is because the APIs in the advanced package handle synchronization of job information across CNs, as well as the association between the primary keys of the PG_JOB and PG_JOB_PROC catalogs. If DML statements are used to add, delete, or modify the PG_JOB catalog, job information will be inconsistent across CNs, and system catalogs cannot associate changes. This will severely affect the internal management of jobs.
- Each job created by a user is bound to a CN. If the CN is faulty while a job is being executed, the job status cannot be updated in real time and will stay at **'r'**. The job status will be updated to **'s'** only after the CN is restored. When a CN is faulty before jobs are executed, all jobs on this CN cannot be scheduled or executed until the CN is restored manually, or deleted and then replaced.
- For each job, the hosting CN updates the real-time job information (including the job status, last execution start time, last execution end time, next execution start time, the number of execution failures [if any]) to the pg_job catalog, and synchronizes the information to other CNs, ensuring consistent job information between different CNs. If other CNs are faulty, job information synchronization is reattempted by the hosting CN, which increases job execution time. Although job information fails to be synchronized between CNs, job information can still be properly updated in the pg_job catalog on the hosting CN, and jobs can be executed successfully. After the faulty CN is restored, job information such as job execution time and status in its pg_job catalog may be incorrect and will be updated only after the jobs are executed again on the hosting CN.
- For each job, a thread is established to execute it. If multiple jobs are triggered concurrently as scheduled, the system will need some time to start the required threads, resulting in a latency of 0.1 ms in job execution.

2.12.2.20 DBE_UTILITY

APIs

Table 2-412 provides all APIs supported by the DBE_UTILITY package.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 2-412 DBE_UTILITY

API	Description
DBE_UTILITY.FORMAT_ERROR...	Outputs the call stack of an abnormal function.
DBE_UTILITY.FORMAT_ERROR...	Outputs detailed information about a function exception.
DBE_UTILITY.FORMAT_CALL_...DBE_UTILITY.FORMAT_CALL_...	Outputs the call stack of a function.
DBE_UTILITY.GET_TIME	Outputs the current time, which is used to obtain the execution duration.
DBE_UTILITY.CANONICALIZE	Canonicalizes the character string of a table name.
DBE_UTILITY.COMMA_TO_TABLE	Converts a comma-delimited string of names into a PL/SQL table of names.
DBE_UTILITY.DB_VERSION	Returns the version number and compatibility version number of the database.
DBE_UTILITY.EXEC_DDL_STATEMENT	Executes DDL statements entered by users.
DBE_UTILITY.EXPAND_SQL_TEXT_PROC	Expands the view of the SQL query.
DBE_UTILITY.GET_CPU_TIME	Returns the measured value of the current CPU processing time.
DBE_UTILITY.GET_ENDIANNESS	Obtains the endianness information of the platform where the database is located.
DBE_UTILITY.GET_HASH_VALUE	Returns the hash value of a given string.
DBE_UTILITY.GET_SQL_HASH	Outputs the hash value of a given string. This stored procedure is used when **proc_outparam_override** is not enabled.
DBE_UTILITY.IS_BIT_SET	Checks whether parameter **n** exists in **r**.
DBE_UTILITY.IS_CLUSTER_DATABASE	Determines whether the current database is running in database cluster mode.
DBE_UTILITY.NAME_RESOLVE	Parses the given object name, including synonym translation and necessary authorization checks.
DBE_UTILITY.NAME_TOKENIZE	Parses names in the format of a [. b [. c]][@ dblink].

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

API	Description
DBE_UTILITY.OLD_CURRENT_SCHEMA	Returns the name of the database schema in the current user environment.
DBE_UTILITY.OLD_CURRENT_USER	Returns the name of the current user.
DBE_UTILITY.TABLE_TO_COMMA	Converts a PL/SQL table of names into a comma-delimited string of names.
DBE_UTILITY.GET_SQL_HASH_FUNC	Equivalent to DBE_UTILITY.GET_SQL_HASH. This function is used when **proc_outparam_override** is enabled.

- DBE_UTILITY.FORMAT_ERROR_BACKTRACE

  Returns the call stack where an error occurs during execution. The prototype of the DBE_UTILITY.FORMAT_ERROR_BACKTRACE function is as follows:

  ```
  DBE_UTILITY.FORMAT_ERROR_BACKTRACE()
  RETURN TEXT;
  ```

- DBE_UTILITY.FORMAT_ERROR_STACK

  Returns the detailed information about the error location when an error occurs during the execution. The prototype of the DBE_UTILITY.FORMAT_ERROR_STACK function is as follows:

  ```
  DBE_UTILITY.FORMAT_ERROR_STACK()
  RETURN TEXT;
  ```

- DBE_UTILITY.FORMAT_CALL_STACK

  Sets the call stack of the output function. The prototype of the DBE_UTILITY.FORMAT_CALL_STACK function is as follows:

  ```
  DBE_UTILITY.FORMAT_CALL_STACK()
  RETURN TEXT;
  ```

- DBE_UTILITY.GET_TIME

  Sets the output time, which is usually used for calculating a time difference. A separate return value is meaningless. The prototype of the DBE_UTILITY.GET_TIME function is as follows:

  ```
  DBE_UTILITY.GET_TIME()
  RETURN BIGINT;
  ```

- DBE_UTILITY.CANONICALIZE

  Canonicalizes the character string of a table name. The procedure handles a single reserved word or keyword, and removes white spaces for a single identifier so that "table" becomes TABLE. The prototype of the DBE_UTILITY.CANONICALIZE function is as follows:

  ```
  DBE_UTILITY.CANONICALIZE(
     name       IN   VARCHAR2,
     canon_name OUT  VARCHAR2,
     canon_len  IN   BINARY_INTEGER DEFAULT 1024
  );
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 2-413 DBE_UTILITY.CANONICALIZE API parameters

Parameter	Type	Input / Output Parameter	Can Be Null	Description
name	VARCHAR2	IN	No	Character string to be canonicalized.
canon_name	VARCHAR2	OUT	Yes	Canonicalized character string.
canon_len	BINARY_INTEGER	IN	Yes	Length of the string to be canonicalized. The default value is **1024** (in bytes). If the value of this parameter is less than the actual length (in bytes) of the character string to be canonicalized, the character string is truncated by byte.

- DBE_UTILITY.COMMA_TO_TABLE

  Converts a comma-delimited string of names into a PL/SQL table of names. The prototype of the DBE_UTILITY.COMMA_TO_TABLE function is as follows:

```
DBE_UTILITY.COMMA_TO_TABLE (
   list   IN  VARCHAR2,
   tablen OUT BINARY_INTEGER,
   tab    OUT VARCHAR2[]
);
```

Table 2-414 DBE_UTILITY.COMMA_TO_TABLE API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
list	VARCHAR2	IN	No	A comma-delimited string of names.
tablen	BINARY_INTEGER	OUT	Yes	Number of names in the table.
tab	VARCHAR2	OUT	Yes	Table which contains the string of names.

- DBE_UTILITY.DB_VERSION

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Returns the version number and compatibility version number of the database. The prototype of the DBE_UTILITY.DB_VERSION function is as follows:

```
DBE_UTILITY.DB_VERSION (
   version OUT VARCHAR2
);
```

Table 2-415 DBE_UTILITY.DB_VERSION API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
version	VARCHAR2	OUT	No	Output parameter, which indicates the internal database software version. The value is a character string.

- DBE_UTILITY.EXEC_DDL_STATEMENT

  NOTE

  When the EXECUTE DIRECT ON syntax is used to execute the DBE_UTILITY.EXEC_DDL_STATEMENT function, if the GUC parameter **enable_udf_execute_direct** is set to **on**, the functions can be executed; otherwise, the functions cannot be executed.

  Executes DDL statements entered by users. The prototype of the DBE_UTILITY.EXEC_DDL_STATEMENT function is as follows:

  ```
  DBE_UTILITY.EXEC_DDL_STATEMENT (
     parse_string IN TEXT
  );
  ```

  Table 2-416 DBE_UTILITY.EXEC_DDL_STATEMENT API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
parse_string	TEXT	IN	Yes	DDL statements to be executed.

- DBE_UTILITY.EXPAND_SQL_TEXT_PROC

  Expands the queried view recursively till the table object layer. The prototype of the DBE_UTILITY.EXPAND_SQL_TEXT_PROC function is as follows:

  ```
  DBE_UTILITY.EXPAND_SQL_TEXT_PROC (
     input_sql_text  IN  CLOB,
     output_sql_text OUT CLOB
  );
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 2-417 DBE_UTILITY.EXPAND_SQL_TEXT_PROC API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
input_sql_text	CLOB	IN	No	Input SQL text.
output_sql_text	CLOB	OUT	No	Output SQL text of the expanded view.

NOTE

In the **input_sql_text** parameter entered by a user, a schema prefix must be added to the object in the SQL statement. Otherwise, the function reports an error indicating that no object is found. If **behavior_compat_options** is set to **bind_procedure_searchpath**, you do not need to forcibly specify the schema prefix.

- DBE_UTILITY.GET_CPU_TIME

  Returns the measured value of the current CPU processing time, in hundredths of a second. The prototype of the DBE_UTILITY.GET_CPU_TIME function is as follows:

```
DBE_UTILITY.GET_CPU_TIME()
RETURN BIGINT;
```

- DBE_UTILITY.GET_ENDIANNESS

  Obtains the endianness information of the platform where the database is located. DBE_UTILITY. The prototype of the GET_ENDIANNESS function is as follows:

```
DBE_UTILITY.GET_ENDIANNESS
RETURN INTEGER;
```

- DBE_UTILITY.GET_HASH_VALUE

  Returns the hash value of a given string. The prototype of the DBE_UTILITY.GET_HASH_VALUE function is as follows:

```
DBE_UTILITY.GET_HASH_VALUE(
   name      IN VARCHAR2(n),
   base      IN INTEGER,
   hash_size IN INTEGER)
RETURN INTEGER;
```

Table 2-418 DBE_UTILITY.GET_HASH_VALUE API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
name	VARCHAR2	IN	No	Character string to be hashed.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Type	Input/Output Parameter	Can Be Null	Description
base	INTEGER	IN	No	Start value of the returned hash value.
hash_size	INTEGER	IN	No	Size of the hash table to which the hash is mapped.

- DBE_UTILITY.GET_SQL_HASH

  Outputs the hash value of a given character string using the MD5 algorithm. The prototype of the DBE_UTILITY.GET_SQL_HASH function is as follows:

```
DBE_UTILITY.GET_SQL_HASH(
   name       IN  VARCHAR2,
   hash       OUT RAW,
   last4bytes OUT BIGINT
)RETURN BIGINT;
```

Table 2-419 DBE_UTILITY.GET_SQL_HASH API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
name	VARCHAR2	IN	No	Character string to be hashed.
hash	RAW	OUT	No	Complete hexadecimal MD5 hash value.
last4bytes	BIGINT	OUT	No	Last four bytes of the MD5 hash value, which is displayed as an unsigned integer.

NOTE

After setting **behavior_compat_options** to a value other than **proc_outparam_override**, call the DBE_UTILITY.GET_SQL_HASH function, instead of DBE_UTILITY.GET_SQL_HASH_FUNC; otherwise, the value assignment will fail.

- DBE_UTILITY.IS_BIT_SET

  Checks whether parameter **n** exists in **r**. DBE_UTILITY. The prototype of the IS_BIT_SET function is as follows:

```
DBE_UTILITY.IS_BIT_SET (
   r IN RAW,
   n IN INTEGER)
RETURN INTEGER;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 2-420 DBE_UTILITY.IS_BIT_SET API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
r	RAW	IN	No	4 bytes plus the actual hexadecimal string.
n	INTEGER	IN	No	Determines whether the value exists in the binary system.

- DBE_UTILITY.IS_CLUSTER_DATABASE

  Determines whether the current database is running in database cluster mode. The prototype of the DBE_UTILITY.IS_CLUSTER_DATABASE function is as follows:

  ```
  DBE_UTILITY.IS_CLUSTER_DATABASE
  RETURN BOOLEAN;
  ```

- DBE_UTILITY.NAME_RESOLVE

  Parses the given object name, including synonym translation and necessary authorization checks. The prototype of the DBE_UTILITY.NAME_RESOLVE function is as follows:

  ```
  DBE_UTILITY.NAME_RESOLVE (
     name          IN   VARCHAR2,
     context       IN   INTEGER,
     schema          OUT VARCHAR2,
     part1         OUT VARCHAR2,
     part2         OUT VARCHAR2,
     dblink        OUT VARCHAR2,
     part1_type    OUT INTEGER,
     object_number OUT OID
  );
  ```

Table 2-421 DBE_UTILITY.NAME_RESOLVE API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
name	VARCHAR2	IN	No	Name of the object to be parsed. The structure is [[a.]b.]c[@d].

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Type	Input/Output Parameter	Can Be Null	Description
context	INTEGER	IN	No	Type of the object to be parsed: ● **0**: table ● **1**: function, procedure, and package ● **2**: sequence ● **3**: trigger ● **4**: Java source ● **5**: Java resource ● **6**: Java class ● **7**: type ● **8**: Java shared data ● **9**: index
schema	VARCHAR2	OUT	No	Schema of an object.
part1	VARCHAR2	OUT	No	First part of the name. The type of this column is specified by **part1_type**.
part2	VARCHAR2	OUT	Yes	If this column is not null, the value is the subprogram name.
dblink	VARCHAR2	OUT	Yes	Database link.
part1_type	INTEGER	OUT	No	Part 1 types: ● **5**: synonym ● **7**: procedure (top level) ● **8**: function (top level) ● **9**: package
object_number	OID	OUT	No	Object ID. In database ORA, **object_number** is of the numeric type, indicating the object ID. In GaussDB, **object_number** is of the OID type and does not support implicit conversion from a number to an OID.

- DBE_UTILITY.NAME_TOKENIZE

  Parses names in the format of a [. b [. c]][@ dblink]. If a name contains double quotation marks, remove the double quotation marks; otherwise, the

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

name will be in uppercase. The prototype of the DBE_UTILITY.NAME_TOKENIZE function is as follows:

```
DBE_UTILITY.NAME_TOKENIZE (
name    IN  VARCHAR2,
a       OUT VARCHAR2,
b       OUT VARCHAR2,
c       OUT VARCHAR2,
dblink  OUT VARCHAR2,
nextpos OUT INTEGER
);
```

Table 2-422 DBE_UTILITY.NAME_TOKENIZE API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
name	VARCHAR2	IN	No	Name, consisting of SQL identifiers (for example, **scott.foo@dblink**).
a	VARCHAR2	OUT	No	First token of the name.
b	VARCHAR2	OUT	Yes	Second token of the name.
c	VARCHAR2	OUT	Yes	Third token of the name.
dblink	VARCHAR2	OUT	Yes	Database link.
nextpos	INTEGER	OUT	No	Next position of a parsed character string.

- DBE_UTILITY.OLD_CURRENT_SCHEMA

  Returns the name of the database schema in the current user environment. The prototype of the DBE_UTILITY.OLD_CURRENT_SCHEMA function is as follows:

  ```
  DBE_UTILITY.OLD_CURRENT_SCHEMA()
  RETURN VARCHAR;
  ```

- DBE_UTILITY.OLD_CURRENT_USER

  Returns the name of the current user. The prototype of the DBE_UTILITY.OLD_CURRENT_USER function is as follows:

  ```
  DBE_UTILITY.OLD_CURRENT_USER()
  RETURN TEXT;
  ```

- DBE_UTILITY.TABLE_TO_COMMA

  Converts a PL/SQL table of names into a comma-delimited string of names. The prototype of the DBE_UTILITY.TABLE_TO_COMMA function is as follows:

  ```
  DBE_UTILITY.TABLE_TO_COMMA (
     tab    IN  VARCHAR2[],
     tablen OUT BINARY_INTEGER,
     list   OUT VARCHAR2
  );
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 2-423 DBE_UTILITY.TABLE_TO_COMMA API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
tab	VARCHAR2[]	IN	No	Structure table array that contains table names.
tablen	BINARY_INTEGER	OUT	No	Number of tables in a structure table.
list	VARCHAR2	OUT	No	A comma-delimited string of names.

- DBE_UTILITY.GET_SQL_HASH_FUNC

  Uses the MD5 algorithm to output the hash value of a given character string. The prototype of the DBE_UTILITY.GET_SQL_HASH_FUNC function is:

```
DBE_UTILITY.GET_SQL_HASH_FUNC(
   name       IN  VARCHAR2,
   hash       OUT RAW,
   last4bytes OUT BIGINT
);
```

Table 2-424 DBE_UTILITY.GET_SQL_HASH_FUNC API parameters

Parameter	Type	Input/Output Parameter	Can Be Null	Description
name	VARCHAR2	IN	No	Character string to be hashed.
hash	RAW	OUT	No	Complete hexadecimal MD5 hash value.
last4bytes	BIGINT	OUT	No	Last four bytes of the MD5 hash value, which is displayed as an unsigned integer.

NOTE

After setting **behavior_compat_options** to **'proc_outparam_override'**, call the DBE_UTILITY.GET_SQL_HASH_FUNC function. If you call the DBE_UTILITY.GET_SQL_HASH function, a parameter mismatch error is reported.

Examples

```
-- Example 1
create or replace procedure print_err() as
DECLARE
```

2.12.2.21 DBE_XMLDOM

APIs

The advanced package DBE_XMLDOM is used to access XMLType objects and implement Document Object Model (DOM), which is an API used to access HTML and XML documents. For details about all types supported by the advanced function package DBE_XMLDOM, see **Table 2-425**. For details about all APIs supported by DBE_XMLDOM, see **Table 2-426**.

NOTE

When the DBE_XMLDOM advanced package is used in the database whose character set is set to **SQL_ASCII**, an error is reported if characters beyond the ASCII range are input.

Table 2-425 DBE_XMLDOM data types

Type	Description
DOMATTR	Implements the DOMAttributes API.
DOMDOCUMENT	Implements the DOMDocument API.
DOMELEMENT	Implements the DOMElement API.
DOMNAMEDNODEMAP	Implements the DOMNamedNodeMap API.
DOMNODELIST	Implements the DOMNodeList API.
DOMNODE	Implements the DOMNode API.
DOMTEXT	Implements the DOMText API.

Table 2-426 DBE_XMLDOM API parameters

API	Description
DBE_XMLDOM.APPENDCHILD	Adds the newchild node to the end of the parent(n) node and returns the newly added node.
DBE_XMLDOM.CREATEELEMENT	Creates a DOMElement object with the specified name.
DBE_XMLDOM.CREATETEXTNODE	Creates a DOMText node.
DBE_XMLDOM.FREEDOCUMENT	Frees resources related to DOMDocument nodes.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

API	Description
DBE_XMLDOM.FREEELEMENT	Frees resources related to DOMElement nodes.
DBE_XMLDOM.FREENODE	Frees resources related to DOMNode nodes.
DBE_XMLDOM.FREENODELIST	Frees resources related to DOMNodeList nodes.
DBE_XMLDOM.GETATTRIBUTE	Returns the attribute values of a DOMElement object by name.
DBE_XMLDOM.GETATTRIBUTES	Returns the attribute values of a DOMNode node as a map.
DBE_XMLDOM.GETCHILDNODES	Converts several subnodes under a node into a node list.
DBE_XMLDOM.GETCHILDRENBYTAGNAME	Returns the subnodes of a DOMElement node by name.
DBE_XMLDOM.GETDOCUMENTELEMENT	Returns the first subnode of the specified document.
DBE_XMLDOM.GETFIRSTCHILD	Returns the first subnode.
DBE_XMLDOM.GETLASTCHILD	Returns the last subnode.
DBE_XMLDOM.GETLENGTH	Obtains the number of subnodes under a specified node.
DBE_XMLDOM.GETLOCALNAME	Returns the local name of a node.
DBE_XMLDOM.GETNAMEDITEM	Returns the node specified by name.
DBE_XMLDOM.GETNEXTSIBLING	Returns the next node of the specified node.
DBE_XMLDOM.GETNODENAME	Returns the name of a node.
DBE_XMLDOM.GETNODETYPE	Returns the type of a node.
DBE_XMLDOM.GETNODEVALUE	Obtains the value of a node, depending on its type.
DBE_XMLDOM.GETPARENTNODE	Returns the parent node of a node.
DBE_XMLDOM.GETTAGNAME	Returns the tag name of the specified DOMElement node.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

API	Description
DBE_XMLDOM.HASCHILDNODES	Checks whether the DOMNode object has any subnode.
DBE_XMLDOM.IMPORTNODE	Copies a node and specifies the document to which the node belongs.
DBE_XMLDOM.ISNULL	Checks whether a node is null.
DBE_XMLDOM.ITEM	Returns the item corresponding to the index parameter in the mapping.
DBE_XMLDOM.MAKEELEMENT	Converts a DOMNode object to the DOMElement type.
DBE_XMLDOM.MAKENODE	Forcibly converts a node to the DOMNode type.
DBE_XMLDOM.NEWDOMDOCUMENT	Returns a new DOMDocument object.
DBE_XMLDOM.SETATTRIBUTE	Sets the value of the DOMElement attribute by name.
DBE_XMLDOM.SETCHARSET	Sets the character set for a DOMDocument object.
DBE_XMLDOM.SETDOCTYPE	Sets the external DTD of a DOMDocument object.
DBE_XMLDOM.SETNODEVALUE	Sets the value of a node in the DOMNode object.
DBE_XMLDOM.WRITETOBUFFER	Writes an XML node to a specified buffer.
DBE_XMLDOM.WRITETOCLOB	Writes an XML node to a specified CLOB.
DBE_XMLDOM.WRITETOFILE	Writes an XML node to a specified file.
DBE_XMLDOM.GETSESSIONTREENUM	Displays the number of DOM trees of all types in the current session.
DBE_XMLDOM.GETDOCTREESINFO	Displays statistics such as the memory usage and number of nodes of the DOM tree of the document type.
DBE_XMLDOM.GETDETAILDOCTREEINFO	Displays the number of nodes of each type for a specific document variable.
DBE_XMLDOM.GETELEMENTSBYTAGNAM	Returns the list of DOMNodeList nodes that matches TAGNAME.

- DBE_XMLDOM.APPENDCHILD

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Adds the newchild node to the end of the parent(n) node and returns the newly added node. The prototype of the DBE_XMLDOM.APPENDCHILD function is as follows:

```
DBE_XMLDOM.APPENDCHILD(
  n IN DOMNode,
  newchild IN DOMNode)
RETURN DOMNODE;
```

Table 2-427 DBE_XMLDOM.APPENDCHILD API parameters

Parameter	Description
n	Node to be added.
newchild	New node added.

NOTE

- The error message "operation not support" is displayed for the APPEND ATTR node under the DOCUMENT node. Database ORA does not report an error in this scenario, but the mounting fails.
- The error message "operation not support" is displayed for the APPEND ATTR node under the ATTR node. Database ORA does not report an error in this scenario, but the mounting fails.
- When multiple child nodes of the ATTR type are added to a parent node, the child nodes with the same key value cannot exist under the same parent node.

Example:

```
-- Add a DOMNode node to a specified DOC tree and use DBE_XMLDOM.HASCHILDNODES() to check whether the subnode is successfully added.
DECLARE
   doc DBE_XMLDOM.DOMDocument;
   doc1 DBE_XMLDOM.DOMDocument;
   root DBE_XMLDOM.DOMElement;
   rootnode DBE_XMLDOM.DOMNode;
   child1 DBE_XMLDOM.DOMElement;
   child2 DBE_XMLDOM.DOMElement;
   attr DBE_XMLDOM.DOMAttr;
   text DBE_XMLDOM.DOMTEXT;
   node DBE_XMLDOM.DOMNode;
   child1_node DBE_XMLDOM.DOMNode;
   attr_node DBE_XMLDOM.DOMNode;
   parent DBE_XMLDOM.DOMNode;
   buf varchar2(1000);
BEGIN
   doc := DBE_XMLDOM.newDOMDocument();
   root := DBE_XMLDOM.createElement(doc, 'root');
   rootnode := DBE_xmldom.makeNode(root);
   node := DBE_XMLDOM.appendChild(DBE_xmldom.makeNode(doc), rootnode);
   child1 := DBE_XMLDOM.createElement(doc, 'child1');
   child1_node := DBE_XMLDOM.makeNode(child1);
   node := DBE_XMLDOM.appendChild(rootnode, child1_node);
   attr := DBE_XMLDOM.createAttribute(doc, 'abc');
   attr_node := DBE_XMLDOM.makeNode(attr);
   node := DBE_XMLDOM.appendChild(child1_node, attr_node);
   IF DBE_XMLDOM.HASCHILDNODES(child1_node) THEN
      DBE_OUTPUT.print_line('HAS CHILD NODES');
   ELSE
      DBE_OUTPUT.print_line('NOT HAS CHILD NODES ');
   END IF;
   parent := DBE_XMLDOM.GETPARENTNODE(attr_node);
   buf := DBE_XMLDOM.GETNODENAME(parent);
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
    DBE_OUTPUT.print_line(buf);
END;
/
-- Expected result:
NOT HAS CHILD NODES
ANONYMOUS BLOCK EXECUTE
```

- DBE_XMLDOM.CREATEELEMENT

  Returns the DOMElement object with the specified name. The prototype of the DBE_XMLDOM.CREATEELEMENT function is as follows:

```
DBE_XMLDOM.CREATEELEMENT(
  doc       IN      DOMDOCUMENT,
  tagName   IN      VARCHAR2)
 RETURN DOMELEMENT;
```

  Returns the DOMElement object with the specified name and namespace. The prototype of the DBE_XMLDOM.CREATEELEMENT function is as follows:

```
DBE_XMLDOM.CREATEELEMENT(
  doc       IN      DOMDOCUMENT,
  tagName   IN      VARCHAR2,
  ns        IN      VARCHAR2)
 RETURN DOMELEMENT;
```

Table 2-428 DBE_XMLDOM.CREATEELEMENT API parameters

Parameter	Description
doc	Specified DOMDocument object.
tagName	Name of the new DOMElement object.
ns	Namespace.

NOTE

- When the **tagName** parameter is set to null or an empty character string, the exception "NULL or invalid TagName argument specified" is thrown.
- The default maximum length of **tagName** and **ns** is 32767. If the length exceeds 32767, an exception is thrown.

Example:

```
-- 1. Create a DOMElement object with the specified name.
DECLARE
  doc dbe_xmldom.domdocument;
  attr DBE_XMLDOM.DOMATTR;
  elem DBE_XMLDOM.DOMELEMENT;
  ans DBE_XMLDOM.DOMATTR;
  buf varchar2(1010);
BEGIN
   doc := dbe_xmldom.newdomdocument('<?xml version="1.0" encoding="UTF-8"?>
      <computer size="ITX"><cpu>Ryzen 9 3950X</cpu>
      <ram>32GBx2 DDR4 3200MHz</ram>
      <motherboard>ROG X570i</motherboard>

      <ssd>1TB NVMe Toshiba + 2TB NVMe WD Black</ssd>
      <hdd>12TB WD Digital</hdd>
      <psu>CORSAIR SF750</psu>
      <case>LIANLI TU150</case>
      </computer>');
   elem := dbe_xmldom.createelement(doc,'elem');
   DBE_XMLDOM.WRITETOBUFFER(dbe_xmldom.makenode(elem), buf);
   DBE_OUTPUT.print_line(buf);
END;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
/
-- Expected result:
ANONYMOUS BLOCK EXECUTE

-- 2. Create a DOMElement object with the specified name and namespace.
DECLARE
  doc dbe_xmldom.domdocument;
  attr DBE_XMLDOM.DOMATTR;
  elem DBE_XMLDOM.DOMELEMENT;
  ans DBE_XMLDOM.DOMNODE;
  buf varchar2(1010);
  list DBE_XMLDOM.DOMNODELIST;
  node DBE_XMLDOM.DOMNODE;
BEGIN
   doc := dbe_xmldom.newdomdocument('<h:data xmlns:h="http://www.w3.org/TR/html4/">
       <h:da1 len="10">test namespace</h:da1><h:da1>bbbbbbbbbb</h:da1></h:data>');
   elem := dbe_xmldom.createelement(doc,'elem','http://www.w3.org/TR/html5/');
   ans := DBE_XMLDOM.APPENDCHILD(dbe_xmldom.makenode(doc), dbe_xmldom.makenode(elem));
   DBE_XMLDOM.WRITETOBUFFER(doc, buf);
   DBE_OUTPUT.print_line(buf);
END;

 <h:da1>bbbbbbbbbb</h:da1>
</h:data>
<elem xmlns="http://www.w3.org/TR/html5/"/>

ANONYMOUS BLOCK EXECUTE
```

- DBE_XMLDOM.CREATETEXTNODE

  Creates and returns a DOMText object. The prototype of the DBE_XMLDOM.CREATETEXTNOD function is as follows:

```
DBE_XMLDOM.CREATETEXTNODE(
  doc IN DOMDocument,
  data IN VARCHAR2)
RETURN DOMTEXT;
```

Table 2-429 DBE_XMLDOM.CREATETEXTNODE API parameters

Parameter	Description
doc	Specified DOMDocument object.
data	Content of the DOMText node.

NOTE

- You can enter an empty string or null value for **data**.
- The default maximum length of **data** is 32767. If the length exceeds 32767, an exception is thrown.

Example:

```
-- Add a DOMText node to the DOC tree and print the DOC tree to the buffer.
DECLARE
  doc DBE_XMLDOM.DOMDOCUMENT;
  doctext DBE_XMLDOM.DOMTEXT;
  node DBE_XMLDOM.DOMNODE;
  buffer varchar2(1010);
BEGIN
  doc := dbe_xmldom.newdomdocument('<?xml version="1.0"?>
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
    <!DOCTYPE note [<!ELEMENT note (to,from,heading,body)>
    <!ELEMENT to (#PCDATA)>
    <!ELEMENT from (#PCDATA)>
    <!ELEMENT heading (#PCDATA)>
    <!ELEMENT body (#PCDATA)>]>
    <note>
      <to>Chinese</to>
      <from>Jani</from>
      <heading>Reminder</heading>
      <body>Don''t forget me this weekend!</body>
    </note>');
  doctext := DBE_XMLDOM.CREATETEXTNODE(doc, 'there is nothing');
  node := DBE_XMLDOM.MAKENODE(doctext);
  dbe_xmldom.writetobuffer(node, buffer);
  dbe_output.print_line('buffer: ');
  dbe_output.print_line(buffer);
END;
/
-- Expected result:
buffer:
there is nothing
ANONYMOUS BLOCK EXECUTE
```

- DBE_XMLDOM.FREEDOCUMENT

  Frees a DOMDocument node. The prototype of the DBE_XMLDOM.FREEDOCUMENT function is as follows:

```
DBE_XMLDOM.FREEDOCUMENT(
  doc     IN     DOMDOCUMENT);
```

Table 2-430 DBE_XMLDOM.FREEDOCUMENT API parameters

Parameter	Description
doc	Specified DOMDocument node.

Example:

```
-- Free the entire DOC tree after the DOMNode node is added to the DOC tree.
DECLARE
  doc dbe_xmldom.domdocument;
  elem dbe_xmldom.domelement;
  doc_node dbe_xmldom.DOMNODE;
  root_elmt dbe_xmldom.DOMELEMENT;
  root_node dbe_xmldom.DOMNODE;
  value  varchar(1000);
BEGIN
  doc := dbe_xmldom.newdomdocument();
  doc_node := dbe_xmldom.MAKENODE(doc);
  root_elmt := dbe_xmldom.CREATEELEMENT(doc,'staff');
  root_node:=dbe_xmldom.APPENDCHILD(doc_node, dbe_xmldom.MAKENODE(root_elmt));
  dbe_xmldom.freedocument(doc);
END;
/
-- Expected result:
ANONYMOUS BLOCK EXECUTE
```

- DBE_XMLDOM.FREEELEMENT

  Frees a DOMElement node. The prototype of the DBE_XMLDOM.FREEELEMENT function is as follows:

```
DBE_XMLDOM.FREEELEMENT(
  elem     IN     DOMELEMENT);
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 2-431 DBE_XMLDOM.FREEELEMENT API parameters

Parameter	Description
elem	Specified DOMElement node.

Example:

```
-- Obtain a DOMElement node from the DOC tree and free the node. Check whether the node is
empty before and after the node is freed.
DECLARE
  doc dbe_xmldom.domdocument;
  elem dbe_xmldom.domelement;
  node dbe_xmldom.domnode;
  node1 dbe_xmldom.domnode;
  nodelist DBE_XMLDOM.DOMNODELIST;
  len INTEGER;
  buffer varchar2(1010);
BEGIN
  doc := dbe_xmldom.newdomdocument('<?xml version="1.0"?>
     <!DOCTYPE note [<!ELEMENT note (to,from,heading,body)>
     <!ELEMENT to (#PCDATA)>
     <!ELEMENT from (#PCDATA)>
     <!ELEMENT heading (#PCDATA)>
     <!ELEMENT body (#PCDATA)>]>
     <note>
       <to>Chinese</to>
       <from>Jani</from>
       <heading>Reminder</heading>
       <body>Don''t forget me this weekend!</body>
     </note>');
  elem := dbe_xmldom.GETDOCUMENTELEMENT(doc);
  IF DBE_XMLDOM.ISNULL(elem) THEN
      dbe_output.print_line('IS NULL');
  ELSE
      dbe_output.print_line('NOT NULL');
  END IF;
  dbe_xmldom.FREEELEMENT(elem);

  IF DBE_XMLDOM.ISNULL(elem) THEN
       dbe_output.print_line('IS NULL');
  ELSE
       dbe_output.print_line('NOT NULL');
  END IF;
END;
/
-- Expected result:
NOT NULL
IS NULL
ANONYMOUS BLOCK EXECUTE
```

- DBE_XMLDOM.FREENODE

  Frees a DOMNode node. The prototype of the DBE_XMLDOM.FREENODE function is as follows:

```
DBE_XMLDOM.FREENODE(
  n IN DOMNODE);
```

Table 2-432 DBE_XMLDOM.FREENODE API parameters

Parameter	Description
n	Specified DOMNode node.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- After GaussDB performs the FREENODE operation, the freed node is not available again. After the database ORA performs the FREENODE operation, the freed node is available again and becomes another node.
- When other APIs call the freed DOMNode node, the calling is different from that in database ORA.

Example:

```
-- Obtain a DOMNode node from the DOC tree and free the node. Check whether the node is empty
before and after the node is freed.
DECLARE
  doc dbe_xmldom.domdocument;
  node dbe_xmldom.domnode;
  node1 dbe_xmldom.domnode;
  nodelist DBE_XMLDOM.DOMNODELIST;
  len INTEGER;
  buffer1 varchar2(1010);
BEGIN
  doc := dbe_xmldom.newdomdocument('<?xml version="1.0"?>
     <!DOCTYPE note [<!ELEMENT note (to,from,heading,body)>
     <!ELEMENT to (#PCDATA)>
     <!ELEMENT from (#PCDATA)>
     <!ELEMENT heading (#PCDATA)>
     <!ELEMENT body (#PCDATA)>]>
     <note>
       <to>Chinese</to>
       <from>Jani</from>
       <heading>Reminder</heading>
       <body>Don''t forget me this weekend!</body>
     </note>');
  node := dbe_xmldom.makenode(doc);
  node := dbe_xmldom.GETFIRSTCHILD(node);
  IF DBE_XMLDOM.ISNULL(node) THEN
        dbe_output.print_line('IS NULL');
  ELSE
        dbe_output.print_line('NOT NULL');
  END IF;
  DBE_XMLDOM.FREENODE(node);
  IF DBE_XMLDOM.ISNULL(node) THEN
        dbe_output.print_line('IS NULL');
  ELSE
        dbe_output.print_line('NOT NULL');
  END IF;
END;
/
-- Expected result:
NOT NULL
IS NULL
ANONYMOUS BLOCK EXECUTE
```

- DBE_XMLDOM.FREENODELIST

  Frees a DOMNodeList node. The prototype of the DBE_XMLDOM.FREENODE function is as follows:

```
DBE_XMLDOM.GETLENGTH(
  nl     IN    DOMNODELIST);
```

Table 2-433 DBE_XMLDOM.FREENODELIST API parameters

Parameter	Description
nl	Specified DOMNodeList node.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- A DOMNodeList node will be completed freed by FREENODELIST.
- When other APIs call the freed DOMNodelist node, the calling is different from that in database ORA.
- The input parameter **freenodelist** cannot be empty.

Example:

```
-- Obtain a DOMNodeList node from the DOC tree and free the node. Check the node length before and after the node is freed.
DECLARE
  doc dbe_xmldom.domdocument;
  node dbe_xmldom.domnode;
  node1 dbe_xmldom.domnode;
  nodelist DBE_XMLDOM.DOMNODELIST;
  len INTEGER;
  buffer1 varchar2(1010);
BEGIN
  doc := dbe_xmldom.newdomdocument('<?xml version="1.0"?>
     <!DOCTYPE note [<!ELEMENT note (to,from,heading,body)>
     <!ELEMENT to (#PCDATA)>
     <!ELEMENT from (#PCDATA)>
     <!ELEMENT heading (#PCDATA)>
     <!ELEMENT body (#PCDATA)>]>
     <note>
       <to>Chinese</to>
       <from>Jani</from>
       <heading>Reminder</heading>
       <body>Don''t forget me this weekend!</body>
     </note>');
  node := dbe_xmldom.makenode(doc);
  node := dbe_xmldom.GETFIRSTCHILD(node);
  nodelist := DBE_XMLDOM.GETCHILDNODES(node);
  len := DBE_XMLDOM.GETLENGTH(nodelist);
  RAISE NOTICE 'len :  %', len;
  DBE_XMLDOM.FREENODELIST(nodelist);
  len := DBE_XMLDOM.GETLENGTH(nodelist);
  RAISE NOTICE 'len :  %', len;
END;
/
-- Expected result:
NOTICE:  len :  4
NOTICE:  len :  0
ANONYMOUS BLOCK EXECUTE
```

- DBE_XMLDOM.GETATTRIBUTE

  Returns the attribute values of a DOMElement object by name. The prototype of the DBE_XMLDOM.GETATTRIBUTE function is as follows:

  ```
  DBE_XMLDOM.GETATTRIBUTE(
    elem       IN      DOMELEMENT,
    name       IN      VARCHAR2)
  RETURN VARCHAR2;
  ```

  Returns the attribute values of a DOMElement object by name and namespace URI. The prototype of the DBE_XMLDOM.GETATTRIBUTE function is as follows:

  ```
  DBE_XMLDOM.GETATTRIBUTE(
    elem      IN     DOMELEMENT,
    name      IN     VARCHAR2,
    ns        IN     VARCHAR2)
  RETURN VARCHAR2;
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 2-434 DBE_XMLDOM.GETATTRIBUTE API parameters

Parameter	Description
elem	Specified DOMElement node.
name	Attribute name.
ns	Namespace.

NOTE

- The **ns** parameter of the DBE_XMLDOM.GETATTRIBUTE API does not support the asterisk (*) parameter.
- GaussDB does not support the namespace prefix as an attribute, and the value of the prefix cannot be queried through the DBE_XMLDOM.GETATTRIBUTE API.

Example:

```
-- 1. Return the attribute values of a DOMElement object by name.
DECLARE
  doc dbe_xmldom.domdocument;
  elem dbe_xmldom.domelement;
  docnode DBE_XMLDOM.DOMNode;
  buffer varchar2(1010);
  value  varchar2(1000);
BEGIN
  doc := dbe_xmldom.newDOMDocument();
  elem := DBE_XMLDOM.CREATEELEMENT(doc, 'root');
  DBE_XMLDOM.setattribute(elem, 'len', '50cm');
  docnode := DBE_XMLDOM.appendChild(DBE_XMLDOM.makeNode(doc),
DBE_XMLDOM.makeNode(elem));
  value := DBE_XMLDOM.getattribute(elem, 'len');
  dbe_output.print_line('value: ');
  dbe_output.print_line(value);
  dbe_xmldom.writetobuffer(doc, buffer);
  dbe_output.print_line('buffer: ');
  dbe_output.print_line(buffer);
END;
/
-- Expected result:
value:

```

- DBE_XMLDOM.GETCHILDNODES

  Converts several subnodes under a node into a node list. The prototype of the DBE_XMLDOM.GETCHILDNODES function is as follows:

```
DBE_XMLDOM.GETCHILDNODES(
  n IN DOMNode)
RETURN DOMNodeList;
```

Table 2-436 DBE_XMLDOM.GETCHILDNODES API parameters

Parameter	Description
n	Specified DOMNode node.

Example:

```
-- After obtaining the first subnode of the DOC tree, convert several subnodes under the node into a node list and output the length information.
DECLARE
    doc dbe_xmldom.domdocument;
    doc_node dbe_xmldom.domnode;
    root_node dbe_xmldom.domnode;
    node_list dbe_xmldom.domnodelist;
    list_len integer;
    node_name varchar2(1000);
    node_type integer;
    buffer varchar2(1010);

- DBE_XMLDOM.GETCHILDRENBYTAGNAME

  Returns the subnodes of a DOMElement node by name. The prototype of the DBE_XMLDOM.GETCHILDRENBYTAGNAME function is as follows:

```
DBE_XMLDOM.GETCHILDRENBYTAGNAME (
  elem       IN      DOMELEMENT,
  name       IN      VARCHAR2)
RETURN DOMNODELIST;
```

  Returns the subnodes of a DOMElement node by name and namespace. The prototype of the DBE_XMLDOM.GETCHILDRENBYTAGNAME function is as follows:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
DBE_XMLDOM.GETCHILDRENBYTAGNAME (
  elem      IN     DOMELEMENT,
  name      IN     VARCHAR2,
  ns        IN     VARCHAR2)
 RETURN DOMNODELIST;
```

Table 2-437 DBE_XMLDOM.GETCHILDRENBYTAGNAME API parameters

Parameter	Description
elem	Specified DOMElement node.
name	Attribute name.
ns	Namespace.

NOTE

The **ns** parameter of the DBE_XMLDOM.GETCHILDRENBYTAGNAME API does not support the asterisk (*) parameter. To obtain all attributes of a node, use the DBE_XMLDOM.GETCHILDNODES API.

Example:

```
-- 1. Return the subnodes of a DOMElement node by name.
DECLARE
  doc dbe_xmldom.domdocument;
  elem dbe_xmldom.domelement;
  docnodelist dbe_xmldom.domnodelist;

```
DBE_XMLDOM.GETNAMEDITEM(
  nnm IN DOMNAMEDNODEMAP,
  name IN VARCHAR2)
RETURN DOMNODE;
```

  Returns the node specified by name and namespace. The prototype of the DBE_XMLDOM.GETNAMEDITEM function is as follows:

```
DBE_XMLDOM.GETNAMEDITEM(
  nnm IN DOMNAMEDNODEMAP,
  name IN VARCHAR2,
  ns IN VARCHAR2)
RETURN DOMNODE;
```

Table 2-443 DBE_XMLDOM.GETNAMEDITEM API parameters

Parameter	Description
nnm	Specified DOMNamedNodeMap object.
name	Name of the element to be retrieved.
ns	Namespace.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- The values of **name** and **nnm** can be null, but they are required arguments.
- The default maximum length of **name** and **ns** is 32767. If the length exceeds 32767, an error is reported.
- The values of **name** and **ns** can be of the int type and contain more than 127 bits.

Example:

```
-- 1. Return the node specified by name.

ANONYMOUS BLOCK EXECUTE
```

- DBE_XMLDOM.IMPORTNODE

  Copies a node to another node and mounts the copied node to a specified document. If the type of the copied node does not belong to the 12 types specified by constants of XML DOM, an exception indicating that the type is not supported will be thrown. The prototype of the DBE_XMLDOM.IMPORTNODE function is as follows:

```
DBE_XMLDOM.IMPORTNODE(
  doc IN DOMDOCUMENT,
  importedNode IN DOMNODE,
  deep IN BOOLEAN)
RETURN DOMNODE;
```

Table 2-451 DBE_XMLDOM.IMPORTNODE API parameters

Parameter	Description
doc	Document to which the node is mounted.
importedNode	Node to be imported.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Description
deep	Specifies whether to perform recursive import. • If the value is **TRUE**, the node and all its subnodes are imported. • If the value is **FALSE**, the node itself is imported.

Example:

```
-- Obtain the root2_node node in the DOC2 tree, copy it, and mount it to the DOC tree.
DECLARE
    doc dbe_xmldom.domdocument;
    doc2 dbe_xmldom.domdocument;
    doc_node dbe_xmldom.domnode;
    doc2_node dbe_xmldom.domnode;
     root_node dbe_xmldom.domnode;
    root2_node dbe_xmldom.domnode;
    import_node dbe_xmldom.domnode;
    result_node dbe_xmldom.domnode;
    buffer varchar2(1010);
BEGIN
    doc := dbe_xmldom.newdomdocument('<bookstore category="web" cover="paperback">
       <book category="cooking"><title lang="en">Everyday Italian</title>

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- DBE_XMLDOM.ISNULL

  Checks whether the given DOMAttr node is null. If so, **TRUE** is returned. If not, **FALSE** is returned. The prototype of the DBE_XMLDOM.ISNULL function is as follows:

  ```
  DBE_XMLDOM.ISNULL(
    a       IN     DOMATTR)
  RETURN BOOLEAN;
  ```

  Checks whether the given DOMDocument node is null. If so, **TRUE** is returned. If not, **FALSE** is returned. The prototype of the DBE_XMLDOM.ISNULL function is as follows:

  ```
  DBE_XMLDOM.ISNULL(
    doc       IN     DOMDOCUMENT)
  RETURN BOOLEAN;
  ```

  Checks whether the given DOMElement node is null. If so, **TRUE** is returned. If not, **FALSE** is returned. The prototype of the DBE_XMLDOM.ISNULL function is as follows:

  ```
  DBE_XMLDOM.ISNULL(
    elem     IN     DOMELEMENT)
  RETURN BOOLEAN;
  ```

  Checks whether the given DOMNamedNodeMap node is null. If so, **TRUE** is returned. If not, **FALSE** is returned. The prototype of the DBE_XMLDOM.ISNULL function is as follows:

  ```
  DBE_XMLDOM.ISNULL(
    nnm       IN     DOMNAMEDNODEMAP)
  RETURN BOOLEAN;
  ```

  Checks whether the given DOMNode node is null. If so, **TRUE** is returned. If not, **FALSE** is returned. The prototype of the DBE_XMLDOM.ISNULL function is as follows:

  ```
  DBE_XMLDOM.ISNULL(
    n      IN     DOMNODE)
  RETURN BOOLEAN;
  ```

  Checks whether the given DOMNodeList node is null. If so, **TRUE** is returned. If not, **FALSE** is returned. The prototype of the DBE_XMLDOM.ISNULL function is as follows:

  ```
  DBE_XMLDOM.ISNULL(
    nl       IN     DOMNODELIST)
  RETURN BOOLEAN;
  ```

  Checks whether the given DOMText node is null. If so, **TRUE** is returned. If not, **FALSE** is returned. The prototype of the DBE_XMLDOM.ISNULL function is as follows:

  ```
  DBE_XMLDOM.ISNULL(
    t       IN     DOMTEXT)
  RETURN BOOLEAN;
  ```

Table 2-452 DBE_XMLDOM.ISNULL API parameters

Parameter	Description
a	Specified DOMAttr node.
doc	Specified DOMDocument node.
elem	Specified DOMElement node.
nnm	Specified DOMNamedNodeMap node.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Description
n	Specified DOMNode node.
nl	Specified DOMNodeList node.
t	Specified DOMText node.

NOTE

Due to the implementation difference of DBE_XMLDOM.FREEDOCUMENT, an error is reported when the DBE_XMLDOM.ISNULL API calls the freed DOMDocument node.

Example:

```
-- 1. Use createAttribute to create a DOMAttr node and check whether the node is empty.
DECLARE
  doc DBE_XMLDOM.DOMDocument;
  attr DBE_XMLDOM.DOMATTR;
  buf VARCHAR2(1000);

- DBE_XMLDOM.ITEM

  Returns the element corresponding to the index in a list based on the index. The prototype of the DBE_XMLDOM.ITEM function is as follows:

```
DBE_XMLDOM.ITEM(
  nl IN DOMNODELIST,
  index IN NUMBER)
RETURN DOMNODE;
```

  Returns the element corresponding to the index in a map based on the index. The prototype of the DBE_XMLDOM.ITEM function is as follows:

```
DBE_XMLDOM.ITEM(
  nnm IN DOMNAMEDNODEMAP,
  index IN NUMBER)
RETURN DOMNODE;
```

Table 2-453 DBE_XMLDOM.ITEM API parameters

Parameter	Description
nl	Specified DOMNodeList object.
nnm	Specified DOMNamedNodeMap object.
index	Index of the element to be retrieved.

> **NOTE**
>
> For improper input parameters such as Boolean and CLOB, the item function of the map type points to the value of the first index by default.

Example:

```
-- 1. Return the element corresponding to the index in a map based on the index.
DECLARE
  doc DBE_XMLDOM.DOMDocument;
  elem DBE_XMLDOM.DOMElement;
  map DBE_XMLDOM.DOMNAMEDNODEMAP;

  DBE_OUTPUT.print_line(buf);
END;
/
-- Expected result:
aaa
ANONYMOUS BLOCK EXECUTE
```

- DBE_XMLDOM.MAKENODE

  Forcibly converts a specified DOMAttr node to a DOMNode node and returns the DOMNode node. The prototype of the DBE_XMLDOM.MAKENODE function is as follows:

  ```
  DBE_XMLDOM.MAKENODE(
    a        IN     DOMATTR)
   RETURN DOMNODE;
  ```

  Forcibly converts a specified DOMDocument node to a DOMNode node and returns the DOMNode node. The prototype of the DBE_XMLDOM.MAKENODE function is as follows:

  ```
  DBE_XMLDOM.MAKENODE(
    doc      IN     DOMDOCUMENT)
   RETURN DOMNODE;
  ```

  Forcibly converts a specified DOMElement node to a DOMNode node and returns the DOMNode node. The prototype of the DBE_XMLDOM.MAKENODE function is as follows:

  ```
  DBE_XMLDOM.MAKENODE(
    elem       IN     DOMELEMENT)
   RETURN DOMNODE;
  ```

  Forcibly converts a specified DOMText node to a DOMNode node and returns the DOMNode node. The prototype of the DBE_XMLDOM.MAKENODE function is as follows:

  ```
  DBE_XMLDOM.MAKENODE(
    t       IN     DOMTEXT)
   RETURN DOMNODE;
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 2-455 DBE_XMLDOM.MAKENODE API parameters

Parameter	Description
a	Specified DOMAttr node.
doc	Specified DOMDocument node.
elem	Specified DOMElement node.
t	Specified DOMText node.

NOTE

Due to syntax restrictions, when DBE_XMLDOM.MAKENODE is used as the return value of a function, it cannot be directly implemented by running the following command:

```
return DBE_XMLDOM.MAKENODE(doc);
```

You are advised to run the following command:

```
tmp_node := DBE_XMLDOM.MAKENODE(doc );
return tmp_node;
```

Example:

```
-- 1. Use createattr to generate ATTR and convert it to a node.
DECLARE
  doc DBE_XMLDOM.DOMDocument;
  attr DBE_XMLDOM.DOMATTR;
  dom_node DBE_XMLDOM.DOMNode;

- DBE_XMLDOM.NEWDOMDOCUMENT

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Returns a new DOMDocument object. The prototype of the DBE_XMLDOM.NEWDOMDOCUMENT function is as follows:

```
DBE_XMLDOM.NEWDOMDOCUMENT
RETURN DOMDOCUMENT;
```

Returns a new DOMDocument instance object created from the specified XMLType type. The prototype of the DBE_XMLDOM.NEWDOMDOCUMENT function is as follows:

```
DBE_XMLDOM.NEWDOMDOCUMENT(
  xmldoc    IN SYS.XMLTYPE)
RETURN DOMDOCUMENT;
```

Returns a new DOMDocument instance object created from the specified CLOB type. The prototype of the DBE_XMLDOM.NEWDOMDOCUMENT function is as follows:

```
DBE_XMLDOM.NEWDOMDOCUMENT(
  cl       IN    CLOB)
RETURN DOMDOCUMENT;
```

Table 2-456 DBE_XMLDOM.NEWDOMDOCUMENT API parameters

Parameter	Description
xmldoc	Specified XMLType type.
cl	Specified CLOB type.

NOTE

- The size of the input parameter must be less than 1 GB.
- Currently, external DTD parsing is not supported.
- The document created by NEWDOMDOCUMENT uses the UTF-8 character set by default.
- Each document parsed from the same XMLType instance is independent, and the modification of the document does not affect the XMLType.
- For details about the differences between our database and database ORA, see **DBE_XMLPARSER.PARSECLOB**.

Example:

```
-- 1. Return a new DOMDocument object.
DECLARE
  doc dbe_xmldom.domdocument;
  buffer varchar2(1010);
BEGIN
  doc := dbe_xmldom.newdomdocument();
  dbe_xmldom.setdoctype(doc, 'note', 'sysid', 'pubid');
  dbe_xmldom.writetobuffer(doc, buffer);
  dbe_output.print_line('buffer: ');
  dbe_output.print_line(buffer);
  dbe_xmldom.freedocument(doc);
END;
/
-- Expected result:
buffer:
<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE note PUBLIC "pubid" "sysid">

- DBE_XMLDOM.SETATTRIBUTE

  Sets the value of the DOMElement attribute by name. The prototype of the DBE_XMLDOM.SETATTRIBUTE function is as follows:

```
DBE_XMLDOM.SETATTRIBUTE(
  elem    IN  DOMELEMENT,
  name    IN  VARCHAR2,
  value   IN  VARCHAR2);
```

  Sets the attribute values of a DOMElement object by name and namespace URI. The prototype of the DBE_XMLDOM.SETATTRIBUTE function is as follows:

```
DBE_XMLDOM.SETATTRIBUTE(
  elem    IN  DOMELEMENT,
  name    IN  VARCHAR2,
  value   IN  VARCHAR2,
  ns      IN  VARCHAR2);
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 2-457 DBE_XMLDOM.SETATTRIBUTE API parameters

Parameter	Description
elem	Specified DOMElement node.
name	Attribute name.
value	Attribute value.
ns	Namespace.

NOTE

Multiple attributes can be added through the DBE_XMLDOM.SETATTRIBUTE API. The attribute name cannot be null, and attributes with the same name cannot exist in the same DOMElement node. If you want to add attributes with the same name, you should explicitly set a namespace for each attribute with the same name, but you are advised not to perform such operations. If an attribute exists in a namespace, the specified namespace must be displayed when you modify the attribute. Otherwise, the attribute with the same name is added.

Example:

```
-- 1. Set the value of the DOMElement attribute by name.
DECLARE
  doc dbe_xmldom.domdocument;
  elem dbe_xmldom.domelement;
  docnode DBE_XMLDOM.DOMNode;
  buffer varchar2(1010);
  value  varchar(1000);
BEGIN
  doc := dbe_xmldom.newDOMDocument();
  elem := DBE_XMLDOM.CREATEELEMENT(doc, 'root');
  DBE_XMLDOM.setattribute(elem, 'len', '50cm');
  docnode := DBE_XMLDOM.appendChild(DBE_XMLDOM.makeNode(doc),
DBE_XMLDOM.makeNode(elem));
  dbe_xmldom.writetobuffer(doc, buffer);
  dbe_output.print_line('buffer: ');

ANONYMOUS BLOCK EXECUTE
```

- DBE_XMLDOM.SETCHARSET

  Sets the character set for a DOMDocument object. The prototype of the DBE_XMLDOM.SETCHARSET function is as follows:

```
DBE_XMLDOM.SETCHARSET(
  doc      IN     DOMDocument,
  charset  IN     VARCHAR2);
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 2-458 DBE_XMLDOM.SETCHARSET API parameters

Parameter	Description
doc	Specified DOMDocument node.
charset	Character set.

NOTE

- The value of **charset** contains a maximum of 60 bytes.
- Currently, the following character sets are supported: UTF-8, UCS-4, UCS-2, ISO-8859-1, ISO-8859-2, ISO-8859-3, ISO-8859-4, ISO-8859-5, ISO-8859-6, ISO-8859-7, ISO-8859-8, ISO-8859-9, ISO-2022-JP, Shift_JIS, EUC-JP and ASCII. If you enter other character sets, an error is reported or garbled characters may be displayed.

Example:

```
-- Set the UTF-8 character set for the DOC tree and print the DOC tree to the buffer.
DECLARE
  doc dbe_xmldom.domdocument;
  buffer varchar2(1010);
BEGIN
  doc := dbe_xmldom.newdomdocument('<?xml version="1.0"?>
      <!DOCTYPE note [<!ELEMENT note (to,from,heading,body)><!ELEMENT to (#PCDATA)>
      <!ELEMENT from (#PCDATA)><!ELEMENT heading (#PCDATA)><!ELEMENT body (#PCDATA)>]>
      <note><to>test</to><from>Jani</from><heading>Reminder</heading>
      <body>Don''t forget me this weekend!</body></note>');
  dbe_xmldom.setcharset(doc, 'utf-8');
  dbe_xmldom.writetobuffer(doc, buffer);
  dbe_output.print_line('buffer: ');
  dbe_output.print_line(buffer);
  dbe_xmldom.freedocument(doc);
END;
/
-- Expected result:

ANONYMOUS BLOCK EXECUTE
```

- DBE_XMLDOM.SETDOCTYPE

  Sets the external DTD of a DOMDocument object. The prototype of the DBE_XMLDOM.SETDOCTYPE function is as follows:

```
DBE_XMLDOM.SETDOCTYPE(
  doc     IN   DOMDocument,
  name    IN   VARCHAR2,
  sysid   IN   VARCHAR2,
  pubid   IN   VARCHAR2);
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 2-459 DBE_XMLDOM.SETDOCTYPE API parameters

Parameter	Description
doc	Specified DOMDocument node.
name	Name of the DOCType to be initialized.
sysid	ID of the system whose DOCType needs to be initialized.
pubid	Public ID of the DOCType to be initialized.

NOTE

The total length of **name**, **sysid**, and **pubid** cannot exceed 32500 bytes.

Example:

```
-- After the initial system ID, public ID, and name are set for the external DTD of the DOMDocument, the DOC tree modified each time is output to the buffer.
DECLARE
  doc dbe_xmldom.domdocument;
  buffer varchar2(1010);
begin
  doc := dbe_xmldom.newdomdocument('<?xml version="1.0"?>
      <!DOCTYPE note [<!ELEMENT note (to,from,heading,body)><!ELEMENT to (#PCDATA)>
      <!ELEMENT from (#PCDATA)><!ELEMENT heading (#PCDATA)><!ELEMENT body (#PCDATA)>]>
      <note><to>test</to><from>Jani</from><heading>Reminder</heading>
      <body>Don''t forget me this weekend!</body></note>');
  dbe_xmldom.setdoctype(doc, 'note', 'sysid', 'pubid');
  dbe_xmldom.writetobuffer(doc, buffer);
  dbe_output.print_line('buffer: ');
  dbe_output.print_line(buffer);
  dbe_output.print_line('-------------------------------------------------');
  dbe_xmldom.setdoctype(doc, 'n0te', NULL, '');
  dbe_xmldom.setdoctype(doc, 'n0t1e', NULL, '');
  dbe_xmldom.writetobuffer(doc, buffer);
  dbe_output.print_line('buffer: ');
  dbe_output.print_line(buffer);
  dbe_xmldom.freedocument(doc);
END;
/
-- Expected result:

ANONYMOUS BLOCK EXECUTE
```

- DBE_XMLDOM.SETNODEVALUE

  Sets the value of a node in the DOMNode object. The prototype of the DBE_XMLDOM.SETNODEVALUE function is as follows:

```
DBE_XMLDOM.SETNODEVALUE(
 n IN DOMNODE,
 nodeValue IN VARCHAR2);
```

Table 2-460 DBE_XMLDOM.SETNODEVALUE API parameters

Parameter	Description
n	Specified DOMNode object.
nodeValue	String to be set in the DOMNode object.

NOTE

- You can enter an empty string or null value for **nodeValue**, but the node value will not be changed.
- **nodeValue** supports the escape character '&', which is automatically escaped during serialization.
- The default maximum length of **nodeValue** is restricted by the VARCHAR2 type and is 32767 bytes. If the length exceeds 32767 bytes, an exception is thrown.

Example:

```
-- After setting a node value different from the initial value for the DOMNode node that is converted from DOMText, obtain and output the node value.
DECLARE
  buf VARCHAR2(1000);
  doc DBE_XMLDOM.DOMDocument;
  text DBE_XMLDOM.DOMText;
  elem2 DBE_XMLDOM.DOMElement;
  node DBE_XMLDOM.DOMNode;
BEGIN
  doc := DBE_XMLDOM.NEWDOMDOCUMENT();
  text := DBE_XMLDOM.createTextNode(doc, 'aaa');
  DBE_XMLDOM.SETNODEVALUE(DBE_XMLDOM.makeNode(text), 'ccc');
  buf := DBE_XMLDOM.GETNODEVALUE(DBE_XMLDOM.makeNode(text));
  DBE_OUTPUT.print_line(buf);
END;
/
-- Expected result:
ccc
ANONYMOUS BLOCK EXECUTE
```

- DBE_XMLDOM.WRITETOBUFFER

  Writes an XML node to a specified buffer using the database character set. The prototype of the DBE_XMLDOM.WRITETOBUFFER function is as follows:

```
DBE_XMLDOM.WRITETOBUFFER(
  doc      IN      DOMDOCUMENT,
  buffer   INOUT  VARCHAR2);
```

  Writes an XML document to a specified buffer using the database character set. The prototype of the DBE_XMLDOM.WRITETOBUFFER function is as follows:

```
DBE_XMLDOM.WRITETOBUFFER(
  n        IN      DOMNODE,
  buffer   INOUT  VARCHAR2);
```

Table 2-461 DBE_XMLDOM.WRITETOBUFFER API parameters

Parameter	Description
doc	Specified DOMDocument node.
buffer	Buffer for the write operation.
n	Specified DOMNode node.

NOTE

- The buffer to which the writetobuffer function writes is less than 1 GB.
- This function adds content such as indentation to format the output. The output document will contain the XML declaration version and encoding.
- By default, XML files are output in the UTF-8 character set.

Example:

```
-- 1. Enter a parameter of the DOMNode type.
DECLARE
   doc dbe_xmldom.domdocument;
   elem DBE_XMLDOM.DOMELEMENT;
   buf varchar2(1000);
BEGIN
    doc := dbe_xmldom.newdomdocument();
    elem := dbe_xmldom.createelement(doc,'elem');
    DBE_XMLDOM.WRITETOBUFFER(dbe_xmldom.makenode(elem), buf);
    DBE_OUTPUT.print_line(buf);
END;
/
-- Expected result:

- DBE_XMLDOM.WRITETOCLOB

  Writes an XML node to a specified CLOB using the database character set. The prototype of the DBE_XMLDOM.WRITETOCLOB function is as follows:

```
DBE_XMLDOM.WRITETOCLOB(
  doc     IN      DOMDOCUMENT,
  cl      INOUT  CLOB);
```

  Writes an XML node to a specified CLOB using the database character set. The prototype of the DBE_XMLDOM.WRITETOCLOB function is as follows:

```
DBE_XMLDOM.WRITETOCLOB(
  n       IN      DOMNODE,
  cl      INOUT  CLOB);
```

Table 2-462 DBE_XMLDOM.WRITETOCLOB API parameters

Parameter	Description
doc	Specified DOMDocument node.
cl	CLOB to be written.
n	Specified DOMNode node.

NOTE

- The **doc** parameter is an input parameter. The CLOB to which the writetoclob function writes is less than 1 GB.
- This function adds content such as indentation to format the output. The output document will contain the XML declaration version and encoding.
- By default, XML files are output in the UTF-8 character set.

Example:

```
-- 1. Enter a parameter of the DOMNode type.
DECLARE
  CL  CLOB;
  N   DBE_XMLDOM.DOMNODE;
BEGIN
  DBE_XMLDOM.WRITETOCLOB(N, CL);
  DBE_OUTPUT.PRINT_LINE(CL);
END;
/
```

- DBE_XMLDOM.WRITETOFILE

  Writes an XML node to a specified file using the database character set. The prototype of the DBE_XMLDOM.WRITETOFILE function is as follows:

  ```
  DBE_XMLDOM.WRITETOCLOB(
    doc     IN      DOMDOCUMENT,
    fileName   IN      VARCHAR2);
  ```

  Writes an XML node to a specified file using the database character set. The prototype of the DBE_XMLDOM.WRITETOFILE function is as follows:

  ```
  DBE_XMLDOM.WRITETOCLOB(
    n       IN      DOMNODE,
    fileName   IN      VARCHAR2);
  ```

  Writes an XML document to a specified file using the specified character set. The prototype of the DBE_XMLDOM.WRITETOFILE function is as follows:

  ```
  DBE_XMLDOM.WRITETOCLOB(
    doc     IN      DOMDOCUMENT,
    fileName   IN      VARCHAR2,
    charset   IN   VARCHAR2);
  ```

  Writes an XML document to a specified file using the specified character set. The prototype of the DBE_XMLDOM.WRITETOFILE function is as follows:

  ```
  DBE_XMLDOM.WRITETOCLOB(
    n       IN      DOMNODE,
    fileName   IN      VARCHAR2,
    charset   IN   VARCHAR2);
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 2-463 DBE_XMLDOM.WRITETOFILE API parameters

Parameter	Description
doc	Specified DOMDocument node.
fileName	File to be written.
n	Specified DOMNode node.
charset	Specified character set.

NOTE

- The **doc** parameter is an input parameter. The value of **filename** can contain a maximum of 255 bytes, and the value of **charset** can contain a maximum of 60 bytes. For details about the character sets supported by **charset**, see the **DBE_XMLDOM.SETCHARSET** API.
- This function adds content such as indentation to format the output. The output document will contain the XML declaration version and encoding.
- If newdomdocument() is used to create a document without parameters, no error is reported when **charset** is not specified. The UTF-8 character set is used by default.
- The **filename** must be in the path created in **pg_directory**. The backslash (\) in the filename will be converted to a slash (/). Only one slash (/) is allowed. The file name must be in the **pg_directory_name/file_name.xml** format. The output file must be in the XML format.
- When the GUC parameter **safe_data_path** is enabled, you can only use an advanced package to read and write files in the file path specified by **safe_data_path**.
- Before creating a directory, ensure that the directory exists in the OS and the user has the read and write permissions on the directory. For details about how to create a directory, see **CREATE DIRECTORY**.

Example:

```
-- Before creating a directory, ensure that the directory exists in the OS and the user has the read and write permissions on the directory.
create directory dir as '/tmp';
-- 1. Write an XML node to a specified file using the database character set.
DECLARE
  FPATH VARCHAR2(1000);

    <B>B TXT</B>
    <C/>
  </ROOT>';
  DOC := DBE_XMLDOM.NEWDOMDOCUMENT(SRC);
  ELE := DBE_XMLDOM.GETDOCUMENTELEMENT(DOC);
  DBE_XMLDOM.WRITETOFILE(DBE_XMLDOM.MAKENODE(ELE), FPATH, 'ASCII');
  DBE_XMLDOM.FREEDOCUMENT(DOC);
END;
/
-- Expected result:
ANONYMOUS BLOCK EXECUTE

-- Clean up the environment.
drop directory dir;
```

- DBE_XMLDOM.GETSESSIONTREENUM

  Queries the number of DOM trees of all types in the current session. The prototype of the DBE_XMLDOM.GETSESSIONTREENUM function is as follows:

  ```
  DBE_XMLDOM.GETSESSIONTREENUM()
  RETURN INTEGER;
  ```

  NOTE

  For DOM trees that have used FREEElement and FREENode, this function still counts them.

  Example:

  ```
  -- Create three documents and obtain the number of DOM trees in the current session.
  DECLARE
    doc DBE_XMLDOM.DOMDocument;
    doc2 DBE_XMLDOM.DOMDocument;
    doc3 DBE_XMLDOM.DOMDocument;

    buffer varchar2(1010);
  BEGIN
  -- Create three documents.
    doc := DBE_XMLDOM.NEWDOMDOCUMENT('<?xml version="1.0"?>
  <root>
     <elem1 attr="attrtest">
        <elem2>Im text</elem2>
        <elem3>Im text too</elem3>
     </elem1>
     <elem4>Text</elem4>
  </root>
  ');

- DBE_XMLDOM.GETELEMENTSBYTAGNAM

  Searches for the DOMNodelist node by name in the XML file and returns the node. The prototype of the DBE_XMLDOM.GETELEMENTSBYTAGNAME function is:

  ```
  DBE_XMLDOM.GETELEMENTSBYTAGNAME(
    doc        IN      DOMDOCUMENT,
    tagname    IN      VARCHAR2)
  RETURN DOMNODELIST;
  ```

  Searches for the DOMNodelist node by name in the XML file and returns the node. The prototype of the DBE_XMLDOM.GETELEMENTSBYTAGNAME function is:

  ```
  DBE_XMLDOM.GETELEMENTSBYTAGNAME(
    elem       IN      DOMELEMENT,
    tagname       IN      VARCHAR2)
  RETURN DOMNODELIST;
  ```

  Searches for the DOMNodelist node by name and namespace in the XML file and returns the node. The prototype of the DBE_XMLDOM.GETELEMENTSBYTAGNAME function is:

  ```
  DBE_XMLDOM.GETELEMENTSBYTAGNAME(
    elem       IN      DOMELEMENT,
    tagname       IN      VARCHAR2,
    ns         IN      VARCHAR2)
   RETURN DOMNODELIST;
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 2-465 DBE_XMLDOM.GETELEMENTSBYTAGNAME API parameters

Parameter	Description
doc	Specified DOMDocument node.
elem	Specified DOMElement node.
tagname	Tag name. Using the wildcard (*) will match any tag.
ns	Namespace. Using the wildcard (*) will match any namespace.

Example:

```
-- 1. Search the DOMDocument node by TAGNAME and return the matched DOMNodelist node list.
DECLARE
  doc DBE_XMLDOM.DOMDocument;
  root_elem DBE_XMLDOM.DOMElement;
  child_node DBE_XMLDOM.DOMNODE;

2.12.2.22 DBE_XMLGEN

APIs

The DBE_XMLGEN system package converts the result of an SQL query into a standard XML format and returns the result. For details about all the supported APIs, see **Table 2-467**.

Table 2-466 DBE_XMLGEN data type

Type	Description
DBE_XMLGEN.CTXHANDLE	Data type used to store the XML output status.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- A maximum of 65,535 context handles can exist in a session. Closing a context handle does not reclaim the resource.
- The CONNECT BY statement is not supported in the distributed system. Therefore, the NEWCONTEXTFROMHIERARCHY function cannot be constructed.
- In a distributed system, the cursor cannot be moved reversely. Therefore, the RESTARTQUERY function is unavailable.
- The case of the table column and type in the output XML file is the same as that of the table column and type created by the user. If you need to write a large column and type name, use double quotation marks ("") to specify the column and type name.
- During NEWCONTEXTFROMHIERARCHY initialization, the SETNULLHANDLING, USENULLATTRIBUTEINDICATOR, and SETCONVERTSPECIALCHARS methods can be used to set this parameter, but the setting does not take effect.
- If ORDER BY is not added for query, the query result is disordered, which affects the return result of the GETXML function.
- When the EXECUTE DIRECT ON syntax is used to execute functions in the DBE_XMLGEN package, if the GUC parameter **enable_udf_execute_direct** is set to **on**, the functions can be executed; if the parameter is set to **off**, the functions cannot be executed.

Table 2-467 DBE_XMLGEN

API	Description
DBE_XMLGEN.CONVERT	Encodes or decodes the input character string in XML format.
DBE_XMLGEN.NEWCONTEXT	Initializes the common context handle.
DBE_XMLGEN.NEWCONTEXTFROMHIERARCHY	Initializes the context handle with recursive elements.
DBE_XMLGEN.SETCONVERTSPECIALCHARS	Specifies whether the output XML needs to be encoded.
DBE_XMLGEN.SETNULLHANDLING	Sets how to display the null value in the XML file.
DBE_XMLGEN.SETROWSETTAG	Sets the name of the XML root node.
DBE_XMLGEN.SETROWTAG	Sets the tag name of each row of data in the XML file.
DBE_XMLGEN.USENULLATTRIBUTEINDICATOR	Adds the **xsi:nil="true"** attribute to the element where the **null** value is located in the XML file.
DBE_XMLGEN.USEITEMTAGSFORCOLL	Adds the suffix **_ITEM** to the element where the variable of the array type is located.
DBE_XMLGEN.GETNUMROWSPROCESSED	Views the number of data rows returned by GETXML or GETXMLTYPE last time.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

API	Description
DBE_XMLGEN.SETMAXROWS	Sets the maximum number of rows returned for a GETXML operation.
DBE_XMLGEN.SETSKIPROWS	Sets the number of SQL rows to be skipped.
DBE_XMLGEN.RESTARTQUERY	Restarts the SQL.
DBE_XMLGEN.GETXMLTYPE	Returns the XML text of the XMLTYPE type.
DBE_XMLGEN.GETXML	Returns the XML text of the CLOB type.
DBE_XMLGEN.CLOSECONTEXT	Disables the context handle.

- DBE_XMLGEN.CONVERT

  Encodes or decodes the input character string in XML format. The conversion is performed according to the following rules.

  Table 2-468 XML encoding rules

Original Value	Code Value
&	&
<	<
>	>
"	"
'	'

  The prototype of the DBE_XMLGEN.CONVERT function is as follows:

```
DBE_XMLGEN.CONVERT(XMLSTR IN VARCHAR2, FLAG IN NUMBER := 0) RETURNS VARCHAR2;
DBE_XMLGEN.CONVERT(XMLCLOB IN CLOB, FLAG IN NUMBER := 0) RETURNS CLOB;
```

  Table 2-469 DBE_XMLGEN.CONVERT API parameters

Parameter	Description
XMLSTR	XML character string to be converted. The value is of the VARCHAR2 type.
XMLCLOB	XML character string to be converted. The value is of the CLOB type.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Description
FLAG	Transcodes or decodes character strings. **0**: encoding. **1**: decoding.

Example:

```
-- XML decoding
SELECT DBE_XMLGEN.CONVERT('<foo/>', 1);
 convert
---------
 <foo/>
(1 row)
-- XML encoding
SELECT DBE_XMLGEN.CONVERT('<foo><qwe</foo>', 0);
           convert
--------------------------------
 &lt;foo&gt;&lt;qwe&lt;/foo&gt;
(1 row)
```

- DBE_XMLGEN.NEWCONTEXT

  Initializes a common context handle. The context handle can be used only in one transaction. Otherwise, an error is reported when **DBE_XMLGEN.RESTARTQUERY** and **DBE_XMLGEN.CLOSECONTEXT** are used to close the context handle.

  The prototype of the DBE_XMLGEN.NEWCONTEXT function is as follows:

  ```
  DBE_XMLGEN.NEWCONTEXT(QUERYSTRING IN VARCHAR2) RETURNS DBE_XMLGEN.CTXHANDLE;
  DBE_XMLGEN.NEWCONTEXT(QUERYSTRING IN SYS_REFCURSOR) RETURNS
  DBE_XMLGEN.CTXHANDLE;
  ```

  Table 2-470 DBE_XMLGEN.NEWCONTEXT API parameters

Parameter	Description
QUERYSTRING	SQL statement or SYS_REFCURSOR used to generate XML files.

- DBE_XMLGEN.NEWCONTEXTFROMHIERARCHY

  Initializes the context handle with recursive elements. The data format must contain two columns. The first column is of the numeric type, and the second column is of the XML or XMLTYPE type. Generally, the value is generated by the CONNECT BY statement. The first column specifies the generation level. The distributed system does not support the connect by statement. Therefore, this function case cannot be constructed.

  NOTE

  The number of nested layers in the generated XML file cannot exceed 50 million.

  The prototype of the DBE_XMLGEN.NEWCONTEXTFROMHIERARCHY function is as follows:

  ```
  DBE_XMLGEN.NEWCONTEXTFROMHIERARCHY(QUERYSTRING IN VARCHAR2);
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 2-471 DBE_XMLGEN.NEWCONTEXTFROMHIERARCHY API parameters

Parameter	Description
QUERYSTRING	XML character string to be converted. The value is of the VARCHAR2 type.

- DBE_XMLGEN.SETCONVERTSPECIALCHARS

  Specifies whether the output XML needs to be encoded. If XML encoding is canceled, XML injection may occur. Due to performance issues, if the XML is secured, XML encoding can be skipped.

  The prototype of the DBE_XMLGEN.SETCONVERTSPECIALCHARS function is as follows:

  ```
  DBE_XMLGEN.SETCONVERTSPECIALCHARS(CTX IN DBE_XMLGEN.CTXHANDLE, CONV IN BOOLEAN);
  ```

  Table 2-472 DBE_XMLGEN.SETCONVERTSPECIALCHARS API parameters

Parameter	Description
CTX	Context handle.
CONV	Specifies whether to encode the output XML file. ● **true**: yes. ● **false**: no.

- DBE_XMLGEN.SETNULLHANDLING

  Sets how to display the null value in the XML file.

  The prototype of the DBE_XMLGEN.SETNULLHANDLING function is as follows:

  ```
  DBE_XMLGEN.SETNULLHANDLING(CTX IN DBE_XMLGEN.CTXHANDLE, FLAG IN NUMBER := 0);
  ```

  Table 2-473 DBE_XMLGEN.SETNULLHANDLING API parameters

Parameter	Description
CTX	Context handle.
FLAG	Null value display format. ● **0**: The element is not displayed. ● **1**: The **xsi:nil="true"** attribute is added to the element. ● **2**: Self-closed elements are displayed.

- DBE_XMLGEN.SETROWSETTAG

  Sets the name of the XML root node.

  The prototype of the DBE_XMLGEN.SETROWSETTAG function is as follows:

  ```
  DBE_XMLGEN.SETROWSETTAG(CTX IN DBE_XMLGEN.CTXHANDLE, ROWSETTAGNAME IN VARCHAR2);
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 2-474 DBE_XMLGEN.SETROWSETTAG API parameters

Parameter	Description
CTX	Context handle.
ROWSETTAGNAME	Name of the XML root node.

- DBE_XMLGEN.SETROWTAG

  Sets the tag name of each row of data in the XML file.

  The prototype of the DBE_XMLGEN.SETROWTAG function is as follows:

  ```
  DBE_XMLGEN.SETROWTAG(CTX IN DBE_XMLGEN.CTXHANDLE, ROWTAGNAME IN VARCHAR2);
  ```

  Table 2-475 DBE_XMLGEN.SETROWTAG API parameters

Parameter	Description
CTX	Context handle.
ROWTAGNAME	Tag name of each row of data.

- DBE_XMLGEN.USENULLATTRIBUTEINDICATOR

  Adds the **xsi:nil="true"** attribute to the element where the **null** value is located in the XML file.

  The prototype of the DBE_XMLGEN.USENULLATTRIBUTEINDICATOR function is as follows:

  ```
  DBE_XMLGEN.USENULLATTRIBUTEINDICATOR(CTX IN DBE_XMLGEN.CTXHANDLE, ATTRIND IN
  BOOLEAN);
  ```

  Table 2-476 DBE_XMLGEN.USENULLATTRIBUTEINDICATOR API parameters

Parameter	Description
CTX	Context handle.
ATTRIND	None.

- DBE_XMLGEN.USEITEMTAGSFORCOLL

  Adds the suffix **_ITEM** to the element where the variable of the array type is located.

  The prototype of the DBE_XMLGEN.USEITEMTAGSFORCOLL function is as follows:

  ```
  DBE_XMLGEN.USEITEMTAGSFORCOLL(CTX IN DBE_XMLGEN.CTXHANDLE);
  ```

  Table 2-477 DBE_XMLGEN.USEITEMTAGSFORCOLL API parameters

Parameter	Description
CTX	Context handle.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Example:

```
-- Preset data.
CREATE TABLE test_for_array(idd number, id INT[]);
INSERT INTO test_for_array VALUES(1, ARRAY[1,2,3]);
SELECT DBE_XMLGEN.GETXML('SELECT * from test_for_array');
-- Add the suffix _ITEM to the array type.
DECLARE
qryctx DBE_XMLGEN.CTXHANDLE;
result CLOB;
BEGIN
    qryctx := DBE_XMLGEN.NEWCONTEXT('SELECT id from test_for_array');
    DBE_XMLGEN.useItemTagsForColl(qryctx);
    result:=DBE_XMLGEN.GETXML(qryctx);
    DBE_XMLGEN.CLOSECONTEXT(qryctx);
    DBE_OUTPUT.PUT_LINE(result);
END;
/
<?xml version="1.0"?>
<ROWSET>
<ROW>
  <id>
    <int4_ITEM>1</int4_ITEM>
    <int4_ITEM>2</int4_ITEM>
    <int4_ITEM>3</int4_ITEM>
  </id>
</ROW>
</ROWSET>
ANONYMOUS BLOCK EXECUTE
DROP TABLE test_for_array;
```

- DBE_XMLGEN.GETNUMROWSPROCESSED

  Views the number of data rows returned by GETXML or GETXMLTYPE last time.

  The prototype of the DBE_XMLGEN.GETNUMROWSPROCESSED function is as follows:

  ```
  DBE_XMLGEN.GETNUMROWSPROCESSED(CTX IN DBE_XMLGEN.CTXHANDLE);
  ```

  Table 2-478 DBE_XMLGEN.GETNUMROWSPROCESSED API parameters

Parameter	Description
CTX	Context handle.

- DBE_XMLGEN.SETMAXROWS

  Sets maximum number of rows returned by each GETXML operation.

  The prototype of the DBE_XMLGEN.SETMAXROWS function is as follows:

  ```
  DBE_XMLGEN.SETMAXROWS(CTX IN DBE_XMLGEN.CTXHANDLE, MAXROWS IN NUMBER);
  ```

  Table 2-479 DBE_XMLGEN.SETMAXROWS API parameters

Parameter	Description
CTX	Context handle.
MAXROWS	Maximum number of rows returned by each GETXML operation.

- DBE_XMLGEN.SETSKIPROWS

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Sets the number of SQL rows to be skipped.

The prototype of the DBE_XMLGEN.SETSKIPROWS function is as follows:

```
DBE_XMLGEN.SETSKIPROWS(CTX IN DBE_XMLGEN.CTXHANDLE, SKIPROWS IN NUMBER);
```

Table 2-480 DBE_XMLGEN.SETSKIPROWS API parameters

Parameter	Description
CTX	Context handle.
SKIPROWS	Number of SQL header rows that are skipped.

- DBE_XMLGEN.RESTARTQUERY

  Restarts the SQL. This API is not supported in distributed mode.

  The prototype of the DBE_XMLGEN.RESTARTQUERY function is as follows:

  ```
  DBE_XMLGEN.RESTARTQUERY(CTX IN DBE_XMLGEN.CTXHANDLE);
  ```

  Table 2-481 DBE_XMLGEN.RESTARTQUERY API parameters

Parameter	Description
CTX	Context handle.

- DBE_XMLGEN.GETXMLTYPE

  Returns the XML text of the XMLTYPE type.

  The prototype of the DBE_XMLGEN.GETXMLTYPE function is as follows:

  ```
  DBE_XMLGEN.GETXMLTYPE(SQLQUERY IN VARCHAR2, DTDORSCHEMA IN NUMBER := 0) RETURNS
  XMLTYPE;
  DBE_XMLGEN.GETXMLTYPE(CTX IN DBE_XMLGEN.CTXHANDLE, DTDORSCHEMA IN NUMBER := 0)
  RETURNS XMLTYPE;
  ```

  Table 2-482 DBE_XMLGEN.GETXMLTYPE API parameters

Parameter	Description
SQLQUERY	SQL statements that need to be converted into XML files.
DTDORSCHEMA	Meaningless.
CTX	Context handle.

- DBE_XMLGEN.GETXML

  Returns the XML text of the CLOB type.

  The prototype of the DBE_XMLGEN.GETXML function is as follows:

  ```
  DBE_XMLGEN.GETXML(SQLQUERY IN VARCHAR2, DTDORSCHEMA IN NUMBER := 0) RETURNS CLOB;
  DBE_XMLGEN.GETXML(CTX IN DBE_XMLGEN.CTXHANDLE, DTDORSCHEMA IN NUMBER := 0)
  RETURNS CLOB;
  DBE_XMLGEN.GETXML(CTX IN DBE_XMLGEN.CTXHANDLE, TMPCLOB INOUT CLOB, DTDORSCHEMA
  IN NUMBER := 0);
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 2-483 DBE_XMLGEN.GETXML API parameters

Parameter	Description
SQLQUERY	SQL statements that need to be converted into XML files.
DTDORSCHEMA	Meaningless.
CTX	Context handle.
TMPCLOB	CLOB variable for storing the output XML.

- DBE_XMLGEN.CLOSECONTEXT

  Disables the context handle.

  The prototype of the DBE_XMLGEN.CLOSECONTEXT function is as follows:

```
DBE_XMLGEN.CLOSECONTEXT(CTX IN DBE_XMLGEN.CTXHANDLE);
```

Table 2-484 DBE_XMLGEN.CLOSECONTEXT API parameters

Parameter	Description
CTX	Context handle.

Example:

```
CREATE TABLE IF NOT EXISTS department(department_id NUMBER, department_name
VARCHAR2(30), manager NUMBER, location NUMBER);
INSERT INTO department VALUES(10, 'administrator', 200, 1700);
INSERT INTO department VALUES(11, 'aaa', 200, 1700);
INSERT INTO department VALUES(12, 'bbb', 300, 1600);
INSERT INTO department VALUES(13, 'ccc', 400, 1600);
INSERT INTO department VALUES(14, 'aaa</row><a>asd</a><row>', 400, 1600);
INSERT INTO department VALUES(15, NULL, 500,1600);
INSERT INTO department VALUES(16, '!@#$ %^&*()+-=<>/\"a3_a', 400, 1600);
-- Disable the context.
DECLARE
    qryctx DBE_XMLGEN.CTXHANDLE;
    result CLOB;
BEGIN
    qryctx := DBE_XMLGEN.NEWCONTEXT('SELECT * from department where department_id=14');
    DBE_XMLGEN.SETCONVERTSPECIALCHARS(qryctx, false);
    result:=DBE_XMLGEN.GETXML(qryctx);
    DBE_XMLGEN.CLOSECONTEXT(qryctx);
    DBE_OUTPUT.PUT_LINE(result);
END;
/
<?xml version="1.0"?>
<ROWSET>
<ROW>
  <department_id>14</department_id>
  <department_name>aaa</row><a>asd</a><row></department_name>
  <manager>400</manager>
  <location>1600</location>
</ROW>
</ROWSET>
ANONYMOUS BLOCK EXECUTE
DROP TABLE department;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

2.12.2.23 DBE_XMLPARSER

APIs

DBE_XMLPARSER is used to deserialize XML character strings and convert the character strings that store XML documents to document nodes. **Table 2-485** lists APIs supported by the DBE_XMLPARSER advanced package.

The XMLPARSER data type is used to store XML data. The maximum number of XML data records that can be stored is 16777215. The XMLPARSER data type can parse and create DOMDocument nodes based on the input string. The advanced package also provides the corresponding SET and GET APIs to parse the constraint attributes of the process.

NOTE

- When the DBE_XMLPARSER advanced package is used in the database whose character set is set to **SQL_ASCII**, an error is reported if characters beyond the ASCII range are input.
- The DBE_XMLPARSER advanced package supports only the ORA-compatible mode.

Table 2-485 DBE_XMLPARSER

API	Description
DBE_XMLPARSER.FREEPARSER	Frees a parser.
DBE_XMLPARSER.GETDOCUMENT	Obtains the parsed document node.
DBE_XMLPARSER.GETVALIDATIONMODE	Obtains the validation attribute.
DBE_XMLPARSER.NEWPARSER	Creates a parser instance.
DBE_XMLPARSER.PARSEBUFFER	Parses the VARCHAR string.
DBE_XMLPARSER.PARSECLOB	Parses the CLOB string.
DBE_XMLPARSER.SETVALIDATIONMODE	Sets the validation attribute.

- DBE_XMLPARSER.FREEPARSER

  Frees a given parser object.

  The prototype of DBE_XMLPARSER.FREEPARSER is as follows:

```
DBE_XMLPARSER.FREEPARSER (
 p    IN    parser);
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 2-486 DBE_XMLPARSER.FREEPARSER API parameters

Parameter	Description
p	Parser object.

Example:

```
-- Create a parser and release it.
DECLARE
  l_parser dbe_xmlparser.parser;
  BEGIN
  l_parser := dbe_xmlparser.newparser();
-- Directly release the l_parser instance.
  dbe_xmlparser.freeparser(l_parser);
END;
/
```

- DBE_XMLPARSER.GETDOCUMENT

  Returns the root node of the DOM tree document constructed by the parser. This function can be called only after the document is parsed.

  The prototype of DBE_XMLPARSER.GETDOCUMENT is as follows:

```
DBE_XMLPARSER.GETDOCUMENT (
  p     IN     parser)
 RETURN DOMDocument;
```

Table 2-487 DBE_XMLPARSER.GETDOCUMENT API parameters

Parameter	Description
p	Parser object.

NOTE

- If the GETDOCUMENT function has no input parameter, an error is reported.
- If the **PARSER** parameter of the GETDOCUMENT function is null, null is returned.
- If **PARSER** input by the GETDOCUMENT function has not parsed any document, null is returned.

Example:

```
-- Create a parser to parse character strings and print the obtained document.
DECLARE
  l_parser dbe_xmlparser.parser;
  l_doc dbe_xmldom.domdocument;
  buffer varchar2 :=
'<?xml version="1.0" encoding="UTF-8"?>
<note>
<to>Tove</to>
<from>Jani</from>
<heading>Reminder</heading>
<body>Do not forget me this weekend!</body>
</note>';
  buffer2 varchar2;
  BEGIN
  l_parser := dbe_xmlparser.newparser();
 -- l_parser parses the character string and obtains the DOMDocument node through GETDOCUMENT.
  dbe_xmlparser.PARSEBUFFER(l_parser, buffer);
  l_doc := dbe_xmlparser.getdocument(l_parser);
 -- Print the content in l_doc.
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
  dbe_xmldom.writetobuffer(l_doc, buffer2);
  RAISE NOTICE '%', buffer2;

  dbe_xmlparser.freeparser(l_parser);
  dbe_xmldom.freedocument(l_doc);
END;
/
```

Execution result:

```
NOTICE:  <?xml version="1.0" encoding="UTF-8"?>
<note>
<to>Tove</to>
<from>Jani</from>
<heading>Reminder</heading>
<body>Do not forget me this weekend!</body>
</note>
```

- DBE_XMLPARSER.GETVALIDATIONMODE

  Obtains the parsing validation mode of a specified parser. If DTD validation is enabled, **true** is returned. Otherwise, **false** is returned.

  The prototype of DBE_XMLPARSER.GETVALIDATIONMODE is as follows:

  ```
  DBE_XMLPARSER.GETVALIDATIONMODE (
   p     IN     parser)
   RETURN BOOLEAN;
  ```

  Table 2-488 DBE_XMLPARSER.GETVALIDATIONMODE API parameters

Parameter	Description
p	Parser object.

  Example:

  ```
  -- Create a parser and use GETVALIDATIONMODE to check whether the parser validation mode is
  enabled.
  DECLARE
    l_parser dbe_xmlparser.parser;
  BEGIN
    l_parser := dbe_xmlparser.newparser();
      IF (dbe_xmlparser.GETVALIDATIONMODE(l_parser) = true) THEN
   RAISE NOTICE 'validation';
      ELSE
      RAISE NOTICE 'no validation';
    END IF;
    dbe_xmlparser.freeparser(l_parser);
  END;
  /
  ```

  Execution result:

  ```
  NOTICE:  validation
  ```

- DBE_XMLPARSER.NEWPARSER

  Creates a parser object and returns a new parser instance.

  The prototype of DBE_XMLPARSER.NEWPARSER is as follows:

  ```
  DBE_XMLPARSER.NEWPARSER
   RETURN Parser;
  ```

  Example:

  ```
  -- Create a parser to parse character strings and then free the parser.
  DECLARE
    -- Create a parser.
    l_parser dbe_xmlparser.parser;
    l_doc dbe_xmldom.domdocument;
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
 buffer varchar2(1000) :=
  '<?xml version="1.0" encoding="UTF-8"?>
  <note>
  <to>Tove</to>
  <from>Jani</from>
  <heading>Reminder</heading>
  <body>Do not forget me this weekend!</body>
  </note>';
 buffer2 varchar2(1000);
 BEGIN
 l_parser := dbe_xmlparser.newparser();
 -- Parse the document and create a new DOM document.
 dbe_xmlparser.PARSEBUFFER(l_parser, buffer);

 dbe_xmlparser.freeparser(l_parser);
END;
/
```

- DBE_XMLPARSER.PARSEBUFFER

  Parses XML documents stored in strings.

  The prototype of DBE_XMLPARSER.PARSEBUFFER is as follows:

```
DBE_XMLPARSER.PARSEBUFFER (
  p     IN     parser,
  doc   IN VARCHAR2);
```

Table 2-489 DBE_XMLPARSER.PARSEBUFFER API parameters

Parameter	Description
p	Parser object.
doc	A string that stores XML documents.

NOTE

- The maximum length of a character string that can be parsed by the PARSEBUFFER function is 32767. If the length exceeds the maximum, an error is reported.
- Different from the ORA database, this database supports only UTF-8 in terms of character encoding, and **version** can only be set to **1.0**. If versions 1.0 to 1.9 are parsed, the execution is normal but a warning appears. For versions later than 1.9, an error is reported.
- DTD validation differences:
  - **!ATTLIST to type (CHECK|check|Check) "Ch..."** reports an error because the default value **"Ch..."** is not an enumerated value in the brackets. However, the ORA database does not report this error.
  - **<!ENTITY baidu "www.baidu.com">..... &Baidu;&writer** reports an error because the letters are case-sensitive. **Baidu** cannot correspond to **baidu**. However, the ORA database does not report this error.
- Namespace validation difference: Undeclared namespace tags are parsed. However, the ORA database reports an error.
- Difference in parsing XML predefined entities: **'** and **"** are parsed and translated into ' and ". However, predefined entities in ORA database are not translated into characters.

Example:

```
-- Create a parser to parse character strings and print the obtained document.
DECLARE
 l_parser dbe_xmlparser.parser;
 l_doc dbe_xmldom.domdocument;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
  buffer varchar2 :=
'<?xml version="1.0" encoding="UTF-8"?>
<note>
<to>Tove</to>
<from>Jani</from>
<heading>Reminder</heading>
<body>Do not forget me this weekend!</body>
</note>';
  buffer2 varchar2;
  BEGIN
  l_parser := dbe_xmlparser.newparser();
  dbe_xmlparser.PARSEBUFFER(l_parser, buffer);
  l_doc := dbe_xmlparser.getdocument(l_parser);

  dbe_xmldom.writetobuffer(l_doc, buffer2);
  RAISE NOTICE '%', buffer2;

  dbe_xmlparser.freeparser(l_parser);
  dbe_xmldom.freedocument(l_doc);
END;
/
```

Execution result:

```
NOTICE:  <?xml version="1.0" encoding="UTF-8"?>
<note>
<to>Tove</to>
<from>Jani</from>
<heading>Reminder</heading>
<body>Do not forget me this weekend!</body>
</note>
```

- DBE_XMLPARSER.PARSECLOB

  Parses XML documents stored in a CLOB.

  The prototype of DBE_XMLPARSER.PARSECLOB is as follows:

  ```
  DBE_XMLPARSER.PARSECLOB (
    p     IN     parser,
    doc   IN CLOB);
  ```

  Table 2-490 DBE_XMLPARSER.PARSECLOB API parameters

Parameter	Description
p	Parser object.
doc	A CLOB that stores XML documents.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- PARSECLOB cannot parse CLOBs larger than 1 GB.
- Different from the ORA database, this database supports only UTF-8 in terms of character encoding, and **version** can only be set to **1.0**. If versions 1.0 to 1.9 are parsed, the execution is normal but a warning appears. For versions later than 1.9, an error is reported.
- DTD validation differences:
  - **!ATTLIST to type (CHECK|check|Check) "Ch..."** reports an error because the default value **"Ch..."** is not an enumerated value in the brackets. However, the ORA database does not report this error.
  - **<!ENTITY baidu "www.baidu.com">..... &Baidu;&writer** reports an error because the letters are case-sensitive. **Baidu** cannot correspond to **baidu**. However, the ORA database does not report this error.
- Namespace validation difference: Undeclared namespace tags are parsed. However, the ORA database reports an error.
- Difference in parsing XML predefined entities: **'** and **"** are parsed and translated into ' and ". However, predefined entities in ORA database are not translated into characters.

Example:

```
-- Create a parser to parse character strings and print the obtained document.
DECLARE

 l_clob clob :=
'<?xml version="1.0" encoding="UTF-8"?>
 <note>
 <to>Tove</to>
 <from>Jani</from>
 <heading>Reminder</heading>
 <body>this weekend!</body>
 </note>';
 -- Create a parser.
 l_parser dbe_xmlparser.parser;
 l_doc dbe_xmldom.domdocument;
 buffer varchar2(1000);
 BEGIN
 l_parser := dbe_xmlparser.newparser();
 -- Parse the document and create a new DOM document.
 dbe_xmlparser.parseclob(l_parser, l_clob);
 l_doc := dbe_xmlparser.getdocument(l_parser);
 dbe_xmldom.writetobuffer(l_doc, buffer);
 RAISE NOTICE '%',buffer;

 dbe_xmlparser.freeparser(l_parser);
 dbe_xmldom.freedocument(l_doc);

 END;
 /
```

Execution result:

```
NOTICE:  <?xml version="1.0" encoding="UTF-8"?>
<note>
 <to>Tove</to>
 <from>Jani</from>
 <heading>Reminder</heading>
 <body>this weekend!</body>
</note>
```

- DBE_XMLPARSER.SETVALIDATIONMODE

  Sets the parsing validation mode of a specified parser.

  The prototype of DBE_XMLPARSER.SETVALIDATIONMODE is as follows:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
DBE_XMLPARSER.SETVALIDATIONMODE(
 p     IN     parser)
 yes   IN BOOLEAN);
```

Table 2-491 DBE_XMLPARSER.SETVALIDATIONMODE API parameters

Parameter	Description
p	Parser object.
yes	Mode to be set: • **true**: DTD validation is enabled. • **false**: DTD validation is disabled.

NOTE

- If the input parameter **yes** of the SETVALIDATIONMODE function is null, the parsing validation mode of the parser is not changed.
- By default, the DTD validation is enabled during parser initialization.

Example 1:

```
-- Create a parser. The XML character string to be parsed does not match the DTD format.
-- If setValidationMode is set to false, the string can be parsed. If setValidationMode is set to true,
an error is reported during parsing.
DECLARE
 l_clob clob :=
'<!DOCTYPE note [
<!ELEMENT note (to,from,heading,body)>
<!ELEMENT to (#PCDATA)>
<!ELEMENT from (#PCDATA)>
<!ELEMENT heading (#PCDATA)>
<!ELEMENT body (#PCDATA)>
]>
<table>
<name attr1="WEB" attr2="web2">African Coffee Table</name>
<width>80</width>
<length>120</length>
</table>';
 l_parser dbe_xmlparser.parser;
 l_doc dbe_xmldom.domdocument;
buffer varchar2(1000);
 BEGIN
 l_parser := dbe_xmlparser.newparser();
 -- Set it to false for parsing.
   dbe_xmlparser.setValidationMode(l_parser, false);
   dbe_xmlparser.parseclob(l_parser, l_clob);
   l_doc := dbe_xmlparser.getdocument(l_parser);
   dbe_xmldom.writetobuffer(l_doc, buffer);
   RAISE NOTICE '%', buffer;
   dbe_xmlparser.freeparser(l_parser);
   dbe_xmldom.freedocument(l_doc);
 END;
 /
```

Execution result:

```
NOTICE:  <?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE note [
<!ELEMENT note (to , from , heading , body)>
<!ELEMENT to (#PCDATA)>
<!ELEMENT from (#PCDATA)>
<!ELEMENT heading (#PCDATA)>
<!ELEMENT body (#PCDATA)>
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
]>
<table>
 <name attr1="WEB" attr2="web2">African Coffee Table</name>
 <width>80</width>
 <length>120</length>
 </table>
```

Example 2:

```
-- Create a parser. The XML character string to be parsed does not match the DTD format.
-- An error is reported during parsing after setValidationMode is set to true.
DECLARE
  l_clob clob :=
 '<!DOCTYPE note [
 <!ELEMENT note (to,from,heading,body)>
 <!ELEMENT to (#PCDATA)>
 <!ELEMENT from (#PCDATA)>
 <!ELEMENT heading (#PCDATA)>
 <!ELEMENT body (#PCDATA)>
 ]>
 <table>
 <name attr1="WEB" attr2="web2">African Coffee Table</name>
 <width>80</width>
 <length>120</length>
 </table>';
  l_parser dbe_xmlparser.parser;
  l_doc dbe_xmldom.domdocument;
 buffer varchar2(1000);
  BEGIN
  l_parser := dbe_xmlparser.newparser();
  -- Set it to true for parsing.
  -- The XML character string does not match the DTD format and is expected to trigger an error.
    dbe_xmlparser.setValidationMode(l_parser, true);
    dbe_xmlparser.parseclob(l_parser, l_clob);
    l_doc := dbe_xmlparser.getdocument(l_parser);
    dbe_xmldom.writetobuffer(l_doc, buffer);
    dbe_xmlparser.freeparser(l_parser);
    dbe_xmldom.freedocument(l_doc);
  END;
  /
```

Execution result:

```
An error is reported during xmlparser parsing.
ERROR:  invalid XML document
```

2.12.2.24 PRVT_ILM

The PRVT_ILM API is an internal API of the ILM feature and cannot be directly called by users. This section lists only the API names and does not provide detailed API prototype description.

API	Description
be_active_ado_window	Triggers a maintenance window and updates the ilmadowindow triggering time and action.
be_create_ado_window_for_each_db	Triggers a maintenance window and creates ilmadowindow in each database of the instance.
be_execute_ilm	Executes ilmadowind for automatic evaluation.
be_execute_ilm_dn	Performs automatic evaluation on distributed DNs. This operation affects the overall ILM background scheduling of the cluster.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

API	Description
flush_task_executestate	Updates the automatic scheduling task status.
generate_taskoid	Generates a task ID for this scheduling on the CN.
evaluate_obj_policy	Triggers evaluation on data objects after scheduling.
change_be_ilm	Calls the DBE_ILM_ADMIN.ENABLE_ILM() and DISABLE_ILM () help functions. This operation affects the overall ILM background scheduling of the cluster.
get_compression_ratio	Calls the DBE_COMPRESSION.GET_COMPRESSION_RATIO() help function.
get_compression_type	Calls the DBE_COMPRESSION.GET_COMPRESSION_TYPE() help function.
get_lastmodified_time	Calls the DBE_HEAT_MAP.ROW_HEAT_MAP() help function.
ilm_job_action	Executes compression tasks, which is called on distributed DNs.
delete_expired_ilm_log	Clears expired logs in distributed mode.
delete_gs_ilm_task	Operates a feature-related system catalog, which is called on distributed DNs.
insert_gs_ilm_jobdetail	Operates a feature-related system catalog, which is called on distributed DNs.
insert_gs_ilm_task	Operates a feature-related system catalog, which is called on distributed DNs.
insert_gs_ilm_taskdetail	Operates a feature-related system catalog, which is called on distributed DNs.
update_gs_ilm_jobdetail	Operates a feature-related system catalog, which is called on distributed DNs.
update_gs_ilm_object	Operates a feature-related system catalog, which is called on distributed DNs.
update_gs_ilm_param	Operates a feature-related system catalog, which is called on distributed DNs. This operation affects the overall ILM background scheduling of the cluster.
update_gs_ilm_task	Operates a feature-related system catalog, which is called on distributed DNs.
gs_ilm_ticker	Triggers a maintenance window and ticks once to record the mapping between an LSN and time.
compress_blocks	Calls the PRVT_ILM.ILM_JOB_ACTION() help function.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

API	Description
compress_block_single	This API has been deprecated. Do not use it.
get_job_status	Calls the DBE_ILM.STOP_ILM help function.
insert_gs_ilm_param	Operates a feature-related system catalog.
query_unfinishedjob_num	Checks whether there are jobs that are not complete, including jobs in the initial or running state.
update_gs_ilm_object_flag2	Operates a feature-related system catalog, which is called on distributed DNs.
ilm_seq_nextval	Obtains the next sequence value of the ILM.
ilm_seq_setval	Sets the current sequence value of the ILM.
check_compatibility	Calls a help function to determine the database compatibility mode in a unified manner.
set_pg_settings	Calls a help function to set the database compatibility mode using a GUC parameter.
check_seq	Checks whether the current value of **GSILMTASK_SEQ** is greater than the maximum value of **taskoid** in the GS_ILM_TASK catalog, which is called on distributed CNs.
get_actual_compression_ratio	Calls the DBE_COMPRESSION.GET_ACTUAL_COMPRESSION_RATIO() help function.
get__hole_ratio	Calls the DBE_COMPRESSION.GET_HOLE_RATIO() help function.
turbo_compress_buffer_stats	Calls the DBE_COMPRESSION.TURBO_COMPRESS_BUFFER_STATS() help function.
get_index_compression_type	Calls the DBE_COMPRESSION.GET_INDEX_COMPRESSION_TYPE() help function.
create_ilm_db_policy	Calls the DBE_ILM_ADMIN.CREATE_ILM_DB_POLICY() help function.
delete_ilm_db_policy	Calls the DBE_ILM_ADMIN.DELETE_ILM_DB_POLICY() help function.
compress_indexes	Calls the PRVT_ILM.ILM_JOB_ACTION() help function.
eval_comp_relgrowth	This API has been deprecated. Do not use it.
delete_gs_ilm_jobdetail	Operates a feature-related system catalog, which is called on distributed DNs.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

2.12.3 Internal Functions

The following APIs are internal APIs of advanced packages. You are advised not to call them directly. Otherwise, unexpected behavior or running effect may occur.

DBE_DESCRIBE

Table 2-492 describes the internal APIs contained in DBE_DESCRIBE.

Table 2-492 Internal APIs of the DBE_DESCRIBE package

API	Description
DBE_DESCRIBE.GET_PROCEDURE_NAME	Extracts the name of a stored procedure or function from the original input of a user.
DBE_DESCRIBE.IS_NUMBER_TYPE	Checks whether the type is numeric.

DBE_UTILITY

Table 2-493 describes the internal APIs contained in DBE_UTILITY.

Table 2-493 Internal APIs of the DBE_UTILITY package

API	Description
DBE_UTILITY.EXPAND_SQL_TEXT	Expands SQL statements that contain views or synonyms into equivalent queries that reference only the base table and join.
DBE_UTILITY.CANONICALIZE_RET	Standardizes the formatting of database object names (such as tables, views, columns, and users).
DBE_UTILITY.COMMA_TO_TABLE_FUNC	Converts a comma-separated list of strings into a PL/SQL index table and returns the number of elements.
DBE_UTILITY.COMPILE_SCHEMA	Compiles invalid or all PL/SQL objects such as stored procedures, functions, and views in a specified schema in batches. pkg_util.gs_compile_schema is recommended.
DBE_UTILITY.NAME_SEPARATE	Parses an object name based on the database object naming rules and obtains the schema name, object name, and database link.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

API	Description
DBE_UTILITY.NAME_TOKENIZE_FUNC	Parses a database object name into five parts (schema name, table name, column name, and total length).
DBE_UTILITY.NAME_TOKENIZE_LOWER	Parses a database object name into five parts (schema name, table name, column name, and total length), and converts all parts into lowercase letters.
DBE_UTILITY.NAME_TOKENIZE_LOWER_FUNC	Equivalent to DBE_UTILITY.NAME_TOKENIZE_LOWER.
DBE_UTILITY.PRIVILEGE_CHECK	Checks the permissions of the current user on a specified database object.
DBE_UTILITY.SEARCH_CLASS_WITH_NSPOID_ONAME_TYPE	Searches for database objects by name and type in the specified namespace, and returns the OIDs and quantity of the objects.
DBE_UTILITY.SEARCH_OBJECTS	Searches for database objects that match the schema name, object name, and object type in the database, and returns the OID, object type, and whether the object is a synonym.
DBE_UTILITY.SEARCH_OBJECTS_SYNONYM_FILL_SCHEMA	Searches for database objects with the specified name and type in multiple possible schemas based on the specified schema search type, and returns information about the found objects.
DBE_UTILITY.SEARCH_PROCEDURE_WITH_NSPOID_ONAME	Retrieves functions, stored procedures, and packages corresponding to the specified schema OID and name.
DBE_UTILITY.SEARCH_SYNONYM_WITH_NSPOID_ONAME	Retrieves the synonym corresponding to the specified schema OID and name.
DBE_UTILITY.TABLE_TO_COMMA_FUNC	Converts an array into a string.
DBE_UTILITY.USER_NAME	Returns the username of the current database.
DBE_UTILITY.SEARCH_OBJECTS_SYNONYM_FILL_SECHEMA	Has the same function as DBE_UTILITY.SEARCH_OBJECTS_SYNONYM_FILL_SCHEMA. You are advised to use DBE_UTILITY.SEARCH_OBJECTS_SYNONYM_FILL_SCHEMA.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

API	Description
DBE_UTILITY.SEARCH_SYNONM_WITH_NSPOID_ONAME	Has the same function as DBE_UTILITY.SEARCH_SYNONYM_WITH_NSPOID_ONAME. You are advised to use DBE_UTILITY.SEARCH_SYNONYM_WITH_NSPOID_ONAME.

2.13 Retry

Retry is a process in which the database executes an SQL statement or stored procedure (including anonymous block) again in the case of execution failure, improving the execution success rate and user experience. In addition, the database checks the error code and retry configuration to determine whether to retry.

If the execution fails, the system rolls back the executed statements and executes the stored procedure again.

Example:

```
gaussdb=# CREATE OR REPLACE PROCEDURE retry_basic ( IN  x INT)
AS
BEGIN
  INSERT INTO t1 (a) VALUES (x);
  INSERT INTO t1 (a) VALUES (x+1);
END;
/

gaussdb=# CALL retry_basic(1);
```

2.14 Package

A package is a combination of PL/SQL programs, such as stored procedures, functions, variables, constants, and cursors. It is object-oriented and can encapsulate PL/SQL program design elements. Functions in a package are created, deleted, and modified in a unified manner.

A package contains two parts: package specifications and package body. The declaration contained in the package specifications can be accessed by external functions and anonymous blocks. The declaration contained in the package body cannot be accessed by external functions or anonymous blocks, but can be accessed only by functions and stored procedures in the package body.

For details about how to create a package, see **CREATE PACKAGE**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTICE

- Cross-package variables cannot be used as control variables in the FOR loop.
- Types defined in a package cannot be deleted or modified, and cannot be used to define tables.
- Cursor variables cannot be referenced in the SCHEMA.PACKAGE.CURSOR format.
- A cursor with parameters can be opened only in the current package.
- In distributed mode, PACKAGE can be used only in an ORA-compatible database.
- In distributed mode, if an SQL statement contains variables or functions in a package, pushdown is not supported.
- A package variable cannot be used as the default value of a function or stored procedure parameter.
- If the input parameters of a stored procedure in a package contain pseudo parameters (for example, **anyelement**), variable-length parameters cannot be specified during a call.
- If the **in**, **out**, and **inout** parameters of a function in the package header and package body are different, the system identifies the functions to be different.

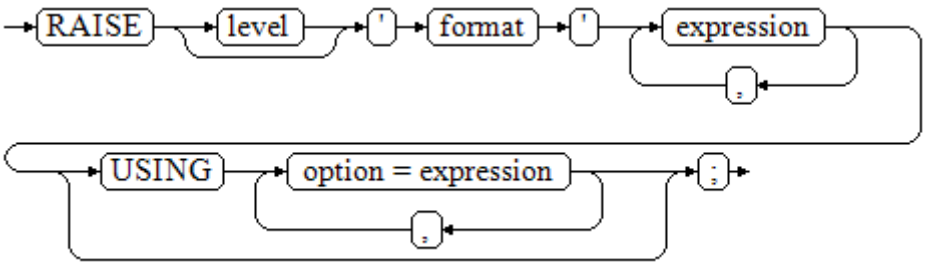
2.15 Debugging

Syntax

RAISE has the following five syntax formats.

- The syntax of raise_format is shown in **Figure 2-51**.

  Figure 2-51 raise_format::=

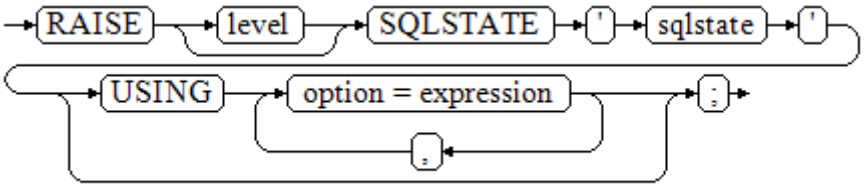
- The syntax of raise_condition is shown in **Figure 2-52**.

  Figure 2-52 raise_condition::=

  
 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

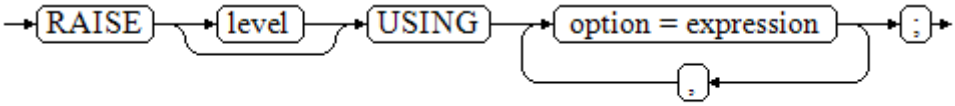
- The syntax of raise_sqlstate is shown in **Figure 2-53**.

  Figure 2-53 raise_sqlstate::=

- The syntax of raise_option is shown in **Figure 2-54**.

  Figure 2-54 raise_option::=

- The syntax of raise is shown in **Figure 2-55**.

  Figure 2-55 raise::=

  
Parameters:

- **level**: specifies the error level, that is, **DEBUG**, **LOG**, **INFO**, **NOTICE**, **WARNING**, or **EXCEPTION** (default). **EXCEPTION** throws an error that normally terminates the current transaction and the others only generate information at their levels. The GUC parameters **log_min_messages** and **client_min_messages** control whether the error messages of specific levels are reported to the client and are written to the server log.
- **format**: specifies the error message text to be reported, which is a format string. The format string can be appended with an expression for insertion to the message text. In a format string, **%** is replaced by the parameter value attached to format and **%%** is used to print **%**. For example:

  ```
  -- v_job_id replaces % in the string.
  RAISE NOTICE 'Calling cs_create_job(%)',v_job_id;
  ```

- **option = expression**: inserts additional information to an error report. The **keyword** option can be **MESSAGE**, **DETAIL**, **HINT**, or **ERRCODE**, and each expression can be any string.
  - **MESSAGE**: specifies the error message text. This option cannot be used in a RAISE statement that contains a format character string in front of USING.
  - **DETAIL**: specifies detailed information of an error.
  - **HINT**: prints hint information.
  - **ERRCODE**: designates an error code (SQLSTATE) in a report. A condition name or a five-character SQLSTATE error code can be used.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **condition_name**: specifies the condition name corresponding to the error code.
- **sqlstate**: specifies the error code.

If neither a condition name nor an SQLSTATE is specified in the **RAISE EXCEPTION** command, **RAISE EXCEPTION (P0001)** is used by default. If no message text is specified, the condition name or SQLSTATE is used as the message text by default.

NOTICE

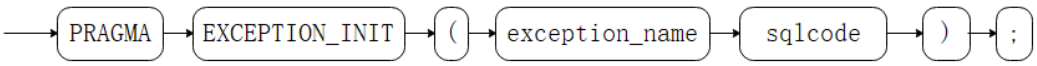
- If **SQLSTATE** specifies an error code, the error code is not limited to a defined error code. It can be any error code containing five digits or ASCII uppercase rather than **00000**. Do not use error codes ended with three zeros because such error codes are category codes and can be captured by the whole category.
- In ORA-compatible mode, **SQLCODE** is equivalent to **SQLSTATE**.
- The syntax described in **Figure 2-55** does not append any parameter. This form is used only for the EXCEPTION statement in a BEGIN block so that the error can be re-processed.

EXCEPTION_INIT

In ORA-compatible mode, EXCEPTION_INIT can be used to define the SQLCODE error code.

Figure 2-56 shows the syntax diagram.

Figure 2-56 exception_init::=



Parameters:

- **exception_name** indicates the name of the exception declared by the user. The EXCEPTION_INIT syntax must follow the declared exception.
- **sqlcode** is a user-defined SQL code, which must be a negative integer ranging from –2147483647 to –1.

Precautions:

- This function can be used in ORA-compatible mode but cannot be bound to system error codes.
- Only exception_init can be used to assign a value to **sqlcode** associated with exception. Other value assignment modes are invalid.
- Cross-database.schema.package.exception calling is not supported.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTICE

- When **EXCEPTION_INIT** is used to define an SQL code, **SQLSTATE** is equivalent to **SQLCODE**, and **SQLERRM** is in the format of *xxx*: **non-GaussDB Exception**. For example, if the user-defined SQL code is **–1**, **SQLSTATE** is **–1** and **SQLERRM** is **1: non-GaussDB Exception**.
- In the same stored procedure or function, if EXCEPTION_INIT is used to set the same error code, the Oracle Database does not support capturing exceptions separately as conditions. GaussDB supports this behavior. For details, see **Examples**.

Examples

Display error and hint information when a transaction terminates.

```
CREATE OR REPLACE PROCEDURE proc_raise1(user_id in integer)
AS
BEGIN
RAISE EXCEPTION 'Noexistent ID --> %',user_id USING HINT = 'Please check your user ID';
END;
/

call proc_raise1(300011);

-- Execution result
ERROR:  Noexistent ID --> 300011
HINT:  Please check your user ID
```

Two methods are available for setting **SQLSTATE**.

```
CREATE OR REPLACE PROCEDURE proc_raise2(user_id in integer)
AS
BEGIN
RAISE 'Duplicate user ID: %',user_id USING ERRCODE = 'unique_violation';
END;
/

\set VERBOSITY verbose
call proc_raise2(300011);

-- Execution result
ERROR:  Duplicate user ID: 300011
SQLSTATE: 23505
```

If the main parameter is a condition name or **SQLSTATE**, the following applies:

```
RAISE division_by_zero;
RAISE SQLSTATE '22012';
```

For example:

```
CREATE OR REPLACE PROCEDURE division(div in integer, dividend in integer)
AS
DECLARE
res int;
   BEGIN
   IF dividend=0 THEN
      RAISE division_by_zero;
      RETURN;
   ELSE
      res := div/dividend;
      RAISE INFO 'division result: %', res;
      RETURN;
   END IF;
   END;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
/
call division(3,0);

-- Execution result
ERROR:  division_by_zero
```

Alternatively:

```
RAISE unique_violation USING MESSAGE = 'Duplicate user ID: ' || user_id;
```

In the same stored procedure or function, if EXCEPTION_INIT is used to set the same error code, Oracle Database does not support exception capture as a condition, but GaussDB supports this behavior.

```
gaussdb=# CREATE OR REPLACE PACKAGE pkg IS
gaussdb$#   err1 EXCEPTION;
gaussdb$#   err2 EXCEPTION;
gaussdb$#   PRAGMA EXCEPTION_INIT(err1, -10001);
gaussdb$#   PRAGMA EXCEPTION_INIT(err2, -10001);
gaussdb$# PROCEDURE pro;
gaussdb$# END pkg;
gaussdb$# /
CREATE PACKAGE
gaussdb=# CREATE OR REPLACE PACKAGE BODY pkg IS
gaussdb$# PROCEDURE pro IS
gaussdb$# BEGIN
gaussdb$#     FOR i IN 1..10 LOOP
gaussdb$#         BEGIN
gaussdb$#         IF i = 1 THEN
gaussdb$#             raise err1;
gaussdb$#         END IF;
gaussdb$#         IF i = 2 THEN
gaussdb$#             raise err2;
gaussdb$#         END IF;
gaussdb$#         EXCEPTION
gaussdb$# -- The same error code is split as two different conditions of EXCEPTION.
gaussdb$#             WHEN err1 THEN
gaussdb$#                 CONTINUE;
gaussdb$#             WHEN err2 THEN
gaussdb$#                 EXIT;
gaussdb$#         END;
gaussdb$#     END LOOP;
gaussdb$# END pro;
gaussdb$# END pkg;
gaussdb$# /
CREATE PACKAGE BODY
gaussdb=# CALL pkg.pro();
 pro
-----

(1 row)
gaussdb=# DROP PACKAGE pkg;
NOTICE:  drop cascades to function public.pro()
DROP PACKAGE
```

2.16 Keyword

NOTE

Keywords are identifiers with special meanings in the PL/SQL and are case-insensitive. Keywords described in **Table 2-494** are PL/SQL keywords. Note that PL/SQL reserved keywords and non-reserved keywords are different from those in SQL. For details about SQL keywords, see **Keywords**.

3 Compatibility Description

3.1 Overview of GaussDB Compatibility

In GaussDB, you can create a database with a compatibility mode of **ORA** (Oracle-compatible), **MYSQL** (MySQL-compatible), **TD** (Teradata-compatible), **PG** (Postgres-compatible), or **M** (M-compatible). The compatibility mode directly affects SQL syntax, data types, system functions, stored procedures, and more. Some compatibility APIs may be supported only in certain compatibility modes.

For details about Oracle-compatible mode, M-compatible mode, and MySQL-compatible mode, see **Oracle Compatibility Description**, **M-compatible Mode**, and **MYSQL-compatible Mode**. You can select a proper compatibility mode based on actual requirements.

3.2 Oracle Compatibility Description

3.2.1 Overview of Oracle Database Compatibility

GaussDB is generally compatible with Oracle Database in terms of basic functions (such as data types, SQL statements, and database objects) and PL/SQL. However, due to architecture design differences, there are still some incompatible items.

This chapter compares the Oracle-compatible mode in GaussDB with Oracle Database 19c.

3.2.2 Basic SQL Elements

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

3.2.2.1 Data Types

Table 3-1 Numeric types

Oracle Database	GaussDB	Difference
NUMBER [(p [, s])]	Supported, with differences.	The precision and usage are different. • When NUMBER contains parameters, the maximum boundary values of precision *p* and scale *s* in GaussDB are greater than those in Oracle Database. • In GaussDB, the default value of *p* when NUMBER does not contain parameters is much greater than the maximum boundary value when NUMBER contains parameters. However, in Oracle Database, the former is equal to the latter. • In GaussDB, the value of *s* cannot be negative. In Oracle Database, a negative *s* value is accurate to an integer. • In GaussDB, NaN values can be inserted. However, in Oracle Database, an error will be reported if NaN values are inserted. • If the scale *s* is not specified in GaussDB, the scale is not limited. In Oracle Database, if the scale *s* is not specified, the default scale is 0. • GaussDB does not support the number(*, s) format. Oracle Database supports this format, where the asterisk (*) indicates that the maximum precision is used (that is, the precision is not limited).
FLOAT [(p)]	Supported.	-
BINARY_FLOAT	Not supported.	-
BINARY_DOUBLE	Supported.	-

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 3-2 Date and time types

Oracle Database	GaussDB	Difference
DATE	Supported, with differences.	If the **mapping_date_to_datea** parameter is not enabled, the precision of GaussDB is different from that in Oracle Database, and GaussDB supports a larger A.D. time range. If **mapping_date_to_datea** is enabled, the syntax, operators, and format control supported by the DATE type in GaussDB are different from those in Oracle Database.
TIMESTAMP [(fractional_seconds_precision)]	Supported, with differences.	-
TIMESTAMP [(fractional_seconds_precision)] WITH TIME ZONE	Supported, with differences.	The timestamptz type of GaussDB is equivalent to the timestampwithlocaltimezone type of Oracle Database. The type corresponding to timestamptz of Oracle Database is missing. Time zone update: In some countries or regions, the time zone information is often updated. Therefore, the database system often needs to modify the time zone file accordingly to ensure that the time is correct. Currently, the GaussDB time zone type involves only timestamp with timezone. When a new time zone file takes effect, the existing data is not changed, and the new data is adjusted based on the time zone file information. Data capabilities of GaussDB are different from those of Oracle Database.
TIMESTAMP [(fractional_seconds_precision)] WITH LOCAL TIME ZONE	Not supported.	-
INTERVAL YEAR [(year_precision)] TO MONTH	Supported.	-

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Oracle Database	GaussDB	Difference
INTERVAL DAY [(day_precision)] TO SECOND [(fractional_seconds_precision)]	Supported.	-

NOTE

- In ORA-compatible mode, the calendar systems are different between GaussDB and Oracle Database as follows:
  - Oracle Database has two calendar systems: the Julian calendar and the Gregorian calendar. Before October 5, 1582, the Julian calendar is used. The leap year calculation rule is that the year must be divisible by 4. After October 5, 1582, the Gregorian calendar is used. The leap year calculation rule is that the year must be divisible by 4 and cannot be divisible by 100, or can be divisible by 400. GaussDB uses only the Gregorian calendar system. The leap year calculation rule is that the year must be divisible by 4 and not divisible by 100, or divisible by 400.
  - In Oracle Database, the year 1582 comprises 355 days, with the missing 10 days spanning from October 5, 1582, to October 14, 1582. The day following October 4, 1582, is October 15, 1582. In GaussDB, however, the year 1582 contains 365 days.
  - The Oracle Database has the year A.D. 0, so the period from '-0001-01-01 00:00:00' to '0001-01-01 00:00:00' contains 731 days. GaussDB does not have the year A.D. 0, so the period from '-0001-01-01 00:00:00' to '0001-01-01 00:00:00' contains 366 days.
- In ORA-compatible mode, when the **mapping_date_to_datea** parameter is not enabled, the DATE type is replaced by TIMESTAMP(0) WITHOUT TIME ZONE. The difference of this type between the two databases is the same as that of TIMESTAMP (0) WITHOUT TIME ZONE. When a timestamp value with a decimal point, for example, **timestamp '2023-01-01 23:59:59.5'**, is inserted into a DATE column, GaussDB rounds the value, and the result inserted into the table is **'2023-01-02 00:00:00'**. Oracle Database truncates the value, and the result inserted into the table is **'2023-01-01 23:59:59'**.
- In ORA-compatible mode, when the **mapping_date_to_datea** parameter is enabled, the DATE type is replaced by DATEA. The differences are the same as those of DATEA.
- In terms of TIMESTAMP [(fractional_seconds_precision)] and TIMESTAMP [(fractional_seconds_precision)] WITH TIME ZONE, the differences between GaussDB and Oracle Database are as follows:
  - The value of **fractional_seconds_precision** ranges from 0 to 6 in GaussDB, but ranges from 0 to 9 in Oracle Database.
  - GaussDB uses **DateStyle** to set the display format of date and time values and the rules of resolving ambiguous values. For details, see the description of date input in **Date/Time Types**. Generally, the input format verification and output display in Oracle Database are controlled by the **NLS_TIMESTAMP_FORMAT** and **NLS_TIMESTAMP_TZ_FORMAT** parameters.
  - By default, GaussDB removes zeros from the end of the decimal part of the second. Oracle Database controls the display of the decimal part based on the setting (**FF/FF1-FF9**) of the formatting parameter. For example, '2017-09-01 10:32:19.212000' is displayed as '2017-09-01 10:32:19.212' in GaussDB. In Oracle Database, it is displayed as '2017-09-01 10:32:19.212' if the **format** parameter contains FF, or '2017-09-01 10:32:19.212000000' if the **format** parameter contains **FF9**.
  - GaussDB supports a wider time range than Oracle Database.
  - For literals with more than six digits of precision, the seventh digit is rounded according to the banker's rounding rule—if the seventh digit is 5, the sixth digit is the nearest even number. For those within six digits of precision, the rounding rule baseline is 2000-01-01 00:00:00. If the time is earlier than the baseline, the banker's rounding rule is used. If the time is later than the baseline, the standard rounding rule is used. The time baseline of TIMESTAMP WITH TIME ZONE is calculated according to the UTC-0 time zone.
- In ORA-compatible mode, when the **mapping_date_to_datea** parameter is enabled, there are the following differences between its DATE type and Oracle Database's DATE type:
  - Literals can be defined as the DATEA type, for example, by running **SELECT datea '2024-10-01' ;**. In GaussDB, literal strings are verified and should comply with the format specified by **nls_date_format**; otherwise, an error is reported or incorrect

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

data is output. However, in Oracle Database, literal strings are verified and should be in the fixed format YYYY-MM-DD.

- Using CREATE TABLE, CREATE VIEW, or PREPARE to create objects are different between GaussDB and Oracle Database.

  In GaussDB, if an UNKNOWN type exists, it is converted to a definite type. If the conversion fails, an error is reported for object creation. If the conversion is successful, the value is saved as a value of the definite type, and subsequent operations are not affected by additional parameters. For example, the following is a typical scenario:

  ```
  WHERE datea_column > 'unknown_text'
  'unknown_text'::datea
  cast('unknown_text' as datea)
  datea'unknown text'
  ```

  Loose verification is used when the original definition contains other expressions such as functions. When defining an object, you can create it successfully as long as the return value type of the expression can be converted to the target type, and executing the expression is not needed during definition. For example:

  ```
  CREATE TABLE t (a DATE DEFAULT to_date('2024-10-01'));
  ```

  The format of the preceding statement will not be verified by **nls_date_format** for table creation.

- For a value of the UNKNOWN, CHAR, CHARACTER, NCHAR, BPCHAR, VARCHAR, CHARACTER VARYING, VARCHAR2, NVARCHAR2, TEXT, or CLOB type in the numeric format, GaussDB supports a DATEA value plus (the left and right operands are interchangeable) or minus the value, but does not support the value minus a DATEA value. For a value of the CHAR, CHARACTER, NCHAR, VARCHAR, CHARACTER VARYING, VARCHAR2, or NVARCHAR2 type in numeric format, Oracle Database supports a DATE value plus (the left and right operands can be exchanged) or minus the value, but does not support the value minus a DATE value.
- For a value of the UNKNOWN, CHAR, CHARACTER, NCHAR, BPCHAR, VARCHAR, CHARACTER VARYING, VARCHAR2, NVARCHAR2, TEXT, or CLOB type in the time format, GaussDB supports the value minus a DATEA value, but does not support a DATEA value plus (the left and right operands can be exchanged) or minus the value. For a value of the CHAR, CHARACTER, NCHAR, VARCHAR, CHARACTER VARYING, VARCHAR2, or NVARCHAR2 type in the time format, Oracle Database supports neither a DATE value plus (the left and right operands can be exchanged) or minus the value, nor the value minus a DATE value.
- In GaussDB, only the **nls_date_format** parameter can control the DATEA format. In Oracle Database, the format can be controlled by **nls_date_format** or **nls_date_language**.
- In GaussDB, implicit conversion between DATEA and CLOB types is supported. Oracle Database does not support this feature in certain scenarios.
- When Oracle Database performs arithmetic operations (+ and –) between the date/time type and numeric type, the operand of the date/time type is implicitly converted to the DATE type, and the operation result is also of the DATE type. GaussDB complies with its own type promotion rules. The type of the operation result is the same as that of the left operand, and implicit downgrade to the DATEA type is not performed.
- GaussDB supports the comparison between the DATEA type and the INTERVAL type, numeric type, or RAW type, but Oracle Database does not. For details, see **Comparison Operators**.
- The behaviors of **nls_date_format** supported by GaussDB differ from that supported by Oracle Database in the following ways:
  1. GaussDB does not support E/EE, but Oracle Database supports.
  2. DL/DS/TS cannot be used for to_date in GaussDB, but they are supported in Oracle Database.
  3. An input string should not contain trailing spaces. For example, an error will be reported when **nls_date_format = 'yyyy-mm-dd';** is executed to convert the

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

following string to the date type: **SELECT date '2024 -10-01' FROM dual;**. However, it is allowed in Oracle Database.

4. In Oracle Database, the input of the "text" separator requires verification; however, in GaussDB, only its output is affected, rather than its input.
5. FX and FM offer the same functions but have different behaviors in GaussDB and Oracle Database. FM suppresses leading zeros and trailing spaces for converting a character string. It can only be used as a prefix and applied in each basic element in GaussDB, which is different from the applicable scope in Oracle Database. FX precisely verifies whether the NLS format is used. In GaussDB, if FX appears once, all subsequent elements need to be precisely verified until FM is encountered, which is different from the applicable scope in Oracle Database.
6. GaussDB supports TH as the suffix, but it does not take effect in Oracle Database.
7. GaussDB does not support THSP and SPTH as the suffix. SP can be set as the suffix, but it does not take effect.
8. In GaussDB, prefixes and suffixes are not allowed to appear consecutively for multiple times within a formatted model element, such as FMFMYYYY or YYYYTHTH.

- The DATEA type in GaussDB supports only B-tree, UB-tree, PSORT, and CB-tree indexes, but does not support GIN, UGIN, and GiST indexes.
- The DATEA type in GaussDB supports only the JDBC, ODBC, and libpq drivers and does not support the Go and Python drivers.
- The DATEA type in GaussDB cannot be used as a range type.
- The arithmetic operators of the DATEA type in GaussDB (including subtraction between DATEA types and addition and subtraction between DATEA types and numeric types) use float8 (double-precision floating point) for intermediate calculation and then convert the calculation result to the output type. The valid precision of float8 is about 15 decimal digits. When the calculation result contains a large number of decimal places, the precision of the last digit may be lost. For example, when the result of subtraction between DATEA types is returned as a numeric type, the maximum number of valid digits is about 15. When the result of addition or subtraction between DATEA types and numeric types is returned as a DATEA type, the hour, minute, and second parts in the result may have microsecond-level precision deviation. In Oracle Database, the arithmetic operation of the DATE type returns the NUMBER type, and there is no such precision restriction. If high-precision date calculation is required, you are advised to use functions such as EXTRACT to extract time elements and then perform calculation.
- The gsql of GaussDB does not display DATEA data in the format specified by **nls_date_format**. Instead, it displays data in the fixed format 'YYYY-MM-DD HH24:MI:SS AD/BC'. The sqlplus of the Oracle Database displays DATE data in the format specified by **nls_date_format**.

- In ORA-compatible mode, the AT TIME ZONE syntax is supported, but its semantics are different from those in Oracle Database. In GaussDB, AT TIME ZONE is a type conversion operator. **timestamp AT TIME ZONE zone** interprets the timestamp without time zone as the UTC time point based on the specified time zone and returns the timestamptz type (converted to the time zone of the current session). **timestamptz AT TIME ZONE zone** converts the timestamp with time zone to the local time of the specified time zone and returns the timestamp type. However, in Oracle Database, AT TIME ZONE is an operator for reinterpreting time semantics. It keeps the return type unchanged (TIMESTAMP WITH TIME ZONE input still returns TIMESTAMP WITH TIME ZONE) and only displays the time value in the target time zone.
- In ORA-compatible mode, there are differences between GaussDB and Oracle Database when you use CREATE TABLE to create objects.

  GaussDB does not support the **REF** keyword, but Oracle Database supports it.

```
CREATE TABLE test_floor_ref (
  ref_id NUMBER,
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
    col_ref REF obj_ref_test_floor
);
```

Table 3-3 Character types

Oracle Database	GaussDB	Difference
VARCHAR2 [(size [BYTE | CHAR])]	Supported, with differences.	In GaussDB, the unit of size is bytes, and the maximum value is **10M**. In Oracle Database, if **MAX_STRING_SIZE** is set to **EXTENDED**, the maximum length is 32767 bytes; if **MAX_STRING_SIZE** is set to **STANDARD**, the maximum length is 4000 bytes.
NVARCHAR2 (size)	Supported, with differences.	In GaussDB, the unit of size is bytes and the maximum value is **10M**. In Oracle Database, if **MAX_STRING_SIZE** is set to **EXTENDED**, the maximum length is 32767 bytes; if **MAX_STRING_SIZE** is set to **STANDARD**, the maximum length is 4000 bytes. For both databases, the actual number of characters that can be contained depends on the character set in use. In GaussDB, trailing spaces in an NVARCHAR2 value are ignored during insertion. In Oracle Database, trailing spaces in an NVARCHAR2 value are not ignored during insertion.
CHAR [(size [BYTE | CHAR])]	Supported, with differences.	In GaussDB, the unit of size is bytes, and the maximum value is **10MB**. In Oracle Database, the maximum length is 2000 bytes.
NCHAR [(size)]	Supported, with differences.	In GaussDB, the size unit is bytes and the maximum value is 10 MB. The maximum number of characters that can be contained depends on the used character set. In Oracle Database, the size unit is characters and the maximum capacity is 2000 bytes. NCHAR is a data type used to store fixed-length Unicode characters.
CLOB	Supported, with differences.	Locators are not supported.
NCLOB	Not supported.	-
LONG	Not supported.	-

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 3-4 Binary types

Oracle Database	GaussDB	Difference
RAW (size)	Supported, with differences.	In GaussDB, **size** indicates the recommended byte length and is not used to verify the byte length of the input raw type.
LONG RAW	Not supported.	-
BLOB	Supported.	-
BFILE	Not supported.	-

Table 3-5 ROWID types

Oracle Database	GaussDB	Difference
ROWID	Supported, with differences.	In GaussDB, the ROWID type is compared based on the values of the **node_slice**, **table_oid**, **bucket_id**, and **row_no** fields in sequence. In Oracle Database, the ROWID type is compared based on the values of the **data object number**, **relate file number**, **block number**, and **row number** fields in sequence. For details about the comparison rules of ROWID operators, see **Operators**.
UROWID	Not supported.	-

Table 3-6 User-defined types

Oracle Database	GaussDB
Object types	Not supported.
REF data types	Not supported.
Variable arrays	Supported.
Nested tables	Supported.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 3-7 Pseudo-types

Oracle Database	GaussDB
anytype	Not supported.
anydata	Not supported.
anydataset	Not supported.

Table 3-8 XML types

Oracle Database	GaussDB	Difference
XMLType	Supported, with differences.	GaussDB does not support some operations. For example, the XMLELEMENT function is used to convert a character string to the XML type instead of the XMLType type. For details, see **XMLType**.
URITYPE	Not supported.	-

Table 3-9 Spatial types

Oracle Database	GaussDB
SDO_GEOMETRY	Not supported.
SDO_TOPO_GEOMETRY	Not supported.
SDO_GEORASTER	Not supported.

Table 3-10 Lock modes

Oracle Database	GaussDB
none	-
null	AccessShare
RS	RowShare
RX	RowExclusive
S	ShareUpdateExclusive
SRX	Share
-	ShareRowExclusive
X	Exclusive

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Oracle Database	GaussDB
-	AccessExclusive
-	INVALID **NOTE** INVALID of GaussDB indicates that an invalid lock is assigned. An invalid lock is assigned only when a lock that cannot be identified by GaussDB occurs during system running.

3.2.2.2 Data Type Comparison Rules

Data type comparison (collation) rules apply only when values of the same data type are compared (collated).

Table 3-11 Comparison rules

Oracle Database	GaussDB	Difference
Numeric values	Supported.	-
Datetime values	Supported.	-
Binary values	Supported.	-
Character values	Supported, with differences.	• GaussDB and Oracle Database support different comparison rules, and the names of the same comparison rules may be different. • GaussDB and Oracle Database differ in specifying comparison rules. For example, table-level comparison rules cannot be specified in GaussDB, but can be specified in Oracle Database. • The syntax for specifying comparison rules in GaussDB and Oracle Database is different. For example, in GaussDB, the **ENCODING**, **LC_CTYPE**, and **LC_COLLATE** parameters are used to determine the character set, collation, and comparison rule used for creating a database. For details, see **CREATE DATABASE**. In Oracle Database, comparison rules at different levels are usually specified by a series of parameters with the NLS prefix.
Object values	Not supported.	-

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Oracle Database	GaussDB	Difference
Varrays and nested tables	Supported, with differences.	Both GaussDB and Oracle Database support the comparison of varrays. Different from Oracle Database, GaussDB not only supports the comparison of the number of elements in two varrays, but also supports the comparison between varrays of the same type.
Data type precedence	Supported.	-
Explicit/ Implicit data type conversion	Supported.	-

3.2.2.3 Literals

Table 3-12 Literals

Oracle Database	GaussDB
Text literals	Supported.
Numeric literals	Supported, with the following difference: Numeric literals of 123.4f and 123.4d (with the f/d suffix) cannot be used as function input parameters.
Datetime literals	Supported.
Interval literals	Supported.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

3.2.2.4 Format Models

Table 3-13 Formats

Oracle Database	GaussDB	Difference
Number formats	Supported, with differences.	GaussDB supports the $, C, TM, TM9, TME, and U formats only when **a_format_version** is set to **10c** and **a_format_dev_version** is set to **s1**. In addition, this parameter does not support the TH, PL, or SG format. For details about the support of GaussDB, see formats for the number type in **Type Conversion Functions**.
Datetime formats	Supported, with differences.	GaussDB: Parameters used for time truncation and rounding are valid only when **a_format_version** is set to **10c** and **a_format_dev_version** is set to **s1**. For details about the support of GaussDB, see formats for formatting date and time in **Date and Time Processing Functions and Operators**.
Format model modifiers	Supported.	-
String-to-date conversion rules	Supported, with differences.	GaussDB: The to_timestamp_tz function is valid only when **a_format_version** is set to **10c** and **a_format_dev_version** is set to **s1**. For details about the support of GaussDB, see "to_date/to_timestamp/to_timestamp_tz" in **Type Conversion Functions**.
XML format models	Not supported.	-

3.2.2.5 Nulls

Table 3-14 Nulls

Oracle Database	GaussDB
IS NULL and IS NOT NULL	Supported.
NULLS in conditions	Supported.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

3.2.2.6 Comments

Table 3-15 Comments

Oracle Database	GaussDB	Difference
A slash and an asterisk (/*)	Supported.	-
Two hyphens (--)	Supported.	-
COMMENT command	Supported.	-
HINT	Supported, with differences.	GaussDB does not support the '--+' hint format. For details, see "Hint-based Optimization" in *SQL Optimization Guide*.

3.2.2.7 Database Objects

Table 3-16 Schema objects

Oracle Database	GaussDB	Difference
Analytic views	Not supported.	-
Attribute dimensions	Not supported.	-
Clusters	Supported.	-
Constraints	Supported.	-
Database links	Supported.	-
Database triggers	Supported.	-
Dimensions	Supported.	-
External procedure libraries	Not supported.	-
Hierarchies	Not supported.	-

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Oracle Database	GaussDB	Difference
Index-organized tables	Not supported.	-
Indexes	Supported.	If the unique index involves composite columns, the processing logic is NULL == NULL in Oracle Database, but it is NULL != NULL in GaussDB, which follows the SQL standard by default. To make the latter compatible with the former in terms of this behavior, enable the GUC parameter **enable_uniq_idx_a_compat**. This parameter is disabled by default in GaussDB ORA-compatible mode.
Index types	Not supported.	-
Java classes	Not supported.	-
Java resources	Not supported.	-
Java source code	Not supported.	-
Join groups	Not supported.	-
Materialized views	Supported.	-
Materialized view logs	Not supported.	-
Mining models	Not supported.	-
Object tables	Not supported.	-
Object types	Not supported.	-
Object views	Not supported.	-
Operators	Supported.	-
Packages	Supported.	-
Sequences	Supported.	-

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Oracle Database	GaussDB	Difference
Storage functions	Supported.	-
Stored procedures	Supported.	-
Synonyms	Supported, with differences.	The names of Oracle Database objects in the same namespace must be unique. In GaussDB, the name of a synonym can be the same as that of a table, view, function, or package in the same namespace. In this case, GaussDB preferentially accesses the table, view, function, or package object with the same name. If no such object is found, GaussDB searches for the synonym object. In addition, the PUBLIC synonym is searched only when the schema name of the object to which the synonym points is a username. For details about the search sequence, see the precautions in **CREATE SYNONYM**. The search process of synonyms is as follows:
Tables	Supported.	-
Views	Supported.	-
Zone map	Not supported.	-

Table 3-17 Non-schema objects

Oracle Database	GaussDB
Contexts	Not supported.
Directories	Supported.
Editions	Not supported.
Flashback archives	Not supported.
Lockdown profiles	Not supported.
Profiles	Not supported.
Restore points	Supported.
Roles	Supported.
Rollback segments	• Ustore supports rollback segments. • Astore does not support rollback segments.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Oracle Database	GaussDB
Tablespaces	Supported.
Tablespace sets	Not supported.
Unified audit policies	Supported.
Users	Supported.

3.2.2.8 Database Object Names and Qualifiers

Table 3-18 Naming rules

Oracle Database	GaussDB	Difference
Database object naming rules	Supported, with differences.	GaussDB uses lowercase letters by default.
Schema object naming rules	Supported.	-

3.2.2.9 Syntax for Schema Objects and Parts in SQL Statements

Table 3-19 Object reference

Oracle Database	GaussDB
General syntax for referring to an object	Supported.
Resolving a reference to an object	Supported.
Referring to objects in other schemas	Supported.
Referring to objects in remote databases	Supported.
Referring to partitions and subpartitions of tables and indexes	Supported.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

3.2.3 Pseudocolumns

Hierarchical Query Pseudocolumns

Table 3-20 Hierarchical query pseudocolumns

Oracle Database	GaussDB
connect_by_iscycle	Supported.
connect_by_isleaf	Supported.
LEVEL pseudocolumn	Supported.

Sequence Pseudocolumns

Table 3-21 Sequences

Oracle Database	GaussDB	Difference
currval	Supported, with differences.	It is implemented as a function in GaussDB. The call mode is compatible with Oracle Database.
nextval	Supported, with differences.	It is implemented as a function in GaussDB. The call mode is compatible with Oracle Database.

ROWID Pseudocolumns

Table 3-22 rowid

Oracle Database	GaussDB	Difference
rowid	Supported, with differences.	Oracle Database supports ROWID pseudocolumns when a table is created. GaussDB supports ROWID pseudocolumns when the **hasrowid** option is used to create a table.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

ROWNUM Pseudocolumn

Table 3-23 rownum

Oracle Database	GaussDB	Difference
rownum	Supported, with differences.	When Oracle Database uses rownum in the left, right, and full join conditions for filtering, the performance varies according to the conditions. The rownum condition may be ignored or partially ignored. However, GaussDB filters the results after left, right, and full join.

XMLDATA Pseudocolumn

Table 3-24 xmldata

Oracle Database	GaussDB
xmldata	Not supported.

3.2.4 Operators

GaussDB is compatible with operators except hierarchical query.

SQL Operators

Table 3-25 SQL operators

Oracle Database	GaussDB
Unary and binary operators	Supported.
Operator precedence	Supported.

Arithmetic Operators

Table 3-26 Arithmetic operators

Oracle Database	GaussDB
Unary operators: positive (+) and negative (–).	Supported.
Binary operators: addition (+) and subtraction (–).	Supported.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Oracle Database	GaussDB
Binary operators: multiplication (*) and division (/).	Supported.

COLLATE Operator

Table 3-27 COLLATE operator

Oracle Database	GaussDB
COLLATE collation_name	Supported.

Connection Operators

Table 3-28 Connection operators

Oracle Database	GaussDB	Difference
||	Supported, but with differences.	For the concatenation of invalid characters, GaussDB does not check the validity of characters and directly concatenates all characters; however, if Oracle Database detects invalid characters, it ignores them. Example: -- GaussDB gaussdb=# SET a_format_version='10c'; SET gaussdb=# SET a_format_dev_version='s2'; SET gaussdb=# SELECT dump(CHR(239) || 'test') FROM dual; dump ---------- Typ=25 Len=5: 239,116,101,115,116 (1 row) -- Oracle SQL> SELECT dump(CHR(239) || 'test') FROM dual; dump(CHR(239)||'TEST') ---------- Typ=1 Len=4: 116,101,115,116

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Hierarchical Query Operators

Table 3-29 Hierarchical query operators

Oracle Database	GaussDB	Difference
prior	Supported, with differences.	GaussDB: Only ordinary columns can be called. Functions cannot be called.
connect_by_root	Supported, with differences.	GaussDB: When connect_by_root is called, if parentheses are used to modify the operation value, the behavior is the same as that of Oracle Database. If parentheses are not used, this operator can be called only for ordinary columns.

Set Operators

Table 3-30 Set operators

Oracle Database	GaussDB
union	Supported.
union all	Supported.
intersect	Supported.
minus	Supported.

Multiset Operators

Table 3-31 Multiset operators

Oracle Database	GaussDB
multiset except	Supported.
multiset intersect	Supported.
multiset union	Supported.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

User-defined Operators

Table 3-32 User-defined operators

Oracle Database	GaussDB
CREATE OPERATOR	Not supported.

Comparison Operators

Oracle Database	GaussDB
< =	Supported.
< >	Supported.
> =	Supported.
^ =	Supported.
! =	Not supported. For !=, if there is a space between an exclamation mark (!) and an equal sign (=), the exclamation mark will be identified as factorial.

For comparison operators <=, <>, >=, and ^=, if there is a space between two symbols, it does not affect normal operations. For !=, if there is a space between an exclamation mark (!) and an equal sign (=), the exclamation mark will be identified as factorial, which may cause the result to be inconsistent with the expected result.

3.2.5 Expressions

GaussDB is compatible with most database expressions.

Table 3-33 Expressions

Oracle Database	GaussDB	Difference
Simple expressions	Supported.	-
Analytic view expressions	Not supported.	-
Compound expressions	Supported.	-
CASE expressions	Supported.	-
Column expressions	Supported.	-

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Oracle Database	GaussDB	Difference
CURSOR expressions	Not supported.	-
Datetime expressions	Supported, with differences.	GaussDB command output does not contain time zone information, but Oracle Database contains time zone information similar to "PM AMERICA/LOS_ANGELES."
Function expressions	Supported.	-
Interval expressions	Partially supported.	GaussDB supports statements in the format of "SELECT INTERVAL '999999999 23:59:59.999' day(9) to second FROM DUAL;" but does not support statements in the format of "SELECT(SYSDATE-SYSDATE) DAY TO SECOND FROM DUAL;". They are supported in Oracle Database.
JSON object access expressions	Partially supported, with differences.	• GaussDB can extract values from JSON objects in "->'key'" mode, while Oracle Database can extract values in ".key" mode. • For JSON array objects, Oracle Database can extract values corresponding to all keys at a time in ".key" mode. However, GaussDB does not support this option.
Model expressions	Not supported.	-
Object expressions	Not supported.	-
Placeholder expressions	Partially supported.	GaussDB supports general placeholder expressions such as ":var", but does not support the combination of two general placeholder expressions using the INDICATOR keyword.
Scalar subquery expressions	Supported.	-
Type constructor expressions	Partially supported.	GaussDB cannot specify the NEW keyword before the type constructor, but Oracle Database can.
Expression lists	Supported.	-

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

<table>
<tr><th>Oracle Database</th><th>GaussDB</th><th>Difference</th></tr>
<tr><td>Expressions with the addition (+) operator</td><td>Partially supported, with differences.</td><td>For an outer join expression connected by the OR operator, GaussDB supports only the outer join expression in which the same single table is used on the left and right sides of the OR operator.
When the addition (+) and OR operators are used together, the behavior of GaussDB is different from that of Oracle Database. The following describes the differences between GaussDB and Oracle Database 19c:
Common statements
-- Run the following statements to create tables and insert data into the tables:
CREATE TABLE a(id int, b int);
CREATE TABLE a2(id int, c int);
INSERT INTO a VALUES(1,1);
INSERT INTO a VALUES (null, 11);
INSERT INTO a VALUES (2, null);
INSERT INTO a VALUES (123,123);
INSERT INTO a VALUES (5, 500);
INSERT INTO a VALUES (null, 600);
INSERT INTO a2 VALUES(1,2);
INSERT INTO a2 VALUES (3,null);
INSERT INTO a2 VALUES (null, 22);
INSERT INTO a2 VALUES (234,234);
INSERT INTO a2 VALUES (5, 700);
INSERT INTO a2 VALUES (null, 800);
• Example 1
SELECT * FROM a,a2 WHERE (a.id(+) = 1 AND a.id(+) <= 2) OR a2.id(+) = 1 ORDER BY 1,2,3,4;
– GaussDB
gaussdb=# CREATE DATABASE gaussdb_o DBCOMPATIBILITY = 'ORA';
gaussdb=# \c gaussdb_o
-- Execute the common statement and then the query statement.
gaussdb_o=# SELECT * FROM a,a2 WHERE (a.id(+) = 1 AND a.id(+) <= 2) OR a2.id(+) = 1 ORDER BY 1,2,3,4;
ERROR: Operator "(+)" is not allowed used with "OR" together
-- Switch to the default database and drop the gaussdb_o database. Change the database name as required.
gaussdb_o=# \c postgres
gaussdb=# DROP DATABASE gaussdb_o;
– Oracle
-- Execute the common statement and then the query statement.
SQL> SELECT * FROM a,a2 WHERE (a.id(+) = 1 AND a.id(+) <= 2) OR a2.id(+) = 1 ORDER BY 1,2,3,4;

ID| B| ID| C
----------|----------|----------|----------
1| 1| 1| 2
1| 1| 3|</td></tr>
</table>

		database name as required. gaussdb_o=# \c postgres gaussdb=# DROP DATABASE gaussdb_o; – Oracle -- Execute the common statement and then the query statement. SQL> SELECT * FROM a,a2 WHERE a.id(+) = a2.id OR a.id IS NULL AND a.id(+) = a2.id ORDER BY 1,2,3,4; ERROR at line 1: ORA-01719: outer join operator (+) not allowed in operand of OR or IN -- After extracting the common expression, execute the converted SQL statement. SQL> SELECT * FROM a,a2 WHERE a.id(+) = a2.id AND (a.id(+) != 2 OR a.id(+) IS NULL) ORDER BY 1,2,3,4; ID| B| ID| C ----------|----------|----------|---------- 1| 1| 1| 2 5| 500| 5| 700 | | 3| | | 234| 234 | | | 22 | | | 800 6 rows selected. -- Drop the data tables created in this example. (You need to modify the table names based on the actual situation.) SQL> DROP TABLE a; SQL> DROP TABLE a2; When the left and right sides of the OR operator in the outer join expression use the same single table, GaussDB does not throw an error because this complies with its rule. However, Oracle Database reports an error (ORA-01719). After extracting the common expression a.id(+) = a2.id, the converted SQL statement is as follows: SELECT * FROM a,a2 WHERE a.id(+) = a2.id AND (a.id(+) != 2 OR a.id(+) IS NULL) ORDER BY 1,2,3,4; The execution results are the same in the two databases.

3.2.6 Conditions

This chapter describes common compatible conditions. The conditions include comparison, floating-point, logical, model, multiset, pattern matching, **NULL** value, XML, SQL/JSON, composite, BETWEEN, EXISTS, IN, and IS OF TYPE, as shown in **Table 3-34**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 3-34 Conditions

Oracle Database	GaussDB	Difference
Comparison conditions	Supported, with differences.	Differences exist when statements contain the ANY, SOME, and ALL operators. Oracle Database supports operations on list objects, but GaussDB needs to convert list objects into array expressions before performing operations.
Floating-point conditions	Not supported.	-
Logical conditions	Supported.	-
Model conditions	Not supported.	-
Multiset conditions	Not supported.	-
Pattern-matching conditions	Supported.	-
NULL conditions	Supported.	-
XML conditions	Not supported.	-
SQL/JSON conditions	Partially supported, with differences.	• GaussDB does not support the IS JSON and JSON_TEXTCONTAINS conditions. • The JSONB_EQ condition in GaussDB is the same as the JSON_EQUAL condition in Oracle Database. However, GaussDB does not support the ERROR clause. • The JSONB_EXISTS condition in GaussDB is the same as the JSON_EXISTS condition in Oracle Database. However, GaussDB does not support the ERROR, EMPTY, or PASSING clauses.
Compound conditions	Supported.	-
BETWEEN condition	Supported.	-
EXISTS condition	Supported.	-
IN condition	Supported.	-

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Oracle Database	GaussDB	Difference
IS OF TYPE condition	Not supported.	-

3.2.7 Drivers

3.2.7.1 JDBC

3.2.7.1.1 Array

This section describes the differences between Oracle Database and GaussDB when the JDBC driver of the java.sql.Array type is used.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 3-35 Constructor reference

Constructor	Oracle Database	GaussDB	API Difference
1. Use the static constructor of ArrayDescriptor to construct an ArrayDescriptor object. 2. Use ArrayDescriptor to construct an array object.	String typeName = "XXX"; Connection conn = getConnection(); Object[] elements = null; ArrayDescriptor desc = ArrayDescriptor.createDescriptor(typeName, conn); Array array = new ARRAY(desc, conn, elements);	String typeName = "xxx"; Connection conn = getConnection(); Object[] elements = null; ArrayDescriptor desc = ArrayDescriptor.getDescriptor(typeName, conn); Array array = new GaussArray(desc, elements);	• Different names of the static constructor for ArrayDescriptor: In Oracle Database, it is createDescriptor, while in GaussDB it is getDescriptor. • Different constructor names for arrays: In Oracle Database, it is ARRAY(ArrayDescriptor, Connection, Object), while in GaussDB, it is GaussArray(ArrayDescriptor, Object). • Variable description: *typeName* indicates the type name and is case-sensitive: uppercase in Oracle Database, while lowercase in GaussDB. *conn* indicates the connection object for the corresponding database. *elements* indicates the element data of the corresponding type.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

1. GaussDB currently does not support the constructors not listed in the aforementioned table.
2. If the element type is the character type and the length of the construction input string exceeds that defined by the element type, Oracle Database reports an error during input parameter binding.

   If the array type is the varray type and the number of elements exceeds the maximum length of varray, Oracle Database reports an error during input parameter binding.

   GaussDB does not verify type modifiers when constructing or binding input parameters. When receiving array objects and executing SQL statements, a database decides whether to report an error.

Table 3-36 API reference

Method	Return Type	Throws	GaussDB
getBaseTypeName()	String	SQLException	Supported.
getBaseType()	int	SQLException	Supported.
getArray()	Object	SQLException	Supported.
getArray(java.util.Map<String,Class<?>> map)	Object	SQLException	Not supported.
getArray(long index, int count)	Object	SQLException	Supported.
getArray(long index, int count, java.util.Map<String,Class<?>> map)	Object	SQLException	Not supported.
getResultSet()	ResultSet	SQLException	Not supported.
getResultSet(java.util.Map<String,Class<?>> map)	ResultSet	SQLException	Not supported.
getResultSet(long index, int count)	ResultSet	SQLException	Not supported.
getResultSet (long index, int count, java.util.Map<String,Class<?>> map)	ResultSet	SQLException	Not supported.
free()	void	SQLException	Not supported.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 3-37 Differences in the getArray() API

Element Database Type	Actual Return Type of the getArray API (Oracle Database)	Actual Return Type of the getArray API (GaussDB)
CHAR	java.lang.String[]	java.lang.String[]
VARCHAR/ VARCHAR2	java.lang.String[]	java.lang.String[]
NCHAR	java.lang.String[]	java.lang.String[]
NVARCHAR2	java.lang.String[]	java.lang.String[]
NUMBER	java.math.BigDecimal[]	java.math.BigDecimal[]
NUMERIC	java.math.BigDecimal[]	java.math.BigDecimal[]
DECIMAL	java.math.BigDecimal[]	java.math.BigDecimal[]
INTEGER	java.math.BigDecimal[]	java.lang.Integer[]
SMALLINT	java.math.BigDecimal[]	java.lang.Short[]
DOUBLE PRECISION	java.math.BigDecimal[]	java.lang.Double[]
FLOAT	java.math.BigDecimal[]	java.lang.Double[]
REAL	java.math.BigDecimal[]	java.lang.Float[]
BINARY_DOUBLE	java.lang.Double[]	java.lang.Double[]
BINARY_INTEGER	java.math.BigDecimal[]	java.lang.Integer[]
BOOLEAN	java.math.BigDecimal[]	java.lang.Boolean[]
TIMESTAMP	java.sql.Timestamp[]	java.sql.Timestamp[]
TIMESTAMP WITH TIME ZONE	java.time.OffsetDateTime[]	java.sql.Timestamp[]
BLOB	oracle.sql.BLOB[]	java.sql.Blob[]
CLOB	oracle.sql.CLOB[]	java.sql.Clob[]
Set/Array	java.lang.Object[]	java.sql.Array[]
RECORD	java.lang.Object[]	java.sql.Struct[]

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

1. GaussDB currently does not support the types not listed in the aforementioned table.
2. For details about the differences in the return values of the getArray(long index, int count) API, see the preceding table.
3. The differences in the **index** parameter of getArray(long index, int count) are as follows:
   - The value range supported by Oracle Database is [1, *Long.MAX_VALUE*]. GaussDB supports a range of [1, *Integer.MAX_VALUE*].
   - If the **index** value is greater than that of *Integer.MAX_VALUE*, it will be truncated in Oracle Database, while an error is reported in GaussDB.

Table 3-38 Differences in the getBaseType() API

Element Database Type	Return Value of getBaseType (Oracle Database)	Return Value of getBaseType (GaussDB)
CHAR	java.sql.Types.CHAR	java.sql.Types.CHAR
VARCHAR/ VARCHAR2	java.sql.Types.VARCHAR	java.sql.Types.VARCHAR
NCHAR	java.sql.Types.NCHAR	java.sql.Types.CHAR
NVARCHAR2	java.sql.Types.NVARCHAR	java.sql.Types.VARCHAR
NUMBER	java.sql.Types.NUMERIC	java.sql.Types.NUMERIC
NUMERIC	java.sql.Types.DECIMAL	java.sql.Types.NUMERIC
DECIMAL	java.sql.Types.DECIMAL	java.sql.Types.NUMERIC
INTEGER	java.sql.Types.NUMERIC	java.sql.Types.INTEGER
SMALLINT	java.sql.Types.NUMERIC	java.sql.Types.SMALLINT
DOUBLE PRECISION	java.sql.Types.FLOAT	java.sql.Types.DOUBLE
FLOAT	java.sql.Types.FLOAT	java.sql.Types.DOUBLE
REAL	java.sql.Types.FLOAT	java.sql.Types.REAL
BINARY_DOUBLE	oracle.jdbc.OracleTypes.BINARY_DOUBLE	java.sql.Types.DOUBLE
BINARY_INTEGER	java.sql.Types.NUMERIC	java.sql.Types.INTEGER
BOOLEAN	java.sql.Types.NUMERIC	java.sql.Types.BIT
TIMESTAMP	java.sql.Types.TIMESTAMP	java.sql.Types.TIMESTAMP
TIMESTAMP WITH TIME ZONE	oracle.jdbc.OracleTypes.TIMESTAMPTZ	java.sql.Types.TIMESTAMP
BLOB	java.sql.Types.BLOB	java.sql.Types.BLOB

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Element Database Type	Return Value of getBaseType (Oracle Database)	Return Value of getBaseType (GaussDB)
CLOB	java.sql.Types.CLOB	java.sql.Types.CLOB
Set/Array	java.sql.Types.ARRAY	java.sql.Types.ARRAY
RECORD	java.sql.Types.STRUCT	java.sql.Types.STRUCT

NOTE

GaussDB currently does not support the types not listed in the aforementioned table.

Table 3-39 Differences in the getBaseTypeName() API

Element Database Type	Return Value of getBaseTypeName (Oracle Database)	Return Value of getBaseTypeName (GaussDB)
CHAR	"CHAR"	"bpchar"
VARCHAR/ VARCHAR2	"VARCHAR"	"varchar"
NCHAR	"NCHAR"	"bpchar"
NVARCHAR2	"NVARCHAR"	"nvarchar2"
NUMBER	"NUMBER"	"numeric"
NUMERIC	"DECIMAL"	"numeric"
DECIMAL	"DECIMAL"	"numeric"
INTEGER	"NUMBER"	"int4"
SMALLINT	"NUMBER"	"int2"
DOUBLE PRECISION	"FLOAT"	"float8"
FLOAT	"FLOAT"	"float8"
REAL	"FLOAT"	"float4"
BINARY_DOUBLE	"BINARY_DOUBLE"	"float8"
BINARY_INTEGER	"NUMBER"	"int4"
BOOLEAN	"NUMBER"	"bool"
TIMESTAMP	"TIMESTAMP"	"timestamp"
TIMESTAMP WITH TIME ZONE	"TIMESTAMP WITH TIME ZONE"	"timestamptz"

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Element Database Type	Return Value of getBaseTypeName (Oracle Database)	Return Value of getBaseTypeName (GaussDB)
BLOB	"BLOB"	"blob"
CLOB	"CLOB"	"clob"
Set/Array	See the description below.	See the description below.
RECORD	See the description below.	See the description below.

NOTE

1. GaussDB currently does not support the types not listed in the aforementioned table.
2. When an element is of the set, array, or RECORD type that is defined within a package, the return rules for getBaseTypeName are as follows:
   - OJDBC11 returns *schemaName.packageName.typeName*.
   - OJDBC8 generally returns *schemaName.packageName.typeName*, or returns *"schemaName"."packageName.typeName"* in the following condition:

     Any of *schemaName*, *packageName*, or *typeName* violates the rule of starting with a letter and containing only letters, digits, and underscores (_).
   - GaussDB generally returns *schemaName.packageName.typeName*, or returns *"schemaName"."packageName"."typeName"* in the following condition:

     Any of *schemaName*, *packageName*, or *typeName* violates the rule of starting with a letter or underscore (_) and containing only letters, digits, and underscores.
3. When an element is of the set, array, or RECORD type that is defined in the schema (but not in the package), the return rules for getBaseTypeName are as follows:
   - OJDBC11 returns *schemaName.typeName*.
   - OJDBC8 generally returns *schemaName.typeName*, or returns *"schemaName"."typeName"* in the following condition:

     Either of *schemaName* or *typeName* violates the rule of starting with a letter and containing only letters, digits, and underscores (_).
   - GaussDB generally returns *schemaName.typeName*, or returns *"schemaName"."typeName"* in the following condition:

     Either *schemaName* or *typeName* violates the rule of starting with a letter or underscore (_) and containing only letters, digits, and underscores.
4. If no special processing is performed during element type creation, the getBaseTypeName API typically returns the type name in uppercase in Oracle Database, while returns the type name in lowercase in GaussDB.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 3-40 Differences in array construction APIs

Element Database Type	Java Types Supported by Element Input Parameters (Oracle Database OJDBC8)	Java Types Supported by Element Input Parameters (GaussDB)	Difference
CHAR	Any Java type	Byte, Short, Integer, Long, BigInteger, BigDecimal, Float, Double, Character, Boolean, java.sql.Date, java.sql.Time, java.sql.Timestamp, and PGClob	The different types supported by element input parameters are listed in the table.
VARCHAR/ VARCHAR2	Any Java type	Byte, Short, Integer, Long, BigInteger, BigDecimal, Float, Double, Character, Boolean, java.sql.Date, java.sql.Time, java.sql.Timestamp, and PGClob	The different types supported by element input parameters are listed in the table.
NCHAR	Any Java type	Byte, Short, Integer, Long, BigInteger, BigDecimal, Float, Double, Character, Boolean, java.sql.Date, java.sql.Time, java.sql.Timestamp, and PGClob	The different types supported by element input parameters are listed in the table.
NVARCHAR2	Any Java type	Byte, Short, Integer, Long, BigInteger, BigDecimal, Float, Double, Character, Boolean, java.sql.Date, java.sql.Time, java.sql.Timestamp, and PGClob	The different types supported by element input parameters are listed in the table.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Element Database Type	Java Types Supported by Element Input Parameters (Oracle Database OJDBC8)	Java Types Supported by Element Input Parameters (GaussDB)	Difference
NUMBER	Byte, Short, Integer, Long, Float, Double, Boolean, BigDecimal, BigInteger, String, and oracle.sql.NUMBER	Byte, Short, Integer, Long, Float, Double, Boolean, BigDecimal, BigInteger, and String	1. The different types supported by element input parameters are listed in the table. 2. When the input parameter is of the Float, Double, BigDecimal, or String type and the decimal part is 0, Oracle Database truncates the decimal part, while GaussDB retains it.
NUMERIC	Byte, Short, Integer, Long, Float, Double, Boolean, BigDecimal, BigInteger, String, and oracle.sql.NUMBER	Byte, Short, Integer, Long, Float, Double, Boolean, BigDecimal, BigInteger, and String	1. The different types supported by element input parameters are listed in the table. 2. When the input parameter is of the Float, Double, BigDecimal, or String type and the decimal part is 0, Oracle Database truncates the decimal part, while GaussDB retains it.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Element Database Type	Java Types Supported by Element Input Parameters (Oracle Database OJDBC8)	Java Types Supported by Element Input Parameters (GaussDB)	Difference
DECIMAL	Byte, Short, Integer, Long, Float, Double, Boolean, BigDecimal, BigInteger, String, and oracle.sql.NUMBER	Byte, Short, Integer, Long, Float, Double, Boolean, BigDecimal, BigInteger, and String	1. The different types supported by element input parameters are listed in the table. 2. When the input parameter is of the Float, Double, BigDecimal, or String type and the decimal part is 0, Oracle Database truncates the decimal part, while GaussDB retains it.
INTEGER	Byte, Short, Integer, Long, Float, Double, Boolean, BigDecimal, BigInteger, String, and oracle.sql.NUMBER	Byte, Short, Integer, Long, Float, Double, Boolean, BigDecimal, BigInteger, and String	1. The different types supported by element input parameters are listed in the table. 2. The target types are inconsistent. For details, see differences in the getArray() API. 3. When the input parameter value exceeds the integer range, GaussDB reports an error.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Element Database Type	Java Types Supported by Element Input Parameters (Oracle Database OJDBC8)	Java Types Supported by Element Input Parameters (GaussDB)	Difference
SMALLINT	Byte, Short, Integer, Long, Float, Double, Boolean, BigDecimal, BigInteger, String, and oracle.sql.NUMBER	Byte, Short, Integer, Long, Float, Double, Boolean, BigDecimal, BigInteger, and String	1. The different types supported by element input parameters are listed in the table. 2. The target types are inconsistent. For details, see differences in the getArray() API. 3. When the input parameter exceeds the Short range, GaussDB reports an error.
DOUBLE PRECISION	Byte, Short, Integer, Long, Float, Double, Boolean, BigDecimal, BigInteger, String, and oracle.sql.NUMBER	Byte, Short, Integer, Long, Float, Double, Boolean, BigDecimal, BigInteger, and String	1. The different types supported by element input parameters are listed in the table. 2. The target types are inconsistent. For details, see differences in the getArray() API. 3. Converting a higher-precision type to Double may result in precision loss.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Element Database Type	Java Types Supported by Element Input Parameters (Oracle Database OJDBC8)	Java Types Supported by Element Input Parameters (GaussDB)	Difference
FLOAT	Byte, Short, Integer, Long, Float, Double, Boolean, BigDecimal, BigInteger, String, and oracle.sql.NUMBER	Byte, Short, Integer, Long, Float, Double, Boolean, BigDecimal, BigInteger, and String	1. The different types supported by element input parameters are listed in the table. 2. The target types are inconsistent. For details, see differences in the getArray() API. 3. Converting a higher-precision type to Double may result in precision loss.
REAL	Byte, Short, Integer, Long, Float, Double, Boolean, BigDecimal, BigInteger, String, and oracle.sql.NUMBER	Byte, Short, Integer, Long, Float, Double, Boolean, BigDecimal, BigInteger, and String	1. The different types supported by element input parameters are listed in the table. 2. The target types are inconsistent. For details, see differences in the getArray() API. 3. Converting a higher-precision type to Float may result in precision loss.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Element Database Type	Java Types Supported by Element Input Parameters (Oracle Database OJDBC8)	Java Types Supported by Element Input Parameters (GaussDB)	Difference
BINARY_DOUBLE	Double and oracle.sql.BINARY_DOUBLE	Byte, Short, Integer, Long, Float, Double, Boolean, BigDecimal, BigInteger, and String	1. The different types supported by element input parameters are listed in the table. 2. The target types are inconsistent. For details, see differences in the getArray() API. 3. Converting a higher-precision type to Double may result in precision loss.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Element Database Type	Java Types Supported by Element Input Parameters (Oracle Database OJDBC8)	Java Types Supported by Element Input Parameters (GaussDB)	Difference
BINARY_INTEGER	Byte, Short, Integer, Long, Float, Double, Boolean, BigDecimal, BigInteger, AtomicInteger, AtomicLong, DoubleAccumulator, DoubleAdder, LongAccumulator, LongAdder, Striped64, String, and oracle.sql.NUMBER	Byte, Short, Integer, Long, Float, Double, Boolean, BigDecimal, BigInteger, and String	1. The different types supported by element input parameters are listed in the table. 2. The input parameters of the OJDBC11 element support the following types: Byte, Short, Integer, Long, Float, Double, Boolean, BigDecimal, BigInteger, String, and oracle.sql.NUMBER. 3. The target types are inconsistent. For details, see differences in the getArray() API. 4. When the input value exceeds the Integer range, GaussDB reports an error. Oracle Database OJDBC8 performs data truncation.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Element Database Type	Java Types Supported by Element Input Parameters (Oracle Database OJDBC8)	Java Types Supported by Element Input Parameters (GaussDB)	Difference
BOOLEAN	Byte, Short, Integer, Long, Float, Double, Boolean, BigDecimal, BigInteger, AtomicInteger, AtomicLong, DoubleAccumulator, DoubleAdder, LongAccumulator, LongAdder, Striped64, String, and oracle.sql.NUMBER	Byte, Short, Integer, Long, Float, Double, Boolean, BigDecimal, BigInteger, and String	1. The different types supported by element input parameters are listed in the table. 2. The input parameters of the OJDBC8 element support the following types: Byte, Short, Integer, Long, Float, Double, Boolean, BigDecimal, BigInteger, String, and oracle.sql.NUMBER. 3. The target types are inconsistent. For details, see differences in the getArray() API. 4. In GaussDB, the target data type is Boolean, which only supports inputs of **1**, **0**, **"true"**, and **"false"**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Element Database Type	Java Types Supported by Element Input Parameters (Oracle Database OJDBC8)	Java Types Supported by Element Input Parameters (GaussDB)	Difference
TIMESTAMP	byte[], java.sql.Date, Calendar, java.util.Date, LocalDate, LocalDateTime, LocalTime, OffsetDateTime, OffsetTime, String, java.sql.Time, java.sql.Timestamp, oracle.sql.DATE, oracle.sql.TIMESTAMP, oracle.sql.TIMESTAMPTZ, oracle.sql.TIMESTAMPLTZ, and ZonedDateTime	java.util.Date, java.sql.Date, java.sql.Time, java.sql.Timestamp, LocalDateTime, and String	The different types supported by element input parameters are listed in the table.
TIMESTAMP WITH TIME ZONE	java.sql.Date, Calendar, java.util.Date, LocalDate, LocalDateTime, LocalTime, OffsetDateTime, OffsetTime, String, java.sql.Time, java.sql.Timestamp, oracle.sql.DATE, oracle.sql.TIMESTAMP, oracle.sql.TIMESTAMPTZ, oracle.sql.TIMESTAMPLTZ, and ZonedDateTime	java.util.Date, java.sql.Date, java.sql.Time, java.sql.Timestamp, LocalDateTime, and String	1. The different types supported by element input parameters are listed in the table. 2. The target types are inconsistent. For details, see differences in the getArray() API.
BLOB	oracle.sql.BLOB and oracle.jdbc.driver.OracleBlob	PGBlob	The different types supported by element input parameters are listed in the table.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Element Database Type	Java Types Supported by Element Input Parameters (Oracle Database OJDBC8)	Java Types Supported by Element Input Parameters (GaussDB)	Difference
CLOB	oracle.sql.CLOB, oracle.jdbc.driver.OracleClob, InputStream, and Reader	PGClob	The different types supported by element input parameters are listed in the table.
Set/Array	Array and Object	GaussArray and Object	1. The different types supported by element input parameters are listed in the table. 2. Oracle Database: No error is reported when the input parameter is of the Array type even if the Array type differs from the element type. GaussDB: An error is reported when the input parameter is of the GaussArray type that differs from the element type. 3. When the input parameter of an element is of the Object type, refer to the differences in array construction APIs.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Element Database Type	Java Types Supported by Element Input Parameters (Oracle Database OJDBC8)	Java Types Supported by Element Input Parameters (GaussDB)	Difference
RECORD	Struct and Object[]	GaussStruct and Object[]	1. The different types supported by element input parameters are listed in the table. 2. Oracle Database: No error is reported when the input parameter is of the Struct type even if the Struct type differs from the element type. GaussDB: An error is reported when the input parameter is of the GaussStruct type that differs from the element type. 3. When the input parameter of an element is of the Object[] type, refer to the differences in struct construction APIs.

NOTE

1. When an array is constructed, if the Java type of the input element does not match the target type, an implicit conversion operation is performed. For details on the Java types of input elements supported by various database element types, refer to the preceding table.
2. GaussDB currently does not support the types not listed in the aforementioned table.
3. The constructor needs to provide an element array. The preceding table describes the differences between elements in the array.

3.2.7.1.2 Struct

This section describes the differences between Oracle Database and GaussDB when the JDBC driver of the java.sql.Struct type is used.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 3-41 Constructor reference

Constructor	Oracle Database	GaussDB	API Difference
1. Use the static constructor of StructDescriptor to construct a StructDescriptor object. 2. Use StructDescriptor to construct a struct object.	String typeName = "XXX"; Connection conn = getConnection(); Object[] attributes = null; StructDescriptor desc = StructDescriptor.createDescriptor(typeName, conn); Struct struct = new STRUCT(desc, conn, attributes);	String typeName = "xxx"; Connection conn = getConnection(); Object[] elements = null; StructDescriptor desc = StructDescriptor.getDescriptor(typeName, conn); Struct struct = new GaussStruct(desc, attributes);	• Different names of the static constructor for StructDescriptor: In Oracle Database, it is createDescriptor, while in GaussDB it is getDescriptor. • Different names of the Struct constructor: In Oracle Database, it is STRUCT(StructDescriptor, Connection, Object[]), while in GaussDB it is GaussStruct(StructDescriptor, Object[]). • Variable description: *typeName* indicates the type name and is case-sensitive: uppercase in Oracle Database, while lowercase in GaussDB. *conn* indicates the connection object for the corresponding database. *attributes* indicates the element data array.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Constructor	Oracle Database	GaussDB	API Difference
Use the createStruct standard API of Connection to construct a struct object.	String typeName = "XXX"; Connection conn = getConnection(); Object[] attributes = null; Struct struct = conn.createStruct(typeName, attributes);	String typeName = "XXX"; Connection conn = getConnection(); Object[] attributes = null; Struct struct = conn.createStruct(typeName, attributes);	• Variable description: *typeName* indicates the type name and is case-sensitive: uppercase in Oracle Database, while lowercase in GaussDB. *conn* indicates the connection object for the corresponding database. *attributes* indicates the element data array.

NOTE

1. GaussDB currently does not support the constructors not listed in the aforementioned table.
2. If **attribute** is of the character type and the length of the construction input string exceeds that defined by the element type, Oracle Database reports an error during input parameter binding.

   GaussDB does not verify type modifiers when constructing or binding input parameters. When receiving struct objects and executing SQL statements, a database decides whether to report an error.
3. If the number of array elements exceeds the actual number of columns of the corresponding type, an error is reported during creation.

   When the number of array elements is less than the actual number of columns, the creation of Oracle Database is successful, but an error is reported during parameter input for execution; GaussDB reports an error during creation.

Table 3-42 API reference

Method	Return Type	Throws	GaussDB
getSQLTypeName()	String	SQLException	Supported.
getAttributes()	Object[]	SQLException	Supported.
getAttributes(java.util.Map<String,Class<?>> map)	Object[]	SQLException	Not supported.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

The differences in the getSQLTypeName API are as follows:

1. For the package type, the struct constructed in the *packageName.typeName* format, the differences in the getSQLTypeName API are as follows:
   - OJDBC11 returns *packageName.typeName*.
   - OJDBC8 generally returns *packageName.typeName*, or returns *"packageName"."typeName"* when *packageName* and *typeName* meet the following condition:

     Either *packageName* or *typeName* violates the rule of starting with a letter and containing only letters, digits, and underscores (_).
   - GaussDB generally returns *schemaName.packageName.typeName*, or returns *"schemaName"."packageName"."typeName"* when *schemaName*, *packageName*, and *typeName* meet the following condition:

     Any of *schemaName*, *packageName*, or *typeName* violates the rule of starting with a letter or underscore (_) and containing only letters, digits, and underscores.
2. For the package type, the differences in the getSQLTypeName API in other scenarios are as follows:
   - OJDBC11 returns *schemaName.packageName.typeName*.
   - OJDBC8 generally returns *schemaName.packageName.typeName*, or returns *"schemaName"."packageName.typeName"* when *schemaName*, *packageName*, and *typeName* meet the following condition:

     Any of *schemaName*, *packageName*, or *typeName* violates the rule of starting with a letter and containing only letters, digits, and underscores (_).
   - GaussDB generally returns *schemaName.packageName.typeName*, or returns *"schemaName"."packageName"."typeName"* when *schemaName*, *packageName*, and *typeName* meet the following condition:

     Any of *schemaName*, *packageName*, or *typeName* violates the rule of starting with a letter or underscore (_) and containing only letters, digits, and underscores.
3. For the non-package type, the differences in the getSQLTypeName API are as follows:
   - OJDBC11 returns *schemaName.typeName*.
   - OJDBC8 generally returns *schemaName.typeName*, or returns *"schemaName"."typeName"* when *schemaName* and *typeName* meet the following condition:

     Either *schemaName* or *typeName* violates the rule of starting with a letter and containing only letters, digits, and underscores (_).
   - GaussDB generally returns *schemaName.typeName*, or returns *"schemaName"."typeName"* when *schemaName* and *typeName* meet the following condition:

     Either *schemaName* or *typeName* violates the rule of starting with a letter or underscore (_) and containing only letters, digits, and underscores.

Table 3-43 Differences in the getAttributes() API

Database Attribute Type	Java Type of the Corresponding Element in the Return Value (Oracle Database OJDBC8)	Java Type of the Corresponding Element in the Return Value (Oracle Database OJDBC11)	Java Type of the Corresponding Element in the Return Value (GaussDB)
CHAR	String	String	String

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Database Attribute Type	Java Type of the Corresponding Element in the Return Value (Oracle Database OJDBC8)	Java Type of the Corresponding Element in the Return Value (Oracle Database OJDBC11)	Java Type of the Corresponding Element in the Return Value (GaussDB)
VARCHAR/ VARCHAR2	String	String	String
NCHAR	String	String	String
NVARCHAR2	String	String	String
NUMBER	BigDecimal	BigDecimal	BigDecimal
NUMERIC	BigDecimal	BigDecimal	BigDecimal
DECIMAL	BigDecimal	BigDecimal	BigDecimal
INTEGER	BigDecimal	BigDecimal	Integer
SMALLINT	BigDecimal	BigDecimal	Short
DOUBLE PRECISION	BigDecimal	BigDecimal	Double
FLOAT	BigDecimal	BigDecimal	Double
REAL	BigDecimal	BigDecimal	Float
BINARY_DOUBLE	Double	Double	Double
BINARY_INTEGER	BigDecimal	Integer	Integer
BOOLEAN	BigDecimal	Integer	Boolean
TIMESTAMP	Timestamp	Timestamp	Timestamp
TIMESTAMP WITH TIME ZONE	TIMESTAMPTZ	TIMESTAMPTZ	Timestamp
BLOB	BLOB	BLOB	PGBlob
CLOB	CLOB	CLOB	PGClob
Set/Array	ARRAY	ARRAY	GaussArray
RECORD	STRUCT	STRUCT	GaussStruct

NOTE

GaussDB currently does not support the types not listed in the aforementioned table.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 3-44 Differences in struct construction APIs

Database Attribute Type	Java Types Supported by Attribute Input Parameters (Oracle Database)	Java Types Supported by Attribute Input Parameters (GaussDB)	Difference
CHAR	Any Java type	Byte, Short, Integer, Long, BigInteger, BigDecimal, Float, Double, Character, Boolean, String, java.sql.Date, java.sql.Time, java.sql.Timestamp, and PGClob	1. The different types supported by the input parameter **attribute** can be seen in the table. 2. When the input parameter is of the String type, Oracle Database adds spaces to the end of the string until it meets the length defined by the type. GaussDB does not add spaces.
VARCHAR/ VARCHAR2	Any Java type	Byte, Short, Integer, Long, BigInteger, BigDecimal, Float, Double, Character, Boolean, String, java.sql.Date, java.sql.Time, java.sql.Timestamp, and PGClob	The different types supported by the input parameter **attribute** can be seen in the table.
NCHAR	Any Java type	Byte, Short, Integer, Long, BigInteger, BigDecimal, Float, Double, Character, Boolean, String, java.sql.Date, java.sql.Time, java.sql.Timestamp, and PGClob	The different types supported by the input parameter **attribute** can be seen in the table.
NVARCHAR2	Any Java type	Byte, Short, Integer, Long, BigInteger, BigDecimal, Float, Double, Character, Boolean, String, java.sql.Date, java.sql.Time, java.sql.Timestamp, and PGClob	The different types supported by the input parameter **attribute** can be seen in the table.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Database Attribute Type	Java Types Supported by Attribute Input Parameters (Oracle Database)	Java Types Supported by Attribute Input Parameters (GaussDB)	Difference
NUMBER	Byte, Short, Integer, Long, Float, Double, Boolean, BigDecimal, BigInteger, String, and oracle.sql.NUMBER	Byte, Short, Integer, Long, Float, Double, Boolean, BigDecimal, BigInteger, and String	1. The different types supported by the input parameter **attribute** can be seen in the table. 2. When the input parameter is of the Float, Double, BigDecimal, or String type and the decimal part is 0, Oracle Database truncates the decimal part, while GaussDB retains it.
NUMERIC	Byte, Short, Integer, Long, Float, Double, Boolean, BigDecimal, BigInteger, String, and oracle.sql.NUMBER	Byte, Short, Integer, Long, Float, Double, Boolean, BigDecimal, BigInteger, and String	1. The different types supported by the input parameter **attribute** can be seen in the table. 2. When the input parameter is of the Float, Double, BigDecimal, or String type and the decimal part is 0, Oracle Database truncates the decimal part, while GaussDB retains it.

Database Attribute Type	Java Types Supported by Attribute Input Parameters (Oracle Database)	Java Types Supported by Attribute Input Parameters (GaussDB)	Difference
DECIMAL	Byte, Short, Integer, Long, Float, Double, Boolean, BigDecimal, BigInteger, String, and oracle.sql.NUMBER	Byte, Short, Integer, Long, Float, Double, Boolean, BigDecimal, BigInteger, and String	1. The different types supported by the input parameter **attribute** can be seen in the table. 2. When the input parameter is of the Float, Double, BigDecimal, or String type and the decimal part is 0, Oracle Database truncates the decimal part, while GaussDB retains it.
INTEGER	Byte, Short, Integer, Long, Float, Double, Boolean, BigDecimal, BigInteger, String, and oracle.sql.NUMBER	Byte, Short, Integer, Long, Float, Double, Boolean, BigDecimal, BigInteger, and String	1. The different types supported by the input parameter **attribute** can be seen in the table. 2. The target types are inconsistent. For details, see differences in the getAttributes() API. 3. When the input parameter value exceeds the integer range, GaussDB reports an error.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Database Attribute Type	Java Types Supported by Attribute Input Parameters (Oracle Database)	Java Types Supported by Attribute Input Parameters (GaussDB)	Difference
SMALLINT	Byte, Short, Integer, Long, Float, Double, Boolean, BigDecimal, BigInteger, String, and oracle.sql.NUMBER	Byte, Short, Integer, Long, Float, Double, Boolean, BigDecimal, BigInteger, and String	1. The different types supported by the input parameter **attribute** can be seen in the table. 2. The target types are inconsistent. For details, see differences in the getAttributes() API. 3. When the input parameter exceeds the Short range, GaussDB reports an error.
DOUBLE PRECISION	Byte, Short, Integer, Long, Float, Double, Boolean, BigDecimal, BigInteger, String, and oracle.sql.NUMBER	Byte, Short, Integer, Long, Float, Double, Boolean, BigDecimal, BigInteger, and String	1. The different types supported by the input parameter **attribute** can be seen in the table. 2. The target types are inconsistent. For details, see differences in the getAttributes() API. 3. Converting a higher-precision type to Double may result in precision loss.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Database Attribute Type	Java Types Supported by Attribute Input Parameters (Oracle Database)	Java Types Supported by Attribute Input Parameters (GaussDB)	Difference
FLOAT	Byte, Short, Integer, Long, Float, Double, Boolean, BigDecimal, BigInteger, String, and oracle.sql.NUMBER	Byte, Short, Integer, Long, Float, Double, Boolean, BigDecimal, BigInteger, and String	1. The different types supported by the input parameter **attribute** can be seen in the table. 2. The target types are inconsistent. For details, see differences in the getAttributes() API. 3. Converting a higher-precision type to Double may result in precision loss.
REAL	Byte, Short, Integer, Long, Float, Double, Boolean, BigDecimal, BigInteger, String, and oracle.sql.NUMBER	Byte, Short, Integer, Long, Float, Double, Boolean, BigDecimal, BigInteger, and String	1. The different types supported by the input parameter **attribute** can be seen in the table. 2. The target types are inconsistent. For details, see differences in the getAttributes() API. 3. Converting a higher-precision type to Float may result in precision loss.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Database Attribute Type	Java Types Supported by Attribute Input Parameters (Oracle Database)	Java Types Supported by Attribute Input Parameters (GaussDB)	Difference
BINARY_DOUBLE	byte[], Double, and oracle.sql.BINARY_DOUBLE	Byte, Short, Integer, Long, Float, Double, Boolean, BigDecimal, BigInteger, and String	1. The different types supported by the input parameter **attribute** can be seen in the table. 2. The target types are inconsistent. For details, see differences in the getAttributes() API. 3. Converting a higher-precision type to Double may result in precision loss.
BINARY_INTEGER	Byte, Short, Integer, Long, Float, Double, Boolean, BigDecimal, BigInteger, AtomicInteger, AtomicLong, DoubleAccumulator, DoubleAdder, LongAccumulator, LongAdder, Striped64, String, and oracle.sql.NUMBER	Byte, Short, Integer, Long, Float, Double, Boolean, BigDecimal, BigInteger, and String	1. The different types supported by the input parameter **attribute** can be seen in the table. 2. If the input value exceeds the integer range, GaussDB reports an error, whereas Oracle Database truncates the value.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Database Attribute Type	Java Types Supported by Attribute Input Parameters (Oracle Database)	Java Types Supported by Attribute Input Parameters (GaussDB)	Difference
BOOLEAN	Byte, Short, Integer, Long, Float, Double, Boolean, BigDecimal, BigInteger, AtomicInteger, AtomicLong, DoubleAccumulator, DoubleAdder, LongAccumulator, LongAdder, Striped64, String, and oracle.sql.NUMBER	Byte, Short, Integer, Long, Float, Double, Boolean, BigDecimal, BigInteger, and String	1. The different types supported by the input parameter **attribute** can be seen in the table. 2. The target types are inconsistent. For details, see differences in the getAttributes() API. 3. In GaussDB, the target data type is Boolean, which only supports inputs of **1**, **0**, **"true"**, and **"false"**.
TIMESTAMP	byte[], java.sql.Date, String, java.sql.Time, java.sql.Timestamp, oracle.sql.TIMESTAMP, and oracle.sql.DATE	java.util.Date, java.sql.Date, java.sql.Time, java.sql.Timestamp, LocalDateTime, and String	The different types supported by the input parameter **attribute** can be seen in the table.
TIMESTAMP WITH TIME ZONE	java.sql.Date, Calendar, java.util.Date, LocalDate, LocalDateTime, LocalTime, OffsetDateTime, OffsetTime, String, java.sql.Time, java.sql.Timestamp, oracle.sql.TIMESTAMP, oracle.sql.TIMESTAMPTZ, oracle.sql.TIMESTAMPLTZ, and ZonedDateTime	java.util.Date, java.sql.Date, java.sql.Time, java.sql.Timestamp, LocalDateTime, and String	1. The different types supported by the input parameter **attribute** can be seen in the table. 2. The target types are inconsistent. For details, see differences in the getAttributes() API.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Database Attribute Type	Java Types Supported by Attribute Input Parameters (Oracle Database)	Java Types Supported by Attribute Input Parameters (GaussDB)	Difference
BLOB	oracle.sql.BLOB and oracle.jdbc.driver.OracleBlob	PGBlob	1. The different types supported by the input parameter **attribute** can be seen in the table. 2. The target types are inconsistent. For details, see differences in the getAttributes() API.
CLOB	oracle.sql.CLOB and oracle.jdbc.driver.OracleClob	PGClob	1. The different types supported by the input parameter **attribute** can be seen in the table. 2. The target types are inconsistent. For details, see differences in the getAttributes() API.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Database Attribute Type	Java Types Supported by Attribute Input Parameters (Oracle Database)	Java Types Supported by Attribute Input Parameters (GaussDB)	Difference
Set/Array	Array and Object	GaussArray and Object	1. The different types supported by the input parameter **attribute** can be seen in the table. 2. Oracle Database does not report an error when the input parameter **attribute** is of the ARRAY type, even if the actual type required by **attribute** is not ARRAY. GaussDB reports an error when the input parameter **attribute** is of the GaussArray type instead of the actual type required by **attribute**. 3. When the input parameter **attribute** is of the Object type, refer to the differences in array construction APIs.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Database Attribute Type	Java Types Supported by Attribute Input Parameters (Oracle Database)	Java Types Supported by Attribute Input Parameters (GaussDB)	Difference
RECORD	Struct and Object[]	GaussStruct and Object[]	1. The different types supported by the input parameter **attribute** can be seen in the table. 2. Oracle Database does not report an error when the input parameter **attribute** is of the STRUCT type, even if the actual type required by **attribute** is not STRUCT. GaussDB reports an error when the input parameter **attribute** is of the GaussStruct type instead of the actual type required by **attribute**. 3. When the input parameter **attribute** is of the Object[] type, refer to the differences in struct construction APIs.

NOTE

1. When a struct is constructed, if the Java type of the input element does not match the target type, an implicit conversion operation is performed. For details on the Java types of input elements supported by various database element types, refer to the preceding table.
2. GaussDB currently does not support the types not listed in the aforementioned table.
3. The constructor needs to provide an attribute array. The preceding table describes the differences of each attribute in the array.

3.2.8 Common SQL DDL Clauses

This chapter describes common compatible SQL DDL clauses, including allocate_extent_clause, constraint, deallocate_unused_clause, file_specification, logging_clause, parallel_clause, physical_attributes_clause, size_clause, storage_clause, aggregate function nesting, sequence creation, and sequence altering, as shown in **Table 3-45**.

Table 3-45 Common SQL DDL clauses

Oracle Database	GaussDB	Difference

allocate_extent_clause
Syntax:
`ALLOCATE EXTENT [ ( { SIZE size_clause | DATAFILE 'filename' | INSTANCE integer } ... ) ]`
For example, after the **employees** table is created, change the allocated extent **size** of the table to **10M**.
`SQL> CREATE TABLE employees(EMPLOYEE_ID NUMBER(38), JOB_ID NUMBER(38), SALARY NUMBER(38), LAST_NAME VARCHAR2(16));`
 	
`Table created.`
 	
`SQL> ALTER TABLE employees ALLOCATE EXTENT (SIZE 10M);`
 	
`Table altered.`
	Not supported.	-

constraint
Syntax:
`{ inline_constraint | out_of_line_constraint | inline_ref_constraint | out_of_line_ref_constraint }`
For example, when you create the **staff** table, the **ID** and **NAME** columns specified in the constraint clause cannot be empty.
`SQL> CREATE TABLE staff(ID INT NOT NULL, NAME char(8) NOT NULL, AGE INT, ADDRESS CHAR(50), SALARY REAL);`
 	
`Table created.`
	Supported.	-

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Oracle Database	GaussDB	Difference
deallocate_unused_clause Syntax: DEALLOCATE UNUSED [KEEP size_clause] For example, after creating the **employees** table and performing some INSERT and DELETE operations, you want to use the deallocate_unused_clause to release the unused space of the **employees** table. SQL> CREATE TABLE employees(EMPLOYEE_ID NUMBER(38), JOB_ID NUMBER(38), SALARY NUMBER(38), LAST_NAME VARCHAR2(16)); Table created. - Perform some INSERT and DELETE operations. SQL> ALTER TABLE employees DEALLOCATE UNUSED; Table altered.	Not supported.	-
file_specification Syntax: {['filename' | 'ASM_filename'] [SIZE size_clause] [REUSE] [autoextend_clause]} | {['filename | ASM_filename' | ('filename | ASM_filename' [, 'filename | ASM_filename']...)] [SIZE size_clause] [BLOCKSIZE size_clause [REUSE]} For example, create a temporary tablespace **tbs_temp_01**. In this clause, create a temporary database file **temp01.dbf** in the tablespace, enable AUTOEXTEND, and allocate the tablespace to the tablespace group **tbs_grp_01**. SQL> CREATE TEMPORARY TABLESPACE tbs_temp_01 TEMPFILE 'temp01.dbf' AUTOEXTEND ON TABLESPACE GROUP tbs_grp_01; Tablespace created.	Not supported.	-

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Oracle Database	GaussDB	Difference

logging_clause
Syntax:
{ LOGGING | NOLOGGING | FILESYSTEM_LIKE_LOGGING }
	Partially supported, with differences.	• GaussDB does not support the LOGGING and FILESYSTEM_LIKE_LOGGING constraint clauses.
		Example:
		When a table is created in GaussDB with the LOGGING constraint clause, a syntax error is reported.
		gaussdb=# CREATE LOGGING TABLE my_tab(id int, name char(16));
		ERROR: syntax error at or near "LOGGING"
		LINE 1: CREATE LOGGING TABLE my_tab(id int, name char(16));
		^
		When a table is created in GaussDB with the FILESYSTEM_LIKE_LOGGING constraint clause, a syntax error is reported.
		gaussdb=# CREATE FILESYSTEM_LIKE_LOGGING TABLE my_tab(id int, name char(16));
		ERROR: syntax error at or near "FILESYSTEM_LIKE_LOGGING"
		LINE 1: CREATE FILESYSTEM_LIKE_LOGGING TABLE my_tab(id int, name cha...
		^
		• GaussDB supports only table-level UNLOGGED constraints and does not support column-level UNLOGGED constraints.
		For example, when a table is created in GaussDB with the column-level UNLOGGED constraint clause, a syntax error is reported.
		gaussdb=# CREATE UNLOGGED TABLE my_tab(id int UNLOGGED, name char(16));
		ERROR: syntax error at or near "UNLOGGED"
		LINE 1: CREATE UNLOGGED TABLE my_tab(id int UNLOGGED, name char(16))...
		^
		• GaussDB uses logging clauses only in the CREATE TABLE, CREATE TABLE AS, and SELECT INTO statements.
		For example, when a TABLESPACE statement with the UNLOGGED constraint clause is created in GaussDB, a syntax error is reported.
		gaussdb=# CREATE UNLOGGED TABLESPACE tbs1 RELATIVE LOCATION 'tablespace1/tablespace_1';
		ERROR: syntax error at or near "TABLESPACE"
		LINE 1: CREATE UNLOGGED TABLESPACE tbs1 RELATIVE LOCATION 'tablespac...
		^

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Oracle Database	GaussDB	Difference
parallel_clause Syntax: { NOPARALLEL | PARALLEL [integer] } For example, if you create table **t1** and specify **PARALLEL 4** in the parallel_clause, a maximum of four parallel processes can be used to query and update table **t1**. SQL> CREATE TABLE t1 (id NUMBER, name VARCHAR2(50)) PARALLEL 4; Table created.	Not supported.	-

physical_attributes_clause
Syntax:
[{ PCTFREE integer | PCTUSED integer | INITRANS integer | storage_clause }...]
	Partially supported, with differences.	• GaussDB does not support PCTUSED. For example, if you run an SQL statement to create the **tbl1_ind** index in the **tbl1** table and set the space usage **PCTUSED** of the index to **20%** in the physical_attributes_clause of the statement, an error is reported when the SQL statement is executed in GaussDB.
		gaussdb=# CREATE INDEX tbl1_ind ON tbl1 (name) PCTUSED 20;
		ERROR: syntax error at or near "PCTUSED"
		LINE 1: CREATE INDEX tbl1_ind ON tbl1 (name) PCTUSED 20;
		^
		• GaussDB uses physical_attributes_clause only in the CREATE TABLE and CREATE INDEX statements.
		For example, if you run an SQL statement to obtain data from the **tbl1** table, create the materialized view **tbl1_mv**, and set the number of initial transactions of the view to **30** in the physical_attributes_clause, an error is reported when GaussDB executes the statement.
		gaussdb=# CREATE MATERIALIZED VIEW tbl1_mv INITRANS 30 as select * from tbl1;
		ERROR: syntax error at or near "INITRANS"
		LINE 1: CREATE MATERIALIZED VIEW tbl1_mv INITRANS 30 as select * fro...
		^

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Oracle Database	GaussDB	Difference
size_clause Syntax: integer [K | M | G | T | P | E] For example, create a temporary tablespace **tbs_temp_01** and create a temporary database file **temp01.dbf** in the tablespace. In this clause, specify the initial size as 5 MB, enable AUTOEXTEND, and allocate the tablespace to tablespace group **tbs_grp_01**. SQL> CREATE TEMPORARY TABLESPACE tbs_temp_01 TEMPFILE 'temp01.dbf' SIZE 5M AUTOEXTEND ON TABLESPACE GROUP tbs_grp_01; Tablespace created.	Not supported.	-

Oracle Database	GaussDB	Difference
storage_clause Syntax: STORAGE ({ INITIAL size_clause | NEXT size_clause | MINEXTENTS integer | MAXEXTENTS { integer | UNLIMITED } | maxsize_clause | PCTINCREASE integer | FREELISTS integer | FREELIST GROUPS integer | OPTIMAL [size_clause | NULL] | BUFFER_POOL { KEEP | RECYCLE | DEFAULT } | FLASH_CACHE { KEEP | NONE | DEFAULT } | (CELL_FLASH_CACHE (KEEP | NONE | DEFAULT)) | ENCRYPT } ...)	Partially supported, with differences.	• In Oracle Database, storage parameters are specified by the STORAGE clause. In GaussDB, storage parameters are specified by the WITH clause. Example: To create the **my_tab1** table in Oracle Database, set the initial size of the table to **10M** in the storage_clause, and add 5 MB each time when more space is required, run the following SQL statement: SQL> CREATE TABLE my_tab1 (id NUMBER(10) PRIMARY KEY, name VARCHAR2(50)) STORAGE (INITIAL 10M NEXT 5M); Table created. To create the **my_tab2** table in GaussDB and set the storage engine type to **ustore** in the storage_clause, run the following SQL statement: gaussdb=# CREATE TABLE my_tab2 (id NUMBER(10) PRIMARY KEY, name VARCHAR2(50)) with (storage_type=ustore); NOTICE: CREATE TABLE / PRIMARY KEY will create implicit index "my_tab2_pkey" for table "my_tab2" CREATE TABLE • Optional storage parameters in GaussDB are greatly different from those in Oracle Database. For details, see the parameter description in **CREATE TABLE** in GaussDB. The "WITH ({storage_parameter = value} [,...])" section describes the storage parameters supported by the CREATE TABLE statement.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Oracle Database	GaussDB	Difference
Aggregate function nesting For example, create the **revenue** table generated by nesting the aggregate functions MIN() and SUM() in the **sales_amount** column of the **sales** table. SQL> CREATE TABLE sales(ID INT, SALES_AMOUNT INT); Table created. SQL> INSERT INTO sales VALUES(1, 100); 1 row created. SQL> INSERT INTO sales VALUES (3, 200); 1 row created. SQL> CREATE TABLE revenue as SELECT SUM(MIN(sales_amount)) as total from sales group by sales_amount; Table created.	Supported.	-
Dropping a system schema Syntax: DROP USER schema_name CASCADE; For example, drop the SYS schema as the **SYS** user. SQL> DROP USER SYS; DROP USER SYS * ERROR at line 1: ORA-28050: specified user or role cannot be dropped	Supported.	-

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Oracle Database	GaussDB	Difference

Dropping a PRIMARY KEY constraint from a table
Syntax:
DROP PRIMARY KEY [CASCADE] [(KEEP | DROP) INDEX] [ONLINE]
	Partially supported, with differences.	• GaussDB supports only the DROP PRIMARY KEY syntax and does not support other options.
		• When this operation is performed, Oracle Database automatically drops the NOT NULL constraint added to the primary key column when the primary key is created, while GaussDB does not drop the NOT NULL constraint but retains it.
		-- GaussDB:
		gaussdb=# CREATE TABLE t1 (id int PRIMARY KEY);
		NOTICE: CREATE TABLE / PRIMARY KEY will create implicit index "t1_pkey" for table "t1"
		CREATE TABLE
		gaussdb=# ALTER TABLE t1 DROP PRIMARY KEY;
		ALTER TABLE
		gaussdb=# INSERT INTO t1 VALUES(null);
		ERROR: The null value in column "id" violates the not-null constraint.
		DETAIL: Failing row contains (null).
		gaussdb=# DROP TABLE t1;
		
		-- Oracle:
		SQL> CREATE TABLE t1 (id int PRIMARY KEY);
		SQL> ALTER TABLE t1 DROP PRIMARY KEY;
		SQL> INSERT INTO t1 VALUES(null);
		-- The operation can be successfully performed, that is, the NOT NULL constraint of the primary key column is also dropped.
		SQL> DROP TABLE t1;

Creating a sequence Syntax: CREATE SEQUENCE [IF NOT EXISTS] [schema.] sequence [SHARING = { METADATA | DATA | NONE }] [{ INCREMENT BY | START WITH } integer | { MAXVALUE integer | NOMAXVALUE } | { MINVALUE integer | NOMINVALUE } | { CYCLE | NOCYCLE } | { CACHE integer | NOCACHE } | { ORDER | NOORDER } | { KEEP | NOKEEP } | { SCALE {EXTEND | NOEXTEND} | NOSCALE } | { SHARD {EXTEND | NOEXTEND} | NOSHARD } | { SESSION | GLOBAL }]...	Partially supported, with differences.	• GaussDB does not support the **SHARING**, **CACHE**, **NOCACHE**, **ORDER**, **NOORDER**, **KEEP**, **NOKEEP**, **SCALE**, **NOSCALE**, **SHARD**, **NOSHARD**, **SESSION**, and **GLOBAL** options. • GaussDB does not check whether the absolute value of the increment is less than the difference between the maximum value and the minimum value. -- GaussDB: gaussdb=# CREATE SEQUENCE seq_test MINVALUE 1 MAXVALUE 10 INCREMENT BY 10; CREATE SEQUENCE -- Oracle: SQL> CREATE SEQUENCE seq_test MINVALUE 1 MAXVALUE 10 INCREMENT BY 10; CREATE SEQUENCE seq_test MINVALUE 1 MAXVALUE 10 INCREMENT BY 10 * ERROR at line 1: ORA-04005: INCREMENT must be less than MAXVALUE minus MINVALUE

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Oracle Database	GaussDB	Difference

Altering a sequence
Syntax:
ALTER SEQUENCE [schema.] sequence { { (INCREMENT BY) | (START WITH) } integer | { MAXVALUE integer | NOMAXVALUE } | { MINVALUE integer | NOMINVALUE } | RESTART | { CYCLE | NOCYCLE } | { CACHE integer | NOCACHE } | { ORDER | NOORDER } | { KEEP | NOKEEP } | { SCALE {EXTEND | NOEXTEND} | NOSCALE } | { SHARD {EXTEND | NOEXTEND} | NOSHARD } | { SESSION | GLOBAL } } ...
	Partially supported, with differences.	• GaussDB does not support the **INCREMENT BY**, **MINVALUE**, **NOMINVALUE**, **RESTART**, **CYCLE**, **NOCYLE**, **CACHE**, **NOCACHE**, **ORDER**, **NOORDER**, **KEEP**, **NOKEEP**, **SCALE**, **NOSCALE**, **SHARD**, **NOSHARD**, **SESSION**, and **GLOBAL** options.
		• When the maximum value is changed in GaussDB, the system does not check whether the absolute value of the increment is less than the difference between the maximum value and the minimum value.
		-- GaussDB:
		gaussdb=# CREATE SEQUENCE seq_test MINVALUE 1 MAXVALUE 100 INCREMENT BY 10;
		CREATE SEQUENCE
		gaussdb=# ALTER SEQUENCE seq_test MAXVALUE 10;
		ALTER SEQUENCE
		
		-- Oracle:
		SQL> CREATE SEQUENCE seq_test MINVALUE 1 MAXVALUE 100 INCREMENT BY 10;
		
		Sequence created.
		
		SQL> ALTER SEQUENCE seq_test MAXVALUE 10;
		ALTER SEQUENCE seq_test MAXVALUE 10
		*
		ERROR at line 1:
		ORA-04005: INCREMENT must be less than MAXVALUE minus MINVALUE
		• When the maximum value is changed in GaussDB, the system checks whether the start value of the sequence is within the range of the maximum value and minimum value.
		-- GaussDB:
		gaussdb=# CREATE SEQUENCE seq_test MINVALUE 1 MAXVALUE 10 START WITH 10 INCREMENT BY -1;
		CREATE SEQUENCE
		gaussdb=# SELECT seq_test.nextval FROM DUAL;
		nextval
		--------- 	
		10
		(1 row)
		
		gaussdb=# SELECT seq_test.nextval FROM DUAL;
		nextval
		--------- 	
		9
		(1 row)
		
		gaussdb=# SELECT seq_test.nextval FROM DUAL;

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Oracle Database	GaussDB	Difference
		nextval --------- 8 (1 row) gaussdb=# ALTER SEQUENCE seq_test MAXVALUE 9; ERROR: START value (10) cannot be greater than MAXVALUE (9). -- Oracle: SQL> CREATE SEQUENCE seq_test MINVALUE 1 MAXVALUE 10 START WITH 10 INCREMENT BY -1; Sequence created. SQL> SELECT seq_test.nextval FROM DUAL; NEXTVAL ---------- 10 SQL> SELECT seq_test.nextval FROM DUAL; NEXTVAL ---------- 9 SQL> SELECT seq_test.nextval FROM DUAL; NEXTVAL ---------- 8 SQL> ALTER SEQUENCE seq_test MAXVALUE 9; Sequence altered. • When nextval is executed for the first time in GaussDB, the internal position is the start value. When the maximum value is changed, the system checks whether the start value of the sequence is within the range of the maximum value and minimum value. -- GaussDB: gaussdb=# CREATE SEQUENCE seq_test MINVALUE 1 MAXVALUE 10 START WITH 6 INCREMENT BY -5; CREATE SEQUENCE gaussdb=# ALTER SEQUENCE seq_test MAXVALUE 9; ALTER SEQUENCE -- Oracle: SQL> CREATE SEQUENCE seq_test MINVALUE 1 MAXVALUE 10 START WITH 6 INCREMENT BY -5; Sequence created. SQL> ALTER SEQUENCE seq_test MAXVALUE 9;

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Oracle Database	GaussDB	Difference
		ALTER SEQUENCE seq_test MAXVALUE 9 * ERROR at line 1: ORA-04009: MAXVALUE cannot be made to be less than the current value

3.2.9 SQL Queries and Subqueries

GaussDB is compatible with SQL queries and subqueries except hierarchical queries.

Table 3-46 SQL queries and subqueries

Oracle Database	GaussDB	Difference
Creating simple queries	Supported.	-
Hierarchical queries	Not supported.	-
UNION [ALL], INTERSECT, MINUS	Supported.	-
Sorting query results	Supported, with differences.	If the GaussDB query does not contain groups and the target column contains both an aggregate function and a set returning function, the sorting of the set returning function column is not ignored. If the query column involves type conversion and the sorting key is the original column name, GaussDB sorts the data based on the converted type because the default alias of the conversion result is the original column name, while Oracle Database sorts the data based on the original column type because the default alias of the conversion result is the conversion expression. The sorting semantics are different, which may cause the result set sequence to be inconsistent.
Joins	Supported, with differences.	GaussDB supports only the same join types as Oracle Database, such as left/right, self, natural, and full outer join. Join optimization methods such as IN-MEMORY JOIN GROUPS are not supported.
Using subqueries	Supported.	-

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Oracle Database	GaussDB	Difference
Unnesting of nested subqueries	Supported, with differences.	HASH_AJ or MERGE_AJ cannot be explicitly specified in GaussDB.
Distributed queries	Supported, with differences.	GaussDB requires explicit database link query.
Aggregate function nesting	Supported.	-

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Oracle Database	GaussDB	Difference

Hierarchical Queries	Supported, but with differences.	• When the PRIOR keyword is used to modify a column in a non-CONNECT BY clause in GaussDB, the returned column name is different from that in Oracle Database. For example, for column **a**, GaussDB returns **__prior_a__**, and Oracle Database returns **PRIORA**.
		• When an expression with the **PRIOR** column is used in the GROUP BY clause of SELECT, the behavior of GaussDB is different from that of Oracle Database. GaussDB supports the use of an expression with the **PRIOR** column in the GROUP BY clause, while Oracle Database reports an error.
		-- GaussDB:
		gaussdb=# CREATE TABLE test (c1 INT, c2 INT, c3 INT);
		NOTICE: The 'DISTRIBUTE BY' clause is not specified. Using 'c1' as the distribution column by default.
		HINT: Please use 'DISTRIBUTE BY' clause to specify suitable data distribution column.
		CREATE TABLE
		gaussdb=# INSERT INTO test VALUES(1,2,3);
		INSERT 0 1
		gaussdb=# INSERT INTO test VALUES(2,3,4);
		INSERT 0 1
		gaussdb=# SELECT PRIOR c1 + 1 AS result FROM test CONNECT BY PRIOR c2 = c1 GROUP BY PRIOR c1 + 1;
		result
		-------- 	
		
		2
		(2 rows)
		
		gaussdb=# DROP TABLE test;
		DROP TABLE
		
		-- Oracle:
		SQL> CREATE TABLE test (c1 INT, c2 INT, c3 INT);
		SQL> INSERT INTO test VALUES(1,2,3);
		SQL> INSERT INTO test VALUES(2,3,4);
		-- This operation will cause the error "not a GROUP BY expression."
		SQL> SELECT PRIOR c1 + 1 AS result FROM test CONNECT BY PRIOR c2 = c1 GROUP BY PRIOR c1 + 1;
		SQL> DROP TABLE test;
		• In GaussDB, ORDER SIBLINGS BY and ORDER BY can be used together. In this case, the sorting result of the outer ORDER BY clause is used. Oracle Database does not support this usage.

Currently, xmltable_clause in GaussDB are different from that in the Oracle Database and PostgreSQL databases, as described in **Table 3-47**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 3-47 Comparison between GaussDB, Oracle Database, and PG

GaussDB	PostgreSQL Database	Oracle Database
XPath 1.0 expressions are used at row_expression and **PATH** in columns_clause.	Same as GaussDB.	XQuery 1.0 expressions are used at row_expression and **PATH** in columns_clause.
The default namespace function is not supported.	Same as GaussDB.	The default namespace function is supported.
A single data record can be passed through passing_clause, but the alias cannot be used.	Same as that in GaussDB. (Note that the input data is of the XML type.)	Multiple data records can be passed through the corresponding clause and aliases can be used.
The passing_clause can be omitted.	The passing_clause cannot be omitted.	The corresponding clause can be omitted.
The RETURNING SEQUENCE BY REF clause cannot be used after passing_clause.	Same as GaussDB.	The RETURNING SEQUENCE BY REF clause can be used after the corresponding clause.
In columns_clause, you cannot use (SEQUENCE) BY REF to modify the returned data of the XMLType type.	Same as GaussDB.	You can use (SEQUENCE) BY REF in the corresponding clause to modify the returned data of the XMLType type.
If the **PATH** part in columns_clause is omitted and the column name is not enclosed using double quotation marks (""), the node can be correctly found for subsequent operations when the node name in the data passed to XMLTABLE is in lowercase.	Same as GaussDB.	If the corresponding part is omitted and the column name is not enclosed using double quotation marks (""), the node can be correctly found for subsequent operations when the node name in the data passed to XMLTABLE is in uppercase.
The declaration of the column type in columns_clause cannot be omitted.	Same as GaussDB.	The declaration of the column type in the corresponding clause can be omitted.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

GaussDB	PostgreSQL Database	Oracle Database
In ORA-compatible mode, the columns_clause can be omitted. In PG-compatible mode, the columns_clause cannot be omitted.	The corresponding clause cannot be omitted.	The corresponding clause can be omitted.
In ORA-compatible mode, if the returned data length exceeds the typmod of the type, the data is truncated. In PG-compatible mode, if the returned data length exceeds the typmod of the type, an error is reported.	An error is reported when the length of the returned data exceeds the typmod of the type.	If the length of the returned data exceeds the typmod of the type, the data is truncated.

Example:

```
gaussdb=# CREATE DATABASE test DBCOMPATIBILITY = 'ORA';
gaussdb=# \c test
test=# SELECT * FROM XMLTABLE(
test(# XMLNAMESPACES('nspace1' AS "ns1", 'nspace2' AS "ns2"), -- Declare two XML namespaces 'nspace1' and 'nspace2' and the corresponding aliases "ns1" and "ns2".
test(# '/ns1:root/*:child' -- Select the root node whose namespace is 'nspace1' from the data passed through row_expression, select all child nodes under the root node, and ignore the child namespaces. ns1 is the alias of 'nspace1'.
test(# PASSING xmltype(
test(# '<root xmlns="nspace1">
test'#     <child>
test'#         <name>peter</name>
test'#         <age>11</age>
test'#     </child>
test'#     <child xmlns="nspace1">
test'#         <name>qiqi</name>
test'#         <age>12</age>
test'#     </child>
test'#     <child xmlns="nspace2">
test'#         <name>hacker</name>
test'#         <age>15</age>
test'#     </child>
test'# </root>')
test(# COLUMNS
test(# columns FOR ORDINALITY, -- Row number column
test(# name varchar(10) path 'ns1:name', -- Select the name node whose namespace is 'nspace1' from each child node obtained by row_expression, convert the value in the node to varchar(10), and return the value. ns1 is the alias of nspace1.
test(# age int); -- Select the age node from each child node obtained by row_expression, convert the value in the node to int, and return the value. The first child node does not explicitly specify the namespace. Therefore, the namespace of the parent node root is followed. Therefore, no value in this column is returned.
 column | name  | age
--------+-------+-----
      1 | peter |
      2 | qiqi  |
      3 |       |
(3 rows)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
-- Switch to the default database and drop the test database. Change the database name as required.
gaussdb=# \c postgres
gaussdb=# DROP DATABASE test;
```

3.2.10 PL/SQL Language

GaussDB is compatible with PL/SQL operators, expressions, control statements, collections, and records, but does not support predefined PL/SQL constants, types, and subtypes.

3.2.10.1 Basic PL/SQL Syntax

Table 3-48 PL/SQL operators

Oracle Database	GaussDB
+	Supported.
:=	Supported.
=>	Supported.
%	Supported.
'	Supported.
.	Supported.
||	Supported.
/	Supported.
**	Not supported.
(	Supported.
)	Supported.
:	Supported.
,	Supported.
<<	Supported.
>>	Supported.
/*	Supported.
*/	Supported.
*	Supported.
"	Supported.
..	Supported.
=	Supported.
<>	Supported.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Oracle Database	GaussDB
!=	Supported.
~=	Supported.
^=	Supported.
<	Supported.
>	Supported.
<=	Supported.
>=	Supported.
@	Supported.
--	Supported.
;	Supported.
-	Supported.

Table 3-49 Logical operators

Oracle Database	GaussDB
NOT	Supported.
AND	Supported.
OR	Supported.

Table 3-50 Comparison expressions

Oracle Database	GaussDB
IS [NOT] NULL	Supported.
LIKE	Supported.
BETWEEN	Supported.
IN	Supported.

Table 3-51 CASE expressions

Oracle Database	GaussDB
simple CASE	Supported.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Oracle Database	GaussDB
searched CASE	Supported.

Table 3-52 Parameters related to variable declaration

Oracle Database	GaussDB	Difference
%TYPE	Supported, with differences.	• GaussDB does not support *record%type*. • GaussDB does not support **pkg.***record%type* and **schema.pkg.***record%type* as the input and output parameter types. • In GaussDB, *Table/View*.**column.***column%type* or **schema.***Table/View*.**column.***column%type* cannot be nested with one or more layers as variable types or input/output parameter type. • In GaussDB, *record*.**column.***column%type* and **pkg.***record*.**column.***column%TYPE* cannot be nested with a column type of records at one or more layers as the variable type or input/output parameter type.
%ROWTYPE	Supported, with differences.	• When GaussDB has multiple CNs, the **%ROWTYPE** and **%TYPE** attributes of the temporary table cannot be declared in a stored procedure. The temporary table is valid only in the current session. During compilation, other CNs cannot view the temporary table of the current CN. Therefore, if there are multiple CNs, the system displays a message indicating that the temporary table does not exist. • GaussDB does not support *view%rowtype* and **schema.***view%rowtype* as the input and output parameter types. • GaussDB does not support the **package.***cursor%rowtype* as the input and output parameter types.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

3.2.10.2 Data Type Compatibility

Table 3-53 Other PL/SQL data types

Oracle Database	GaussDB	Difference
CHARACTER	Supported, with differences.	• GaussDB: The length ranges from 1 to 10485760 bytes. • Oracle Database: The length ranges from 1 to 32767 bytes.
VARCHAR	Supported, with differences.	• GaussDB: The length ranges from 1 to 10485760 bytes. • Oracle Database: The length ranges from 1 to 32767 bytes.
STRING	Not supported.	-
PLS_INTEGER	Not supported.	In GaussDB, you can use the INT type instead.
BINARY_INTEGER	Supported.	-

3.2.10.3 Control Statements

Table 3-54 Conditional statements

Oracle Database	GaussDB
IF THEN	Supported.
IF THEN ELSE	Supported.
IF THEN ELSIF	Supported.
simple CASE: CASE selector WHEN selector_value_1 THEN statements_1 WHEN selector_value_2 THEN statements_2 ... WHEN selector_value_n THEN statements_n [ELSE else_statements END CASE;]	Supported.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Oracle Database	GaussDB
searched CASE: CASE WHEN condition_1 THEN statements_1 WHEN condition_2 THEN statements_2 ... WHEN condition_n THEN statements_n [ELSE else_statements END CASE;]	Supported.

Table 3-55 LOOP statements

Oracle Database	GaussDB
[label] LOOP statements END LOOP [label];	Supported.
EXIT;	Supported.
EXIT WHEN;	Supported.
CONTINUE;	Supported.
CONTINUE WHEN;	Supported.

Table 3-56 FOR LOOP statements

Oracle Database	GaussDB	Difference
[label] FOR index IN [REVERSE] lower_bound..upper_bound LOOP statements END LOOP [label];	Supported, with differences.	When the keyword REVERSE is used in GaussDB, the lower bound must be greater than or equal to the upper bound; otherwise, the loop body is not executed.
EXIT WHEN;	Supported.	-
CONTINUE WHEN;	Supported.	-

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 3-57 WHILE LOOP statement

Oracle Database	GaussDB
[label] WHILE condition LOOP statements END LOOP [label];	Supported.

Table 3-58 GOTO statement

Oracle Database	GaussDB
GOTO	Supported.

Table 3-59 NULL statement

Oracle Database	GaussDB
NULL	Supported.

3.2.10.4 Collections and Records

Table 3-60 Types

Oracle Database	GaussDB
Associative array (or index-by table)	Supported.
VARRAY (variable-size array)	Supported.
Nested table	Supported.
record	Supported.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 3-61 Syntax

Oracle Database	GaussDB	Difference
Associative array (or index-by table) syntax: TABLE OF datatype [NOT NULL] INDEX BY { PLS_INTEGER | BINARY_INTEGER | VARCHAR2 (v_size) | data_type }	Supported, but with differences.	• GaussDB does not support the PLS_INTEGER type. In GaussDB, the value of **data_type** can be a base data type or a record type, collection type, or array type defined in a stored procedure. The ref cursor type is not supported. • In GaussDB, NOT NULL is syntactically supported but functionally not effective. That is, the system does not check whether an element is NULL. • For details, see **Collections**.
VARRAY (variable-size array) syntax: { VARRAY | [VARYING] ARRAY } (size_limit) OF datatype [NOT NULL]	Supported, but with differences.	• GaussDB does not support the NOT NULL syntax. • In GaussDB, **datatype** cannot be set to **varray** (varray cannot be nested). • To make the size_limit function take effect, enable the **varray_compat** parameter in the GUC parameter **behavior_compat_options**. • For details, see **Arrays**.
Nested table syntax: TABLE OF datatype [NOT NULL]	Supported, but with differences.	• In GaussDB, NOT NULL is syntactically supported but functionally not effective. • For details, see **Collections**.
record syntax: TYPE record_type IS RECORD (field_definition [, field_definition]...) ;	Supported.	• Record columns can be defined as NOT NULL or a default value can be specified. If the record type is nested in other types, the default value and NOT NULL of the record type do not take effect. If a record variable is created using the package.record_type access type, the default value and NOT NULL of the record variable do not take effect. • For details, see **Records**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 3-62 Constructor

Oracle Database	GaussDB
collection_type ([value [, value]...])	Supported.

Table 3-63 Variable assignment

Oracle Database	GaussDB	Difference
Associative array (or index-by table)	Supported.	-
VARRAY (variable-size array)	Supported, but with differences.	• Values of different VARRAY data in GaussDB can be assigned to each other, depending on whether elements in the data can be implicitly converted to each other. • For details, see **Arrays**.
Nested table	Supported.	-
record	Supported, but with differences.	• Values of different record data in GaussDB can be assigned to each other, depending on whether columns can be implicitly converted. • For details, see **Records**.

Table 3-64 Collection operators

Oracle Database	GaussDB	Difference
=	Supported, but with differences.	• Oracle Database: The sequence of collection members is ignored during comparison. • GaussDB: The comparison is performed strictly based on the sequence of collection members.
<>	Supported, but with differences.	• Oracle Database: The sequence of collection members is ignored during comparison. • GaussDB: The comparison is performed strictly based on the sequence of collection members.
IS [NOT] NULL	Supported.	-

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Oracle Database	GaussDB	Difference
^=	Supported, but with differences.	• Oracle Database: The sequence of collection members is ignored during comparison. • GaussDB: The comparison is performed strictly based on the sequence of collection members.
~=	Not supported.	-
IS [NOT] A SET	Not supported.	-
IS [NOT] EMPTY	Not supported.	-
expr [NOT] MEMBER [OF] nested_table	Not supported.	-
nested_table1 [NOT] SUBMULTISET [OF] nested_table2	Not supported.	-
[NOT] IN	Supported.	• Oracle Database: The sequence of collection members is ignored during comparison. • GaussDB: The comparison is performed strictly based on the sequence of collection members.

Table 3-65 MULTISET functions

Oracle Database	GaussDB
MULTISET UNION [ALL | DISTINCT]	Supported.
MULTISET EXCEPT [ALL | DISTINCT]	Supported.
MULTISET INTERSECT [ALL | DISTINCT]	Supported.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 3-66 Collection type functions

Oracle Database	GaussDB	Difference
exists(idx)	Supported.	-
extend[(count[, idx])]	Supported, but with differences.	GaussDB supports only nested tables.
delete[(idx1[, idx2])]	Supported.	-
trim[(n)]	Supported, but with differences.	GaussDB supports only nested tables.
count	Supported.	-
first	Supported.	-
last	Supported.	-
prior(idx)	Supported.	-
next(idx)	Supported.	-
limit	Supported, but with differences.	GaussDB supports only nested tables.

Table 3-67 Record variable operations

Oracle Database	GaussDB
Constructors	Supported.
%ROWTYPE to declare a variable	Supported.
Defining constants	Not supported.

Table 3-68 Collection-related functions

Oracle Database	GaussDB	Difference
unnest_table(anynesttable)	Supported.	-
unnest_table(anyindexbytable)	Supported.	-
table(anyarray)	Not supported.	GaussDB uses the unnest (anyarray) function for equivalent rewriting.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

3.2.10.5 Static SQL Statements

Table 3-69 Static query SQL statements

Oracle Database	GaussDB	Difference
SELECT	Supported, but with differences.	GaussDB and Oracle Database are different in some scenarios. In GaussDB, FOR SHARE adds a shared lock to the retrieved rows. The shared locks of different transactions do not block each other. If data is locked by FOR SHARE in one transaction and SELECT FOR SHARE SKIP LOCKED is used in another transaction, SKIP LOCKED does not skip the lock.

Table 3-70 Static DML SQL statements

Oracle Database	GaussDB	Difference
INSERT	Supported, but with differences.	• Oracle Database allows the number of columns in the target table to be greater than the number of columns in the subquery result. However, you must explicitly specify the names of columns to be inserted to ensure alignment with the number of columns. • GaussDB eliminates the need to explicitly specify the names of columns to be inserted. In this case, the value of the first column in the subquery result is inserted into the first column of the target table, and so on. If the target table contains extra columns, they will receive either **NULL** (if permitted) or the default value (if any).
UPDATE	Supported.	-
DELETE	Supported.	-
MERGE	Supported.	-
LOCK TABLE	Supported.	-

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Oracle Database	GaussDB	Difference
INSERT ALL	Supported, but with differences.	• Oracle Database does not support alias setting for the tables of into_clause, but GaussDB supports. • When into_clause specifies the sequence: – Oracle Database: If nextval is referenced for the first time, the next number of the current value is generated. Otherwise, the same number will always be returned. – GaussDB: The number generated by referencing nextval can increment automatically. • The plan_hint statement can take effect in Oracle Database but does not take effect in GaussDB. • Oracle Database allows the number of columns in the target table to be greater than the number of columns in the subquery result. However, you must explicitly specify the names of columns to be inserted to ensure alignment with the number of columns. GaussDB eliminates the need to explicitly specify the names of columns to be inserted. In this case, the value of the first column in the subquery result is inserted into the first column of the target table, and so on. If the target table contains extra columns, they will receive either **NULL** (if permitted) or the default value (if any).

Table 3-71 Static TCL SQL statements

Oracle Database	GaussDB	Difference
COMMIT	Supported.	-
ROLLBACK	Supported.	-
SAVEPOINT	Supported.	-
SET TRANSACTION	Supported, but with differences.	GaussDB does not support the NAME string and USE ROLLBACK SEGMENT rollback_segment syntax.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 3-72 Pseudocolumns

Oracle Database	GaussDB	Difference
CURRVAL and NEXTVAL	Supported.	-
LEVEL	Not supported.	-
OBJECT_VALUE	Not supported.	-
ROWID	Supported.	-
ROWNUM	Supported, but with differences.	It is not recommended that the ROWNUM condition be used in the JOIN ON clause. In GaussDB, when the ROWNUM condition is used in the JOIN ON clause, the behavior in the LEFT JOIN, RIGHT JOIN, FULL JOIN, and MERGE INTO scenarios is different from that in other databases, causing risks in service migration.

Table 3-73 Implicit cursor attributes

Oracle Database	GaussDB	Difference
SQL%FOUND	Supported, but with differences.	GaussDB does not update the implicit cursor result after COMMIT or ROLLBACK. Oracle Database updates the implicit cursor result after COMMIT or ROLLBACK.
SQL %NOTFOUND	Supported, but with differences.	
SQL %ROWCOUNT	Supported, but with differences.	
SQL%ISOPEN	Supported, but with differences.	
SQL %BULK_ROWCOUNT	Not supported.	
SQL %BULK_EXCEPTIONS	Not supported.	

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 3-74 Explicit cursor syntax and keywords

Oracle Database	GaussDB	Difference
CURSOR cursor_name [parameter_list] RETURN return_type;	Supported.	-
CURSOR cursor_name [parameter_list] [RETURN return_type] IS select_statement;	Supported.	-
OPEN	Supported.	-
CLOSE	Supported, but with differences.	GaussDB is automatically closed in the exception, but Oracle Database is not automatically closed in the exception.
FETCH	Supported.	-
CURRENT OF CURSOR	Supported.	-

Table 3-75 Explicit cursor attributes

Oracle Database	GaussDB
SQL%FOUND	Supported.
SQL%NOTFOUND	Supported.
SQL%ROWCOUNT	Supported.
SQL%ISOPEN	Supported.

Table 3-76 Cursor loop

Oracle Database	GaussDB
FOR LOOP	Supported, but with differences. In the FORALL+BULK COLLECT INTO scenario, the *INTO* variable returns only the execution result of a single DML statement in GaussDB, while in Oracle Database, it returns the accumulated execution results of DML statements.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 3-77 Scenarios supported by autonomous transactions

Oracle Database	GaussDB
Stored procedures	Supported.
Anonymous blocks	Supported.
Functions	Supported.
Packages	Supported.

3.2.10.6 Dynamic SQL Statements

Table 3-78 Dynamic SQL statement execution modes

Oracle Database	GaussDB	Difference
EXECUTE IMMEDIATE	Supported, but with differences.	• GaussDB uses the **dynamic_sql_compat** parameter to determine whether variables with the same name read the same parameter and checks whether the input and output parameter types of the bound parameters are the same as those of the statement parameters when a stored procedure is called. • GaussDB does not support the scenario where some bound parameters in an anonymous block are called, for example, dynamic statements are nested in an anonymous block and parameters are bound using expressions. For details, see **Dynamically Calling Anonymous Blocks**. • GaussDB does not support RETURNING or RETURN INTO.
OPEN FOR, FETCH, CLOSE	Supported.	GaussDB uses the **dynamic_sql_compat** parameter to determine whether a variable reads parameters with the same name. When a stored procedure is called, GaussDB checks whether the input and output parameter types are consistent with the statement parameter types.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

3.2.10.7 Triggers

Table 3-79 Trigger types

Oracle Database	GaussDB	Difference
DML TRIGGER	Supported, but with differences.	GaussDB: Compound DML triggers are not supported.
SYSTEM TRIGGER	Not supported.	-

Table 3-80 CREATE triggers

Oracle Database	GaussDB	Difference
CREATE syntaxes: CREATE [OR REPLACE] [EDITIONABLE | NONEDITIONABLE] TRIGGER plsql_trigger_source	Supported, but with differences.	GaussDB does not support OR REPLACE or EDITIONABLE | NONEDITIONABLE, but supports some behaviors of plsql_trigger_source.
plsql_trigger_source ::= syntax: [schema.] trigger_name [sharing_clause] [default_collation_clause] { simple_dml_trigger | instead_of_dml_trigger | compound_dml_trigger | system_trigger }	Supported, but with differences.	GaussDB: The schema, sharing_clause, and default_collation_clause are not supported.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Oracle Database	GaussDB	Difference
simple_dml_trigger ::= syntax: { BEFORE | AFTER } dml_event_clause [referencing_clause] [FOR EACH ROW] [trigger_edition_clause] [trigger_ordering_clause] [ENABLE | DISABLE] [WHEN (condition)] trigger_body	Supported, but with differences.	GaussDB does not support referencing_clause (instead, from referencing_table is used), trigger_edition_clause, trigger_ordering_clause, and ENABLE | DISABLE. It supports some behaviors of trigger_body. No error is reported in GaussDB when a statement-level BEFORE/ AFTER TRIGGER is created in a view without INSTEAD OF TRIGGER. An error is reported when DML is executed.
dml_event_clause ::= syntax: { DELETE | INSERT | UPDATE [OF column [, column]...] } [OR { DELETE | INSERT | UPDATE [OF column [, column]...] }... ON [schema.] { table | view }	Not supported.	-
trigger_body ::= syntax: { plsql_block | CALL routine_clause }	Supported, but with differences.	GaussDB: The plsql_block is not supported. A function can be executed only in the EXECUTE PROCEDURE function_name (arguments); format. In addition, the function needs to be defined by users and declared that it does not contain parameters and the return type is trigger. It is executed when a trigger is triggered.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Oracle Database	GaussDB	Difference
instead_of_dml_trigger ::= syntax: INSTEAD OF { DELETE | INSERT | UPDATE } [OR { DELETE | INSERT | UPDATE }]... ON [NESTED TABLE nested_table_column OF] [schema.] noneditioning_view [referencing_clause] [FOR EACH ROW] [trigger_edition_clause] [trigger_ordering_clause] [ENABLE | DISABLE] trigger_body	Supported, but with differences.	GaussDB: The NESTED TABLE nested_table_column OF, referencing_clause, trigger_edition_clause, trigger_ordering_clause, and ENABLE | DISABLE are not supported.
compound_dml_trigger ::= syntax: CREATE trigger FOR dml_event_clause ON view COMPOUND TRIGGER INSTEAD OF EACH ROW IS BEGIN statement; END INSTEAD OF EACH ROW;	Not supported.	-
system_trigger ::= syntax: { BEFORE | AFTER | INSTEAD OF } { ddl_event [OR ddl_event]... | database_event [OR database_event]... } ON { [schema.] SCHEMA | [PLUGGABLE] DATABASE } [trigger_ordering_clause] [ENABLE | DISABLE] trigger_body	Not supported.	-

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 3-81 ALTER trigger

Oracle Database	GaussDB	Difference
ALTER TRIGGER [schema.] trigger_name { trigger_compile_clause | { ENABLE | DISABLE } | RENAME TO new_name | { EDITIONABLE | NONEDITIONABLE } } ;	Supported, but with differences.	GaussDB: The schema, trigger_compile_clause, { ENABLE | DISABLE }, and { EDITIONABLE | NONEDITIONABLE } are not supported.

Table 3-82 drop trigger

Oracle Database	GaussDB	Difference
DROP TRIGGER [schema.] trigger ;	Supported, but with differences.	GaussDB does not support schemas. You need to add **ON table_name** to the end of **trigger_name**.

The views whose names are *_TRIGGERS in Oracle Database collect statistics about triggers, but such views in GaussDB are different. For details about such views in GaussDB, see **DB_TRIGGERS**, **ADM_TRIGGERS**, and **MY_TRIGGERS**.

Table 3-83 Compatibilities of nested, package, and standalone subprograms

Oracle Database	GaussDB	Difference
Nested subprograms (subblocks)	Supported, but with differences.	GaussDB does not support overloading. GaussDB does not support the definition of autonomous transactions. GaussDB does not support SETOF. Only one qualifier can reference nested subprograms or variables of nested subprograms.
Package subprograms	Supported.	-
Standalone subprograms (including functions and procedures)	Supported.	-
Anonymous blocks	Supported.	-

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 3-84 RETURN statements

Oracle Database	GaussDB
Functions	Supported.
Procedures	Supported.
Anonymous blocks	Supported.

Table 3-85 Function-related parameters

Oracle Database	GaussDB	Difference
DETERMINISTIC	Supported, but with differences.	In GaussDB, it is IMMUTABLE.
PARALLEL_ENABLE	Not supported.	-
PIPELINED	Not supported.	-
RESULT_CACHE	Not supported.	-

Table 3-86 Parameter formats

Oracle Database	GaussDB
IN	Supported.
OUT	Supported.
IN OUT	Supported.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 3-87 CREATE statements

Oracle Database	GaussDB	Difference
CREATE FUNCTION	Supported, but with differences.	GaussDB does not support the IF NOT EXISTS syntax, sharing_clause, or keywords [EDITIONABLE | NONEDITIONABLE]. Only some clauses that specify the **function** attribute are supported (only the invoker_rights_clause clause is supported). For details about the syntax in GaussDB, see **CREATE FUNCTION**.
CREATE LIBRARY	Not supported.	-
CREATE PACKAGE	Supported, but with differences.	GaussDB does not support the IF NOT EXISTS syntax, sharing_clause, or keywords [EDITIONABLE | NONEDITIONABLE]. Only some clauses that specify the **package** attribute are supported (only the invoker_rights_clause clause is supported). For details about the syntax in GaussDB, see **CREATE PACKAGE**.
CREATE PACKAGE BODY	Supported, but with differences.	GaussDB does not support the IF NOT EXISTS syntax, sharing_clause, or keywords [EDITIONABLE | NONEDITIONABLE]. For details about the syntax in GaussDB, see **CREATE PACKAGE**.
CREATE PROCEDURE	Supported, but with differences.	GaussDB does not support the IF NOT EXISTS syntax, sharing_clause, or keywords [EDITIONABLE | NONEDITIONABLE]. For details about the syntax in GaussDB, see **CREATE PROCEDURE**.
CREATE TRIGGER	Supported, but with differences.	For details about the syntax in GaussDB, see **CREATE TRIGGER**.
CREATE TYPE	Supported, but with differences.	GaussDB does not support the varray, object type, and UNDER syntax. For details about the syntax in GaussDB, see **CREATE TYPE**.
CREATE TYPE BODY	Not supported.	-
CREATE OR REPLACE TYPE	Not supported.	-

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 3-88 ALTER statements

Oracle Database	GaussDB	Difference
ALTER FUNCTION	Supported, but with differences.	GaussDB does not support keywords [EDITIONABLE | NONEDITIONABLE], REUSE, SETTINGS, and DEBUG. For details about the syntax in GaussDB, see **ALTER FUNCTION**.
ALTER LIBRARY	Not supported.	-
ALTER PACKAGE	Supported, but with differences.	GaussDB does not support keywords [EDITIONABLE | NONEDITIONABLE], REUSE, SETTINGS, and DEBUG. For details about the syntax in GaussDB, see **ALTER PACKAGE**.
ALTER PROCEDURE	Supported, but with differences.	GaussDB does not support keywords [EDITIONABLE | NONEDITIONABLE], REUSE, SETTINGS, and DEBUG.
ALTER TRIGGER	Supported, but with differences.	In GaussDB, only the trigger name can be modified. For details about the syntax in GaussDB, see **ALTER TRIGGER**.
ALTER TYPE	Supported, but with differences.	GaussDB supports only some statements. For details about the syntax in GaussDB, see **ALTER TYPE**.

Table 3-89 DROP statements

Oracle Database	GaussDB	Difference
DROP FUNCTION	Supported.	-
DROP LIBRARY	Not supported.	-
DROP PACKAGE	Supported.	-
DROP PROCEDURE	Supported.	-

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Oracle Database	GaussDB	Difference
DROP TRIGGER	Supported, but with differences.	The syntax of GaussDB is different from that of Oracle Database. For details about the syntax in GaussDB, see **DROP TRIGGER**.
DROP TYPE	Supported, but with differences.	GaussDB does not support keywords FORCE and VALIDATE. For details about the syntax in GaussDB, see **DROP TYPE**.
DROP TYPE BODY	Not supported.	-

Table 3-90 Keywords related to functions, procedures, and anonymous blocks

Oracle Database	GaussDB	Difference
ACCESSIBLE BY	Not supported.	-
AGGREGATE	Supported, but with differences.	• GaussDB does not support Oracle Database's aggregate using [schema.] implementation_type. • For details about the usage of GaussDB, see **CREATE AGGREGATE**. The syntax is different, but the implementation functions are the same.
DETERMINISTIC	Supported, but with differences.	GaussDB supports the keyword DETERMINISTIC only in syntax, but does not support this function.
PIPE ROW	Not supported.	-
PIPELINED	Not supported.	-
SQL_MACRO	Not supported.	-
RESTRICT_REFERENCES	Not supported.	-
INLINE	Not supported.	-

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 3-91 Keywords related to exception handling

Oracle Database	GaussDB	Difference
EXCEPTION_INIT	Supported, but with differences.	Binding with system error codes is not supported in GaussDB. In the same stored procedure or function, if EXCEPTION_INIT is used to set the same error code, the Oracle database does not support capturing exceptions separately as conditions. GaussDB supports this behavior. For details, see **Examples**.
Exception	Supported.	-
Exception Handler	Supported.	-
SQLCODE	Supported.	-
SQLERRM	Supported.	-

Table 3-92 Other PL/SQL keywords

Oracle Database	GaussDB
COVERAGE	Not supported.
COLLATION	Supported.
DEPRECATE	Not supported.
FORALL	Supported.
NOCOPY	Not supported.
RETURNING	Supported.
SERIALLY_REUSABLE	Not supported.
SHARING	Not supported.
BULK COLLECT	Supported.

3.2.11 System Functions

Compatible functions are classified into single-row functions, user-defined functions, aggregate functions, analytic functions, object reference functions, model functions, and OLAP functions.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

3.2.11.1 Single-Row Functions

Oracle Database	GaussDB
Table 3-93	Supported, but with differences.
Table 3-94	Supported, but with differences.
Table 3-95	Supported, but with differences.
Character set functions	Not supported.
Collation functions	Not supported.
Table 3-96	Supported, but with differences.
Table 3-97	Supported, but with differences.
Table 3-98	Supported, but with differences.
Table 3-99	Supported, but with differences.
Collection functions	Not supported.
Table 3-100	Supported.
Data mining functions	Not supported.
Table 3-101	Supported, but with differences.
Table 3-102	Supported, but with differences.
Table 3-103	Supported, but with differences.
Table 3-104	Supported.
Table 3-105	Supported, but with differences.

Table 3-93 Numeric functions

Oracle Database	GaussDB	Difference
ABS	Supported.	-
ACOS	Supported, with differences.	If the parameter is of the BINARY_DOUBLE or BINARY_FLOAT type and the value is not in the range of –1 to 1, GaussDB reports an error, while Oracle Database returns NaN.
ASIN	Supported, with differences.	If the parameter is of the BINARY_DOUBLE or BINARY_FLOAT type and the value is not in the range of –1 to 1, GaussDB reports an error, while Oracle Database returns NaN.
ATAN	Supported.	-

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Oracle Database	GaussDB	Difference
ATAN2	Supported, with differences.	When both parameters are **0**, GaussDB returns **0**, while Oracle Database reports an error.
BITAND	Supported, with differences.	• The maximum value of the input parameter in GaussDB is of the BIGINT type, while that in Oracle Database is of the NUMBER type. • If a parameter contains a decimal, GaussDB rounds the value before calculation, while Oracle Database truncates the value before calculation.
CEIL	Supported.	-
COS	Supported, with differences.	• The data types and precision of the return values are different. GaussDB: The return value is of the float8 type, and the result precision retains 15 valid digits. Oracle Database: The return type is number. • If the parameter value is **Infinity** or **-Infinity**, GaussDB reports an error, while Oracle Database returns NaN.
COSH	Supported, with differences.	The data types and precision of the return values are different. GaussDB: If the input is of the numeric type, the return value is of the numeric type. If the input is of another type, the return value is of the float8 type, and the result precision retains 15 valid digits. Oracle Database: The return type is number.
EXP	Supported.	-
FLOOR	Supported.	The return types are different. GaussDB: • If one of the inputs is of the numeric type, the return value is of the numeric type. • For other data types, the return value is of the float8 type. Oracle Database: • The return type is numeric.
LN	Supported.	The return values are different: • Oracle Database returns a value with 37 decimal places, and GaussDB returns a value with 15 decimal places.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Oracle Database	GaussDB	Difference
LOG	Supported.	The input parameter types are different: ● GaussDB checks invalid input parameters, such as **NaN**, **0.0**, **-Infinity**, **0**, and **Infinity**.
MOD	Supported, but with differences.	● The return types are different. In Oracle Database, the return types include BINARY_DOUBLE, BINARY_FLOAT, and NUMBER. In GaussDB, the return types include int2, int4, int8, and numeric. ● The return values are different. When the input parameter is a string containing decimals (for example, '2.5'), Oracle Database implicitly converts the string to the NUMBER type and retains the decimal part for calculation, while GaussDB implicitly converts the string to the integer type and rounds the decimal part to the nearest integer for calculation. As a result, the result is different from that of Oracle Database. ● If the first input parameter is of the numeric type, the second parameter must be of the int, numeric, or a type that can be converted to numeric. If **a_format_version** is set to **10c**, **a_format_dev_version** is set to **s6**, and the first parameter is of the text type that can be converted to numeric, the second parameter must be of the numeric type that does not exceed int4 or of the character type that contains only digits.
NANVL	Supported, but with differences.	GaussDB: NaN cannot be obtained by directly declaring or dividing a floating-point number by 0.
POWER	Supported, but with differences.	The return types are different. GaussDB: ● If one of the inputs is of the numeric type, the return value is of the numeric type. If the numeric result is less than 10^16, **0** is returned. ● For other data types, the return value is of the float8 type. Oracle Database: The return type is number.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Oracle Database	GaussDB	Difference
REMAINDER	Supported, but with differences.	The return types are different. GaussDB: ● If one input value is of the float4 type and the other is of the numeric type, values of the float4 type are returned. ● If both input values are of the float4 type, values of the float4 type are returned. ● If both input values are of the float8 type, values of the float8 type are returned. ● If both inputs are of the character type, the return value is of the float8 type. ● For other data types, values of the numeric type are returned. Oracle Database: The return type is number. The return results are inconsistent: ● Oracle Database uses ROUND to obtain the quotient, while GaussDB uses FLOOR to obtain the quotient. When the decimal part of n2/n1 is 0.5, the two databases use different rounding methods. As a result, the remainder results are inconsistent.
ROUND	Supported, but with differences.	● For the first parameter **n** of the float type, GaussDB has precision loss, and the precision is lower than that of Oracle Database. ● The returned types are different. For round(n, integer), Oracle Database returns the NUMBER type, and GaussDB returns the numeric type. For round(n), Oracle Database returns the data type of **n**, and GaussDB returns only the float8 and numeric types. The float4 return type is missing. ● The logic for the GaussDB to determine that the input parameter is null and the execution framework to return null is different from that in Oracle Database. `SELECT round(NULL,'q');` Oracle Database reports null, and GaussDB reports the error: invalid input syntax for integer: "q".
SIGN	Supported, with differences.	The return types are different. GaussDB: If the input is of the numeric type, the return value is of the numeric type. Otherwise, the return value is of the float8 type. Oracle Database: The return type is number.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Oracle Database	GaussDB	Difference
SIN	Supported, with differences.	• The data types and precision of the return values are different. GaussDB: The return value is of the float8 type, and the result precision retains 15 valid digits. Oracle Database: The return type is number. • If the parameter value is **Infinity** or **-Infinity**, GaussDB reports an error, while Oracle Database returns NaN.
SINH	Supported, but with differences.	The data types and precision of the return values are different. GaussDB: If the input is of the numeric type, the return value is of the numeric type. If the input is of another type, the return value is of the float8 type, and the result precision retains 15 valid digits. Oracle Database: The return type is number.
SQRT	Supported.	-
TAN	Supported, with differences.	• The data types and precision of the return values are different. GaussDB: The return value is of the float8 type, and the result precision retains 15 valid digits. Oracle Database: The return type is number. • If the parameter value is **Infinity** or **-Infinity**, GaussDB reports an error, while Oracle Database returns NaN.
TANH	Supported, with differences.	The data types and precision of the return values are different. GaussDB: If the input is of the numeric type, the return value is of the numeric type. If the input is of another type, the return value is of the float8 type, and the result precision retains 15 valid digits. Oracle Database: The return type is number.
TRUNC	Supported.	The input parameter types are different: • In GaussDB, if the second input parameter is of the text type, the first input parameter must be of the time type. The return types are different. • In GaussDB, if the number of input parameters is 1 and the parameter is not of the numeric type, the return value is of the float8 type.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Oracle Database	GaussDB	Difference
WIDTH_BUCKET	Supported.	The input parameter types are different: GaussDB: • The input parameter cannot be of a time type. • The last input parameter of the function cannot be in scientific notation.

Table 3-94 Character functions returning character values

Oracle Database	GaussDB	Difference
CHR	Supported, but with differences.	• If the entered number does not comply with the existing character set, GaussDB reports an error in JDBC and Oracle Database returns garbled characters. • If you enter **0** or **256**, Oracle Database returns characters whose ASCII code is 0, and GaussDB truncates the characters at **'\0;**. • When the input parameter is a decimal number in the range of (–1,1), the parameter is rounded to 0 in GaussDB, and the function output is null; however, in Oracle Database, an error is reported, indicating that the parameter is out of range.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Oracle Database	GaussDB	Difference
CONCAT	Supported, with differences.	• The return type of the function is different. In GaussDB, the return type is text, while in Oracle Database, the return type is dynamically determined based on the type of the input parameter. • For the concatenation of invalid characters, GaussDB does not check the validity of characters and directly concatenates all characters; however, if Oracle Database detects invalid characters, it ignores them. The || operator has similar differences. Example: -- GaussDB gaussdb=# SET a_format_version='10c'; SET gaussdb=# SET a_format_dev_version='s2'; SET gaussdb=# SELECT dump(CHR(239) || 'test') FROM dual; dump ---------- Typ=25 Len=5: 239,116,101,115,116 (1 row) -- Oracle SQL> SELECT dump(CHR(239) || 'test') FROM dual; dump(CHR(239)||'TEST') ---------- Typ=1 Len=4: 116,101,115,116
INITCAP	Supported, but with differences.	The return value is restricted by the database character set. As a result, the return result is different from that in Oracle Database. When the input parameter is EMPTY_CLOB(), GaussDB returns an empty string, while Oracle Database returns null.
LOWER	Supported, but with differences.	• The return types are different. The data types of Oracle Database are the same as the input types. • The time format is implicitly converted. When the time type is entered, the time type is implicitly converted to a character string and then the lower operation is performed. SELECT LOWER(TO_DATE('2012-12-10','YYYY-MM-DD')); Oracle Database returns 10-DEC-12, and GaussDB returns 2012-12-10 00:00:00. • The return value is restricted by the database character set. As a result, the return result is different from that in Oracle Database.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Oracle Database	GaussDB	Difference
LPAD	Supported, with differences.	• GaussDB returns a text type. If the second parameter exceeds the int range, an error is reported. Oracle Database returns a varchar2 type. If the second parameter exceeds the int range, the value is truncated to 4000 characters based on the maximum length of varchar2, and the result is output normally. • For invalid characters, Oracle Database directly fills the invalid characters, while GaussDB checks the validity of the characters first. If the characters are invalid, an error is reported.
LTRIM	Supported, but with differences.	• The return types are different. If the input is of the character data type, Oracle Database returns the VARCHAR2 type. If the input is of the national character set specified during database creation, Oracle Database returns the NVARCHAR2 type. If the input is of the LOB type, Oracle Database returns the LOB type, and GaussDB returns the TEXT type. • When the source string is EMPTY_CLOB(), Oracle Database returns an empty character, while GaussDB returns null. • Oracle Database supports only the deletion of a single character, while GaussDB supports the deletion of a string. • When the character to be deleted is EMPTY_CLOB(), Oracle Database directly returns null, while GaussDB considers that the empty character is deleted and returns the source string.
NCHR	Supported, but with differences.	• The byte length of the return value is different from that of Oracle Database. • The return value is restricted by the database character set. As a result, the return result is different from that in Oracle Database. • When the byte array corresponding to the input parameter is returned, a question mark (?) is returned if a single byte ranges from 0x80 to 0xFF. In Oracle Database, a question mark (?) is returned, no output is returned, or an error is reported.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Oracle Database	GaussDB	Difference
NLS_LOWER	Supported, but with differences.	• The return types are different. If the input is of the character data type, Oracle Database returns the VARCHAR2 type. If the input is of the LOB type, Oracle Database returns the LOB type. GaussDB returns the TEXT type. • In Oracle Database, the **nlsparam** parameter can be of a type except nls_sort, and no error is reported. GaussDB supports only nls_sort. • The return value is restricted by the database character set. As a result, the return result is different from that in Oracle Database.
NLS_UPPER	Supported, but with differences.	• The return types are different. If the input is of the character data type, Oracle Database returns the VARCHAR2 type. If the input is of the LOB type, Oracle Database returns the LOB type. GaussDB returns the TEXT type. • In Oracle Database, the **nlsparam** parameter can be of a type except nls_sort, and no error is reported. GaussDB supports only nls_sort. • The return value is restricted by the database character set. As a result, the return result is different from that in Oracle Database.
NLSSORT	Supported.	-

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Oracle Database	GaussDB	Difference

REGEXP_REPLACE	Supported, with differences.	• GaussDB input parameter **source_char** does not support the NCLOB, BLOB, or XMLTYPE type.
		• The meaning of the **'n'** option in the **match_param** input parameter is different. In GaussDB, the **'n'** option has the same meaning as the **'m'** option, indicating that the multi-row matching mode is used. In Oracle Database, it indicates that the dot (.) can match the '\n' character. If this option is not specified, the '\n' character cannot be matched by default. In GaussDB, the dot (.) matches '\n' by default. You do not need to specify the option.
		• The matching results of some regular expressions may be different.
		`SELECT REGEXP_REPLACE('abc01234xyz', '(.*?)(\d+)(.*)', '#', 'g') FROM DUAL;`
		Oracle Database reports an error, and GaussDB returns **#####xyz**.
		• The matching results may be different when Chinese characters are entered in the UTF-8 character set. Oracle Database needs to implement regular expression matching for Chinese character strings in the GBK character set.
		• The matching results of regular expressions that contain some escape characters may be different.
		`SELECT REGEXP_REPLACE('abcabc', '\abc', '#', 'g') FROM DUAL;`
		Oracle Database reports an error, and GaussDB returns **abcabc**.
		• The matching rules are affected by the **aformat_regexp_match** parameter. For details about the affected specifications, see the description of the REGEXP_REPLACE function in **Character Processing Functions and Operators**.
		• If the character class [] in a regular expression contains escape characters (such as \t, \n, \r, \s, \d, and \w), GaussDB escapes them to tab characters, while Oracle Database regards them as common characters and does not escape them.
		• For an incomplete regular expression (for example, '{2,', GaussDB strictly verifies the correctness of the regular expression and reports an error, while Oracle Database regards it as a common character.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Oracle Database	GaussDB	Difference
		• The rounding mode of the fourth and fifth parameters is different. GaussDB rounds the value to the nearest integer, while Oracle Database truncates the value to an integer. • GaussDB does not support the regular expression [A-Z]?? with more than three question marks, while Oracle Database supports it. • GaussDB supports regular expressions whose length exceeds 512 characters, while Oracle Database does not support it. • When four parameters are entered, the fourth parameter in GaussDB cannot be a number in string format, while Oracle Database supports it. • GaussDB supports the non-capturing group syntax (?:...), while Oracle Database does not support it.
REGEXP_SUBSTR	Supported, but with differences.	• The matching rules are affected by the **aformat_regexp_match** parameter. For details about the affected specifications, see the description of the REGEXP_SUBSTR function in **Character Processing Functions and Operators**. • GaussDB limits the maximum value of the regular expression A{1,xxx} to 255. • In GaussDB, the CHR(9) tab character or CHR(10) newline character in the regular expression 'x' is regarded as a blank and ignored, while in Oracle Database, the CHR(9) tab character or CHR(10) newline character is regarded as a common matching character. • GaussDB does not support six input parameters. • GaussDB supports the third parameter as a decimal number ranging from 0 to 1, while Oracle Database does not support this.
REPLACE	Supported, with differences.	• GaussDB does not support the input of the XMLTYPE type, while Oracle Database supports it. • GaussDB does not support the input of the BLOB type, while Oracle Database supports it.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Oracle Database	GaussDB	Difference
RPAD	Supported, with differences.	• GaussDB returns a text type. If the second parameter exceeds the int range, an error is reported. Oracle Database returns a varchar2 type. If the second parameter exceeds the int range, the value is truncated to 4000 characters based on the maximum length of varchar2, and the result is output normally. • For invalid characters, Oracle Database directly fills the invalid characters, while GaussDB checks the validity of the characters first. If the characters are invalid, an error is reported.
RTRIM	Supported, with differences.	• When the source string is EMPTY_CLOB(), Oracle Database returns an empty character, while GaussDB returns null. • Oracle Database supports only the deletion of a single character, while GaussDB supports the deletion of a string. • When the character to be deleted is EMPTY_CLOB(), Oracle Database directly returns null, while GaussDB considers that the empty character is deleted and returns the source string.
SUBSTR	Supported, with differences.	• When the source string is EMPTY_CLOB(), GaussDB returns null, while Oracle Database returns an empty CLOB. • When the second or third parameter is a number with decimal places, GaussDB rounds the number to the nearest integer, while Oracle Database rounds the number down to the nearest integer. • When the initial index of the second parameter exceeds the total length of the source string, GaussDB reports an error, while Oracle Database returns null. • GaussDB does not support the scientific notation of a string (such as '1E2') as the second or third parameter, while Oracle Database supports it.
TRANSLATE	Supported, with differences.	When the source string is EMPTY_CLOB(), GaussDB returns an empty string, while Oracle Database returns null.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Oracle Database	GaussDB	Difference
TRIM	Supported, with differences.	• When the source string is EMPTY_CLOB(), Oracle Database returns an empty character, while GaussDB returns null. • Oracle Database requires that the keyword specifying the truncation direction or the truncation character be specified before FROM, while GaussDB allows all parameters before FROM to be omitted. • Oracle Database supports only the deletion of a single character, while GaussDB supports the deletion of a string. • When the character to be deleted is EMPTY_CLOB(), Oracle Database directly returns null, while GaussDB considers that the empty character is deleted and returns the source string.
UPPER	Supported, but with differences.	• The return types are different. The data types of Oracle Database are the same as the input types. GaussDB returns the TEXT type. • The time format is implicitly converted. When the time type is entered, the time type is implicitly converted to a character string and then the upper operation is performed. `SELECT UPPER(TO_DATE('2012-12-10','YYYY-MM-DD'));` Oracle Database returns 10-DEC-12, and GaussDB returns 2012-12-10 00:00:00. • The return value is restricted by the database character set. As a result, the return result is different from that in Oracle Database.
REVERSE	Supported, with differences.	• Oracle Database does not support the input of the CLOB, NUMBER, DATE, TIMESTAMP, TIMESTAMPTZ, INTERVAL, FLOAT, or DOUBLE data type, while GaussDB supports it. • For multi-byte characters, Oracle Database performs reversal by byte. As a result, garbled characters are displayed after conversion, while GaussDB performs conversion by character.
INSTRB	Supported.	-

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 3-95 Character functions returning number values

Oracle Database	GaussDB	Difference
ASCII	Supported, but with differences.	• The return types are different. Oracle Database returns the uint4 type, while GaussDB returns the int4 type. • For invalid characters, GaussDB checks whether the characters are invalid (for example, 0x80), while Oracle Database is relatively loose and returns the ASCII code of the invalid characters. • When the input parameter is EMPTY_CLOB(), GaussDB returns **0**, while Oracle Database returns null.
INSTR	Supported, with differences.	• The third parameter in GaussDB is of the int type, and that in Oracle Database is of the numeric type. • The rules for rounding off the third and fourth parameters are different. GaussDB uses the rounding-off rule, while Oracle Database uses the integer truncation rule. • The fourth parameter in Oracle Database is truncated to an integer. When the value is a negative number or a decimal ranging from 0 to 1, the truncation result is **0** or a negative number. When the value is an invalid number, an error is reported. In GaussDB, no error is reported and **0** is returned directly. • GaussDB does not support the JSON type as the source parameter.
LENGTH	Supported, with differences.	The return types are different. Oracle Database returns the numeric type, while GaussDB returns the int type.
LENGTHB	Supported, with differences.	GaussDB supports only the text string type as the input parameter and does not support the BLOB type, while Oracle Database supports the BLOB type as the input parameter.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Oracle Database	GaussDB	Difference
REGEXP_COUNT	Supported, but with differences.	• GaussDB input parameter **source_char** does not support the NCLOB type. • The meaning of the **'n'** option in the **match_param** input parameter is different. In GaussDB, the **'n'** option has the same meaning as the **'m'** option, indicating that the multi-row matching mode is used. In Oracle Database, it indicates that the dot (.) can match the '\n' character. If this option is not specified, the '\n' character cannot be matched by default. In GaussDB, the dot (.) matches '\n' by default. You do not need to specify the option. • The matching results of some regular expressions may be different. • The matching results may be different when Chinese characters are entered in the UTF-8 character set. Oracle Database needs to implement regular expression matching for Chinese character strings in the GBK character set. • The matching results of regular expressions that contain some escape characters may be different. • The matching rules are affected by the **aformat_regexp_match** parameter. For details about the affected specifications, see the description of the REGEXP_COUNT function in **Character Processing Functions and Operators**. • GaussDB supports the non-capturing group syntax (?:...), while Oracle Database does not. • In x extended mode, GaussDB ignores the whitespace characters (spaces and tabs) and comments in the pattern, while Oracle Database does not support this function. • If the regular expression contains an undefined escape character, such as '\x', GaussDB reports an error, while Oracle Database degrades it to a common character for matching. • When the flag is **m**, if the source string contains concatenated CHR(10), the return result is different. Oracle Database does not count the last line. • [[:blank:]] can match CHR(9) in GaussDB, but cannot match CHR(9) in Oracle Database.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Oracle Database	GaussDB	Difference
REGEXP_INSTR	Supported, but with differences.	• The matching rules are affected by the **aformat_regexp_match** parameter. For details about the affected specifications, see the description of the REGEXP_INSTR function in **Character Processing Functions and Operators**. • The behavior of \s in the character class [...] is different in the two databases. The GaussDB regular expression engine (based on POSIX ERE/Perl style) supports the use of \s as a whitespace character class in [], and \s = [\t\n \r\f\v] (all whitespace characters), while the Oracle Database regular expression engine does not support the use of \s as a whitespace character class in []. • Parameter type: – GaussDB does not support the BLOB type as the source string parameter, while Oracle Database supports it. – The third, fourth, and fifth parameters in GaussDB are of the int type, and an error is reported if the value of the parameters exceeds the int range. The third, fourth, and fifth parameters in Oracle Database are of the numeric type. • Rounding mode: The third, fourth, and fifth parameters in GaussDB are rounded off, while those in Oracle Database are truncated. • Number of parameters: GaussDB does not support seven input parameters, while Oracle Database supports them.
REGEXP_LIKE	Supported, with differences.	• GaussDB does not support parameters identified by 'n'. • For an incorrect regular expression, GaussDB reports an error, while Oracle Database returns **false**. • The regular expression in GaussDB does not support '^X{4000}$' greater than 255.
LENGTHC	Supported.	-

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Oracle Database	GaussDB	Difference
DUMP	Supported, with differences.	• If the second, third, or fourth parameter is null, GaussDB directly returns null, while Oracle Database uses the default value. The default value of the second parameter is **10**, the third parameter is **1**, and the fourth parameter is **all** (that is, all bytes of the expression are read). • Parameter type: – GaussDB does not support the XMLType and name types as the first parameter, while Oracle Database supports these types. – The second, third, and fourth parameters in GaussDB are of the int type, while the second, third, and fourth parameters in Oracle Database are of the numeric type. • Rounding mode: The second, third, and fourth parameters in GaussDB are rounded off, while Oracle Database uses the rounding mode. • If the source input is null, GaussDB returns null, while Oracle Database returns the string 'NULL'.

Table 3-96 Datetime functions

Oracle Database	GaussDB	Difference
ADD_MONTHS	Supported, but with differences.	• From A.D. to B.C., the difference between GaussDB and Oracle Database is one year. • The earliest year can be –4714 in GaussDB and –4713 in Oracle Database. • When a character type literal is entered, GaussDB prefers the overloaded function of timestamp, whereas Oracle Database only has functions with input parameters of the date type.
CURRENT_DATE	Supported, but with differences.	• GaussDB: The **nls_date_format** parameter cannot be used to set the time display format. • When **mapping_date_to_datea** is enabled, the return value of **current_date** is of the datea type. When **mapping_date_to_datea** is disabled, the return value of **current_date** is of the date type.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Oracle Database	GaussDB	Difference
CURRENT_TIMESTAMP	Supported, but with differences.	The value ranges from 0 to 9 in Oracle Database. The value ranges from 0 to 6 in GaussDB. The trailing zeros in microseconds are not displayed.
DBTIMEZONE	Supported, but with differences.	GaussDB: The timestamp API with the built-in tz cannot be called.
EXTRACT	Supported.	-
LAST_DAY	Supported, but with differences.	GaussDB has two overloaded functions with input parameters of the datea and timestamp types. When a literal of the character type is entered, GaussDB preferentially selects the overloaded function of the timestamp type. However, Oracle Database has only functions with input parameters of the date type.
LOCALTIMESTAMP	Supported, but with differences.	The value ranges from 0 to 9 in Oracle Database. The value ranges from 0 to 6 in GaussDB. The trailing zeros in microseconds are not displayed.
MONTHS_BETWEEN	Supported, but with differences.	GaussDB has two overloaded functions with input parameters of the datea and timestamp types. When a literal of the character type is entered, GaussDB preferentially selects the overloaded function of the timestamp type. However, Oracle Database has only functions with input parameters of the date type.
NEW_TIME	Supported, but with differences.	GaussDB has two overloaded functions with input parameters of the datea and timestamp types. When a literal of the character type is entered, GaussDB preferentially selects the overloaded function of the timestamp type. However, Oracle Database has only functions with input parameters of the date type.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Oracle Database	GaussDB	Difference
NEXT_DAY	Supported.	GaussDB has two overloaded functions with input parameters of the datea and timestamp types. When a literal of the character type is entered, GaussDB preferentially selects the overloaded function of the timestamp type. However, Oracle Database has only functions with input parameters of the date type.
NUMTODSINTERVAL	Supported, but with differences.	GaussDB: The dsinterval type is not supported. Currently, interval is used to be compatible with the dsinterval type.
NUMTOYMINTERVAL	Supported, but with differences.	• GaussDB: The yminterval type is not supported. Currently, interval is used to be compatible with the yminterval type. • GaussDB does not support the BLOB type as an input parameter. • The rounding of floating-point numbers is different. As a result, when the input parameter is a floating-point number, the return results are different. -- Oracle SQL> SELECT NUMTOYMINTERVAL(0.01, 'YEAR') FROM DUAL; NUMTOYMINTERVAL(0.01,'YEAR') ---------- +000000000-01 -- GaussDB gaussdb=# SET a_format_version='10c'; SET gaussdb=# SET a_format_dev_version='s2'; SET gaussdb=# SELECT NUMTOYMINTERVAL(0.01, 'YEAR') FROM DUAL; numtoyminterval ---------- 00:00:00 (1 row)
SESSIONTIMEZONE	Supported, but with differences.	• The assignment syntax is different. In GaussDB, the SET SESSION TIME ZONE 8 syntax is used. In Oracle Database, alter session set time_zone= '+08:00' is used. • The default values are different. GaussDB: The time zone name is displayed, for example, **PRC**. The offset is used in Oracle Database, for example, **+08:00**.

Oracle Database	GaussDB	Difference
SYS_EXTRACT_UTC	Supported, with differences.	If the input time value is in the DST gap, Oracle Database reports the ORA-01878 error, while GaussDB does not report any error. The UTC time is calculated based on the time zone offset before the time shift. For example, the DST starts at 02:00:00 on October 6, 2024 in the Australia/Sydney time zone (the time changes from 02:00:00 AEST to 03:00:00 AEDT). In this case, the SYS_EXTRACT_UTC(TIMESTAMP '2024-10-06 02:00:00 Australia/Sydney') function returns an error in Oracle Database, but returns 2024-10-05 16:00:00 (calculated based on the offset UTC+10 before the time shift) in GaussDB.
SYSDATE	Supported, but with differences.	The return types are different. In GaussDB, when **mapping_date_to_datea** is disabled, the return type is timestamp without time zone; when it is enabled, the return type is datea. The return type in Oracle Database is date.
SYSTIMESTAMP	Supported, but with differences.	• GaussDB supports only six digits for millisecond calculation, while Oracle Database supports nine digits. • In GaussDB, the SYSTIMESTAMP function obtains the current time of the OS each time it is called in the same SQL statement. Therefore, different time values may be returned when the function is called multiple times in the same statement. In Oracle Database, the SYSTIMESTAMP function returns the same statement-level snapshot time in the same SQL statement.
TO_DSINTERVAL	Supported, but with differences.	• GaussDB: The dsinterval type is not supported. Currently, interval is used to be compatible with the dsinterval type. • GaussDB does not support the **nlsparam** parameter. If the **nlsparam** parameter is passed, an error indicating that the function does not exist is reported. Oracle Database supports the **nlsparam** parameter, but this parameter is reserved only for backward compatibility and has no actual function.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Oracle Database	GaussDB	Difference
TO_TIMESTAMP	Supported, but with differences.	• GaussDB supports only six digits for millisecond calculation, while Oracle Database supports nine digits. If the format string specifies FF7 to FF9, Oracle Database can store and return the decimal seconds with the corresponding precision. For example, if FF7 is specified, Oracle Database returns the decimal seconds with seven digits. However, the maximum physical precision of the TIMESTAMP type in GaussDB is six digits and the decimal seconds with more than six digits are directly truncated (rather than rounded off). A maximum of six decimal digits are returned. **NOTE** This truncation behavior is different from the rounding rules of TIMESTAMP literals. For details about the rounding rules of TIMESTAMP literals, see **Data Types**. • When the input year is specified as 0000 in the *YYYY* format, the year is changed to the current year in GaussDB, and an error is reported in Oracle Database. • If the input parameter contains the text delimiter "text", GaussDB does not verify the text delimiter in the input, while Oracle Database verifies the text delimiter in the input. • If the input parameter contains the day format such as DAY/DY, GaussDB may return an unknown result. • If the decimal part of the value is **0**, the decimal places are not displayed in GaussDB, while nine decimal places are displayed in Oracle Database.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Oracle Database	GaussDB	Difference
TO_TIMESTAMP_TZ	Supported, but with differences.	• The timestamptz type in GaussDB is equivalent to the timestampwithlocaltimezone type in Oracle Database. There is no exact type mapping between the two databases. The value of **nls_date_language** can only be **ENGLISH** or **AMERICAN**. • GaussDB uses the IANA time zone database (tzdata) at the bottom layer. For some countries or regions (such as PRC), the IANA database uses the local mean time (LMT) to define the local time offset of the region when the time value is far earlier than the date when the standard time was introduced (for example, before 1900). The fixed standard time zone offset is not used. Oracle Database uses the fixed standard time zone offset for dates far earlier than the date when the standard time was introduced, and does not use the LMT. Therefore, for the timestamp with time zone of a date far earlier than the date when the standard time was introduced, the time zone offset in GaussDB may be different from that in Oracle Database. -- Oracle SQL> SELECT DBTIMEZONE AS "Database", SESSIONTIMEZONE AS "Session" FROM DUAL; Dat Session --- --- PRC PRC SQL> SELECT TO_TIMESTAMP_TZ('0001-01-01 00:00:00 +00:00', 'YYYY-MM-DD HH24:MI:SS TZH:TZM') FROM DUAL; TO_TIMESTAMP_TZ('0001-01-0100:00:00+00:00','YYYY-MM-DDHH24:MI:SSTZH:TZM') --- 0001-01-01 00:00:00.000000000 +00:00 -- GaussDB gaussdb=# SET a_format_version='10c'; SET gaussdb=# SET a_format_dev_version='s1'; SET gaussdb=> SET TIMEZONE = 'Asia/Beijing'; SET gaussdb=> SELECT TO_TIMESTAMP_TZ('0001-01-01 00:00:00 +00:00', 'YYYY-MM-DD HH24:MI:SS TZH:TZM') FROM DUAL; to_timestamp_tz ---

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Oracle Database	GaussDB	Difference
		0001-01-01 08:00:00+08 (1 row) gaussdb=> SET TIMEZONE = 'PRC'; SET gaussdb=# SELECT TO_TIMESTAMP_TZ('0001-01-01 00:00:00 +00:00', 'YYYY-MM-DD HH24:MI:SS TZH:TZM') FROM DUAL; to_timestamp_tz ---------- 0001-01-01 08:05:43+08:05:43 (1 row)
TO_YMINTERVAL	Supported, but with differences.	GaussDB: The yminterval type is not supported. Currently, interval is used to be compatible with the yminterval type.
TRUNC	Supported, but with differences.	The return type in GaussDB is the same as the type of the first input parameter. In Oracle Database, the return type is always date. The supported formats are different. For details, see **Date and Time Processing Functions and Operators**.
TZ_OFFSET	Supported, with differences.	• When a time zone name is received as an input parameter, the number of time zone names supported by GaussDB is less than that supported by Oracle Database. For example, GaussDB does not support time zone abbreviations (such as PST, CST, and EST). You can use the IANA time zone region name (such as US/Pacific) instead. • When the input parameter is in the time zone offset format (such as '+hh:mi' or '-hh:mi') and the offset is zero (such as '-00:00'), Oracle Database normalizes the output to +00:00, while GaussDB retains the original sign and returns **-00:00**. • If the input parameter contains only blank characters (such as spaces), GaussDB returns an empty value, while Oracle Database reports an error.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Oracle Database	GaussDB	Difference
ROUND	Supported, but with differences.	The return types are different. In GaussDB, when **mapping_date_to_datea** is disabled, the return type is timestamp without time zone; when it is enabled, the return type is datea. The return type in Oracle Database is date. In GaussDB, the input parameter can be of the character type, whereas Oracle Database does not support an input parameter of the character type for the ROUND function. When the second input parameter has a specified unit as a year defined in the ISO 8601 standard that includes the calendar week, such as **'iyyy'** or **'iy'**, there are differences in the returned results between Oracle Database and GaussDB for certain years.

Table 3-97 General comparison functions

Oracle Database	GaussDB	Difference
GREATEST	Supported, but with differences.	• GaussDB: The comparison mode specified by the **NLS_SORT** parameter is not supported. Only binary comparison is supported. • GaussDB: Expressions in multiple languages are not supported.
LEAST	Supported, but with differences.	• GaussDB: The comparison mode specified by the **NLS_SORT** parameter is not supported. Only binary comparison is supported. • GaussDB: Expressions in multiple languages are not supported.

Table 3-98 Conversion functions

Oracle Database	GaussDB	Difference
ASCIISTR	Supported.	-

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Oracle Database	GaussDB	Difference
CAST	Supported, but with differences.	• GaussDB: The MULTISET clause is not supported. • GaussDB: The **nlsparam** parameter is not supported. • When the CAST(expr AS NUMBER, fmt) operation is performed, GaussDB requires that the number of commas in the input data be greater than or equal to the number of commas in *fmt*. Otherwise, an error is reported. In Oracle Database, the extra commas in *fmt* are ignored. -- Oracle SELECT CAST('10' AS NUMBER, '99,99,99') FROM DUAL; -- 10 -- GaussDB gaussdb=# SET a_format_version='10c'; SET gaussdb=# SET a_format_dev_version='s1'; SET gaussdb=# SELECT CAST('10' AS NUMBER, '99,99,99') FROM DUAL; ERROR: surplus fmt. CONTEXT: referenced column: numeric
HEXTORAW	Supported.	-

RAWTOHEX	Supported, with differences.	When the input parameter of a function is of the numeric type (including integer and floating point) or time type (such as DATEA and TIMESATMP), the return results of the function are inconsistent.
		-- Oracle
		SQL> SELECT RAWTOHEX(1), RAWTOHEX(1.12) FROM DUAL;
		RAWT RAWTOH
		---- ------
		C102 C1020D

Oracle Database	GaussDB	Difference

TO_BINARY_DOUBLE	Supported, but with differences.	• GaussDB: The **nlsparam** parameter is not supported.
		• In GaussDB, literals are parsed according to the IEEE 754 floating-point standard, and values within the target type range can be correctly returned. In Oracle Database, numeric literals (without the f/d suffix) are first converted to the NUMBER type, which is restricted by the NUMBER type range (1E-130 to 1E+126) and the maximum length of a string that can be parsed. If the value exceeds the upper limit, an error is reported. If the value is less than the lower limit, **0** is returned.
		-- Oracle
		SELECT TO_BINARY_DOUBLE(1e+400) FROM DUAL; -- The literal exceeds the NUMBER range.
		-- numeric overflow
		SELECT TO_BINARY_DOUBLE(LPAD('9', 4000, '9')) FROM DUAL; -- The string length exceeds the upper limit.
		invalid number
		SELECT TO_BINARY_DOUBLE(-2.2250738585072014E-308) FROM DUAL;
		-- 0
		
		-- GaussDB
		gaussdb=# SET a_format_version='10c';
		SET
		gaussdb=# SET a_format_dev_version='s2';
		SET
		gaussdb=# SELECT TO_BINARY_DOUBLE(1e+400) FROM DUAL;
		to_binary_double

		to_binary_double
		------------------ 	
		Infinity
		(1 row)
		
		gaussdb=# SELECT TO_BINARY_DOUBLE(-2.2250738585072014E-308) FROM DUAL;
		to_binary_double
		---------------------- 	
		-2.2250738585072e-308
		(1 row)
		• The differences between the **fmt** options in GaussDB and Oracle Database are as follows:
		1. GaussDB does not support the C format.
		2. GaussDB does not support the EEEE format.
		3. When the format 9 parses non-digit characters, GaussDB skips the characters, while Oracle Database reports an error.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Oracle Database	GaussDB	Difference

		• If the **fmt** parameter is not specified, GaussDB requires that the string be in strict compliance with the floating-point literal format. Otherwise, an error is reported. Oracle Database truncates the valid prefix of a non-standard string containing characters related to the numeric format (such as hyphens (-) and plus signs (+)) and returns the valid prefix instead of reporting an error. For a string containing characters that are not in the numeric format, Oracle Database reports an error.
		`-- Oracle`
		`SELECT TO_BINARY_DOUBLE('1-23') FROM DUAL;`
		`-- 1`
		
		`-- GaussDB`

Oracle Database	GaussDB	Difference
		instead of reporting an error. For a string containing characters that are not in the numeric format, Oracle Database reports an error. -- Oracle SELECT TO_BINARY_FLOAT('1-23') FROM DUAL; -- 1 -- GaussDB gaussdb=# SET a_format_version='10c'; SET gaussdb=# SET a_format_dev_version='s2'; SET gaussdb=# SELECT TO_BINARY_FLOAT('1-23') FROM DUAL; ERROR: invalid input syntax for type real: "1-23" CONTEXT: referenced column: to_binary_float ● If the input parameter contains a null value, GaussDB directly returns null, while Oracle Database executes the function as normal. ● The result of TO_BINARY_FLOAT('NAN') is NAN. In the numeric operation with 0, the result in GaussDB is different from that in Oracle Database. – In Oracle Database, the result of the calculation between NAN and 0 is always NAN. – In GaussDB, the calculation between NAN and 0 complies with the normal arithmetic logic of the calculation with 0.
TO_BLOB	Supported, but with differences.	● GaussDB: The long raw type is not supported. ● GaussDB: The bfile and mime_type types are not supported.
TO_CLOB	Supported, with differences.	GaussDB does not support the BLOB type as an input parameter, while Oracle Database supports it.

Oracle Database	GaussDB	Difference

TO_DATE	Supported, but with differences.	• Multi-language parameters are not supported.
		• GaussDB does not support the BLOB type as an input parameter, while Oracle Database supports it.
		• The returned types are different. In GaussDB, when **mapping_date_to_datea** is enabled, the return type is datea; when it is disabled, the return type is timestamp.
		• In GaussDB, when **mapping_date_to_datea** is enabled, it is affected by the control parameter **nls_date_format**. Otherwise, it is not affected.
		• Some formats are not supported.
		• fmt = 'j'. The output before October 15, 1582 in Oracle Database is inconsistent with that in GaussDB.
		• If there is no separator, the value may be different from that in Oracle Database. Take to_date('220725','yymmdd') as an example. If yy/rr is parsed based on the fixed length 4, the year is parsed as 2207 and the month is parsed as 25. The month 25 is invalid, and an error will be reported.
		• If the input parameter contains a null value, GaussDB directly returns null, while Oracle Database executes the function as normal.
		• In some scenarios, Oracle Database can ignore the spaces in *fmt*, but GaussDB strictly verifies the spaces. Therefore, it is recommended that the input parameter string strictly match *fmt*.
		`-- Oracle`
		`SQL> SELECT TO_DATE('15-JANUARY -2024', 'DD-MONTH-YYYY') FROM DUAL;`
		`TO_DATE`
		`-------------------`
		`2024-01-15 00:00:00`
		
		`-- GaussDB (with a space after the month JANUARY)`
		`gaussdb=# SELECT TO_DATE('15-JANUARY -2024', 'DD-MONTH-YYYY') FROM DUAL;`
		`ERROR:  Invalid data exists in a string for matching date.`
		`CONTEXT:  referenced column: to_date`

TO_MULTI_BYTE	Supported.	-
TO_NCHAR	Supported, but with differences.	• GaussDB: The input parameter type is converted to text. • Oracle Database: The input parameter type is converted to the national character set. For other differences, see the TO_CHAR function.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Oracle Database	GaussDB	Difference
TO_NUMBER	Supported, but with differences.	GaussDB does not support the **NLS_PARAM** parameter. GaussDB does not support the CLOB type as an input parameter, while Oracle Database supports it. The differences between the format options of GaussDB and Oracle Database are as follows: 1. $ GaussDB does not support this format. 2. , (comma) GaussDB: Commas (,) can appear at any position of a format. Oracle Database: ● In the format, commas can only appear in the integer part and cannot appear at the beginning of a number. In the original data, commas can appear at the beginning of a number. ● The number and position of commas in the format can be different from those in the original data, but the position of the last comma must be the same. ● Consecutive commas in the original data and the format are equivalent to no comma. ● If the original data does not contain commas, the number of digits after the last comma in the format must be the same as that in the original data. 3. B GaussDB does not support this function. 4. C GaussDB does not support the **NLS** parameter. 5. G GaussDB does not support the **NLS** parameter. 6. L GaussDB does not support the **NLS** parameter. 7. U GaussDB does not support the **NLS** parameter. 8. D GaussDB does not support the **NLS** parameter. 9. PR GaussDB: It is equivalent to S. A negative number is returned. Oracle Database:

Oracle Database	GaussDB	Difference
		• Returns the negative value in the angle brackets (< >). • Returns a positive value with leading and trailing spaces. • Limitation: PR elements can only appear at the last position of the digital format model. 10.RN | rn GaussDB does not support this function. 11.TM| TM9 | TMe GaussDB does not support this function. 12.V GaussDB does not support this function. 13.FM • In GaussDB, when there is FM, the comma in the format can be more than that in the original data. In other words, the number of commas is not necessarily the same. • In Oracle Database, spaces before and after the return value are retained. 14.EEEE GaussDB does not support this function. 15.XXXX The processing of negative input parameters is different between GaussDB and Oracle Database.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Oracle Database	GaussDB	Difference

TO_CHAR	Supported, with differences.	• GaussDB: The **nlsparam** parameter is not supported.
		• The fmt '5' is not included in Oracle Database documents and is not adapted.
		• When the input parameter is of the character type, Oracle Database returns the same type as the input parameter, while GaussDB returns the text type.
		• When the input parameter is of the INTERVAL type and **fmt** is not explicitly specified, the format of the return result in GaussDB is different from that in Oracle Database.
		`-- GaussDB`
		`gaussdb=# SELECT TO_CHAR(INTERVAL '2 12:30:45' DAY TO SECOND) FROM DUAL;`
		`to_char`
		`------------------`
		`2.52135416666667`
		`(1 row)`
		
		`-- Oracle`
		`SQL> SELECT TO_CHAR(INTERVAL '2 12:30:45' DAY TO SECOND) FROM DUAL;`
		`TO_CHAR(INTERVAL'21`
		`-------------------`
		`+02 12:30:45.000000`
		• The processing logic of zero-value placeholders is different. In Oracle Database, the specified number of zeros are retained according to the format template. In GaussDB, only one zero is returned.
		`-- GaussDB`
		`gaussdb=# SELECT TO_CHAR(0, '999V99') FROM DUAL;`
		`to_char`
		`---------`
		`0`
		`(1 row)`
		
		`-- Oracle`

		• In the format, the SP suffix is not supported. That is, the suffix cannot be converted into English words. If the suffix is specified, it does not take effect and the value is still output in number format.

TO_SINGLE_BYTE	Supported.	-
TREAT	Supported, but with differences.	In GaussDB, the period (.) operator cannot be used to obtain values, and the values cannot be converted to the object type.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Oracle Database	GaussDB	Difference
UNISTR	Supported, but with differences.	GaussDB supports only UTF-8 encoding. Oracle Database supports UTF-8 and UTF-16 encodings.

Table 3-99 Large object functions

Oracle Database	GaussDB	Difference
EMPTY_BLOB	Supported.	-
EMPTY_CLOB	Supported, but with differences.	GaussDB: The CLOB type does not support the locator concept in Oracle Database.

Table 3-100 Hierarchical functions

Oracle Database	GaussDB	Difference
SYS_CONNECT_BY_PATH	Supported, but with differences.	In GaussDB, the column specified by the first input parameter can only be of the CHAR, VARCHAR, NVARCHAR2, TEXT, INT1, INT2, INT4, INT8, FLOAT4, FLOAT8, or NUMERIC type. Currently, the **col** input of the function cannot be an expression. If the column content is the same as the separator, no error is reported.
CONNECT_BY_ROOT	Supported, but with differences.	In GaussDB, the CONNECT_BY_ROOT operation has the following syntax restrictions: If the specified column name is a non-reserved keyword, the column name must be enclosed in parentheses, for example, CONNECT_BY_ROOT(*column_name*), to assign an alias to the expression. If the column name is not enclosed in parentheses, a syntax error occurs. For example, CONNECT_BY_ROOT *unreserved_keyword_column_name* AS *alias_name* needs to be changed to CONNECT_BY_ROOT (*unreserved_keyword_column_name*) AS *alias_name*.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 3-101 XML functions

Oracle Database	GaussDB	Difference
EXISTSNODE	Supported, but with differences.	If the input parameter has a namespace, aliases must be defined for both the XPath and namespace.
EXTRACTVALUE	Supported, but with differences.	Currently, only XPath 1.0 is supported.
SYS_XMLAGG	Supported, but with differences.	This is an alias of xmlagg and can be replaced with xmlagg.
XMLAGG	Supported, but with differences.	For details about the differences, see the note below.
XMLCOMMENT	Supported, but with differences.	
XMLCONCAT	Supported, but with differences.	
XMLELEMENT	Supported, but with differences.	For xmlelement and xmlattributes, when the value of **name** is **NULL**, the database behavior is different from that in Oracle Database. • When the **name** column of **xmlelement** is set to **NULL**, the name information is empty and the attribute information is not displayed. • When the **name** column of **xmlattributes** is set to **NULL**, the attribute information is not displayed.
XMLEXISTS	Supported, but with differences.	GaussDB input parameter is of the XML type.
XMLFOREST	Supported, but with differences.	GaussDB return value is of the XML type. GaussDB does not support the EVALNAME syntax.
XMLPARSE	Supported, but with differences.	GaussDB return value is of the XML type. GaussDB does not support the WELLFORMED syntax.
XMLROOT	Supported, but with differences.	GaussDB return value is of the XML type.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Oracle Database	GaussDB	Difference
XMLSERIALIZE	Supported, with differences.	The syntax rules are different. In GaussDB, the input parameter must be followed by AS type after value, which can be omitted in Oracle Database.
XMLTABLE	Supported, but with differences.	GaussDB: ● The XPath 1.0 expression is used to select data from XML text. ● The default namespace cannot be declared. ● Multiple groups of input and aliasing are not supported. ● The RETURNING SEQUENCE BY REF and (SEQUENCE) BY REF clauses are not supported. ● The XPath query and output functionalities are implemented based on the libxml2 library. This implementation inherits the character processing mechanism of libxml2, including the escape rules for XML special characters (such as < > & " '). ● When the input is a sequence consisting of numbers and XML text, the differences are as follows: – A standard XPath and XML text cannot be combined to form a sequence for input. – The XML text can carry version information. – In scientific notation, such as '1e10', spaces are allowed between 'e' or 'E' and the exponent. Oracle Database: XQuery expressions are used to select data from XML text.
XMLQUERY	Supported, but with differences.	GaussDB: ● Only the XPath 1.0 syntax is supported. ● The root node of the XML text is fixed as the context space where text search is started. Oracle Database: XQuery expressions are used to select data from XML text.
XMLCAST	Supported, but with differences.	Some data types supported by GaussDB are different from those supported by Oracle Database, causing the variance in output data format and precision.
GETSTRINGVAL	Supported, but with differences.	For details about the differences, see the note below.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Oracle Database	GaussDB	Difference
GETCLOBVAL	Supported, but with differences.	
XMLSEQUENCE	Supported, but with differences.	

NOTE

- The XML functions listed in **Table 3-101** are implemented based on libxml2. Therefore, the behavior of these functions in GaussDB is different from that in Oracle Database in some scenarios, including XML parsing, escape rules for special characters, and XPath query result formats.

  The following example shows the differences in the output of the same XML query in GaussDB and Oracle Database.

  GaussDB in ORA-compatible mode:

```
gaussdb=# SELECT * FROM xmltable('/' passing xmltype('<a>&lt; &gt; &quot; &amp; &apos;</a>'));
       column_value
----------------------------
 <a>&lt; &gt; " &amp; '</a>+

(1 row)
```

  Oracle Database:

```
SQL> SELECT * FROM xmltable('/' passing xmltype('<a>&lt; &gt; &quot; &amp; &apos;</a>'));
COLUMN_VALUE
--------------------------------------------------------------------------------
<a>&lt; &gt; &quot; &amp; &apos;</a>
```

- When the libxml2 library on which GaussDB depends is upgraded, incompatible changes may be introduced.

Table 3-102 JSON functions

Oracle Database	GaussDB	Difference
JSON_ARRAY	Supported, but with differences.	GaussDB: The input parameter is a variable parameter list **([VARIADIC "any"])**. Oracle Database: The input parameter is more complex, that is, **(expr [FORMAT JSON] [, expr [FORMAT JSON]]... [JSON_on_null_clause] [JSON_returning_clause] [STRICT])**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Oracle Database	GaussDB	Difference
JSON_OBJECT	Supported, with differences.	GaussDB: The JSON_OBJECT([key, val[, key1, val1]...]) function is supported. If the key is duplicate, the first key-value pair is retained. Oracle Database: The input parameter is more complex, that is, (key_name VARCHAR2, value_expr [, key_name VARCHAR2, value_expr]... [JSON_on_null_clause] [JSON_returning_clause] [STRICT]). Explicit key-value pairing, independent NULL value processing policies (such as ABSENT ON NULL or NULL ON NULL), return type control, and strict mode (**STRICT**, which prevents duplicate key names or type mismatches. If duplicate keys exist and are not specified, all keys are retained by default.) are supported.

Table 3-103 Encoding and decoding functions

Oracle Database	GaussDB	Difference
DECODE	Supported, with differences.	During the comparison of conditional expressions, if one side is of the fixed-length character type and the other side is of the variable-length character type, GaussDB ignores the spaces at the end of the value (the same as the behavior of the comparison operator), while Oracle Database does not ignore the spaces at the end of the value.
DUMP	Supported, with differences.	The return results of the numeric and time types in GaussDB are inconsistent with those in Oracle Database due to different storage formats. For example: ● In GaussDB, "SELECT dump(123);" returns "Typ=23 Len=4: 123,0,0,0" (you need to run **SET a_format_version='10c';** and **SET a_format_dev_version='s2';** first). ● In Oracle Database, **SELECT dump(123) FROM dual;** returns **Typ=2 Len=3: 194,2,24**.
ORA_HASH	Supported, but with differences.	GaussDB has the following behaviors: ● The input parameter of the time type is converted into the character string type and then hashed. ● The **maxbucket** parameter is not supported.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Oracle Database	GaussDB	Difference
VSIZE	Supported, with differences.	• The return results of the numeric and time types in GaussDB are inconsistent with those in Oracle Database due to different storage formats. For example: – In GaussDB, **SELECT vsize(999);** returns **4** (you need to run **SET a_format_version='10c';** and **SET a_format_dev_version='s2';** first). – In Oracle Database, **SELECT vsize(999) FROM dual;** returns **3**. • GaussDB does not support input parameters of the XMLType type.

Table 3-104 Null-related functions

Oracle Database	GaussDB	Difference
COALESCE	Supported.	-
LNNVL	Supported.	-
NULLIF	Supported, with differences.	During the comparison of expressions, if one side is of the fixed-length character type and the other side is of the variable-length character type, GaussDB ignores the spaces at the end of the value (the same as the behavior of the comparison operator), while Oracle Database does not ignore the spaces at the end of the value.
NVL	Supported, with differences.	If the first expression is NULL, GaussDB returns the text type, while Oracle Database returns the data type of the second expression.
NVL2	Supported.	-

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 3-105 Environment and identifier functions

Oracle Database	GaussDB	Difference
SYS_CONTEXT	Supported, with differences.	• GaussDB supports SYS_CONTEXT(namespace, attribute) and does not support the function of specifying the length of the return value using SYS_CONTEXT(namespace, attribute, len). • GaussDB returns NULL for unsupported parameters. The following parameters are not supported: – 'action' – 'is_application_root' – 'is_application_pdb' – 'audited_cursorid' – 'authenticated_identity' – 'authentication_data' – 'authentication_method' – 'cdb_domain' – 'cdb_name' – 'client_identifier' – 'con_id' – 'con_name' – 'current_sql_length' – 'db_domain' – 'db_supplemental_log_level' – 'dblink_info' – 'drain_status' – 'entryid' – 'enterprise_identity' – 'fg_job_id' – 'global_uid' – 'identification_type' – 'instance' – 'is_dg_rolling_upgrade' – 'ldap_server_type' – 'module' – 'network_protocol' – 'nls_calendar' – 'nls_sort' – 'nls_territory' – 'oracle_home'

Oracle Database	GaussDB	Difference
Table 3-130	DBE_XMLGEN	For details about the usage in GaussDB, see DBE_XMLGEN.
Table 3-129	DBE_STATS	For details about the usage in GaussDB, see DBE_STATS.
Table 3-131	DBE_OBFUSCATION_TOOLKIT	For details about the usage in GaussDB, see DBE_OBFUSCATION_TOOLKIT.

Table 3-110 DBMS_LOB compatibility

Oracle Database	GaussDB	Difference
APPEND Procedures	APPEND Procedures	-
CLOB2FILE Procedure	Not supported.	-
CLOSE Procedure	BFILECLOSE Procedure	GaussDB: The parameter type is BFILE, and no function overloading exists. Oracle Database: There are three overloaded procedures. The procedures have three parameters **lob_loc**, **lob_loc**, and **file_loc**, which are of the BLOB, CLOB CHARACTER SET ANY_CS, and BFILE types, respectively.
COMPARE Functions	COMPARE Functions	GaussDB: There are three overloaded functions. The third parameter (**len**) is of the BIGINT type. Oracle Database: There are three overloaded functions. The third parameter (**amount**) is of the INTEGER type.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Oracle Database	GaussDB	Difference
CONVERTTOBLOB Procedure	LOB_CONVERTTOBLOB Procedure	GaussDB: This procedure has five parameters, and the third, fourth, and fifth parameters are of the BIGINT type. Oracle Database: This procedure has eight parameters. In addition to all GaussDB parameters, the **blob_csid**, **lang_context**, and **warning** parameters are added, which are of the NUMBER, INTEGER, and INTEGER types, respectively. The third, fourth, and fifth parameters are of the INTEGER type.
CONVERTTOCLOB Procedure	LOB_CONVERTTOCLOB Procedure	GaussDB: This procedure has five parameters. The third, fourth, and fifth parameters are of the BIGINT type. Oracle Database: This procedure has eight parameters. The third, fourth, and fifth parameters are of the INTEGER type. In addition to all GaussDB parameters, this procedure in Oracle Database adds three parameters: **blob_csid**, **lang_context**, and **warning**, which are of NUMBER, INTEGER, and INTEGER types, respectively.
COPY Procedures	LOB_COPY Functions	-
COPY_DBFS_LINK Procedures	Not supported.	-
COPY_FROM_DBFS_LINK	Not supported.	-

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Oracle Database	GaussDB	Difference
CREATETEMPORARY Procedures	CREATE_TEMPORARY Procedures	GaussDB: There are two overloaded procedures. The first parameter (**lob_loc**) of the first overloaded procedure is of the BLOB type, and the first parameter (**lob_loc**) of the second overloaded procedure is of the CLOB type. The third parameter (**dur**) of the two overloaded procedures is of the INTEGER type, and the default value is **10**. Oracle Database: There are two overloaded procedures. The first parameter (**lob_loc**) of the first overloaded procedure is of the BLOB type. The first parameter (**lob_loc**) of the second overloaded procedure is of the CLOB type. The third parameter (**dur**) of the two overloaded procedures is of the PLS_INTEGER type. The default value of **dur** of the first overloaded procedure is **DBMS_LOB.SESSION**, and the default value of **dur** of the second overloaded procedure is **10**.
DBFS_LINK_GENERATE_PATH Functions	Not supported.	-
ERASE Procedures	LOB_ERASE Procedures	-
FILECLOSE Procedure	Not supported.	-
FILECLOSEALL Procedure	Not supported.	-
FILEEXISTS Function	Not supported.	-
FILEGETNAME Procedure	Not supported.	-
FILEISOPEN Function	Not supported.	-
FILEOPEN Procedure	Not supported.	-

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Oracle Database	GaussDB	Difference
FRAGMENT_DELETE Procedure	Not supported.	-
FRAGMENT_INSERT Procedures	Not supported.	-
FRAGMENT_MOVE Procedure	Not supported.	-
FRAGMENT_REPLACE Procedures	Not supported.	-
FREETEMPORARY Procedures	Not supported.	-
GET_DBFS_LINK Functions	Not supported.	-
GET_DBFS_LINK_STATE Procedures	Not supported.	-
GETCHUNKSIZE Functions	GETCHUNKSIZE Functions	-
GETCONTENTTYPE Functions	Not supported.	-
GETLENGTH Functions	Not supported.	-
GETOPTIONS Functions	Not supported.	-
GET_STORAGE_LIMIT Function	Not supported.	-
INSTR Functions	MATCH Functions	GaussDB: There are three overloaded functions. The third and fourth parameters of the three overloaded functions are of the BIGINT type. Oracle Database: There are three overloaded functions. The third and fourth parameters of the three overloaded functions are of the INTEGER type.
ISOPEN Functions	Not supported.	-
ISREMOTE Function	Not supported.	-
ISSECUREFILE Function	Not supported.	-

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Oracle Database	GaussDB	Difference
ISTEMPORARY Functions	Not supported.	-
LOADBLOBFROMFILE Procedure	LOADBLOBFROMFILE Procedure	-
LOADCLOBFROMFILE Procedure	LOADCLOBFROMFILE Procedure	-
LOADFROMFILE Procedure	LOADFROMFILE Procedure	-
MOVE_TO_DBFS_LINK Procedures	Not supported.	-
OPEN Procedures	BFILEOPEN Procedure	GaussDB: There is no overloaded procedure. The first parameter (**bfile**) is of the DBE_LOB.BFILE type, and the second parameter (**open_mode**) is of the TEXT type. Only the read mode is supported. Oracle Database: There are three overloaded procedures. In the first overloaded procedure, the first parameter (**lob_loc**) is of the NOCOPY BLOB type, and the second parameter (**openmode**) is of the BINARY_INTEGER type. In the second overloaded procedure, the first parameter (**lob_loc**) is of the NOCOPY CLOB CHARACTER SET ANY_CS type, and the second parameter (**openmode**) is of the BINARY_INTEGER type. In the third overloaded procedure, the first parameter (**file_loc**) is of the NOCOPY BFILE type, and the second parameter (**openmode**) is of the BINARY_INTEGER type, and the value can only be **file_readonly**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Oracle Database	GaussDB	Difference
READ Procedures	READ Procedures	GaussDB: There are two overloaded procedures. Oracle Database: There are three overloaded procedures. The first two overloaded procedures are the same as those in GaussDB. The third overloaded procedure includes four parameters: **file_loc**, **amount**, **offset**, and **buffer**, which are of the BFILE, NOCOPY INTEGER, INTEGER, and RAW types, respectively.
SET_DBFS_LINK Procedures	Not supported.	-
SETCONTENTTYPE Procedure	Not supported.	-
SETOPTIONS Procedures	Not supported.	-
SUBSTR Functions	LOB_SUBSTR Functions	-
TRIM Procedures	STRIP Functions	GaussDB: There are two overloaded procedures. The second parameter (**newlen**) of the two overloaded procedures is of the BIGINT type. Oracle Database: There are two overloaded procedures. The second parameter (**newlen**) of the two overloaded procedures is of the INTEGER type.
WRITE Procedures	WRITE Functions	-
WRITEAPPEND Procedures	WRITEAPPEND Functions	-

Table 3-111 DBMS_RANDOM compatibility

Oracle Database	GaussDB	Difference
INITIALIZE Procedure	Not supported.	-
NORMAL Function	Not supported.	-

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Oracle Database	GaussDB	Difference
RANDOM Function	Not supported.	-
SEED Procedures	DBE_RANDOM.SET_SEED Function	GaussDB: There is no overloaded function. The parameter is of the INTEGER type. Oracle Database: There are two overloaded procedures. The parameter types of the two overloaded procedures are VARCHAR2 and BINARY_INTEGER, respectively.
STRING Function	Not supported.	-
TERMINATE Procedure	Not supported.	-
VALUE Functions	DBE_RANDOM.GET_VALUE Function	GaussDB: There is no overloaded function. Oracle Database: The VALUE function without parameters is overloaded, and the return type is NUMBER.

Table 3-112 DBMS_OUTPUT compatibility

Oracle Database	GaussDB	Difference
DISABLE Procedure	DISABLE Function	-
ENABLE Procedure	ENABLE Function	-
GET_LINE Procedure	GET_LINE Function	GaussDB: There is no overloaded function. The first parameter (**lines**) is of the VARCHAR[] type. Oracle Database: There are two overloaded procedures. The first parameters (**lines**) of the two overloaded procedures are of the CHARARR and DBMSOUTPUT_LINESARRAY types, respectively.
GET_LINES Procedure	GET_LINES Function	-
NEW_LINE Procedure	NEW_LINE Function	-

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Oracle Database	GaussDB	Difference
PUT Procedure	PUT Function	GaussDB: If the character set of the database server (**server_encoding**) is not encoded in UTF-8 and the character encoding of the input parameter is valid UTF-8, this function converts character encoding based on the relationship "UTF-8 > server_encoding" and then outputs the result regardless of the data type of the input parameter. Oracle Database: If the character set of the database server (**server_encoding**) is not encoded in UTF-8, the character encoding of the input parameter is valid UTF-8, and the input parameter type is NVARCHAR2, this procedure coverts the character encoding based on the relationship "UTF-8 > server_encoding" and then outputs the result. If the input parameter is of other character types, the character encoding is regarded as an invalid character and output as a placeholder.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Oracle Database	GaussDB	Difference
PUT_LINE Procedure	PUT_LINE Function	GaussDB: If the character set of the database server (**server_encoding**) is not encoded in UTF-8 and the character encoding of the input parameter is valid UTF-8, this function converts character encoding based on the relationship "UTF-8 > server_encoding" and then outputs the result regardless of the data type of the input parameter. Oracle Database: If the character set of the database server (**server_encoding**) is not encoded in UTF-8, the character encoding of the input parameter is valid UTF-8, and the input parameter type is NVARCHAR2, this procedure coverts the character encoding based on the relationship "UTF-8 > server_encoding" and then outputs the result. If the input parameter is of other character types, the character encoding is regarded as an invalid character and output as a placeholder.

Table 3-113 UTL_RAW compatibility

Oracle Database	GaussDB	Difference
BIT_AND Function	BIT_AND Function	-
BIT_COMPLEMENT Function	BIT_COMPLEMENT Function	-
BIT_OR Function	BIT_OR Function	GaussDB: The two parameters are defined as the TEXT type and returned as the TEXT type. Oracle Database: The two parameters are of the RAW type and returned as the RAW type.
BIT_XOR Function	BIT_XOR Function	-
CAST_FROM_BINARY_DOUBLE Function	CAST_FROM_BINARY_DOUBLE_TO_RAW Function	-

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Oracle Database	GaussDB	Difference
CAST_FROM_BINARY_FLOAT Function	CAST_FROM_BINARY_FLOAT_TO_RAW Function	GaussDB: The **n** parameter is of the FLOAT4 type, and it is truncated based on its range and precision before conversion. Oracle Database: The **n** parameter is of the FLOAT type.
CAST_FROM_BINARY_INTEGER Function	CAST_FROM_BINARY_INTEGER_TO_RAW Function	GaussDB: The **value** parameter is of the BIGINT type. Oracle Database: The **value** parameter is of the INTEGER type.
CAST_FROM_NUMBER Function	CAST_FROM_NUMBER_TO_RAW Function	GaussDB: The **n** parameter is of the NUMERIC type. Oracle Database: The **n** parameter is of the NUMBER type.
CAST_TO_BINARY_DOUBLE Function	CAST_FROM_RAW_TO_BINARY_DOUBLE Function	-
CAST_TO_BINARY_FLOAT Function	CAST_FROM_RAW_TO_BINARY_FLOAT Function	GaussDB: The function returns the FLOAT4 type. Oracle Database: The function returns the FLOAT type.
CAST_TO_BINARY_INTEGER Function	CAST_FROM_RAW_TO_BINARY_INTEGER Function	GaussDB: The **endianess** parameter is of the INTEGER type, and the function returns the INTEGER type. Oracle Database: The **endianess** parameter is of the PLS_INTEGER type, and the function returns the BINARY_INTEGER type.
CAST_TO_NUMBER Function	CAST_FROM_RAW_TO_NUMBER Function	GaussDB: The function returns the NUMERIC type. Oracle Database: The function returns the NUMBER type.
CAST_TO_NVARCHAR2 Function	CAST_FROM_RAW_TO_NVARCHAR2 Function	-
CAST_TO_RAW Function	CAST_FROM_VARCHAR2_TO_RAW Function	-
CAST_TO_VARCHAR2 Function	CAST_TO_VARCHAR2 Function	-

Table 3-121 DBMS_APPLICATION_INFO compatibility

Oracle Database	GaussDB	Difference
READ_CLIENT_INFO Function	READ_CLIENT_INFO Procedure	GaussDB: The **client_info** parameter is of the TEXT type. Oracle Database: The **client_info** parameter is of the VARCHAR2 type.
READ_MODULE Procedure	READ_MODULE Procedure	GaussDB: The **module_name** and **action_name** parameters are of the TEXT type. Oracle Database: The **module_name** and **action_name** parameters are of the VARCHAR2 type.
SET_ACTION Procedure	SET_ACTION Procedure	GaussDB: The **action_name** parameter is of the TEXT type. Oracle Database: The **action_name** parameter is of the VARCHAR2 type.
SET_CLIENT_INFO Function	SET_CLIENT_INFO Procedure	GaussDB: The **str** parameter is of the TEXT type, and the return type is VOID. Oracle Database: The **client_info** parameter is of the VARCHAR2 type and no value is returned. Both of them are written to the client. The maximum length is 64 bytes. If the length exceeds 64 bytes, it will be truncated.
SET_MODULE Procedure	SET_MODULE Procedure	GaussDB: The **module_name** and **action_name** parameters are of the TEXT type. Oracle Database: The **module_name** and **action_name** parameters are of the VARCHAR2 type.
SET_SESSION_LONGOPS Procedure	Not supported.	-

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 3-122 DBMS_XMLDOM compatibility

Oracle Database	GaussDB	Difference
DBMS_XMLDOM.APPENDCHILD	DBE_XMLDOM.APPENDCHILD	• GaussDB: The error message "operation not support" is displayed for the APPEND ATTR node under the DOCUMENT node. Oracle Database: No error is reported in this scenario, but the mounting fails. • GaussDB: The error message "operation not support" is displayed for the APPEND ATTR node under the ATTR node. Oracle Database: No error is reported in this scenario, but the mounting fails. • GaussDB: When multiple child nodes of the ATTR type are added to a parent node, the child nodes with the same key value cannot exist under the same parent node. Oracle Database: Child nodes with the same key value can exist under the same parent node.
DBMS_XMLDOM.CREATEELEMENT	DBE_XMLDOM.CREATEELEMENT	-
DBMS_XMLDOM.CREATETEXTNODE	DBE_XMLDOM.CREATETEXTNODE	-
DBMS_XMLDOM.FREEDOCUMENT	Supported, but with differences in DBE_XMLDOM.FREEDOCUMENT.	GaussDB: Objects are not released immediately. They are released after a certain number of objects are accumulated. All nodes in the document are invalid. Oracle Database: The object is released immediately.
DBMS_XMLDOM.FREEELEMENT	DBE_XMLDOM.FREEELEMENT	-
DBMS_XMLDOM.FREENODE	DBE_XMLDOM.FREENODE	-

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Oracle Database	GaussDB	Difference
DBMS_XMLDOM.FREENODELIST	Supported, but with differences in DBE_XMLDOM.FREENODELIST.	GaussDB: The nodelist will be released. Oracle Database: After the nodelist is released, it can still be queried in the original document.
DBMS_XMLDOM.GETATTRIBUTE	DBE_XMLDOM.GETATTRIBUTE	-
DBMS_XMLDOM.GETATTRIBUTES	DBE_XMLDOM.GETATTRIBUTES	-
DBMS_XMLDOM.GETCHILDNODES	DBE_XMLDOM.GETCHILDNODES	GaussDB: When the document node is used, DTD is included. Oracle Database: DTD is not included.
DBMS_XMLDOM.GETCHILDRENBYTAGNAME	DBE_XMLDOM.GETCHILDRENBYTAGNAME	GaussDB: The **ns** parameter of the DBE_XMLDOM.GETCHILDRENBYTAGNAME API does not support the asterisk (*) parameter. To obtain all attributes of a node, use the DBE_XMLDOM.GETCHILDNODES API. Oracle Database: The input parameter ***** is supported.
DBMS_XMLDOM.GETDOCUMENTELEMENT	DBE.XMLDOM.GETDOCUMENTELEMENT	-
DBMS_XMLDOM.GETFIRSTCHILD	DBE_XMLDOM.GETFIRSTCHILD	-
DBMS_XMLDOM.GETLASTCHILD	DBE_XMLDOM.GETLASTCHILD	-
DBMS_XMLDOM.GETLENGTH	DBE_XMLDOM.GETLENGTH	-
DBMS_XMLDOM.GETLOCALNAME	DBE_XMLDOM.GETLOCALNAME	-
DBMS_XMLDOM.GETNAMEDITEM	DBE_XMLDOM.GETNAMEDITEM	-
DBMS_XMLDOM.GETNEXTSIBLING	DBE_XMLDOM.GETNEXTSIBLING	-
DBMS_XMLDOM.GETNODENAME	DBE_XMLDOM.GETNODENAME	-

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Oracle Database	GaussDB	Difference
DBMS_XMLDOM.GETNODETYPE	DBE_XMLDOM.GETNODETYPE	-
DBMS_XMLDOM.GETTAGNAME	DBE_XMLDOM.GETTAGNAME	-
DBMS_XMLDOM.IMPORTNODE	DBE_XMLDOM.IMPORTNODE	-
DBMS_XMLDOM.ISNULL	DBE_XMLDOM.ISNULL	GaussDB: When the input parameter is of the DOMNODELIST type, an error is reported if the object does not exist in the hash table. Oracle Database: No error is reported.
DBMS_XMLDOM.ITEM	DBE_XMLDOM.ITEM	-
DBMS_XMLDOM.MAKENODE	DBE_XMLDOM.MAKENODE	GaussDB: This function cannot be directly returned as the function return value. Oracle Database: It is directly returned as the function return value.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Oracle Database	GaussDB	Difference
DBMS_XMLDOM.NEWDOMDOCUMENT	DBE_XMLDOM.NEWDOMDOCUMENT	• GaussDB: The size of the input parameter must be less than 1 GB. Oracle Database: The size is the same as that of the CLOB type. • Currently, external DTD parsing is not supported in GaussDB. Oracle Database: External DTD can be parsed. • GaussDB: The default character set of doc created by newdomdocument is UTF-8. Oracle Database: It is generated based on the character set of the server. • GaussDB: Each doc parsed from the same xmltype instance is independent, and the modification of the doc does not affect the xmltype. Oracle Database: Each doc parsed from the same xmltype instance is not independent but associated. • GaussDB: The **version** column supports only **1.0**. If 1.0 to 1.9 are parsed, a warning is reported but the execution is normal. For versions later than 1.9, an error is reported. Oracle Database: No error is reported. • DTD validation difference: GaussDB reports an error for **! ATTLIST to type (CHECK|check|Check) "Ch..."** because the default value **"Ch..."** is not an enumerated value in the brackets. However, Oracle Database does not report this error. An error will be reported for **<!ENTITY baidu "www.baidu.com">..... &Baidu;&writer** because the letters are case-sensitive and **Baidu** cannot correspond to **baidu**. Oracle Database: No error is reported.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Oracle Database	GaussDB	Difference
		• Namespace verification difference between GaussDB and Oracle Database: Undeclared namespace tags are parsed in GaussDB. Oracle Database: An error is reported.
DBMS_XMLDOM.SETATTRIBUTE	DBE_XMLDOM.SETATTRIBUTE	GaussDB: The attribute **key** cannot be null or an empty string. Oracle Database: The attribute **key** can be null or an empty string.
DBMS_XMLDOM.SETCHARSET	DBE_XMLDOM.SETCHARSET	Currently, the following character sets are supported in GaussDB: UTF-8, UCS-4, UCS-2, ISO-8859-1, ISO-8859-2, ISO-8859-3, ISO-8859-4, ISO-8859-5, ISO-8859-6, ISO-8859-7, ISO-8859-8, ISO-8859-9, ISO-2022-JP, Shift_JIS, EUC-JP, and ASCII. If you enter other character sets, an error is reported or garbled characters may be displayed.
DBMS_XMLDOM.SETDOCTYPE	DBE_XMLDOM.SETDOCTYPE	GaussDB: The total length of name, sysid, and pubid cannot exceed 32,500 bytes. Oracle Database: The maximum size is 32,767 bytes.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Oracle Database	GaussDB	Difference
DBMS_XMLDOM.WRITETOBUFFER	Supported, but with differences in DBE_XMLDOM.WRITETOBUFFER.	• GaussDB: The writetobuffer output buffer is limited to less than 1 GB. Oracle Database: The maximum size is 32,767 bytes. • GaussDB: The output doc will contain the XML declaration version and encoding. Oracle Database: It is not contained unless being specified by users. • GaussDB: If the input parameter is of the domnode type and the node is converted from a doc, the output node contains the XML declaration version and encoding. Oracle Database: It is not contained unless being specified by users. • GaussDB: By default, XML files are output in the UTF-8 character set. Oracle Database: It is generated based on the database character set.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Oracle Database	GaussDB	Difference
DBMS_XMLDOM.WRITETOCLOB	DBE_XMLDOM.WRITETOCLOB	• GaussDB: The writetoclob size cannot exceed 1 GB. Oracle Database: The supported size depends on the CLOB size. • GaussDB: The output doc will contain the XML declaration version and encoding. Oracle Database: It is not contained unless being specified by users. • GaussDB: If the input parameter is of the domnode type and the node is converted from a doc, the output node contains the XML declaration version and encoding. Oracle Database: It is not contained unless being specified by users. • GaussDB: By default, XML files are output in the UTF-8 character set. Oracle Database: It is generated based on the database character set.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Oracle Database	GaussDB	Difference
DBMS_XMLDOM.WRITETOFILE	DBE_XMLDOM.WRITETOFILE	• GaussDB: For an input parameter of the document type, the length of **filename** cannot exceed 255 bytes. For details about **charset**, see the dbe_xmldom.setcharset API. Oracle Database: The length of **filename** is affected by the OS and is greater than 255 bytes. • GaussDB: For an input parameter of the domnode type, the length of **filename** cannot exceed 255 bytes. For details about **charset**, see the dbe_xmldom.setcharset API. Oracle Database: The length of **filename** is affected by the OS and is greater than 255 bytes. • GaussDB: This function adds content such as indentation to format the output. The output doc will contain the XML declaration version and encoding. If the input parameter is of the domnode type and the node is converted from a doc, the output node contains the XML declaration version and encoding. Oracle Database: It is not contained unless being specified by users. • GaussDB: If newdomdocument() is used to create a doc without parameters, no error is reported when **charset** is not specified. The UTF-8 character set is used by default. Oracle Database: An error is reported. • GaussDB: The filename must be in the path created in pg_directory. The backslash (\) in the filename will be converted to a slash (/). Only one slash (/) is allowed. The file name must be in the pg_directory_name/file_name format.

Oracle Database	GaussDB	Difference
DBMS_XMLPARSER.NEWPARSER	Supported, but with differences in DBE_XMLPARSER.NEWPARSER.	The maximum number of parser objects in GaussDB is 16,777,215, and that in Oracle Database is about 100 million.
DBMS_XMLPARSER.PARSEBUFFER	Supported, but with differences in DBE_XMLPARSER.PARSEBUFFER.	• Difference in parsing columns: Only UTF-8 is supported in terms of character encoding, and **version** can only be set to **1.0**. If versions 1.0 to 1.9 are parsed, a warning appears but the execution is normal. For versions later than 1.9, an error is reported. • Namespace validation difference: Undeclared namespace tags are parsed. However, Oracle Database reports an error. • Difference in parsing XML predefined entities: **'** and **"** are parsed and escaped to **'** and **"**. However, predefined entities in Oracle Database are not escaped to characters. • DTD validation differences: – An error will be reported for **! ATTLIST to type (CHECK|check|Check) "Ch..."** because the default value **"Ch..."** is not an enumerated value in the brackets. However, Oracle Database does not report this error. – An error will be reported for **<!ENTITY baidu "www.baidu.com">..... &Baidu;&writer**, because the letters are case-sensitive and **Baidu** cannot correspond to **baidu**. However, Oracle Database does not report this error.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Oracle Database	GaussDB	Difference
DBMS_XMLPARSER.PARSECLOB	Supported, but with differences in DBE_XMLPARSER.PARSECLOB.	• PARSECLOB cannot parse CLOBs greater than or equal to 2 GB. • Difference in parsing columns: Only UTF-8 is supported in terms of character encoding, and **version** can only be set to **1.0**. If versions 1.0 to 1.9 are parsed, a warning appears but the execution is normal. For versions later than 1.9, an error is reported. • Namespace validation difference: Undeclared namespace tags are parsed. However, Oracle Database reports an error. • Difference in parsing XML predefined entities: **'** and **"** are parsed and escaped to **'** and **"**. However, predefined entities in Oracle Database are not escaped to characters. • DTD validation differences: – An error will be reported for **! ATTLIST to type (CHECK|check|Check) "Ch..."** because the default value **"Ch..."** is not an enumerated value in the brackets. However, Oracle Database does not report this error. – An error will be reported for **<!ENTITY baidu "www.baidu.com">..... &Baidu;&writer**, because the letters are case-sensitive and **Baidu** cannot correspond to **baidu**. However, Oracle Database does not report this error.

Table 3-124 DBMS_ILM compatibility

Oracle Database	GaussDB	Difference
DBMS_ILM.ADD_TO_ILM	Not supported.	-
DBMS_ILM.ARCHIVESTATENAME	Not supported.	-
DBMS_ILM.EXECUTE_ILM	DBE_ILM.EXECUTE_ILM	• The input parameter **Schema** in GaussDB corresponds to **owner** in Oracle Database. • GaussDB does not support the operation of specifying **ilm_scope** (specifying multiple objects at a time).
DBMS_ILM.EXECUTE_ILM_TASK	Not supported.	-
DBMS_ILM.PREVIEW_ILM	Not supported.	-
DBMS_ILM.REMOVE_FROM_ILM	Not supported.	-
DBMS_ILM.STOP_ILM	DBE_ILM.STOP_ILM	-

Table 3-125 DBMS_ILM_ADMIN compatibility

Oracle Database	GaussDB	Difference
DBMS_ILM_ADMIN.CLEAR_HEAT_MAP_ALL	Not supported.	-
DBMS_ILM_ADMIN.CLEAR_HEAT_MAP_TABLE	Not supported.	-

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Oracle Database	GaussDB	Difference
DBMS_ILM_ADMIN.CUSTOMIZE_ILM	DBE_ILM_ADMIN.CUSTOMIZE_ILM	The feature parameters corresponding to the values of input parameters are different. • The value of **param** in GaussDB can be **1**, **2**, **7**, **11**, **12**, **13**, **14**, or **15**. • When the value of **param** in GaussDB is **14**, the corresponding feature parameter is **WIND_DURATION** which is used to control the duration of the execution window in automatic scheduling. However, Oracle Database does not have the corresponding feature parameter.
DBMS_ILM_ADMIN.DISABLE_ILM	DBE_ILM_ADMIN.DISABLE_ILM	-
DBMS_ILM_ADMIN.ENABLE_AUTO_OPTIMIZE	Not supported.	-
DBMS_ILM_ADMIN.ENABLE_ILM	DBE_ILM_ADMIN.ENABLE_ILM	-
DBMS_ILM_ADMIN. IGNORE_AUTO_OPTIMIZE_ CRITERIA	Not supported.	-
DBMS_ILM_ADMIN.SET_HEAT_MAP_ALL	Not supported.	-
DBMS_ILM_ADMIN.SET_HEAT_MAP_START	Not supported.	-
DBMS_ILM_ADMIN.SET_HEAT_MAP_TABLE	Not supported.	-

Table 3-126 DBMS_COMPRESSION compatibility

Oracle Database	GaussDB	Difference
DBMS_COMPRESSION.GET_COMPRESSION_RATIO	DBE_COMPRESSION.GET_COMPRESSION_RATIO	• GaussDB cannot obtain compression ratios of LOBs. • For obtaining a compression ratio of a single object: – The value of the input parameter **comptype** in GaussDB can only be **1** (uncompressed) or **2** (advanced compression) while Oracle Database also supports values such as **1024** and **2048**. – The value of the input parameter **objtype** in GaussDB can only be **1** (table object) while Oracle Database also supports the value **2** (index object). – Oracle Database uses the **subset_numrows** parameter to directly determine the number of rows to be sampled (that is, the value of the parameter). GaussDB uses **sample_ratio** (sampling rate) to indirectly determine the number of rows to be sampled.
DBMS_COMPRESSION.GET_COMPRESSION_TYPE	DBE_COMPRESSION.GET_COMPRESSION_TYPE	• Oracle Database uses a row ID to specify the row whose compression type is to be obtained, while GaussDB uses a CTID to specify the row. • The value of **comptype** is returned. The value difference is the same as that of GET_COMPRESSION_RATIO. • In GaussDB, this API can be called only on DNs. For details, see **DBE_COMPRESSION**.

DBMS_HEAT_MAP.BLOCK_HEAT_MAP	Not supported.	-
DBMS_HEAT_MAP.EXTENT_HEAT_MAP	Not supported.	-
DBMS_HEAT_MAP.OBJECT_HEAT_MAP	Not supported.	-
DBMS_HEAT_MAP.SEGMENT_HEAT_MAP	Not supported.	-
DBMS_HEAT_MAP.TABLESPACE_HEAT_MAP	Not supported.	-
Not supported.	DBE_HEAT_MAP.ROW_HEAT_MAP	In GaussDB, this API can be called only on DNs. For details, see **DBE_HEAT_MAP**.

Table 3-128 DBMS_DESCRIBE compatibility

Oracle Database	GaussDB	Difference
DBMS_DESCRIBE.DESCRIBE_PROCEDURE	DBE_DESCRIBE.DESCRIBE_PROCEDURE	• The **datatype** parameter is different from Oracle Database. GaussDB returns the OID of the data type, and Oracle Database returns the ID of the data type within Oracle Database. • The **datalength**, **dataprecision**, and **scale** parameters are set to **0** because type constraints (such as number (7,2) and varchar2(20)) cannot be retained when GaussDB creates stored procedures or functions. Oracle Database can use the %type method to obtain constrained data types. • For details about the usage in GaussDB, see **DBE_DESCRIBE**.

3.3 MySQL Compatibility Description

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

3.3.1 Overview of MySQL Compatibility

Overview of M-compatible Mode

M-compatible Mode compares GaussDB in M-compatible mode (**sql_compatibility** set to **'M'**) with MySQL 5.7. Only compatibility features added later than GaussDB 505.2.0 are described. You are advised to view the specifications and restrictions of the features in *M Compatibility Developer Guide*.

GaussDB is compatible with MySQL in terms of data types, SQL functionalities, and database objects.

The execution plans, optimization, and EXPLAIN results in GaussDB are different from those in MySQL.

Due to variances in the underlying framework implementations, there are still some differences between GaussDB and MySQL.

NOTE

The underlying architecture of GaussDB is different from that of MySQL. Therefore, the performance of querying the same schemas under information_schema and m_schema may be different from that in MySQL. For details, see "Schemas" in *M Compatibility Developer Guide*. For example, the execution of the count function cannot be optimized. The time consumed by the SELECT * and SELECT COUNT(*) statements is similar.

Overview of MySQL-compatible Mode

MYSQL-compatible Mode compares GaussDB in MySQL-compatible mode (that is, when **sql_compatibility** is set to **'MYSQL'**, **b_format_version** is set to **'5.7'**, and **b_format_dev_version** is set to **'s1'**) with MySQL 5.7. Only the compatibility features added after version 503.0.0 are described.

NOTE

- The MySQL-compatible mode delivers high compatibility with MySQL in terms of syntax, data types, metadata, and protocols. The MySQL-compatible mode will not evolve because it is not compatible with the MySQL architecture.
- Only the features described in **MYSQL-compatible Mode** are compatible with MySQL. The behavior of other features remain the same as that in GaussDB.
- The implementation logic of the MySQL-compatible mode (**sql_compatibility** set to **'MYSQL'**) is similar to that of the B-compatible mode (**sql_compatibility** set to **'B'**) in centralized deployment.

GaussDB is compatible with MySQL in terms of data types, SQL functionalities, and database objects.

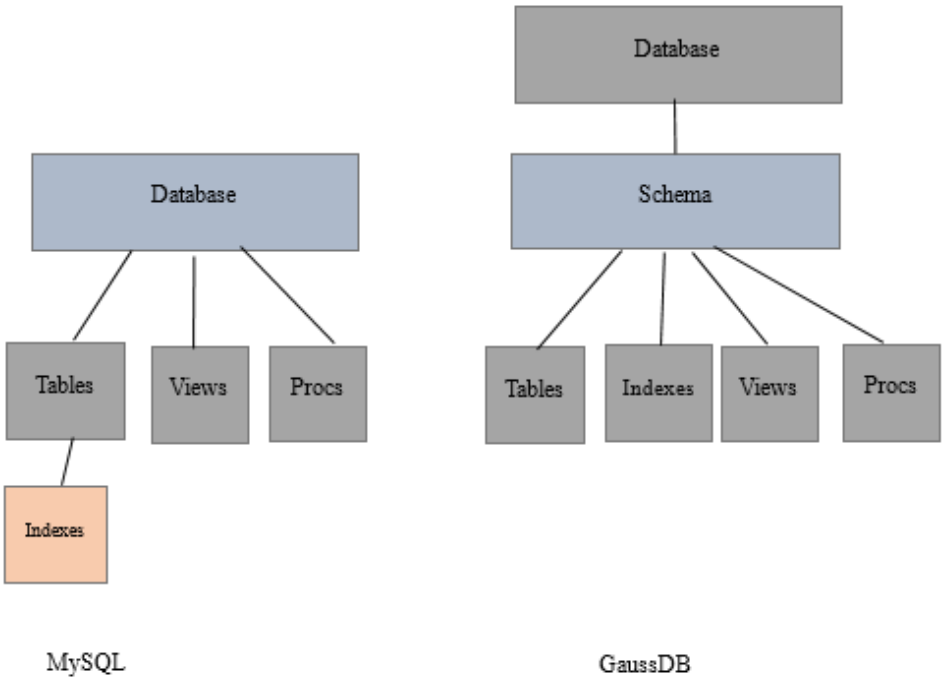
Due to variances in the underlying framework implementations, there are still some differences between GaussDB and MySQL.

Database and Schema Design

MySQL data objects include database, table, index, view, trigger, and proc. From top to bottom, each of them may correspond to multiple objects in GaussDB, as shown in **Figure 3-1**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Figure 3-1 Differences between databases and schemas in MySQL and GaussDB



- In MySQL, database and schema are synonyms. In GaussDB, a database can have multiple schemas. In this feature, each database in MySQL is mapped to a schema in GaussDB.
- In MySQL, an index belongs to a table. In GaussDB, an index belongs to a schema. As a result, an index name must be unique in a schema in GaussDB and must be unique in a table in MySQL. This difference will be retained as a current constraint.

3.3.2 M-compatible Mode

3.3.2.1 Data Types

3.3.2.1.1 Numeric Data Types

Unless otherwise specified, the precision, scale, and number of digits cannot be set to floating-point values in M-compatible mode by default. You are advised to use valid integer values.

Table 3-132 Integer types

Data Type	Differences Compared with MySQL
BOOL	Output format: The output of SELECT TRUE/FALSE in GaussDB is **t** or **f**, and that in MySQL is **1** or **0**. MySQL: The BOOL/BOOLEAN type is actually mapped to the TINYINT type.
BOOLEAN	

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Data Type	Differences Compared with MySQL
TINYINT[(M)] [UNSIGNED] [ZEROFILL] SMALLINT[(M)] [UNSIGNED] [ZEROFILL]	Input format: • MySQL: If a character string with multiple decimal points (such as "1.2.3.4.5") is entered, MySQL will misparse the character string in loose mode, throw a warning, but insert the character string into the table successfully. For example, after "1.2.3.4.5" is inserted into the table, the value is **12**. • GaussDB: If a character string with multiple decimal points (such as "1.2.3.4.5") is entered in loose mode, the characters after the second decimal point are truncated as invalid characters, a warning is thrown, but the character string is inserted into the table successfully. For example, after "1.2.3.4.5" is inserted into the table, the value is **1**. After "1.6.3.4.5" is inserted into the table, the value is **2**.
MEDIUMINT[(M)] [UNSIGNED] [ZEROFILL]	MySQL requires 3 bytes to store MEDIUMINT data. • The signed range is –8388608 to +8388607. • The unsigned range is 0 to +16777215. GaussDB is mapped to the INT type. Four bytes are required for storage. The value range is determined based on boundary values. • The signed range is –8388608 to +8388607. • The unsigned range is 0 to +16777215. For other differences, see the description below the table.
INT[(M)] [UNSIGNED] [ZEROFILL] INTEGER[(M)] [UNSIGNED] [ZEROFILL] BIGINT[(M)] [UNSIGNED] [ZEROFILL]	Input format: • MySQL: If a character string with multiple decimal points (such as "1.2.3.4.5") is entered, MySQL will misparse the character string in loose mode, throw a warning, but insert the character string into the table successfully. For example, after "1.2.3.4.5" is inserted into the table, the value is **12**. • GaussDB: If a character string with multiple decimal points (such as "1.2.3.4.5") is entered in loose mode, the characters after the second decimal point are truncated as invalid characters, a warning is thrown, but the character string is inserted into the table successfully. For example, after "1.2.3.4.5" is inserted into the table, the value is **1**. After "1.6.3.4.5" is inserted into the table, the value is **2**.

Table 3-133 Arbitrary precision types

Data Type	Differences Compared with MySQL
DECIMAL[(M[,D])] [ZEROFILL]	-
NUMERIC[(M[,D])] [ZEROFILL]	
DEC[(M[,D])] [ZEROFILL]	
FIXED[(M[,D])] [ZEROFILL]	

Table 3-134 Floating-point types

Data Type	Differences Compared with MySQL
FLOAT[(M,D)] [ZEROFILL]	The FLOAT data type does not support partitioned tables with the key partitioning policy.
FLOAT(p) [ZEROFILL]	The FLOAT data type does not support partitioned tables with the key partitioning policy.
DOUBLE[(M,D)] [ZEROFILL]	The DOUBLE data type does not support partitioned tables with the key partitioning policy.
DOUBLE PRECISION[(M,D)] [ZEROFILL]	The DOUBLE PRECISION data type does not support partitioned tables with the key partitioning policy.
REAL[(M,D)] [ZEROFILL]	The REAL data type does not support partitioned tables with the key partitioning policy.

3.3.2.1.2 Date and Time Data Types

Table 3-135 Date and Time Data Types

Data Type	Differences Compared with MySQL
DATE	GaussDB supports the DATE data type and differs from MySQL in terms of the following specifications: A backslash (\) is regarded as an escape character in both MySQL and GaussDB. However, MySQL supports \0, but GaussDB does not support \0. Therefore, GaussDB reports an error when the backslash is used as a separator and followed by 0.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Data Type	Differences Compared with MySQL
DATETIME[(fsp)]	GaussDB supports the DATETIME data type and differs from MySQL in terms of the following specifications: A backslash (\) is regarded as an escape character in both MySQL and GaussDB. However, MySQL supports \0, but GaussDB does not support \0. Therefore, GaussDB reports an error when the backslash is used as a separator and followed by 0.
TIMESTAMP[(fsp)]	GaussDB supports the TIMESTAMP data type and differs from MySQL in terms of the following specifications: ● A backslash (\) is regarded as an escape character in both MySQL and GaussDB. However, MySQL supports \0, but GaussDB does not support \0. Therefore, GaussDB reports an error when the backslash is used as a separator and followed by 0. ● MySQL supports **explicit_defaults_for_timestamp**. When **explicit_defaults_for_timestamp** is set to **off**, setting the default value of the TIMESTAMP column and inserting **NULL** are non-standard behaviors. The default value of **explicit_defaults_for_timestamp** is **off** in MySQL 5.7 and **on** in MySQL 8.0. GaussDB does not support setting **explicit_defaults_for_timestamp**. Its behavior is equivalent to MySQL with **explicit_defaults_for_timestamp** set to **on**. For details about **explicit_defaults_for_timestamp**, see the note below the table.
TIME[(fsp)]	GaussDB supports the TIME data type and differs from MySQL in terms of the following specifications: ● A backslash (\) is regarded as an escape character in both MySQL and GaussDB. However, MySQL supports \0, but GaussDB does not support \0. Therefore, GaussDB reports an error when the backslash is used as a separator and followed by 0. ● When the hour, minute, second, and nanosecond of the TIME type are 0, the sign bits of GaussDB and MySQL may be different.
YEAR[(4)]	-

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- GaussDB does not support ODBC syntax literals:

  { d 'str' }

  { t 'str' }

  { ts 'str' }
- If you specify precision for the DATETIME, TIME, or TIMESTAMP data type greater than the maximum precision supported by the data type, GaussDB truncates the precision to the maximum precision supported by the data type, whereas MySQL reports an error.
- In MySQL, when **explicit_defaults_for_timestamp** is set to **off**, the processing logic for TIMESTAMP columns is as follows:
  - If the **NULL** or **NOT NULL** attribute is not explicitly specified for a column, the **NOT NULL** attribute will be automatically added. When the **NULL** value is inserted into such a column, the **NULL** value will be replaced with the current timestamp.
  - If the **NULL** attribute is not specified for the first TIMESTAMP column in a table, the **DEFAULT CURRENT_TIMESTAMP** and **ON UPDATE CURRENT_TIMESTAMP** attributes will be automatically added to the column.
  - If the **NULL** attribute is not specified for the second and subsequent TIMESTAMP columns in a table, the **DEFAULT '0000-00-00 00:00:00'** attribute will be automatically added to the columns.
- In MySQL, when **explicit_defaults_for_timestamp** is set to **on**, the processing logic for TIMESTAMP columns is as follows:
  - When the **NULL** value is inserted into a TIMESTAMP column, the **NULL** value will not be replaced with the current timestamp.
  - If the **NULL** or **NOT NULL** attribute is not explicitly specified for a column, the **NULL** attribute will be automatically added.
  - When the **NULL** value is inserted into a column with the **NOT NULL** attribute specified, an error will be reported in strict mode, and **'0000-00-00 00:00:00'** will be inserted in loose mode.
  - The **DEFAULT CURRENT_TIMESTAMP** and **ON UPDATE CURRENT_TIMESTAMP** attributes will not be automatically added to any TIMESTAMP columns.

3.3.2.1.3 String Data Types

Table 3-136 String data types

Data Type	Differences Compared with MySQL
CHAR(M)	Input format: If a binary or hexadecimal character string is input, GaussDB outputs a hexadecimal character string, and MySQL escapes the character string based on the ASCII code table. If the character string cannot be escaped, the output is empty.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Data Type	Differences Compared with MySQL
VARCHAR(M)	Input format: • GaussDB cannot verify the length of parameters and return values of user-defined functions or the length of stored procedure parameters. However, MySQL supports their verification. • GaussDB can verify the length of temporary variables in user-defined functions and stored procedures, and an error or truncation alarm is reported in strict or loose mode. However, MySQL does not support these functions. • After a binary or hexadecimal character string is entered, GaussDB outputs a hexadecimal character string, and MySQL escapes the character string based on the ASCII code table. If the character string cannot be escaped, the output is empty.
TINYTEXT	• Input format: If a binary or hexadecimal character string is input, GaussDB outputs a hexadecimal character string, and MySQL escapes the character string based on the ASCII code table. If the character string cannot be escaped, the output is empty. • Default value: The default value cannot be set in MySQL 5.7 but can be set in GaussDB and MySQL 8.0. • Primary key: When creating a primary key, you must specify the prefix length in MySQL, but you cannot specify the prefix length in GaussDB. • Index: In MySQL, the TINYTEXT type does not support other index methods except prefix indexes. GaussDB supports these index methods.
TEXT	• Input format: If a binary or hexadecimal character string is input, GaussDB outputs a hexadecimal character string, and MySQL escapes the character string based on the ASCII code table. If the character string cannot be escaped, the output is empty. • Default value: The default value cannot be set in MySQL 5.7 but can be set in GaussDB and MySQL 8.0. • Primary key: When creating a primary key, you must specify the prefix length in MySQL, but you cannot specify the prefix length in GaussDB. • Index: In MySQL, the TEXT type does not support other index methods except prefix indexes. GaussDB supports these index methods.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Data Type	Differences Compared with MySQL
MEDIUMTEXT	• Input format: If a binary or hexadecimal character string is input, GaussDB outputs a hexadecimal character string, and MySQL escapes the character string based on the ASCII code table. If the character string cannot be escaped, the output is empty. • Default value: The default value cannot be set in MySQL 5.7 but can be set in GaussDB and MySQL 8.0. • Primary key: When creating a primary key, you must specify the prefix length in MySQL, but you cannot specify the prefix length in GaussDB. • Index: In MySQL, the MEDIUMTEXT type does not support other index methods except prefix indexes. GaussDB supports these index methods.
LONGTEXT	• Input format: If a binary or hexadecimal character string is input, GaussDB outputs a hexadecimal character string, and MySQL escapes the character string based on the ASCII code table. If the character string cannot be escaped, the output is empty. • Default value: The default value cannot be set in MySQL 5.7 but can be set in GaussDB and MySQL 8.0. • Primary key: When creating a primary key, you must specify the prefix length in MySQL, but you cannot specify the prefix length in GaussDB. • Index: In MySQL, the LONGTEXT type does not support other index methods except prefix indexes. GaussDB supports these index methods.

3.3.2.1.4 Binary Data Types

Table 3-137 Binary data types

Data Type	Differences Compared with MySQL
BINARY[(M)]	• Input format: – After a binary or hexadecimal character string is entered, GaussDB outputs a hexadecimal character string, and MySQL escapes the character string based on the ASCII code table. If the character string cannot be escaped, the output is empty. – If the length of the inserted string is less than the target length, the padding character is 0x20 in GaussDB and 0x00 in MySQL. • Character set: The default character set is the initialized character set of the database. For MySQL, the default character set is BINARY. • Output formats: – When the JDBC protocol is used, a space at the end of the BINARY type is displayed as a space, and that in MySQL is displayed as \x00. – In loose mode, if a character (such as Chinese character) of the BINARY type exceeds *n* bytes, the entire character is truncated. MySQL retains the first *n* bytes. However, garbled characters are displayed in the output. – In MySQL 8.0 and later versions, results starting with 0x are returned by default. In GaussDB, results in the format of "\x...\x...\x..." are returned. **NOTE** Due to the differences between GaussDB and MySQL in BINARY fillers and \0 truncation, GaussDB and MySQL have different performance in scenarios such as operator comparison calculation, character string-related system function calculation, index matching, and data import and export. For details about the difference scenarios, see the examples in this section.

Data Type	Differences Compared with MySQL
VARBINARY(M)	• Input format: If a binary or hexadecimal character string is input, GaussDB outputs a hexadecimal character string, and MySQL escapes the character string based on the ASCII code table. If the character string cannot be escaped, the output is empty. • Character set: The default character set is the initialized character set of the database. For MySQL, the default character set is BINARY. • Output formats: – When the JDBC protocol is used, a space at the end of the BINARY type is displayed as a space, and that in MySQL is displayed as \x00. – In MySQL 8.0 and later versions, results starting with 0x are returned by default. In GaussDB, results in the format of "\x...\x...\x..." are returned.
TINYBLOB	• Input format: – Default value: When creating a table column, you can set a default value in the syntax. However, this operation is not allowed in MySQL. – After a binary or hexadecimal character string is entered, GaussDB outputs a hexadecimal character string, and MySQL escapes the character string based on the ASCII code table. If the character string cannot be escaped, the output is empty. • Primary key: In MySQL, the TINYBLOB type does not support primary keys, but GaussDB supports. • Index: In MySQL, the TINYBLOB type does not support other index methods except prefix indexes. GaussDB supports these index methods. • Foreign key: In MySQL, the TINYTEXT type cannot be used as the referencing column or referenced column of a foreign key, but GaussDB supports this operation. • Output format: In MySQL 8.0 and later versions, results starting with 0x are returned by default. In GaussDB, results in the format of "\x...\x...\x..." are returned.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Data Type	Differences Compared with MySQL
BLOB	• Input format: – Default value: When creating a table column, you can set a default value in the syntax. However, this operation is not allowed in MySQL. – After a binary or hexadecimal character string is entered, GaussDB outputs a hexadecimal character string, and MySQL escapes the character string based on the ASCII code table. If the character string cannot be escaped, the output is empty. • Primary key: In MySQL, the BLOB type does not support primary keys, but GaussDB supports. • Index: In MySQL, the BLOB type does not support other index methods except prefix indexes. GaussDB supports these index methods. • Foreign key: In MySQL, the TINYTEXT type cannot be used as the referencing column or referenced column of a foreign key, but GaussDB supports this operation. • Output format: In MySQL 8.0 and later versions, results starting with 0x are returned by default. In GaussDB, results in the format of "\x...\x...\x..." are returned.
MEDIUMBLOB	• Input format: – Default value: When creating a table column, you can set a default value in the syntax. However, this operation is not allowed in MySQL. – After a binary or hexadecimal character string is entered, GaussDB outputs a hexadecimal character string, and MySQL escapes the character string based on the ASCII code table. If the character string cannot be escaped, the output is empty. • Primary key: In MySQL, the MEDIUMBLOB type does not support primary keys, but GaussDB supports. • Index: In MySQL, the MEDIUMBLOB type does not support other index methods except prefix indexes. GaussDB supports these index methods. • Foreign key: In MySQL, the TINYTEXT type cannot be used as the referencing column or referenced column of a foreign key, but GaussDB supports this operation. • Output format: In MySQL 8.0 and later versions, results starting with 0x are returned by default. In GaussDB, results in the format of "\x...\x...\x..." are returned.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Data Type	Differences Compared with MySQL
LONGBLOB	• Value range: a maximum of 1 GB. MySQL supports a maximum of 4 GB minus 1 byte. • Input format: – Default value: When creating a table column, you can set a default value in the syntax. However, this operation is not allowed in MySQL. – After a binary or hexadecimal character string is entered, GaussDB outputs a hexadecimal character string, and MySQL escapes the character string based on the ASCII code table. If the character string cannot be escaped, the output is empty. • Primary key: In MySQL, the LONGBLOB type does not support primary keys, but GaussDB supports. • Index: In MySQL, the LONGBLOB type does not support other index methods except prefix indexes. GaussDB supports these index methods. • Foreign key: In MySQL, the TINYTEXT type cannot be used as the referencing column or referenced column of a foreign key, but GaussDB supports this operation. • Output format: In MySQL 8.0 and later versions, results starting with 0x are returned by default. In GaussDB, results in the format of "\x...\x...\x..." are returned.
BIT[(M)]	Output formats: • All outputs are displayed as binary character strings. MySQL escapes the character string based on the ASCII code table. If the character string cannot be escaped, the output is empty. • In MySQL 8.0 and later versions, 0 is added at the beginning of each result by default. In GaussDB, 0 is not added.

Example:

```
-- GaussDB
m_db=# CREATE TABLE test(a BINARY(10)) DISTRIBUTE BY REPLICATION;
CREATE TABLE
m_db=# INSERT INTO test VALUES(0x8000);
INSERT 0 1
m_db=# SELECT hex(a) FROM test;
        hex
----------------------
 80202020202020202020
(1 row)

m_db=# SELECT * FROM test WHERE hex(a) = 80000000000000000000;
 a
---
(0 rows)

3.3.2.1.5 Attributes Supported by Data Types

Table 3-138 Attributes supported by data types

MySQL	GaussDB
NULL	Supported.
NOT NULL	Supported.
DEFAULT	Supported.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

MySQL	GaussDB
ON UPDATE	Supported.
PRIMARY KEY	Supported.
AUTO_INCREMENT	Supported.
CHARACTER SET name	Supported.
COLLATE name	Supported.
ZEROFILL	Supported.

When CREATE TABLE AS is used to create a table and default values are set for columns of the VARBINARY type, the command output of **SHOW CREATE TABLE**, **DESC**, or **\d** is different from that of MySQL. The value displayed in GaussDB is a hexadecimal value, but MySQL displays the original value.

Example:

```
m_db=# CREATE TABLE test_int(
        int_col INT
);
m_db=# CREATE TABLE test_varbinary(
        varbinary_col VARBINARY(20) default 'gauss'
) AS SELECT * FROM test_int;
m_db=# SHOW CREATE TABLE test_varbinary;
     Table      |                              Create Table
----------------+-----------------------------------------------------------------------------
 test_varbinary | SET search_path = public;                                                    +
                | CREATE TABLE test_varbinary (                                               +
                |     varbinary_col varbinary(20) DEFAULT X'6761757373',                      +
                |     int_col integer                                                         +
                | )                                                                           +
                | CHARACTER SET = "UTF8" COLLATE = "utf8mb4_general_ci"                       +
                | WITH (orientation=row, compression=no, storage_type=USTORE, segment=off);
(1 row)
m_db=# DROP TABLE test_int, test_varbinary;

mysql> CREATE TABLE test_int(
        int_col INT
);
mysql> CREATE TABLE test_varbinary(
        varbinary_col VARBINARY(20) default 'gauss'
) AS SELECT * FROM test_int;
mysql> SHOW CREATE TABLE test_varbinary;

3.3.2.1.6 Data Type Conversion

Conversion between different data types is supported. Data type conversion is involved in the following scenarios:

- The data types of operands of operators (such as comparison and arithmetic operators) are inconsistent. It is commonly used for comparison operations in query conditions or join conditions.
- The data types of arguments and parameters are inconsistent when a function is called.
- The data types of target columns to be updated by DML statements (including INSERT, UPDATE, MERGE, and REPLACE) and the defined column types are inconsistent.
- Explicit type conversion: CAST(expr AS datatype), which converts an expression to a data type.
- After the target data type of the final projection column is determined by set operations (UNION and EXCEPT), the type of the projection column in each SELECT statement is inconsistent with the target data type.
- In other expression calculation scenarios, the target data type used for comparison or final result is determined based on the data type of different expressions.
- When the operand of an operator is a function, implicit conversion may occur on the return value type of the function (such as GREATEST, LEAST, IF, NULLIF, IFNULL, ELTM, DAYNAME, UUID, ACOS, ASIN, TIMESTAMP, CONVERTTZ, and AVGFINALF). The return value type is different from that when the function is used independently.

There are three types of data type conversion differences: implicit conversion, explicit conversion, and UNION/CASE.

Differences in Double Colon Conversion

- In GaussDB, if you use double colons to convert input parameters of a function to another type, the result may be unexpected. In MySQL, double colons do not take effect.

  Example:

```
m_db=# SELECT POW("12"::VARBINARY,"12"::VARBINARY);
ERROR:  The value is out of range, and an overflow occurred.
CONTEXT:  referenced column: pow

varbinary col
m_db=# CREATE TABLE test_varbinary (
       A VARBINARY(10)
);
m_db=# INSERT INTO test_varbinary VALUES ('12');
m_db=# SELECT POW(A, A) FROM test_varbinary;
     pow
---------------
 8916100448256
(1 row)
```

Differences in Implicit Type Conversion

- In GaussDB, the conversion rules from small types to small types are used. In MySQL, the conversion rules from small types to large types and from large types to small types are used.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- Due to data type differences, some output formats of implicit conversion in GaussDB are inconsistent.
- During implicit conversion from the BIT data type to the character data type and binary data type in GaussDB, some output behaviors are inconsistent. GaussDB outputs a hexadecimal character string, and MySQL escapes the character string based on the ASCII code table. If the character string cannot be escaped, the output is empty.

  Example:

```
m_db=# CREATE TABLE bit_storage (
    VS_COL1 BIT(4),
    VS_COL2 BIT(4),
    VS_COL3 BIT(4),
    VS_COL4 BIT(4),
    VS_COL5 BIT(4),
    VS_COL6 BIT(4),
    VS_COL7 BIT(4),
    VS_COL8 BIT(4)
) DISTRIBUTE BY REPLICATION;
m_db=# CREATE TABLE string_storage (
    VS_COL1 BLOB,
    VS_COL2 TINYBLOB,
    VS_COL3 MEDIUMBLOB,
    VS_COL4 LONGBLOB,
    VS_COL5 TEXT,
    VS_COL6 TINYTEXT,
    VS_COL7 MEDIUMTEXT,
    VS_COL8 LONGTEXT
) DISTRIBUTE BY REPLICATION;
m_db=# INSERT INTO bit_storage VALUES(B'101', B'101', B'101', B'101', B'101', B'101', B'101', B'101');
m_db=# INSERT INTO string_storage SELECT * FROM bit_storage;
m_db=# SELECT * FROM string_storage;
 VS_COL1 | VS_COL2 | VS_COL3 | VS_COL4 | VS_COL5 | VS_COL6 | VS_COL7 | VS_COL8
---------+---------+---------+---------+---------+---------+---------+---------
 \x05    | \x05    | \x05    | \x05    | \x05    | \x05    | \x05    | \x05
(1 row)
m_db=# DROP TABLE bit_storage, string_storage;

mysql> CREATE TABLE bit_storage (
    VS_COL1 BIT(4),
    VS_COL2 BIT(4),
    VS_COL3 BIT(4),
    VS_COL4 BIT(4),
    VS_COL5 BIT(4),
    VS_COL6 BIT(4),
    VS_COL7 BIT(4),
    VS_COL8 BIT(4)
);
mysql> CREATE TABLE bit_storage (
    VS_COL1 BIT(4),
    VS_COL2 BIT(4),
    VS_COL3 BIT(4),
    VS_COL4 BIT(4),
    VS_COL5 BIT(4),
    VS_COL6 BIT(4),
    VS_COL7 BIT(4),
    VS_COL8 BIT(4)
);
mysql> INSERT INTO bit_storage VALUES(B'101', B'101', B'101', B'101', B'101', B'101', B'101', B'101');
mysql> INSERT INTO string_storage SELECT * FROM bit_storage;
mysql> SELECT * FROM string_storage;
+---------+---------+---------+---------+---------+---------+---------+---------+
| VS_COL1 | VS_COL2 | VS_COL3 | VS_COL4 | VS_COL5 | VS_COL6 | VS_COL7 | VS_COL8 |
+---------+---------+---------+---------+---------+---------+---------+---------+
|         |         |         |         |         |         |         |         |

```
1 row in set (0.00 sec)
mysql> DROP TABLE bit_storage, string_storage;
```

- When a binary or hexadecimal character string with 0x00 is inserted into the binary data type, GaussDB inserts part of the string and truncates the characters following 0x00. MySQL can insert the entire string.

  Example:

```
m_db=# CREATE TABLE blob_storage (
        A BLOB
) DISTRIBUTE BY REPLICATION;
m_db=# INSERT INTO blob_storage VALUES (0xBB00BB);
m_db=# SELECT hex(A) FROM blob_storage;
 hex
-----
 BB
(1 row)
m_db=# DROP TABLE blob_storage;

mysql> CREATE TABLE blob_storage (
        A BLOB
);
mysql> INSERT INTO blob_storage VALUES (0xBB00BB);
mysql> SELECT hex(A) FROM blob_storage;
+--------+
| hex(a) |
+--------+
| BB00BB |
+--------+
1 row in set (0.01 sec)
mysql> DROP TABLE blob_storage;
```

- When a binary or hexadecimal string with 0x00 in the middle is inserted into the string data type, GaussDB inserts part of the string and truncates the characters following 0x00. In MySQL, the string cannot be inserted in strict mode, and an empty string is inserted in loose mode.

  Example:

```
m_db=# CREATE TABLE text_storage (
        A TEXT
);
m_db=# INSERT INTO text_storage VALUES (b'101110110000000010111011');
m_db=# SELECT hex(A) FROM text_storage;
 hex
-----
 BB
(1 row)
m_db=# DROP TABLE text_storage;

mysql> CREATE TABLE text_storage (
        A TEXT
);
mysql> INSERT INTO text_storage VALUES (b'101110110000000010111011');
ERROR 1366 (HY000): Incorrect string value: '\xBB\x00\xBB' for column 'A' at row 1
mysql> SELECT hex(A) FROM text_storage;
Empty set (0.00 sec)
mysql> SET SQL_MODE='';
mysql> INSERT INTO text_storage VALUES (b'101110110000000010111011');
mysql> SELECT hex(A) FROM text_storage;
+--------+
| hex(A) |
+--------+
|        |
+--------+
1 row in set (0.01 sec)
mysql> DROP TABLE text_storage;
```

- The WHERE clause contains only common character strings. GaussDB returns **TRUE** for **'t'**, **'true'**, **'yes'**, **'y'**, and **'on'**, returns **FALSE** for **'no'**, **'f'**, **'off'**, **'false'**,

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

and **'n'**, and reports an error for other character strings. MySQL determines whether to return **TRUE** or **FALSE** by converting a character string to an INT1 value.

Example:

```
m_db=# CREATE TABLE test_where (
       A INT
);
m_db=# INSERT INTO test_where VALUES (1);
m_db=# SELECT * FROM test_where WHERE '111';
ERROR:  invalid input syntax for type boolean: "111"
LINE 1: SELECT * FROM test_where WHERE '111';
m_db=# DROP TABLE test_where;

mysql> CREATE TABLE test_where (
       A INT
);
mysql> INSERT INTO test_where VALUES (1);
mysql> SELECT * FROM test_where WHERE '111';
+------+
| a    |
+------+
|    1 |
+------+
1 row in set (0.01 sec)
mysql> DROP TABLE test_where;
```

- When converting strings of the YEAR type to integers, MySQL uses scientific notation, but GaussDB does not support scientific notation and truncates the strings.

  Example:

```
m_db=# CREATE TABLE test_year (
       A YEAR
);
m_db=# SET sql_mode = '';
m_db=# INSERT INTO test_year VALUES ('2E3x');
WARNING:  Data truncated for column.
LINE 1: INSERT INTO test_year VALUES ('2E3x');
                                      ^
CONTEXT:  referenced column: a
m_db=# SELECT * FROM test_year ORDER BY A;
  a
------
 2002
(1 row)
m_db=# DROP TABLE test_year;

mysql> CREATE TABLE test_year (
       A YEAR
);
mysql> INSERT INTO test_year VALUES ('2E3x');
mysql> SELECT * FROM test_year ORDER BY A;
+------+
| a    |
+------+
| 2000 |
+------+
1 row in set (0.01 sec)
mysql> DROP TABLE test_year;
```

- MySQL 5.7 has two different behaviors when converting strings to integers. The criteria for determining whether a string prefix is blank are different. As a result, the result of converting the same string to an integer varies in different scenarios. MySQL 8.0 and GaussDB use the same behavior when converting a string to an integer. Only spaces and tab characters are considered as leading spaces.

```

Differences in Explicit Type Conversion

- In GaussDB, the conversion rules for each target type are used. In MySQL, C++ polymorphic overloading functions are used, causing inconsistent behavior in nesting scenarios.

  Example:

```
m_db=# SELECT CAST(GREATEST(date'2023-01-01','2023-01-01') AS SIGNED);
WARNING:  Truncated incorrect INTEGER value: '2023-01-01'
CONTEXT:  referenced column: cast

 2023
(1 row)

mysql> SELECT CAST(GREATEST(date'2023-01-01','2023-01-01') AS SIGNED);
+-----------------------------------------------------------+
| CAST(GREATEST(date'2023-01-01','2023-01-01') AS SIGNED) |
+-----------------------------------------------------------+
|                                                  20230101 |
+-----------------------------------------------------------+
```

Differences Between UNION, CASE, and Related Structures

- In MySQL, POLYGON+NULL, POINT+NULL, and POLYGON+POINT return the GEOMETRY type. They are not involved in GaussDB and considered as errors.
- The SET and ENUM types are not supported currently and are considered as errors.
- When the constant type is aggregated with other types, the precision of the output type is the precision of other types. For example, the precision of the result of "SELECT "helloworld" UNION SELECT p FROM t;" is the precision of attribute p.
- When fixed-point constants and types without precision constraints (non-string types such as int, bool, and year, and the type of the aggregation result is the fixed-point type) are aggregated, the precision constraint is output based on the default precision 31 of fixed-point numbers.
- Differences in merge rules:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

In MySQL 5.7, if YEAR is aggregated with TINYINT, INT, MEDIUMINT, BIGINT, or BOOL, the result is of the type with UNSIGNED. In GaussDB, it is of the type without UNSIGNED. In MySQL, if BIT is aggregated with a numeric type such as INT, NUMERIC, FLOAT, or DOUBLE, the result type is VARBINARY. In GaussDB, the result type is NUMERIC for aggregation between BIT and INT or NUMERIC, DOUBLE for aggregation between BIT and FLOAT or DOUBLE, and UINT8 for aggregation between BIT and unsigned integers.

- In MySQL, BINARY and CHAR use different padding characters. BINARY is padded with '\0', and CHAR is padded with spaces. In GaussDB, BINARY and CHAR are padded with spaces.

3.3.2.2 System Functions

3.3.2.2.1 System Function Compatibility Overview

GaussDB is compatible with most MySQL system functions, but there are some differences.

Currently, some system functions in GaussDB with the same names as those in MySQL are not supported in M-compatible mode. For some of them, the message indicating that they are not supported in M-compatible mode is displayed. Other functions still retain the behaviors of the original GaussDB system functions. The behavior of functions with the same name is greatly different from that of MySQL. Therefore, you are advised to avoid using them but use only system functions in M-compatible mode.

The following table lists the functions with the same name.

Table 3-139 Same-name functions for which a message indicating that they are not supported in M-compatible mode is displayed

cot	isEmpty	mod	octet_length	overlaps
point	radians	regexp_instr	regexp_like	regexp_replace
regexp_substr	stddev_pop	stddev_samp	var_pop	var_samp
variance	-	-	-	-

Table 3-140 Same-name functions that retain the behaviors of the original GaussDB system functions in M-compatible mode

ceil	decode	encode	format	instr
position	round	stddev	row_num	-

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- MySQL allows you to add user-defined functions to the database through the loadable functions. When such functions are called, aliases can be specified in the input parameters of the functions. GaussDB does not support loadable functions. When a function is called, aliases cannot be specified for input parameters of the function.
- In M-compatible mode, system functions have the following differences:
  - The return value type of a system function is the same as that of MySQL only when the node type of the input parameter is Var (table data) or Const (constant input). In other cases (for example, the input parameter is a calculation expression or function expression), the return value type may be different from that of MySQL.
  - When an aggregate function uses an expression such as another function, operator, or SELECT clause as the input parameter (for example, **SELECT sum(abs(n)) FROM t;**), the aggregate function cannot obtain the precision passed by the input parameter expression. As a result, the precision of the function result is different from that of MySQL.
  - Calling system functions by pg_catalog.func_name() is not recommended. If the called function has input parameters in the format of syntax (such as SELECT substr('demo' from 1 for 2)), an error may occur when the function is called.
  - For a system function that supports multiple input parameters, if an input parameter is **NULL**, GaussDB does not verify the input parameters and directly returns **NULL**; MySQL verifies the input parameters that are not **NULL**. If an input parameter is invalid, the function returns **NULL** and generates a warning.
  - When MySQL calls a system function with backquotes (``), the system function is case-insensitive. When GaussDB calls a system function with backquotes (``), the function name must be in lowercase.

```
-- GaussDB
m_db=# SELECT `abs`(1);
 abs
-----
   1
(1 row)

m_db=# SELECT `Abs`(1);
ERROR:  Function Abs(integer) does not exist.
LINE 1: select `Abs`(1);
               ^
HINT:  No function matches the given name and argument types. You might need to add explicit type casts.

3.3.2.2.2 Flow Control Functions

Table 3-141 Flow control functions

Function	Differences Compared with MySQL
IF()	If the first parameter is **TRUE** and the third parameter expression contains an implicit type conversion error, or if the first parameter is **FALSE** and the second parameter expression contains an implicit type conversion error, MySQL ignores the error while GaussDB displays a type conversion error.
IFNULL()	If the first parameter is not **NULL** and the expression of the second parameter contains an implicit type conversion error, MySQL ignores the error while GaussDB reports a type conversion error.
NULLIF()	The return type of a function differs in MySQL 5.7 and MySQL 8.0. Return types are compatible with MySQL 8.0 because it is more appropriate.

3.3.2.2.3 Date and Time Functions

The date and time functions in the M-compatible mode in GaussDB, with the same behavior as MySQL, are described as follows:

- Functions may use time expressions as their input parameters.

  Time expressions (mainly including TEXT, DATETIME, DATE, and TIME) and types that can be implicitly converted to time expressions can be used as input parameters. For example, a number can be implicitly converted to text and then used as a time expression.

  However, different functions take effect in different ways. For example, the DATEDIFF function calculates only the difference between dates. Therefore, the time expression is parsed as the date type. The TIMESTAMPDIFF function parses the time expression as DATE, TIME, or DATETIME based on the **UNIT** parameter before calculating the time difference.

- The input parameters of functions may contain an invalid date.

  Generally, the supported DATE and DATETIME ranges are the same as those in MySQL. The value of DATE ranges from '0000-01-01' to '9999-12-31', and the value of DATETIME ranges from '0000-01-01 00:00:00' to '9999-12-31 23:59:59'. Although the DATE and DATETIME ranges supported by GaussDB are greater than those supported by MySQL, out-of-bounds dates are still invalid.

  In most cases, time functions report an alarm and return NULL if the input date is invalid, unless the invalid date can be converted by CAST.

Most date and time functions in the GaussDB M-compatible framework are the same as those in MySQL. **Table 3-142** lists the differences between them in terms of some functions.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 3-142 Date and time functions

Function	Differences Compared with MySQL
ADDDATE()	-
ADDTIME()	-

CONVERT_TZ()	• MySQL allows you to use 'system' to specify the system time zone. GaussDB does not support the use of 'system' to specify the time zone.
	• Before converting the time, CONVERT_TZ checks whether the time is valid and within the range of the TIMESTAMP type ('1970-01-01 00:00:01' UTC to '2038-01-19 03:14:07' UTC). If the time is valid but not within the range, the original value is returned. MySQL checks whether the value of the first input parameter converted to UTC using the second input parameter (from_tz) meets the requirements. GaussDB only checks the original value of the first input parameter.
	-- GaussDB
	m_db=# SELECT convert_tz('1970-01-01 00:00:01', '-01:00', '+01:00'),
	convert_tz('1970-01-01 00:00:01', '+01:00', '+03:00');

Function	Differences Compared with MySQL
CURDATE()	-
CURRENT_DATE() /CURRENT_DATE	-
CURRENT_TIME() /CURRENT_TIME	In MySQL, an integer input value is wrapped when it reaches **255** (maximum value of a one-byte integer value), for example, **SELECT CURRENT_TIME(257) == SELECT CURRENT_TIME(1)**. GaussDB supports only valid values ranging from 0 to 6. For other values, an error is reported.
CURRENT_TIMESTAMP()/ CURRENT_TIMESTAMP	
CURTIME()	
LOCALTIME()/ LOCALTIME	
LOCALTIMESTAMP/ LOCALTIMESTAMP()	
NOW()	
SYSDATE()	
UTC_TIME()	
UTC_TIMESTAMP()	
DATE()	-
DATE_ADD()	-
DATE_FORMAT()	-
DATE_SUB()	-
DATEDIFF()	-
DAY()	-
DAYNAME()	-
DAYOFMONTH()	-
DAYOFWEEK()	-
DAYOFYEAR()	-

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Function	Differences Compared with MySQL

EXTRACT()	• When the value of **unit** in EXTRACT(unit FROM date) is **DAY_HOUR**, **DAY_MINUTE**, DAY_SECOND, or **DAY_MICROSECOND**, GaussDB parses the date input parameter based on the datetime format, while MySQL parses the date input parameter based on the time format.
	-- GaussDB
	m_db=# SELECT EXTRACT(DAY_HOUR FROM '10:30:45') AS res;
	WARNING: Incorrect datetime value: '10:30:45'
	CONTEXT: referenced column: res
	res
	----- 	
	
	(1 row)
	
	-- MySQL
	mysql> SELECT EXTRACT(DAY_HOUR FROM '10:30:45') AS res;
	+------+
	| res |
	+------+
	| 10 |
	+------+
	1 row in set (0.00 sec)
	• In EXTRACT(unit FROM date), when the input parameter **date** is of the datetime type and the value of the input parameter **unit** is **DAY_HOUR**, **DAY_MINUTE**, **DAY_SECOND**, or **DAY_MICROSECOND**, GaussDB returns the DAY part in the result, while MySQL returns the DAY part only when **date** is the table data. For example:
	-- Behaviors in GaussDB:
	m_db=# DROP TABLE IF EXISTS t_datetime;
	DROP TABLE
	
	m_db=# CREATE TABLE t_datetime(c1 datetime(6));
	CREATE TABLE
	
	m_db=# INSERT INTO t_datetime VALUES('2023-01-27 10:11:12.400000');
	INSERT 0 1
	
	-- When the input parameter **date** is table data, the result contains the DAY part.
	m_db=# SELECT EXTRACT(DAY_MICROSECOND FROM c1) FROM t_datetime;
	extract
	---------- 	
	27101112400000
	(1 row)
	
	-- When the input parameter **date** is constant data, the result also contains the DAY part.
	m_db=# SELECT EXTRACT(DAY_MICROSECOND FROM cast('2023-01-27 10:11:12.400000' as datetime(6)));
	extract
	---------- 	
	27101112400000
	(1 row)
	
	m_db=# DROP TABLE IF EXISTS t_datetime;
	DROP TABLE

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Function	Differences Compared with MySQL

PERIOD_ADD()
PERIOD_DIFF()
	MySQL 8.0 has fixed the following issues. In the following scenarios, the behavior of this function is the same as that in MySQL 8.0 and is different from that in MySQL 5.7.
	● Processing integer overflow:
	In MySQL 5.7, the maximum value of an input parameter result of this function is **2^32=4294967296**. When the accumulated value of the month corresponding to **period** and the value of **month_number** in the input parameter or result exceed the uint32 range, integer wraparound occurs. This issue does not occur in GaussDB.
	● Performance when the value of **period** is negative:
	In MySQL 5.7, a negative year is parsed as an abnormal value instead of an error. Conversely, GaussDB reports an error when any input parameter or result is negative (for example, January 100 minus 10000 months).
	● Performance when the month in **period** exceeds the range:
	When dealing with a month greater than 12 or equal to 0, for example, **200013** or **199900**, MySQL 5.7 postpones it to the next year or views month 0 as December of the previous year. GaussDB reports an error for months beyond the range.
	● Behavior when the input parameter cannot be strictly converted to an integer:
	In MySQL 5.7, if the input parameter cannot be strictly converted to an integer, the parameter is forcibly converted to an integer. In GaussDB, an error is reported.
	-- GaussDB

3.3.2.2.4 String Functions

Table 3-143 String functions

Function	Differences Compared with MySQL
ASCII()	-
BIT_LENGTH()	-
CHAR()	If the return value contains invalid characters, GaussDB directly returns the invalid characters, while MySQL returns the truncated string in loose mode and returns NULL in strict mode.
CHAR_LENGTH()	In GaussDB, if the character set is SQL_ASCII, CHAR_LENGTH() returns the number of bytes instead of characters.
CHARACTER_LENGTH()	In GaussDB, if the character set is SQL_ASCII, CHARACTER_LENGTH() returns the number of bytes instead of characters.
CONCAT()	For binary return values, MySQL offers various options (including BINARY, VARBINARY, and BLOB), while GaussDB offers only one—LONGBLOB. For non-binary return values, MySQL offers various options (including CHAR, VARCHAR, and TEXT), while GaussDB only offers TEXT.
CONCAT_WS()	For binary return values, MySQL offers various options (including BINARY, VARBINARY, and BLOB), while GaussDB offers only one—LONGBLOB. For non-binary return values, MySQL offers various options (including CHAR, VARCHAR, and TEXT), while GaussDB only offers TEXT.
HEX()	-
LENGTH()	-

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Function	Differences Compared with MySQL
LPAD()	• The default maximum padding length in MySQL is **1398101**, and that in GaussDB is **1048576**. The maximum padding length varies depending on the character set. For example, if the character set is GBK, the default maximum padding length in GaussDB is **2097152**. • When GaussDB uses the SQL_ASCII, the server interprets byte values 0 to 127 according to the ASCII standard, and byte values 128 to 255 are regarded as characters that cannot be parsed. If the input and output of the function contain any non-ASCII data, the database cannot convert or verify non-ASCII characters. As a result, the behavior of the function is greatly different from that of MySQL. • For binary return values, MySQL offers various options (including BINARY, VARBINARY, and BLOB), while GaussDB offers only one—LONGBLOB. For non-binary return values, MySQL offers various options (including CHAR, VARCHAR, and TEXT), while GaussDB only offers TEXT.
REPEAT()	For binary return values, MySQL offers various options (including BINARY, VARBINARY, and BLOB), while GaussDB offers only one—LONGBLOB. For non-binary return values, MySQL offers various options (including CHAR, VARCHAR, and TEXT), while GaussDB only offers TEXT.
REPLACE()	For binary return values, MySQL offers various options (including BINARY, VARBINARY, and BLOB), while GaussDB offers only one—LONGBLOB. For non-binary return values, MySQL offers various options (including CHAR, VARCHAR, and TEXT), while GaussDB only offers TEXT.

3.3.2.2.5 Forced Conversion Functions

Table 3-144 Forced conversion functions

Function	Differences Compared with MySQL

CAST()	• In GaussDB, CAST(expr AS CHAR[(N)] charset_info or CAST(expr AS NCHAR[(N)]) cannot be used to convert character sets.
	• In GaussDB, you can use CAST(expr AS FLOAT[(p)]) or CAST(expr AS DOUBLE) to convert an expression to the floating-point type. MySQL 5.7 does not support this conversion.
	• When the CAST(expr AS FLOAT[(p)]) function is used, if the parameter **p** meets the condition of 0 ≤ **p** < 24, the return value type of the function is FLOAT. However, when the function is used in the CREATE TABLE/VIEW [AS] SELECT statement, the type of the corresponding column in the created table or view changes to DOUBLE. This behavior is inconsistent with that in MySQL 8.0.
	• In GaussDB, CAST(expr AS JSON) cannot be used to convert expressions to JSON.
	• In the CAST nested subquery scenario, if the subquery statement returns the FLOAT type, an accurate value is returned in GaussDB while a distorted value is returned in MySQL 5.7. The same rule applies to the BINARY function implemented using CAST.
	--GaussDB
	m_db=# CREATE TABLE sub_query_table(myfloat float) DISTRIBUTE BY REPLICATION;
	CREATE TABLE
	m_db=# INSERT INTO sub_query_table(myfloat) VALUES (1.23);
	INSERT 0 1
	m_db=# SELECT binary(SELECT myfloat FROM sub_query_table) FROM sub_query_table;
	binary
	-------- 	
	1.23
	(1 row)
	m_db=# SELECT cast((SELECT myfloat FROM sub_query_table) AS char);
	cast
	------ 	
	1.23
	(1 row)
	--MySQL 5.7
	mysql> CREATE TABLE sub_query_table(myfloat float);
	Query OK, 0 rows affected (0.02 sec)
	mysql> INSERT INTO sub_query_table(myfloat) VALUES (1.23);
	Query OK, 1 row affected (0.00 sec)
	mysql> SELECT binary(SELECT myfloat FROM sub_query_table) FROM sub_query_table;
	+---+
	| binary(SELECT myfloat FROM sub_query_table) |
	+---+
	| 1.2300000190734863 |
	+---+
	1 row in set (0.00 sec)
	mysql> SELECT cast((SELECT myfloat FROM sub_query_table) AS char);
	+---+

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Function	Differences Compared with MySQL

		cast((SELECT myfloat FROM sub_query_table) AS char) |
		+---+
		| 1.2300000190734863 |
		+---+
		1 row in set (0.00 sec)
		• When CAST(expr as CHAR[(p)]) is used, MySQL supports the specified character set, but GaussDB does not.
		-- GaussDB
		m_db=# SELECT CAST('hello' AS CHAR CHARACTER SET utf8);
		ERROR: syntax error at or near "CHARACTER"
		LINE 1: SELECT CAST('hello' AS CHAR CHARACTER SET utf8);
		^
		-- Mysql 5.7
		mysql> SELECT CAST('hello' AS CHAR CHARACTER SET utf8);
		+---+
		| CAST('hello' AS CHAR CHARACTER SET utf8) |
		+---+
		| hello |
		+---+
		1 row in set (0.00 sec)
		• When CAST(expr AS CHAR[(p)]) is used, if the returned result is an invalid character, MySQL 5.7 and GaussDB directly return the invalid character, and MySQL 8.0 returns the truncated string in loose mode and NULL in strict mode.

CONVERT()	• In GaussDB, CONVERT(expr, CHAR[(N)] charset_info or CAST(expr, NCHAR[(N)]) cannot be used to convert character sets. • In GaussDB, you can use **CONVERT(expr, FLOAT[(p)])** or **CONVERT(expr, DOUBLE)** to convert an expression to the one of the floating-point type. MySQL 5.7 does not support this conversion. • When the CONVERT(expr, FLOAT[(p)]) function is used, if the parameter **p** meets the condition of 0 ≤ **p** < 24, the return value type of the function is FLOAT. However, when the function is used in the CREATE TABLE/VIEW [AS] SELECT statement, the type of the corresponding column in the created table or view changes to DOUBLE. This behavior is inconsistent with that in MySQL 8.0. • In GaussDB, CONVERT(expr, JSON) cannot be used to convert expressions to JSON.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

3.3.2.2.6 Encryption Functions

Table 3-145 Encryption functions

Function	Differences Compared with MySQL
AES_DECRYPT()	• GaussDB does not support ECB mode, which is an insecure encryption mode, but uses CBC mode by default. • When characters are specified to be encoded in SQL_ASCII for GaussDB, the server parses byte values 0 to 127 according to the ASCII standard, and byte values 128 to 255 cannot be parsed. If the input and output of the function contain any non-ASCII characters, the database cannot convert or verify them. • The return type in MySQL is BINARY, VARBINARY, BLOB, MEDIUMBLOB, or LONGBLOB, while the return type in GaussDB is fixed to LONGBLOB.
AES_ENCRYPT()	
SHA()/SHA1()	-
SHA2()	-

3.3.2.2.7 Comparison Functions

Table 3-146 Comparison functions

Function	Differences Compared with MySQL
COALESCE()	In the union distinct scenario, the precision of the return value is different from that in MySQL. • When an implicit type conversion error occurs in the subsequent parameter expression of the first parameter that is not NULL, MySQL ignores the error, but GaussDB displays a type conversion error. When the parameter is the MIN or MAX function, the return value type is different from that in MySQL. • If all parameters passed to a function are integers and there are unsigned integer input parameters, the return value type in MySQL 5.7 is bigint. If the result is greater than the upper limit of bigint, the result will be truncated. GaussDB and MySQL 8.0 return a value of the decimal type. When the parameter is greater than the upper limit of bigint, the result is not truncated.
INTERVAL()	-

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Function	Differences Compared with MySQL
GREATEST()	• When the data types of parameters passed to a function are inconsistent, the return value type of the function is different from that in MySQL. • For binary return values, MySQL offers various options (including BINARY, VARBINARY, and BLOB), while GaussDB offers only one—LONGBLOB. For non-binary return values, MySQL offers various options (including CHAR, VARCHAR, and TEXT), while GaussDB only offers TEXT. • If the input parameter of the function contains **NULL** and the function is called after the WHERE keyword, the returned result is inconsistent with that of MySQL 5.7. This problem lies in MySQL 5.7. Since MySQL 8.0 has resolved this problem, GaussDB are consistent with MySQL 8.0.
LEAST()	
ISNULL()	-

3.3.2.2.8 Aggregate Functions

Table 3-147 Aggregate functions

Function	Differences Compared with MySQL
AVG()	• If **DISTINCT** is specified and the SQL statement contains the GROUP BY clause, GaussDB does not sort the results, while MySQL sorts the results. • In GaussDB, if the columns in **expr** are of the BIT, BOOL, or integer type and the sum of all rows exceeds the range of BIGINT, overflow occurs, reversing integers. • In GaussDB, if the type of expr is BIT, the return value type is double. In MySQL, the return value type is decimal.
BIT_AND()	-
BIT_OR()	-
BIT_XOR()	-
COUNT()	If **DISTINCT** is specified and the SQL statement contains the GROUP BY clause, GaussDB does not sort the results, while MySQL sorts the results.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Function	Differences Compared with MySQL
GROUP_CONCAT()	• If **DISTINCT** is specified and the SQL statement contains the GROUP BY clause, GaussDB does not sort the results, while MySQL sorts the results. • If GROUP_CONCAT is to return a binary type, only the BLOB type will be returned. In other cases, the TEXT type will be returned. MySQL may return the longtext, tinytext, longblob, or tinyblob type based on the return length. • In GaussDB, if the parameters in GROUP_CONCAT contain both the DISTINCT and ORDER BY syntaxes, all expressions following ORDER BY must be in the DISTINCT expression. • In GaussDB, **GROUP_CONCAT(... ORDER BY** *Number***)** does not indicate the sequence of the parameter. The number is only a constant expression, which is equivalent to no sorting. • In GaussDB, the **group_concat_max_len** parameter is used to limit the maximum return length of GROUP_CONCAT. If the return length exceeds the maximum, the length is truncated. Currently, the maximum length that can be returned is **1073741823**, which is smaller than that in MySQL.

UUID_SHORT()	-

3.3.2.3 Operators

GaussDB is compatible with most MySQL operators, but there are some differences. If not listed, the operator behavior is the native behavior of GaussDB by default. Currently, there are statements that are not supported by MySQL but supported by GaussDB. In MySQL-compatible mode, they are usually used inside the system, so they are not recommended. You are advised to combine operators according to the rules in MySQL.

Operator Differences

- NULL values in ORDER BY are sorted in different ways. MySQL sorts NULL values first, while GaussDB sorts NULL values last. In GaussDB, you can use **NULLS FIRST** and **NULLS LAST** to set the sorting sequence of NULL values.
- If ORDER BY is used, the output sequence of GaussDB is the same as that of MySQL. Without ORDER BY, GaussDB does not guarantee that the results are ordered.
- When using MySQL operators, use parentheses to ensure the combination of expressions. Otherwise, an error is reported. For example, SELECT 1 regexp ('12345' regexp '123').

  The GaussDB M-compatible operators can be successfully executed without using parentheses to strictly combine expressions.
- NULL values are displayed in different ways. MySQL displays a NULL value as **"NULL"**. GaussDB displays a NULL value as empty.

  MySQL output:

  ```
  mysql> SELECT NULL;
  +------+
  | NULL |
  +------+
  | NULL |
  +------+
  1 row in set (0.00 sec)
  ```

  GaussDB output:

  ```
  m_db=# SELECT NULL;
   ?column?
  ----------

  (1 row)
  ```
- After the operator is executed, the column names are displayed in different ways. MySQL displays a NULL value as **"NULL"**. GaussDB displays a NULL value as empty.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- When character strings are being converted to the double type but there is an invalid one, the alarm is reported differently. MySQL reports an error when there is an invalid constant character string, but does not report an error for an invalid column character string. GaussDB reports an error in either situation.
- The results returned by the comparison operator are different. For MySQL, **1** or **0** is returned. For GaussDB, **t** or **f** is returned.

Table 3-150 Operators

Operators	Differences Compared with MySQL
<>	MySQL supports indexes, but GaussDB does not.
<=>	MySQL supports indexes, but GaussDB does not support indexes, hash joins, or merge joins.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Operators	Differences Compared with MySQL

Row expressions	• MySQL supports row comparison using the <=> operator, but GaussDB does not support row comparison using the <=> operator.
	• MySQL does not support comparison between row expressions and NULL values. In GaussDB, the <, <=, =, >=, >, and <> operators can be used to compare row expressions with NULL values.
	• IS NULL or ISNULL operations on row expressions are not supported in MySQL. GaussDB supports the IS NULL operator but does not support the ISNULL operator for row expressions.
	• For operations by using operators that cannot be performed on row expressions, the error information in GaussDB is inconsistent with that in MySQL.
	GaussDB:
	m_db=# SELECT (1,2) <=> row(2,3);
	ERROR: could not determine interpretation of row comparison operator <=>
	LINE 1: SELECT (1,2) <=> row(2,3);
	^
	HINT: unsupported operator.
	m_db=# SELECT (1,2) < NULL;
	?column?
	---------- 	
	
	(1 row)
	m_db=# SELECT (1,2) <> NULL;
	?column?
	---------- 	
	(1 row)
	m_db=# SELECT (1, 2) IS NULL;
	?column?
	---------- 	
	f
	(1 row)
	m_db=# SELECT ROW(0,0) BETWEEN ROW(1,1) AND ROW(2,2);
	ERROR: Unsupport type.
	MySQL:
	mysql> SELECT (1,2) <=> row(2,3);
	+--------------------+
	| (1,2) <=> row(2,3) |
	+--------------------+
	| 0 |
	+--------------------+
	1 row in set (0.00 sec)
	
	mysql> SELECT (1,2) < NULL;
	ERROR 1241 (21000): Operand should contain 2 column(s)
	mysql> SELECT (1,2) <> NULL;
	ERROR 1241 (21000): Operand should contain 2 column(s)
	mysql> SELECT (1, 2) IS NULL;
	ERROR 1241 (21000): Operand should contain 1 column(s)
	mysql> SELECT ISNULL((1, 2));
	ERROR 1241 (21000): Operand should contain 1 column(s)
	mysql> SELECT NULL BETWEEN NULL AND ROW(2,2);
	ERROR 1241 (21000): Operand should contain 1 column(s)

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Operators	Differences Compared with MySQL
--	MySQL indicates that an operand is negated twice and the result is equal to the original operand. GaussDB indicates a comment.
!!	MySQL: The meaning of !! is the same as that of !, indicating NOT. GaussDB: ! indicates NOT. If there is a space between two exclamation marks, it indicates double NOT (! !). If there is no space between them, it indicates factorial (!!). **NOTE** • In GaussDB, when both factorial (!!) and NOT (!) are used, a space must be added between them. Otherwise, an error is reported. • In GaussDB, when multiple NOT operations are required, use a space between exclamation marks (! !).

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Operators	Differences Compared with MySQL
[NOT] REGEXP	• GaussDB and MySQL support different metacharacters in regular expressions. For example, GaussDB allows \d to indicate digits, \w to indicate letters, digits, and underscores (_), and \s to indicate spaces. However, MySQL does not support these metacharacters and considers them as normal character strings. • In GaussDB, "\b" can match "\\b", but in MySQL, the matching will fail. • In GaussDB, a backslash (\) indicates an escape character. In MySQL, two backslashes (\\) are used. • MySQL does not support two operators to be used together. • If the input parameter of the pattern string is invalid with only the right parenthesis ()), GaussDB and MySQL 5.7 will report an error, but MySQL 8.0 will not. • In the rule of matching the de|abc sequence with de or abc, when there are empty values on the left and right of the pipe symbol (|), MySQL 5.7 will report an error, but GaussDB and MySQL 8.0 will not. • The regular expression of the tab character "\t" can match the character class [:blank:] in GaussDB and MySQL 8.0 but cannot in MySQL 5.7. • GaussDB supports non-greedy pattern matching. That is, the number of matching characters is as small as possible. A question mark (?) is added after some special characters, for example, ?? *? +? {n}? {n,}? {n,m}? MySQL 5.7 does not support non-greedy pattern matching, and the error message "Got error 'repetition-operator operand invalid' from regexp" is displayed. MySQL 8.0 already supports this function. • In the BINARY character set, the TEXT and BLOB types are converted to the BYTEA type. The REGEXP operator does not support the BYTEA type. Therefore, the two types cannot be matched.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Operators	Differences Compared with MySQL
LIKE	• MySQL: The left operand of LIKE can only be an expression of a bitwise or arithmetic operation, or expression consisting of parentheses. The right operand of LIKE can only be an expression consisting of unary operators (excluding NOT) or parentheses. GaussDB: The left and right operands of LIKE can be any expression. • When the right operand of LIKE uses the setFloat API of JDBC for binding parameters and JDBC uses the PBE mode for execution, the query results in GaussDB and MySQL are different. However, in an equivalent scenario where the parameter bound by setFloat is replaced with float data in the table, the behavior of GaussDB remains consistent, while the behavior of MySQL is inconsistent.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Operators	Differences Compared with MySQL

[NOT] BETWEEN AND	MySQL: [NOT] BETWEEN AND is nested from right to left. The first and second operands of [NOT] BETWEEN AND can only be expressions of bitwise or arithmetic operations, or expressions consisting of parentheses.
	GaussDB: [NOT] BETWEEN AND is nested from left to right. The first and second operands of [NOT] BETWEEN AND can be any expression.
	In some special scenarios, for example, the expression contains the repeat() function, the result of [NOT] BETWEEN AND may be different from that of [NOT] (>= AND <=) in MySQL. However, GaussDB ensures that the result of [NOT] BETWEEN AND is consistent with that of [NOT] (>= AND <=).
	-- GaussDB: The behavior of BETWEEN AND is the same as that of (>= AND <=).
	m_db=# CREATE TABLE test_between(c0 YEAR);
	CREATE TABLE
	m_db=# INSERT INTO test_between(c0) VALUES('1963');
	INSERT 0 1
	m_db=# SELECT (''<>'Lt') BETWEEN '' AND c0 AS ref0 FROM test_between;
	 ref0
	------ 	
	 f
	(1 row)
	
	m_db=# SELECT (''<>'Lt') >= '' AND (''<>'Lt') <= c0 AS ref0 FROM test_between;
	 ref0

Operators	Differences Compared with MySQL
IN	MySQL: The left operand of IN can only be an expression of a bitwise or arithmetic operation, or expression consisting of parentheses. GaussDB: The left operand of IN can be any expression.
!	MySQL: The operand of ! can only be an expression consisting of unary operators (excluding NOT) or parentheses. GaussDB: The operand of ! can be any expression.
#	MySQL supports the comment tag (#), but GaussDB does not.
BINARY	Expressions (including some functions and operators) supported by GaussDB are different from those supported by MySQL. For GaussDB-specific expressions such as "~" and "IS DISTINCT FROM", due to the higher priority of the BINARY keyword, when BINARY expr is used, BINARY is combined with the left parameters of "~" and "IS DISTINCT FROM" first. As a result, an error is reported.
Negation (-)	If the number of consecutive negation times exceeds 1, GaussDB identifies the negations as comments. As a result, it returns results different from MySQL.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Operators	Differences Compared with MySQL

XOR, |, & , < , > , <=, >=, =, and !=	The execution mechanism of MySQL is as follows: After the left operand is executed, the system checks whether the result is empty and then determines whether to execute the right operand.
	As for the execution mechanism of GaussDB, after the left and right operands are executed, the system checks whether the result is empty.
	If the result of the left operand is empty and an error is reported during the execution of the right operand, MySQL does not report an error but directly returns an error. GaussDB reports an error during the execution.
	Behavior in MySQL:
	`mysql> SELECT version();`
	`+-----------------+`
	`| version() |`
	`+-----------------+`
	`| 5.7.44-debug-log |`
	`+-----------------+`
	`1 row in set (0.00 sec)`
	
	`mysql> dROP TABLE IF EXISTS data_type_table;`
	`Query OK, 0 rows affected (0.02 sec)`
	
	`mysql> CREATE TABLE data_type_table (`
	`-> MyBool BOOL,`
	`-> MyBinary BINARY(10),`
	`-> MyYear YEAR`
	`-> );`
	`Query OK, 0 rows affected (0.02 sec)`
	
	`mysql> INSERT INTO data_type_table VALUES (TRUE, 0x1234567890, '2021');`
	`Query OK, 1 row affected (0.00 sec)`
	
	`mysql> SELECT (MyBool % MyBinary) | (MyBool - MyYear) FROM data_type_table;`
	`+----------------------------------------+`
	`| (MyBool % MyBinary) | (MyBool - MyYear) |`
	`+----------------------------------------+`
	`| NULL |`
	`+----------------------------------------+`
	`1 row in set, 2 warnings (0.00 sec)`
	Behavior in GaussDB:
	`m_db=# DROP TABLE IF EXISTS data_type_table;`
	`DROP TABLE`
	`m_db=# CREATE TABLE data_type_table (`
	`m_db(# MyBool BOOL,`
	`m_db(# MyBinary BINARY(10),`
	`m_db(# MyYear YEAR`
	`m_db(# );`
	`CREATE TABLE`
	`m_db=# INSERT INTO data_type_table VALUES (TRUE, 0x1234567890, '2021');`
	`INSERT 0 1`
	`m_db=# SELECT (MyBool % MyBinary) | (MyBool - MyYear) FROM data_type_table;`
	`WARNING: Truncated incorrect double value: '4Vx '`
	`CONTEXT: referenced column: (MyBool % MyBinary) | (MyBool - MyYear)`
	`WARNING: division by zero`
	`CONTEXT: referenced column: (MyBool % MyBinary) | (MyBool - MyYear)`
	`ERROR: Bigint is out of range.`
	`CONTEXT: referenced column: (MyBool % MyBinary) | (MyBool - MyYear)`

Table 3-151 Differences in operator combinations

Example of Operator Combination	MySQL	GaussDB	Description
SELECT 1 LIKE 3 & 1;	Not supported	Supported	The right operand of LIKE cannot be an expression consisting of bitwise operators.
SELECT 1 LIKE 1 +1;	Not supported	Supported	The right operand of LIKE cannot be an expression consisting of arithmetic operators.
SELECT 1 LIKE NOT 0;	Not supported	Supported	The right operand of LIKE can only be an expression consisting of unary operators (such as +, -, or ! but except NOT) or parentheses.
SELECT 1 BETWEEN 1 AND 2 BETWEEN 2 AND 3;	Right-to-left combination	Left-to-right combination	You are advised to add parentheses to specify the calculation priority to prevent result deviation caused by sequence differences.
SELECT 2 BETWEEN 1=1 AND 3;	Not supported	Supported	The second operand of BETWEEN cannot be an expression consisting of comparison operators.
SELECT 0 LIKE 0 BETWEEN 1 AND 2;	Not supported	Supported	The first operand of BETWEEN cannot be an expression consisting of pattern matching operators.
SELECT 1 IN (1) BETWEEN 0 AND 3;	Not supported	Supported	The first operand of BETWEEN cannot be an expression consisting of IN operators.
SELECT 1 IN (1) IN (1);	Not supported	Supported	The second left operand of the IN expression cannot be an expression consisting of INs.
SELECT ! NOT 1;	Not supported	Supported	The operand of ! can only be an expression consisting of unary operators (such as +, -, or ! but except NOT) or parentheses.

Index Differences

- Currently, GaussDB supports only UB-tree and B-tree indexes.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- For fuzzy match (LIKE operator), the default index created can be used in MySQL, but cannot be used in GaussDB. You need to use the following syntax to specify **opclass** to, for example, **text_pattern_ops**, so that LIKE operators can be used as indexes:
  ```
  CREATE INDEX indexname ON tablename(col [opclass]);
  ```
- In the B-tree/UB-tree index scenario, the original logic of the native GaussDB is retained. That is, index scan supports comparison of types in the same operator family, but does not support other index types currently.
- When GaussDB JDBC is used to connect to the database, the YEAR type of GaussDB cannot use indexes in the PBE scenario that contains bind parameters.
- When some functions are nested in operator expressions, implicit conversion occurs on the return value type. If the return value type of a function is converted to a type different from that of the expression index, index scan cannot be used.
- In the operation scenarios involving index column type and constant type, the conditions that indexes of a WHERE clause are supported in GaussDB are different from those in MySQL. For details, see **Table 3-152**. For example, GaussDB does not support indexes in the following statement:
  ```
  CREATE TABLE t(_int int);
  CREATE INDEX idx ON t(_int) USING BTREE;
  SELECT * FROM t WHERE _int > 2.0;
  ```

  NOTE

  In the operation scenarios involving index column type and constant type in the WHERE clause, you can use the cast function to explicitly convert the constant type to the column type for indexing.

  ```
  SELECT * FROM t WHERE _int > cast(2.0 AS signed);
  ```

Table 3-152 Differences in index support

Index Column Type	Constant Type	Supported by GaussDB	Supported by MySQL
Integer	Integer	Yes	Yes
Floating-point	Floating-point	Yes	Yes
Fixed-point	Fixed-point	Yes	Yes
String	String	Yes	Yes
Binary	Binary	Yes	Yes
Time with date	Time with date	Yes	Yes
TIME	TIME	Yes	Yes
Time with date	Type that can be converted to time type with date (for example, integers such as 20231130)	Yes	Yes

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Index Column Type	Constant Type	Supported by GaussDB	Supported by MySQL
Time with date	TIME	Yes	Yes
TIME	Constants that can be converted to the TIME type (for example, integers such as 203008)	Yes	Yes
Floating-point	Integer	Yes	Yes
Floating-point	Fixed-point	Yes	Yes
Floating-point	String	Yes	Yes
Floating-point	Binary	Yes	Yes
Floating-point	Time with date	Yes	Yes
Floating-point	TIME	Yes	Yes
Fixed-point	Integer	Yes	Yes
String	Time with date	Yes	No
String	TIME	Yes	No
Binary	String	Yes	Yes
Binary	Time with date	Yes	No
Binary	TIME	Yes	No
Integer	Floating-point	No	Yes
Integer	Fixed-point	No	Yes
Integer	String	No	Yes
Integer	Binary	No	Yes
Integer	Time with date	No	Yes
Integer	TIME	No	Yes
Fixed-point	Floating-point	No	Yes
Fixed-point	String	No	Yes
Fixed-point	Binary	No	Yes
Fixed-point	Time with date	No	Yes
Fixed-point	TIME	No	Yes
String	Binary	No	Yes

Table 3-153 Whether index use is supported

Index Column Type	Constant Type	Use Index or Not in GaussDB	Use Index or Not in MySQL
String	Integer	No	No
String	Floating-point	No	No
String	Fixed-point	No	No
Binary	Integer	No	No
Binary	Floating-point	No	No
Binary	Fixed-point	No	No
Time with date	Character string (that cannot be converted to the time type with date)	No	No
Time with date	Binary (that cannot be converted to the time type with date)	No	No
TIME	Floating-point (that cannot be converted to the TIME type)	No	No
TIME	Fixed-point (that cannot be converted to the TIME type)	No	No
BIT	String	No	No

3.3.2.4 Character Sets

GaussDB allows you to specify the following character sets for databases, schemas, tables, or columns.

Table 3-154 Character sets

MySQL	GaussDB
utf8mb4	Supported
utf8	Supported
gbk	Supported

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

MySQL	GaussDB
gb18030	Supported
binary	Supported

NOTE

- GaussDB regards utf8 and utf8mb4 as the same character set. The maximum length of the code is 4 bytes. If the current character set is utf8 and the collation is set to **utf8mb4_bin**, **utf8mb4_general_ci**, **utf8mb4_unicode_ci**, or **utf8mb4_0900_ai_ci** (for example, by running **SELECT _utf8'a' collate utf8mb4_bin**), MySQL reports an error but GaussDB does not. The difference also exists when the character set is **utf8mb4** and the collation is set to **utf8_bin**, **utf8_general_ci**, or **utf8_unicode_ci**.
- Lexical and syntax parsing is performed based on the byte stream. When a multi-byte character contains the same encoding as the symbols such as '\', '\'' and '\\'. The behavior is inconsistent with that of MySQL. You are advised to disable the escape character processing to avoid this problem.
- GaussDB does not strictly verify the encoding logic of invalid characters that do not belong to the current character set. In strict mode, some character functions may allow such invalid characters to be successfully entered. Conversely, MySQL will report an error upon detecting such characters. In loose mode, GaussDB truncates such invalid characters and then inserts the value, which is the same as the behavior of MySQL. The strict and loose modes are determined by the **strict_trans_tables** configuration item of the GUC parameter **sql_mode**.
- The logic for converting between character sets in GaussDB is different from that in MySQL. When the binary character set is used together with other character sets, the transcoding process may cause inconsistent behavior. Therefore, when the binary character set is used, it is recommended that the character set-related parameters such as **client_encoding**, **server_encoding**, and **character_set_connection** be consistent and only characters within the ASCII range be entered.

3.3.2.5 Collation Rules

GaussDB allows you to specify the following collation rules for schemas, tables, or columns.

Table 3-155 Collation rules

MySQL	GaussDB
binary	Supported
gb18030_bin	Supported
gb18030_chinese_ci	Supported
gbk_bin	Supported
gbk_chinese_ci	Supported
utf8_bin	Supported
utf8_general_ci	Supported

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

MySQL	GaussDB
utf8_unicode_ci	Supported
utf8mb4_0900_ai_ci	Supported
utf8mb4_bin	Supported
utf8mb4_general_ci	Supported
utf8mb4_unicode_ci	Supported

NOTE

Differences in collation rules:

- Currently, collation rules can only be specified for the character string type and some binary types. Other types do not support specifying collation rules. You can check the **typcollation** attribute of a type in the pg_type system catalog. If it is not **0**, the type supports the collation. In MySQL, collation can be specified for all types; however, specifying collation rules for types other than character strings and binary types has no practical meaning.
- The current collation rules (except binary) can be specified only when the corresponding character set is the same as the database-level character set. In GaussDB, the character set must be the same as the database character set, and multiple character sets cannot be used together in a table.
- The default collation of the utf8mb4 character set is utf8mb4_general_ci, which is the same as that in MySQL 5.7.

3.3.2.6 Transactions

GaussDB is compatible with MySQL transactions, but there are some differences. This section describes transaction-related differences in GaussDB M-compatible databases.

Default Transaction Isolation Levels

The default isolation level of an M-compatible database is READ COMMITTED, and that of MySQL is REPEATABLE READ.

```
-- View the current transaction isolation level.
m_db=# SHOW transaction_isolation;
```

Sub-transactions

In an M-compatible database, SAVEPOINT is used to create a savepoint (sub-transaction) in the current transaction, and ROLLBACK TO SAVEPOINT is used to roll back to a savepoint (sub-transaction). After the sub-transaction is rolled back, the parent transaction can continue to run, the rollback of a sub-transaction does not affect the transaction status of the parent transaction.

No savepoint (sub-transaction) can be created in MySQL.

Nested Transactions

A nested transaction refers to a new transaction started in a transaction block.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

In an M-compatible database, if a new transaction is started in a normal transaction block, a warning is displayed indicating that an ongoing transaction exists and the start command is ignored. If a new transaction is started in an abnormal transaction block, an error is reported. The transaction can be executed only after **ROLLBACK** or **COMMIT** is executed. If **ROLLBACK** or **COMMIT** is executed, the previous statement is rolled back.

In MySQL, before a new transaction is started in a normal transaction block, the previous one must be committed. If a new transaction is started in an abnormal transaction block, the error is ignored and the previous correct statement is committed.

```
-- In an M-compatible database, if a new transaction is started in a normal transaction block, a warning is generated and the transaction is ignored.
m_db=# DROP TABLE IF EXISTS test_t;
m_db=# CREATE TABLE test_t(a int, b int);
m_db=# BEGIN;
m_db=# INSERT INTO test_t values(1, 2);
m_db=# BEGIN; -- The warning "There is already a transaction in progress" is displayed.
m_db=# SELECT * FROM test_t ORDER BY 1;
m_db=# COMMIT;

-- In an M-compatible database, if a new transaction is started in an abnormal transaction block, an error is reported. The transaction can be executed only after ROLLBACK or COMMIT is executed.
m_db=# BEGIN;
m_db=# ERROR sql; -- Error statement.
m_db=# BEGIN; -- An error is reported.
m_db=# COMMIT; -- It can be executed only after ROLLBACK/COMMIT is executed.
```

Statements Committed Implicitly

An M-compatible database uses GaussDB for storage and inherits the GaussDB transaction mechanism. If a DDL or DCL statement is executed in a transaction, the transaction is not automatically committed.

In MySQL, if DDL, DCL, management-related, or lock-related statements are executed, the transaction is automatically committed.

```
-- In M-compatible database, table creation and GUC parameter setting support rollback.
m_db=# DROP TABLE IF EXISTS test_table_rollback;
m_db=# BEGIN;
m_db=# CREATE TABLE test_table_rollback(a int, b int);
m_db=# \d test_table_rollback;
m_db=# ROLLBACK;
m_db=# \d test_table_rollback; -- This table does not exist.
```

Differences in SET TRANSACTION

In an M-compatible database, if SET TRANSACTION is used to set the isolation level or transaction access mode for multiple times, only the last setting takes effect. Transaction features can be separated by spaces or commas (,).

In MySQL, SET TRANSACTION cannot be used to set the isolation level or transaction access mode for multiple times. Transaction features can only be separated by commas (,).

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 3-156 Differences in SET TRANSACTION

Syntax	Description	Difference
SET TRANSACTION	Sets transactions.	In an M-compatible database, SET TRANSACTION takes effect in session-level transactions. In MySQL, SET TRANSACTION takes effect in the next transaction.
SET SESSION TRANSACTION	Sets session-level transactions.	-
SET GLOBAL TRANSACTION	Sets global session-level transactions. This feature applies to subsequent sessions and has no impact on the current session.	In an M-compatible database, GLOBAL takes effect in global session-level transactions and is applicable only to the current database instance. In MySQL, this feature takes effect in all databases.

```
-- SET TRANSACTION takes effect in session-level transactions.
m_db=# SET TRANSACTION ISOLATION LEVEL READ COMMITTED READ WRITE;
m_db=# SHOW transaction_isolation;
m_db=# SHOW transaction_read_only;
-- In an M-compatible database, if the isolation level or transaction access mode is set for multiple times, only the last setting takes effect.
m_db=# SET SESSION TRANSACTION ISOLATION LEVEL READ COMMITTED, ISOLATION LEVEL REPEATABLE READ, READ WRITE, READ ONLY;
m_db=# SHOW transaction_isolation; -- repeatable read
m_db=# SHOW transaction_read_only; -- on
```

Differences in START TRANSACTION

In an M-compatible database, when START TRANSACTION is used to start a transaction, the isolation level can be set. If the isolation level or transaction access mode is set for multiple times, only the last setting takes effect. In the current version, consistency snapshot cannot be enabled immediately. Transaction features can be separated by spaces or commas (,).

In MySQL, if START TRANSACTION is used to start a transaction, the isolation level cannot be set and the transaction access mode cannot be set for multiple times. Transaction features can only be separated by commas (,).

```
-- Start a transaction and set the isolation level.
m_db=# START TRANSACTION ISOLATION LEVEL READ COMMITTED;
m_db=# COMMIT;
-- Set the access mode for multiple times.
m_db=# START TRANSACTION READ ONLY, READ WRITE;
m_db=# COMMIT;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Transaction-related GUC Parameters

Table 3-157 Differences in transaction-related GUC parameters

GUC Parameter	Description	Difference
autocommit	Sets the automatic transaction commit mode.	-
transaction_isolation	Sets the isolation level of the current transaction in an M-compatible database. Sets the isolation level of a session-level transaction in MySQL.	• In GaussDB, you can only change the isolation level of the current transaction by running the **SET transaction_isolation =** *value* command. To change the session-level isolation level, use **default_transaction_isolation**. In MySQL, you can run the **SET** command to change the isolation level of a session-level transaction. • The supported range is different. MySQL supports the following isolation levels, which are case-insensitive but space-sensitive: – READ COMMITTED – READ UNCOMMITTED – REPEATABLE READ – SERIALIZABLE GaussDB supports the following isolation levels, which are case-sensitive and space-sensitive: – read committed – read uncommitted (It can be set, but **read committed** takes effect.) – repeatable read – serializable (It can be set, but **repeatable read** takes effect.) – default (same as the default isolation level in the session) – If **m_format_dev_version** is set to **'s2'**, the isolation levels of MySQL can be set. • In GaussDB, the value of **transaction_isolation** of a new transaction is initialized to the value of **default_transaction_isolation**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

GUC Parameter	Description	Difference
tx_isolation	Sets the transaction isolation level. **tx_isolation** and **transaction_isolation** are synonyms.	This parameter does not support query or modification in an M-compatible database. If necessary, you are advised to use **transaction_isolation** for query.
default_transaction_isolation	Sets the transaction isolation level.	In an M-compatible database, the **SET** command is used to change the transaction isolation level for a session. MySQL does not support this system parameter.
transaction_read_only	Sets the access mode of a transaction.	• In an M-compatible database, only the access mode of the current transaction can be changed by using the **SET** command. If you want to change the access mode of a session-level transaction, you can use **default_transaction_read_only**. In MySQL, you can run the **SET** command to change the isolation level of a session-level transaction. • In GaussDB, the value of **transaction_read_only** of a new transaction is initialized to the value of **default_transaction_read_only**.
tx_read_only	Sets the access mode of a transaction. **tx_read_only** and **transaction_read_only** are synonyms.	This parameter does not support query or modification in an M-compatible database. If necessary, you are advised to use **transaction_read_only** for query.
default_transaction_read_only	Sets the access mode of a transaction.	In an M-compatible database, the **SET** command is used to change the access mode of a session-level transaction. MySQL does not support this system parameter.

3.3.2.7 SQL

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

3.3.2.7.1 SQL Compatibility Overview

GaussDB is compatible with most MySQL syntax, but there are some differences. This section describes the MySQL syntax supported by GaussDB.

- Some keywords can be used as identifiers in MySQL, but cannot or are restricted to be identifiers in M-compatible mode, as listed in **Table 3-158**.

  Table 3-158 Restricted identifiers

Keyword Type	Keyword	Restriction
Reserved (Type or function is allowed.)	COLLATION and COMPACT	They cannot be used as identifiers in other databases except for functions and variables.
Non-reserved (Type or function is not allowed.)	BIT, BOOLEAN, COALESCE, DATE, NATIONAL, NCHAR, NONE, NUMBER, TEXT, TIME, TIMESTAMP, and TIMESTAMPDIFF	They cannot be used as identifiers for functions or variables.
Reserved	ANY, ARRAY, BUCKETS, DO, END, LESS, MODIFY, OFFSET, ONLY, RETURNING, SOME, and USER	They cannot be used as identifiers in any database.

- The GaussDB optimizer is different from the MySQL optimizer. Due to the difference in the execution plans generated by optimizers, the GaussDB behavior may be inconsistent with the MySQL behavior, but it does not affect the service data result.

  For example, in the following scenario involving WHERE comparison, GaussDB calls the cast function when calculating **col1** and using **col1**; therefore, two WARNING records are generated. MySQL calls the cast function when calculating **col1** and then directly uses the calculated value for comparison; therefore, only one WARNING record is generated.

```
-- Behavior in GaussDB:
m_db=# SELECT * FROM (SELECT cast('abc' AS decimal) AS col1) t1 WHERE col1=0;
WARNING:  The DECIMAL value 'abc' is incorrect.
WARNING:  The DECIMAL value 'abc' is incorrect.
CONTEXT:  referenced column: col1
 col1
------
    0
(1 row)

m_db=# EXPLAIN VERBOSE SELECT * FROM (SELECT cast('abc' AS decimal) AS col1) t1 WHERE col1=0;
WARNING:  The DECIMAL value 'abc' is incorrect.
WARNING:  The DECIMAL value 'abc' is incorrect.
CONTEXT:  referenced column: col1
                QUERY PLAN
------------------------------------------
 Result  (cost=0.00..0.01 rows=1 width=0)
   Output: 0::decimal
(2 rows)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
-- Behavior in MySQL:
mysql>  SELECT * FROM (SELECT cast('abc' AS decimal) AS col1) t1 WHERE col1=0;
+------+
| col1 |
+------+
|    0 |
+------+
1 row in set, 1 warning (0.00 sec)

mysql> SHOW warnings;
+---------+------+----------------------------------------+
| Level   | Code | Message                                |
+---------+------+----------------------------------------+
| Warning | 1292 | Truncated incorrect DECIMAL value: 'abc' |
+---------+------+----------------------------------------+
1 row in set (0.00 sec)

mysql> EXPLAIN SELECT * FROM (SELECT cast('abc' AS decimal) AS col1) t1 WHERE col1=0;
+----+-------------+------------+------------+--------+---------------+------+---------+------+------+----------
+----------------+
| id | select_type | table      | partitions | type   | possible_keys | key  | key_len | ref  | rows | filtered |
Extra          |
+----+-------------+------------+------------+--------+---------------+------+---------+------+------+----------
+----------------+
|  1 | PRIMARY     | <derived2> | NULL       | system | NULL          | NULL | NULL    | NULL |    1 |
100.00 | NULL           |
|  2 | DERIVED     | NULL       | NULL       | NULL   | NULL          | NULL | NULL    | NULL | NULL |
NULL | No tables used |
+----+-------------+------------+------------+--------+---------------+------+---------+------+------+----------
+----------------+
2 rows in set, 2 warnings (0.01 sec)

mysql> SHOW warnings;
+---------+------+------------------------------------------------------------------+
| Level   | Code | Message                                                          |
+---------+------+------------------------------------------------------------------+
| Warning | 1292 | Truncated incorrect DECIMAL value: 'abc'                         |
| Note    | 1003 | /* select#1 */ select '0' AS `col1` from dual where ('0' = 0) |
+---------+------+------------------------------------------------------------------+
2 rows in set (0.00 sec)
```

3.3.2.7.2 Keywords

The constraint differences are as follows:

- If a keyword is a reserved one in M-compatible mode but non-reserved in MySQL, it cannot be a table name, column name, column alias, AS column alias, AS table alias, table alias, function name, or variable name in M-compatible mode, but can be any of these names or aliases in MySQL.
- If a keyword is a non-reserved one in M-compatible mode but reserved in MySQL, it can be a table name, column name, column alias, AS column alias, AS table alias, table alias, function name, or variable name in M-compatible mode, but cannot be any of these names or aliases in MySQL.
- If a keyword is a reserved one (function or type) both in M-compatible mode and MySQL, it can be a column alias, AS column alias, function name, or variable name in M-compatible mode, but cannot be any of these names or aliases in MySQL.
- If a keyword is a reserved one (function or type) in M-compatible mode but non-reserved in MySQL, it cannot be a table name, column name, AS table alias, or table alias in M-compatible mode, but can be one of these names or aliases in MySQL.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- If a keyword is a non-reserved one (excluding function and type) in M-compatible mode but reserved in MySQL, it can be a table name, column name, column alias, AS column alias, AS table alias, table alias, function name, or variable name in M-compatible mode, but cannot be any of these names or aliases in MySQL.
- If a keyword is a non-reserved one (excluding function and type) both in M-compatible mode and MySQL, it cannot be a function name in M-compatible mode, but can be a function name in MySQL.

  NOTE

  Among non-reserved keywords, reserved keywords (functions or types), and non-reserved keywords (not functions or types) in M-compatible mode, the following keywords cannot be used as column aliases:

  BETWEEN, BIGINT, BLOB, CHAR, CHARACTER, COMPILE, CROSS, DEC, DECIMAL, DIV, DOUBLE, EXISTS, FLOAT, FLOAT4, FLOAT8, GROUPING, INNER, INOUT, INT, INT1, INT2, INT3, INT4, INT8, INTEGER, JOIN, LEFT, LIKE, LONGBLOB, LONGTEXT, MEDIUMBLOB, MEDIUMINT, MEDIUMTEXT, MOD, NATURAL, NUMERIC, OUT, OUTER, PRECISION, REAL, RIGHT, ROW, ROW_NUMBER, SIGNED, SMALLINT, SOUNDS, TINYBLOB, TINYINT, TINYTEXT, VALUES, VARCHAR, VARYING, and WITHOUT.

  SIGNED and WITHOUT can be used as column aliases in MySQL.

3.3.2.7.3 Identifiers

Differences in identifiers in M-compatible mode are as follows:

- In GaussDB, unquoted identifiers cannot start with a dollar sign ($). In MySQL unquoted identifiers can start with a dollar sign ($).
- GaussDB unquoted identifiers support case-sensitive database objects.
- GaussDB identifiers support extended characters from U+0080 to U+00FF. MySQL identifiers support extended characters from U+0080 to U+FFFF.
- As for unquoted identifier, a table that starts with a digit and ends with an e or E as the identifier cannot be created in GaussDB. For example:

```
-- GaussDB reports an error indicating that this operation is not supported. MySQL supports this operation.
m_db=# CREATE TABLE 23e(c1 int);
ERROR:  syntax error at or near "23"
LINE 1: CREATE TABLE 23e(c1 int);
                     ^
m_db=# CREATE TABLE t1(23E int);
ERROR:  syntax error at or near "23"
LINE 1: CREATE TABLE t1(23E int);
                        ^
```

- As for quoted identifiers, tables whose column names contain only digits or scientific computing cannot be directly used in GaussDB. You need to use them in quotes. This rule also applies to the dot operator (.) scenarios. For example:

```
-- Create a table whose column names contain only numbers or scientific computing.
m_db=# CREATE TABLE t1(`123` int, `1e3` int, `1e` int);
CREATE TABLE

-- Insert data into the table.
m_db=# INSERT INTO t1 VALUES(7, 8, 9);
INSERT 0 1

-- The result is not as expected, but is the same as that in MySQL.
m_db=# SELECT 123 FROM t1;
 ?column?
----------
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
     123
(1 row)

-- The result is not as expected, but is the same as that in MySQL.
m_db=# SELECT 1e3 FROM t1;
 ?column?
----------
    1000
(1 row)

-- The result is not as expected and is not the same as that in MySQL.
m_db=# SELECT 1e FROM t1;
 e
---
 1
(1 row)

-- The correct way to use is as follows:
m_db=# SELECT `123` FROM t1;
 123
-----
   7
(1 row)

m_db=# SELECT `1e3` FROM t1;
 1e3
-----
   8
(1 row)

m_db=# SELECT `1e` FROM t1;
 1e
----
  9
(1 row)

-- Dot operator scenarios are not supported by GaussDB but supported by MySQL.
m_db=# SELECT t1.123 FROM t1;
ERROR:  syntax error at or near ".123"
LINE 1: SELECT t1.123 FROM t1;
                ^
m_db=# SELECT t1.1e3 FROM t1;
ERROR:  syntax error at or near "1e3"
LINE 1: SELECT t1.1e3 FROM t1;
                 ^
m_db=# SELECT t1.1e FROM t1;
ERROR:  syntax error at or near "1"
LINE 1: SELECT t1.1e FROM t1;
                 ^
-- The correct way to use in dot operator scenarios is as follows:
m_db=# SELECT t1.`123` FROM t1;
 123
-----
   7
(1 row)

m_db=# SELECT t1.`1e3` FROM t1;
 1e3
-----
   8
(1 row)

m_db=# SELECT t1.`1e` FROM t1;
 1e
----
  9
(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
m_db=# DROP TABLE t1;
DROP TABLE
```

- In GaussDB, the partition name is case-sensitive when it is enclosed in double quotation marks (**SQL_MODE** must include **ANSI_QUOTES**) or backquotes, but in MySQL the partition name is case-insensitive.
- The maximum length of a MySQL identifier is 64 characters, while that of a GaussDB identifier is 63 bytes. If the length of an identifier exceeds the limit, MySQL reports an error, while GaussDB truncates the identifier and generates an alarm.

3.3.2.7.4 DDL

Table 3-159 DDL syntax compatibility

Description	Syntax	Difference
Create primary keys, UNIQUE indexes, and foreign keys during table creation and modification.	ALTER TABLE and CREATE TABLE	• In GaussDB, when the table joined with the constraint is Ustore and USING BTREE is specified in the SQL statement, the underlying index is created as UB-tree. • GaussDB: Foreign keys can be used as partition keys. • The index name, constraint name, and key name are unique in a schema in GaussDB and unique in a table in MySQL.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description	Syntax	Difference
Support auto-increment columns.	ALTER TABLE and CREATE TABLE	• It is recommended that an auto-increment column in GaussDB be the first column of an index. Otherwise, an alarm is generated during table creation. The auto-increment column in MySQL must be the first column of the index. Otherwise, an error is reported during table creation. In GaussDB, an error occurs when some operations (such as ALTER TABLE EXCHANGE PARTITION) are performed on a table that contains auto-increment columns. • In GaussDB, for the AUTO_INCREMENT [=] value syntax, **value** must be a positive integer ranging from 1 to 2^{127} - 1. In MySQL, this parameter can be set to **0** (actual value: **1**). In GaussDB, this parameter cannot be set to **0**. • In GaussDB, when the value has reached the maximum value of the column data type during auto-increment and auto-increment continues, if **sql_mode** is set to strict, an error occurs. If **sql_mode** is set to loose, auto-increment can proceed but the value remains at the maximum value. The type conversion rules used by the GaussDB auto-increment counter and table column value conversion are the same as those used by expressions. The logic for

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description	Syntax	Difference
		processing maximum value overflow is proper. In MySQL, when a value in an auto-increment column of the BIGINT UNSIGNED type reaches the maximum and auto-increment continues, an error is reported. In some scenarios, an error is reported as soon as it reaches the maximum value **–2**. However, there is no unified standard. If the MySQL auto-increment column is of the BIGINT or smaller integer type, when the maximum value is reached and auto-increment proceeds, the value is still the maximum value. ● GaussDB does not support the *innodb_autoinc_lock_mode* system variable, but when its GUC parameter **auto_increment_cache** is set to **0**, the behavior of inserting auto-increment columns in batches is similar to that when the MySQL system variable *innodb_autoinc_lock_mode* is set to **1**. ● In GaussDB, when 0s, NULLs, and definite values are imported or batch inserted into auto-increment columns, the auto-increment values inserted after an error occurs in GaussDB may not be the same as those in MySQL. The **auto_increment_cache** parameter is provided to control the number of reserved auto-increment values.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description	Syntax	Difference
		• In GaussDB, when auto-increment is triggered by parallel import or insertion of auto-increment columns, the cache value reserved for each parallel thread is used only in the thread. If the cache value is not used up, the values of auto-increment columns in the table are discontinuous. The auto-increment value generated by parallel insertion cannot be guaranteed to be the same as that generated in MySQL. • GaussDB does not allow the value of **auto_increment_offset** to be greater than that of **auto_increment_increment**. Otherwise, an error occurs. MySQL allows it and states that **auto_increment_offset** will be ignored. • If a table has a primary key or index, the sequence in which the **ALTER TABLE** command rewrites table data may be different from that in MySQL. GaussDB rewrites table data based on the table data storage sequence, while MySQL rewrites table data based on the primary key or index sequence. As a result, the auto-increment sequence may be different. • When the ALTER TABLE statement is used to add or modify auto-increment columns in GaussDB, the number reserved for values in the first auto-

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description	Syntax	Difference
		increment is the number of rows in the table statistics, which may not be the same as that in MySQL. As a result, the auto-increment values are discontinuous in GaussDB and may be different from those in MySQL. • If the values of the GUC parameters **auto_increment_offset** and **auto_increment_increment** in GaussDB are out of range, an error occurs. MySQL automatically changes the value to a boundary value. • Temporary tables do not support auto-increment columns. • The local auto-increment columns are independent on each DN. The values of the LAST_INSERT_ID function and GeneratedKey cannot be updated when the insertion is successful. • If the **no_auto_value_on_zero** parameter is set for **sql_mode**, the auto-increment column defined in the table is subject to non-NOT NULL constraints. If no value is specified for auto-increment columns of a table during data insertion, **NULL** values are inserted into the columns in GaussDB. In MySQL, auto-increment is triggered and **NULL** values are inserted into the columns.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description	Syntax	Difference
		• In different execution plans, the auto-increment sequence of local auto-increment columns and the number of reserved auto-increment columns may be different from those in MySQL. For example, "INSERT INTO table VALUES(...),(...),..." is distributed to different DNs. Therefore, in some execution plans, DNs cannot obtain the number of rows to be inserted. • Auto-increment and initial value update of the global auto-increment column in GaussDB are earlier than those in MySQL. Therefore, hole values are more likely to be generated when error occurs during data insertion. For example, if the CHECK constraint is violated during the INSERT process, the auto-increment column in MySQL 8.0 stops working, and the global auto-increment column in GaussDB distributed mode proceeds. • When ALTER TABLE is used to add a global auto-increment column in GaussDB, each DN applies for global auto-increment from the GTM. As a result, its auto-increment sequence is different from that in MySQL, and the hole values are also different. • The UPDATE statement updates the values of auto-increment columns. If a new value is not **0**,

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description	Syntax	Difference
		NULL, or **DEFAULT** and is greater than the maximum value of auto-increment, the initial value of auto-increment will be updated. The behavior is the same as that in MySQL 8.0. ● When the INSERT INTO ON DUPLICATE KEY statement is used to insert multiple rows of data at a time, if the UNIQUE constraint is violated, the generated holes may be different from those in MySQL. ● When the TRUNCATE is performed on a table in GaussDB, the global auto-increment column cannot be reset to automatically increase from the initial value, but you can do this with the AUTOINC_RESETVAL() function. Exercise caution when using this function. If data in the table is not cleared, duplicate values will be generated in the auto-increment column. ● When the INSERT INTO ON DUPLICATE KEY statement updates the value of the global auto-increment column due to primary key conflicts, for the getGeneratedKeys() API of JDBC, GaussDB returns the auto-increment value of the auto-increment column, and MySQL returns the updated value of the auto-increment column. ● When data is inserted into the global auto-increment column, the auto-

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description	Syntax	Difference
		increment time and the time for updating the auto-increment start value in GaussDB are earlier than those in MySQL. If an error is reported during data insertion and GaussDB may have updated the value of **last_insert_id**, the next query result of the last_insert_id() function may be the auto-increment value generated by the last statement for which the error is reported, which is different from that in MySQL.
Prefix indexes	CREATE INDEX, ALTER TABLE, and CREATE TABLE	• In GaussDB, the prefix length cannot exceed 2676. The actual length of the key value is restricted by the internal page. If a column contains multi-byte characters or an index has multiple keys, an error may be reported when the index line length exceeds the threshold. • In GaussDB, the primary key index does not support prefix keys. The prefix length cannot be specified when a primary key is created or added.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description	Syntax	Difference
Specify character sets and collation rules.	ALTER SCHEMA, ALTER TABLE, CREATE SCHEMA, and CREATE TABLE	• When you specify a database-level character set, except binary character sets, the character set of a new database or schema cannot be different from that specified by **server_encoding** of the database. • When you specify a table-level or column-level character set and collation, MySQL allows you to specify a character set and collation that are different from the database-level character set and collation. In GaussDB, the table-level and column-level character sets and collations support only the binary character sets and collations or can be the same as the database-level character sets and collations.
Add columns before the first column of a table or after a specified column during table modification.	ALTER TABLE	-
Alter the column name/definition.	ALTER TABLE	Currently, the DROP INDEX, DROP KEY, or ORDER BY is not supported.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description	Syntax	Difference
Create a partitioned table.	CREATE TABLE PARTITION	• MySQL supports expressions but does not support multiple partition keys in the following scenarios: – The LIST/RANGE partitioning policy is used and the COLUMNS keyword is not specified. – The hash partitioning policy is used. • MySQL does not support expressions but supports multiple partition keys in the following scenarios: – The LIST/RANGE partitioning policy is used and the COLUMNS keyword is specified. – The KEY partitioning policy is used. • In GaussDB, expressions cannot be used as partition keys, and partitions cannot be specified. • GaussDB supports multiple partition keys only when the LIST or RANGE partitioning policy is used. • In GaussDB partitioned tables, generated columns cannot be used as partition keys.
Specify table-level and column-level comments during table creation and modification.	CREATE TABLE and ALTER TABLE	-
Specify index-level comments during index creation.	CREATE INDEX	-

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description	Syntax	Difference
Exchange the partition data of an ordinary table and a partitioned table.	ALTER TABLE PARTITION	Differences in ALTER TABLE EXCHANGE PARTITION: ● After **ALTER EXCHANGE PARTITION** is executed, the auto-increment columns are reset in MySQL, but in GaussDB, they are not reset and continue the auto-increment based on their old values. ● If MySQL tables or partitions use tablespaces, data in partitions and ordinary tables cannot be exchanged. If GaussDB tables or partitions use different tablespaces, data in partitions and ordinary tables can still be exchanged. ● MySQL does not verify the default values of columns. Therefore, data in partitions and ordinary tables can be exchanged even if the default values are different. GaussDB verifies the default values. If they are different, data in partitions and ordinary tables cannot be exchanged. ● After the DROP COLUMN operation is performed on a partitioned table or an ordinary table in MySQL, if the table definition is still consistent, data can be exchanged between partitions and ordinary tables. In GaussDB, data can be exchanged between partitions and ordinary tables only when the deleted columns of ordinary tables and partitioned tables are strictly aligned.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description	Syntax	Difference
		• MySQL and GaussDB use different hash algorithms. Therefore, data stored in the same hash partition may be inconsistent. As a result, the exchanged data may also be inconsistent. • MySQL's partitioned tables do not support foreign keys. If an ordinary table contains foreign keys or other tables reference the foreign keys of an ordinary table, data in partitions and ordinary tables cannot be exchanged. GaussDB's partitioned tables support foreign keys. If the FOREIGN KEY constraints of two tables are the same, data in partitions and ordinary tables can be exchanged. If a partitioned table does not contain foreign keys, an ordinary table is referenced by other tables, and the partitioned table is the same as the ordinary table, GaussDB also allows the partitioned table to exchange data with the ordinary table.
Modify the partition key information of a partitioned table.	ALTER TABLE	MySQL allows you to modify the partition key information of a partitioned table, but GaussDB does not.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description	Syntax	Difference
CREATE TABLE... LIKE syntax	CREATE TABLE ... LIKE	• In versions earlier than MySQL 8.0.16, CHECK constraints are parsed but their functions are ignored. In this case, CHECK constraints are not replicated. GaussDB supports replication of CHECK constraints. • During table creation, MySQL fixes all PRIMARY KEY constraint names at **PRIMARY KEY**. GaussDB does not support copying PRIMARY KEY constraint names. • When a table is created, MySQL supports replication of UNIQUE constraint names, but GaussDB does not. • When a table is created, MySQL versions earlier than 8.0.16 do not have CHECK constraint information, but GaussDB supports replication of CHECK constraint names. • During table creation, MySQL supports copying index names, but GaussDB does not. • When a table is created across sql_mode, MySQL is controlled by the loose mode and strict mode. The strict mode may become invalid in GaussDB. For example, if the source table has the default value **"0000-00-00"**, a table with the default value **"0000-00-00"** can be created in "no_zero_date" strict mode in GaussDB, which means that the strict mode is invalid. In MySQL, the table creation

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description	Syntax	Difference
		will fail because it is controlled by the strict mode.
Truncate a partition.	ALTER TABLE [IF EXISTS] table_name truncate_clause;	For truncate_clause, the supported subitems are different: • M-compatible mode: TRUNCATE PARTITION { { ALL | partition_name [, ...] } | FOR (partition_value [, ...]) } [UPDATE GLOBAL INDEX] • MySQL: TRUNCATE PARTITION {partition_names | ALL}
Index name of a primary key	CREATE TABLE table_name (col_definition ,PRIMARY KEY [index_name] [USING method] ({ column_name | (expression) }[ASC | DESC] } [, ...]) index_parameters [USING method| COMMENT 'string'])	The index name created after being specified by a primary key in GaussDB is the index name specified by a user. In MySQL, the index name is **PRIMARY**.
Drop dependent objects.	DROP drop_type name CASCADE;	In GaussDB, **CASCADE** needs to be added to drop dependent objects. In MySQL, **CASCADE** is not required.
The NOT NULL constraint does not allow NULL values to be inserted.	CREATE TABLE t1(id int NOT NULL DEFAULT 8); INSERT INTO t1 VALUES(NULL); INSERT INTO t1 VALUES(1), (NULL),(2);	In MySQL loose mode, NULL is converted and data is successfully inserted. In MySQL strict mode, NULL values cannot be inserted. GaussDB does not support this feature. NULL values cannot be inserted in loose or strict mode.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description	Syntax	Difference
The CHECK constraint takes effect.	CREATE TABLE	• CREATE TABLE that contains the CHECK constraint takes effect in MySQL 8.0. MySQL 5.7 parses the syntax but the syntax does not take effect. GaussDB synchronizes this function of MySQL 8.0, and the GaussDB CHECK constraint can reference other columns, but MySQL cannot. • A maximum of 32767 CHECK constraints can be added to a table in GaussDB.
The **algorithm** and **lock** options of an index do not take effect.	CREATE INDEX ... DROP INDEX ...	Currently, the index options **algorithm_option** and **lock_option** in the CREATE/DROP INDEX statement in M-compatible mode are supported only in syntax. No error is reported during creation, but they do not take effect.
The storage of hash partitions and subpartitions in CREATE TABLE in GaussDB is different from that in MySQL.	CREATE TABLE	In GaussDB, the hash functions used by hash partitioned tables and subpartitioned tables in the CREATE TABLE statement are different from those in MySQL. Therefore, the storage of hash partitioned tables and subpartitioned tables is different from that in MySQL.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description	Syntax	Difference
Partitioned table index	CREATE INDEX	• GaussDB partitioned table indexes are classified into local and global indexes. A local index is bound to a specific partition, and a global index corresponds to the entire partitioned table. • For details about how to create local and global indexes and their default rules, see **CREATE INDEX**. For example, if you create a unique index on a non-partition key, the index is created as a global index by default. • MySQL does not have global indexes. In GaussDB, if the partitioned table index is a global index, the global index is not updated by default when operations such as DROP, TRUNCATE, and EXCHANGE are performed on table partitions. As a result, the global index becomes invalid and cannot be selected in subsequent statements. To avoid this problem, you are advised to explicitly specify the UPDATE GLOBAL INDEX clause at the end of the partition syntax or set the global GUC parameter **enable_gpi_auto_update** to **true** (recommended) so that global indexes can be automatically updated during partition operations. You can also set the global GUC parameter **enable_drop_truncate_partition_keep_gpi** to **true** so that global indexes are

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description	Syntax	Difference
		automatically updated when partitions are dropped or truncated.
If the table is partitioned by key in the CREATE/ALTER TABLE statement, algorithms cannot be specified. Input parameters of some partition definition do not support expressions.	CREATE TABLE and ALTER TABLE	GaussDB: If the table is partitioned by key in the CREATE/ALTER TABLE statement, algorithms cannot be specified. The syntaxes that do not support expressions as input parameters are as follows: • PARTITION BY HASH() • PARTITION BY KEY() • VALUES LESS THAN()
Partitioned tables do not support LINEAR/KEY hash.	CREATE TABLE ... PARTITION ...	GaussDB: Partitioned tables do not support LINEAR/KEY hash.
The CHECK and AUTO_INCREMENT syntaxes cannot be used in the same column.	CREATE TABLE	The column using CHECK does not take effect in MySQL 5.7. When both CHECK and AUTO_INCREMENT are used on the same column, only AUTO_INCREMENT takes effect. However, GaussDB reports an error.
Delete dependent tables.	DROP TABLE	In GaussDB, CASCADE must be added to delete dependent tables. In MySQL, CASCADE is not required.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description	Syntax	Difference
Options related to table definition.	CREATE TABLE ... and ALTER TABLE ...	• GaussDB does not support the following options: **AVG_ROW_LENGTH**, **CHECKSUM**, **COMPRESSION**, **CONNECTION**, **DATA DIRECTORY**, **INDEX DIRECTORY**, **DELAY_KEY_WRITE**, **ENCRYPTION**, **INSERT_METHOD**, **KEY_BLOCK_SIZE**, **MAX_ROWS**, **MIN_ROWS**, **PACK_KEYS**, **PASSWORD**, **STATS_AUTO_RECALC**, **STATS_PERSISTENT**, and **STATS_SAMPLE_PAGES**. • The following options do not report errors in GaussDB and do not take effect: **ENGINE** and **ROW_FORMAT**.
The GENERATED ALWAYS AS statement cannot reference columns generated by GENERATED ALWAYS AS.	Generated Always AS	In GaussDB, the GENERATED ALWAYS AS statement cannot reference columns generated by GENERATED ALWAYS AS, but it can in MySQL.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description	Syntax	Difference
Alter table names.	ALTER TABLE tbl_name RENAME [TO | AS | =] new_tbl_name;	• The ALTER RENAME syntax in GaussDB supports only the function of changing the table name and cannot be coupled with other function operations. • In GaussDB, only the old table name column supports the schema.table_name format, and the new and old table names belong to the same schema. • GaussDB does not support renaming of old and new tables across schemas. However, if you have the permission, you can modify the names of tables in other schemas in the current schema.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description	Syntax	Difference
Support the CREATE VIEW AS SELECT syntax.	CREATE VIEW table_name AS query;	• For the following types, the query using the CREATE VIEW view_name AS query syntax cannot contain calculation operations (such as function call and calculation using operators): – BINARY[(n)] – BOOLEAN/BOOL – VARBINARY(n) – CHAR[(n)] – VARCHAR(n) – TIME[(p)] – DATETIME[(p)] – TIMESTAMP[(p)] – BIT[(n)] – NUMERIC[(p[,s])] – DECIMAL[(p[,s])] – DEC[(p[,s])] – FIXED[(p[,s])] – FLOAT4[(p, s)] – FLOAT8[(p,s)] – FLOAT[(p)] – REAL[(p, s)] – FLOAT[(p, s)] – DOUBLE[(p,s)] – DOUBLE PRECISION[(p,s)] – TEXT – TINYTEXT – MEDIUMTEXT – LONGTEXT – BLOB – TINYBLOB – MEDIUMBLOB – LONGBLOB • In the simple query scenario, an error message is displayed for the

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description	Syntax	Difference

		preceding calculation operations in M-compatible mode. For example:
		m_db=# CREATE TABLE TEST (salary int(10));
		CREATE TABLE
		
		m_db=# INSERT INTO TEST VALUES(8000);
		INSERT 0 1
		
		m_db=# CREATE VIEW view1 AS SELECT salary/10 as te FROM TEST;
		ERROR: Unsupported type numeric used with expression in CREATE VIEW statement.
		
		m_db=# CREATE VIEW view2 AS SELECT sec_to_time(salary) as te FROM TEST;
		ERROR: Unsupported type time used with expression in CREATE VIEW statement.
		• In non-simple query scenarios such as composite query and subquery, the calculation operations of the preceding types in M-compatible mode are different from those in MySQL. In M-compatible mode, the data type column precision attribute of the created table is not retained.

Range of index names that can be duplicated	CREATE TABLE, CREATE INDEX	In MySQL, an index name is unique in a table. Different tables can have the same index name. In M-compatible mode, the index name must be unique in the same schema. In M-compatible mode, the same rules apply to constraints and keys that automatically create indexes.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description	Syntax	Difference
View dependency differences	CREATE VIEW and ALTER TABLE	In MySQL, view storage records only the table name, column name, and database name of the target table, but does not record the unique identifier of the target table. GaussDB parses the SQL statement used for creating a view and stores the unique identifier of the target table. Therefore, the differences are as follows: • In MySQL, you can modify the data type of a column on which a view depends because the view is unaware of the modification of the target table. In GaussDB, such modification is forbidden and the attempt will fail. • In MySQL, you can rename a column on which a view depends because the view is unaware of the modification of the target table, but the view cannot be queried after the operation. In GaussDB, each column precisely stores the unique identifier of the corresponding table and column. Therefore, the column name in the table can be modified successfully without changing the column name in the view. In addition, the view can be queried after the operation.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description	Syntax	Difference
Foreign key differences	CREATE TABLE	• In GaussDB, FOREIGN KEY constraints are insensitive to types. If the data types of the columns in the main and child tables are implicitly converted, foreign keys can be created. In MySQL, FOREIGN KEY constraints are sensitive to types. If the column types of the two tables are different, foreign keys cannot be created. • MySQL does not allow you to modify the data type or name of a table column where the foreign key of the column is located by running **MODIFY COLUMN** or **CHANGE COLUMN**, but GaussDB supports such operation.
Differences in index ascending and descending orders	CREATE INDEX	In MySQL 5.7, **ASC | DESC** is parsed but ignored, and the default behavior is **ASC**. In MySQL 8.0 and GaussDB, **ASC | DESC** is parsed and takes effect.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description	Syntax	Difference

Setting default values of columns	CREATE TABLE and ALTER TABLE	• For MySQL 5.7, only the default value without parentheses is supported. MySQL 8.0 and GaussDB support default values in parentheses.
		-- GaussDB
		m_db=# DROP TABLE IF EXISTS t1, t2;
		DROP TABLE
		m_db=# CREATE TABLE t1(a DATETIME DEFAULT NOW());
		CREATE TABLE
		m_db=# CREATE TABLE t2(a DATETIME DEFAULT (NOW()));
		CREATE TABLE
		
		-- MySQL 5.7
		mysql> DROP TABLE IF EXISTS t1, t2;
		Query OK, 0 rows affected (0.04 sec)
		
		mysql> CREATE TABLE t1(a DATETIME DEFAULT NOW());
		Query OK, 0 rows affected (0.04 sec)
		
		mysql> CREATE TABLE t2(a DATETIME DEFAULT (NOW()));
		ERROR 1064 (42000): You have an error in your SQL syntax; check the manual that corresponds to your MySQL server version for the right syntax to use near '(NOW()))' at line 1
		
		-- MySQL 8.0
		mysql> DROP TABLE IF EXISTS t1, t2;
		Query OK, 0 rows affected (0.17 sec)
		
		mysql> CREATE TABLE t1(a DATETIME DEFAULT NOW());
		Query OK, 0 rows affected (0.19 sec)
		
		mysql> CREATE TABLE t2(a DATETIME DEFAULT (NOW()));
		Query OK, 0 rows affected (0.20 sec)
		• In MySQL, when specifying default values for BLOB, TEXT, and JSON data types, you must add parentheses to the default values. In GaussDB, you do not need to add parentheses when specifying default values

		-- MySQL 8.0
		mysql> DROP TABLE IF EXISTS t1, t2;
		Query OK, 0 rows affected (0.14 sec)
		
		mysql> CREATE TABLE t1(a TIMESTAMP DEFAULT TIMESTAMP '2000-01-01 00:00:00');
		ERROR 1067 (42000): Invalid default value for 'a'
		mysql> CREATE TABLE t2(a TIMESTAMP DEFAULT (TIMESTAMP '2000-01-01 00:00:00'));
		Query OK, 0 rows affected (0.19 sec)

3.3.2.7.5 DML

Table 3-160 DML syntax compatibility

Description	Syntax	Difference
DELETE supports deleting data from a specified partition (or subpartition).	DELETE	-
SELECT INTO syntax	SELECT	• In GaussDB, you can use SELECT INTO to create a table based on the query result. MySQL does not support this function. • In GaussDB, the SELECT INTO syntax does not support the query result that is obtained after the set operation of multiple queries is performed.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description	Syntax	Difference

REPLACE INTO syntax	REPLACE	Difference between the initial values of the time type. For example:
		• MySQL is not affected by the strict or loose mode. You can insert time 0 into a table.
		`mysql> CREATE TABLE test(f1 TIMESTAMP NOT NULL, f2 DATETIME NOT NULL, f3 DATE NOT NULL);`
		`Query OK, 1 row affected (0.00 sec)`
		
		`mysql> REPLACE INTO test VALUES(f1, f2, f3);`
		`Query OK, 1 row affected (0.00 sec)`
		
		`mysql> SELECT * FROM test;`
		`+---------------------+---------------------+------------+`
		`| f1 | f2 | f3 |`
		`+---------------------+---------------------+------------+`
		`| 0000-00-00 00:00:00 | 0000-00-00 00:00:00 | 0000-00-00 |`
		`+---------------------+---------------------+------------+`
		`1 row in set (0.00 sec)`
		• The time 0 can be successfully inserted only when GaussDB is in loose mode.
		`gaussdb=# SET sql_mode = '';`
		`SET`
		`gaussdb=# CREATE TABLE test(f1 TIMESTAMP NOT NULL, f2 DATETIME NOT NULL, f3 DATE NOT NULL);`
		`CREATE TABLE`
		`gaussdb=# REPLACE INTO test VALUES(f1, f2, f3);`
		`REPLACE 0 1`
		`gaussdb=# SELECT * FROM test;`
		`f1 | f2 | f3`
		`---------------------+---------------------+------------`
		`0000-00-00 00:00:00 | 0000-00-00 00:00:00 | 0000-00-00`
		`(1 row)`
		In strict mode, the error "Incorrect Date/Time/Datetime/Timestamp/Year value" is reported.

SELECT supports multi-partition query.	SELECT	-
UPDATE supports multi-partition update.	UPDATE	-

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description	Syntax	Difference

Import data by using LOAD DATA.	LOAD DATA	When LOAD DATA is used to import data, GaussDB differs from MySQL in the following aspects:
		• The execution result of the LOAD DATA syntax is the same as that in MySQL strict mode. The loose mode is not adapted currently. For example, if the source data to be imported contains invalid characters, GaussDB reports an error, while MySQL reports an error in strict mode, or truncates the invalid characters and then import the data in loose mode.
		-- GaussDB
		m_db=# SET sql_mode='';
		SET
		m_db=# DROP TABLE IF EXISTS t1;
		DROP TABLE
		m_db=# CREATE TABLE t1(a text) CHARSET gbk;
		CREATE TABLE
		m_db=# SELECT unhex('1AFF1F') INTO OUTFILE '/tmp/3.data';
		COPY 1
		m_db=# LOAD DATA INFILE '/tmp/3.data' INTO TABLE t1 CHARACTER SET gbk;
		ERROR: invalid byte sequence for encoding "GBK": 0xff 0x1f
		CONTEXT: COPY t1, line 1.
		m_db=# DROP TABLE t1;
		DROP TABLE
		
		-- MySQL
		mysql> SET sql_mode='';
		Query OK, 0 rows affected (0.00 sec)
		mysql> DROP TABLE IF EXISTS t1;
		Query OK, 0 rows affected (0.02 sec)
		mysql> CREATE TABLE t1(a text) CHARSET gbk;
		Query OK, 0 rows affected (0.03 sec)
		mysql> SELECT unhex('1AFF1F') INTO OUTFILE '/tmp/3.data';
		Query OK, 1 row affected (0.00 sec)
		mysql> LOAD DATA INFILE '/tmp/3.data' INTO TABLE t1 CHARACTER SET gbk;
		Query OK, 1 row affected, 1 warning (0.01 sec)
		Records: 1 Deleted: 0 Skipped: 0 Warnings: 1
		mysql> SHOW warnings;
		+---------+------
		+----------
		----------+

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description	Syntax	Difference
		<pre>| Level | Code | Message | +---------+------ +---------- ---------- ----------+ | Warning | 1366 | Incorrect string value: '\xFF\x1F' for column 'a' at row 1 | +---------+------ +---------- ---------- ----------+ 1 row in set (0.00 sec) mysql> SELECT hex(a) FROM t1; +--------+ | hex(a) | +--------+ | 1A | +--------+ 1 row in set (0.00 sec) mysql> DROP TABLE t1; Query OK, 0 rows affected (0.02 sec)</pre> • The **IGNORE** and **LOCAL** parameters are used only to ignore the conflicting rows when the imported data conflicts with the data in the table and to automatically fill default values for other columns when the number of columns in the file is less than that in the table. Other functions are not supported currently. • If the keyword **LOCAL** is specified and the file path is a relative path, the file is searched from the binary directory. If the keyword **LOCAL** is not specified and the file path is a relative path, the file is searched from the data directory. • LOAD DATA can only be used to import files from the server. • The **[(col_name_or_user_var [, col_name_or_user_var]...)]** parameter cannot be used to specify a column repeatedly. • The newline character specified by **[FIELDS TERMINATED BY 'string']**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description	Syntax	Difference
		cannot be the same as the separator specified by **[LINES TERMINATED BY'string']**. ● If the data written to a table by running **LOAD DATA** cannot be converted to the data type of the table, an error is reported. ● The LOAD DATA SET expression does not support the calculation of a specified column name. ● LOAD DATA applies only to tables but not views. ● The default newline character of the file in Windows is different from that in Linux. LOAD DATA cannot identify this scenario and reports an error. You are advised to check the newline character at the end of lines in the file to be imported. ● If the number of columns in the source data is greater than that in the target table, GaussDB displays an alarm, while MySQL displays an alarm in the following scenarios and reports an error in other scenarios: – The strict mode is not enabled for **sql_mode**. – The **IGNORE** option is specified. – The **LOCAL** option is specified and the **REPLACE** option is not specified. ● When the source data file ends with a column delimiter, MySQL processes the file as if there is no new column after the delimiter, while GaussDB processes the file as if there is an empty

Description	Syntax	Difference

		string column after the delimiter.
		-- Source data in **1.csv**
		1,2,
		
		-- GaussDB
		m_db=# DROP TABLE IF EXISTS t1;
		NOTICE: table "t1" does not exist, skipping
		DROP TABLE
		m_db=# CREATE TABLE t1(a char(30), b char(30), c char(30));
		CREATE TABLE
		m_db=# LOAD DATA infile '/tmp/1.csv' INTO TABLE t1 fields terminated by ',';
		COPY 1
		m_db=# SELECT c IS NULL, length(c) FROM t1;
		?column? | length
		----------+--------
		f | 0
		(1 row)
		
		-- MySQL
		mysql> DROP TABLE IF EXISTS t1;
		Query OK, 0 rows affected (0.06 sec)
		
		mysql> CREATE TABLE t1(a char(30), b char(30), c char(30));
		Query OK, 0 rows affected (0.04 sec)
		
		mysql> LOAD DATA infile '/tmp/1.csv' INTO TABLE t1 fields terminated by ',';
		ERROR 1261 (01000): Row 1 doesn't contain data for all columns

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description	Syntax	Difference
LIMIT differences	DELETE, SELECT, and UPDATE	The LIMIT clauses of each statement in GaussDB are different from those in MySQL. The maximum parameter value of LIMIT (of the BIG INT type) in GaussDB is **9223372036854775807**. If the actual value exceeds the number, an error is reported. In MySQL, the maximum value of LIMIT (of the unsigned LONGLONG type) is **18446744073709551615**. If the actual value exceeds the number, an error is reported. You can set a small value in LIMIT, which is rounded off during execution. The value cannot be a decimal in MySQL. In GaussDB, limit 0 is not allowed in the DELETE statement. In MySQL, limit 0 is allowed in the DELETE statement.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description	Syntax	Difference
Difference in using backslashes (\)	INSERT	The usage of backslashes (\) can be determined by parameters in GaussDB and MySQL, but their default usages are different. In MySQL, the **NO_BACKSLASH_ESCAPES** parameter is used to determine whether backslashes (\) in character strings and identifiers are parsed as common characters or escape characters. By default, backslashes (\) are parsed as escape characters in character strings and identifiers. If **SET sql_mode='NO_BACKSLASH_ESCAPES';** is used, the backslashes (\) cannot be parsed as escape characters in strings and identifiers. In GaussDB, the **standard_conforming_strings** parameter is used to determine whether backslashes (\) in character strings and identifiers are parsed as common characters or escape characters. The default value is **on**, indicating that backslashes (\) are parsed as common text in common character string texts according to the SQL standard. If **SET standard_conforming_strings=off;** is used, backslashes (\) can be parsed as escape characters in character strings and identifiers.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description	Syntax	Difference
If the inserted value is less than the number of columns, MySQL reports an error while GaussDB supplements null values.	INSERT	In GaussDB, if the column list is not specified and the inserted value is less than the number of columns, values are assigned based on the column sequence when the table is created by default. If a column has a NOT NULL constraint, an error is reported. If no NOT NULL constraint exists and a default value is specified, the default value is added to the column. If no default value is specified, **null** is added.
The columns sorted in ORDER BY must be included in the columns of the result set.	SELECT	In GaussDB, when used with the GROUP BY clause, the columns to be sorted in ORDER BY must be included in the columns of the result set retrieved by the SELECT statement. When used with the DISTINCT keyword, the columns to be sorted in ORDER BY must be included in the columns of the result set retrieved by the SELECT statement.
Duplicate column names are allowed in the SELECT result.	SELECT	-
NATURAL JOIN in GaussDB is different from that in MySQL.	SELECT	In GaussDB, NATURAL [[LEFT | RIGHT] OUTER] JOIN allows you not to specify **LEFT | RIGHT**. If **LEFT | RIGHT** is not specified, **NATURAL OUTER JOIN** is **NATURAL JOIN**. You can use JOIN consecutively.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description	Syntax	Difference

Support of UPDATE or DELETE for ORDER BY and LIMIT	UPDATE/DELETE	When the ORDER BY and LIMIT clauses are used together with the UPDATE/DELETE clause, if the tuple to be updated or deleted is concurrently modified by another session, the system obtains the latest value of the sorted tuple from the session and performs matching again. If the condition is still met, the tuple is updated. During this process, MySQL obtains the sorting result again for update. However, GaussDB updates or deletes only the tuples that have been sorted by the session and involve concurrent update, which may cause data inconsistency.
		• Behavior in GaussDB:
		m_db=# CREATE TABLE t1(a INT, b INT);
		CREATE TABLE
		m_db=# CREATE TABLE t2(a INT, b INT);
		CREATE TABLE
		m_db=# INSERT INTO t1 VALUES(1,1),(2,2);
		INSERT 0 2
		-- Session one.
		m_db=# START TRANSACTION;
		START TRANSACTION
		-- The session one is updated first, but the transaction is not committed.
		m_db=# UPDATE t1 SET a=3 WHERE a=1;
		UPDATE 1
		-- Session two.
		m_db=# START TRANSACTION;
		START TRANSACTION
		-- The session two is updated after the session one is updated. The update is successful after the session one transaction ends.
		m_db=# UPDATE t1 SET b=4 ORDER BY a LIMIT 1;
		UPDATE 1
		-- The session one commits the transaction.
		m_db=# COMMIT;
		COMMIT
		-- Query data after the session two is updated successfully.
		m_db=# SELECT * FROM t1;
		a | b
		---+---
		3 | 4
		2 | 2
		(2 rows)

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description	Syntax	Difference

		• Behavior in MySQL:
		-- Session one.
		mysql> START TRANSACTION;
		Query OK, 0 rows affected (0.00 sec)
		-- The session one is updated first, but the transaction is not committed.
		mysql> UPDATE t1 SET a=3 WHERE a=1;
		Query OK, 1 row affected (0.00 sec)
		Rows matched: 1 Changed: 1 Warnings: 0
		-- Session two.
		mysql> START TRANSACTION;
		Query OK, 0 rows affected (0.00 sec)
		mysql> UPDATE t1 SET b=4 ORDER BY a LIMIT 1;
		-- The session two is updated after the session one is updated. The update is successful after the session one transaction ends.
		Query OK, 1 row affected (5.12 sec)
		Rows matched: 1 Changed: 1 Warnings: 0
		-- The session one commits the transaction.
		mysql> COMMIT;
		Query OK, 0 rows affected (0.00 sec)
		-- Query data after the session two is updated successfully.
		mysql> SELECT * FROM t1;
		+------+------+
		| a | b |
		+------+------+
		| 3 | 1 |
		| 2 | 4 |
		+------+------+
		2 rows in set (0.00 sec)

If the foreign key data type is timestamp or datetime, an error is reported for attempts to perform UPDATE or DELETE on a foreign table.	UPDATE/DELETE	If the foreign key data type is timestamp or datetime, an error is reported for attempts to perform UPDATE or DELETE on a foreign table, but such operations are allowed in MySQL.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description	Syntax	Difference

Compatibility in terms of natural join and using	SELECT	• In GaussDB, join sequence is strictly from left to right. MySQL may adjust the sequence.
		• In GaussDB and MySQL, columns involving **join** in the left or right table cannot be ambiguous during natural join or using. (Generally, ambiguity is caused by duplicate names of columns in the left or right temporary table.) The join sequence differs in two databases, which may lead to different behaviors.
		– Behavior in GaussDB:
		m_regression=# CREATE TABLE t1(a int,b int);
		CREATE TABLE
		m_regression=# CREATE TABLE t2(a int,b int);
		CREATE TABLE
		m_regression=# CREATE TABLE t3(a int,b int);
		CREATE TABLE
		m_regression=# SELECT * FROM t1 JOIN t2;
		a | b | a | b
		---+---+---+---
		(0 rows)
		m_regression=# SELECT * FROM t1 JOIN t2 natural join t3; -- Failed. Duplicate contents exist in columns **a** and **b** of the temporary table obtained by **t1 join t2**. Therefore, there is ambiguity in natural join.
		ERROR: common column name "a" appears more than once in left table
		– Behavior in MySQL:
		mysql> SELECT * FROM t1 JOIN t2 NATURAL JOIN t3;
		Empty set (0.00 sec)
		mysql> SELECT * FROM (t1 join t2) NATURAL JOIN t3;
		ERROR 1052 (23000): Column 'a' in from clause is ambiguous

The WITH clause is compatible with MySQL 8.0.	SELECT, INSERT, UPDATE, and DELETE	-

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description	Syntax	Difference
Compatibility in terms of join	SELECT	Commas (,) cannot be used as a way of join in GaussDB, but can be used in MySQL. GaussDB does not support use index for join.
If the column expression in the SELECT statement is a function expression or arithmetic expression, the column name in the query result is **?column?**.	SELECT	In GaussDB, if the column expression in the SELECT statement is a function expression or arithmetic expression, the column name in the query result is **?column?**. In MySQL, the name is the corresponding expression.
SELECT export file (into outfile)	SELECT ... INTO OUTFILE ...	In the file exported by using the SELECT INTO OUTFILE syntax, the display precision of values of the FLOAT, DOUBLE, and REAL types in GaussDB is different from that in MySQL. The syntax does not affect the import using COPY the values after import.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description	Syntax	Difference

Specify schema names and table names by using SELECT/UPDATE/ INSERT/REPLACE.	SELECT/UPDATE/ INSERT/REPLACE	• When the SELECT statement is used to the projection column, MySQL supports the three-segment format of *schema name.table alias.column name*, but GaussDB does not.
		m_db=# CREATE SCHEMA test;
		CREATE SCHEMA
		m_db=# CREATE TABLE test.t1(a int);
		CREATE TABLE
		m_db=# SELECT test.alias1.a FROM t1 alias1;
		ERROR: invalid reference to FROM-clause entry for table "alias1"
		LINE 1: SELECT test.alias1.a FROM t1 alias1;
		^
		HINT: There is an entry for table "alias1", but it cannot be referenced from this part of the query.
		CONTEXT: referenced column: a
		• The three-segment format for UPDATE/REPLACE SET is *database.table.column* in MySQL, and is *table.column.field* in GaussDB, where *field* indicates the attribute in the specified composite type.
		• For INSERT ... SET, MySQL supports *column*, *table.column*, and *database.table.column*. GaussDB supports only *column* and does not support *table.column* and *database.table.column*.
		• For INSERT... SET, you can reference column names and expressions that contain column names on the right of the SET clause in MySQL. GaussDB does not support this operation.
		– Behavior in GaussDB:
		m_db=# CREATE TABLE t2 (a int default 3, b int default 5);
		CREATE TABLE
		
		m_db=# INSERT INTO t2 SET a = b + 1;
		ERROR: Column "b" does not exist.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description	Syntax	Difference

		LINE 1: INSERT INTO t2 SET a = b + 1;
		^
		HINT: There is a column named "b" in table "t2", but it cannot be referenced from this part of the query.
		
		m_db=# INSERT INTO t2 SET a = b + 1, b = 0;
		ERROR: Column "b" does not exist.
		LINE 1: INSERT INTO t2 SET a = b + 1, b = 0;
		^
		HINT: There is a column named "b" in table "t2", but it cannot be referenced from this part of the query.
		
		m_db=# INSERT INTO t2 SET b = 0, a = b + 1;
		ERROR: Column "b" does not exist.
		LINE 1: INSERT INTO t2 SET b = 0, a = b + 1;
		^
		HINT: There is a column named "b" in table "t2", but it cannot be referenced from this part of the query.
		
		m_db=# INSERT INTO t2 SET a = a + 1;
		ERROR: Column "a" does not exist.
		LINE 1: INSERT INTO t2 SET a = a + 1;
		^
		HINT: There is a column named "a" in table "t2", but it cannot be referenced from this part of the query.
		
		m_db=# DROP TABLE t2;
		DROP TABLE
		– Behavior in MySQL:
		mysql> CREATE TABLE t2 (a int default 3, b int default 5);
		Query OK, 0 rows affected (0.07 sec)
		
		mysql> INSERT INTO t2 SET a = b + 1;
		Query OK, 1 row affected (0.02 sec)
		
		mysql> SELECT * FROM t2;
		+------+------+
		| a | b |
		+------+------+
		| 6 | 5 |
		+------+------+
		1 row in set (0.00 sec)

		mysql> INSERT INTO t2 SET a = a + 1;
		Query OK, 1 row affected (0.02 sec)
		
		mysql> SELECT * FROM t2;
		+------+------+
		| a | b |
		+------+------+
		| 6 | 5 |
		| 6 | 0 |
		| 1 | 0 |
		| 4 | 5 |
		+------+------+
		4 rows in set (0.00 sec)
		
		mysql> DROP TABLE t2;
		Query OK, 4 rows affected (0.40 sec)

The execution sequence of UPDATE SET is different from that of MySQL.	UPDATE ... SET	In MySQL, UPDATE SET is performed in sequence. The results of UPDATE at the front affect subsequent results of UPDATE, and the same column can be updated for multiple times. In GaussDB, all related data is obtained first, and then UPDATE is performed on the data at a time. The same column cannot be updated for multiple times.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description	Syntax	Difference
IGNORE feature	UPDATE/DELETE/ INSERT	The execution process in MySQL is different from that in GaussDB. Therefore, the number and information of generated warnings may be different.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description	Syntax	Difference

SHOW COLUMNS syntax	SHOW	• User permission verification is different from that of MySQL.
		– In GaussDB, you need the USAGE permission on the schema of a specified table and table-level or column-level permissions on the specified table. Only information about columns with the SELECT, INSERT, UPDATE, REFERENCES, and COMMENT permissions is displayed.
		– In MySQL, you need table-level or column-level permissions on a specified table. Only information about columns with the SELECT, INSERT, UPDATE, REFERENCES, and COMMENT permissions is displayed.
		• When the LIKE and WHERE clauses involve string comparison operations, the collation is different from that in MySQL.
		– **utf8_general_ci** is used in MySQL.
		– The **collation_connection** of the current client is used as the collation in GaussDB.
		In GaussDB, you are advised not to select columns other than the returned fields in the WHERE clause. Otherwise, unexpected errors may occur.
		`-- Expected error`
		`m_db=# SHOW FULL COLUMNS FROM t02 WHERE `b`='pri';`
		`ERROR: Column "b" does not exist.`
		`LINE 1: SHOW FULL COLUMNS FROM t02 WHERE `b`='pri';`

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description	Syntax	Difference
		^ -- Unexpected error m_db=# SHOW FULL COLUMNS FROM t02 WHERE `c`='pri'; ERROR: input of anonymous composite types is not implemented LINE 1: SHOW FULL COLUMNS FROM t02 WHERE `c`='pri'; ^
SHOW CREATE DATABASE syntax	SHOW	User permission verification is different from that of MySQL. ● In GaussDB, you need the USAGE permission on a specified schema. ● In MySQL, you need database-level permissions (except GRANT OPTION and USAGE), table-level permissions (except GRANT OPTION), or column-level permissions.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description	Syntax	Difference
SHOW CREATE TABLE syntax	SHOW	• User permission verification is different from that of MySQL. – In GaussDB, you need the USAGE permission on the schema where a specified table is located and table-level permissions on the specified table. – Table-level permissions (except GRANT OPTION) of the specified table are required in MySQL. • The returned statements for table creation are different from those in MySQL. – In GaussDB, indexes are returned as CREATE INDEX statements. In MySQL, indexes are returned as CREATE TABLE statements. In GaussDB, the range of optional parameters supported by the CREATE INDEX syntax is different from that supported by the CREATE TABLE syntax. Therefore, some indexes cannot be created in CREATE TABLE statements. – In GaussDB, the **ENGINE** and **ROW_FORMAT** options of CREATE TABLE are adapted only for the syntax but do not take effect. Therefore, they are not displayed in the returned statements for table creation. • These statements are compatible with MySQL only after the compatibility parameter **m_format_dev_version** is set to **'s2'**. The compatibility parameter takes effect by

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description	Syntax	Difference
		changing the positions of column comments, table comments, **ON COMMIT** option for global temporary tables, PRIMARY KEY and UNIQUE constraints (where the **USING INDEX TABLESPACE** option is no longer displayed), and index comments.
SHOW CREATE VIEW syntax	SHOW	• User permission verification is different from that of MySQL. – In GaussDB, you need the USAGE permission on the schema where a specified view is located and table-level permissions on the specified view. – In MySQL, you need the table-level SELECT and table-level SHOW VIEW permissions on the specified view. • The returned statements for view creation are different from those in MySQL. If a view is created in the format of **SELECT * FROM** *tbl_name*, * is not expanded in GaussDB but expanded in MySQL. • The *character_set_client* and *collation_connection* columns in the returned result are different from those in MySQL. – The session values of system variables *character_set_client* and *collation_connection* are displayed during view creation in MySQL – Related metadata is not recorded in GaussDB and **NULL** is displayed.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description	Syntax	Difference
SHOW PROCESSLIST syntax	SHOW	In GaussDB, the column content and case in the query result of this command are the same as those in the information_schema.processlist view. In MySQL, the column content and case may be different. • In GaussDB, common users can access only their own thread information. Users with the SYSADMIN permission can access thread information of all users. • In MySQL, common users can access only their own thread information. Users with the PROCESS permission can access thread information of all users.
SHOW [STORAGE] ENGINES	SHOW	In GaussDB, the column content and case of the query result of this command are the same as those in the information_schema.engines view. In MySQL, they may be different from those in the view. The query results of this command are different in MySQL and GaussDB because the databases have different storage engines.
SHOW [SESSION] STATUS	SHOW	In GaussDB, the column content and case of the query result of this command are the same as those in the information_schema.session_status view. In MySQL, they may be different from those in the view. Currently, GaussDB supports only **Threads_connected** and **Uptime**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description	Syntax	Difference
SHOW [GLOBAL] STATUS	SHOW	In GaussDB, the column content and case of the query result of this command are the same as those in the information_schema.global_status view. In MySQL, they may be different from those in the view. Currently, GaussDB supports only **Threads_connected** and **Uptime**.
SHOW INDEX	SHOW	• User permission verification is different from that of MySQL. – In GaussDB, you need the USAGE permission on a specified schema and table-level or column-level permissions on a specified table. – In MySQL, you need table-level (except GRANT OPTION) or column-level permission on the specified table. • Temporary tables in GaussDB are stored in independent temporary schemas. When using the FROM or IN db_name condition to display the index information of a specified temporary table, you must specify **db_name** as the schema where the temporary table is located. Otherwise, the system displays a message indicating that the temporary table does not exist. This is different from MySQL in some cases.
SHOW SESSION VARIABLES	SHOW	In GaussDB, the column content and case of the query result are the same as those in the information_schema.session_variables view. In MySQL, they may be different from those in the view.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description	Syntax	Difference
SHOW GLOBAL VARIABLES	SHOW	In GaussDB, the column content and case of the query result are the same as those in the information_schema.global_variables view. In MySQL, they may be different from those in the view.
SHOW CHARACTER SET	SHOW	In GaussDB, the column content and case of the query result are the same as those in the information_schema.character_sets view. In MySQL, they may be different from those in the view.
SHOW COLLATION	SHOW	In GaussDB, the column content and case of the query result are the same as those in the information_schema.collations view. In MySQL, they may be different from those in the view.
EXCEPT Syntax	SELECT	-
SELECT supports the STRAIGHT_JOIN syntax.	SELECT	The execution plans generated in the multi-table JOIN scenarios in GaussDB may be different from those in MySQL.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description	Syntax	Difference
SHOW TABLES	SHOW	• The LIKE behavior is different. For details, see "LIKE" in **Operators**. • The WHERE expression behavior is different. For details, see "WHERE" in GaussDB. • In GaussDB, permissions on tables and databases must be assigned to users separately. The database to be queried must be available to users on the SHOW SCHEMAS. Users must have permissions on both tables and databases. MySQL can be accessed as long as you have table permissions. • In GaussDB, the verification logic preferentially checks whether a schema exists and then checks whether the current user has the permission on the schema, which is different from that in MySQL.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description	Syntax	Difference
SHOW TABLE STATUS	SHOW	• In GaussDB, the syntax displays data depending on the tables view under information_schema. In MySQL, the tables view specifies tables. • In GaussDB, permissions on tables and databases must be assigned to users separately. The database to be queried must be available to users on the SHOW SCHEMAS. Users must have permissions on both tables and databases. MySQL can be accessed as long as you have table permissions. • In GaussDB, the verification logic preferentially checks whether a schema exists and then checks whether the current user has the permission on the schema, which is different from that in MySQL.
HAVING syntax	SELECT	In GaussDB, HAVING can only reference columns in the GROUP BY clause or columns used in aggregate functions. In addition, MySQL allows HAVING to reference SELECT columns in the list and columns in external subqueries.

SELECT followed by a row expression	SELECT	In MySQL, SELECT cannot be followed by a row expression, but in GaussDB, SELECT can be followed by a row expression.
		Behavior in MySQL:
		`mysql> SELECT row(1,2);`
		`ERROR 1241 (21000): Operand should contain 1 column(s)`
		Behavior in GaussDB:
		`m_db=# SELECT row(1,2);`
		` row(1,2)`
		`----------`
		` (1,2)`
		`(1 row)`

Description	Syntax	Difference

SELECT FOR SHARE/FOR UPDATE/ LOCK IN SHARE MODE	SELECT	• The FOR SHARE/FOR UPDATE/LOCK IN SHARE MODE and UNION/EXCEPT/ DISTINCT/GROUP BY/ HAVING clauses cannot be used together in GaussDB. They can be used together in MySQL 5.7 (except in the FOR SHARE/EXCEPT syntax) and MySQL 8.0.
		• When a locking clause is used together with the LEFT/ RIGHT [OUTER] JOIN clause, the LEFT JOIN cannot be used to lock the right table, and the RIGHT JOIN clause cannot be used to lock the left table. In MySQL, tables on both sides of JOIN can be locked at the same time.
		• When a lock clause is used together with the ORDER BY clause, if GaussDB detects that the tuple to be locked is concurrently modified by another session, it obtains the latest value of the sorted tuple from the session. During this process, MySQL obtains the sorting result again.
		• Behavior in GaussDB:
		gaussdb=# CREATE TABLE t1(a INT,b INT);
		CREATE TABLE
		gaussdb=# INSERT INTO t1 VALUES(1,1),(2,2);
		INSERT 0 2
		-- Session one.
		gaussdb=# START TRANSACTION;
		START TRANSACTION
		-- The session one is updated first, but the transaction is not committed.
		gaussdb=# UPDATE t1 SET a=3 WHERE a=1;
		UPDATE 1
		-- The session two starts a transaction.
		gaussdb=# START TRANSACTION;
		START TRANSACTION
		-- The session two is queried after the session one is updated. The query is successful after the session one transaction ends.
		gaussdb=# SELECT * FROM t1 ORDER

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description	Syntax	Difference

		BY a FOR UPDATE;
		commit a | b
		---+---
		3 | 1
		2 | 2
		(2 rows)
		-- The session one commits the transaction.
		gaussdb=# COMMIT;
		COMMIT
		• Behavior in MySQL:
		mysql> CREATE TABLE t1(a INT,b INT);
		Query OK, 0 rows affected (0.00 sec)
		mysql> INSERT INTO t1 VALUES(1,1),(2,2);
		Query OK, 2 rows affected (0.00 sec)
		Records: 2 Duplicates: 0 Warnings: 0
		-- Session one.
		mysql> START TRANSACTION;
		Query OK, 0 rows affected (0.00 sec)
		-- The session one is updated first, but the transaction is not committed.
		mysql> UPDATE t1 SET a=3 WHERE a=1;
		Query OK, 1 row affected (0.00 sec)
		Rows matched: 1 Changed: 1 Warnings: 0
		-- The session two starts a transaction.
		mysql> START TRANSACTION;
		Query OK, 0 rows affected (0.00 sec)
		-- The session two is queried after the session one is updated. The query is successful after the session one transaction ends.
		mysql> SELECT * FROM t1 ORDER BY a FOR UPDATE;
		+------+------+
		| a | b |
		+------+------+
		| 3 | 1 |
		| 2 | 4 |
		+------+------+
		2 rows in set (0.00 sec)
		-- The session one commits the transaction.
		mysql> COMMIT;
		Query OK, 0 rows affected (0.00 sec)
		• In MySQL, multiple lock clauses cannot be specified for the same table, while GaussDB supports this operation and the strongest lock will take effect.
		-- GaussDB
		m_db=# DROP TABLE IF EXISTS t1;
		DROP TABLE
		
		m_db=# CREATE TABLE t1(a INT, b INT);
		CREATE TABLE

Description	Syntax	Difference

		m_db=# INSERT INTO t1 VALUES(1,2);
		INSERT 0 1
		
		m_db=# SELECT * FROM t1 FOR UPDATE OF t1 LOCK IN SHARE MODE;
		a | b
		---+---
		1 | 2
		(1 row)
		
		m_db=# DROP TABLE t1;
		DROP TABLE
		
		-- MySQL
		mysql> DROP TABLE IF EXISTS t1;
		Query OK, 0 rows affected (0.05 sec)
		
		mysql> CREATE TABLE t1(a INT, b INT);
		Query OK, 0 rows affected (0.09 sec)
		
		mysql> INSERT INTO t1 VALUES(1,2);
		Query OK, 1 row affected (0.01 sec)
		
		mysql> SELECT * FROM t1 FOR UPDATE OF t1 LOCK IN SHARE MODE;
		ERROR 3569 (HY000): Table t1 appears in multiple locking clauses.
		
		mysql> DROP TABLE t1;
		Query OK, 0 rows affected (0.05 sec)

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description	Syntax	Difference

SELECT syntax	SELECT	• In GaussDB, the HAVING clause must be used together with the GROUP BY clause or aggregate functions. In MySQL, users can specify only the HAVING clause in a query statement.
		• In GaussDB, HAVING can only reference columns in the GROUP BY clause or columns used in aggregate functions. In addition, MySQL allows HAVING to reference SELECT columns in the list and columns in external subqueries.
		• In GaussDB and MySQL 5.7, GROUP BY WITH ROLLUP cannot be used together with the DISTINCT or ORDER BY clause. However, MySQL 8.0 supports this operation.
		• In GaussDB, when an empty table is queried by using the specified WITH ROLLUP statement, the query result is an empty row. In contrast, the query result in MySQL is empty.
		• In GaussDB, a table alias with the column name can be specified by using the FROM clause. In MySQL 5.7, a table alias with the column name cannot be specified. In MySQL 8.0, it is allowed only in a subquery.
		`-- GaussDB`
		`m_db=# DROP TABLE IF EXISTS t1;`
		`DROP TABLE`
		`m_db=# CREATE TABLE t1(a INT, b INT);`

Description	Syntax	Difference

Differences in assigning values to user variables in SELECT projection columns	SELECT @var_name := expr	• In MySQL, user-defined variable names can be escaped using escape characters or double quotation marks, but this feature is not supported in GaussDB.
		Variable names enclosed in single quotation marks cannot contain other single quotation marks. For example, @'', @''', and @'\'' are not supported. During parsing, the single quotation marks (') cannot be matched or an error will be reported. For example:
		-- An error is reported during parsing.
		m_db=# SET @''' = 1;
		ERROR: syntax error at or near "@"
		LINE 1: SET @''' = 1;
		
		-- The single quotation marks (') cannot be matched during parsing.
		m_db=# SET @'\'' = 1;
		m_db'#
		Variable names enclosed in double quotation marks cannot contain double quotation marks ("). For example, @"", @"""" and @"\"" are not supported. The double quotation marks cannot be matched or an error will be reported during parsing. For example:
		-- An error is reported during parsing.
		m_db=# SET @"""" = 1;
		ERROR: syntax error at or near "@"
		LINE 1: SET @"""" = 1;
		
		-- The double quotation marks (") cannot be matched during parsing.
		m_db=# SET @"\"" = 1;
		m_db"#
		The variable name enclosed by backquotes cannot contain backquotes. For example, @````, @`````, and @`\`` are not supported. During parsing, the backquotes (`) cannot be matched or an error will be reported. For example:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description	Syntax	Difference
		-- An error is reported during parsing. m_db=# SET @```` = 1; ERROR: syntax error at or near "@" LINE 1: SET @```` = 1; -- The backquotes (`) cannot be matched during parsing. m_db=# SET @`\`` = 1; m_db`# • When an SQL statement simultaneously assigns values to and reads user variables, the evaluation order of the variables is undefined, which may lead to differences in the final results compared to MySQL. The following is an example of assigning a value to a user variable and using the user variable as the parameter of the MAX function: -- GaussDB m_db=# SELECT @a := 2; @a ---- 2 (1 row) m_db=# SELECT MAX(@a), @a := 3; max | @a -----+---- 2 | 3 (1 row) m_db=# SELECT @a; @a ---- 3 (1 row) -- MySQL 5.7 mysql> SELECT @a := 2; +------+ | @a | +------+ | 2 | +------+ 1 row in set (0.00 sec) mysql> SELECT max(@a), @a := 3; +---------+---------+ | max(@a) | @a := 3 | +---------+---------+ | 3 | 3 | +---------+---------+ 1 row in set (0.00 sec) mysql> SELECT @a; +------+

Description	Syntax	Difference
INSERT ... ON DUPLICATE KEY UPDATE syntax	INSERT	• The format of *table name.column name* is not supported by VALUES() in the ON DUPLICATE KEY UPDATE clause in GaussDB, but is supported in MySQL. • In GaussDB, constraint columns cannot be modified by using ON DUPLICATE KEY UPDATE, but this operation is allowed in MySQL. • In the INSERT... query ON DUPLICATE KEY UPDATE statement, if query is a subquery, the ON DUPLICATE KEY UPDATE clause cannot reference column names in the subquery in GaussDB, while MySQL supports this behavior. • In MySQL, when you use the ON DUPLICATE KEY UPDATE clause to update multiple columns, the result of the previous UPDATE statement affects the subsequent results. In addition, you can update the same column for multiple times. In GaussDB, the result of the previous UPDATE operation does not affect the subsequent results. In addition, the same column cannot be updated for multiple times. • When the UPDATE operation is performed on inserted data that violates the UNIQUE constraint, the number of affected rows returned by GaussDB is different from that returned by MySQL. When a data record is updated, GaussDB returns **1** and MySQL returns **2**. If such update does not change the value of an existing row, GaussDB

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description	Syntax	Difference

		returns **1** and MySQL returns **0**.
		• In scenarios where a table column is of the VARCHAR type and is implicitly converted to a numeric data type, if the length of the string that fails to be converted is 2 characters shorter than the original string, MySQL does not generate an alarm or error; if the length of the string that fails to be converted is not 2 characters shorter than the original string, MySQL generates an alarm or error. However, GaussDB always generates an alarm or error when the string fails to be converted.
		-- GaussDB
		m_db=# CREATE TABLE t1(a int PRIMARY KEY, b varchar(10));

3.3.2.7.6 DCL

Table 3-161 DCL syntax compatibility

Description	Syntax	Difference
Set names with COLLATE specified.	SET [SESSION | LOCAL] NAMES {'charset_name' [COLLATE 'collation_name'] | DEFAULT};	GaussDB does not allow **charset_name** to be different from the database character set. For details, see "SQL Reference > SQL Syntax > SQL Statements > S > SET" in *M Compatibility Developer Guide*.

Switch the current mode with USE.	USE schema_name	When the USE statement is used to specify a schema and the user does not have permissions on the schema, MySQL reports an error while GaussDB specifies the current schema as null.
		-- MySQL
		mysql> USE test;
		ERROR 1044 (42000): Access denied for user 'u1'@'%' to database 'test'
		
		-- GaussDB
		m_db=> USE test;
		SET
		m_db=> SELECT database();
		ERROR: function returned NULL
		CONTEXT: referenced column: database

3.3.2.7.7 Other Statements

Table 3-162 Compatibility of other syntaxes

Description	Syntax	Difference
Transaction-related syntax	Default database isolation level	The default isolation level of an M-compatible database is READ COMMITTED, and that of MySQL is REPEATABLE READ. Only the READ COMMITTED and REPEATABLE READ isolation levels take effect in M-compatible databases.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description	Syntax	Difference
Transaction-related syntax	Transaction nesting	In M-compatible mode, nested transactions are not automatically committed, but in MySQL, they are automatically committed.
Transaction-related syntax	Autocommit	In M-compatible mode, GaussDB is used for storage and the GaussDB transaction mechanism is inherited. If DDL or DCL is executed in a transaction, the transaction is not automatically committed. In MySQL, if DDL, DCL, management-related, or lock-related statements are executed, the transaction is automatically committed.
Transaction-related syntax	Rollback is required after an error is reported.	If an error is reported for a transaction in an M-compatible database, rollback needs to be performed. There is no such restriction in MySQL.
Transaction-related syntax	Lock mechanism	The M-compatible lock mechanism can be used only in transaction blocks. There is no such restriction in MySQL.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description	Syntax	Difference
Lock mechanism	Lock mechanism	• After the read lock is obtained, write operations cannot be performed on the current session in MySQL, but write operations can be performed on the current session in an M-compatible database. • After MySQL locks a table, an error is reported when other tables are read. M-compatible does not have such restriction. • In MySQL, if the lock of the same table is obtained in the same session, the previous lock is automatically released and the transaction is committed. M-compatible databases do not have this mechanism. • M-compatible databases allow LOCK TABLE to be used only inside a transaction block, and have no UNLOCK TABLE command. Locks are always released at the end of transactions.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description	Syntax	Difference
PBE	PBE	• In an M-compatible database, if a PREPARE statement with the same name is repeatedly created, an error is reported, indicating that the statement already exists. You need to delete the existing statement first. In MySQL, the old statement will be overwritten. • M-compatible databases and MySQL report errors in different phases, such as parsing and execution, during SQL statement execution. PREPARE statements process prepared statements till the parsing phrase. Therefore, in abnormal scenarios in PBE, an M-compatible database may be different from that in MySQL in terms of whether the error is reported in the PREPARE or EXECUTE phase.

3.3.2.7.8 Users and Permissions

Overview

In M-compatible mode, the behaviors and syntaxes related to user and permission control inherit the GaussDB mechanism but are not synchronized with those in MySQL.

User and permission behaviors are the same as those in GaussDB. For details, see "Database Security > Users and Permissions" in *Developer Guide*

Some syntaxes for users and permissions are tailored in GaussDB. For details about the syntaxes, see "SQL Reference > SQL Syntax > SQL Statements" in *M Compatibility Developer Guide*. For details about the syntax differences between an M-compatible database and GaussDB, see **Table 3-163**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 3-163 Syntax differences between an M-compatible database and GaussDB

Syntax	Overview	Difference
CREATE ROLE	Creates a role.	In M-compatible mode, options involving the following keywords cannot be specified: **ENCRYPTED**, **UNENCRYPTED**, **RESOURCE POOL**, **PERM SPACE**, **TEMP SPACE**, and **SPILL SPACE**. When a user is created, a schema with the same name as the user is automatically created in an M-compatible database, but it is not created in MySQL.
CREATE USER	Creates a user.	
CREATE GROUP	Creates a user group. CREATE GROUP is the alias of CREATE ROLE and is not recommended.	
ALTER ROLE	Modifies role attributes.	
ALTER USER	Modifies user attributes.	
ALTER GROUP	Modifies the attributes of a user group.	-
DROP ROLE	Drops a role.	-
DROP USER	Drops a user.	-
DROP GROUP	Drops a user group.	-
DROP OWNED	Drops the database objects owned by a database role.	-
REASSIGN OWNED	Changes the owner of a database object.	This syntax is not supported in an M-compatible database.
GRANT	Grants permissions to roles and users.	In an M-compatible database, permissions on objects such as functions, stored procedures, tablespaces, and database links cannot be granted or revoked.
REVOKE	Revokes permissions from one or more roles.	
ALTER DEFAULT PRIVILEGES	Sets the permissions that will be granted to objects created in the future. (It does not affect permissions granted to existing objects.)	In M-compatible mode, you cannot change functions, types, and permissions on client master keys and column encryption keys of encrypted databases.

Differences

- Syntax format differences

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

For details about the permission granting syntaxes in M-compatible mode, see "SQL Reference > SQL Syntax > G > GRANT" in *M Compatibility Developer Guide*. The permission granting syntax in MySQL is as follows:

```
-- Global, database-level, table-level, and stored procedure–level permission granting syntax
GRANT
    priv_type [(column_list)]
      [, priv_type [(column_list)]] ...
    ON [object_type] priv_level

- Differences in types of permissions granted

  In MySQL, the following types of permissions can be granted.

Table 3-164 Types of permissions that can be granted in MySQL

Permission Type	Definition and Permission Level
ALL [PRIVILEGES]	Grants all permissions of a specified access level, except **GRANT OPTION** and **PROXY**.
ALTER	Enables **ALTER TABLE**. Level: global, database, and table.
ALTER ROUTINE	Allows you to modify or delete stored procedures. Level: global, database, and routine.
CREATE	Enables database and table creation. Level: global, database, and table.
CREATE ROUTINE	Enables stored procedure creation. Level: global and database.
CREATE TABLESPACE	Allows you to create, modify, or delete tablespaces or log file groups. Level: global.
CREATE TEMPORARY TABLES	Enables **CREATE TEMPORARY TABLE**. Level: global and database.
CREATE USER	Enables **CREATE USER**, **DROP USER**, **RENAME USER**, and **REVOKE ALL PRIVILEGES**. Level: global.
CREATE VIEW	Allows you to create or modify views. Level: global, database, and table.
DELETE	Enables **DELETE**. Level: global, database, and table.
DROP	Allows you to delete databases, tables, or views. Level: global, database, and table.
EVENT	Enables scheduled tasks. Level: global and database.
EXECUTE	Allows you to execute stored procedures. Level: global, database, and stored procedure.
FILE	Allows you to enable the server to read or write files. Level: global.
GRANT OPTION	Allows you to grant permissions to or remove permissions from other accounts. Level: global, database, table, stored procedure, and proxy.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Permission Type	Definition and Permission Level
INDEX	Allows you to create or delete indexes. Level: global, database, and table.
INSERT	Enables **INSERT**. Level: global, database, table, and column.
LOCK TABLES	LOCK TABLES can be enabled on tables with the SELECT permission. Level: global and database.
PROCESS	Allows users to view all running threads through **SHOW PROCESSLIST**. Level: global.
PROXY	Enables a user proxy. Level: from user to user.
REFERENCES	Enables foreign key creation. Level: global, database, table, and column.
RELOAD	Enables **FLUSH**. Level: global.
REPLICATION CLIENT	Allows you to query the location of the source server or replica server. Level: global.
REPLICATION SLAVE	Allows replicas to read binary logs from the source. Level: global.
SELECT	Enables **SELECT**. Level: global, database, table, and column.
SHOW DATABASES	Enables **SHOW DATABASES** to display all databases. Level: global.
SHOW VIEW	Enables **SHOW CREATE VIEW**. Level: global, database, and table.
SHUTDOWN	Enables **mysqladmin shutdown**. Level: global.
SUPER	Enables other management operations, such as **CHANGE MASTER TO**, **KILL**, **PURGE BINARY LOGS**, and **SET GLOBAL**, as well as the **mysqladmin debug** command. Level: global.
TRIGGER	Enables TRIGGER. Level: global, database, and table.
UPDATE	Enables **UPDATE**. Level: global, database, table, and column.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Permission Type	Definition and Permission Level
USAGE	Equivalent to "no privilege".

M-compatible databases support the following permissions by level:

Table 3-165 Types of permissions that can be granted in M-compatible databases

Object	Permissions That Can Be Granted
Database	CREATE, CONNECT, TEMPORARY, TEMP, ALTER, DROP, and COMMENT
Schema	CREATE, USAGE, ALTER, DROP, and COMMENT
Table and view	SELECT, INSERT, UPDATE, DELETE, TRUNCATE, REFERENCES, TRIGGER, ALTER, DROP, COMMENT, INDEX, and VACUUM
Column	SELECT, INSERT, UPDATE, REFERENCES, and COMMENT
Sequence	SELECT, USAGE, UPDATE, ALTER, DROP, and COMMENT

- In MySQL, *'*.*'* represents a global-level authorization object; in GaussDB, *'{DATABASE} db_name'* represents a database-level authorization object. The database level in GaussDB corresponds to the global level in MySQL.
- In MySQL, *'schema_name.*'* represents a database/schema-level authorization object; in GaussDB, *'{SCHEMA} schema_name'* represents a schema-level authorization object. The schema level in GaussDB corresponds to the database/schema level in MySQL.
- In MySQL, a username consists of two parts: *username*@*hostname*; in an M-compatible database, a username consists of only the username itself.
- MySQL allows you to modify user verification, secure connection, and resource parameter attributes (including **auth_option**, **tls_option**, and **resource option**) using the GRANT syntax. In M-compatible databases, these cannot be modified using the GRANT syntax; instead, you need to use CREATE USER and ALTER USER to set user attributes.
- MySQL supports permission granting with a user proxy. GRANT PROXY ON is used to manage permissions of users in a unified manner. MySQL 5.7 does not provide the role mechanism, but MySQL 8.0 and M-compatible databases provide the role mechanism. If a role can manage and control the permissions of users in a unified manner, it can replace GRANT PROXY ON.
- M-compatible databases have a concept called "public". All users have the public permission and can query some system catalogs and system views. Users can grant or revoke public permissions. In MySQL, newly created users

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

have only the global usage permission, which is almost low to none. They have only the permission to connect to the database and query the information_schema database.

- In M-compatible databases, the owner of an object has all permissions on the object by default. For security purposes, the owner can discard some permissions. However, ALTER, DROP, COMMENT, INDEX, VACUUM, and re-grantable permissions on the object are implicitly inherent, unrevocable permissions of the owner. In MySQL, there is no notion of "owner". Even if a user creates a table, they cannot perform operations such as IUD on the table without being granted the corresponding permissions.
- In MySQL, all users have the USAGE permission, which indicates no permission. When **REVOKE** or **GRANT USAGE** is executed, no modification is made. In M-compatible databases, the USAGE permission has the following meanings:
  - For schemas, USAGE allows access to objects contained in the schema. Without this permission, it is still possible to see the object names.
  - For sequences, USAGE allows use of the nextval function.
- In M-compatible databases, administrator roles can be set for users, including the system administrator (SYSADMIN), security administrator (CREATEROLE), audit administrator (AUDITADMIN), monitor administrator (MONADMIN), O&M administrator (OPRADMIN), and security policy administrator (POLADMIN). By default, SYSADMIN have the highest permission in the system. After separation of duties is enabled, system administrators no longer possess the CREATEROLE or AUDITADMIN attribute. That is, system administrators can neither create roles or users, nor view or maintain database audit logs. In MySQL, administrator roles cannot be set for users, and there is no design for separation of duties.
- In M-compatible databases, the ANY permission can be granted to users, allowing them to have the corresponding permissions in non-system schemas, including CREATE ANY TABLE, SELECT ANY TABLE, TRUNCATE ANY TABLE, and CREATE ANY INDEX. In MySQL, the ANY permission cannot be granted.
- MySQL provides SHOW GRANTS to query user permissions. In M-compatible databases, you can run gsql client meta-commands such as **'\l+'**, **'\dn+'**, or **'\dp'** to query permission information, or query related columns in system catalogs such as pg_namespace, pg_class, and pg_attribute for permission information.
- When a database, table, or column is deleted, the related permission granting information is still retained in system catalogs in MySQL. If an object with the same name is created again, the user still has the original permissions. However, M-compatible databases will not retain such permission granting information. If an object with the same name is created again, permissions need to be granted again.
- When granting database-level permissions, MySQL supports fuzzy match of database names using underscores (_) and percent signs (%). However, M-compatible databases do not support fuzzy match of object names using special characters such as underscores (_) or percent signs (%), which are identified as common characters.
- In MySQL, if a non-existing user is specified in the GRANT statement, a user account is created by default (this feature has been removed from MySQL

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

8.0). In M-compatible databases, permissions cannot be granted to users who have not been created.

3.3.2.7.9 System Catalogs and System Views

Table 3-166 Differences between M-compatible databases and GaussDB in terms of system catalogs or views

System Catalog or System View	Column	Difference
information_schema.columns	generation_expression	The output of this column varies due to different string concatenation logics of expressions in M-compatible mode and MySQL.
information_schema.columns	data_type	The output result of this column in M-compatible mode, having not been modified due to the data type format_type involved, is different from that in MySQL.
information_schema.columns	column_type	The output result of this column in M-compatible mode, having not been modified due to the data type format_type involved, is different from that in MySQL.
information_schema.tables	engine	In M-compatible mode: • ENGINE is aligned with data of information_schema.engines. • In some system catalogs, ENGINE is left empty. • If the default table is an ASTORE table and **STORAGE_TYPE** is not specified, **ENGINE** is empty.
information_schema.tables	version	This column is not supported in M-compatible mode.
information_schema.tables	row_format	This column is not supported in M-compatible mode.
information_schema.tables	avg_row_length	In M-compatible mode, the result of dividing the size of the data files by the number of all tuples (including live tuples and dead tuples) is used. If there is no tuple in the table, the value is **null**.
information_schema.tables	max_data_length	This column is not supported in M-compatible mode.
information_schema.tables	data_free	In M-compatible mode, it indicates the result of (Number of dead tuples/Total number of tuples) x Data file size. If there is no tuple in the table, the value is **null**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

System Catalog or System View	Column	Difference
information_schema.tables	check_time	This column is not supported in M-compatible mode.
information_schema.tables	create_time	The behavior of this column in M-compatible mode is different from that in MySQL. When a view is created in MySQL, this column is set to **null**. In M-compatible mode, the actual table creation time is displayed. The value is **null** if it is a table or view provided by the database.
information_schema.tables	update_time	The value is **null** if it is a table or view provided by the M-compatible database.
information_schema.statistics	collation	The value can only be **A** or **D** but not NULL in M-compatible mode.
information_schema.statistics	packed	This column is not supported in M-compatible mode.
information_schema.statistics	sub_part	This column is not supported in M-compatible mode.
information_schema.statistics	comment	This column is not supported in M-compatible mode.
information_schema.partitions	subpartition_name	In M-compatible mode, if the specified object is not a subpartition, the value is **null**.
information_schema.partitions	subpartition_ordinal_position	In M-compatible mode, if the specified object is not a subpartition, the value is **null**.
information_schema.partitions	partition_method	In M-compatible mode: Partitioning policy. If it is not a partition, the value is **null**. ● **'r'**: range partition. ● **'i'**: interval partition. ● **'l'**: list partition. ● **'h'**: hash partition

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

System Catalog or System View	Column	Difference
information_schema.partitions	subpartition_method	In M-compatible mode: Subpartitioning policy. If it is not a subpartition, the value is **null**. ● **'r'**: range partition. ● **'i'**: interval partition. ● **'l'**: list partition. ● **'h'**: hash partition
information_schema.partitions	partition_description	In M-compatible mode, there are partitions and subpartitions.
information_schema.partitions	partition_expression	This column is not supported in M-compatible mode.
information_schema.partitions	subpartition_expression	This column is not supported in M-compatible mode.
information_schema.partitions	data_length	This column is not supported in M-compatible mode.
information_schema.partitions	max_data_length	This column is not supported in M-compatible mode.
information_schema.partitions	index_length	This column is not supported in M-compatible mode.
information_schema.partitions	data_free	This column is not supported in M-compatible mode.
information_schema.partitions	create_time	This column is not supported in M-compatible mode.
information_schema.partitions	update_time	This column is not supported in M-compatible mode.
information_schema.partitions	check_time	This column is not supported in M-compatible mode.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

System Catalog or System View	Column	Difference
information_schema.partitions	checksum	This column is not supported in M-compatible mode.
information_schema.partitions	partition_comment	This column is not supported in M-compatible mode.
information_schema.partitions	nodegroup	This column is not supported in M-compatible mode.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- The precision range cannot be specified for the command output of the integer type in a view. For example, the bigint(1) type in MySQL corresponds to the bigint type in M-compatible mode, and the bigint(21) unsigned type in MySQL corresponds to the bigint unsigned type in M-compatible mode.
- The int type in MySQL corresponds to the integer type in M-compatible mode.
- M-compatible mode does not support columns of the set and enum types that are supported in MySQL. This version does not support or display **Column_priv** column in the m_schema.columns_priv view, **Table_priv,Column_priv** column in the m_schema.tables_priv view, **Routine_type,Proc_priv** column in the m_schema.procs_priv view, the **type,language,sql_data_access,is_deterministic,security_type,sql_mode** column in the m_schema.proc view, or the **type** column in the m_schema.func view.
- **table_rows**, **avg_row_length**, **data_length**, **data_free**, **index_length**, and **cardinality** in information_schema.tables and **cardinality** in information_schema.statistics are obtained based on statistics. Therefore, run **ANALYZE** to update statistics before viewing them. (If data is updated in the database, you are advised to delay running **ANALYZE**.)
- The index columns contained in information_schema.statistics must be complete table columns in the created indexes. If the index columns are expressions, they are not in this view.
- **table_row** in information_schema.partitions is obtained based on statistics. Before viewing the value, run **ANALYZE** to update the statistics. (If data is updated in the database, you are advised to delay running **ANALYZE**.)
- The format of the **grantee** column supported in MySQL is '*user_name*'**@**'*host_name*'. In an M-compatible database, it is the name of the user or role to which the permission is granted.
- For the **host** column supported in the M-compatible database, the **hostname** of the current node is returned.
- In MySQL, you need the permission before viewing m_schema.tables_priv, information_schema.user_privileges, information_schema.schema_privileges, information_schema.table_privileges, information_schema.column_privileges, m_schema.columns_priv, m_schema.func, and m_schema.procs_priv. In an M-compatible database, you can view them with the default permission. For example, for table **t1**, you need the corresponding permission in MySQL so that you can view the corresponding permission information in the permission view. In an M-compatible database, you can view the permission information related to table **t1** in the view.
- A system view in m_schema is a system catalog in MySQL.
- The collations of **VIEW_DEFINITION** in information_schema.views and **ROUTINE_DEFINITION** in information_schema.routines are not controlled.
- For the view columns of the character type listed in "Schemas" in *M Compatibility Developer Guide*, the character set is utf8mb4, and the collation is utf8mb4_bin or utf8mb4_general_ci, and the collation priority is the priority of columns of data types that support collation described in "SQL Reference > Character Set and Collations > Rules for Combining Character Sets and Collations" in *M Compatibility Developer Guide*. These features are different from those in MySQL.

3.3.3 MYSQL-compatible Mode

3.3.3.1 Data Types

3.3.3.1.1 Numeric Data Types

Integer Types

Unless otherwise specified, the precision, scale, and number of digits cannot be set to the floating-point values in MySQL-compatible mode by default. You are advised to use valid integer values.

Differences in terms of the integer types:

- Input format:
  - MySQL

    For characters such as "asbd", "12dd", and "12 12", the system truncates them or returns 0 and reports a WARNING. Data fails to be inserted into a table in strict mode.
  - GaussDB
    - For integer types (TINYINT, SMALLINT, MEDIUMINT, INT, INTEGER, and BIGINT), if the invalid part of a character string is truncated, for example, "12@3" or "1E09" is converted into a scientific notation of an integer, no message is displayed. Data is successfully inserted into a table.
    - If the whole integer is truncated (for example, "@123") or the character string is empty, 0 is returned and data is successfully inserted into a table.
- Operators:
  - +, -, and *

    GaussDB: When INT, INTEGER, SMALLINT, or BIGINT is used for calculation, a value of the original type is returned and is not changed to a larger type. If the return value exceeds the range, an error is reported.

    MySQL: The value can be changed to BIGINT for calculation.
  - |, &, ^, and ~

    GaussDB: The value is calculated in the bits occupied by the type. In GaussDB, ^ indicates the exponentiation operation. If the XOR operator is required, replace it with #.

    MYSQL: The value is changed to a larger type for calculation.
  - <, <=, <=>, <>, =, >, and >=

    GaussDB: When an integer is compared with a string, the string is converted to an integer before the comparison. If a string contains non-digit characters such as decimal points and letters, the non-integer part is directly truncated for comparison. If the string is completely truncated (for example, "@123") or is empty, the string type is converted to 0 before being compared with the integer type.

    MYSQL: When an integer is compared with a string, they are converted to floating-point numbers for comparison.
- Explicit type conversion of negative numbers:

  GaussDB: The result is **0** in loose mode and an error is reported in strict mode.

  MySQL: The most significant bit is replaced with a numeric bit based on the corresponding binary value, for example, (-1)::uint4 = 4294967295.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- Other differences:

  The precision of INT[(M)] controls formatted output in MySQL. GaussDB supports only the syntax but does not support the function.

- Aggregate function:
  - variance: indicates the sample variance in GaussDB and the population variance in MySQL.
  - stddev: indicates the sample standard deviation in GaussDB and the overall standard deviation in MySQL.
- Display width:
  - If **ZEROFILL** is not specified when the width information is specified for an integer column, the width information is not displayed in the table definition.
  - When the INSERT statement is used to insert a column of the character type, GaussDB pads 0s before inserting the column.
  - The JOIN USING statement involves type derivation. In MySQL, the first table column is used by default. In GaussDB, if the result is of the signed type, the width information is invalid. Otherwise, the width of the first table column is used.
  - For GREATEST/LEAST, IFNULL/IF, and CASE WHEN/DECODE, MySQL does not pad 0s. In GaussDB, 0s are padded when the type and width information is consistent.
  - MySQL supports this function when it is used as the input or output parameter or return value of a function or stored procedure. GaussDB neither reports syntax errors nor supports this function.

For details about the differences in GaussDB and MySQL in terms of the integer types, see **Table 3-167**.

Table 3-167 Integer types

MySQL	GaussDB	Difference
BOOL	Supported, but with differences.	MySQL: The BOOL/BOOLEAN type is actually mapped to the TINYINT type. GaussDB: BOOL is supported.
BOOLEAN	Supported, but with differences.	• Valid literal values for the "true" state include: **TRUE**, **'t'**, **'true'**, **'y'**, **'yes'**, **'1'**, **'TRUE'**, **true**, **'on'**, and all non-zero values. • Valid literal values for the "false" state include: **FALSE**, **'f'**, **'false'**, **'n'**, **'no'**, **'0'**, **0**, **'FALSE'**, **false**, and **'off'**. **TRUE** and **FALSE** are standard expressions, compatible with SQL statements.
TINYINT[(M)] [UNSIGNED]	Supported, but with differences.	For details, see **Differences in terms of the integer types**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

MySQL	GaussDB	Difference
SMALLINT[(M)] [UNSIGNED]	Supported, but with differences.	For details, see **Differences in terms of the integer types**.
MEDIUMINT[(M)] [UNSIGNED]	Supported, but with differences.	MySQL requires 3 bytes to store MEDIUMINT data. • The signed range is –8388608 to +8388607. • The unsigned range is 0 to +16777215. GaussDB maps data to the INT type and requires 4 bytes for storage. • The signed range is –2147483648 to +2147483647. • The unsigned range is 0 to +4294967295. For details about other differences, see **Differences in terms of the integer types**.
INT[(M)] [UNSIGNED]	Supported, but with differences.	For details, see **Differences in terms of the integer types**.
INTEGER[(M)] [UNSIGNED]	Supported, but with differences.	For details, see **Differences in terms of the integer types**.
BIGINT[(M)] [UNSIGNED]	Supported, but with differences.	For details, see **Differences in terms of the integer types**.

NOTE

If data is different due to different compatibility, the column has an index, and the compatibility environment when the index is used is different from that when the index is built, the index may become invalid. In this case, you need to reindex it.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Arbitrary precision types

Table 3-168 Arbitrary precision types

MySQL	GaussDB	Difference
DECIMAL[(M[,D])]	Supported, but with differences.	• Operator: In GaussDB, "^" indicates the exponentiation operation. If the XOR operator is required, replace it with "#". In MySQL, "^" indicates the XOR operation. • Value range: The precision **M** and scale **D** support only integers and do not support floating-point values. • Input format: No error is reported when all input parameters of a character string (for example, "@123") are truncated. An error is reported only when it is partially truncated, for example, "12@3".
NUMERIC[(M[,D])]	Supported, but with differences.	
DEC[(M[,D])]	Supported, but with differences.	
FIXED[(M[,D])]	Not supported.	-

Floating-point types

Table 3-169 Floating-point types

MySQL	GaussDB	Difference
FLOAT[(M,D)]	Supported, but with differences.	• Partitioned table: The FLOAT data type does not support partitioned tables with the key partitioning policy. • Operator: In GaussDB, "^" indicates the exponentiation operation. If the XOR operator is required, replace it with "#". In MySQL, "^" indicates the XOR operation. • Value range: The precision **M** and scale **D** support only integers and do not support floating-point values. • Output format: An ERROR message is reported for invalid input parameters. No WARNING is reported in loose mode (that is, **sql_mode** is set to **''**).

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

MySQL	GaussDB	Difference
FLOAT(p)	Supported, but with differences.	• Partitioned table: The FLOAT data type does not support partitioned tables with the key partitioning policy. • Operator: The ^ operator is used for the numeric types, which is different from that in MySQL. In GaussDB, the ^ operator is used for exponential calculation. • Value range: When the precision **p** is defined, only valid integer data types are supported. • Output format: An ERROR message is reported for invalid input parameters. No WARNING is reported in loose mode (that is, **sql_mode** is set to **''**).
DOUBLE[(M, D)]	Supported, but with differences.	• Partitioned table: The DOUBLE data type does not support partitioned tables with the key partitioning policy. • Operator: In GaussDB, "^" indicates the exponentiation operation. If the XOR operator is required, replace it with "#". In MySQL, "^" indicates the XOR operation. • Value range: The precision **M** and scale **D** support only integers and do not support floating-point values. • Output format: An ERROR message is reported for invalid input parameters. No WARNING is reported in loose mode (that is, **sql_mode** is set to **''**).
DOUBLE PRECISION[(M,D)]	Supported, but with differences.	• Operator: In GaussDB, "^" indicates the exponentiation operation. If the XOR operator is required, replace it with "#". In MySQL, "^" indicates the XOR operation. • Value range: The precision **M** and scale **D** support only integers and do not support floating-point values. • Output format: An ERROR message is reported for invalid input parameters. No WARNING is reported in loose mode (that is, **sql_mode** is set to **''**).

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

MySQL	GaussDB	Difference
REAL[(M,D)]	Supported, but with differences.	• Partitioned table: The REAL data type does not support partitioned tables with the key partitioning policy. • Operator: In GaussDB, "^" indicates the exponentiation operation. If the XOR operator is required, replace it with "#". In MySQL, "^" indicates the XOR operation. • Value range: The precision **M** and scale **D** support only integers and do not support floating-point values. • Output format: An ERROR message is reported for invalid input parameters. No WARNING is reported in loose mode (that is, **sql_mode** is set to **''**).

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Sequential Integers

Table 3-170 Sequential integers

MySQL	GaussDB	Difference
SERIAL	Supported, but with differences.	For details about SERIAL in GaussDB, see **Numeric Types**. The differences in specifications are as follows: `CREATE TABLE test(f1 serial, f2 CHAR(20));` • Difference in type definition: MySQL maps serial to BIGINT(20) UNSIGNED NOT NULL AUTO_INCREMENT UNIQUE, and GaussDB maps serial to INTEGER NOT NULL DEFAULT nextval('test_f1_seq'::regclass). For example: `-- Definition of MySQL SERIAL:` `mysql> SHOW CREATE TABLE test\G` `*************************** 1. row ***************************` `Table: test` `Create Table: CREATE TABLE `test` (` `  `f1` bigint(20) unsigned NOT NULL AUTO_INCREMENT,` `  `f2` char(20) DEFAULT NULL,` `  UNIQUE KEY `f1` (`f1`)` `) ENGINE=InnoDB DEFAULT CHARSET=utf8` `1 row in set (0.00 sec)` `-- Definition of GaussDB SERIAL` `gaussdb=# \d+ test` `Table "public.test"` ` Column	Type	Modifiers	Storage	Stats target	Description` `--------+---------- +---------- +---------- +--------------+-------------` ` f1	integer	not null default nextval('test_f1_seq'::regclass)	plain		` ` f2	character(20)		extended		` `Has OIDs: no` `Options: orientation=row, compression=no, storage_type=USTORE` • Differences in using INSERT to insert default values of the SERIAL type. For example: `-- Inserting default values of the SERIAL type in MySQL` `mysql> INSERT INTO test VALUES(DEFAULT, 'aaaa');` `Query OK, 1 row affected (0.00 sec)`  `mysql> INSERT INTO test VALUES(10, 'aaaa');` `Query OK, 1 row affected (0.00 sec)`  `mysql> INSERT INTO test VALUES(DEFAULT, 'aaaa');` `Query OK, 1 row affected (0.00 sec)`  `mysql> SELECT * FROM test;` `+----+------+` `| f1	f2 |` `+----+------+` `| 1	aaaa |` `| 10	aaaa |` `| 11	aaaa |` `+----+------+` `3 rows in set (0.00 sec)`

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

MySQL	GaussDB	Difference

		-- Inserting default values of the SERIAL type in GaussDB
		gaussdb=# INSERT INTO test VALUES(DEFAULT, 'aaaa');
		INSERT 0 1
		gaussdb=# INSERT INTO test VALUES(10, 'aaaa');
		INSERT 0 1
		gaussdb=# INSERT INTO test VALUES(DEFAULT, 'aaaa');
		INSERT 0 1
		gaussdb=# SELECT * FROM test;
		f1 | f2
		----+----------------------
		1 | aaaa
		2 | aaaa
		10 | aaaa
		(3 rows)
		• Differences in referencing columns of the serial type in REPLACE scenarios. For details about how to reference columns in GaussDB, see **REPLACE**. For example:
		-- Inserting values of the referencing columns of the SERIAL type in MySQL
		mysql> REPLACE INTO test VALUES(f1, 'aaaa');
		Query OK, 1 row affected (0.00 sec)
		
		mysql> REPLACE INTO test VALUES(f1, 'bbbb');
		Query OK, 1 row affected (0.00 sec)
		
		mysql> SELECT * FROM test;
		+----+------+
		| f1 | f2 |
		+----+------+
		| 1 | aaaa |
		| 2 | bbbb |
		+----+------+
		2 rows in set (0.00 sec)
		
		-- Inserting values of the referencing columns of the SERIAL type in GaussDB
		gaussdb=# REPLACE INTO test VALUES(f1, 'aaaa');
		REPLACE 0 1
		gaussdb=# REPLACE INTO test VALUES(f1, 'bbbb');
		REPLACE 0 1
		gaussdb=# SELECT * FROM test;
		f1 | f2
		----+----------------------
		0 | aaaa
		0 | bbbb
		(2 rows)

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

3.3.3.1.2 Date and Time Data Types

Table 3-171 Date and Time Data Types

MySQL	GaussDB	Difference
DATE	Supported, with differences	GaussDB supports the date data type. Compared with MySQL, GaussDB has the following differences in specifications: ● Input format – GaussDB supports only the character type and does not support the numeric type. For example, the format can be '2020-01-01' or '20200101', but cannot be 20200101. MySQL supports conversion from numeric input to the date type. – Separator: GaussDB does not support the plus sign (+) or colon (:) as the separator between the year, month, and day. Other symbols are supported. MySQL supports all symbols as separators. Sometimes, the mixed use of separators is not supported, which is different from MySQL, such as '2020-01>01' and '2020/01+01'. You are advised to use hyphens (-) or slashes (/) as separators. – No separator: You are advised to use the complete format, for example, 'YYYYMMDD' or 'YYMMDD'. The parsing rules of incomplete formats (including the ultra-long format) are different from those of MySQL. An error may be reported or the parsing result may be inconsistent with that of MySQL. Therefore, the incomplete format is not recommended. ● Output format If the **sql_mode** parameter of GaussDB does not contain **'strict_trans_tables'** (the strict mode is used unless otherwise defined as the loose mode), the year, month, and day can be set to **0**. However, the value is converted to a valid value in the sequence of year, month, and day. For example, date '0000-00-10' is converted to 0002-12-10 BC. If the input is invalid or exceeds the range, a warning message is reported and the value **0000-00-00** is returned. MySQL outputs the date value as it is, even if the year, month, and day are set to **0**. ● Value range

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

MySQL	GaussDB	Difference

		The value range of GaussDB is 4713-01-01 BC to 5874897-12-31 AD. BC dates are supported. In loose mode, if the value exceeds the range, **0000-00-00** is returned. In strict mode, an error is reported. In MySQL, the value range is 0000-00-00 to 9999-12-31. In loose mode, if the value exceeds the range, the performance varies in different scenarios. An error may be reported (for example, in the SELECT statement) or the value **0000-00-00** may be returned (for example, in the INSERT statement). As a result, when the date type is used as the input parameter of the function, the results returned by the function are different.
		● Operator
		– GaussDB supports only the comparison operators =, !=, <, <=, >, and >= between date types and returns **true** or **false**. For the addition operation between the date and interval types, the return result is of the date type. For the subtraction operation between the date and interval types, the return result is of the date type. For the subtraction operation between date types, the return result is of the interval type.
		– When the MySQL date type and other numeric types are calculated, the date type is converted to the numeric type, and then the calculation is performed based on the numeric type. The result is also of the numeric type. It is different from GaussDB. For example:
		`-- MySQL: date+numeric. Convert the date type to 20200101 and add it to 1. The result is 20200102.`
		`mysql> SELECT date'2020-01-01' + 1;`
		`+----------------------+`
		`| date'2020-01-01' + 1 |`
		`+----------------------+`
		`| 20200102 |`
		`+----------------------+`
		`1 row in set (0.00 sec)`
		
		`-- GaussDB: date+numeric. Convert the numeric type to the interval type (1 day), and then add them up to obtain a new date.`
		`gaussdb=# SELECT date'2020-01-01' + 1;`
		`?column?`
		`------------`
		`2020-01-02`
		`(1 row)`
		● Type conversion

MySQL	GaussDB	Difference
		Compared with MySQL, GaussDB supports conversion between the date type and char(n), nchar(n), datetime, or timestamp type, but does not support conversion between the date type and binary, decimal, JSON, integer, unsigned integer, or time type. The principles for determining common types in scenarios such as collections and complex expressions are different from those in MySQL. For details, see **Data Type Conversion**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

MySQL	GaussDB	Difference
DATETIME[(fsp)]	Supported, with differences.	GaussDB supports the datetime data type. Compared with MySQL, GaussDB has the following differences in specifications: ● Input format – GaussDB supports only the character type and does not support the numeric type. For example, '2020-01-01 10:20:30.123456' or '20200101102030.123456' is supported, but 20200101102030.123456 is not supported. MySQL supports conversion from numeric input to the datetime type. – Separator: GaussDB does not support the plus sign (+) or colon (:) as the separator between the year, month, and day. Other symbols are supported. Only colons (:) can be used as separators between hours, minutes, and seconds. Sometimes, the mixed use of separators is not supported, which is different from MySQL. Therefore, it is not recommended. MySQL supports all symbols as separators. – No separator: In GaussDB, the complete format 'YYYYMMDDhhmiss.ffffff' is recommended. The parsing rules of incomplete formats (including the ultra-long format) may be different from those of MySQL. An error may be reported or the parsing result may be inconsistent with that of MySQL. Therefore, the incomplete format is not recommended. ● Output format: – The format is 'YYYY-MM-DD hh:mi:ss.ffffff', which is the same as that of MySQL and is not affected by the **DateStyle** parameter. However, for the precision part, if the last several digits are 0, they are not displayed in GaussDB but displayed in MySQL. – If the **sql_mode** parameter of GaussDB does not contain **'strict_trans_tables'** (the strict mode is used unless otherwise defined as the loose mode), the year, month, and day can be set to **0**. However, the value is converted to a valid value in the sequence of year, month, and day. For example, datetime '0000-00-10 00:00:00'

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

MySQL	GaussDB	Difference
		is converted to 0002-12-10 00:00:00 BC. If the input is invalid or exceeds the range, a warning message is reported and the value **0000-00-00 00:00:00** is returned. MySQL outputs the datetime value as it is, even if the year, month, and day are set to **0**. ● Value range 4713-11-24 00:00:00.000000 BC to 294277-01-09 04:00:54.775806 AD. If the value is **294277-01-09 04:00:54.775807 AD**, **infinity** is returned. If the value exceeds the range, GaussDB reports an error in strict mode. Whether MySQL reports an error depends on the application scenario. Generally, no error is reported in the query scenario. However, an error is reported when the DML or SQL statement is executed to change the value of a table attribute. In loose mode, GaussDB returns **0000-00-00 00:00:00**. MySQL may report an error, return **0000-00-00 00:00:00**, or return **null** based on the application scenario. As a result, the execution result of the function that uses the datetime type as the input parameter is different from that of MySQL. ● Precision The value ranges from 0 to 6. For a table column, the default value is **0**, which is the same as that in MySQL. In the datetime[(p)]'str' expression, GaussDB parses **(p)** as the precision. The default value is **6**, indicating that **'str'** is formatted to the datetime type based on the precision specified by **p**. MySQL does not support the datetime[(p)]'str' expression. ● Operator – GaussDB supports only the comparison operators =, !=, <, <=, >, and >= between datetime types and returns **true** or **false**. For the addition operation between the datetime and interval types, the return result is of the datetime type. For the subtraction operation between the datetime and interval types, the return result is of the datetime type. For the subtraction operation between datetime types, the return result is of the interval type.

MySQL	GaussDB	Difference

		– When the MySQL datetime type and other numeric types are calculated, the datetime type is converted to the numeric type, and then the calculation is performed based on the numeric type. The result is also of the numeric type. It is different from GaussDB. For example:
		-- MySQL: datetime+numeric. Convert the datetime type to 20201010123456 and add it to 1. The result is 20201010123457.
		mysql> SELECT cast('2020-10-10 12:34:56.123456' AS datetime) + 1;
		+--+
		| cast('2020-10-10 12:34:56.123456' AS datetime) + 1 |
		+--+
		| 20201010123457 |
		+--+
		1 row in set (0.00 sec)
		
		-- GaussDB: datetime+numeric. Convert the numeric type to the interval type (1 day), and then add them up to obtain the new datetime.
		gaussdb=# SELECT cast('2020-10-10 12:34:56.123456' AS datetime) + 1;
		?column?
		--------------------- 	
		2020-10-11 12:34:56
		(1 row)
		If the calculation result of the datetime type and numeric type is used as the input parameter of a function, the result of the function may be different from that of MySQL.
		• Type conversion
		Compared with MySQL, GaussDB supports only the conversion between the datetime type and the char(n), varchar(n), or timestamp type, and the conversion from datetime to date or time (only value assignment and explicit conversion). Conversion between binary, decimal, json, integer, and unsigned integer types is not supported. The principles for determining common types in scenarios such as collections and complex expressions are different from those in MySQL. For details, see **Data Type Conversion**.
		• Time zone
		In GaussDB, the datetime value can carry the time zone information (time zone offset or time zone name), for example, '2020-01-01 12:34:56.123456 +01:00' or '2020-01-01 2:34:56.123456 CST'. GaussDB converts the time to the time of the current server time

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

MySQL	GaussDB	Difference
		zone. MySQL 5.7 does not support this function. MySQL 8.0 and later versions support this function. • The table columns of the datetime data type in GaussDB are actually converted to the timestamp(p) without time zone. When you query the table information or use a tool to export the table definition, the data type of columns is timestamp(p) without time zone instead of datetime. For MySQL, datetime(p) is displayed.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

MySQL	GaussDB	Difference
TIMESTAMP[(fsp)]	Supported, with differences	GaussDB supports the timestamp data type and differs from MySQL in terms of the following specifications: ● Input format: – It supports only the character type and does not support the numeric type. For example, '2020-01-01 10:20:30.123456' or '20200101102030.123456' is supported, but 20200101102030.123456 is not supported. MySQL supports conversion from numeric input to the timestamp type. – Separator: It does not support the plus sign (+) or colon (:) as the separator between the year, month, and day. Other symbols are supported. Only colons (:) can be used as separators between hours, minutes, and seconds. Sometimes, the mixed use of separators is not supported, which is different from MySQL. Therefore, it is not recommended. MySQL supports all symbols as separators. – No separator: The complete format 'YYYYMMDDhhmiss.ffffff' is recommended. The parsing rules of incomplete formats (including the ultra-long format) may be different from those of MySQL. An error may be reported or the parsing result may be inconsistent with that of MySQL. Therefore, the incomplete format is not recommended. ● Output format: – The format is 'YYYY-MM-DD hh:mi:ss.ffffff', which is the same as that of MySQL and is not affected by the **DateStyle** parameter. However, for the precision part, if the last several digits are 0, they are not displayed in GaussDB but displayed in MySQL. – If the **sql_mode** parameter of GaussDB does not contain **'strict_trans_tables'** (the strict mode is used unless otherwise defined as the loose mode), the year, month, and day can be set to **0**. However, the value is converted to a valid value in the sequence of year, month, and day. For example, timestamp '0000-00-10

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

MySQL	GaussDB	Difference
		00:00:00' is converted to 0002-12-10 00:00:00 BC. If the input is invalid or exceeds the range, a warning message is reported and the value **0000-00-00 00:00:00** is returned. MySQL outputs the timestamp value as it is, even if the year, month, and day are set to **0**. ● Value range: 4713-11-24 00:00:00.000000 BC to 294277-01-09 04:00:54.775806 AD. If the value is **294277-01-09 04:00:54.775807 AD**, **infinity** is returned. If the value exceeds the range, GaussDB reports an error in strict mode. Whether MySQL reports an error depends on the application scenario. Generally, no error is reported in the query scenario. However, an error is reported when the DML or SQL statement is executed to change the value of a table attribute. In loose mode, GaussDB returns **0000-00-00 00:00:00**. MySQL may report an error, return **0000-00-00 00:00:00**, or return **null** based on the application scenario. As a result, the execution result of the function that uses the timestamp type as the input parameter is different from that of MySQL. ● Precision: The value ranges from 0 to 6. For a table column, the default value is **0**, which is the same as that in MySQL. In the timestamp[(p)] 'str' expression: – GaussDB parses **(p)** as the precision. The default value is **6**, indicating that **'str'** is formatted to the timestamp type based on the precision specified by **p**. – The meaning of timestamp 'str' in MySQL is the same as that in GaussDB. The default precision is **6**. However, timestamp(p) 'str' is parsed as a function call. **p** is used as the input parameter of the timestamp function. The result returns a value of the timestamp type, and **'str'** is used as the alias of the projection column. ● Operators: – GaussDB supports only the comparison operators =, !=, <, <=, >, and >= between timestamp types and returns **true** or **false**. For the addition operation between

MySQL	GaussDB	Difference

		the timestamp and interval types, the return result is of the timestamp type. For the subtraction operation between the timestamp and interval types, the return result is of the timestamp type. For the subtraction operation between timestamp types, the return result is of the interval type.
		– When the MySQL timestamp type and other numeric types are calculated, the timestamp type is converted to the numeric type, and then the calculation is performed based on the numeric type. The result is also of the numeric type. It is different from GaussDB. For example:
		`-- MySQL: timestamp+numeric. Convert the timestamp type to 20201010123456.123456 and add it to 1. The result is 20201010123457.123456.`
		`mysql> SELECT timestamp '2020-10-10 12:34:56.123456' + 1;`
		`+-------------------------------------------+`
		`| timestamp '2020-10-10 12:34:56.123456' + 1 |`
		`+-------------------------------------------+`
		`| 20201010123457.123456 |`
		`+-------------------------------------------+`
		`1 row in set (0.00 sec)`
		
		`-- GaussDB: timestamp+numeric. Convert the numeric type to the interval type (1 day), and then add them up to obtain a new timestamp.`
		`gaussdb=# SELECT timestamp '2020-10-10 12:34:56.123456' + 1;`
		`?column?`
		`---------------------------`
		`2020-10-11 12:34:56.123456`
		`(1 row)`
		If the calculation result of the timestamp type and numeric type is used as the input parameter of a function, the result of the function may be different from that of MySQL.
		• Type conversion:
		Compared with MySQL, GaussDB supports only the conversion between the timestamp type and the char(n), varchar(n), or datetime type, and the conversion from timestamp to date or time (only value assignment and explicit conversion). Conversion between binary, decimal, json, integer, and unsigned integer types is not supported. The principles for determining common types in scenarios such as collections and complex expressions are different from those in MySQL. For details, see **Data Type Conversion**.

MySQL	GaussDB	Difference
		• Time zone In GaussDB, the timestamp value can carry the time zone information (time zone offset or time zone name), for example, '2020-01-01 12:34:56.123456 +01:00' or '2020-01-01 2:34:56.123456 CST'. GaussDB converts the time to the time of the current server time zone. If the time zone of the server is changed, the timestamp value is converted to the timestamp of the new time zone. MySQL 5.7 does not support this function. MySQL 8.0 and later versions support this function. • The table columns of the timestamp data type in GaussDB are actually converted to the timestamp(p) with time zone. When you query the table information or use a tool to export the table definition, the data type of columns is timestamp(p) with time zone instead of timestamp. For MySQL, timestamp(p) is displayed.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

MySQL	GaussDB	Difference
TIME[(fsp)]	Supported, with differences	GaussDB supports the time data type and differs from MySQL in terms of the following specifications: ● Input format: – It supports only the character type and does not support the numeric type. For example, '1 10:20:30' or '102030' is supported, but 102030 is not supported. MySQL supports conversion from numeric input to the time type. – Separator: GaussDB supports only colons (:) as separators between hours, minutes, and seconds. MySQL supports all symbols as separators. – No separator: The complete format 'hhmiss.ffffff' is recommended. The parsing rules of incomplete formats (including the ultra-long format) may be different from those of MySQL. An error may be reported or the parsing result may be inconsistent with that of MySQL. Therefore, the incomplete format is not recommended. – When a negative value is entered for minute, second, or precision, GaussDB may ignore the first part of the negative value, which is parsed as 0. For example, '00:00:-10' is parsed as '00:00:00'. An error may also be reported. For example, if '00:00:-10000' is parsed, an error will be reported. The result depends on the range of the input value. However, MySQL reports an error in both cases. ● Output format: The format is hh:mi:ss.ffffff, which is the same as that of MySQL. However, for the precision part, if the last several digits are 0, they are not displayed in GaussDB but displayed in MySQL. ● Value range: –838:59:59.000000 to 838:59:59.000000, which is the same as that of MySQL. For values that exceed the range, when GaussDB performs DML operations such as SELECT, INSERT, and UPDATE in loose mode, it returns the nearest boundary values such as **-838:59:59** or **838:59:59**. In MySQL, an error is reported during query, or the nearest

MySQL	GaussDB	Difference

		boundary value is returned after a DML operation. As a result, when the time type is used as the input parameter of the function, the results returned by the function are different.
		● Precision:
		The value ranges from 0 to 6. For a table column, the default value is **0**, which is the same as that in MySQL. In the time(p) 'str' expression, GaussDB parses **(p)** as the precision. The default value is **6**, indicating that **'str'** is formatted to the time type based on the precision specified by **p**. MySQL parses it as a time function, **p** is an input parameter, and **'str'** is the alias of the projection column.
		● Operators:
		– GaussDB supports only the comparison operators =, !=, <, <=, >, and >= between time types and returns **true** or **false**. For the addition operation between the time and interval types, the return result is of the time type. For the subtraction operation between the time and interval types, the return result is of the time type. For the subtraction operation between time types, the return result is of the interval type.
		– When the MySQL time type and other numeric types are calculated, the time type is converted to the numeric type, and then the calculation is performed based on the numeric type. The result is also of the numeric type. It is different from GaussDB. For example:
		`-- MySQL: time+numeric. Convert the time type to 123456 and add it to 1. The result is 123457.`
		`mysql> SELECT time '12:34:56' + 1;`
		`+---------------------+`
		`| time '12:34:56' + 1 |`
		`+---------------------+`
		`| 123457 |`
		`+---------------------+`
		`1 row in set (0.00 sec)`
		
		`-- GaussDB: time+numeric. Convert the numeric type to the interval type (1 day), and then add them up to obtain the new time. Because 24 hours are added, the obtained time is still 12:34:56.`
		`gaussdb=# SELECT time '12:34:56' + 1;`
		` ?column?`
		`----------`

MySQL	GaussDB	Difference
		12:34:56 (1 row) If the calculation result of the time type and numeric type is used as the input parameter of a function, the result of the function may be different from that of MySQL. • Type conversion: Compared with MySQL, GaussDB supports only the conversion between the time type and the char(n) or nchar(n) type, and the conversion from datetime or timestamp to the time type. The conversion between the binary, decimal, date, json, integer, and unsigned integer types is not supported. The principles for determining common types in scenarios such as collections and complex expressions are different from those in MySQL. For details, see **Data Type Conversion**.
YEAR[(4)]	Supported, with differences	GaussDB supports the year data type and differs from MySQL in terms of the following specifications: • Operators: – GaussDB supports only the comparison operators =, !=, <, <=, >, and >= between YEAR types and returns **true** or **false**. – GaussDB supports only the arithmetic operators + and - between the YEAR and int4 types and returns integer values. MySQL returns unsigned integer values. • Type conversion: Compared with MySQL, GaussDB supports only the conversion between the year type and int4 type, and supports only the conversion from the int4, varchar, numeric, date, time, timestamp, or timestamptz type to the year type. The principles for determining common types in scenarios such as collections and complex expressions are different from those in MySQL. For details, see **Data Type Conversion**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

MySQL	GaussDB	Difference
INTERVAL	Supported, with differences	GaussDB supports the INTERVAL data type, but INTERVAL is an expression in MySQL. The differences are as follows: ● The date input of the character string type cannot be used as an operation, for example, SELECT '2023-01-01' + interval 1 day. ● In the INTERVAL expr unit syntax, **expr** cannot be a negative integer or floating-point number, for example, SELECT date'2023-01-01' + interval -1 day. ● In the INTERVAL expr unit syntax, **expr** cannot be the input of an operation expression, for example, SELECT date'2023-01-01' + interval 4/2 day. ● When the INTERVAL expression is used for calculation, the return value is of the datetime type. For MySQL, the return value is of the datetime or date type. The calculation logic is the same as that of GaussDB but different from that of MySQL. ● In the INTERVAL expr unit syntax, the value range of **expr** varies with the unit. The maximum value range is [–2147483648, 2147483647]. If the value exceeds the range, an error is reported in strict mode, and a warning is reported in loose mode and **0** is returned. ● In the INTERVAL expr unit syntax, if the number of columns specified by **expr** is greater than the expected number of columns in unit, an error is reported in strict mode, and a warning is reported in loose mode and **0** is returned. For example, if the value of **unit** is **DAY_HOUR**, the expected number of columns is 2. If the value of **expr** is **'1-2-3'**, the expected number of columns is 3.

3.3.3.1.3 String Data Types

Table 3-172 String data types

MySQL	GaussDB	Difference
CHAR[(M)]	Supported, but with differences.	• Input format – The length of parameters and return values of GaussDB user-defined functions cannot be verified. The length of stored procedure parameters cannot be verified. In addition, correct spaces cannot be supplemented when **PAD_CHAR_TO_FULL_LENGTH** is enabled. However, MySQL supports these functions. – GaussDB does not support escape characters or double quotation marks (""). MySQL supports these inputs. • Syntax The CAST(expr as char) syntax of GaussDB cannot convert the input string to the corresponding type based on the string length. It can only be converted to the varchar type. CAST('' as char) and CAST('' as char(0)) cannot convert an empty string to the char(0) type. MySQL supports conversion to the corresponding type by length. • Operator – After performing addition, subtraction, multiplication, division, or modulo operations on a string (that can be converted to a floating-point value) and an integer value, GaussDB returns an integer, while MySQL returns a floating-point value. – If a value is divided by 0, GaussDB reports an error, and MySQL returns **null**. – "~": returns a negative number in GaussDB and an 8-byte unsigned integer in MySQL. – "^": indicates a power in GaussDB and a bitwise XOR in MySQL.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

MySQL	GaussDB	Difference
VARCHAR(M)	Supported, but with differences.	• Input format – The length of parameters and return values of GaussDB user-defined functions cannot be verified. The length of stored procedure parameters cannot be verified. However, MySQL supports these functions. – The length of temporary variables in GaussDB user-defined functions and stored procedures can be verified, and an error or truncation alarm is reported in strict or loose mode. However, MySQL does not support these functions. – GaussDB does not support escape characters or double quotation marks (""). MySQL supports these inputs. • Operator – After performing addition, subtraction, multiplication, division, or modulo operations on a string (that can be converted to a floating-point value) and an integer value, GaussDB returns an integer, while MySQL returns a floating-point value. – If a value is divided by 0, GaussDB reports an error, and MySQL returns **null**. – "~": returns a negative number in GaussDB and an 8-byte unsigned integer in MySQL. – "^": indicates a power in GaussDB and a bitwise XOR in MySQL.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

MySQL	GaussDB	Difference
TINYTEXT	Supported, but with differences.	• Input format – In GaussDB, the length of this type cannot exceed 1 GB. If the length exceeds 1 GB, an error is reported. In MySQL, the length of this type cannot exceed 255 bytes. Otherwise, an error is reported in strict mode, and data is truncated and an alarm is generated in loose mode. – GaussDB does not support escape characters or double quotation marks (""). MySQL supports these inputs. • Operator – After performing addition, subtraction, multiplication, division, or modulo operations on a string (that can be converted to a floating-point value) and an integer value, GaussDB returns an integer, while MySQL returns a floating-point value. – If a value is divided by 0, GaussDB reports an error, and MySQL returns **null**. – "~": returns a negative number in GaussDB and an 8-byte unsigned integer in MySQL. – "^": indicates a power in GaussDB and a bitwise XOR in MySQL.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

MySQL	GaussDB	Difference
TEXT	Supported, but with differences.	• Input format – In GaussDB, the length of this type cannot exceed 1 GB. If the length exceeds 1 GB, an error is reported. In MySQL, the length of this type cannot exceed 65535 bytes. Otherwise, an error is reported in strict mode, and data is truncated and an alarm is generated in loose mode. – GaussDB does not support escape characters or double quotation marks (""). MySQL supports these inputs. • Operator – After performing addition, subtraction, multiplication, division, or modulo operations on a string (that can be converted to a floating-point value) and an integer value, GaussDB returns an integer, while MySQL returns a floating-point value. – If a value is divided by 0, GaussDB reports an error, and MySQL returns **null**. – "~": returns a negative number in GaussDB and an 8-byte unsigned integer in MySQL. – "^": indicates a power in GaussDB and a bitwise XOR in MySQL.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

MySQL	GaussDB	Difference
MEDIUMTEXT	Supported, but with differences.	• Input format – In GaussDB, the length of this type cannot exceed 1 GB. If the length exceeds 1 GB, an error is reported. In MySQL, the length of this type cannot exceed 16777215 bytes. Otherwise, an error is reported in strict mode, and data is truncated and an alarm is generated in loose mode. – GaussDB does not support escape characters or double quotation marks (""). MySQL supports these inputs. • Operator – After performing addition, subtraction, multiplication, division, or modulo operations on a string (that can be converted to a floating-point value) and an integer value, GaussDB returns an integer, while MySQL returns a floating-point value. – If a value is divided by 0, GaussDB reports an error, and MySQL returns **null**. – "~": returns a negative number in GaussDB and an 8-byte unsigned integer in MySQL. – "^": indicates a power in GaussDB and a bitwise XOR in MySQL.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

MySQL	GaussDB	Difference
LONGTEXT	Supported, but with differences.	• Input format – GaussDB supports a maximum of 1 GB, and MySQL supports a maximum of 4 GB minus 1 byte. – GaussDB does not support escape characters or double quotation marks (""). MySQL supports these inputs. • Operator – After performing addition, subtraction, multiplication, division, or modulo operations on a string (that can be converted to a floating-point value) and an integer value, GaussDB returns an integer, while MySQL returns a floating-point value. – If a value is divided by 0, GaussDB reports an error, and MySQL returns **null**. – "~": returns a negative number in GaussDB and an 8-byte unsigned integer in MySQL. – "^": indicates a power in GaussDB and a bitwise XOR in MySQL.
ENUM('value1','value2',...)	Not supported.	-
SET('value1','value2',...)	Not supported.	-

3.3.3.1.4 Binary Data Types

Table 3-173 Binary data types

MySQL	GaussDB	Difference
BINARY[(M)]	Not supported.	-
VARBINARY(M)	Not supported.	-

MySQL	GaussDB	Difference
TINYBLOB	Supported, with differences.	• Value range: In GaussDB, this type is mapped from the BYTEA type. Its length cannot exceed 1 GB. Otherwise, an error is reported. In MySQL, the length of this type cannot exceed 255 bytes. Otherwise, an error is reported in strict mode, and data is truncated and an alarm is generated in loose mode. • Input format: Escape characters and double quotation marks ("") are not supported. • Output format: For the '\0' character, the query result is displayed as "\000". If the getBytes API of the JDBC driver is used, the result is the '\0' character. • Operator: Arithmetic operators (+ - * / %) are not supported. Common logical operators OR, AND, NOT (|| && !) are not supported. Common bitwise operators (~ & | ^) are not supported.
BLOB	Supported, with differences.	• Value range: In GaussDB, this type is mapped from the BYTEA type. Its length cannot exceed 1 GB. Otherwise, an error is reported. In MySQL, the length of this type cannot exceed 65535 bytes. Otherwise, an error is reported in strict mode, and data is truncated and an alarm is generated in loose mode. • Input format: Escape characters and double quotation marks ("") are not supported. • Output format: For the '\0' character, the query result is displayed as "\000". If the getBytes API of the JDBC driver is used, the result is the '\0' character. • Operator: Arithmetic operators (+ - * / %) are not supported. Common logical operators OR, AND, NOT (|| && !) are not supported. Common bitwise operators (~ & | ^) are not supported.

3.3.3.1.5 JSON Data Type

Table 3-174 JSON Data Type

MySQL	GaussDB	Difference
JSON	Supported, with differences	• The JSON types in GaussDB in MYSQL-compatible mode are the same as the native JSON type of GaussDB but greatly different from that of MySQL. Therefore, the JSON types are not listed one by one. • For details about the JSON type behavior of GaussDB in MySQL-compatible mode, see **JSON/JSONB Types**.

3.3.3.1.6 Attributes Supported by Data Types

Table 3-175 Attributes Supported by Data Types

MySQL	GaussDB
NULL	Supported
NOT NULL	Supported
DEFAULT	Supported
ON UPDATE	Supported
PRIMARY KEY	Supported
CHARACTER SET name	Supported
COLLATE name	Supported

3.3.3.1.7 Data Type Conversion

Conversion between different data types is supported. Data type conversion is involved in the following scenarios:

- The data types of operands of operators (such as comparison and arithmetic operators) are inconsistent. It is commonly used for comparison operations in query or join conditions.
- The data types of arguments and parameters are inconsistent when a function is called.
- The data types of target columns to be updated by DML statements (including INSERT, UPDATE, MERGE, and REPLACE) and the defined column types are inconsistent.
- Using CAST(expr AS datatype) can explicitly convert an expression to a data type.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- After the target data type of the final projection column is determined by set operations (UNION and EXCEPT), the type of the projection column in each SELECT statement is inconsistent with the target data type.
- In other expression calculation scenarios, the target data type used for comparison or final result is determined based on the data type of different expressions.
  - DECODE
  - CASE WHEN
  - lexpr [NOT] IN (expr_list)
  - BETWEEN AND
  - JOIN USING(a,b)
  - GREATEST and LEAST
  - NVL and COALESCE

GaussDB and MySQL have different rules for data type conversion and target data types. The following examples show the differences between the two processing modes:

- Example 1

```
-- MySQL: The execution result of IN is 0, indicating false. According to the rule, '1970-01-01' is compared with the expressions in the list in sequence. The results are all 0s. Therefore, the final result is 0.
mysql> SELECT '1970-01-01' IN ('1970-01-02', 1, '1970-01-02');
+-------------------------------------------------+
| '1970-01-01' IN ('1970-01-02', 1, '1970-01-02') |
+-------------------------------------------------+
|                                               0 |
+-------------------------------------------------+

-- GaussDB: The execution result of IN is true, which is opposite to the MySQL result. The common type selected based on the rule is int. Therefore, the left expression '1970-01-01' is converted to the int type and compared with the value after the expression in the list is converted to the int type.
-- When '1970-01-01' and '1970-01-02' are converted to the int type, the values are 1970. (In MySQL-compatible mode, invalid characters and the following content are ignored during conversion, and the previous part is converted to the int type.) The comparison result is equal. Therefore, the returned result is true.
gaussdb=# SELECT '1970-01-01' IN ('1970-01-02', 1::int, '1970-01-02') AS result;
 result
--------
 t
(1 row)
```

- Example 2

```
-- In MySQL, when an integer is compared with a string, they are converted to floating-point numbers for comparison.
mysql> SELECT '2.1' = 2, '2.1' > 2, '2.1' < 2, '.123' = 0;
+-----------+-----------+-----------+------------+
| '2.1' = 2 | '2.1' > 2 | '2.1' < 2 | '.123' = 0 |
+-----------+-----------+-----------+------------+
|         0 |         1 |         0 |          0 |
+-----------+-----------+-----------+------------+
1 row in set (0.00 sec)

-- In GaussDB, when an integer is compared with a string, the string is converted to an integer before the comparison. For instance, when '2.1' is converted to an integer, the non-integer part is truncated, resulting in 2; when '.123' is converted to an integer, it is directly converted to 0.
gaussdb=# SELECT '2.1' = 2, '2.1' > 2, '2.1' < 2, '.123' = 0;
 ?column? | ?column? | ?column? | ?column?
----------+----------+----------+----------
 t        | f        | f        | t
(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Differences in data type conversion rules:

- The GaussDB clearly defines the conversion rules between different data types.
  - Whether to support conversion: Conversion is supported only when the conversion path of two types is defined in the pg_cast system catalog.
  - Conversion scenarios: conversion in any scenario, conversion only in CAST expressions, and conversion only during value assignment. In scenarios that are not supported, data type conversion cannot be performed even if the conversion path is defined.
- MySQL supports conversion between any two data types.

Due to the preceding differences, when MySQL-based applications are migrated to GaussDB, an error may be reported because the SQL statement does not support the conversion between different data types. In the scenario where conversion is supported, different conversion rules result in different execution results of SQL statements.

You are advised to use the same data type in SQL statements for comparison or value assignment to avoid unexpected results or performance loss caused by data type conversion.

Differences in target data type selection rules:

In some scenarios, the data type to be compared or returned can be determined only after the types of multiple expressions are considered. For example, in the UNION operation, projection columns at the same position in different SELECT statements are of different data types. The final data type of the query result needs to be determined based on the data type of the projection columns in each SELECT statement.

GaussDB and MySQL have different rules for determining the target data types.

- GaussDB rules:
  - If the operand types of operators are inconsistent, the operand types are not converted to the target type before calculation. Instead, operators of two data types are directly registered, and two types of processing rules are defined during operator processing. In this mode, implicit type conversion does not exist, but the customized processing rule implies the conversion operation.
  - Rules for determining the target data type in the set operation and expression scenarios:
    - If all types are the same, it is the target type.
    - If the two data types are different, check whether the data types are of the same type, such as the numeric type, character type, and date and time type. If they do not belong to the same type, the target type cannot be determined. In this case, an error is reported during SQL statement execution.
    - For data types with the same **category** attribute (defined in the pg_type system catalog), the data type with the **preferred** attribute (defined in the pg_type system catalog) is selected as the target type. If operand 1 can be converted to operand 2 (no conversion

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

path), but operand 2 cannot be converted to operand 1 or the priority of the numeric type is lower than that of operand 2, then operand 2 is selected as the target type.

- If three or more data types are involved, the rule for determining the target type is as follows: common_type(type1,type2,type3) = common_type(common_type(type1,type2),type3). Perform iterative processing in sequence to obtain the final result.
- For IN and NOT IN expressions, if the target type cannot be determined based on the preceding rules, each expression in **lexpr** and **expr_list** is compared one by one based on the equivalent operator (=).
- Precision determination: The precision of the finally selected expression is used as the final result.

- MySQL rules:
  - If the operand types of operators are inconsistent, determine the target type based on the following rules. Then, convert the inconsistent operand types to the target type and then process the operands.
    - If both parameters are of the string type, they are compared based on the string type.
    - If both parameters are of the integer type, they are compared based on the integer type.
    - If a hexadecimal value is not compared with a numeric value, they are compared based on the binary string.
    - If one parameter is of the datetime/timestamp type, and the other parameter is a constant, the constant is converted to the timestamp type for comparison.
    - If one parameter is of the decimal type, the data type used for comparison depends on the other parameter. If the other type is decimal or integer, the decimal type is used. If the other type is not decimal, the real type is used.
    - In other scenarios, the data type is converted to the real type for comparison.
  - Rules for determining the target data type in the set operation and expression scenarios:
    - Establish a target type matrix between any two types. Given two types, the target type can be determined by using the matrix.
    - If three or more data types are involved, the rule for determining the target type is as follows: common_type(type1,type2,type3) = common_type(common_type(type1,type2),type3). Perform iterative processing in sequence to obtain the final result.
    - If the target type is integer and each expression type contains signed and unsigned integers, the type is promoted to an integer type with higher precision. The result is unsigned only when all expressions are unsigned. Otherwise, the result is signed.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- The highest precision in the expression is used as the final result.

According to the preceding rules, GaussDB and MySQL differ greatly in data type conversion rules and types cannot be directly compared. In the preceding scenario, the execution result of SQL statements may be different from that in MySQL. In the current version, you are advised to use the same type for all expressions or use CAST to convert the type to the required type in advance to avoid differences.

3.3.3.2 System Functions

3.3.3.2.1 System Function Compatibility Overview

GaussDB is compatible with most MySQL system functions, but there are some differences.

Unless otherwise specified, the function behavior in MYSQL-compatible mode is the native GaussDB behavior by default.

NOTE

For most GaussDB system functions compatible with MySQL, the return value precision (the number of trailing zeros in the result) is inconsistent with that of MySQL. This is because the precision of some data types is lost in some scenarios and the precision cannot be correctly obtained. As a result, some functions are not fully adapted.

3.3.3.2.2 Flow Control Functions

Table 3-176 Flow control functions

MySQL	GaussDB	Difference
IF()	Supported, with differences.	• The **expr1** input parameter supports only the Boolean type. If an input parameter of the non-BOOL type cannot be converted to the BOOL type, an error is reported. • If the types of **expr2** and **expr3** are different and no implicit conversion function exists between the two types, an error is reported. • If the two input parameters are of the same type, the input parameter type is returned. • If the **expr2** and **expr3** input parameters are of the NUMERIC, STRING, or TIME type respectively, GaussDB outputs the TEXT type, while MySQL outputs the VARCHAR type.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

MySQL	GaussDB	Difference
IFNULL()	Supported, with differences.	• If the types of **expr1** and **expr2** are different and no implicit conversion function exists between the two types, an error is reported. • If the two input parameters are of the same type, the input parameter type is returned. • If the **expr1** and **expr2** input parameters are of the NUMERIC, STRING, or TIME type respectively, GaussDB outputs the TEXT type, while MySQL outputs the VARCHAR type. • If one input parameter is of the FLOAT4 type and the other is of any type in the numeric category, GaussDB returns the DOUBLE type. In MySQL, if one input parameter is of FLOAT4 type and the other is of the TINYINT, UNSIGNED TINYINT, SMALLINT, UNSIGNED SMALLINT, MEDIUMINT, UNSIGNED MEDIUMINT, or BOOL type, the FLOAT4 type is returned. If the first is of FLOAT4 type and the second is of BIGINT or UNSIGNED BIGINT type, the FLOAT type is returned.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

MySQL	GaussDB	Difference

NULLIF()	Supported, with differences.	• The NULLIF() type derivation in GaussDB complies with the following logic:
		– If the data types of two parameters are different and the two input parameter types have an equality comparison operator, the left value type corresponding to the equality comparison operator is returned. Otherwise, the two input parameter types are forcibly compatible.
		– If an equality comparison operator exists after forcible type compatibility, the left value type of the equality comparison operator after forcible type compatibility is returned.
		– If the corresponding equality operator cannot be found after forcible type compatibility, an error is reported.
		-- The two input parameter types have an equality comparison operator.
		gaussdb=# SELECT pg_typeof(nullif(1::int2, 2::int8));
		pg_typeof
		----------- 	
		smallint
		(1 row)
		-- The two input parameter types do not have the equality comparison operator, but the equality comparison operator can be found after forcible type compatibility.
		gaussdb=# SELECT pg_typeof(nullif(1::int1, 2::int2));
		pg_typeof
		----------- 	
		bigint
		(1 row)
		
		-- The two input parameter types do not have the equality comparison operator, and the equality comparison operator does not exist after forcible type compatibility.
		gaussdb=# SELECT nullif(1::bit, '1'::MONEY);
		ERROR: operator does not exist: bit = money
		LINE 1: SELECT nullif(1::bit, '1'::MONEY);
		^
		HINT: No operator matches the given name and argument type(s). You might need to add explicit type casts.
		CONTEXT: referenced column: nullif
		• The MySQL output type is related only to the type of the first input parameter.
		– If the type of the first input parameter is TINYINT, SMALLINT, MEDIUMINT, INT, or BOOL, the output is of the INT type.
		– If the type of the first input parameter is BIGINT, the output is of the BIGINT type.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

MySQL	GaussDB	Difference
		– When the type of the first input parameter is UNSIGNED TINYINT, UNSIGNED SMALLINT, UNSIGNED MEDIUMINT, UNSIGNED INT, or BIT, the output is of the UNSIGNED INT type. – If the type of the first input parameter is UNSIGNED BIGINT, the output is of the UNSIGNED BIGINT type. – If the type of the first input parameter is of the FLOAT, DOUBLE, or REAL type, the output is of the DOUBLE type. – If the type of the first input parameter DECIMAL or NUMERIC, the output is of the DECIMAL type. – If the type of the first input parameter is DATE, TIME, DATETIME, TIMESTAMP, CHAR, VARCHAR, TINYTEXT, ENUM, or SET, the output is of the VARCHAR type. – If the type of the first input parameter is TEXT, MEDIUMTEXT, or LONGTEXT, the output is of the LONGTEXT type. – If the type of the first input parameter is TINYBLOB, the output is of the VARBINARY type. – If the type of the first input parameter is MEDIUMBLOB or LONGBLOB, the output is of the LONGBLOB type. – If the type of the first input parameter is BLOB, the output is of the BLOB type.
ISNULL()	Supported, with differences.	In GaussDB, the return value is **t** or **f** of the BOOLEAN type. In MySQL, the return value is **1** or **0** of the INT type.

3.3.3.2.3 Date and Time Functions

The date and time functions in GaussDB in MYSQL-compatible mode, with the same behavior as MySQL, are described as follows:

- Functions may use time expressions as their input parameters.

  Time expressions mainly include text, datetime, date, and time. Besides, all types that can be implicitly converted to time expressions can be input parameters. For example, a number can be implicitly converted to text and then used as a time expression.

  However, different functions take effect in different ways. For example, the datediff function calculates only the difference between dates. Therefore, time expressions are parsed as the date type. The timestampdiff function parses

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

time expressions as date, time, or datetime based on the **unit** parameter before calculating the time difference.

- The input parameters of functions may contain an invalid date.

  Generally, the supported date and datetime ranges are the same as those of MySQL. The value of date ranges from '0000-01-01' to '9999-12-31', and the value of datetime ranges from '0000-01-01 00:00:00' to '9999-12-31 23:59:59'. Although GaussDB supports larger date and datetime ranges than MySQL, dates out of range are still considered invalid.

  In most cases, time functions report an alarm and return NULL if the input date is invalid, unless the invalid date can be converted by CAST.

- Separators for input parameters of functions:

  For a time function, all non-digit characters are regarded as separators when input parameters are processed. The standard format is recommended: Use hyphens (-) to separate year, month, and day, use colons (:) to separate hour, minute, and second, and use a period (.) before milliseconds.

  Error-prone scenario: When **SELECT timestampdiff(hour, '2020-03-01 00:00:00', '2020-02-28 00:00:00+08');** is executed in a MYSQL-compatible database, the time function does not automatically calculate the time zone. Therefore, +08 is not identified as the time zone. Instead, + is used as the separator for calculation as seconds.

Most function scenarios of GaussDB date and time functions are the same as those of MySQL, but there are still differences. Some differences are as follows:

- If an input parameter of a function is NULL, the function returns NULL, and no warning or error is reported. These functions include:

  from_days, date_format, str_to_date, datediff, timestampdiff, date_add, subtime, month, time_to_sec, to_days, to_seconds, dayname, monthname, convert_tz, sec_to_time, addtime, adddate, date_sub, timediff, last_day, weekday, from_unixtime, unix_timestamp, subdate, day, year, weekofyear, dayofmonth, dayofyear, week, yearweek, dayofweek, time_format, hour, minute, second, microsecond, quarter, get_format, extract, makedate, period_add, timestampadd, period_diff, utc_time, utc_timestamp, maketime, and curtime.

  Example:

  ```
  gaussdb=# SELECT day(null);
   day
  -----

  (1 row)
  ```

- Some functions with pure numeric input parameters are different from those of MySQL. Numeric input parameters without quotation marks are converted into text input parameters for processing.

  Example:

  ```
  gaussdb=# SELECT day(19231221.123141);
  WARNING:  Incorrect datetime value: "19231221.123141"
  CONTEXT:  referenced column: day
   day
  -----

  (1 row)
  ```

- Time and date calculation functions are adddate, subdate, date_add, and date_sub. If the calculation result is a date, the supported range is

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

[0000-01-01,9999-12-31]. If the calculation result is a date and time, the supported range is [0000-01-01 00:00:00.000000,9999-12-31 23:59:59.999999]. If the calculation result exceeds the supported range, an ERROR is reported in strict mode, or a WARNING is reported in loose mode. If the date result after calculation is within the range [0000-01-01,0001-01-01], GaussDB returns the result normally. MySQL returns '0000-00-00'.

Example:

```
gaussdb=# SELECT subdate('0000-01-01', interval 1 hour);
ERROR:  Datetime function: datetime field overflow
CONTEXT:  referenced column: subdate

gaussdb=# SELECT subdate('0001-01-01', interval 1 day);
  subdate
-------------
 0000-12-31

(1 row)
```

- If the input parameter of the date or datetime type of the date and time function contains month 0 or day 0, the value is invalid. In strict mode, an error is reported. In loose mode, if the input is a character string or number, a warning is reported. If the input is of the date or datetime type, the system processes the input as December of the previous year or the last day of the previous month.

  If the type of the CAST function is converted to date or datetime, an error is reported in strict mode. In loose mode, no warning is reported. Instead, the system processes the input as December of the previous year or the last day of the previous month. Pay attention to this difference. MySQL outputs the value as it is, even if the year, month, and day are set to **0**.

  Example:

```
gaussdb=# SELECT adddate('2023-01-00', 1);-- Strict mode
ERROR:  Incorrect datetime value: "2023-01-00"
CONTEXT:  referenced column: adddate

gaussdb=# SELECT adddate('2023-01-00', 1); -- Loose mode
WARNING:  Incorrect datetime value: "2023-01-00"
CONTEXT:  referenced column: adddate
 adddate
---------

(1 row)

gaussdb=# SELECT adddate(date'2023-00-00', 1); -- Loose mode
  adddate
------------
 2022-12-01
(1 row)

gaussdb=# SELECT cast('2023/00/00' as date); -- Loose mode
    date
------------
 2022-11-30
(1 row)

gaussdb=# SELECT cast('0000-00-00' as datetime); -- Loose mode
      timestamp
---------------------
 0000-00-00 00:00:00
(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- If the input parameter of the function is of the numeric data type, no error is reported in the case of invalid input, and the input parameter is processed as 0.

  Example:

```
gaussdb=# SELECT from_unixtime('aa');
    from_unixtime
---------------------
 1970-01-01 08:00:00
(1 row)
```

- A maximum of six decimal places are allowed. Decimal places with all 0s are not allowed.

  Example:

```
gaussdb=# SELECT from_unixtime('1234567899.00000');
    from_unixtime
---------------------
 2009-02-14 07:31:39
(1 row)
```

- If the time function parameter is a character string, the result is correct only when the year, month, and day are separated by a hyphen (-) and the hour, minute, and second are separated by a colon (:).

  Example:

```
gaussdb=# SELECT adddate('20-12-12',interval 1 day);
  adddate
------------
 2020-12-13
(1 row)
```

- If the return value of a function is of the varchar type in MySQL, the return value of the function is of the text type in GaussDB.

```
-- Return value of a function in GaussDB.
gaussdb=# SELECT pg_typeof(adddate('2023-01-01', 1));
 pg_typeof
-----------
 text
(1 row)

-- Return value of a function in MySQL.
mysql> CREATE VIEW v1 AS SELECT adddate('2023-01-01', 1);
Query OK, 0 rows affected (0.00 sec)

mysql> DESC v1;
+--------------------------+-------------+------+-----+---------+-------+
| Field                    | Type        | Null | Key | Default | Extra |
+--------------------------+-------------+------+-----+---------+-------+
| adddate('2023-01-01', 1) | varchar(29) | YES  |     | NULL    |       |
+--------------------------+-------------+------+-----+---------+-------+
1 row in set (0.00 sec)
```

Table 3-177 Date and time functions

MySQL	GaussDB	Difference
ADDDATE()	Supported, with differences	The performance of this function is different from that of MySQL due to interval expression differences. For details, see **INTERVAL**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

MySQL	GaussDB	Difference
ADDTIME()	Supported, with differences	• MySQL returns NULL if the second input parameter is a string in the DATETIME format. GaussDB can calculate the value. • The value range of an input parameter is ['0001-01-01 00:00:00', 9999-12-31 23:59:59.999999]. • If the first parameter of the ADDTIME function in MySQL is a dynamic parameter (for example, in a prepared statement), the return type is TIME. Otherwise, the parse type of the function is derived from the parse type of the first parameter. The return value rules of the ADDTIME function in GaussDB are as follows: – The first input parameter is of the date type, the second input parameter is of the date type, and the return value is of the time type. – The first input parameter is of the date type, the second input parameter is of the text type, and the return value is of the text type. – The first input parameter is of the date type, the second input parameter is of the datetime type, and the return value is of the time type. – The first input parameter is of the date type, the second input parameter is of the time type, and the return value is of the time type. – The first input parameter is of the text type, the second input parameter is of the date type, and the return value is of the text type. – The first input parameter is of the text type, the second input parameter is of the text type, and the return value is of the text type. – The first input parameter is of the text type, the second input parameter is of the datetime type, and the return value is of the text type. – The first input parameter is of the text type, the second input parameter is of the time type, and the return value is of the text type.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

MySQL	GaussDB	Difference
		– The first input parameter is of the datetime type, the second input parameter is of the date type, and the return value is of the datetime type. – The first input parameter is of the datetime type, the second input parameter is of the text type, and the return value is of the text type. – The first input parameter is of the datetime type, the second input parameter is of the datetime type, and the return value is of the datetime type. – The first input parameter is of the datetime type, the second input parameter is of the time type, and the return value is of the datetime type. – The first input parameter is of the time type, the second input parameter is of the date type, and the return value is of the time type. – The first input parameter is of the time type, the second input parameter is of the text type, and the return value is of the text type. – The first input parameter is of the time type, the second input parameter is of the datetime type, and the return value is of the time type. – The first input parameter is of the time type, the second input parameter is of the time type, and the return value is of the time type.
CONVERT_TZ()	Supported	-
CURDATE()	Supported	-
CURRENT_DATE(), CURRENT_DATE	Supported	-

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

MySQL	GaussDB	Difference
CURRENT_TIME(), CURRENT_TIME	Supported, with differences	The time value (after the decimal point) output by precision is rounded off in GaussDB and directly truncated in MySQL. The trailing 0s of the time value (after the decimal point) output by precision are not displayed in GaussDB but displayed in MySQL. GaussDB supports only an integer value within the range of [0,6] as the precision of the returned time. For other values, an error is reported. In MySQL, a precision value within [0,6] is valid, but an input integer value is divided by 256 to get a remainder. For example, if the input integer value is **257**, the time value with precision 1 is returned.
CURRENT_TIMESTAMP(), CURRENT_TIMESTAMP	Supported, with differences	The time value (after the decimal point) output by precision is rounded off in GaussDB and directly truncated in MySQL. The trailing 0s of the time value (after the decimal point) output by precision are not displayed in GaussDB but displayed in MySQL. GaussDB supports only an integer value within the range of [0,6] as the precision of the returned time. If the input integer value is greater than 6, an alarm is generated and the time value is output based on the precision 6. In MySQL, a precision value within [0,6] is valid, but an input integer value is divided by 256 to get a remainder. For example, if the input integer value is **257**, the time value with precision 1 is returned.
CURTIME()	Supported, with differences	In GaussDB, if a character string or a non-integer value is entered, the value is implicitly converted into an integer and then the precision is verified. If the value is beyond the [0,6] range, an error is reported. If the value is within the range, the time value is output normally. In MySQL, an error is reported. The time value (after the decimal point) output by precision is rounded off in GaussDB and directly truncated in MySQL. The trailing 0s of the time value (after the decimal point) output by precision are not displayed in GaussDB but displayed in MySQL. GaussDB supports only an integer value within the range of [0,6] as the precision of the returned time. For other values, an error is reported. In MySQL, a precision value within [0,6] is valid, but an input integer value is divided by 256 to get a remainder. For example, if the input integer value is **257**, the time value with precision 1 is returned.

MySQL	GaussDB	Difference
NOW()	Supported, with differences	The time value (after the decimal point) output by precision is rounded off in GaussDB and directly truncated in MySQL. The trailing 0s of the time value (after the decimal point) output by precision are not displayed in GaussDB but displayed in MySQL. GaussDB supports only an integer value within the range of [0,6] as the precision of the returned time. If the input integer value is greater than 6, an alarm is generated and the time value is output based on the precision 6. In MySQL, a precision value within [0,6] is valid, but an input integer value is divided by 256 to get a remainder. For example, if the input integer value is **257**, the time value with precision 1 is returned.
PERIOD_ADD()	Supported, with differences	If the input parameter **period** or result is less than 0, GaussDB reports an error by referring to the performance in MySQL 8.0.x. Integer wrapping occurs in MySQL 5.7. As a result, the calculation result is abnormal.
PERIOD_DIFF()	Supported, with differences	If the input parameter or result is less than 0, GaussDB reports an error by referring to the performance in MySQL 8.0.x. Integer wrapping occurs in MySQL 5.7. As a result, the calculation result is abnormal.
QUARTER()	Supported	-
SEC_TO_TIME()	Supported	-
SECOND()	Supported	-
STR_TO_DATE()	Supported, with differences	GaussDB returns values of the text type, while MySQL returns values of the datetime or date type.
SUBDATE()	Supported, with differences	The performance of this function is different from that of MySQL due to interval expression differences. For details, see **INTERVAL**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

MySQL	GaussDB	Difference
SUBTIME()	Supported, with differences	• MySQL returns NULL if the second input parameter is a string in the DATETIME format. GaussDB can calculate the value. • The value range of an input parameter is ['0001-01-01 00:00:00', 9999-12-31 23:59:59.999999]. • If the first parameter of the SUBTIME function in MySQL is a dynamic parameter (for example, in a prepared statement), the return type is TIME. Otherwise, the parse type of the function is derived from the parse type of the first parameter. The return value rules of the SUBTIME function in GaussDB are as follows: – The first input parameter is of the date type, the second input parameter is of the date type, and the return value is of the time type. – The first input parameter is of the date type, the second input parameter is of the text type, and the return value is of the text type. – The first input parameter is of the date type, the second input parameter is of the datetime type, and the return value is of the time type. – The first input parameter is of the date type, the second input parameter is of the time type, and the return value is of the time type. – The first input parameter is of the text type, the second input parameter is of the date type, and the return value is of the text type. – The first input parameter is of the text type, the second input parameter is of the text type, and the return value is of the text type. – The first input parameter is of the text type, the second input parameter is of the datetime type, and the return value is of the text type. – The first input parameter is of the text type, the second input parameter is of the time type, and the return value is of the text type.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

MySQL	GaussDB	Difference
		– The first input parameter is of the datetime type, the second input parameter is of the date type, and the return value is of the datetime type. – The first input parameter is of the datetime type, the second input parameter is of the text type, and the return value is of the text type. – The first input parameter is of the datetime type, the second input parameter is of the datetime type, and the return value is of the datetime type. – The first input parameter is of the datetime type, the second input parameter is of the time type, and the return value is of the datetime type. – The first input parameter is of the time type, the second input parameter is of the date type, and the return value is of the time type. – The first input parameter is of the time type, the second input parameter is of the text type, and the return value is of the text type. – The first input parameter is of the time type, the second input parameter is of the datetime type, and the return value is of the time type. – The first input parameter is of the time type, the second input parameter is of the time type, and the return value is of the time type.
SYSDATE()	Supported, with differences	In MySQL, an integer input value is wrapped when it reaches **255** (maximum value of a one-byte integer value), while GaussDB does not.
YEAR()	Supported	-
TIME_FORMAT()	Supported	-
TIME_TO_SEC()	Supported	-
TIMEDIFF()	Supported	-
WEEKOFYEAR()	Supported	-

3.3.3.2.4 String Functions

Table 3-178 String functions

MySQL	GaussDB	Difference
BIN()	Supported, with differences.	In GaussDB, the types supported by function input parameters are as follows: • Integer types: tinyint, smallint, mediumint, int, and bigint. • Unsigned integer types: tinyint unsigned, smallint unsigned, int unsigned, and bigint unsigned. • Character and text types: char, varchar, tinytext, text, mediumtext, and longtext. Only numeric integer strings are supported, and the integer range is within the bigint range. • Floating-point types: float, real, and double. • Fixed-point types: numeric, decimal, and dec. • Boolean type: bool.
CONCAT()	Supported, with differences.	The data type of the return value of CONCAT is always text regardless of the data type of the parameter. However, in MySQL, if CONCAT contains binary parameters, the return value is binary.
CONCAT_WS()	Supported, with differences.	The data type of the return value of CONCAT_WS is always text regardless of the data type of the parameter. However, in MySQL, if CONCAT_WS contains binary parameters, the return value is binary. In other cases, the return value is a string.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

MySQL	GaussDB	Difference
ELT()	Supported, with differences.	• In GaussDB, the types supported by function input parameter 1 are as follows: – Integer types: tinyint, smallint, mediumint, int, and bigint. – Unsigned integer types: tinyint unsigned, smallint unsigned, and int unsigned. – Character and text types: char, varchar, tinytext, text, mediumtext, and longtext. Only numeric integer strings are supported, and the integer range is within the bigint range. – Floating-point types: float, real, and double. – Fixed-point types: numeric, decimal, and dec. – Boolean type: bool. • In GaussDB, the types supported by function input parameter 2 are as follows: – Integer types: tinyint, smallint, mediumint, int, and bigint. – Unsigned integer types: tinyint unsigned, smallint unsigned, int unsigned, and bigint unsigned. – Character and text types: char, varchar, tinytext, text, mediumtext, and longtext. – Floating-point types: float, real, and double. – Fixed-point types: numeric, decimal, and dec. – Boolean type: bool. – Large object types: tinyblob, blob, mediumblob, and longblob. – Date types: datetime, timestamp, date, and time.
FIELD()	Supported, with differences.	When function input parameters range from the maximum bigint value to the maximum bigint unsigned value, incompatibility occurs. When function input parameters are of the float(m, d), double(m, d), or real(m, d) type, the precision is higher and incompatibility occurs.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

MySQL	GaussDB	Difference
FIND_IN_SET()	Supported, with differences.	When the database encoding is set to **'SQL_ASCII'**, the default case sensitivity rule is not supported. That is, if no character set rule is specified, uppercase and lowercase letters are treated as distinct.
INSERT()	Supported, with differences.	• The range of input parameters of the Int64 type is from –9223372036854775808 to +9223372036854775807. If a value is out of range, an error is reported. MySQL does not limit the range of input parameters of the numeric type. If an exception occurs, an alarm is generated, indicating that the value is set to the upper or lower limit. • The maximum length of the input parameter of the text type is 2^30 – 5 bytes, and the maximum length of the input parameter of the BYTEA type is 2^30 – 512 bytes. • If any of the **s1** and **s2** parameters is of the BYTEA type and the result contains invalid characters, the displayed result may be different from that of MySQL, but the character encoding is the same as that of MySQL.
LOCATE()	Supported, with differences.	When input parameter 1 is of the BYTEA type and input parameter 2 is of the text type, the behavior of GaussDB is different from that of MySQL.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

MySQL	GaussDB	Difference
MAKE_SET()	Supported, with differences.	• When the **bits** parameter is an integer, the maximum range is int128, which is smaller than the MySQL range. • When the **bits** parameter is of the date type (datetime, timestamp, date, or time), it is not supported because the conversion from the date type to the integer type is different from that in MySQL. • GaussDB and MySQL are inherently different in the bit and Boolean types, causing different returned results. When the **bits** input parameter is of the Boolean type, and the **str** input parameter is of the bit or Boolean type, they are not supported. • When the **bits** input parameter is of the character string or text type, only the pure integer format is supported. In addition, the value range of pure integers is limited to bigint. • The integer value of the **str** input parameter exceeds the range from 81 negative nines to 81 positive nines. The return value is different from that of MySQL. • When the **str** input parameter is expressed in scientific notation, trailing zeros are displayed in GaussDB but not displayed in MySQL. This is an inherent difference.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

MySQL	GaussDB	Difference
QUOTE()	Supported, with differences.	• If the **str** character string contains "\Z", "\r", "\%", or "_", GaussDB does not escape it, which is different from MySQL. The slash followed by digits may also cause differences, for example, "\563". This function difference is the escape character difference between GaussDB and MySQL. • The output format of "\b" in the **str** character string is different from that in MySQL. This is an inherent difference between GaussDB and MySQL. • If the **str** character string contains "\0", GaussDB cannot identify the character because the UTF-8 character set cannot identify the character. As a result, the input fails. This is an inherent difference between GaussDB and MySQL. • If **str** is of the bit or Boolean type, this type is not supported because it is different in GaussDB and MySQL. • GaussDB transmits up to 1 GB data. The maximum length of the **str** input parameter is 536870908 bytes, and the maximum length of the result string returned by the function is 1 GB. • The integer value of the **str** input parameter exceeds the range from 81 negative nines to 81 positive nines. The return value is different from that of MySQL. • When the **str** input parameter is expressed in scientific notation, trailing zeros are displayed in GaussDB but not displayed in MySQL. This is an inherent difference.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

MySQL	GaussDB	Difference
SPACE()	Supported, with differences.	• GaussDB allows an input parameter of no more than 1073741818 bytes. If the length exceeds the limit, an empty string is returned. By default, MySQL allows an input parameter of no more than 4194304 bytes. If the length exceeds the limit, an alarm is generated. • In GaussDB, the types supported by function input parameters are as follows: – Integer types: tinyint, smallint, mediumint, int, and bigint. – Unsigned integer types: tinyint unsigned, smallint unsigned, and int unsigned. – Character and text types: char, varchar, tinytext, text, mediumtext, and longtext. Only numeric integer strings are supported, and the integer range is within the bigint range. – Floating-point types: float, real, and double. – Fixed-point types: numeric, decimal, and dec. – Boolean type: bool.
SUBSTR()	Supported.	-
SUBSTRING()	Supported.	-
SUBSTRING_INDEX()	Supported.	-
STRCMP()	Supported, with differences.	• In GaussDB, the types supported by function input parameters are as follows: – Character types: char, varchar, nvarchar2, and text – Binary type: BYTEA – Value type: tinyint [unsigned], smallint [unsigned], integer [unsigned], bigint [unsigned], float4, float8, and numeric – Date and time type: date, time without time zone, datetime, and timestamptz • For the floating-point type in the numeric type, the precision may be different from that in MySQL due to different connection parameter settings. Therefore, this scenario is not recommended, or the NUMERIC type is used instead.

MySQL	GaussDB	Difference
SHA()/ SHA1()	Supported.	-
SHA2()	Supported.	-

3.3.3.2.5 Forced Conversion Functions

Table 3-179 Forced conversion functions

MySQL	GaussDB	Difference
CAST()	Supported, with differences.	The data type conversion rules and supported conversion types are subject to the conversion scope and rules supported by GaussDB.
CONVERT()	Supported, with differences.	The data type conversion rules and supported conversion types are subject to the conversion scope and rules supported by GaussDB.

3.3.3.2.6 Encryption Functions

Table 3-180 Encryption functions

MySQL	GaussDB	Difference
AES_DECRYPT()	Supported.	-
AES_ENCRYPT()	Supported.	-

3.3.3.2.7 JSON Functions

JSON function differences:

- If you add escape characters as input parameters to JSON functions and other functions that allow character inputs, the processing is different from that in MySQL by default. To be compatible with MySQL, set the GUC parameter **standard_conforming_strings** to **off**. In this case, the processing of escape characters is compatible with MySQL, but a warning is generated for non-standard character input. The escape characters \t and \u and escape digits are different from those in MySQL. The JSON_UNQUOTE() function is compatible with MySQL. Even if the GUC parameter is not set, no alarm is generated.
- When processing an ultra-long number (the number contains more than 64 characters), the JSON function of GaussDB parses the number as a DOUBLE

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

and uses scientific notation for counting. The input parameters of the non-JSON type are the same as those of MySQL. However, when input parameters of the JSON type are used, the JSON type is not completely compatible with MySQL. As a result, differences occur in this scenario. MySQL displays complete numbers. (When the number length exceeds 82, MySQL displays an incorrect result.) GaussDB still parses an ultra-long number into a double-precision value. Long numbers are stored using floating-point numbers. During calculation, precision loss occurs in both GaussDB and MySQL. Therefore, you are advised to use character strings to store long numbers.

```
gaussdb=# SELECT json_insert('[1, 4,
99999999999999999999999999999999999999999999999999999999999999999999999999]','$[6]',json
_insert('[1,4]','$[5]',99999999999999999999999999999999999999999999999999999999999999999999999999
999999));
        json_insert
------------------------------
 [1, 4, 1e+74, [1, 4, 1e+74]]
(1 row)
```

Table 3-181 JSON functions

MySQL	GaussDB	Difference
JSON_APPEND()	Supported.	-
JSON_ARRAY()	Supported.	-
JSON_ARRAY_APPEND()	Supported.	-
JSON_ARRAY_INSERT()	Supported.	-
JSON_CONTAINS()	Supported.	-
JSON_CONTAINS_PATH()	Supported.	-
JSON_DEPTH()	Supported, with differences	GaussDB returns values of the int type, while MySQL returns values of the bigint type.
JSON_EXTRACT()	Supported.	-
JSON_INSERT()	Supported.	-
JSON_KEYS()	Supported.	-
JSON_LENGTH()	Supported, with differences	GaussDB returns values of the int type, while MySQL returns values of the bigint type.
JSON_MERGE()	Supported.	-

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

MySQL	GaussDB	Difference
JSON_OBJECT()	Supported.	-
JSON_QUOTE()	Supported, with differences	Return value difference: In GaussDB, JSON is returned. In MySQL, varchar or text is returned.
JSON_REMOVE()	Supported.	-
JSON_REPLACE()	Supported.	-
JSON_SEARCH()	Supported, with differences	GaussDB returns values of the text type, while MySQL returns values of the JSON type.
JSON_SET()	Supported.	-
JSON_TYPE()	Supported, with differences	JSON values of the numeric type are identified as number, which is different from MySQL.
JSON_UNQUOTE()	Supported.	-
JSON_VALID()	Supported.	-

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

3.3.3.2.8 Aggregate Functions

Table 3-182 Aggregate functions

MySQL	GaussDB	Difference
GROUP_CONCAT()	Supported, with differences	• If the **group_concat** parameter contains both the DISTINCT and ORDER BY syntaxes, all expressions following ORDER BY must be in the DISTINCT expression. • **group_concat(... order by** *Number***)** does not indicate the sequence of the parameter. The number is only a constant expression, which is equivalent to no sorting. • The data type of the return value of **group_concat** is always text regardless of the data type of the parameter. For MySQL, if **group_concat** contains binary parameters, the return value is binary. In other cases, the return value is a character string. If the return value length is greater than 512 bytes, the data type is a character large object or binary large object. • The value of **group_concat_max_len** ranges from 0 to 1073741823. The maximum value is smaller than that of MySQL.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

MySQL	GaussDB	Difference
DEFAULT()	Supported, with differences	• The default value of a column is an array. GaussDB returns an array. MySQL does not support the array type. • GaussDB columns are hidden columns (such as **xmin** and **cmin**). The default function returns a null value. • GaussDB supports default values of partitioned tables, temporary tables, and multi-table join query. • GaussDB supports the query of nodes whose column names contain character string values (indicating names) and A_Star nodes (indicating asterisks [*]), for example, **default(tt.t4.id)** and **default(tt.t4.*)**. For invalid query column names and A_Star nodes, the error information reported by GaussDB is different from that reported by MySQL. • When the default value of a column is created in GaussDB, the range of the column type is not verified. As a result, an error may be reported when the default function is used. • If the default value of a column is a function expression, the default function in GaussDB returns the calculated value of the default expression of the column during table creation. The default function in MySQL returns NULL.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

3.3.3.2.9 Numeric Operation Functions

Table 3-183 Numeric operation functions

MySQL	GaussDB	Difference
log2()	Supported, but with differences.	• The display of decimal places is different from that in MySQL. Due to the limitation of the GaussDB floating-point data type, the **extra_float_digits** parameter is used to control the number of decimal places to be displayed. • Due to the internal processing difference of the input precision, the calculation results of GaussDB and MySQL are different. • The following data types are supported: – Integer types: bigint, int16, int, smallint, and tinyint. – Unsigned integer types: bigint unsigned, integer unsigned, smallint unsigned, and tinyint unsigned. – Floating-point number type: numeric and real. – Character string type: character, character varying, clob, and text. Only numeric integer strings are supported. – SET type. – NULL type.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

MySQL	GaussDB	Difference
log10()	Supported, but with differences.	• The display of decimal places is different from that in MySQL. Due to the limitation of the GaussDB floating-point data type, the **extra_float_digits** parameter is used to control the number of decimal places to be displayed. • Due to the internal processing difference of the input precision, the calculation results of GaussDB and MySQL are different. • The following data types are supported: – Integer types: bigint, int16, int, smallint, and tinyint. – Unsigned integer types: bigint unsigned, integer unsigned, smallint unsigned, and tinyint unsigned. – Floating-point number type: numeric and real. – Character string type: character, character varying, clob, and text. Only numeric integer strings are supported. – SET type. – NULL type.
RAND([seed])	Supported, but with differences.	Due to the random number generation algorithm used in the function, the random number returned by the function is different from that in MySQL.

3.3.3.2.10 Other Functions

Table 3-184 Other functions

MySQL	GaussDB	Difference
UUID()	Supported	-
UUID_SHORT()	Supported	-

3.3.3.3 Operators

GaussDB is compatible with most MySQL operators, but there are some differences. Unless otherwise specified, the operator behavior in MYSQL-compatible mode is the native GaussDB behavior by default.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 3-185 Operators

MySQL	GaussDB	Difference
NULL-safe equal (<=>)	Supported.	-
[NOT] REGEXP	Supported, with differences.	• If the GUC parameter **b_format_dev_version** is set to **'s2'** and a pattern string with escape characters such as "\\a", "\\d", "\\e", "\\n", "\\Z", or "\\u" is matched with source character strings "\a", "\d", "\e", "\n", "\Z", or "\u", the behavior of GaussDB is different from that of MySQL 5.7 but the same as that of MySQL 8.0. • When the GUC parameter **b_format_dev_version** is set to **'s2'**, "\b" in GaussDB can match "\\b", but the matching will fail in MySQL. • If the input parameter of the pattern string is invalid with only the right parenthesis ()), GaussDB and MySQL 5.7 will report an error, but MySQL 8.0 will not. • In the rule of matching the de|abc sequence with de or abc, when there are empty values on the left and right of the pipe symbol (|), MySQL 5.7 will report an error, but GaussDB and MySQL 8.0 will not. • The regular expression of the tab character "\t" can match the character class [:blank:] in GaussDB and MySQL 8.0 but cannot in MySQL 5.7. • GaussDB supports non-greedy pattern matching. That is, the number of matching characters is as small as possible. A question mark (?) is added after some special characters, for example, ?? *? +? {n}? {n,}? {n,m}? MySQL 5.7 does not support non-greedy pattern matching, and the error message "Got error 'repetition-operator operand invalid' from regexp" is displayed. MySQL 8.0 already supports this function. • In the BINARY character set, the TEXT and BLOB types are converted to the BYTEA type. The REGEXP operator does not support the BYTEA type. Therefore, the two types cannot be matched.
[NOT] RLIKE	Supported, with differences.	Same as [NOT] REGEXP.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

3.3.3.4 Character Sets

GaussDB allows you to specify the following character sets for databases, schemas, tables, or columns.

Table 3-186 Character sets

MySQL	GaussDB
utf8mb4	Supported
gbk	Supported
gb18030	Supported

NOTE

Currently, GaussDB does not perform strict encoding logic verification on invalid characters that do not belong to the current character set. As a result, such invalid characters may be successfully entered. However, an error is reported during verification in MySQL.

3.3.3.5 Collation Rules

GaussDB allows you to specify the following collation rules for schemas, tables, or columns.

Table 3-187 Collation rules

MySQL	GaussDB
binary	Supported.
gb18030_bin	Supported.
gb18030_chinese_ci	Supported.
gbk_bin	Supported.
gbk_chinese_ci	Supported.
utf8_bin	Supported.
utf8_general_ci	Supported.
utf8mb4_0900_ai_ci	Supported.
utf8mb4_bin	Supported.
utf8mb4_general_ci	Supported.
utf8mb4_unicode_ci	Supported.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

Differences in collation rules:

- Currently, collation rules can only be specified for the character string type and some binary types. Other types do not support specifying collation rules. You can check the **typcollation** attribute of a type in the pg_type system catalog. If it is not **0**, the type supports the collation. In MySQL, collation can be specified for all types; however, specifying collation rules for types other than character strings and binary types has no practical meaning.
- The current collation rules can be specified only when the corresponding character set is the same as the database-level character set.
- The default collation of the utf8mb4 character set is utf8mb4_general_ci, which is the same as that in MySQL 5.7. utf8mb4_0900_ai_ci is not the default collation of utf8mb4.
- In GaussDB, UTF-8 and utf8mb4 are the same character set.

3.3.3.6 SQL

3.3.3.6.1 DDL

Table 3-188 DDL syntax compatibility

Description	Syntax	Difference
Create primary keys and UNIQUE indexes during table creation and modification.	ALTER TABLE and CREATE TABLE	• GaussDB does not support the UNIQUE INDEX|KEY index_name syntax. An error will be reported when the UNIQUE INDEX|KEY index_name syntax is used. However, MySQL supports these functions. • When a constraint is created as a global secondary index and USING BTREE is specified in the SQL statement, the underlying index is created as UB-tree. • When the table joined with the constraint is Ustore and USING BTREE is specified in the SQL statement, the underlying index is created as UB-tree.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description	Syntax	Difference
Support prefix indexes.	CREATE INDEX	• The prefix length cannot exceed 2676. The actual length of the key value is restricted by the internal page. If a column contains multi-byte characters or an index has multiple keys, an error may be reported when the index line length exceeds the threshold. • In the CREATE INDEX syntax, the following keywords cannot be used as prefix keys for column names: COALESCE, EXTRACT, GREATEST, LEAST, LNNVL, NULLIF, NVL, NVL2, OVERLAY, POSITION, REGEXP_LIKE, SUBSTRING, TIMESTAMPDIFF, TREAT, TRIM, XMLCONCAT, XMLELEMENT, XMLEXISTS, XMLFOREST, XMLPARSE, XMLPI, XMLROOT, and XMLSERIALIZE. • Prefix keys are not supported in primary key and unique key indexes.
Specify character sets and collation rules.	ALTER SCHEMA, ALTER TABLE, CREATE SCHEMA, and CREATE TABLE	-
Create a partitioned table.	CREATE TABLE PARTITION	-
Specify table-level and column-level comments during table creation and modification.	CREATE TABLE and ALTER TABLE	-
Specify index-level comments during index creation.	CREATE INDEX	-

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description	Syntax	Difference
Exchange the partition data of an ordinary table and a partitioned table.	ALTER TABLE PARTITION	Differences in ALTER TABLE EXCHANGE PARTITION: ● If MySQL tables or partitions use tablespaces, data in partitions and ordinary tables cannot be exchanged. If GaussDB tables or partitions use different tablespaces, data in partitions and ordinary tables can still be exchanged. ● MySQL does not verify the default values of columns. Therefore, data in partitions and ordinary tables can be exchanged even if the default values are different. GaussDB verifies the default values. If they are different, data in partitions and ordinary tables cannot be exchanged. ● After the DROP COLUMN operation is performed on a partitioned table or an ordinary table in MySQL, if the table definition is still consistent, data can be exchanged between partitions and ordinary tables. In GaussDB, data can be exchanged between partitions and ordinary tables only when the deleted columns of ordinary tables and partitioned tables are strictly aligned. ● MySQL and GaussDB use different hash algorithms. Therefore, data stored in the same hash partition may be inconsistent. As a result, the exchanged data may also be inconsistent. ● MySQL partitioned tables do not support foreign

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description	Syntax	Difference
		keys. If an ordinary table contains foreign keys or other tables reference foreign keys of an ordinary table, data in partitions and ordinary tables cannot be exchanged. GaussDB partitioned tables support foreign keys. If the FOREIGN KEY constraints of two tables are the same, data in partitions and ordinary tables can be exchanged. If a GaussDB partitioned table does not contain foreign keys, an ordinary table is referenced by other tables, and the partitioned table is the same as the ordinary table, data in the partitioned table can be exchanged with that in the ordinary table.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description	Syntax	Difference
Support auto-increment columns.	ALTER TABLE and CREATE TABLE	• Currently, only local auto-increment columns of each DN are supported. • It is recommended that the auto-increment column be the first column of a non-global secondary index. Otherwise, an alarm is generated when a table is created, and errors may occur when some operations (such as ALTER TABLE EXCHANGE PARTITION) are performed on a table that contains auto-increment columns. The auto-increment column in MySQL must be the first column of the index. • In the syntax AUTO_INCREMENT = value, **value** must be a positive number less than 2^127. MySQL does not verify the value. • An error occurs if the auto-increment continues after an auto-increment value reaches the maximum value of a column data type. In MySQL, errors or warnings may be generated during auto-increment, and sometimes auto-increment continues until the maximum value is reached. • GaussDB does not support the *innodb_autoinc_lock_mode* system variable, but when its GUC parameter **auto_increment_cache** is set to **0**, the behavior of inserting auto-increment columns in batches is

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description	Syntax	Difference
		similar to that when the MySQL system variable *innodb_autoinc_lock_mode* is set to **1**. ● When 0s, NULLs, and definite values are imported or batch inserted into auto-increment columns, the auto-increment values inserted after an error occurs in GaussDB may not be the same as those in MySQL. The **auto_increment_cache** parameter is provided to control the number of reserved auto-increment values. ● In different execution plans, the auto-increment sequence and reserved auto-increment values may be different from those in MySQL. For example, "INSERT INTO table VALUES(...),(...),..." is distributed to different DNs. Therefore, in some execution plans, DNs cannot obtain the number of rows to be inserted. The **auto_increment_cache** parameter is provided to control the number of reserved auto-increment values. ● When auto-increment is triggered by parallel import or insertion of auto-increment columns, the cache value reserved for each parallel thread is used only in the thread. If the cache value is not used up, the values of auto-increment columns in the table are discontinuous. The auto-

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description	Syntax	Difference
		increment values generated by parallel insertion may not be the same as those generated in MySQL. • The SERIAL data type of GaussDB is an original auto-increment column, which is different from the **AUTO_INCREMENT** column. The SERIAL data type of MySQL is the **AUTO_INCREMENT** column. • The value of **auto_increment_offset** cannot be greater than that of **auto_increment_increment**. Otherwise, an error occurs. MySQL allows it and states that **auto_increment_offset** will be ignored. • If a table has a primary key or index, the sequence in which the **ALTER TABLE** command rewrites table data may be different from that in MySQL. GaussDB rewrites table data based on the table data storage sequence, while MySQL rewrites table data based on the primary key or index sequence. As a result, the auto-increment sequence may be different. • When the **ALTER TABLE** command is used to add or modify auto-increment columns, the number of auto-increment values reserved for the first time is the number of rows in the table statistics. The number of rows in the

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description	Syntax	Difference
		statistics may not be the same as that in MySQL. • When auto-increment is performed in a trigger or user-defined function, the return value of last_insert_id is updated. MySQL does not update it. • If the values of the GUC parameters **auto_increment_offset** and **auto_increment_increment** are out of range, an error occurs. MySQL automatically changes the value to a boundary value. • The last_insert_id function is not supported. • Currently, local temporary tables do not support auto-increment columns. • If **sql_mode** is set to **no_auto_value_on_zero**, the auto-increment columns of the table are not subject to NOT NULL constraints. In GaussDB and MySQL, when the value of an auto-increment column is not specified, **NULL** will be inserted into the auto-increment column, but auto-increment is triggered for the former and not triggered for the latter.
Delete the PRIMARY KEY constraints of a table.	ALTER TABLE	-

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description	Syntax	Difference
CREATE TABLE... LIKE syntax	CREATE TABLE ... LIKE	• In versions earlier than MySQL 8.0.16, CHECK constraints are parsed but their functions are ignored. In this case, CHECK constraints are not replicated. GaussDB supports replication of CHECK constraints. • For the set data type, MySQL supports replication while GaussDB does not during table creation. • When a table is created, all PRIMARY KEY constraint names in MySQL are fixed to **PRIMARY KEY**. GaussDB does not support replication of PRIMARY KEY constraint names. • When a table is created, MySQL supports replication of UNIQUE KEY constraint names, but GaussDB does not. • When a table is created, MySQL versions earlier than 8.0.16 do not have CHECK constraint information, but GaussDB supports replication of CHECK constraint names. • When a table is created, MySQL supports replication of index names, but GaussDB does not. • When a table is created across sql_mode, MySQL is controlled by the loose mode and strict mode. The strict mode may become invalid in GaussDB. For example, if the source table has the default value

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description	Syntax	Difference
		"0000-00-00", GaussDB can create a table that contains the default value **"0000-00-00"** in "no_zero_date" strict mode, which means that the strict mode is invalid. MySQL fails to create the table because it is controlled by the strict mode. • MySQL supports cross-database table creation, but GaussDB does not. • If the source table is a temporary table, you can create a non-temporary table in MySQL but not in GaussDB.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description	Syntax	Difference
Compatible with syntax for changing table names.	ALTER TABLE[IF EXISTS] tbl_name RENAME [TO | AS | =] new_tbl_name; RENAME {TABLE | TABLES} tbl_name TO new_tbl_name [, tbl_name2 TO new_tbl_name2, ...];	• The ALTER RENAME syntax in GaussDB supports only the function of changing the table name and cannot be coupled with other function operations. • In GaussDB, only the old table name column supports the schema.table_name format, and the new and old table names belong to the same schema. • GaussDB does not support renaming of old and new tables across schemas. However, if you have the permission, you can modify the names of tables in other schemas in the current schema. • The syntax for renaming multiple groups of tables in GaussDB supports renaming of all local temporary tables, but does not support the combination of local temporary tables and non-local temporary tables.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description	Syntax	Difference
Create a partition.	ALTER TABLE [IF EXISTS] { table_name [*] | ONLY table_name | ONLY (table_name)} action [, ...]; action: move_clause | exchange_clause | row_clause | merge_clause | modify_clause | split_clause | add_clause | drop_clause | ilm_clause add_clause: ADD {{partition_less_than_item | partition_start_end_item | partition_list_item} | PARTITION({partition_less_than_item | partition_start_end_item | partition_list_item})}	• The ALTER TABLE table_name ADD PARTITION (partition_definition1, partition_definition1,…); syntax cannot be used to add multiple partitions. • Only the original syntax for adding multiple partitions is supported: ALTER TABLE table_name ADD PARTITION (partition_definition1), ADD PARTITION (partition_definition2[y1]), …;.

3.3.3.6.2 DML

Table 3-189 DML syntax compatibility

Description	Syntax	Difference
DELETE supports ORDER BY and LIMIT.	DELETE	-
UPDATE supports ORDER BY and LIMIT.	UPDATE	-

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description	Syntax	Difference

Support the REPLACE INTO syntax.	REPLACE	• Difference between the initial values of the time type. For example:
		– MySQL is not affected by the strict or loose mode. You can insert time 0 into a table.
		mysql> CREATE TABLE test(f1 TIMESTAMP NOT NULL, f2 DATETIME NOT NULL, f3 DATE NOT NULL);
		Query OK, 1 row affected (0.00 sec)
		
		mysql> REPLACE INTO test VALUES(f1, f2, f3);
		Query OK, 1 row affected (0.00 sec)
		
		mysql> SELECT * FROM test;
		+---------------------
		+---------------------+------------
		+
		| f1 | f2
		| f3 |
		+---------------------
		+---------------------+------------
		+
		| 0000-00-00 00:00:00 |
		0000-00-00 00:00:00 |
		0000-00-00 |
		+---------------------
		+---------------------+------------
		+
		1 row in set (0.00 sec)
		– The time 0 can be successfully inserted only when GaussDB is in loose mode.
		gaussdb=# SET b_format_version = '5.7';
		SET
		gaussdb=# SET b_format_dev_version = 's1';
		SET
		gaussdb=# SET sql_mode = '';
		SET
		gaussdb=# CREATE TABLE test(f1 TIMESTAMP NOT NULL, f2 DATETIME NOT NULL, f3 DATE NOT NULL) DISTRIBUTE BY HASH(f1);
		CREATE TABLE
		gaussdb=# REPLACE INTO test VALUES(f1, f2, f3);
		REPLACE 0 1
		gaussdb=# SELECT * FROM test;
		f1 | f2 | f3
		--------------------- 	
		+---------------------+------------

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description	Syntax	Difference

		0000-00-00 00:00:00 |
		0000-00-00 00:00:00 |
		0000-00-00
		(1 row)
		In strict mode, the error is reported: date/time field value out of range: "0000-00-00 00:00:00".
		• Difference between the initial values of the BIT type when NOT NULL exists. For example:
		– The initial value of the BIT type is an empty string '' in MySQL, that is:
		mysql> CREATE TABLE test(f1 BIT(3) NOT NULL);
		Query OK, 0 rows affected (0.01 sec)
		
		mysql> REPLACE INTO test VALUES(f1);
		Query OK, 1 row affected (0.00 sec)
		
		mysql> SELECT f1, f1 IS NULL FROM test;
		+----+------------+
		| f1 | f1 is null |
		+----+------------+
		| | 0 |
		| | 0 |
		+----+------------+
		2 rows in set (0.00 sec)
		– If the initial value of the BIT type is **NULL** in GaussDB, an error is reported.
		gaussdb=# CREATE TABLE test(f1 int, f2 BIT(3) NOT NULL) DISTRIBUTE BY HASH(f1);
		CREATE TABLE
		gaussdb=# REPLACE INTO test VALUES(1, f2);
		ERROR: null value in column "f2" violates not-null constraint
		DETAIL: Failing row contains (1, null).

SELECT supports multi-partition query.	SELECT	-

Description	Syntax	Difference
UPDATE supports multi-partition update.	UPDATE	-

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description	Syntax	Difference

Import data by using LOAD DATA.	LOAD DATA	• The execution result of the LOAD DATA syntax is the same as that in MySQL strict mode. The loose mode is not adapted currently. For example, if the source data to be imported contains invalid characters, GaussDB reports an error, while MySQL reports an error in strict mode, or truncates the invalid characters and then import the data in loose mode.
		-- GaussDB
		gaussdb=# SET sql_mode='';
		SET
		gaussdb=# DROP TABLE IF EXISTS t1;
		DROP TABLE
		gaussdb=# CREATE TABLE t1(a text) CHARSET gbk;
		CREATE TABLE
		gaussdb=# SELECT unhex('1AFF1F') INTO OUTFILE '/tmp/3.data';
		COPY 1
		gaussdb=# LOAD DATA INFILE '/tmp/3.data' INTO TABLE t1 CHARACTER SET gbk;
		ERROR: invalid byte sequence for encoding "GBK": 0xff 0x1f
		CONTEXT: COPY t1, line 1.
		gaussdb=# DROP TABLE t1;
		DROP TABLE
		
		-- MySQL
		mysql> SET sql_mode='';
		Query OK, 0 rows affected (0.00 sec)
		mysql> DROP TABLE IF EXISTS t1;
		Query OK, 0 rows affected (0.02 sec)
		mysql> CREATE TABLE t1(a text) CHARSET gbk;
		Query OK, 0 rows affected (0.03 sec)
		mysql> SELECT unhex('1AFF1F') INTO OUTFILE '/tmp/3.data';
		Query OK, 1 row affected (0.00 sec)
		mysql> LOAD DATA INFILE '/tmp/3.data' INTO TABLE t1 CHARACTER SET gbk;
		Query OK, 1 row affected, 1 warning (0.01 sec)
		Records: 1 Deleted: 0 Skipped: 0 Warnings: 1
		mysql> SHOW warnings;
		+---------+------

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description	Syntax	Difference
		+----------+------+ Message | +----------+------ +----------+ | Warning | 1366 | Incorrect string value: '\xFF\x1F' for column 'a' at row 1 | +----------+------ +----------+ 1 row in set (0.00 sec) mysql> SELECT hex(a) FROM t1; +--------+ | hex(a) | +--------+ | 1A | +--------+ 1 row in set (0.00 sec) mysql> DROP TABLE t1; Query OK, 0 rows affected (0.02 sec) • The **IGNORE** and **LOCAL** parameters are used only to ignore the conflicting rows when the imported data conflicts with the data in the table and to automatically fill default values for other columns when the number of columns in the file is less than that in the table. Other functions are not supported currently. • If the keyword LOCAL is specified and the file path is a relative path, the file is searched from the binary directory. If the keyword LOCAL is not specified and the file path is a relative path, the file is searched from the data directory. • If single quotation marks are specified as separators, escape characters, and newline characters in the syntax, lexical parsing errors occur.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description	Syntax	Difference
		• The **[(col_name_or_user_var [, col_name_or_user_var]...)]** parameter cannot be used to specify a column repeatedly. • The newline character specified by **[FIELDS TERMINATED BY 'string']** cannot be the same as the separator specified by **[LINES TERMINATED BY'string']**. • If the data written to a table by running **LOAD DATA** cannot be converted to the data type of the table, an error is reported. • Columns can only be specified by column name instead of user variables. • The LOAD DATA SET expression does not support the calculation of a specified column name. • If there is no implicit conversion function between the return value type of the SET expression and the corresponding column type, an error is reported. • LOAD DATA does not support the INSERT or DELETE trigger. • LOAD DATA applies only to tables but not views. • The default newline character of the file in Windows is different from that in Linux. LOAD DATA cannot identify this scenario and reports an error. You are advised to check the newline character at the end of

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description	Syntax	Difference

		lines in the file to be imported.
		● If the number of columns in the source data is greater than that in the target table, GaussDB displays an alarm, while MySQL displays an alarm in the following scenarios and reports an error in other scenarios:
		– The strict mode is not enabled for **sql_mode**.
		– The **IGNORE** option is specified.
		– The **LOCAL** option is specified and the **REPLACE** option is not specified.
		● When the source data file ends with a column delimiter, MySQL processes the file as if there is no new column after the delimiter, while GaussDB processes the file as if there is an empty string column after the delimiter.
		-- Source data in **1.csv**
		1,2,
		
		-- GaussDB
		gaussdb=# DROP TABLE IF EXISTS t1;
		NOTICE: table "t1" does not exist, skipping

		| f1 |
		+------+
		| NULL |
		+------+
		1 row in set (0.00 sec)
		• The implementation mechanism of Boolean and serial in GaussDB is different from that in MySQL. Therefore, the default zero value in GaussDB is different from that in MySQL. For example:
		– Behavior in GaussDB
		gaussdb=# CREATE TABLE test(f1 SERIAL, f2 BOOL NOT NULL);
		NOTICE: CREATE TABLE will create implicit sequence "test_f1_seq" for serial column "test.f1"
		CREATE TABLE
		gaussdb=# INSERT IGNORE INTO test values(NULL,NULL);
		WARNING: null value in column "f1" violates not-null constraint
		DETAIL: Failing row contains (null, null).
		WARNING: null value in column "f2" violates not-null constraint
		DETAIL: Failing row contains (null, null).
		INSERT 0 1
		gaussdb=# SELECT * FROM test;
		f1 | f2
		----+----
		0 | f
		(1 row)
		– Behavior in MySQL
		mysql> CREATE TABLE test(f1 SERIAL, f2 BOOL NOT NULL);
		Query OK, 0 rows affected (0.00 sec)
		
		mysql> INSERT IGNORE INTO test values(NULL,NULL);
		Query OK, 1 row affected, 1 warning (0.00 sec)

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description	Syntax	Difference
		mysql> SELECT * FROM test; +----+----+ | f1 | f2 | +----+----+ | 1 | 0 | +----+----+ 1 row in set (0.00 sec)

3.3.3.6.3 DCL

Table 3-190 DCL syntax compatibility

Description	Syntax	Difference
Set names with COLLATE specified.	SET [SESSION | LOCAL] NAMES {'charset_name' [COLLATE 'collation_name'] | DEFAULT};	GaussDB does not allow **charset_name** to be different from the database character set. For details, see **SET**.

3.3.3.7 Drivers

3.3.3.7.1 JDBC API Reference

The JDBC API definitions in GaussDB are the same as those in MySQL and comply with industry standards. This section describes the behavior differences of JDBC APIs between GaussDB in MySQL-compatible mode and MySQL.

Obtaining Data from a Result Set

ResultSet objects provide a variety of methods to obtain data from a result set. **Table 3-191** describes the common methods for obtaining data. If you want to know more about other methods, see JDK official documents.

Table 3-191 Common methods for obtaining data from a result set

Method	Description	Difference
int getInt(int columnIndex)	Obtains int data by column index.	-
int getInt(String columnLabel)	Obtains int data by column name.	-

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Method	Description	Difference
String getString(int columnIndex)	Obtains string data by column index.	If the column type is integer and the column contains the **ZEROFILL** attribute, GaussDB pads 0s to meet the width required by the **ZEROFILL** attribute and outputs the result. MySQL directly outputs the result.
String getString(String columnLabel)	Obtains string data by column name.	If the column type is integer and the column contains the **ZEROFILL** attribute, GaussDB pads 0s to meet the width required by the **ZEROFILL** attribute and outputs the result. MySQL directly outputs the result.
Date getDate(int columnIndex)	Obtains date data by column index.	-
Date getDate(String columnLabel)	Obtains date data by column name.	-

4 Tool Reference

4.1 Downloading and Installing Tools

Downloading and Installing Tools

1. Download the driver package and its verification package listed in **Table 4-1**.

   Table 4-1 Driver package download list

Version	Download Address
V2.0-10.x	**Driver package** **Verification package for the driver package**

2. Verify the driver package.

   To prevent a software package from being tampered with during transmission or storage, download the corresponding verification package and perform the following steps to verify the software package:

   - Verifying the software package integrity on a Linux server:
     i. Upload the software package and verification package to the same directory on the VM.
     ii. Run the following command to verify the integrity of the software package:

     ```
     F=$(echo DBS-GaussDB-driver*.tar.gz);echo "$(awk '{print $1}' "$F.sha256")  $F" | sha256sum -c -
     ```

     If **OK** is displayed in the command output, the verification is successful. For example:

     ```
     DBS-GaussDB-driver_507.0_20260629130806.133858239.tar.gz: OK
     ```

   - Verifying the software package integrity on a Windows server:
     i. Press **Win+R** to open the **Run** dialog box. Type **cmd** in the text box and press **Enter** to open the **Command Prompt** window.
     ii. Run the following command to obtain the hash value of the driver package:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

certutil -hashfile *{local_directory_of_the_driver_package}*\ *{driver_package_name}* **sha256**

- Replace *{local_directory_of_the_driver_package}* with the actual download path, for example, **C:\Users**.
- Replace *{driver_package_name}* with the name of the downloaded driver package, for example, **DBS-GaussDB-driver_507.0_20260629130806.133858239.tar.gz**.

Example: **certutil -hashfile** *C:|Users|DBS-GaussDB-driver_507.0_20260629130806.133858239.tar.gz* **sha256**

iii. Compare the hash value obtained in **2.ii** with the hash value of the verification package obtained in **Table 4-1**.

- If they are consistent, the verification is successful.
- If they are inconsistent, download the driver package again and repeat **2.i** to **2.iii** to verify the driver package.

3. Log in to the server and create a directory for storing the tool package.
```
mkdir -p /opt/bin
```
4. Upload the driver package obtained in **1** to the created directory.
5. Run the following commands to decompress the driver package. Replace the driver package name with the actual one. **DBS-GaussDB-driver_507.0_20260629130806.133858239.tar.gz** is used as an example.
```
cd /opt/bin
tar -zxvf DBS-GaussDB-driver_507.0_20260629130806.133858239.tar.gz
```
6. Run the following commands to obtain the gsql client tool package:
```
cd /opt/bin/DBS-GaussDB-driver_507.0_20260629130806.133858239/Distributed/
tar -zxvf gsql_driver.tar.gz
cd /opt/bin/DBS-GaussDB-driver_507.0_20260629130806.133858239/Distributed/gsql_driver/Euler2.5_X86_64
tar -zxvf GaussDB-Kernel_507.0.0.B071_Gsql_X86_Distributed.tar.gz
```

NOTE

- The relative path of the tool package varies depending on where you decompressed it. In this section, the tool package of Euler2.5_x86_64 is used as an example.
- Replace the client tool package name with the actual one. **GaussDB-Kernel_507.0.0.B071_Gsql_x86_Distributed.tar.gz** is used as an example.

7. Copy the decompressed **GaussDB-Kernel_507.0.0_Euler_64bit_Gsql.tar.gz** client tool package to the **/opt/bin** directory.
```
cp GaussDB-Kernel_507.0.0_Euler_64bit_Gsql.tar.gz /opt/bin
```

NOTE

The gsql tool package contains the gsql client, gs_dump, gs_dumpall, and gs_restore.

8. Run the following commands to decompress the package:
```
cd /opt/bin
tar -zxvf GaussDB-Kernel_507.0.0_Euler_64bit_Gsql.tar.gz
```
9. Use the script to automatically configure the environment variables.
```
source gsql_env.sh
```

4.2 Database Connection Tools

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

4.2.1 gsql for Connecting to a Database

4.2.1.1 gsql Usage Guide

Description

gsql, provided by GaussDB, is a database connection tool running in the command-line interface. You can use gsql to connect to the server and perform operations and maintenance on it. gsql enables users to perform basic operations on the database and provides several advanced features.

Basic functions:

- Connect to a database: By default, only the localhost can be connected. To connect to a remote database, you must configure it on the localhost. For details, see "Database Quick Start > Connecting to a Database > Using gsql to Connect to a Database" in *Developer Guide*.

  NOTE

  If gsql is used to connect to a database, the connection timeout period will be 5 minutes. If the database has not correctly set up a connection and authenticated the identity of the client within this period, gsql will time out and exit. To resolve this problem, see **FAQ**.

- Run SQL statements: You can interactively enter SQL statements and run them, or run specified SQL statements in a file.
- Run meta-commands: Meta-commands can help administrators view database object information, query cache information, format SQL output, and connect to a new database. For details about meta-commands, see **Meta-Command Reference**.

Advanced functions:

Table 4-2 lists the advanced features of gsql.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 4-2 Advanced gsql features

Feature	Description
Variable	gsql provides a variable feature that is similar to the **shell** command of Linux. The following **\set** meta-command of gsql can be used to set a variable: \set *varname value* To delete the variables set by the **\set** command, run the following command: \unset *varname* **NOTE** • A variable is a simple name-value pair. The value can be any characters in any length. • Variable names must consist of case-sensitive letters (including non-Latin letters), digits, and underscores (_). • If the **\set** *varname* meta-command (without the second parameter) is used, the variable is set without a value specified. • If the **\set** meta-command without parameters is used, values of all variables are displayed. For details about variable examples and descriptions, see **Variables**.
SQL substitution	Common SQL statements can be set to variables using the variable feature of gsql to simplify operations. For details about examples and descriptions about SQL substitution, see **SQL substitution**.
Custom prompt	Prompts of gsql can be customized. Prompts can be modified by changing the reserved three variables of gsql: *PROMPT1*, *PROMPT2*, and *PROMPT3*. These variables can be user-defined or set to the values predefined by gsql. For details, see **Prompt**.
Historical client operation records	gsql can record historical client operations. This function is enabled by specifying the **-r** parameter when a client is connected. The number of historical records can be set using the **\set** command. For example, **\set HISTSIZE 50** indicates that the number of historical records is set to **50**. **\set HISTSIZE 0** indicates that the operation history is not recorded. **NOTE** • The default number of historical records is 32. The maximum number of historical records is 500. If interactively entered commands contain Chinese characters, only the UTF-8 encoding environment is supported. • For security purposes, SQL statements containing case-insensitive character strings such as PASSWORD, IDENTIFIED, GS_ENCRYPT_AES128, GS_DECRYPT_AES128, GS_ENCRYPT, GS_DECRYPT, GS_ENCRYPT_BYTEA, GS_DECRYPT_BYTEA, PG_CREATE_PHYSICAL_REPLICATION_SLOT_EXTERN, SECRET_ACCESS_KEY, SECRETKEY, CREATE_CREDENTIAL, ACCESSKEY, SECRET_KEY, DESENCRYPT, DESDECRYPT, DES3ENCRYPT and DES3DECRYPT are identified as statements containing sensitive information and are not recorded in historical information. That is, the statements cannot be displayed by scrolling up or down.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- Variables

  To set a variable, run the **\set** meta-command of gsql. For example, to set variable *foo* to **bar**, run the following command:

  ```
  gaussdb=#  \set foo bar
  ```

  To reference the value of a variable, add a colon (:) before the variable. For example, to view the value of variable *foo*, run the following command:

  ```
  gaussdb=#  \echo :foo
  bar
  ```

  This variable reference method is applicable to regular SQL statements and meta-commands except **\copy**, **\ef**, **\help**, **\sf**, and **\!**.

  gsql pre-defines some special variables and plans the values of these variables. To ensure compatibility with later versions, do not use these variables for other purposes. For details about special variables, see **Table 4-3**.

  NOTE

  - All the special variables consist of upper-case letters, digits, and underscores (_).
  - To view the default value of a special variable, run the **\echo :***varname* meta-command, for example, **\echo :***DBNAME*.

  Table 4-3 Settings of special variables

Variable	Setting Method	Description
DBNAME	\set DBNAME *dbname*	Name of the connected database. This variable is set again when a database is connected.
ECHO	\set ECHO all | queries	• If this variable is set to **all**, only the query information is displayed. This has the same effect as specifying the **-a** parameter when gsql is used to connect to a database. • If this variable is set to **queries**, the command line and query information are displayed. This has the same effect as specifying the **-e** parameter when gsql is used to connect to a database.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Variable	Setting Method	Description
ECHO_HIDDEN	\set ECHO_HIDDEN on | off | noexec	When a meta-command (such as **\dg**) is used to query database information, the value of this variable determines the query behavior. ● If this variable is set to **on**, the query statements that are called by the meta-command are displayed, and then the query result is displayed. This has the same effect as specifying the **-E** parameter when gsql is used to connect to a database. ● If this variable is set to **off**, only the query result is displayed. ● If this variable is set to **noexec**, only the query information is displayed, and the query is not run.
ENCODING	\set ENCODING *encoding*	Character set encoding of the current client.
FETCH_COUNT	\set FETCH_COUNT *variable*	● If the value is an integer greater than 0, for example, *n*, *n* lines will be selected from the result set to the cache and displayed on the screen when the SELECT statement is run. ● If this variable is not set or set to a value less than or equal to 0, all results are selected at a time to the cache when the SELECT statement is run. **NOTE** A proper variable value helps reduce the memory usage. The recommended value range is from 100 to 1000.
HISTCONTROL	\set HISTCONTROL ignorespace | ignoredups | ignoreboth | none	● **ignorespace**: A line started with a space is not written to the historical record. ● **ignoredups**: A line that exists in the historical record is not written to the historical record. ● **ignoreboth**, **none**, or other values: All the lines read in interaction mode are saved in the historical record. **NOTE** **none** indicates that **HISTCONTROL** is not set.
HISTFILE	\set HISTFILE *filename*	Specifies the file for storing historical commands. The default value is **~/.bash_history**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Variable	Setting Method	Description
HISTSIZE	\set HISTSIZE *size*	Specifies the number of commands to store in the command history. The default value is **500**.
HOST	\set HOST *hostname*	Specifies the name of a connected host.
IGNOREEOF	\set IGNOREEOF *variable*	• If this variable is set to a number, for example, **10**, the first nine EOF characters (generally **Ctrl**+**C**) entered in gsql are neglected and the gsql program exits when the tenth **Ctrl**+**C** is entered. • If this variable is set to a non-numeric value, the default value is **10**. • If this variable is deleted, gsql exits when an EOF is entered.
LASTOID	\set LASTOID *oid*	Specifies the last OID, which is the value returned by an **INSERT** or **lo_import** command. This variable is valid only before the output of the next SQL statement is displayed.
ON_ERROR_ROLLBACK	\set ON_ERROR_ROLLBACK on | interactive | off	• **on**: When an error occurs in a statement in a transaction block, the system automatically rolls back to the state before the previous command is executed and continues to execute subsequent commands. This mode works by implicitly creating a SAVEPOINT before each command of a transaction block. When an error occurs, the system automatically rolls back to the previously created SAVEPOINT to cancel the impact of the failed command. • **interactive**: Automatic rollback is enabled only in interactive sessions. • **off** (default value): The entire transaction is terminated when an error occurs in a statement in a transaction block.
ON_ERROR_STOP	\set ON_ERROR_STOP on | off	• **on**: The execution stops if an error occurs. In interactive mode, gsql returns the output of executed commands immediately. • **off** (default value): An error, if occurring during the execution, is ignored, and the execution continues.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Variable	Setting Method	Description
PORT	\set PORT *port*	Specifies the port number of a connected database.
USER	\set USER *username*	Specifies the database user you are currently connected as.
VERBOSITY	\set VERBOSITY terse | default | verbose	Controls the detail level of the error report. • **terse**: Only critical and major error texts and text locations are returned (which is generally suitable for single-line error information). • **default**: Critical and major error texts and text locations, error details, and error messages (possibly involving multiple lines) are all returned. • **verbose**: All error information is returned.

- SQL substitution

  gsql, like a parameter of a meta-command, provides a key feature that enables you to substitute a standard SQL statement for a gsql variable. gsql also provides a new alias or identifier for the variable. To replace the value of a variable using the SQL substitution method, add a colon (:) before the variable. For example:

```
gaussdb=#  \set foo 'HR.areaS'
-- Run the following command to query the HR.areaS table:
gaussdb=#  SELECT * FROM :foo;
 area_id |       area_name
---------+------------------------
       4 | Middle East and Africa
       3 | Asia
       1 | Europe
       2 | Americas
(4 rows)
```

  NOTE

  The value of a variable is copied word by word and can even contain asymmetric quotation marks or backslash commands. Therefore, the input content must be meaningful.

- Prompts

  The gsql prompt can be set using the three variables in **Table 4-4**. These variables consist of characters and special escape characters.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 4-4 Prompt variables

Variable	Description	Example

PROMPT1	Specifies the normal prompt used when gsql requests a new command.
	The default value of *PROMPT1* is **%o%R%#**.
		PROMPT1 can be used to change the prompt.
		• Change the prompt to **local**:
		`gaussdb=# \set PROMPT1 %M`
		`local:/data/huawei/wisequery/perfadm_mppdb`
		• Change the prompt to **name**:
		`gaussdb=# \set PROMPT1 name`
		`name`
		• Change the prompt to **=**:
		`gaussdb=# \set PROMPT1 %R`
		`=`

PROMPT2	Specifies the prompt displayed when more input is expected (when the command is not terminated with a semicolon (;) or the quotation marks ("") are not in pair).	*PROMPT2* can be used to display the prompt. `gaussdb=#  \set PROMPT2 TEST` `gaussdb=#  SELECT * FROM HR.areaS` `TEST;` ` area_id	area_name` `---------+--------------------` `1	Europe` `2	Americas` `4	Middle East and Africa` `3	Asia` `(4 rows)`

PROMPT3	Specifies the prompt displayed when the **COPY** statement (such as **COPY FROM STDIN**) is run and data input is expected.	*PROMPT3* can be used to display the COPY prompt.
		`gaussdb=#  \set PROMPT3 '>>>>'`
		`gaussdb=#  COPY HR.areaS FROM STDIN;`
		`Enter data to be copied followed by a newline.`
		`End with a backslash and a period on a line by itself.`
		`>>>>1 aa`
		`>>>>2 bb`
		`>>>>\.`

The value of the selected prompt variable is printed literally. However, a value containing a percent sign (%) is replaced by the predefined contents depending on the character following the percent sign (%). For details about the defined substitutions, see **Table 4-5**.

Table 4-5 Defined substitutions

Symbol	Description
%M	Replaced by the full host name (with domain name). The full name is **[local]** if the connection is over a UDS, or **[local:/dir/name]** if the UDS is not at the compiled default location.
%m	Replaced by the host name truncated at the first dot. It is **[local]** if the connection is over a UDS.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Symbol	Description
%o	Database name. For the **postgres** database, **gaussdb** is displayed. For other databases, the database name is displayed.
%>	Replaced by the number of the port that the host is listening on.
%n	Replaced by the database session username.
%/	Replaced by the name of the current database.
%~	Similar to %/. However, the tilde (~) is used if the database is your default database.
%#	The number sign (#) is used if the session user is the database administrator; otherwise, the greater-than sign (>) is used.
%R	• For *PROMPT1*, **=** typically, but **^** in single-line mode, or **!** if the session is disconnected from the database (which can happen if **\connect** fails). • For *PROMPT2*, it is replaced by a hyphen (-), an asterisk (*), a single or double quotation mark, or a dollar sign ($), depending on whether gsql expects more input, for example, the query is not terminated, in a /* ... */ the comment, enclosed with quotation marks, or in a dollar sign extension.
%x	Replaced by the transaction status. • An empty string when it is not in a transaction block • An asterisk (*) when it is in a transaction block • An exclamation mark (!) when it is in a failed transaction block • A question mark (?) when the transaction status is indefinite (for example, because there is no connection).
%digits	Replaced by the character with the specified byte.
%:name	Replaced by the value of the *name* variable of gsql.
%`command`	Replaced by the output of the command specified by **command**, similar to the backquote substitution.
%[. . . %]	Prompts may contain terminal control characters which, for example, change the color, background, or style of the prompt text, or change the title of the terminal window. For example: `gaussdb=# \set PROMPT1 '%[%033[1;33;40m%]%n@%/%R%[%033[0m%]%#'` The output is a boldfaced (1;) yellow-on-black (33;40) prompt on VT100-compatible, color-capable terminals.

Environment variables:

For details about gsql-related environment variables, see **Table 4-6**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 4-6 Environment variables related to gsql

Name	Description
COLUMNS	If **\set columns** is set to **0**, this parameter controls the width of the wrapped format. This width determines whether to change the wide output mode into the vertical output mode if automatic expansion is enabled.
PAGER	If the query results do not fit on the screen, they are redirected through this command. You can use the **\pset** command to disable the pager. Typically, the **more** or **less** command is used for viewing the query result page by page. The default is platform-dependent. **NOTE** Display of the **less** command is affected by the *LC_CTYPE* environment variable.
PSQL_EDITOR	The **\e** and **\ef** commands use the editor specified by the environment variables. The variables are examined in the order listed. The default editor on Unix is vi.
EDITOR	
VISUAL	

PSQL_EDITOR_LINENUMBER_ARG	When the **\e** or **\ef** command is used with a line number parameter, this variable specifies the command-line parameter used to pass the starting line number to the editor. For the Emacs or Vi editor, the value of this parameter is a plus sign (+). Include a space in the value of the variable if space is needed between the option name and the line number. For example:
	`PSQL_EDITOR_LINENUMBER_ARG = '+'`
	`PSQL_EDITOR_LINENUMBER_ARG='--line '`
	A plus sign (+) is used by default on Unix.

PSQLRC	Specifies the location of the user's .gsqlrc file.
SHELL	Using the **\!** command has the same effect as executing the shell command.
TMPDIR	Specifies the directory for storing temporary files. The default value is **/tmp**.

NOTE

gsql does not support displaying dates of the datea type in the format specified by **nls_date_format**. Currently, only the YYYY-MM-DD HH24-MI-SS AD format is supported.

Prerequisites

- The user using gsql must have the permission to access the database.
- gsql must match the database version.
- If the gsql client-side encoding is set to UTF-8 and the data encoding format returned by GaussDB is not UTF-8, the data cannot be correctly displayed on the gsql client.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- You can use the **gsql_env.sh** script in the release package to set environment variables, for example, **source gsql_env.sh**.
- If environment variables have been set, the environment variables in the script take precedence after the **gsql_env.sh** script is executed.

Syntax

```
gsql [OPTION]... [DBNAME [USERNAME]]
```

Parameters

For details about gsql parameters, see **Table 4-7**, **Table 4-8**, **Table 4-9**, **Table 4-10**, and **Table 4-11**.

Table 4-7 Common parameters

Parameter	Description	Value Range
-c, --command=COMMAND	Specifies that gsql is to run a string command and then exit.	-
-d, --dbname=DBNAME	Specifies the name of the database to be connected. If the database name is not specified, the default database name generated during initialization is used. In addition, gsql allows you to use extended DBNAMEs, that is, connection strings in the format of "postgres[ql]://[user[:password]@][netloc][:port][, ...][/dbname][?param1=value1&...]" or "[key=value] [...]" as DBNAMEs. gsql parses connection information from the connection strings and preferentially uses the information. **NOTE** When gsql uses the extended DBNAMEs to create a connection, the **replication** parameter cannot be specified.	A string.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Description	Value Range
-f, --file=FILENAME	Specifies that files are used as the source of commands instead of reading commands entered interactively. After the files are processed, gsql exits. If *FILENAME* is set to a hyphen (-), then standard input is read. **NOTE** If the server-side encoding format is GB18030 or GB18030_2022 and **gsql -f** is executed together with the pipe character ('>'), for example, **gsql -f xxx.sql > xxx.log**, the encoding format of the imported file must be the same as that of the server. You are advised to manually set **client_encoding** to the server-side encoding format in the file.	An absolute path or relative path that meets the OS path naming convention.
-l, --list	Lists all available databases and then exits.	-
-v, --set=, --variable=NAME=VALUE	Sets gsql variable *NAME* to *VALUE*. For details about variable examples and descriptions, see **Variables**.	-
-X, --no-gsqlrc	Does not read the startup file (neither the system-wide **gsqlrc** file nor the user's **~/.gsqlrc** file). **NOTE** The startup file is **~/.gsqlrc** by default or it can be specified by the environment variable *PSQLRC*.	-
-1 ("one"), --single-transaction	When gsql uses the **-f** option to execute a script, "START TRANSACTION" and "COMMIT" are added to the start and end of the script, respectively, so that the script is executed as one transaction. This ensures that the script is executed successfully. If the script cannot be executed, the script is invalid. **NOTE** If the script already contains "START TRANSACTION", "COMMIT", and "ROLLBACK", this parameter is invalid.	-

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Description	Value Range
-y, --slash-command	Terminates the current statement and sends it to the kernel for execution or re-executes executed statements (excluding gsql meta-commands). **NOTE** • This function applies to only ORA-compatible databases and does not support the **-c, --command** parameter. • In ORA-compatible mode, statements are separated using semicolons (;) by default. In the PL/SQL syntax, the slash (/) is used as the separator. When this parameter is used, the separator cannot be changed.	-
-?, --help	Displays help information about gsql command-line parameters, and exits.	-
-V, --version	Prints the gsql version information and exits.	-

Table 4-8 Input and output parameters

Parameter	Description	Value Range
-a, --echo-all	Prints all input lines to the standard output as they are read. **NOTE** When this parameter is used in some SQL statements, the sensitive information, such as user password, may be disclosed. Use this parameter with caution.	-
-B, --base64	Indicates that the **-c** parameter passes the content encoded using Base64. **NOTE** This parameter must be used with **-c**.	-
-e, --echo-queries	Displays all queries sent to the server to the standard output as well. **NOTE** When this parameter is used in some SQL statements, the sensitive information, such as user password, may be disclosed. Use this parameter with caution.	-
-E, --echo-hidden	Echoes the actual queries generated by **\d** and other backslash commands.	-

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Description	Value Range
-k, --with-key=KEY	Uses gsql to decrypt imported encrypted files. **NOTE** • For key characters, such as the single quotation mark (') or double quotation mark (") in shell commands, Linux shell checks whether the input single quotation mark (') or double quotation mark (") matches. If no match is found, Linux shell does not enter the gsql program until the input is complete. • Stored procedures and functions cannot be decrypted and imported.	-
-L, --log-file=FILENAME	Writes normal output source and all query output into the file specified by *FILENAME*. **NOTE** • When this parameter is used in some SQL statements, the sensitive information, such as user password, may be disclosed. Use this parameter with caution. • This parameter retains only the query result in the corresponding file, so that the result can be easily found and parsed by other callers (for example, automatic O&M scripts). Logs about gsql operations are not retained.	An absolute path or relative path that meets the OS path naming convention.
-m, --maintenance	Allows a cluster to be connected when a two-phase transaction is being restored. **NOTE** The parameter is for developers only. When this parameter is used, gsql can be connected to the standby node to check data consistency between the primary and standby nodes.	-
-n, --no-libedit	Closes command line editing.	-
-o, --output=FILENAME	Puts all query output into the file specified by *FILENAME*.	An absolute path or relative path that meets the OS path naming convention.
-q, --quiet	Specifies the quiet mode. No additional information will be printed.	By default, gsql displays various information.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Description	Value Range
-s, --single-step	Runs in single-step mode. It indicates that the user is prompted before each command is sent to the server. This option can also be used for canceling execution. This option is mainly used to debug scripts. **NOTE** When this parameter is used in some SQL statements, the sensitive information, such as user password, may be disclosed. Use this parameter with caution.	-
-S, --single-line	Runs in single-line mode where a line break terminates a command.	-
-C, -C1, --enable-client-encryption=1	Enables the encrypted database feature. In this way, encrypted equality query is supported.	-
-C3, --enable-client-encryption=3	Enables a memory decryption emergency channel. The encrypted equality query and memory decryption emergency channel features are supported.	-

Table 4-9 Output format parameters

Parameter	Description	Value Range
-A, --no-align	Switches to unaligned output mode. The default output mode is aligned.	-
-F, --field-separator=STRING	Specifies the field separator, which is the vertical bar (|) by default.	-
-H, --html	Enables the HTML output format.	-
-P, --pset=VAR[=ARG]	Specifies the print option in the **\pset** format in the command line. **NOTE** The equal sign (=), instead of the space, is used here to separate the name and value. For example, enter **-P format=latex** to set the output format to **LaTeX**.	-
-R, --record-separator=STRING	Sets the record separator.	-

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Description	Value Range
-r	Enables the insert mode on the client. It is disabled by default.	-
-t, --tuples-only	Prints only tuples.	-
-T, --table-attr=TEXT	Specifies options to be placed within the HTML table tag. Use this parameter with the **-H,--html** parameter to specify the output to the HTML format.	-
-x, --expanded	Displays in the expanded format.	-
-z, --field-separator-zero	Sets the field separator in the unaligned output mode to be blank. Use this parameter with the **-A, --no-align** parameter to switch to unaligned output mode.	-
-0, --record-separator-zero	Sets the record separator in the unaligned output mode to be blank. Use this parameter with the **-A, --no-align** parameter to switch to unaligned output mode.	-
-2, --pipeline	Uses a pipe to transmit the password. This parameter cannot be used on devices and must be used together with the **-c** or **-f** parameter.	-

Table 4-10 Connection parameters

Parameter	Description	Value Range
-h, --host=HOSTNAME	Specifies the host name of the running server, the UDS path, or the domain name. You can specify multiple host addresses by using character strings separated by commas (,), or specify an IPv6 host address. If multiple host addresses are specified, the faulty node is skipped by default and the first available primary node is automatically selected for connection. You can set the *PGTARGETSESSIONATTRS* environment variable to connect to different types of nodes. The values of the *PGTARGETSESSIONATTRS* variable are as follows: • **read-write**: readable and writable node. • **read-only**: read-only node. • **primary** or not set: primary node. • **standby**: standby node. • **prefer-standby**: preferred standby node. If there is no standby node, **any** is used. • **any**: no role check. **NOTE** Primary CNs and DNs are primary nodes. Generally, DNs are read-only nodes. You can set **PGTARGETSESSIONATTRS** to **read-write** to connect to CNs.	If the host name is omitted, gsql connects to the localhost over UDS or TCP/IP if no UDS is available.
-p, --port=PORT	Port number of the database server. You can configure one or more port numbers. When one port number is configured, all host addresses use the same port for connection. When multiple port numbers are configured, the sequence is the same as the host address sequence, and the number of port numbers must be the same as the number of host addresses. If they are different, an error is reported. You can modify the default port number using the **-p, --port=PORT** parameter.	The default port number can be specified by using compilation parameters. If the port number is not specified, the default port number **5432** is used.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Description	Value Range
-U, --username=USERNAME	Specifies the user who connects to the database. **NOTE** • If this parameter is specified, you also need to enter your password for identity authentication when connecting to a database. You can enter the password interactively or use the **-W** parameter to specify a password. • To connect to a database, add an escape character before any dollar sign ($) in the username.	A string. The default user is the current user who operates the system.
-W, --password=PASSWORD	Specifies a password when the **-U** parameter is used to connect to the local database or a remote database. **NOTE** • When you attempt to connect to the CN after you have logged in to the server where the CN resides, the trust connection is used by default, and this parameter does not need to be set. • To connect to a database, add an escape character before any backslash (\) or back quote (`) in the password. • If this parameter is not specified but database connection requires your password, you will be prompted to enter your password in interactive mode. The maximum length of the password is 999 bytes, which is restricted by the maximum value of the GUC parameter **password_max_length**.	A string.

Table 4-11 O&M command of the UDS O&M channel

Parameter	Description	Value Range

-O, --emergency-command=EMERGENCYCOMMAND	O&M command of the UDS O&M channel.
	If gsql cannot connect to GaussDB in extreme cases, you can run this command for emergency O&M. This command communicates with GaussDB through the UDS O&M channel to implement one-click O&M.
	The parameters of the **-O** option are described as follows:
	`"{port} {command} [{param} [...]]"`
	{port}: database listening port.
	{command}: specific O&M command.
	{param}: parameter of the O&M command. There may be zero or more parameters.
	NOTE
	• When this option is used, the gsql tool must be located on the same server as the GaussDB process.
	• If the parameter of the O&M command contains spaces, enclose the parameter with quotation marks.
		• **"*{port}* mem_log"**: records the global memory overview, including details about the top 20 memory context usage at the global, thread, and session levels. This function is valid only when the GUC parameter **use_workload_manager** is enabled. The range is the same as that of the **mem_log** feature (recording memory overloading). There is no parameter. Example:
		`-O "19995 mem_log"`
		• **"*{port}* kill_wait_event *{wait_event}*"**: kills the session of a specified wait event. The *{wait_event}* parameter indicates information about locks, lightweight locks, and I/Os. Example:
		`-O "19995 kill_wait_event relation"`
		• **"*{port}* kill_business_sql"**: kills all service SQL statements of non-**rdsAdmin** users. There is no parameter. Example:
		`-O "19995 kill_business_sql"`
		• **"*{port}* kill_slow_sql *{username}*"**: kills SQL statements that are executed for more than 1 minute and are not in the idle state in a non-default database in batches. The *{username}* parameter specifies the username. Example:
		`-O "19995 kill_slow_sql omm"`
		• **"*{port}* kill_slow_sql *{username} {database}*"**: kills SQL statements that are executed for more

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Description	Value Range

		than 1 minute in a specified database by a specified user in batches. The *{username}* parameter specifies the username, and the *{database}* parameter specifies the database name. Example:
		`-O "19995 kill_slow_sql omm db1"`
		• "*{port}* **kill_executing_sql** *{username}*": kills the SQL statements that are being executed by a specified user whose status is **active** in a non-default database. The *{username}* parameter specifies the username. Example:
		`-O "19995 kill_executing_sql omm"`
		• "*{port}* **kill_mem_topn** *{top n}*": kills the SQL statements that occupy top *n* memory. The *{top n}* parameter specifies the top *n*. Example:
		`-O "19995 kill_mem_topn 10"`
		• "*{port}* **kill_cpu_topn** *{top n}*": kills the SQL statements that occupy top *n* CPU time. The *{top n}* parameter specifies the top *n*. Example:
		`-O "19995 kill_cpu_topn 10"`

Example

Example 1

Connect to a database and run the command.

Step 1 Connect to the GaussDB server using the gsql tool.

The gsql tool uses the **-d** parameter to specify the target database name, the **-U** parameter to specify the database username, the **-h** parameter to specify the host name, and the **-p** parameter to specify the port number. For details about the gsql parameters, see **Parameters**.

```
-- Connect to the 8000 port of the postgres database on the remote host as user jack. (Replace the parameter values as required.)
gsql -h 10.180.123.163 -d postgres -U jack -p 8000
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- If the database name is not specified, the default database name generated during initialization is used.
- If the database username is not specified, the current OS user is used as the database username by default.
- When the preceding parameters (such as **-d** or **-U**) are not specified, if the database name is not specified in the connection command (**-d**), the parameter is interpreted as the database name; if the database name is specified (**-d**) but the database username is not specified (**-U**), this parameter is interpreted as the database username.

  For example, in the following command, **postgres** and **omm** are not options and are interpreted as the database name and username, respectively.

  ```
  gsql postgres omm -p 8000
  ```

  It is equivalent to the following command:

  ```
  gsql -d postgres -U omm -p 8000
  ```

Step 2 Execute gsql meta-commands and SQL statements.

```
-- Create the human_staff database.
gaussdb=# CREATE DATABASE human_staff;
CREATE DATABASE

-- List all databases and description information in GaussDB.
gaussdb=#  \l
                                 List of databases
     Name      |  Owner   | Encoding  | Collate | Ctype |   Access privileges
---------------+----------+-----------+---------+-------+-----------------------
 human_resource | omm | SQL_ASCII | C       | C     |
 postgres       | omm | SQL_ASCII | C       | C     |
 template0      | omm | SQL_ASCII | C       | C     | =c/omm          +
                |          |           |         |       | omm=CTc/omm
 template1      | omm | SQL_ASCII | C       | C     | =c/omm          +
                |          |           |         |       | omm=CTc/omm
 human_staff    | omm | SQL_ASCII | C       | C     |
 gaussdb        | omm | SQL_ASCII | C       | C     |
(6 rows)
