1 SQL Reference

1.1 GaussDB SQL

What Is SQL?

SQL is a standard computer language used to control the access to databases and manage data in databases.

SQL provides different statements to enable you to:

- Query data.
- Insert, update, and delete rows.
- Create, replace, modify, and delete objects.
- Control the access to a database and its objects.
- Maintain the consistency and integrity of a database.

SQL consists of commands and functions that are used to manage databases and database objects. This language can also forcibly implement the rules for data types, expressions, and texts. Therefore, **SQL Reference** describes data types, expressions, functions, and operators in addition to SQL syntax.

Development of SQL Standards

The development history of SQL standards is as follows:

- 1986: ANSI X3.135-1986, ISO/IEC 9075:1986, SQL-86
- 1989: ANSI X3.135-1989, ISO/IEC 9075:1989, SQL-89
- 1992: ANSI X3.135-1992, ISO/IEC 9075:1992, SQL-92
- 1999: ISO/IEC 9075:1999, SQL:1999
- 2003: ISO/IEC 9075:2003, SQL:2003
- 2011: ISO/IEC 9075:2011, SQL:2011
- 2016: ISO/IEC 9075:2016, SQL:2016
- 2019: ISO/IEC 9075:2019, SQL:2019

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

SQL Standards Supported by GaussDB

By default, GaussDB supports most features of SQL:2016.

1.2 Keywords

SQL statements are classified into reserved keywords and non-reserved keywords. For details about common SQL keywords, see **Table 1-1**. Standards require that reserved keywords not be used as other identifiers. Non-reserved keywords have special meanings only in a specific environment and can be used as identifiers in other environments.

NOTICE

- Currently, the non-reserved keywords have the following restrictions when being used as the identifier of a database object:
  - It cannot be directly used as a column alias. That is, usage similar to SELECT 1 ABORT may cause errors.
  - Keywords ENTITYESCAPING, NOENTITYESCAPING, and WELLFORMED cannot be used as identifiers of table names, column names, table aliases, column aliases, and function names if they are not enclosed in double quotation marks.
  - The RAW keyword without double quotation marks cannot be used as the identifier of a table name or function name.
  - The SET keyword without double quotation marks cannot be used as an identifier of a table alias. That is, usage similar to SELECT * FROM T1 SET may cause errors.
  - Keywords such as BEGIN, BY, CLOSE, CURSOR, DECLARE, DELETE, EXECUTE, FUNCTION, IF, IMMEDIATE, INSERT, LOOP, MOVE, OF, REF, RELEASE, RETURN, SAVEPOINT, STRICT, TYPE, and UPDATE without double quotation marks cannot be used as variable names.
  - When the SYS_REFCURSOR keyword is used as the identifier of a database object, if double quotation marks are not attached, a database object named **REFCURSOR** is created. If double quotation marks are attached, a database object named **SYS_REFCURSOR** is created.
- Similar to the non-reserved keywords, the non-reserved (cannot be a function or type) keywords cannot be directly used as column aliases, either.
- The reserved keyword CURRENT_TIMESTAMP without double quotation marks ("") cannot be used as a function name.
- CONVERT, TIMESTAMPADD, ADDDATE, DATE_ADD, SUBDATE, DATE_SUB, and GET_FORMAT are used as keywords only in MySQL-compatible and M-compatible modes. JSON_OBJECT, LAST_DAY, and IFNULL are used as keywords only in MySQL-compatible mode.
- The keyword NOORDER is used only in ORA-compatible mode.

Identifier Naming Conventions

Identifier naming must comply with the following rules:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- An identifier name can only contain letters, digits (0–9), underscores (_), and dollar signs ($).
- An identifier name must start with a letter or an underscore (_).

  NOTE

  - The naming rules are recommended but not required.
  - In special cases, double quotation marks (") can be used to avoid special character errors.

TABLEOID	XC_NODE_ID	XC_NODE_HASH	TABLEBUCKETID	GS_TUPLE_UID

1.3 Data Types

A data type is a basic data attribute. Occupied storage space and allowed operations vary according to data types. Data is stored in tables in a database. Each column of a data table specifies a data type and data must be stored according to data types.

GaussDB supports implicit conversions between certain data types. For details, see **PG_CAST**.

1.3.1 Numeric Types

Table 1-2 lists all available types. For arithmetic operators and related built-in functions, see **Arithmetic Functions and Operators**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 1-2 Integer types

Name	Description	Storage Space	Range
TINYINT [UNSIGNED]	Tiny integer. The signed alias is INT1, and the unsigned alias is UINT1. The UNSIGNED type can be used only in M- or MySQL-compatible mode.	1 byte	• The signed value ranges from 0 to +255. • The unsigned value ranges from 0 to +255. • When **sql_compatibility** is set to **'MYSQL'**, **b_format_version** is set to **'5.7'**, and **b_format_dev_version** is set to **'s1'**, the signed value ranges from –128 to +127.
SMALLINT [UNSIGNED]	Small integer. The signed alias is INT2, and the unsigned alias is UINT2. The UNSIGNED type can be used only in M- or MySQL-compatible mode.	2 bytes	• The signed value ranges from –32,768 to +32,767. • The unsigned value ranges from 0 to +65,535.
MEDIUMINT [UNSIGNED]	Medium-sized integer. The signed alias is INT4, and the unsigned alias is UINT4. The UNSIGNED type can be used only in M- or MySQL-compatible mode.	4 bytes	• The signed value ranges from –2147483648 to +2147483647. • The unsigned value ranges from 0 to +4294967295.
INTEGER [UNSIGNED]	Common integer. The signed alias is INT4, and the unsigned alias is UINT4. The UNSIGNED type can be used only in M- or MySQL-compatible mode.	4 bytes	• The signed value ranges from –2147483648 to +2147483647. • The unsigned value ranges from 0 to +4294967295.
BINARY_INTEGER	Common integer. The signed alias is INTEGER.	4 bytes	–2,147,483,648 to +2,147,483,647.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Name	Description	Storage Space	Range
BIGINT [UNSIGNED]	Large integer. The signed alias is INT8, and the unsigned alias is UINT8. The UNSIGNED type can be used only in M- or MySQL-compatible mode.	8 bytes	• The signed value ranges from –9,223,372,036,854,775,808 to +9,223,372,036,854,775,807. • The unsigned value ranges from 0 to +18,446,744,073,709,551,615.
INT16 [SIGNED]	A 16-byte integer cannot be used to create tables.	16 bytes	–170,141,183,460,469,231,731,687,303,715,884,105,728 to +170,141,183,460,469,231,731,687,303,715,884,105,727

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- When **sql_compatibility** is set to **'MYSQL'**, **b_format_version** is set to **'5.7'**, and **b_format_dev_version** is set to **'s1'**, integers support the display width and **ZEROFILL** attribute.
- The display width does not limit the range of values that can be stored in a column, nor does it affect the correct display of values that exceed the display width. For example, a column defined as SMALLINT(3) can store the full range of values for the SMALLINT type (–32768 to 32767). Even if some values have more than three digits, they will be displayed in full without being truncated or altered.
- When the display width is used together with the **ZEROFILL** attribute, zeros are padded on the left of the value until the total length reaches the specified display width. For example, if you insert the value **5** into a column defined as INT(4) ZEROFILL, the query result will be displayed as **0005**.
- If you specify **ZEROFILL** for a numeric column, the **UNSIGNED** attribute is automatically added.
- If **ZEROFILL** is not specified for a numeric column and only the width information is specified, the width information is not displayed in the table definition description.
- If **UNSIGNED** is specified, negative values are not allowed.
- Numbers of the TINYINT, SMALLINT, INTEGER, BIGINT, or INT16 type, that is, integers can be stored. Saving a number with a decimal in any of the data types will result in errors.
- The INTEGER type is the most common choice, as it offers the best balance between range, storage size, and performance. Generally, use the SMALLINT type only if you are sure that the value range is within the SMALLINT value range. The storage speed of INTEGER is much faster. BIGINT is used only when the range of INTEGER is not large enough.
- When a minus sign, plus sign, or multiplication sign is used between integer values (one of which is of the UNSIGNED type), the result is unsigned.
- The return value of the addition (+), subtraction (–), and multiplication (x) operations of the INT1, UINT1, UINT2, UINT4, or UINT8 type can exceed the range of the corresponding type. The return value of the addition (+), subtraction (–), and multiplication (x) operations of the INT2, INT4, or INT8 type cannot exceed the range of the corresponding type.
- The UNSIGNED type cannot be converted to the SET type. Do not calculate or compare the UNSIGNED type with the SET type.
- When **sql_compatibility** is set to **'MYSQL'**, non-numeric characters are automatically truncated or the value **0** is returned.

Example:

```
-- Create a database.
gaussdb=# CREATE DATABASE b_database dbcompatibility = 'MYSQL';
gaussdb=# \c b_database

-- Create a table containing TINYINT data.
b_database=# CREATE TABLE int_type_t1
        (
         IT_COL1 TINYINT,
         IT_COL2 TINYINT UNSIGNED
        );

-- Insert data.
b_database=# INSERT INTO int_type_t1 VALUES(10,20);

-- View data.
b_database=# SELECT * FROM int_type_t1;
it_col1 | it_col2
--------+---------
     10 |      20
```

```
(1 row)

-- Drop the table.
b_database=# DROP TABLE int_type_t1;

-- Create a table containing TINYINT, INTEGER, and BIGINT data.
b_database=# CREATE TABLE int_type_t2
(
    a TINYINT,
    b TINYINT,
    c INTEGER,
    d INTEGER UNSIGNED,
    e BIGINT,
    f BIGINT UNSIGNED
);

-- Insert data.
b_database=# INSERT INTO int_type_t2 VALUES(100, 10, 1000, 10000, 200, 2000);

-- View data.
b_database=# SELECT * FROM int_type_t2;
  a  | b  |  c   |   d    |  e  |  f
-----+----+------+--------+-----+------
 100 | 10 | 1000 |  10000 | 200 | 2000
(1 row)

-- Drop the table.
b_database=# DROP TABLE int_type_t2;

-- Drop the database.
b_database=# \c postgres
gaussdb=# DROP DATABASE b_database;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 1-3 Arbitrary precision types

Name	Description	Storage Space	Range
NUMERIC[(p[,s])], DECIMAL[(p[,s])]	• The value range of **p** is [1,1000], and the value range of **s** is [0,*p*]. • When **sql_compatibility** is set to **'MYSQL'**, **b_format_version** is set to **'5.7'**, and **b_format_dev_version** is set to **'s1'**, if the precision and scale are not specified, the default precision **p** is **10** and the scale **s** is **0**. If a numeric type is not attached with parentheses, it is set to numeric (10,0) only when being applied to table columns. In other scenarios, the numeric type is used based on the original range by default.	The precision is specified by users. Every four decimal digits occupy two bytes, and an extra eight-byte overhead is added to the entire data.	Up to 131,072 digits before the decimal point, and up to 16,383 digits after the decimal point when no precision is specified.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Name	Description	Storage Space	Range
	NOTE • **p** indicates the total digits, and **s** indicates the decimal digit. • If the number of decimal places in the inserted data exceeds the specified scale **s**, the number will be rounded off to the specified scale.		
NUMBER[(p[,s])]	Alias of the NUMERIC type.	The precision is specified by users. Every four decimal digits occupy two bytes, and an extra eight-byte overhead is added to the entire data.	Up to 131,072 digits before the decimal point, and up to 16,383 digits after the decimal point when no precision is specified.

Example:

```
-- Create a table.
gaussdb=# CREATE TABLE decimal_type_t1
(
    DT_COL1 DECIMAL(10,4)
);

-- Insert data.
gaussdb=# INSERT INTO decimal_type_t1 VALUES(123456.122331);

-- Query data in the table.
gaussdb=# SELECT * FROM decimal_type_t1;
   dt_col1
-------------
 123456.1223
(1 row)

-- Drop the table.
gaussdb=# DROP TABLE decimal_type_t1;

-- Create a table.
gaussdb=# CREATE TABLE numeric_type_t1
(
    NT_COL1 NUMERIC(10,4)
);

-- Insert data.
gaussdb=# INSERT INTO numeric_type_t1 VALUES(123456.12354);

-- Query data in the table.
gaussdb=# SELECT * FROM numeric_type_t1;
   nt_col1
-------------
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
 123456.1235
(1 row)

-- Insert data.
gaussdb=# INSERT INTO numeric_type_t1 VALUES(10000.12355);

-- Query data in the table.
gaussdb=# SELECT * FROM numeric_type_t1;
   nt_col1
-------------
 123456.1235
  10000.1236
(2 rows)

-- Drop the table.
gaussdb=# DROP TABLE numeric_type_t1;
```

NOTE

- Compared to the integer types, the arbitrary precision numbers require larger storage space and have lower storage efficiency, operation efficiency, and poorer compression ratio results. The integer type is the common choice when number types are defined. Arbitrary precision numbers are used when numbers exceed the maximum range indicated by the integers.
- When NUMERIC/DECIMAL is used for defining a column, you are advised to specify the precision (**p**) and scale (**s**) for the column.
- When **sql_compatibility** is set to **'MYSQL'**, **b_format_version** is set to **'5.7'**, and **b_format_dev_version** is set to **'s1'**, the input and output range specifications of the NUMERIC[(p[,s])] and DECIMAL[(p[,s])] types are different.
  - Input format: The value can be a number or a numeric string.
    - If the value of **sql_mode** contains **strict_trans_tables**, an error is reported if the input value is invalid or exceeds the range.
    - If the value of **sql_mode** does not contain **strict_trans_tables** and the input value is invalid or exceeds the range, a warning message is reported and **0** or the truncated value is returned.
  - Output format: The output format of the DECIMAL[(p[,s])] type is different from that of the NUMERIC[(p[,s])] type when the precision and scale are not specified. If NUMERIC has no precision or scale, the decimal part is retained during type conversion. For details, see the output format in the scenario where no parameter is set. If DECIMAL has no precision or scale, the precision is **10** and the scale is **0** during type conversion.

Table 1-4 Sequence integer

Name	Description	Storage Space	Range
SMALLSERIAL	2-byte serial integer.	2 bytes.	–32,768 to +32,767.
SERIAL	4-byte serial integer.	4 bytes.	–2,147,483,648 to +2,147,483,647.
BIGSERIAL	8-byte serial integer.	8 bytes.	–9,223,372,036,854,775,808 to +9,223,372,036,854,775,807.

Example:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
-- Create a table.
gaussdb=# CREATE TABLE smallserial_type_tab(a SMALLSERIAL);

-- Insert data.
gaussdb=# INSERT INTO smallserial_type_tab VALUES(default);

-- Insert data again.
gaussdb=# INSERT INTO smallserial_type_tab VALUES(default);

-- View data.
gaussdb=# SELECT * FROM smallserial_type_tab;
 a
---
 1
 2
(2 rows)

-- Create a table.
gaussdb=# CREATE TABLE serial_type_tab(b SERIAL);

-- Insert data.
gaussdb=# INSERT INTO serial_type_tab VALUES(default);

-- Insert data again.
gaussdb=# INSERT INTO serial_type_tab VALUES(default);

-- View data.
gaussdb=# SELECT * FROM serial_type_tab;
 b
---
 1
 2
(2 rows)

-- Create a table.
gaussdb=# CREATE TABLE bigserial_type_tab(c BIGSERIAL);

-- Insert data.
gaussdb=# INSERT INTO bigserial_type_tab VALUES(default);

-- Insert data again.
gaussdb=# INSERT INTO bigserial_type_tab VALUES(default);

-- View data.
gaussdb=# SELECT * FROM bigserial_type_tab;
 c
---
 1
 2
(2 rows)

-- Drop the table.
gaussdb=# DROP TABLE smallserial_type_tab;

gaussdb=# DROP TABLE serial_type_tab;

gaussdb=# DROP TABLE bigserial_type_tab;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

SMALLSERIAL, SERIAL, and BIGSERIAL are not real types. They are concepts used for setting a unique identifier for a table. Therefore, an integer column is created and its default value is set to be read from a sequencer. A NOT NULL constraint is used to ensure NULL is not inserted. In most cases, you may also want to attach a UNIQUE or PRIMARY KEY constraint to prevent duplicate values from being inserted unexpectedly. Finally, the sequencer belongs to the column. When the column or table is deleted, the sequencer is deleted at the same time. Currently, the **SERIAL** column can be specified only when you create a table. You cannot add the **SERIAL** column in an existing table. In addition, **SERIAL** columns cannot be created in temporary tables because **SERIAL** is not a real type. Therefore, column types in temporary tables cannot be converted to **SERIAL**.

Table 1-5 lists the floating-point types.

NOTE

- For the behavior of the REAL, FLOAT, and DEC[(p[,s])] data types when **sql_compatibility** is set to **'MYSQL'**, **b_format_version** is set to **'5.7'**, and **b_format_dev_version** is set to **'s1'**, see **Table 1-5**.
- In **Table 1-5**, **p** is the precision, indicating the minimum acceptable total number of integral places, and **s** indicates the decimal digit.

Table 1-5 Floating-point types

Name	Description	Storage Space	Range
REAL, FLOAT4	Single-precision floating-point number, which has precision errors. The REAL data type is mapped to the double-precision floating-point number FLOAT8 when the scenario described in **NOTE** is met. For details about the application scenario, see FLOAT8.	4 bytes.	–3.402E+38 to +3.402E +38, 6-bit decimal digits.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Name	Description	Storage Space	Range
REAL(p,s)	The value range of **p** is [1,1000], and the value range of **s** is [0,*p*]. If the precision and scale are not specified, the precision **p** is **10** and the scale **s** is **0** by default. This type maps to NUMERIC. For details about the application scenario, see NUMERIC. This type can be used only when **sql_compatibility** is set to **'MYSQL'**, **b_format_version** is set to **'5.7'**, and **b_format_dev_version** is set to **'s1'**.	The precision is specified by users. Every four decimal digits occupy two bytes, and an extra eight-byte overhead is added to the entire data.	Maximum 131,072 digits before the decimal point and 16,383 digits after the decimal point when the precision and scale are specified to the maximum.
DOUBLE PRECISION, FLOAT8	Double-precision floating-point number, which has precision errors.	8 bytes.	–1.79E+308 to +1.79E+308, 15-bit decimal digits.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Name	Description	Storage Space	Range
DOUBLE	Double-precision floating-point number, which has precision errors. This type maps to double-precision floating-point number FLOAT8. For details about the application scenario, see FLOAT8. This type can be used only when **sql_compatibility** is set to **'MYSQL'**, **b_format_version** is set to **'5.7'**, and **b_format_dev_version** is set to **'s1'**.	8 bytes.	–1.79E+308 to +1.79E+308, 15-bit decimal digits.
DOUBLE(p, s)	The value range of **p** is [1,1000], and the value range of **s** is [0,*p*]. If the precision and scale are not specified, the precision **p** is **10** and the scale **s** is **0** by default. This type maps to NUMERIC. For details about the application scenario, see NUMERIC. This type can be used only when **sql_compatibility** is set to **'MYSQL'**, **b_format_version** is set to **'5.7'**, and **b_format_dev_version** is set to **'s1'**.	The precision is specified by users. Every four decimal digits occupy two bytes, and an extra eight-byte overhead is added to the entire data.	Maximum 131,072 digits before the decimal point and 16,383 digits after the decimal point when the precision and scale are specified to the maximum.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Name	Description	Storage Space	Range
FLOAT[(p)]	Floating-point number, which has precision errors. The value range of precision (p) is [1,53]. The type is selected based on the precision **p**. When **p** is less than or equal to 24, the mapping type is REAL. When **p** is greater than 24 or not specified, the mapping type is DOUBLE PRECISION. In the scenario described in **NOTE**, if the precision **p** is less than or equal to 24, or it is not specified, the mapping type is FLOAT4. If **p** is greater than 24, the mapping type is DOUBLE PRECISION.	4 bytes or 8 bytes.	-

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Name	Description	Storage Space	Range
FLOAT(p,s)	The value range of **p** is [1,1000], and the value range of **s** is [0,*p*]. If the precision and scale are not specified, the precision **p** is **10** and the scale **s** is **0** by default. This type maps to NUMERIC. For details about the application scenario, see NUMERIC. This type can be used only when **sql_compatibility** is set to **'MYSQL'**, **b_format_version** is set to **'5.7'**, and **b_format_dev_version** is set to **'s1'**.	The precision is specified by users. Every four decimal digits occupy two bytes, and an extra eight-byte overhead is added to the entire data.	Maximum 131,072 digits before the decimal point and 16,383 digits after the decimal point when the precision and scale are specified to the maximum.
BINARY_DOUBLE	DOUBLE PRECISION alias, compatible with Oracle Database.	8 bytes.	–1.79E+308 to +1.79E+308, 15-bit decimal digits.
DEC[(p[,s])]	The value range of **p** is [1,1000], and the value range of **s** is [0,*p*]. If the scenario in **Note** is met and the precision and scale are not specified, the precision **p** is **10** and the scale **s** is **0** by default. This type maps to NUMERIC. For details about the application scenario, see NUMERIC.	The precision is specified by users. Every four decimal digits occupy two bytes, and an extra eight-byte overhead is added to the entire data.	Maximum 131,072 digits before the decimal point and 16,383 digits after the decimal point when the precision and scale are specified to the maximum.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Name	Description	Storage Space	Range
INTEGER[(p[,s])]	The value range of **p** is [1,1000], and the value range of **s** is [0,*p*]. If the precision and scale are not specified, the precision **p** is **10** and the scale **s** is **0** by default. If the precision and scale are not specified, this type is mapped to INTEGER. If the precision and scale are specified, this type is mapped to NUMERIC.	The precision is specified by users. Every four decimal digits occupy two bytes, and an extra eight-byte overhead is added to the entire data.	Maximum 131,072 digits before the decimal point and 16,383 digits after the decimal point when the precision and scale are specified to the maximum. If the precision and scale are not specified, the value ranges from –2,147,483,648 to +2,147,483,647.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- The binary floating-point data types REAL, FLOAT4, DOUBLE, DOUBLE PRECISION, FLOAT8, FLOAT[(p)], and BINARY_DOUBLE are imprecise numeric types. Their internal storage is approximate, which may result in slight differences during storage and retrieval. When using binary floating-point data types, pay attention to the following points:
  - Precise storage and calculation: If precise storage and calculation are required (such as for monetary values), use exact data types (for example, numeric) instead.
  - Complex calculation: When you perform complex calculation with imprecise data types to obtain critical data, it is important to carefully evaluate the results.
  - Floating-point number comparison: The result of comparing two floating-point numbers for equality may differ from expectations.
  - Underflow error: If a floating-point number is too close to zero, it cannot be accurately represented. As a result, an underflow error occurs.
- For the precision of the floating-point type, only the number of precision bits can be ensured when the data is directly read. When distributed computing is involved, the computation is executed on each DN and is finally aggregated to a CN. Therefore, the error may be amplified as the number of compute nodes increases.
- When **sql_compatibility** is set to **'MYSQL'**, **b_format_version** is set to **'5.7'**, and **b_format_dev_version** is set to **'s1'**, the input and output ranges of the FLOAT[(p[,s])], DOUBLE[(p[,s])], DEC[(p[,s])], and REAL[(p[,s])] types are different.
  - Input format: The value can be a number or a numeric string.
    - If the value of **sql_mode** contains **strict_trans_tables**, an error is reported if the input value is invalid or exceeds the range.
    - If the value of **sql_mode** does not contain **strict_trans_tables** and the input value is invalid or exceeds the range, a warning message is reported and **0** or the truncated value is returned.
  - Output format: The output format of the DEC[(p[,s])] type is different from that of the mapping NUMERIC[(p[,s])] type when the precision and scale are not specified. If NUMERIC has no precision or scale, the decimal part is retained during type conversion. For details, see the output format in the scenario where no parameter is set. If DEC has no precision or scale, the precision is **10** and the scale is **0** during type conversion.

Example:

```
-- Create a table.
gaussdb=# CREATE TABLE float_type_t2
(
    FT_COL1 INTEGER,
    FT_COL2 FLOAT4,
    FT_COL3 FLOAT8,
    FT_COL4 FLOAT(3),
    FT_COL5 BINARY_DOUBLE,
    FT_COL6 DECIMAL(10,4),
    FT_COL7 INTEGER(6,3)
)DISTRIBUTE BY HASH ( ft_col1);

-- Insert data.
gaussdb=# INSERT INTO float_type_t2 VALUES(10,10.365456,123456.1234,10.3214, 321.321, 123.123654,
123.123654);

-- View data.
gaussdb=# SELECT * FROM float_type_t2 ;
 ft_col1 | ft_col2 |   ft_col3   | ft_col4 | ft_col5 | ft_col6  | ft_col7
---------+---------+-------------+---------+---------+----------+---------
      10 | 10.3655 | 123456.1234 | 10.3214 | 321.321 | 123.1237 | 123.124
(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
-- Drop the table.
gaussdb=# DROP TABLE float_type_t2;

-- Example: REAL(p,s), FLOAT(p,s), DOUBLE, and DOUBLE(p,s).
gaussdb=# CREATE DATABASE gaussdb_m  WITH dbcompatibility  'MYSQL';
gaussdb=# \c gaussdb_m
-- Set compatible version control parameters.
gaussdb_m=# SET b_format_version='5.7';
gaussdb_m=# SET b_format_dev_version='s1';
-- Create a table.
gaussdb_m=# CREATE TABLE t1(a real(10,2), b float(10,2), c double, d double(10,2));
-- Insert data.
gaussdb_m=# INSERT INTO t1 VALUES (1000.12, 2000.23, 3000.34, 4000.45);
-- Query data in the table.
gaussdb_m=# SELECT * FROM t1;
   a    |    b    |    c    |    d
--------+---------+---------+---------
 1000.12 | 2000.23 | 3000.34 | 4000.45
(1 row)

-- Drop the table and database.
gaussdb_m=# DROP TABLE t1;
gaussdb_m=# \c postgres;
gaussdb=# DROP DATABASE gaussdb_m;

-- Reset parameters.
gaussdb=# RESET ALL;
```

1.3.2 Monetary Types

The monetary type stores a currency amount with fixed fractional precision.

The range displayed in **Table 1-6** is based on two decimal places. This type supports multiple input formats, including integers, floating-point numbers, and typical currency formats (such as $1,000.00). Output is generally in the last format but depends on the locale.

Table 1-6 Monetary type

Name	Description	Storage Space	Range
money	Currency amount.	8 bytes	-92233720368547758.08 ~ +92233720368547758.07

Values of the numeric, int, and bigint data types can be directly cast to money. For the real and double precision data types, you are advised to convert the data type to numeric first, and then to money. The following is an example:

```
gaussdb=# SELECT '12.34'::float8::numeric::money;
 money
--------
 $12.34
(1 row)
```

This usage is not recommended. Floating-point numbers have a risk of precision loss. Therefore, they should not be used to process currency types.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

A money value can be cast to numeric without loss of precision. Conversion to other types could potentially lose precision, and must also be done in two stages:

```
gaussdb=# SELECT '52093.89'::money::numeric::float8;
  float8
----------
 52093.89
(1 row)
```

When two values of the money type are divided, the result is of the double precision type (a pure number, not the money type). The currency units offset each other during the operation.

1.3.3 Boolean Types

Table 1-7 lists the Boolean types supported by GaussDB.

Table 1-7 Boolean Types

Name	Description	Storage Space	Value
BOOLEAN	Boolean type.	1 byte	• **true** • **false** • **null**: unknown

- Valid literal values for the "true" state include:
  TRUE, **'t'**, **'true'**, **'y'**, **'yes'**, **'1'**, **'TRUE'**, **true**, **'on'**, and all non-zero values.
- Valid literal values for the "false" state include:
  FALSE, **'f'**, **'false'**, **'n'**, **'no'**, **'0'**, **0**, **'FALSE'**, **false**, and **'off'**.

If the query result is of the Boolean type, only **t** or **f** is displayed.

TRUE and **FALSE** are standard expressions, compatible with SQL statements.

Examples

```
-- Create a table.
gaussdb=# CREATE TABLE bool_type_t1
(
    BT_COL1 BOOLEAN,
    BT_COL2 TEXT
)DISTRIBUTE BY HASH(BT_COL2);

-- Insert data.
gaussdb=# INSERT INTO bool_type_t1 VALUES (TRUE, 'sic est');

gaussdb=# INSERT INTO bool_type_t1 VALUES (FALSE, 'non est');

-- View data.
gaussdb=# SELECT * FROM bool_type_t1;
 bt_col1 | bt_col2
---------+---------
 t       | sic est
 f       | non est
(2 rows)

gaussdb=# SELECT * FROM bool_type_t1 WHERE bt_col1 = 't';
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
 bt_col1 | bt_col2
---------+---------
 t       | sic est
(1 row)

-- Drop the table.
gaussdb=# DROP TABLE bool_type_t1;
```

1.3.4 Character Types

Table 1-8 lists the character types supported by GaussDB. For string operators and related built-in functions, see **Character Processing Functions and Operators**.

Table 1-8 Character types

Name	Description	Storage Space
CHAR(n) CHARACTER(n) NCHAR(n)	The string is fixed-length. If the length is insufficient, empty characters are filled in with blank spaces. **n** indicates the number of bytes. If **n** is not specified, the default value **1** is used.	The maximum value of **n** is **10485760** (10 MB).

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Name	Description	Storage Space
	When **sql_compatibility** is set to **'MYSQL'**, if **b_format_version** is set to **'5.7'** and **b_format_dev_version** is set to **'s1'**: ● Type: **n** indicates the character length and the range is [0,10485760]. If the precision **n** is not specified, the default value **1** is used. The string is fixed-length. If the length is insufficient, empty characters are filled in with blank spaces. ● Input: – Data type of table columns and temporary variables: If the number of characters in an input string is within the range, the string can be entered normally. If the value of **sql_mode** contains **strict_trans_tables**, an error is reported. Otherwise, the string is truncated based on the maximum string length specified by **n** and an alarm is generated. ● Output: – Data type of table columns and temporary variables: If the value of **sql_mode** contains **pad_char_to_full_length**, the character string containing spaces at the end is output. Otherwise, the character string without spaces at the end is output. – Function parameter and return value or stored procedure parameter: The length cannot be verified. For example, if the input parameter of a user-defined function is of the CHAR(5) type and a string **'123456'** is input, the parameter can be set without length verification.	The value contains a maximum of 10485760 characters.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Name	Description	Storage Space
	When **sql_compatibility** is set to **'ORA'**: ● CHAR(n) and CHARACTER(n) can explicitly specify the unit of the length parameter **n** after it. The unit can only be byte or char (character). The default unit is byte. ● NCHAR(n) cannot specify the unit of the length parameter **n**. ● In the single-byte character set, even if **char** is specified as the unit, the unit of **n** is still byte. For example, in the SQL_ASCII character set, if **CHAR(1 char)** is specified, an error is reported when a Chinese character is entered. ● The storage space of a type is limited to 10 MB. Therefore, when **CHAR(*n* char)** or **CHARACTER(*n* char)** is specified, it does not mean that the type can contain *n* characters. – When the storage space limit is triggered, the number of characters that can be contained in a type depends on the current character set. For example, if **CHAR(10485760 char)** is specified in the GBK character set, a maximum of 5242880 Chinese characters can be contained. – When a fixed-length character string is padded with spaces, it will be padded up to the maximum storage space limit.	The maximum size is 10 MB.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Name	Description	Storage Space
VARCHAR(n) CHARACTER VARYING(n)	Variable-length string. In PG-compatible mode, **n** indicates the string length. In other compatibility modes, **n** indicates the byte length.	The maximum value of **n** is 10 MB. If **n** is not specified, the maximum storage length is 1 GB – 85 – 4 (space for storing length parameter) – Length of other columns. For example, in a table with columns (a int, b varchar, c int), the maximum length for the varchar column is 1 GB – 85 – 4 (space for storing length parameter) – 4 (length of column **a** int) – 4 (length of column **c** int) = 1,073,741,727.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Name	Description	Storage Space
	When **sql_compatibility** is set to **'MYSQL'**, if **b_format_version** is set to **'5.7'** and **b_format_dev_version** is set to **'s1'**: ● **n** indicates the string length. The value range is [0,10485760]. If the precision **n** is not specified, there is no length limit by default. The length is the same as that of the TEXT type. ● Input: – Data type of table columns and temporary variables: If the number of characters in an input string is within the range, the string can be entered normally. If the value of **sql_mode** contains **strict_trans_tables**, an error is reported. Otherwise, the string is truncated based on the maximum string length specified by **n** and an alarm is generated. ● Output: The original character string is output.	The maximum value of **n** is **10485760**. If **n** is not specified, the maximum storage length is 1 GB – 85 – 4 (space for storing length parameter) – Length of other columns. For example, in a table with columns (a int, b varchar, c int), the maximum length for the varchar column is 1 GB – 85 – 4 (space for storing length parameter) – 4 (length of column **a** int) – 4 (length of column **c** int) = 1,073,741,727.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Name	Description	Storage Space
	When **sql_compatibility** is set to **'ORA'**: ● You can explicitly specify the unit of the length parameter **n** after it. The unit can only be byte or char (character). The unit is byte by default. ● In the single-byte character set, even if **char** is specified as the unit, the unit of **n** is still byte. For example, in the SQL_ASCII character set, if **VARCHAR(1 char)** is specified, an error is reported when a Chinese character is inserted. ● The storage space of a type is limited to 10 MB. Therefore, when **VARCHAR(*n* char)** or **CHARACTER VARYING(*n* char)** is specified, it does not mean that the type can contain *n* characters. When the storage space limit is triggered, the number of characters that can be contained in a type depends on the current character set. For example, if **VARCHAR(10485760 char)** is specified in the GBK character set, a maximum of 5242880 Chinese characters can be contained.	The maximum size is 10 MB.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Name	Description	Storage Space
VARCHAR2(n)	Variable-length string. It is the alias of the VARCHAR(n) type.	The maximum value of **n** is **10485760** (10 MB). If **n** is not specified, the maximum storage length is 1 GB – 85 – 4 (space for storing length parameter) – Length of other columns. For example, in a table with columns (a int, b varchar2, c int), the maximum length for the varchar2 column is 1 GB – 85 – 4 (space for storing length parameter) – 4 (length of column **a** int) – 4 (length of column **c** int) = 1,073,741,727.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Name	Description	Storage Space
NVARCHAR2(n)	Variable-length string. In the SQL_ASCII character set, **n** indicates bytes. In the non-SQL_ASCII character set, **n** indicates characters.	The maximum value of **n** is 10 MB. If **n** is not specified, the maximum storage length is 1 GB – 85 – 4 (space for storing length parameter) – Length of other columns. For example, in a table with columns (a int, b nvarchar2, c int), the maximum length for the nvarchar2 column is 1 GB – 85 – 4 (space for storing length parameter) – 4 (length of column **a** int) – 4 (length of column **c** int) = 1,073,741,727.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Name	Description	Storage Space
TEXT	Variable-length string.	The maximum storage length is 1 GB – 85 – 4 (space for storing length parameter) – Length of other columns. For example, in a table with columns (a int, b text, c int), the maximum length for the text column is 1 GB – 85 – 4 (space for storing length parameter) – 4 (length of column **a** int) – 4 (length of column **c** int) = 1,073,741,727.
CLOB	Big text object.	The maximum size is 1 GB minus 1 byte. However, the size of the column description header and the size of the tuple (less than 1 GB minus 1 byte) where the column is located must also be considered. Therefore, the maximum size of the CLOB type may be less than 1 GB minus 1 byte.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Name	Description	Storage Space
TINYTEXT MEDIUMTEXT LONGTEXT	When **sql_compatibility** is set to **'MYSQL'**, if **b_format_version** is set to **'5.7'** and **b_format_dev_version** is set to **'s1'**, these types can be used. Converts a data type to the TEXT type. The application scenario is the same as that of the TEXT type.	The maximum size is 1 GB minus 1 byte. However, the size of the column description header and the size of the tuple (less than 1 GB minus 1 byte) where the column is located must also be considered. Therefore, the maximum size of the TEXT type may be less than 1 GB minus 1 byte.

NOTE

- In addition to the restriction on the size of each column, the total size of each tuple cannot exceed 1 GB minus 1 byte and is affected by the control header information of the column, the control header information of the tuple, and whether null fields exist in the tuple.
- NCHAR is the alias of the bpchar type, and VARCHAR2(n) is the alias of the VARCHAR(n) type.
- In ORA-compatible mode, the received empty string is converted to null by default.

Table 1-9 lists the two other fixed-length character types supported by GaussDB. The name type exists only for the storage of identifiers in the internal system catalogs and is not intended for use by general users. Its length is currently defined as 64 bytes (63 usable characters plus terminator). The char type uses only one byte of storage. It is internally used in the system catalogs as a simplistic enumeration type.

Table 1-9 Special character types

Name	Description	Storage Space
name	Internal type for object names	64 bytes
"char"	Single-byte internal type	1 byte

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

1.3.5 Binary Types

Table 1-10 lists the binary types supported by GaussDB.

Table 1-10 Binary types

Name	Description	Storage Space
BLOB	Binary large object (BLOB). Currently, BLOB supports only the following external access APIs: • DBE_LOB.GET_LENGTH • DBE_LOB.READ • DBE_LOB.WRITE • DBE_LOB.WRITE_APPEND • DBE_LOB.COPY • DBE_LOB.ERASE For details about the APIs, see DBE_LOB.	The maximum size is 1 GB minus 1 byte. However, the size of the column description header and the size of the tuple (less than 1 GB minus 1 byte) where the column is located must also be considered. Therefore, the maximum size of the BLOB type may be less than 1 GB minus 1 byte.
	When **sql_compatibility** is set to **'MYSQL'**, **b_format_version** is set to **'5.7'**, and **b_format_dev_version** is set to **'s1'**, the BLOB type is mapped to the BYTEA type, and the alias is BYTEA.	For details about the storage specifications, see the BYTEA type.
TINYBLOB MEDIUMBLOB LONGBLOB	Binary large object (BLOB).	For details about the storage specifications, see the BYTEA type.
	This type can be used only when **sql_compatibility** is set to **'MYSQL'**, **b_format_version** is set to **'5.7'**, and **b_format_dev_version** is set to **'s1'**. The type is mapped to the BYTEA type, and the alias is BYTEA.	

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Name	Description	Storage Space
RAW	Variable-length hexadecimal string.	4 bytes plus the actual binary string. The maximum size is 1 GB minus 1 byte. However, the size of the column description header and the size of the tuple (less than 1 GB minus 1 byte) where the column is located must also be considered. Therefore, the maximum size of this type may be less than 1 GB minus 1 byte.
BYTEA	Variable-length binary string.	4 bytes plus the actual binary string. The maximum size is 1 GB minus 1 byte. However, the size of the column description header and the size of the tuple (less than 1 GB minus 1 byte) where the column is located must also be considered. Therefore, the maximum size of this type may be less than 1 GB minus 1 byte.
BYTEAWITHOUTORDERWITHEQUALCOL	Variable-length binary character string (new type for the encryption feature. If the encryption type of an encrypted column is specified as deterministic encryption, the column type is BYTEAWITHOUTORDERWITHEQUALCOL). The original data type is displayed when an encrypted table is printed by running the meta-command.	4 bytes plus the actual binary string. The maximum value is 1,073,741,771 bytes (1 GB minus 53 bytes).
BYTEAWITHOUTORDERCOL	Variable-length binary character string (new type for the encryption feature. If the encryption type of an encrypted column is specified as random encryption, the column type is BYTEAWITHOUTORDERCOL). The original data type is displayed when an encrypted table is printed by running the meta-command.	4 bytes plus the actual binary string. The maximum value is 1,073,741,771 bytes (1 GB minus 53 bytes).

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Name	Description	Storage Space
_BYTEAWITHOUTORDERWITHEQUALCOL	Variable-length binary string, which is a new type for the encryption feature.	4 bytes plus the actual binary string. The maximum value is 1,073,741,771 bytes (1 GB minus 53 bytes).
_BYTEAWITHOUTORDERCOL	Variable-length binary string, which is a new type for the encryption feature.	4 bytes plus the actual binary string. The maximum value is 1,073,741,771 bytes (1 GB minus 53 bytes).

NOTE

- In addition to the size limit of each column, the total size of each tuple cannot exceed 1 GB minus 1 byte.
- BYTEAWITHOUTORDERWITHEQUALCOL, BYTEAWITHOUTORDERCOL, _BYTEAWITHOUTORDERWITHEQUALCOL, and _BYTEAWITHOUTORDERCOL cannot be directly used to create a table.
- *n* in RAW(*n*) indicates the recommended byte length and is not used to verify the byte length of the input raw type.
- When **sql_compatibility** is set to **'MYSQL'**, **b_format_version** is set to **'5.7'**, and **b_format_dev_version** is set to **'s1'**, the TINYBLOB, BLOB, MEDIUMBLOB, and LONGBLOB types are displayed as BYTEA. For example, the table structure query result shows the BYTEA type.

Example:

```
-- Create a table.
gaussdb=# CREATE TABLE blob_type_t1
(
    BT_COL1 INTEGER,
    BT_COL2 BLOB,
    BT_COL3 RAW,
    BT_COL4 BYTEA
) DISTRIBUTE BY REPLICATION;

-- Insert data.
gaussdb=# INSERT INTO blob_type_t1 VALUES(10,empty_blob(),
HEXTORAW('DEADBEEF'),E'\\xDEADBEEF');

-- Query data in the table.
gaussdb=# SELECT * FROM blob_type_t1;
 bt_col1 | bt_col2 | bt_col3  |  bt_col4
---------+---------+----------+------------
      10 |         | DEADBEEF | \xdeadbeef
(1 row)

-- Drop the table.
gaussdb=# DROP TABLE blob_type_t1;

-- Example: TINYBLOB, MEDIUMBLOB, and LONGBLOB types
gaussdb=# CREATE DATABASE gaussdb_m WITH dbcompatibility  'MYSQL';
gaussdb=# \c gaussdb_m
-- Set compatible version control parameters.
gaussdb_m=# SET b_format_version='5.7';
gaussdb_m=# SET b_format_dev_version='s1';
-- Create a table.
gaussdb_m=# CREATE TABLE t1(num int, a tinyblob, b blob, m mediumblob, l longblob);
-- Insert data.
gaussdb_m=# INSERT INTO t1 VALUES (1, 'tinyblobtest', 'blobtest', 'mediumblobtest', 'longblobtest');
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
-- Query data in the table.
gaussdb_m=# SELECT * FROM t1;
 num |      a       |    b     |       m        |      l
-----+--------------+----------+----------------+--------------
   1 | tinyblobtest | blobtest | mediumblobtest | longblobtest
(1 row)

-- Drop the table and database.
gaussdb_m=# DROP TABLE t1;
gaussdb_m=# \c postgres;
gaussdb=# DROP DATABASE gaussdb_m;
-- Reset parameters.
gaussdb=# RESET ALL;
```

1.3.6 Date/Time Types

Table 1-11 lists the date/time types that can be used in GaussDB. For the operators and built-in functions of the types, see **Date and Time Processing Functions and Operators**.

NOTE

- If the time format of another database is different from that of GaussDB, modify the value of the **DateStyle** parameter to keep them consistent.
- The current date is expressed according to the ISO standard. The year consists of four digits. For example, 1 A.D. is 0001, 1 B.C. is 0000, and 2 B.C. is -0001. The rest may be deduced by analogy.
- In Oracle-compatible mode, when the GUC parameter **mapping_date_to_datea** is set to **off**, the DATE type is replaced with TIMESTAMP(0) WITHOUT TIME ZONE. When the GUC parameter **mapping_date_to_datea** is set to **on**, the DATE type is replaced with the DATEA type. The differences are as follows:
  - The OID of the DATEA type is different from that of the TIMESTAMP(0) type. The DATEA type is a new data type implemented in GaussDB and has corresponding operators and conversion functions.
  - The value ranges supported by the DATEA and TIMESTAMP(0) types are different.
  - When the DATEA type is input, the string format needs to be verified. Only strings in the format specified by **nls_date_format** can be converted to the DATEA type. The TIMESTAMP(0) type supports only several fixed formats. The DATEA type does not support special value inputs, such as NOW, EPOCH, and TODAY.
  - In terms of driver usage, metadata (including OID and language data type) of the TIMESTAMP(0) type is different from metadata of the DATEA type. When setting precompilation parameters in JDBC, you need to use **SetTimestamp** or **GetTimestamp** for the TIMESTAMP(0) type and use **SetDate** or **GetDate** for the DATEA type.
  - When COPY is used to import data, you can set the **WITH** option to specify the format in which the imported data is parsed. For the TIMESTAMP(0) type, you need to use **TIMESTAMP_FORMAT** to specify it. For the DATEA type, you need to use **DATEA_FORMAT** to specify it. For details, see **Syntax**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 1-11 Date/Time types

Name	Description	Storage Space
DATE	Date and time. Minimum value: **4714-11-24 BC** (4713 B.C.). Maximum value: **5874897-12-31AD** (5874897 A.D.) After **sql_compatibility** is set to **'MYSQL'**, **b_format_version** is set to **'5.7'**, and **b_format_dev_version** is set to **'s1'**, the input and output formats and ranges are different. • Input format: YYYY-MM-DD with separators and YYYYMMDD without separators are supported. – In the scenario where separators are used, the plus sign (+) and colon (:) cannot be used as separators between the year, month, and day of a date. (Some separators are not supported when they are used together. The specifications inherit the existing implementation. Example: **date'2020-12?12'**.) The input format is not affected by the **DateStyle** parameter. – In the scenario where separators are not used, the output result may be incorrect though no error is reported. • Output format: Only YYYY-MM-DD is supported and the format is not affected by the **DateStyle** parameter. • Value range: 4713-01-01 BC to 5874897-12-31 AD. – If the value of **sql_mode** contains **strict_trans_tables**, an error is reported if the value is invalid or exceeds the range. – If the value of **sql_mode** does not contain **strict_trans_tables**, the values	4 bytes (8 bytes in ORA-compatible mode)

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Name	Description	Storage Space
	of year, month, and day can be 0. However, the values will be converted to valid values in the sequence of year, month, and day. For example, '0000-00-10' will be converted to 0002-12-10 BC. If the input is invalid or exceeds the range, a warning message is reported and the value **0000-00-00 00:00:00** is returned. **NOTE** In ORA-compatible mode, if **mapping_date_to_datea** is disabled, the DATE type is replaced with TIMESTAMP(0) WITHOUT TIME ZONE. In ORA-compatible mode, if **mapping_date_to_datea** is enabled, the DATE type is replaced with DATEA.	

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Name	Description	Storage Space
TIME [(p)] [WITHOUT TIME ZONE]	Time within one day (without a time zone). **p** indicates the precision after the decimal point. The value ranges from **0** to **6**. Minimum value: **00:00:00**. Maximum value: **24:00:00**. After **sql_compatibility** is set to **'MYSQL'**, **b_format_version** is set to **'5.7'**, and **b_format_dev_version** is set to **'s1'**, they are not limited to the time in a day. For example, they can indicate concepts such as duration and relative time, and the format, range, and precision are different. ● Input format: [D] hh:mi:ss.ff with separators and hhmiss.ff without separators are supported. **D** indicates the number of days. The value is an integer (negative numbers are supported). This parameter is optional. The value is converted into the number of hours on the basis of 24 hours in a day. The value is displayed after hh is added. Only colons (:) can be used as separators. ● Output format: hh:mi:ss.ff. All zeros at the end of the decimal part are automatically ignored during display. ● Value range: –838:59:59.000000 to +838:59:59.000000. – If the value of **sql_mode** contains **strict_trans_tables**, **00:00:00** is returned for invalid input. If the value exceeds the range, an error is reported. – If the value of **sql_mode** does not contain **strict_trans_tables**, **00:00:00** is returned for invalid input. If the input is valid but exceeds the range, the nearest boundary value is returned.	8 bytes

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Name	Description	Storage Space
	For example, inputting 838:59:59.000001 returns 838:59:59, and inputting –838:59:59.000001 returns –838:59:59. • Precision: **p** indicates the precision after the decimal point. The value ranges from 0 to 6. If **p** is set to a value greater than 6, the value **6** is used. – When it is used as the data type of a table column, the default precision is **0**. – When it is used as an expression (for example, time '10:10:10.123456'), the default precision is **6**.	
TIME [(p)] [WITH TIME ZONE]	Time within one day (with a time zone). **p** indicates the precision after the decimal point. The value ranges from **0** to **6**. Minimum value: **00:00:00+15:59**. Maximum value: **24:00:00–15:59**.	12 bytes

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Name	Description	Storage Space
TIMESTAMP[(p)] [WITHOUT TIME ZONE]	Date and time (without a time zone). **p** indicates the precision after the decimal point. The value ranges from **0** to **6**. Minimum value: **4714-11-24 BC 00:00:00.000000** (4713 B.C.). Maximum value: **294277-01-09 AD 04:00:54.775807** (294277 A.D.), representing infinity After **sql_compatibility** is set to **'MYSQL'**, **b_format_version** is set to **'5.7'**, and **b_format_dev_version** is set to **'s1'**, they will be replaced with the TIMESTAMP[(p)] [WITH TIME ZONE] type. However, the format, range, and precision specifications are different. ● Input format: YYYY-MM-DD hh:mi:ss.ff+timezone with separators and YYYYMMDDhhmiss.ff without separators are supported. – If separators are used, the plus sign (+) and colon (:) cannot be used as separators between the year, month, and day. (Some separators are not supported when they are used together. The specifications inherit the existing implementation. For example, timestamp '2020-12?12 00:00:00'.) Only colons (:) can be used as separators in the time part. The input format is not affected by the **DateStyle** parameter. – In the scenario where separators are not used and the input is incomplete, the output result may be incorrect though no error is reported. – If the year has only two digits, 00–69 corresponds to 2000–2069, and 70–99 corresponds to 1970–1999.	8 bytes

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Name	Description	Storage Space
	– If the year contains only one digit, for example, timestamp '1-1-1 00:00:00', the result is '0001-01-01 00:00:00'. ● Output format: Only YYYY-MM-DD hh:mi:ss.ff is supported and the format is not affected by the **DateStyle** parameter. All zeros at the end of the decimal part of the time are automatically ignored. ● Range – If the value of **sql_mode** contains **strict_trans_tables**, the value range is the same as that of TIMESTAMP[(p)] WITH TIME ZONE. If the value is invalid or exceeds the range, an error is reported. – If the value of **sql_mode** does not contain **strict_trans_tables**, the values of year, month, and day can be 0. However, the values will be converted to valid values in the sequence of year, month, and day. For example, '0000-00-10 00:00:00' will be converted to 0002-12-10 00:00:00 BC. If the input is invalid or exceeds the range, a warning message is reported and the value **0000-00-00 00:00:00** is returned. ● Precision: **p** indicates the precision after the decimal point. The value ranges from 0 to 6. If **p** is set to a value greater than 6, the value **6** is used. – When it is used as the data type of a table column, the default precision is **0**. – When it is used as an expression (for example, timestamp '2000-01-01 00:00:00.123456'), the default precision is **6**.	

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Name	Description	Storage Space
	• Time zone: The value ranges from –15:59 to +15:59. You can also use the time zone name (see the system view **PG_TIMEZONE_NAMES**). The time zone specifications are the same as those of the TIMESTAMP[(p)] WITH TIME ZONE type. Converts the time value of a specified time zone to the time of the UTC-0 time zone. When it is displayed, the time in the UTC-0 time zone is converted to the time in the current time zone of the server. You can run **SHOW TIME ZONE** to view the time zone of the server. Therefore, when you use the SET TIME ZONE statement to change the time zone of the server, the displayed result also changes.	

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Name	Description	Storage Space
TIMESTAMP[(p)] [WITH TIME ZONE]	Date and time (with time zone). TIMESTAMP is also called TIMESTAMPTZ. **p** indicates the precision after the decimal point. The value ranges from **0** to **6**. Minimum value: **4714-11-24 BC 00:00:00.000000 +0** (4713 B.C.). Maximum value: **294277-01-09 AD 04:00:54.775807 +0** (294277 A.D.), representing infinity. Note that the original date and time, the date and time converted to the UTC-0 time zone, and the date and time converted to the current server time zone cannot be greater than 294277-01-09 AD 04:00:54.775807 or less than 4714-11-24 BC 00:00:00.000000. Otherwise, an error may be reported during usage, indicating that the date and time are out of range. Time zone update: In some countries or regions, the time zone information is frequently updated due to political, economic, and war factors. Therefore, the database system needs to modify the time zone file to ensure that the time is correct. Currently, the GaussDB time zone type involves only timestamp with timezone. When a new time zone file takes effect, the existing data is not changed, and the new data is adjusted based on the time zone file information.	8 bytes
SMALLDATETIME	Date and time (without a time zone). The precision level is minute. 30s to 59s are rounded into one minute. Minimum value: **4714-11-24 BC 00:00:00** (4713 B.C.). Maximum value: **294277-01-09 AD 04:00:00** (294277 A.D.).	8 bytes

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Name	Description	Storage Space
INTERVAL DAY (l) TO SECOND (p)	Specifies the time interval (*X* days *X* hours *X* minutes *X* seconds). • **l**: indicates the precision of days. The value ranges from 0 to 6. For compatibility, the precision functions are not supported. • **p**: indicates the precision of seconds. The value ranges from 0 to 6. The digit 0 at the end of a decimal number is not displayed.	16 bytes
INTERVAL [FIELDS] [(p)]	Time interval. • **FIELDS**: **YEAR**, **MONTH**, **DAY**, **HOUR**, **MINUTE**, **SECOND**, **DAY TO HOUR**, **DAY TO MINUTE**, **DAY TO SECOND**, **HOUR TO MINUTE**, **HOUR TO SECOND**, or **MINUTE TO SECOND**. • **p**: indicates the precision of seconds. The value ranges from 0 to 6. **p** takes effect only when **FIELDS** is set to **SECOND**, **DAY TO SECOND**, **HOUR TO SECOND**, or **MINUTE TO SECOND**. The digit 0 at the end of a decimal number is not displayed.	12 bytes
reltime	Relative time interval. • The format is as follows: X years X mons X days XX:XX:XX. • The Julian calendar is used. It specifies that a year has 365.25 days and a month has 30 days. The relative time interval needs to be calculated based on the input value.	4 bytes
abstime	Date and time. • Format: YYYY-MM-DD hh:mi:ss +timezone. • The value range is from 1901-12-13 20:45:53 to 2038-01-18 23:59:59 in the current time zone, with precision of seconds. If the inserted data exceeds the range, the data is converted to an invalid value for storage.	4 bytes

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Name	Description	Storage Space
datetime[(p)]	Date and time. This parameter takes effect only when **sql_compatibility** is set to **'MYSQL'**, **b_format_version** is set to **'5.7'**, and **b_format_dev_version** is set to **'s1'**. The datetime[(p)] type is replaced by the TIMESTAMP[(p)] WITHOUT TIME ZONE type, but the format, range, precision, and time zone processing specifications are different. ● Input format: YYYY-MM-DD hh:mi:ss.ff+timezone with separators and YYYYMMDDhhmiss.ff without separators are supported. – If separators are used, the plus sign (+) and colon (:) cannot be used as separators between the year, month, and day. (Some separators are not supported when they are used together. The specifications inherit the existing implementation. For example, **datetime '2020-12?12 00:00:00'**.) Only colons (:) can be used as separators in the time part. The input format is not affected by the **DateStyle** parameter. – In the scenario where separators are not used and the input is incomplete, the output result may be incorrect though no error is reported. – If the year has only two digits, 00–69 corresponds to 2000–2069, and 70–99 corresponds to 1970–1999. – If the year contains only one digit, for example, datetime '1-1-1 00:00:00', the result is '0001-01-01 00:00:00'. ● Output format: Only YYYY-MM-DD hh:mi:ss.ff is supported and the format is not affected by the **DateStyle** parameter. All zeros at	8 bytes

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Name	Description	Storage Space
	the end of the decimal part of the time are automatically ignored. • Range – If the value of **sql_mode** contains **strict_trans_tables**, the value range is the same as that of TIMESTAMP[(p)] WITHOUT TIME ZONE. If the value is invalid or exceeds the range, an error is reported. – If the value of **sql_mode** does not contain **strict_trans_tables**, the values of year, month, and day can be 0. However, the values will be converted to valid values in the sequence of year, month, and day. For example, '0000-00-10 00:00:00' will be converted to 0002-12-10 00:00:00 BC. If the input is invalid or exceeds the range, a warning message is reported and the value **0000-00-00 00:00:00** is returned. • Precision: **p** indicates the precision after the decimal point. The value ranges from 0 to 6. If the specified precision exceeds 6, the value **6** is used. – When it is used as the data type of a table column, the default precision is **0**. – When it is used as an expression (for example, datetime '2000-01-01 00:00:00.123456'), the default precision is **6**. • Time zone: The value ranges from –15:59 to +15:59. You can also use the time zone name (see the system view **PG_TIMEZONE_NAMES**). The time zone specifications are the same as those of the TIMESTAMP[(p)] WITH TIME ZONE type. It converts the time

Name	Description	Storage Space
	value of a specified time zone to the time of the current time zone of the server. You can run **SHOW TIME ZONE** to view the time zone of the server. If the converted date and time are saved to the table, the time zone is not converted when the time zone of the server changes.	

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Name	Description	Storage Space
year[(w)]	Year. It takes effect only after **sql_compatibility** is set to **'MYSQL'**. ● Input formats: – A string of four digits, ranging from '1901' to '2155' (that is, the years from 1901 to 2155). – Four digits, ranging from 1901 to 2155 (that is, the years from 1901 to 2155). – A string of one or two digits, ranging from '0' to '99'. The values '0' to '69' indicate the years from 2000 to 2069, and the values '70' to '99' indicate the years from 1970 to 1999. **'0'** and **'00'** indicate the year 2000. – One or two digits, ranging from **0** to **99**. The values **1** to **69** indicate the years from 2001 to 2069, and **70** to **99** indicate the years from 1970 to 1999. The value **0** indicates 0000. – Return values of other time functions, for example, now(). ● Output format: Only the YYYY format is supported. **w** indicates the number of digits in the output format. Only four digits are supported. If not specified, the default value is **4**. ● Value range: **1901** to **2155**. – If the value of **sql_mode** contains **strict_trans_tables**, an error is reported if the value is invalid or exceeds the range. – If the value of **sql_mode** does not contain **strict_trans_tables**, the invalid value is converted to **0000** and inserted, and an alarm is generated.	1 byte

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Name	Description	Storage Space
DATEA	Date and time. It takes effect only after **sql_compatibility** is set to **'ORA'**. Minimum value: 4712-01-01 00:00:00 B.C. Maximum value: 9999-12-31 23:59:59 A.C. Input format: The input format must comply with the format specified by **nls_date_format**. For details about the formats supported by **nls_date_format**, see **Table 1-12**. • You can use the following special characters or strings enclosed in double quotation marks as the separator: - / , . % : • In the scenario where separators are not used and the input is incomplete, the output result may be incorrect though no error is reported. • If the input format contains *YY*, datea attempts to parse the two-digit year first. If the parsing fails, datea attempts to parse the 4-digit year. The final error information is returned when the four-digit year fails to be parsed. Output format: Only the YYYY-MM-DD HH24:MI:SS AD/BC format is supported and is not affected by the **DateStyle** parameter. Value range: 4712-01-01 00:00:00 B.C. to 9999-12-31 23:59:59 A.C. If an invalid value is entered or the entered value exceeds the range, an error is reported. Precision: The precision is not accurate to the decimal point, with the minimum precision being seconds.	8 bytes

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Name	Description	Storage Space

	NOTE
	• It replaces the DATE type when **mapping_date_to_datea** is enabled in ORA-compatible mode.
	• The DATEA type is used for internal function implementation. You are advised not to use it directly.
	• The DATEA type cannot be used as a user-defined range type.
	• If the input format does not comply with the format specified by **nls_date_format**, the following results may occur:
	  • An error message is displayed, indicating that the input format does not meet the requirements.
	  • The input is successful, but the input time is not as expected.	

NOTE

- The data of the time type automatically ignores all zeros at the end of the data when it is displayed.
- The default value of **p** is **6**.
- For the INTERVAL type, the date and time are stored in the int32 and double types in the system. Therefore, the value ranges of the two types are the same as those of the corresponding data type.
- If the insertion time is out of the range, the system may not report an error, but the behavior may not be normal.
- If the values of **a_format_version** and **a_format_dev_version** are **10c** and **s1**, the default DATE value is determined by the following:
  - Year: returned through SYSDATE
  - Month: returned through SYSDATE
  - Day: 01 (first day of the month)
  - Hour, minute, and second: all 0

Example:

```
-- Create a table.
gaussdb=# CREATE TABLE date_type_tab(coll date);

-- Insert data.
gaussdb=# INSERT INTO date_type_tab VALUES (date '12-10-2010');

Table 1-12 Formats supported by nls_date_format

Format	Description
A.D.	A.D.
AD	A.D.
A.M.	Morning.
AM	Morning.
B.C.	B.C.
BC	B.C.
CC	Century in a 2-digit format. The 21st century starts from 2001-01-01.
DAY	Full uppercase date name (padded to nine characters).
DL	Returns a specified long date format.
DS	Returns a specified short date format.
DDD	Day of the year (001–366).
DD	Day of the month (01–31).
DY	Abbreviated uppercase date name (three characters).
D	Day of the week (1–7; Sunday is 1).
FX	Forces a function to parse or format a date strictly according to the specified format.
HH24	Hour of the day (00–23).
HH12	Hour of the day (01–12).
HH	Hour of the day (01–12).

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Format	Description
IW	ISO week number of the year (the first week contains the first Thursday).
IYYY	ISO year (with four digits or more).
IYY	Last three digits of the ISO year.
IY	Last two digits of the ISO year.
I	Last one digit of the ISO year.
J	Julian day (number of days after January 1, 4713 B.C.).
MI	Minutes (00–59).
MM	Month number (01–12).
MONTH	Full uppercase month name (padded to nine characters).
MON	Abbreviated uppercase month name (three characters).
P.M.	Afternoon.
PM	Afternoon.
Q	Quarter.
RM	Roman numeral representation of the month (I–XII, where I = JAN).
RRRR	Returns the four-digit year of a date.
RR	Returns the two-digit year of a date.
SSSSS	Seconds since midnight (0–86399).
SCC	Century, B.C.
SS	Seconds (00–59).
SYEAR	Returns the year as a string, with a hyphen (-) for B.C.
SYYYY	Returns the year as a number, with a hyphen (-) for B.C.
TS	Returns a specified time format.
WW	Week number of the year (1–53; the first week starts on the first day of the year).
W	Week number of the month (1–5; the first week starts on the first day of the month).
Y,YYY	Year with a comma (with four digits or more).

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Format	Description
YEAR	Returns the year as a string.
YYYY	Year (with four digits or more).
YYY	Last three digits of the year.
YY	Last two digits of the year.
Y	Last one digit of the year.

NOTE

In GaussDB, the value of **nls_date_format** can be suffixed with **TH**. This suffix is used to skip two bytes in the specified part of the format when the input time string is parsed. The formats that support the **TH** suffix include *HH*, *HH12*, *HH24*, *MI*, *SS*, *SSSSS*, *MM*, *DDD*, *DD*, *D*, *Y,YYY*, *YYYY*, *YYY*, *YY*, *Y*, *RRRR*, *RR*, *J*, and *SYYYY*. If the value of the **nls_date_format** parameter contains the **TH** suffix and the suffix is not at the end of the string, two bytes must be reserved for the input time. Otherwise, a parsing error occurs or the result is abnormal. The following are examples:

- The parsing is normal.
```
gaussdb=# select to_datea('2000TH-10-24', 'YYYYTH-MM-DD');   -- When TH is placed following YYYY, two bytes (which can be any characters) must be reserved after the input year 2000.
to_datea
------------------------
2000-10-24 00:00:00 AD
(1 row)

gaussdb=# select to_datea('2000TH-10-24', 'YYYYTH-MM-DDTH');   -- When TH is placed following the nls_date_format parameter, the parsing is normal.
       to_datea
------------------------
 2000-10-24 00:00:00 AD
(1 row)
```
- An error occurs during parsing.
```
gaussdb=# select to_datea('2000-10-24', 'YYYYTH-MM-DD');
ERROR:  The data of "month = 0" is invalid. The value must be between 1 and 12.
CONTEXT:  referenced column: to_datea
```
- The result is abnormal.
```
gaussdb=# select to_datea('2000-11-24', 'YYYYTH-MM-DD');   -- When TH is placed following YYYY, the input year 2000 is not followed by two reserved bytes. During parsing, -1 is skipped, and MM is parsed as January. As a result, the result is abnormal.
       to_datea
------------------------
 2000-01-24 00:00:00 AD
(1 row)
```

Date Inputs

Date and time input is accepted in almost any reasonable formats, including ISO 8601 and SQL-compatible. The system allows you to customize the sequence of day, month, and year in the date input. Set the **DateStyle** parameter to **MDY** to select month-day-year interpretation, **DMY** to select day-month-year interpretation, or **YMD** to select year-month-day interpretation.

Remember that any date or time literal input needs to be enclosed with single quotation marks (''), and the syntax is as follows:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
type [ ( p ) ] 'value'
```

The **p** that can be selected in the precision statement is an integer, indicating the number of fractional digits in the **seconds** column. **Table 1-13** lists the input formats of the date type.

Table 1-13 Date input formats

Example	Description
1999-01-08	ISO 8601 (recommended format). January 8, 1999 in any format.
January 8, 1999	Unambiguous in any **datestyle** input mode
1/8/1999	January 8 in MDY format. August 1 in DMY format.
1/18/1999	January 18 in MDY format, rejected in other formats.
01/02/03	• January 2, 2003 in MDY format. • February 1, 2003 in DMY format. • February 3, 2001 in YMD format.
1999-Jan-08	January 8 in any mode
Jan-08-1999	January 8 in any mode
08-Jan-1999	January 8 in any mode
99-Jan-08	January 8 in **YMD** mode, else error
08-Jan-99	January 8, except error in YMD format.
Jan-08-99	January 8, except error in YMD format.
19990108	ISO 8601. January 8, 1999 in any format.
990108	ISO 8601. January 8, 1999 in any format.
1999.008	Year and day of year.
J2451187	Julian date.
January 8, 99 BC	Year 99 B.C.

Example:

```
-- Create a table.
gaussdb=# CREATE TABLE date_type_tab(coll date);

-- Insert data.
gaussdb=# INSERT INTO date_type_tab VALUES (date '12-10-2010');

-- View data.
gaussdb=# SELECT * FROM date_type_tab;
        coll
---------------------
 2010-12-10
(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
-- View the date format.
gaussdb=# SHOW datestyle;
 DateStyle
-----------
 ISO, MDY
(1 row)

-- Set the date format.
gaussdb=# SET datestyle='YMD';
SET

-- Insert data.
gaussdb=# INSERT INTO date_type_tab VALUES(date '2010-12-11');

-- View data.
gaussdb=# SELECT * FROM date_type_tab;
        coll
---------------------
 2010-12-10
 2010-12-11
(2 rows)

-- Drop the table.
gaussdb=# DROP TABLE date_type_tab;
```

Time

The time-of-day types are **TIME [(p)] [WITHOUT TIME ZONE]** and **TIME [(p)] [WITH TIME ZONE]**. **TIME** alone is equivalent to **TIME WITHOUT TIME ZONE**.

If a time zone is specified in the input for **TIME WITHOUT TIME ZONE**, it is silently ignored.

For details about the time input types, see **Table 1-14**. For details about time zone input types, see **Table 1-15**.

Table 1-14 Time input types

Example	Description
05:06.8	ISO 8601
4:05:06	ISO 8601
4:05	ISO 8601
040506	ISO 8601
4:05 AM	Same as 04:05. Input hours must be less than or equal to 12.
4:05 PM	Same as 16:05. Input hours must be less than or equal to 12.
04:05:06.789-8	ISO 8601
04:05:06-08:00	ISO 8601
04:05-08:00	ISO 8601
040506-08	ISO 8601

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Example	Description
04:05:06 PST	Time zone specified by abbreviation.
2003-04-12 04:05:06 America/New_York	Time zone specified by full name.

Table 1-15 Time zone input types

Example	Description
PST	Abbreviation (for Pacific Standard Time).
America/New_York	Full time zone name.
-8:00	ISO-8601 offset for PST.
-800	ISO-8601 offset for PST.
-8	ISO-8601 offset for PST.

Example:

```
gaussdb=# SELECT time '04:05:06';
   time
----------
 04:05:06
(1 row)

gaussdb=# SELECT time '04:05:06 PST';
   time
----------
 04:05:06
(1 row)

gaussdb=# SELECT time with time zone '04:05:06 PST';
   timetz
-------------
 04:05:06-08
(1 row)
```

Special Values

The special values supported by GaussDB are converted to common date/time values when being read. For details, see **Table 1-16**.

Table 1-16 Special values

Input String	Applicable Type	Description
epoch	date and timestamp	1970-01-01 00:00:00+00 (Unix system time zero).
infinity	timestamp	Infinity, later than any other timestamp.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Input String	Applicable Type	Description
-infinity	timestamp	Infinity, earlier than any other timestamp.
now	date, time, and timestamp	Start time of the current transaction.
today	date and timestamp	Today at midnight.
tomorrow	date and timestamp	Tomorrow at midnight.
yesterday	date and timestamp	Yesterday at midnight.
allballs	time	00:00:00.00 UTC

Example:

```
-- Create a table.
gaussdb=# CREATE TABLE realtime_type_special(col1 varchar(20), col2 date, col3 timestamp, col4 time);

-- Insert data.
gaussdb=# INSERT INTO realtime_type_special VALUES('epoch', 'epoch', 'epoch', NULL);
gaussdb=# INSERT INTO realtime_type_special VALUES('now', 'now', 'now', 'now');
gaussdb=# INSERT INTO realtime_type_special VALUES('today', 'today', 'today', NULL);
gaussdb=# INSERT INTO realtime_type_special VALUES('tomorrow', 'tomorrow', 'tomorrow', NULL);
gaussdb=# INSERT INTO realtime_type_special VALUES('yesterday', 'yesterday', 'yesterday', NULL);

-- View data.
gaussdb=# SELECT * FROM realtime_type_special;
   col1    |        col2         |            col3            |      col4
-----------+---------------------+----------------------------+-----------------
 epoch     | 1970-01-01 00:00:00 | 1970-01-01 00:00:00        |

gaussdb=# DROP TABLE realtime_type_special;
```

Interval Input

The input of **reltime** can be any valid interval in text format. It can be a number (negative numbers and decimals are also allowed) or a specific time, which must be in SQL standard format or ISO-8601 format. In addition, the text input needs to be enclosed with single quotation marks ('').

For details about interval input, see **Table 1-17**.

Table 1-17 Interval input types

Input	Output	Description
60	2 mons	Numbers are used to indicate intervals. The default unit is day. Decimals and negative numbers are allowed. Particularly, a negative interval syntactically means how long before.
31.25	1 mons 1 days 06:00:00	
-365	-12 mons -5 days	
1 years 1 mons 8 days 12:00:00	1 years 1 mons 8 days 12:00:00	Intervals are in POSTGRES format. They can contain both positive and negative numbers and are case-insensitive. Output is a simplified POSTGRES interval converted from the input.
-13 months -10 hours	-1 years -25 days -04:00:00	
-2 YEARS +5 MONTHS 10 DAYS	-1 years -6 mons -25 days -06:00:00	

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Input	Output	Description
P-1.1Y10M	-3 mons -5 days -06:00:00	Intervals are in ISO-8601 format. They can contain both positive and negative numbers and are case-insensitive. Output is a simplified POSTGRES interval converted from the input.
-12H	-12:00:00	

Example:

```
-- Create a table.
gaussdb=# CREATE TABLE reltime_type_tab(col1 character(30), col2 reltime);

-- Insert data.
gaussdb=# INSERT INTO reltime_type_tab VALUES ('90', '90');
gaussdb=# INSERT INTO reltime_type_tab VALUES ('-366', '-366');
gaussdb=# INSERT INTO reltime_type_tab VALUES ('1975.25', '1975.25');
gaussdb=# INSERT INTO reltime_type_tab VALUES ('-2 YEARS +5 MONTHS 10 DAYS', '-2 YEARS +5
MONTHS 10 DAYS');
gaussdb=# INSERT INTO reltime_type_tab VALUES ('30 DAYS 12:00:00', '30 DAYS 12:00:00');
gaussdb=# INSERT INTO reltime_type_tab VALUES ('P-1.1Y10M', 'P-1.1Y10M');

-- View data.
gaussdb=# SELECT * FROM reltime_type_tab;
              col1              |                col2
--------------------------------+-----------------------------------
 90                             | 3 mons
 -366                           | -1 years -18:00:00
 1975.25                        | 5 years 4 mons 29 days
 -2 YEARS +5 MONTHS 10 DAYS     | -1 years -6 mons -25 days -06:00:00
 30 DAYS 12:00:00               | 1 mon 12:00:00
 P-1.1Y10M                      | -3 mons -5 days -06:00:00
(6 rows)

-- Drop the table.
gaussdb=# DROP TABLE reltime_type_tab;
```

1.3.7 Geometric Types

Table 1-18 lists the geometric types that can be used in GaussDB. The most fundamental type is the point, which forms the basis for all of the other geometric types.

Table 1-18 Geometric Types

Name	Storage Space	Description	Representation
point	16 bytes	Point on a plane	(x,y)
lseg	32 bytes	Finite line segment	((x1,y1),(x2,y2))
box	32 bytes	Box	((x1,y1),(x2,y2))
path	16 + 16*n* bytes	Closed path (similar to polygon)	((x1,y1),...)

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Name	Storage Space	Description	Representation
path	16 + 16*n* bytes	Open path	[(x1,y1),...]
polygon	40 + 16*n* bytes	Polygon (similar to closed path)	((x1,y1),...)
circle	24 bytes	Circle	<(x,y),r> (center point and radius)

A rich set of functions and operators is available in GaussDB to perform various geometric operations, such as scaling, translation, rotation, and determining intersections. For details, see **Geometric Functions and Operators**.

Points

Points are the fundamental two-dimensional building block for geometric types. Values of the point type are specified using either of the following syntaxes:

```
( x , y )
x , y
```

x and **y** are the respective coordinates, as floating-point numbers. The value type of the points is float8.

Points are output using the first syntax.

Example:

```
gaussdb=# SELECT point(1.1, 2.2);
   point
-----------
 (1.1,2.2)
(1 row)
```

Line Segments

Line segments (lseg) are represented by pairs of points. Values of the lseg type are specified using either of the following syntaxes:

```
[ ( x1 , y1 ) , ( x2 , y2 ) ]
( ( x1 , y1 ) , ( x2 , y2 ) )
( x1 , y1 ) , ( x2 , y2 )
x1 , y1   ,   x2 , y2
```

(x1,y1) and **(x2,y2)** are the end points of the line segment. The value type of the points is float8.

Line segments are output using the first syntax.

Example:

```
gaussdb=# SELECT lseg(point(1.1, 2.2), point(3.3, 4.4));
        lseg
-----------------------
 [(1.1,2.2),(3.3,4.4)]
(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Boxes

A box is represented by pairs of points that are opposite corners of the box. Values of the box type are specified using either of the following syntaxes:

```
( ( x1 , y1 ) , ( x2 , y2 ) )
( x1 , y1 ) , ( x2 , y2 )
x1 , y1   ,   x2 , y2
```

(x1,y1) and **(x2,y2)** are any two opposite corners of the box. The value type of the points is float8.

Boxes are output using the second syntax.

Any two diagonals can be used. However, the upper right corner endpoint is placed before the lower left corner endpoint for reordering and storage.

Example:

```
gaussdb=# SELECT box(point(1.1, 2.2), point(3.3, 4.4));
        box
---------------------
 (3.3,4.4),(1.1,2.2)
(1 row)
```

Paths

Paths are represented by lists of connected points. Paths can be open or closed. An open path does not connect the start and end points, while a closed path considers the start and end points connected.

Values of the **path** type are specified using any of the following syntaxes:

```
[ ( x1 , y1 ) , ... , ( xn , yn ) ]
( ( x1 , y1 ) , ... , ( xn , yn ) )
( x1 , y1 ) , ... , ( xn , yn )
( x1 , y1   , ... ,   xn , yn )
x1 , y1   , ... ,   xn , yn
```

The points are the end points of the line segments comprising the path. The value type of the points is float8. Square brackets ([]) indicate an open path, while parentheses (()) indicate a closed path. When the outermost parentheses are omitted (as in the third through fifth syntax), the path is assumed to be closed.

Paths are output using the first or second syntax.

Example:

```
gaussdb=# SELECT path(polygon '((0,0),(1,1),(2,0))');
       path
---------------------
 ((0,0),(1,1),(2,0))
(1 row)
```

Polygons

Polygons are represented by lists of points (the vertexes of the polygon). Polygons are very similar to closed paths, but are stored differently and have their own set of support functions.

Values of the polygon type are specified using any of the following syntaxes:

```
( ( x1 , y1 ) , ... , ( xn , yn ) )
( x1 , y1 ) , ... , ( xn , yn )
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
( x1 , y1   , ... ,   xn , yn )
x1 , y1   , ... ,   xn , yn
```

A point indicates the vertex of a polygon. The value type of a point is float8.

Polygons are output using the first syntax.

Example:

```
gaussdb=# SELECT polygon(box '((0,0),(1,1))');
         polygon
--------------------------
 ((0,0),(0,1),(1,1),(1,0))
(1 row)
```

Circle

A circle represented by a center and a radius. Values of the **circle** type are specified using the following syntax:

```
< ( x , y ) , r >
( ( x , y ) , r )
( x , y ) , r
x , y   , r
```

(x,y) is the center point and **r** is the radius of the circle. The value type of the points is float8.

Circles are output using the first syntax.

Example:

```
gaussdb=# SELECT circle(point(0,0),1);
  circle
-----------
 <(0,0),1>
(1 row)
```

1.3.8 Network Address Types

GaussDB provides data types for storing IPv4, IPv6, and MAC addresses, as listed in **Table 1-19**. Compared with pure text types, these types provide input error check and special operations and functions (see **Network Address Functions and Operators**).

Table 1-19 Network Address Types

Name	Storage Space	Description
cidr	7 or 19 bytes	IPv4 or IPv6 networks.
inet	7 or 19 bytes	IPv4 or IPv6 hosts and networks.
macaddr	6 bytes	MAC address.

When sorting inet or classless inter-domain routing (cidr) data types, IPv4 addresses will always sort before IPv6 addresses, including IPv4 addresses encapsulated or mapped to IPv6 addresses, such as ::10.2.3.4 or ::ffff:10.4.3.2.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

cidr

The cidr type holds an IPv4 or IPv6 network address, as described in **Table 1-20**. The format for specifying networks is **address/y** where **address** is the network represented as an IPv4 or IPv6 address, and **y** is the number of bits in the netmask. If **y** is omitted, it is calculated using assumptions from the older classful network numbering system, except it will be at least large enough to include all of the octets written in the input.

Table 1-20 cidr type input examples

cidr Input	cidr Output	abbrev(cidr)
192.168.100.128/25	192.168.100.128/25	192.168.100.128/25
192.168/24	192.168.0.0/24	192.168.0/24
192.168/25	192.168.0.0/25	192.168.0.0/25
192.168.1	192.168.1.0/24	192.168.1/24
192.168	192.168.0.0/24	192.168.0/24
10.1.2	10.1.2.0/24	10.1.2/24
10.1	10.1.0.0/16	10.1/16
10	10.0.0.0/8	10/8
10.1.2.3/32	10.1.2.3/32	10.1.2.3/32
2001:4f8:3:ba::/64	2001:4f8:3:ba::/64	2001:4f8:3:ba::/64
2001:4f8:3:ba:2e0:81ff:fe22:d1f1/128	2001:4f8:3:ba:2e0:81ff:fe22:d1f1/128	2001:4f8:3:ba:2e0:81ff:fe22:d1f1
::ffff:127.0.0.0/120	::ffff:127.0.0.0/120	::ffff:127.0.0.0/120
::ffff:127.0.0.0/128	::ffff:127.0.0.0/128	::ffff:127.0.0.0/128

inet

The inet type stores an IPv4 or IPv6 host address, and optionally its subnet, all in one field. The subnet is represented by the number of network address bits present in the host address (the "netmask"). If the netmask is 32 and the address is an IPv4 address, then the value does not indicate a subnet, only a single host. In IPv6, because the address length is 128 bits, 128 bits specify a unique host address.

The input format for this type is **address/y** where **address** is an IPv4 or IPv6 address and **y** is the number of binary bits in the netmask. If **/y** is omitted, the subnet mask is **32** for an IPv4 address and **128** for an IPv6 address, and the value represents just a single host. On display, the **/y** portion is suppressed if the netmask specifies a single host.

The essential difference between the **inet** and **cidr** data types is that **inet** accepts values with nonzero bits to the right of the netmask, whereas **cidr** does not.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

macaddr

The macaddr type stores MAC addresses, known for example from Ethernet card hardware addresses (although MAC addresses are used for other purposes as well). Input is accepted in the following formats:

```
'08:00:2b:01:02:03'
'08-00-2b-01-02-03'
'08002b:010203'
'08002b-010203'
'0800.2b01.0203'
'08002b010203'
```

These examples would all specify the same address. Data bits **a** to **f** are case-insensitive and are displayed in the first format.

1.3.9 Bit String Types

Bit strings are strings of binary digits (1 and 0). They can be used to store bit masks.

GaussDB supports two bit string types: bit(n) and bit varying(n), where *n* is a positive integer. The maximum value of *n* is **83886080**, which is equivalent to 10 MB.

Data of the bit type must match the length *n*. If the storage length is not *n*, an error is reported. Data of the bit varying type is of variable length up to the maximum length *n*. Longer strings will be rejected. Writing **bit** without a specified length is equivalent to **bit(1)**, while **bit varying** without a specified length means unlimited length.

NOTE

- If you convert a bit string value to bit(*n*), the content that exceeds *n* digits on the right of the bit string will be truncated, or the bit string will be padded with zeros to *n* digits on the right if the bit string value is less than *n* digits. In this case, no error is reported.
- Similarly, if one explicitly casts a bit string value to **bit varying(n)**, the bit string will be truncated on the right if it is more than *n* bits.
- When the ADMS platform driver version 8.1.3-200 or earlier is used, use **::bit varying** to convert the bit type. Otherwise, an error may occur.

```
-- Create a table.
gaussdb=# CREATE TABLE bit_type_t1
(
    BT_COL1 INTEGER,
    BT_COL2 BIT(3),
    BT_COL3 BIT VARYING(5)
) DISTRIBUTE BY REPLICATION;

-- Insert data.
gaussdb=# INSERT INTO bit_type_t1 VALUES(1, B'101', B'00');

-- Specify the type length. An error is reported if an inserted string exceeds this length.
gaussdb=# INSERT INTO bit_type_t1 VALUES(2, B'10', B'101');
ERROR:  bit string length 2 does not match type bit(3)
CONTEXT:  referenced column: bt_col2

-- Specify the type length. Data is converted if it exceeds this length.
gaussdb=# INSERT INTO bit_type_t1 VALUES(2, B'10'::bit(3), B'101');

-- View data.
gaussdb=# SELECT * FROM bit_type_t1;
 bt_col1 | bt_col2 | bt_col3
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
---------+---------+---------
       1 | 101     | 00
       2 | 100     | 101
(2 rows)

-- Drop the table.
gaussdb=# DROP TABLE bit_type_t1;
```

1.3.10 UUID Type

The data type UUID stores universally unique identifiers (UUID) as defined by RFC 4122, ISO/IEC 9834-8:2005, and related standards. This identifier is a 128-bit quantity (16 bytes in size) that is generated by an algorithm chosen to make it very unlikely that the same identifier will be generated by anyone else in the known universe.

Therefore, for distributed systems, these identifiers provide a better uniqueness guarantee than sequence generators, which are only unique within a single database.

A UUID in standard format is composed of 32 lower-case hexadecimal digits, 128 bits in size, and divided into several groups by hyphens, specifically a group of 8 digits, three groups of 4 digits, and a group of 12 digits. An example is as follows:

```
a0eebc99-9c0b-4ef8-bb6d-6bb9bd380a11
```

GaussDB also accepts the following alternative forms for input: use of upper-case letters and digits, the standard format surrounded by braces, omitting some or all hyphens, and adding a hyphen after any group of four digits. An example is provided as follows:

```
A0EEBC99-9C0B-4EF8-BB6D-6BB9BD380A11
{a0eebc99-9c0b-4ef8-bb6d-6bb9bd380a11}
a0eebc999c0b4ef8bb6d6bb9bd380a11
a0ee-bc99-9c0b-4ef8-bb6d-6bb9-bd38-0a11
```

Output is in the standard format by default.

Examples

```
-- Generate a UUID sequence number.
gaussdb=# SELECT uuid();
                 uuid
--------------------------------------
 846b9d00-172d-c63d-4a03-e8b4700370e0
(1 row)

-- Create a table.
gaussdb=# CREATE TABLE uuid_test(id int, test uuid) DISTRIBUTE BY HASH(test);

-- Use the UUID generated by the system to insert data.
gaussdb=# INSERT INTO uuid_test VALUES(1, uuid()::uuid);

-- Insert data in the example format.
gaussdb=# INSERT INTO uuid_test VALUES(2, 'A0EEBC99-9C0B-4EF8-BB6D-6BB9BD380A11');
gaussdb=# INSERT INTO uuid_test VALUES(3, '{a0eebc99-9c0b-4ef8-bb6d-6bb9bd380a11}');
gaussdb=# INSERT INTO uuid_test VALUES(4, 'a0eebc999c0b4ef8bb6d6bb9bd380a11');
gaussdb=# INSERT INTO uuid_test VALUES(5, 'a0ee-bc99-9c0b-4ef8-bb6d-6bb9-bd38-0a11');

-- View data and output the data in the standard format.
gaussdb=# SELECT * FROM uuid_test;
 id |                 test
----+--------------------------------------
  1 | 1b52051c-1731-c63d-4a03-e8b4700370e0
  2 | a0eebc99-9c0b-4ef8-bb6d-6bb9bd380a11
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
 3 | a0eebc99-9c0b-4ef8-bb6d-6bb9bd380a11
 4 | a0eebc99-9c0b-4ef8-bb6d-6bb9bd380a11
 5 | a0eebc99-9c0b-4ef8-bb6d-6bb9bd380a11
(5 rows)

-- Drop the table.
gaussdb=# DROP TABLE uuid_test;
```

1.3.11 Text Search Types

GaussDB provides two data types to support full-text search. The tsvector type is a document data type optimized by full-text search. The tsquery type indicates the text query type.

tsvector

The tsvector type represents a retrieval unit, usually a textual column within a row of a database table, or a combination of such columns. A tsvector value is a sorted list of distinct lexemes, which are words that have been normalized to merge different variants of the same word. Sorting and deduplication are done automatically during input, as shown below:

```
gaussdb=# SELECT 'a fat cat sat on a mat and ate a fat rat'::tsvector;
                      tsvector
-----------------------------------------------------
 'a' 'and' 'ate' 'cat' 'fat' 'mat' 'on' 'rat' 'sat'
(1 row)
```

To represent lexemes containing spaces or punctuations, enclose them with quotation marks:

```
gaussdb=# SELECT $$the lexeme '    ' contains spaces$$::tsvector;
                 tsvector
-------------------------------------------
 '    ' 'contains' 'lexeme' 'spaces' 'the'
(1 row)
```

Use double dollar signs ($$) to mark entries requiring single quotation marks ('').

```
gaussdb=# SELECT $$the lexeme 'Joe''s' contains a quote$$::tsvector;
                    tsvector
-------------------------------------------------
 'Joe''s' 'a' 'contains' 'lexeme' 'quote' 'the'
(1 row)
```

Optionally, positions can be attached to lexemes:

```
gaussdb=# SELECT 'a:1 fat:2 cat:3 sat:4 on:5 a:6 mat:7 and:8 ate:9 a:10 fat:11 rat:12'::tsvector;
                                  tsvector
-------------------------------------------------------------------------------
 'a':1,6,10 'and':8 'ate':9 'cat':3 'fat':2,11 'mat':7 'on':5 'rat':12 'sat':4
(1 row)
```

A position normally indicates the source word's location in the document. Positional information can be used for ranking. Position values range from 1 to 16383. Values greater than 16383 are automatically set to **16383**. Duplicate positions for the same lexeme are discarded.

Lexemes that have positions can further be labeled with a weight, which can be A, B, C, or D. The default value is **D**, which is not displayed in the output.

```
gaussdb=# SELECT 'a:1A fat:2B,4C cat:5D'::tsvector;
          tsvector
----------------------------
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
 'a':1A 'cat':5 'fat':2B,4C
(1 row)
```

Weights are typically used to reflect the document structure, for example, by marking title words differently from body words. Full-text search ranking functions can assign different priorities to different weight markers.

The tsvector type itself does not perform any word normalization. It assumes that the given word has already been properly normalized. The following example is the standard usage of the tsvector type. Example:

```
gaussdb=# SELECT 'The Fat Rats'::tsvector;
     tsvector
--------------------
 'Fat' 'Rats' 'The'
(1 row)
```

For most English text search applications, the preceding words are considered non-normalized, but tsvector does not perform normalization. Therefore, you need to use the to_tsvector function to normalize these words.

```
gaussdb=# SELECT to_tsvector('english', 'The Fat Rats');
   to_tsvector
-----------------
 'fat':2 'rat':3
(1 row)
```

"The" in the preceding example is a stop word. Some words are recognized as stop words due to their high frequency, rendering them ineffective in searches. Consequently, stop words are ignored during the search process, and the to_tsvector function removes them during normalization. However, stop words affect the sequence of words in tsvector (for example, the missing first word in the preceding example), which will affect the ranking result.

tsquery

The tsquery type represents a retrieval condition, stores the terms used for retrieval, and uses the following operators:

- Boolean operators: **&** (AND), **|** (OR), and **!** (NOT).
- Phrase operator (PHRASE): **<->** or **<*n*>**. **<*n*>** indicates that the distance between two words in a document is *n* (leading zeros are allowed). **<->** is equivalent to **<1>**. To parse phrase operators, the GUC parameter **system_function_version** must contain the **parse_phrase_fix** option.

Parentheses can be used to force operator grouping. If there is no parenthesis, **!** (NOT) has the highest priority, and it is followed by **<->** or **<*n*>** (PHRASE), then **&** (AND), and finally **|** (OR).

```
gaussdb=# SELECT 'fat & rat'::tsquery;
    tsquery
----------------
 'fat' & 'rat'
(1 row)

gaussdb=# SELECT 'fat & (rat | cat)'::tsquery;
          tsquery
---------------------------
 'fat' & ( 'rat' | 'cat' )
(1 row)

gaussdb=# SELECT 'fat & rat & ! cat'::tsquery;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
        tsquery
------------------------
 'fat' & 'rat' & !'cat'
(1 row)

gaussdb=# SELECT 'fat <-> cat'::tsquery;
     tsquery
-----------------
 'fat' <-> 'cat'
(1 row)
```

Words in tsquery can be marked with one or more weight letters, which restricts them to match only tsvector lexemes with one of those weights. If the corresponding lexeme of tsvector does not have position information, the weight restriction in tsquery is ignored.

```
gaussdb=# SELECT 'fat:ab & cat'::tsquery;
     tsquery
------------------
 'fat':AB & 'cat'
(1 row)
gaussdb=# SELECT 'fat:1C'::tsvector @@ 'fat:ab'::tsquery AS RESULT;
 result
--------
 f
(1 row)

gaussdb=# SELECT 'fat'::tsvector @@ 'fat:ab'::tsquery AS RESULT;
 result
--------
 t
(1 row)
```

In addition, lexemes in a tsquery can be labeled with asterisks (*) to specify prefix matching:

```
gaussdb=# SELECT 'super:*'::tsquery;
  tsquery
-----------
 'super':*
(1 row)
```

This query will match any word in a tsvector that begins with "super".

Note that to_tsquery performs normalization in the same way as other functions. The following example returns true:

```
gaussdb=# SELECT to_tsvector( 'seriousness' ) @@ to_tsquery( 'series:*' ) AS RESULT;
  result
----------
 t
(1 row)
```

After the "series" is processed, the "seri" is obtained. In this way, the "seriousness" can be matched.

```
gaussdb=# SELECT to_tsquery('series:*');
 to_tsquery
------------
 'seri':*
(1 row)
```

Note that the tsquery type itself does not perform any word normalization, so you need to normalize the words before converting to the tsquery type. The to_tsquery function is used to perform the following normalization:

```
gaussdb=# SELECT to_tsquery('Fat:ab & Cats');
    to_tsquery
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
------------------
 'fat':AB & 'cat'
(1 row)
```

1.3.12 JSON/JSONB Types

JavaScript Object Notation (JSON) data can be a single scalar, an array, or a key-value pair object. The array and object can be called a container:

- Scalar: a single number, Boolean value, string, or **null**.
- Array: defined in a pair of square brackets ([]), in which elements can be any type of JSON data, and are not necessarily of the same type.
- Object: defined in a pair of braces ({}), in which objects are stored in the format of *key:value*. Each key must be a string enclosed by a pair of double quotation marks (""), and its value can be any type of JSON data. In case of duplicate keys, the last key value will be used.

GaussDB provides the JSON and JSONB data types to store JSON data. In the preceding information:

- The JSON data type stores the complete copy of the input text and parses the data when the data is used. During this process, the entered spaces, duplicate keys, and sequence are retained.
- The JSONB data type stores data in binary format. During parsing, JSONB deletes semantic-irrelevant details and duplicate keys, and sorts key values, so that the data does not need to be parsed again during use.

Both data types are JSON and accept the same string as input. The difference between them lies in the efficiency. Because JSON data type stores a complete copy of the input text, the data must be parsed on every execution. In contrast, JSONB data is stored in its parsed binary form and can be processed faster, though this makes it slightly slower to input due to the conversion mechanism. In addition, because the JSONB data form is normalized, it supports more operations, for example, comparing sizes according to a specific rule. In addition, JSONB also supports indexing, which is a significant advantage.

Input Format

An input must be a JSON-compliant string, which is enclosed in single quotation marks ('').

null (null-json): The value can only be **null** in lowercase.

```
gaussdb=# SELECT 'null'::json;   -- suc
 json
------
 null
(1 row)

gaussdb=# SELECT 'NULL'::jsonb;  -- err
ERROR:  invalid input syntax for type json
```

Number (num-json): The value can be a positive or negative integer, decimal fraction, or 0. The scientific notation is supported.

```
gaussdb=# SELECT '1'::json;
 json
------
 1
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
(1 row)

gaussdb=# SELECT '-1.5'::json;
 json
------
 -1.5
(1 row)

gaussdb=# SELECT '-1.5e-5'::jsonb, '-1.5e+2'::jsonb;
   jsonb   | jsonb
-----------+-------
 -0.000015 | -150
(1 row)

gaussdb=# SELECT '001'::json, '+15'::json, 'NaN'::json;  -- Redundant leading zeros, plus signs (+), NaN, and infinity are not supported.
ERROR:  invalid input syntax for type json
```

Boolean (bool-json): The value can only be **true** or **false** in lowercase.

```
gaussdb=# SELECT 'true'::json;
 json
------
 true
(1 row)

gaussdb=# SELECT 'false'::jsonb;
 jsonb
-------
 false
(1 row)
```

String (str-json): The value must be a string enclosed in double quotation marks ("").

```
gaussdb=# SELECT '"a"'::json;
 json
------
 "a"
(1 row)

gaussdb=# SELECT '"abc"'::jsonb;
 jsonb
-------
 "abc"
(1 row)
```

Array (array-json): Arrays are enclosed in square brackets ([]). Elements in the array can be any valid JSON data, and are unnecessarily of the same type.

```
gaussdb=# SELECT '[1, 2, "foo", null]'::json;
        json
--------------------
 [1, 2, "foo", null]
(1 row)

gaussdb=# SELECT '[]'::json;
 json
------
 []
(1 row)

gaussdb=# SELECT '[1, 2, "foo", null, [[]], {}]'::jsonb;
             jsonb
--------------------------------
 [1, 2, "foo", null, [[]], {}]
(1 row)
```

Object (object-json): The value is enclosed in braces ({}). The key must be a JSON-compliant string, and the value can be any valid JSON string.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gaussdb=# SELECT '{}'::json;
 json
------
 {}
(1 row)

gaussdb=# SELECT '{"a": 1, "b": {"a": 2,  "b": null}}'::json;
                json
-------------------------------------
 {"a": 1, "b": {"a": 2,  "b": null}}
(1 row)

gaussdb=# SELECT '{"foo": [true, "bar"], "tags": {"a": 1, "b": null}}'::jsonb;
                        jsonb
-----------------------------------------------------
 {"foo": [true, "bar"], "tags": {"a": 1, "b": null}}
(1 row)
```

NOTICE

- Note that **'null'::json** and **null::json** are different, which are similar to the strings **str="null"** and **str=null**.
- For numbers, when scientific notation is used, JSONB expands them, while JSON stores an exact copy of the input text.

JSONB Advanced Features

- Precautions
  - It cannot be used as a partition key.
  - Foreign tables are not supported.

The main difference between JSON and JSONB lies in the storage mode. JSONB stores the parsed binary format, which reflects the JSON hierarchy and facilitates direct access. Therefore, JSONB has more advanced features than JSON.

- Format normalization
  - After the input object-json string is parsed into JSONB binary format, semantically irrelevant details, such as spaces, are automatically removed.

    ```
    gaussdb=# SELECT '   [1, " a ", {"a"    :1     }]   '::jsonb;
           jsonb
    ----------------------
     [1, " a ", {"a": 1}]
    (1 row)
    ```

  - For object-json, duplicate key-values are deleted and only the last key-value is retained. For example:

    ```
    gaussdb=# SELECT '{"a" : 1, "a" : 2}'::jsonb;
      jsonb
    ----------
     {"a": 2}
    (1 row)
    ```

  - For object-json, key-values will be re-sorted. The collation rule is as follows: 1. Longer key-values are sorted last. 2. If the key-values are of the same length, the key-values with a larger ASCII code are sorted after the key-values with a smaller ASCII code:

    ```
    gaussdb=# SELECT '{"aa" : 1, "b" : 2, "a" : 3}'::jsonb;
              jsonb
    ---------------------------
    ```

```
{"a": 3, "b": 2, "aa": 1}
(1 row)
```

- Size comparison

  Format normalization ensures that only one form of JSONB data exists in the same semantics. Therefore, sizes may be compared according to a specific rule.

  - First, type comparison: object-jsonb > array-jsonb > bool-jsonb > num-jsonb > str-jsonb > null-jsonb
  - Content comparison if the data type is the same:
    - str-jsonb: The default text sorting rule of the database is used for comparison. A positive value indicates greater than, a negative value indicates less than, and **0** indicates equal.
    - num-jsonb: numeric comparison
    - bool-jsonb: **true** > **false**
    - array-jsonb: long elements > short elements. If the lengths are the same, compare each element in sequence.
    - object-jsonb: If the length of a key-value pair is longer than that of a short key-value pair, the keys are compared first, and then the values are compared.

      NOTE

      For comparison within the object-jsonb type, the final result after format sorting is used for comparison. Therefore, the comparison result may not be intuitive compared with the direct input.

- Creating indexes and primary keys
  - B-tree index

    B-tree indexes and primary keys can be created for the JSONB type.
- Inclusion and existence

  Querying whether a JSON contains some elements or whether some elements exist in a JSON is an important capability of JSONB.

```
-- Simple scalar/primitive values contain only the identical value.
gaussdb=# SELECT '"foo"'::jsonb @> '"foo"'::jsonb;
 ?column?
----------
 t
(1 row)

-- The array on the left contains the character string on the right.
gaussdb=# SELECT '[1, "aa", 3]'::jsonb ? 'aa';
 ?column?
----------
 t
(1 row)

-- The array on the left contains all elements of the array on the right, regardless of the sequence and repetition.
gaussdb=# SELECT '[1, 2, 3]'::jsonb @> '[1, 3, 1]'::jsonb;
 ?column?
----------
 t
(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
-- The object-json on the left contains all key-value pairs of object-json on the right.
gaussdb=# SELECT '{"product": "PostgreSQL", "version": 9.4, "jsonb":true}'::jsonb @>
'{"version":9.4}'::jsonb;
 ?column?
----------
 t
(1 row)

-- The array on the left does not contain all elements of the array on the right. The three elements on
the left are 1, 2, and [1,3], but the elements on the right are 1 and 3.
gaussdb=# SELECT '[1, 2, [1, 3]]'::jsonb @> '[1, 3]'::jsonb;
 ?column?
----------
 f
(1 row)

gaussdb=# SELECT '{"foo": {"bar": "baz"}}'::jsonb @> '{"bar": "baz"}'::jsonb;
 ?column?
----------
 f
(1 row)
```

For details about the operators, see **JSON/JSONB Functions and Operators**.

- Functions and operators

  For details about the functions and operators supported by the JSON/JSONB type, see **JSON/JSONB Functions and Operators**.

  NOTE

  GINs can be used to effectively search for keys or key-value pairs that appear in a large number of JSONB documents (datums). Two GIN operator classes (jsonb_ops and jsonb_hash_ops) are provided for different performance and flexibility choices. The default GIN operator class supports @>, <@, ?, ?&, and ?| operator query. The non-default GIN operator class jsonb_hash_ops supports only the @> and <@ operators.

  Internal functions used by GIN indexes and JSON/JSONB aggregate functions:

  - gin_compare_jsonb
  - gin_consistent_jsonb
  - gin_consistent_jsonb_hash
  - gin_extract_jsonb
  - gin_extract_jsonb_hash
  - gin_extract_jsonb_query
  - gin_extract_jsonb_query_hash
  - gin_triconsistent_jsonb
  - gin_triconsistent_jsonb_hash

1.3.13 HLL Type

HyperLogLog (HLL) is an approximation algorithm for efficiently counting the number of distinct values in a data set. It features faster computing and lower space usage. You only need to store HLL data structures, instead of data sets. When new data needs to be collected, the database performs hash calculation on the data and inserts the data into the HLL. Then, you can obtain the final result based on the HLL.

Table 1-21 compares HLL with other algorithms.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 1-21 Comparison between HLL and other algorithms

Item	Sorting Algorithm	Hash Algorithm	HLL
Time complexity	O(nlogn)	O(n)	O(n)
Space complexity	O(n)	O(n)	log(logn)
Error rate	0	0	≈0.8%
Storage space requirement	Size of original data	Size of original data	The maximum size is 16 KB by default.

HLL has advantages in both the computing speed and storage efficiency. In terms of time complexity, the sorting algorithm needs O(*nlogn*) time for sorting, and the hash algorithm and HLL need O(*n*) time for full table scanning. However, in terms of storage efficiency, the sorting algorithm and hash algorithm need to store raw data before collecting statistics, which consumes a large amount of storage space. The HLL algorithm does not need to store raw data. It only needs to maintain the HLL data structure, saving a lot of storage space. By default, the maximum space of the HLL data structure is about 16 KB.

NOTICE

- In the current default specifications, the maximum number of distinct values that can be calculated is about 1.1e + 15, and the error rate is about 0.8%. If the calculation result exceeds the maximum, the error rate of the calculation result will increase, or the calculation will fail and an error will be reported.
- When using this feature for the first time, you need to evaluate the distinct values of the service, properly select configuration parameters, and perform verification to ensure that the accuracy meets requirements.
  - By default, the maximum number of distinct values that can be calculated is 1.1e+15. If the number of distinct values is **NaN**, you need to adjust **log2m** or use another algorithm to calculate the number of distinct values.
  - Although the hash algorithm has a low probability of hash conflicts, you are advised to select two or three different hash seeds for verification when using the hash algorithm for the first time. If the calculation results of the seeds are similar, you can select any of them as the hash seed.

Table 1-22 describes main HLL data structures.

Table 1-22 Main HLL data structures

Data Type	Description
HLL	The HLL header is a 27-byte column. By default, the data length ranges from 0 KB to 16 KB. The distinct value can be obtained.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

When you create an HLL data type, 0 to 4 input parameters are supported. The parameter meanings and specifications are the same as those of the hll_empty function. The first parameter is **log2m**, indicating the logarithm of the number of buckets, and its value ranges from 10 to 16. The second parameter is **log2explicit**, indicating the threshold in explicit mode, and its value ranges from 0 to 12. The third parameter is **log2sparse**, indicating the threshold of the Sparse mode, and its value ranges from 0 to 14. The fourth parameter is **duplicatecheck**, indicating whether to enable duplicate check, and its value ranges from 0 to 1. When the input parameter is set to **–1**, the default value of the HLL parameter is used. You can run the **\d** or **\d+** command to view the parameters of the HLL type.

NOTE

When the HLL data type is created, the result varies depending on the input parameter behavior:

- When creating an HLL type, do not set the input parameter or set it to **–1**. Use the default value of the corresponding HLL parameter.
- If a valid value is set for the input parameter, the corresponding HLL parameter uses the input value.
- If the input value is invalid, an error is reported when the HLL type is created.

```
-- Create an HLL table without specifying input parameters.
gaussdb=# CREATE TABLE t1 (id integer, set hll);
gaussdb=# \d t1
      Table "public.t1"
 Column |  Type   | Modifiers
--------+---------+-----------
 id     | integer |
 set    | hll     |

-- Create an HLL table, specify the first two input parameters, and use the default values for the last two input parameters.
gaussdb=# CREATE TABLE t2 (id integer, set hll(12,4));
gaussdb=# \d t2
          Table "public.t2"
 Column |      Type      | Modifiers
--------+----------------+-----------
 id     | integer        |
 set    | hll(12,4,12,0) |

-- Create an HLL table, specify the third input parameter, and use default values for other parameters.
gaussdb=# CREATE TABLE t3(id int, set hll(-1,-1,8,-1));
gaussdb=# \d t3
          Table "public.t3"
 Column |      Type      | Modifiers
--------+----------------+-----------
 id     | integer        |
 set    | hll(14,10,8,0) |

-- When a user creates an HLL table and specifies an invalid input parameter, an error is reported.
gaussdb=# CREATE TABLE t4(id int, set hll(5,-1));
ERROR:  log2m = 5 is out of range, it should be in range 10 to 16, or set -1 as default

-- Drop the created HLL table.
gaussdb=# DROP TABLE t1,t2,t3;
DROP TABLE
```

NOTE

When inserting an HLL object to an HLL table, ensure that the parameters of the HLL type are the same as those of the inserted object. Otherwise, an error is reported.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
-- Create an HLL table.
gaussdb=# CREATE TABLE t1(id integer, set hll(14));

-- Insert an HLL object to a table. The insertion succeeds because parameter types are consistent.
gaussdb=# INSERT INTO t1 VALUES (1, hll_empty(14,-1));

-- Insert an HLL object to a table. The insertion fails because parameter types are inconsistent.
gaussdb=# INSERT INTO t1(id, set) VALUES (1, hll_empty(14,5));
ERROR:  log2explicit does not match: source is 5 and dest is 10

-- Drop the table.
gaussdb=# DROP TABLE t1;
```

The following describes HLL application scenarios:

- Scenario 1: "Hello World"

  The following example shows how to use the HLL data type:

  ```
  -- Create an HLL table.
  gaussdb=# CREATE TABLE helloworld (id integer, set hll);

  -- Insert an empty HLL to the table.
  gaussdb=# INSERT INTO helloworld(id, set) VALUES (1, hll_empty());

  -- Add a hashed integer to the HLL.
  gaussdb=# UPDATE helloworld SET set = hll_add(set, hll_hash_integer(12345)) WHERE id = 1;

  -- Add a hashed string to the HLL.
  gaussdb=# UPDATE helloworld SET set = hll_add(set, hll_hash_text('hello world')) WHERE id = 1;

  -- Obtain the number of distinct values of the HLL.
  gaussdb=# SELECT hll_cardinality(set) FROM helloworld WHERE id = 1;
   hll_cardinality
  -----------------
                2
  (1 row)

  -- Drop the table.
  gaussdb=# DROP TABLE helloworld;
  ```

- Scenario 2: Collect statistics about website visitors.

  The following example shows how an HLL collects statistics on the number of users visiting a website within a period of time:

  ```
  -- Create a raw data table to show that a user has visited the website at a certain time.
  gaussdb=# CREATE TABLE facts (
          date            date,
          user_id         integer
  );

  -- Create a raw data table to show that a user has visited the website at a certain time.
  gaussdb=# INSERT INTO facts VALUES ('2019-02-20', generate_series(1,100));
  gaussdb=# INSERT INTO facts VALUES ('2019-02-21', generate_series(1,200));
  gaussdb=# INSERT INTO facts VALUES ('2019-02-22', generate_series(1,300));
  gaussdb=# INSERT INTO facts VALUES ('2019-02-23', generate_series(1,400));
  gaussdb=# INSERT INTO facts VALUES ('2019-02-24', generate_series(1,500));
  gaussdb=# INSERT INTO facts VALUES ('2019-02-25', generate_series(1,600));
  gaussdb=# INSERT INTO facts VALUES ('2019-02-26', generate_series(1,700));
  gaussdb=# INSERT INTO facts VALUES ('2019-02-27', generate_series(1,800));

  -- Create another table and specify an HLL column:
  gaussdb=# CREATE TABLE daily_uniques (
     date            date UNIQUE,
     users           hll
  );

  -- Group data by date and insert the data into the HLL:
  gaussdb=# INSERT INTO daily_uniques(date, users)
     SELECT date, hll_add_agg(hll_hash_integer(user_id))
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
    FROM facts
    GROUP BY 1;

-- Calculate the numbers of users visiting the website every day.
gaussdb=# SELECT date, hll_cardinality(users) FROM daily_uniques ORDER BY date;
    date    | hll_cardinality
------------+------------------
 2019-02-20 |              100
 2019-02-21 | 200.217913059312
 2019-02-22 |  301.76494508014
 2019-02-23 | 400.862858326446
 2019-02-24 | 502.626933349694
 2019-02-25 | 601.922606454213
 2019-02-26 | 696.602316769498
 2019-02-27 | 798.111731634412
(8 rows)

-- Calculate the number of users who had visited the website in the week from February 20, 2019 to
February 26, 2019.
gaussdb=# SELECT hll_cardinality(hll_union_agg(users)) FROM daily_uniques WHERE date >=
'2019-02-20'::date AND date <= '2019-02-26'::date;
 hll_cardinality
------------------
 696.602316769498
(1 row)

-- Calculate the number of users who had visited the website yesterday but have not visited the
website today:
gaussdb=# SELECT date, (#hll_union_agg(users) OVER two_days) - #users AS lost_uniques FROM
daily_uniques WINDOW two_days AS (ORDER BY date ASC ROWS 1 PRECEDING);  -- The default
compatibility details (M-compatibility) are listed as follows:
    date    | lost_uniques
------------+--------------
 2019-02-20 |            0
 2019-02-21 |            0
 2019-02-22 |            0
 2019-02-23 |            0
 2019-02-24 |            0
 2019-02-25 |            0
 2019-02-26 |            0
 2019-02-27 |            0
(8 rows)

-- Drop the table.
gaussdb=# DROP TABLE facts;
gaussdb=# DROP TABLE daily_uniques;
```

- Scenario 3: The data to be inserted does not meet the requirements of the HLL data structure.

  When inserting data into a column of the HLL type, ensure that the data meets the requirements of the HLL data structure. If the data does not meet the requirements after being parsed, an error will be reported. In the following example, **'E\\1234'** to be inserted does not meet the requirements of the HLL data structure after being parsed. As a result, an error is reported.

```
gaussdb=# CREATE TABLE test(id integer, set hll);
gaussdb=# INSERT INTO test VALUES(1, 'E\\1234');
ERROR:  not a hll type, size=6 is not enough
gaussdb=# DROP TABLE test;
```

1.3.14 Range Types

A range type is a data type that represents the range of a value of an element type (called the subtype of a range). For example, the range of timestamp can be used to indicate the reservation time period of a meeting room. In this case, the data type is tsrange (short for range of timestamp), and the timestamp is the

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

subtype. The subtype must be ordered, so that the element value can be clearly specified within, before, after a range.

Range types have the following advantages: They can express multiple element values as a single range value, and clearly express concepts such as range overlapping. For example, time and date ranges used for time arrangement, price ranges, and instrument ranges can be expressed.

Built-in Range

The system provides the following built-in range types:

- int4range: integer range.
- int8range: bigint range.
- numrange: numeric range.
- tsrange: range of timestamp without the time zone.
- tstzrange: range of timestamp with the time zone
- daterange: date range.

In addition, you can customize range types. For details, see **CREATE TYPE**.

Example

```
-- Create a table and insert data into the table.
gaussdb=# CREATE TABLE reservation (room int, during tsrange);
gaussdb=# INSERT INTO reservation VALUES (1108, '[2010-01-01 14:30, 2010-01-01 15:30)');

-- Check whether the range contains the specified data.
gaussdb=# SELECT int4range(10, 20) @> 3;
 ?column?
----------
 f
(1 row)

-- Check whether the two ranges overlap.
gaussdb=# SELECT numrange(11.1, 22.2) && numrange(20.0, 30.0);
 ?column?
----------
 t
(1 row)

-- Upper bound extraction.
gaussdb=# SELECT upper(int8range(15, 25));
 upper
-------
    25
(1 row)

-- Calculate the intersection.
gaussdb=# SELECT int4range(10, 20) * int4range(15, 25);
 ?column?
----------
 [15,20)
(1 row)

-- Check whether the range is empty.
gaussdb=# SELECT isempty(numrange(1, 5));
 isempty
---------
 f
(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
-- Drop the table.
gaussdb=# DROP TABLE reservation;
```

See the complete list of operators and functions on a range type in **Range Functions and Operators**.

> **NOTE**
>
> In ORA-compatible mode, after the **mapping_date_to_datea** parameter is enabled, the DATE type is mapped to the DATEA type. The DATEA type does not support being used as a range type, and the daterange function does not support the DATEA type as an input parameter.

Including and Excluding Bounds

Each non-empty range has two bounds, a lower bound and an upper bound. All values between the upper and lower bounds are included in the range. An inclusion bound means that the bound value itself is included in the range, while an exclusion bound means that the bound value is not included in the range.

In the textual form of a range, the inclusion lower bound is expressed as "[", and the exclusion lower bound is expressed as "("; the inclusion upper bound is expressed as "]", and the exclusion upper bound is expressed as ")". For details, see **Range Input/Output**.

The lower_inc and upper_inc functions detect the upper and lower bounds of a range value, respectively.

Infinite (Unbounded) Range

When the lower bound of a range is unbounded, it means that all values less than the upper bound are included in the range. Similarly, when the upper bound of a range is unbounded, all values greater than the lower bound are included in the range. When both the upper and lower bounds are unbounded, all values of the element type are considered within the range. When the upper bound and the lower bound of the range are not set, that is, the upper bound is positive infinity and the lower bound is negative infinity, the range is an infinite (unbounded) range.

Element types with the **infinity** values can be used as explicit bound values. For example, the range of timestamp [today,infinity) indicates that the special timestamp value **infinity** is not included, which is similar to [today,). The range of timestamp [today,infinity] indicates that the special timestamp value infinity is included, which is similar to [today,].

The lower_inf and upper_inf functions detect the infinite upper and lower bounds of a range, respectively.

Range Input/Output

The input of a range value must follow one of the following formats:

```
(lower-bound, upper-bound)
(lower-bound, upper-bound]
[lower-bound, upper-bound)
[lower-bound, upper-bound]
Empty
```

The output of a range value must follow one of the following formats:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
[lower-bound, upper-bound)
Empty
```

Parentheses or square brackets are used to indicate whether the upper and lower bounds are included or excluded. **empty** specifies an empty range (a range that does not contain vertices).

The value of *lower-bound* can be a valid input string of the subtype or null, indicating that there is no lower bound. Similarly, *upper-bound* can be a valid input string of the subtype or null, indicating that there is no upper bound.

The double quotation marks ("") are required for quotation if a bound value contains parentheses (), square brackets [], commas (,), double quotation marks (""), or backslashes (\). Otherwise, those characters will be considered as part of the range syntax. If the quoted bound value contains double quotation marks ("") or backslashes (\), add a backslash (\) before them for escape. (Two consecutive double quotation marks in the quoted bound value indicate one double quotation mark, which is the same as the single quotation mark escape logic in SQL strings.) In addition, all characters that may be parsed as range syntax must be escaped. An empty string boundary value must be written as **""**. If no any value is written, it indicates an infinite bound.

Spaces are allowed before and after a range value, but any space between parentheses or square brackets is used as part of the upper or lower bound value (whether the space has semantics depends on the element type).

Examples:

```
-- 3 is included, 7 is not included, and all values between 3 and 7 are included.
gaussdb=# SELECT '[3,7)'::int4range;
 int4range
-----------
 [3,7)
(1 row)
-- 3 and 7 are not included, but all values between 3 and 7 are included.
gaussdb=# SELECT '(3,7)'::int4range;
 int4range
-----------
 [4,7)
(1 row)
-- Only a single value 4 is included.
gaussdb=# SELECT '[4,4]'::int4range;
 int4range
-----------
 [4,5)
(1 row)
-- Any value is excluded (and will be normalized to empty).
gaussdb=# SELECT '[4,4)'::int4range;
 int4range
-----------
Empty
(1 row)
```

Constructing Range

Each range type has a constructor function with the same name. Using constructor functions is often more convenient than writing a range literal constant because it avoids extra references to bound values. Constructor functions receive two or three parameters.

- Two parameters: Construct a range in the standard format (the lower bound is included and the upper bound is excluded).

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- Three parameters: Construct a range according to the boundary type specified by the third parameter. The third parameter must be one of the following strings: (), (], [), or [].

Examples:

```
-- The complete format is: lower bound, upper bound, and textual parameters indicating the inclusion/exclusion of bounds.
gaussdb=# SELECT numrange(1.0, 14.0, '(]');
  numrange
------------
 (1.0,14.0]
(1 row)
-- If the third parameter is ignored, it is '[)' by default.
gaussdb=# SELECT numrange(1.0, 14.0);
  numrange
------------
 [1.0,14.0)
(1 row)
-- For discrete range types (such as int8range), although the third parameter is specified as '(]', the value will be converted to the standard format when being displayed.
gaussdb=# SELECT int8range(1, 14, '(]');
 int8range
-----------
 [2,15)
(1 row)
-- If NULL is used as the bound value, the corresponding bound is infinite.
gaussdb=# SELECT numrange(NULL, 2.2);
 numrange
----------
 (,2.2)
(1 row)
```

Discrete Range

A range element type (such as integer or date) has a clear definition of "step". In these types, if there is no valid value between two elements, they can be called adjacent elements. This is different from a continuous range, in which other element values can be identified between two given values. For example, the range of the numeric type is continuous, and the range of the timestamp type is also continuous. (Although timestamp has limited precision and can be considered discrete in theory, it can also be considered continuous because its step is not concerned.)

Another feature of the discrete range type is that each element value in the range has a next value and a previous value. Based on this feature, you can switch between inclusion and exclusion attributes of a range bound by replacing it with the original given next or previous element value. For example, in an integer range type, [4,8] and (3,9) represent the same set of values, but not for numeric ranges.

A discrete range type should have a regularization function that knows the specified step size of the element type. The regularization function is used to convert different range expressions with the same value set to the same format, in particular consistent with the inclusion or exclusion bounds. If you do not specify a regularization function, ranges with different formats will always be considered as unequal, even if they actually express the same set of values.

The built-in range types int4range, int8range, and daterange use the standard format that includes the lower bound and excludes the upper bound, that is, [). However, user-defined range types can use other conventions.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Index

In addition, B-tree indexes can be created on table columns of the range type. For such indexes, only the equality operation is meaningful. Although the B-tree sorting order is defined for range values when the < and > operators are used, the sorting order is random and has limited value in actual applications. The B-tree support for range types is primarily designed to allow sorting within a query, rather than creating an index.

1.3.15 OID Types

GaussDB uses object identifiers (OIDs) as primary keys in system catalogs. You are advised not to use the OID column as the primary key in user-created tables. The OID type is implemented using a 4-byte unsigned integer. The system does not automatically add the OID column to user-created tables. **Table 1-23** describes the OID types.

Table 1-23 OID types

Name	Reference	Description	Examples
OID	-	OID represented in digits.	564182
CID	-	32-bit command identifier. It is the data type of the system columns **cmin** and **cmax**.	-
XID	-	64-bit transaction identifier. It is the data type of the system columns **xmin** and **xmax**.	-
TID	-	Row identifier. It is the data type of the system column **ctid**. A row ID is a pair (block number, tuple index within block) that identifies the physical location of the row within its table.	-
REGCONFIG	pg_ts_config	Text search configuration.	english
REGDICTIONARY	pg_ts_dict	Text search dictionary.	simple
REGOPER	pg_operator	Operator name.	-
REGOPERATOR	pg_operator	Operator with argument types	*(integer,integer) or -(NONE,integer)
REGPROC	pg_proc	Function name.	sum

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Name	Reference	Description	Examples
REGPROCEDURE	pg_proc	Function with parameter types.	sum(int4)
REGCLASS	pg_class	Relation name.	pg_type
REGTYPE	pg_type	Data type name.	integer

The **OID** type is used for a column in the database system catalog.

Example:

```
gaussdb=# SELECT oid FROM pg_class WHERE relname = 'pg_type';
 oid
------
 1247
(1 row)
```

The alias type for **OID** is **REGCLASS** which allows simplified search for **OID** values.

Example:

```
gaussdb=# SELECT attrelid,attname,atttypid,attstattarget FROM pg_attribute WHERE attrelid =
'pg_type'::REGCLASS;
 attrelid |  attname   | atttypid | attstattarget
----------+------------+----------+---------------
     1247 | xc_node_id     |       23 |             0
     1247 | tableoid       |       26 |             0
     1247 | cmax           |       29 |             0
     1247 | xmax           |       28 |             0
     1247 | cmin           |       29 |             0
     1247 | xmin           |       28 |             0
     1247 | oid            |       26 |             0
     1247 | ctid           |       27 |             0
     1247 | typname        |       19 |            -1
     1247 | typnamespace   |       26 |            -1
     1247 | typowner       |       26 |            -1
     1247 | typlen         |       21 |            -1
     1247 | typbyval       |       16 |            -1
     1247 | typtype        |       18 |            -1
     1247 | typcategory    |       18 |            -1
     1247 | typispreferred |       16 |            -1
     1247 | typisdefined   |       16 |            -1
     1247 | typdelim       |       18 |            -1
     1247 | typrelid       |       26 |            -1

1.3.16 Pseudo-Types

The data types of GaussDB contain a number of special-purpose types that are collectively called pseudo-types, as listed in **Table 1-24**. A pseudo-type cannot be used as a column data type, but it can be used to declare a function's argument or result type.

Pseudo-types are useful when a function not only simply accepts or returns a certain SQL data type. **Table 1-24** lists all pseudo-types.

Table 1-24 Pseudo-types

Name	Description
any	Indicates that a function accepts any input data type.
anyelement	Indicates that a function accepts any data type.
anyarray	Indicates that a function accepts any array data type.
anynonarray	Indicates that a function accepts any non-array data type.
anyenum	Indicates that a function accepts any enum data type.
anyrange	Indicates that a function accepts any range data type.
cstring	Indicates that a function accepts or returns a null-terminated C string.
internal	Indicates that a function accepts or returns a server-internal data type.
language_handler	Indicates that a procedural language call handler is declared to return **language_handler**.
fdw_handler	Indicates that a foreign-data wrapper handler is declared to return **fdw_handler**.
record	Identifies a function returning an unspecified row type.
trigger	Indicates that a trigger function is declared to return **trigger**.
void	Indicates that a function returns no value.
opaque	Indicates an obsolete type name that formerly served all the above purposes.

Functions coded in C language (whether built in or dynamically loaded) can declare any pseudo-type data as an input or output argument. When a pseudo-type is used as an argument type, the user needs to ensure that the function can run properly.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Functions coded in procedural languages can use pseudo-types only as allowed by their implementation languages. At present the procedural languages all forbid use of a pseudo-type as an argument type, and allow only void or record as a return type. Some also support polymorphic functions using the anyelement, anyarray, anynonarray, anyenum, and anyrange types.

Each location (parameter or return value) declared as the anyelement type is allowed to have any specific actual data type, but they must all be of the same actual type in any given query.

The internal pseudo-type is used to declare functions that are meant only to be called internally by the database system, and not by direct calling in an SQL query. If a function has at least one internal-type argument, then it cannot be called from SQL. You are advised not to create any function that is declared to return the internal type unless it has at least one internal argument.

Example:

```
-- Create a table.
gaussdb=# CREATE TABLE t1 (a int);

-- Insert two data records.
gaussdb=# INSERT INTO t1 values(1),(2);

-- Create the showall() function.
gaussdb=# CREATE OR REPLACE FUNCTION showall() RETURNS SETOF record
AS $$ SELECT count(*) from t1; $$
LANGUAGE SQL;

-- Call the showall() function.
gaussdb=# SELECT showall();
 showall
---------
 (2)
(1 row)

-- Drop the function.
gaussdb=# DROP FUNCTION showall();

-- Drop the table.
gaussdb=# DROP TABLE t1;
```

1.3.17 Data Types Used by the Ledger Database

The ledger database uses the hash16 data type to store row-level hash digests or table-level hash digests, and uses the hash32 data type to store global hash digests or history table verification hash values.

Table 1-25 Hash types of the ledger database

Name	Description	Storage Space	Range
HASH16	Stored as an unsigned 64-bit integer.	8 bytes	0 to +18446744073709551615

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Name	Description	Storage Space	Range
HASH32	Stored as an unsigned integer array of 16 elements.	16 bytes	Value range of an unsigned integer array of 16 elements.

The hash16 data type is used to store row-level or table-level hash digests in the ledger database. After obtaining the hash sequence of a 16-character hexadecimal string, the system calls the hash16in function to convert the sequence into an unsigned 64-bit integer and stores the integer in a hash16 variable. For example:

```
Hexadecimal string: e697da2eaa3a775b; 64-bit unsigned integer: 16615989244166043483
Hexadecimal string: ffffffffffffffff; 64-bit unsigned integer: 18446744073709551615
```

Example:

```
gaussdb=# CREATE TABLE hash16test(id int, data hash16);
gaussdb=# INSERT INTO hash16test VALUES (1, 'e697da2eaa3a775b');
gaussdb=# SELECT * FROM hash16test;
 id |              data
----+----------------------------------
  1 | e697da2eaa3a775b
(1 row)
gaussdb=# DROP TABLE hash16test;
```

The hash32 data type is used to store the global hash digest or history table verification hash in the ledger database. After obtaining the hash sequence of a 32-character hexadecimal string, the system calls the hash32in function to convert the sequence to an array containing 16 unsigned integer elements. For example:

```
Hexadecimal string: 685847ed1fe38e18f6b0e2b18c00edee
Hash32 array: [104,88,71,237,31,227,142,24,246,176,226,177,140,0,237,238]
```

Example:

```
gaussdb=# CREATE TABLE hash32test(id int, data hash32);
gaussdb=# INSERT INTO hash32test VALUES (1, '685847ed1fe38e18f6b0e2b18c00edee');
gaussdb=# SELECT * FROM hash32test;
 id |              data
----+----------------------------------
  1 | 685847ed1fe38e18f6b0e2b18c00edee
(1 row)
gaussdb=# DROP TABLE hash32test;
```

1.3.18 XML Types

The XML data type can store well-formed documents as defined by the XML standard, as well as content fragments, which are defined by referencing broader "DOCUMENT NODE" XQuery and XPath data models, allowing content fragments to contain multiple top-level elements or character nodes. The expression XMLVALUE IS DOCUMENT can be used to determine whether a specific XML value is a complete document or a document fragment. The internal format of XML is the same as that of the TEXT data type. Its advantage over storing XML data in a TEXT field is that, XML data supports standard XML operation functions based on LIBXML2 and XML standardization check. For details about functions related to XML types, see **Functions of the XML Type**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

The XML parser converts an XML document into an XML DOM object. The document object model (DOM) defines standard methods for accessing and manipulating documents. XML DOM defines standard methods for accessing and manipulating XML documents. XML DOM considers XML documents as a tree structure. All elements can be accessed through the DOM tree, and their content can be modified or deleted. New elements can be created. An element, the text of an element, and the attributes of an element are considered as nodes.

The XML bottom layer uses the same data structure as the TEXT type for storage. The maximum size is 1 GB.

Example:

```
gaussdb=# CREATE TABLE xmltest ( id int, data xml );
gaussdb=# INSERT INTO xmltest VALUES (1, 'one');
gaussdb=# INSERT INTO xmltest VALUES (2, XMLCONCAT(('<?xml version="1.0" encoding="UTF8"
standalone="no"?><bar>foo</bar>'), ('<?xml version="1.0" encoding="UTF8" standalone="no"?><bar>foo</
bar>')));
gaussdb=# SELECT * FROM xmltest ORDER BY 1;
 id |                          data
----+-------------------------------------------------------------------
  1 | one
  2 | <?xml version="1.0" standalone="no"?><bar>foo</bar><bar>foo</bar>
(2 rows)
gaussdb=# DROP TABLE xmltest;
```

The XML type does not support the following operations:

- Logical expressions AND, OR, and NOT.
- Input parameter of a system function that is used as a non-XML operation function.
- Used as a distribution key, partition key, subpartition key, primary key, or unique constraint.
- Implicit conversion related to XML, including the conversion between strings and the XML data type.
- Array expression, row expression, subquery expression, TABLE OF, and TABLE OF INDEX.
- Used to create an ordinary index, unique index, global index, local index, or partial index using XML columns.
- Comparison expressions >, <, >=, <=, =, <>, !=, ^=, <=>, BETWEEN AND, IS DISTINCT FROM, and IS NOT DISTINCT FROM.
- Condition expressions DECODE, NULLIF, GREATEST, and LEAST.
- Parameters of the DISTINCT, GROUP BY, and ORDER BY expressions.
- Aggregate functions, including sum, max, min, avg, list_agg, corr, covar_pop, covar_samp, stddev, stddev_pop, stddev_samp, var_pop, var_samp, variance, bit_and, bit_or, bool_and, bool_or, every, regr_avgx, regr_avgy, regr_count, regr_intercept, regr_r2, regr_slope, regr_sxx, regr_sxy, regr_syy, rank, and spread.
- ODBC-related APIs with binding parameters.

The XML type supports the following operations:

- Physical backup and restoration.
- NULL value determinations IS NULL and IS NOT NULL.
- Condition expressions CASE and COALESCE.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- Global temporary tables and local temporary tables.
- Forcible type conversion.
- Expression indexes.
- Input XML values that comply with the XML standard.
- gs_dump and gs_restore.
- Parallel query, supporting Astore and Ustore.
- Input parameters, output parameters, customized variables, and return values of a user-defined function.
- Input parameters, output parameters, customized variables, and return values of a stored procedure. Stored procedures in autonomous transactions are supported.
- Character processing functions quote_literal(string text) (explicitly converted to the character type) and quote_nullable(string text) (explicitly converted to the character type).
- Aggregate functions count, array_agg, and checksum (explicitly converted to the character type), and string_agg (explicitly converted to the character type).
- If addition, deletion, modification, and query of user-defined composite types involve XML types that are similar to XML columns in ordinary tables, the composite types must be inserted and modified based on the XML syntax.
- JDBC and ODBC operations on XML data types are supported. The SELECT, UPDATE, INSERT, and DELETE operations can be performed on an XML column. You can enter an XML value using the SQL syntax and use the getSQLXML method of the ResultSet class to obtain the XML value. JDBC-related APIs with binding parameters are supported. For example, you can use the setSQLXML method in the PreparedStatement API and the getSQLXML(int columnIndex) method in the ResultSet execution result set API.

  In the calling process, use the java.sql.SQLXML API class to construct an XML object, set the specified object type to Oid.XML, and send the type ID and XML value to the server. After obtaining the result returned from the server, call ResultSet.getString. Then, use the java.sql.SQLXML API class to construct the obtained character string to an XML object. In this case, the system checks whether the content complies with the XML standard again. Therefore, you can also use ResultSet.getString to directly obtain the string object.

1.3.19 XMLType

The XMLType type stores well-formed "documents" that comply with the XML standard. Data is stored in character strings. Its advantage over storing XML data in a TEXT field is that, XMLType data supports standard XML operation functions based on LIBXML2 and XML standardization check. For details about functions related to XMLType, see **Functions of the XMLType Type**.

The XML parser converts an XML document into an XML DOM object. The document object model (DOM) defines standard methods for accessing and manipulating documents. XML DOM defines standard methods for accessing and manipulating XML documents. XML DOM considers XML documents as a tree structure. All elements can be accessed through the DOM tree, and their content can be modified or deleted. New elements can be created. An element, the text of

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

an element, and the attributes of an element are considered as nodes. The maximum size is 1 GB.

Example:

```
gaussdb=# CREATE TABLE xmltypetest(id int, data xmltype);
gaussdb=# INSERT INTO xmltypetest VALUES (1, '<ss/>');
gaussdb=# INSERT INTO xmltypetest VALUES (2, '<xx/>');
gaussdb=# SELECT * FROM xmltypetest ORDER BY 1;
 id | data
----+-------
  1 | <ss/>
  2 | <xx/>
(2 rows)
gaussdb=# DROP TABLE xmltypetest;
```

The XMLType type does not support the following operations:

- Logical expressions AND, OR, and NOT.
- Input parameter of a system function that is used as a non-XMLType operation function.
- Used as a distribution key, partition key, subpartition key, primary key, or unique constraint.
- Implicit conversion related to XMLType, including the conversion between strings and the XMLType data type.
- Array expression, row expression, subquery expression, TABLE OF, and TABLE OF INDEX.
- Used to create an ordinary index, unique index, global index, local index, or partial index using XMLType columns.
- Comparison expressions >, <, >=, <=, =, <>, !=, ^=, <=>, BETWEEN AND, IS DISTINCT FROM, and IS NOT DISTINCT FROM.
- Condition expressions DECODE, NULLIF, GREATEST, and LEAST.
- Parameters of the DISTINCT, GROUP BY, and ORDER BY expressions.
- Aggregate functions, including sum, max, min, avg, list_agg, corr, covar_pop, covar_samp, stddev, stddev_pop, stddev_samp, var_pop, var_samp, variance, bit_and, bit_or, bool_and, bool_or, every, regr_avgx, regr_avgy, regr_count, regr_intercept, regr_r2, regr_slope, regr_sxx, regr_sxy, regr_syy, rank, and spread.
- ODBC-related APIs with binding parameters.

The XMLType type supports the following operations:

- Physical backup and restoration.
- NULL value determinations IS NULL and IS NOT NULL.
- Condition expressions CASE and COALESCE.
- Global temporary tables and local temporary tables.
- Forcible type conversion.
- Expression indexes.
- Input XMLType values that comply with the XML standard.
- gs_dump and gs_restore.
- Parallel query, supporting Astore and Ustore.
- Input parameters, output parameters, customized variables, and return values of a user-defined function.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- Input parameters, output parameters, customized variables, and return values of a stored procedure. Stored procedures in autonomous transactions are supported.
- Character processing functions quote_literal(string text) (explicitly converted to the character type) and quote_nullable(string text) (explicitly converted to the character type).
- Aggregate functions count, array_agg, and checksum (explicitly converted to the character type), and string_agg (explicitly converted to the character type).
- If addition, deletion, modification, and query of user-defined composite types involve XMLType types that are similar to XMLType columns in ordinary tables, the composite types must be inserted and modified based on the XMLType syntax.
- You can perform the SELECT, UPDATE, INSERT, or DELETE operation on the column and use the SQL syntax to enter the XMLType value.

You can create a schema named **xmltype**. In the schema, you can create functions, but cannot use schema.func() to call functions defined in the schema.

When the XMLType type is output, the encoding attribute in the XML text declaration is changed to the current database encoding.

1.3.20 ACLItem Type

The ACLItem data type is used to store object permission information. The internal implementation is based on the int type, and the supported format is "*user1*=*privs*/*user2*".

The aclitem[] data type is an array consisting of multiple ACLItem elements. The supported format is "**{***user1*=*privs1*/*user3*, *user2*=*privs2*/*user3***}**".

user1, *user2*, and *user3* indicate the existing users or roles in the database, and *privs* indicates the permissions supported by the database. For details, see **Table 7-105**.

Example:

```
-- Create a user.
gaussdb=# CREATE USER user1 WITH PASSWORD '********';
gaussdb=# CREATE USER user2 WITH PASSWORD '********';
gaussdb=# CREATE USER omm WITH PASSWORD '********';

-- Create a data table table_acl that contains three columns of the int, aclitem, and aclitem[] types.
gaussdb=# CREATE TABLE table_acl (id int,priv aclitem,privs aclitem[]);

-- Insert a data record whose content is (1,'user1=arw/omm','{omm=d/user2,omm=w/omm}') into the
table_acl table.
gaussdb=# INSERT INTO table_acl VALUES (1,'user1=arw/omm','{omm=d/user2,omm=w/omm}');

-- Insert a data record whose content is (2,'user1=aw/omm','{omm=d/user2}') into the table_acl table.
gaussdb=# INSERT INTO table_acl VALUES (2,'user1=aw/omm','{omm=d/user2}');
gaussdb=# SELECT * FROM  table_acl;
 id |     priv      |          privs
----+---------------+-------------------------
  1 | user1=arw/omm | {omm=d/user2,omm=w/omm}
  2 | user1=aw/omm  | {omm=d/user2}
(2 rows)

-- Drop the table and users.
gaussdb=# DROP USER user1;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gaussdb=# DROP USER user2;
gaussdb=# DROP USER omm;
gaussdb=# DROP TABLE table_acl;
```

1.3.21 Array Types

Array types can be used to store several elements of the same type. For details about how to use array types and related functions, see **Arrays**.

Array Type Definition

Generally, an array type is defined by adding square brackets ([]) to the end of the data type name of an array element.

Example 1: Create a table named **sal_emp**. The table has the following columns: **name** of the text type, indicating employee names; **pay_by_quarter** of the integer element type, indicating an array of quarterly salaries; **phone_numbers** of the varchar(11) element type, indicating an array of mobile numbers.

```
gaussdb=# CREATE TABLE sal_emp (
  name            text,
  pay_by_quarter  integer[],
  phone_numbers   varchar(11)[]
);
gaussdb=# DROP TABLE sal_emp;
```

Example 2: Define an array type in other ways. For details about the definition method and behavior, see the comments in the example.

```
gaussdb=# CREATE TABLE sal_emp (
  name             text,
  pay_by_quarter1  integer[][],      -- Two-dimensional array of the int type.
  pay_by_quarter2  integer[3],       -- One-dimensional array of the int type. The size is 3.
  pay_by_quarter3  integer[3][3],    -- Two-dimensional array of the int type. The size of each dimension is 3.
  pay_by_quarter4  integer ARRAY,    -- One-dimensional array of the int type.
  pay_by_quarter5  integer ARRAY[3]  -- One-dimensional array of the int type. The size is 3.
);
gaussdb=# DROP TABLE sal_emp;
```

NOTE

- The number of dimensions can be specified in the definition of an array type. However, this definition is only a part of the type declaration and does not restrict the number of dimensions of the actually stored array.
- The size can be specified in the definition of an array type. However, this definition is only a part of the type declaration and does not restrict the size of the actually stored array.
- An array can have up to six dimensions.
- The restrictions on the number of array elements are as follows:
  - The maximum number of elements is 134217727.
  - The maximum storage space of all elements cannot exceed 1 GB minus 1 byte, that is, 1073741823 bytes.

Array Constructor

An array constructor is an expression used to build array values. A simple array constructor consists of the keyword ARRAY and an expression list of array element values which are separated by commas (,) and enclosed by square brackets ([]). For example:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gaussdb=# SELECT ARRAY[1, 2, 3 + 4];
  array
---------
 {1,2,7}
(1 row)
```

By default, the element type of an array is the common type of member expressions and follows the same type inference rules as the UNION or CASE structure (for details, see **UNION, CASE, and Related Constructs**). You can construct an array to the desired data type through explicit type conversion. The following is an example:

```
gaussdb=# SELECT ARRAY[1, 2, 3]::varchar[];
  array
---------
 {1,2,3}
(1 row)

gaussdb=# SELECT ARRAY['a', 'b', 'c']::varchar[];
  array
---------
 {a,b,c}
(1 row)
```

In addition to the preset basic types, the record type and table type can also be defined as array types. The following is an example:

```
gaussdb=# CREATE TYPE rec IS (c1 int, c2 int);
gaussdb=# SELECT ARRAY[(1, 1), (2, 2)]::rec[];
       array
-------------------
 {"(1,1)","(2,2)"}
(1 row)

gaussdb=# CREATE TABLE tab (c1 int, c2 int);
gaussdb=# SELECT ARRAY[(1, 1), (2, 2)]::tab[];
       array
-------------------
 {"(1,1)","(2,2)"}
(1 row)

gaussdb=# DROP TYPE rec;
gaussdb=# DROP TABLE tab;
```

An array must have a specific type. Therefore, when constructing an empty array, you must specify the required type. The following is an example:

```
gaussdb=# SELECT ARRAY[]::int[];
 array
-------
 {}
(1 row)
```

You can also construct an array from the result of a subquery. In this case, the array constructor consists of the keyword ARRAY and a subquery enclosed in parentheses. The subquery must return only one separate column. The generated one-dimensional array generates an element for each row of the result in the subquery. The element type matches the output column of the subquery. For example:

```
gaussdb=# SELECT ARRAY(SELECT generate_series(1, 6));
     array
---------------
 {1,2,3,4,5,6}
(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Multidimensional array values can be created by nesting array constructors. The ARRAY keyword in the inner constructor can be omitted. For example, the following two examples will produce the same result:

```
gaussdb=# SELECT ARRAY[ARRAY[1,2], ARRAY[3,4]];
     array
---------------
 {{1,2},{3,4}}
(1 row)

gaussdb=# SELECT ARRAY[[1,2], [3,4]];
     array
---------------
 {{1,2},{3,4}}
(1 row)
```

NOTE

- Inner constructors at the same layer must generate subarrays of the same dimension.
- Any type conversion applied to the outer ARRAY constructor is automatically applied to all inner constructors.

String Inputs of the Array Type

To write an array value as a literal constant (constant input), enclose the element values with braces and separate them with commas. The general format of an array constant is as follows:

```
'{ val1 delim val2 delim ... }'
```

In the preceding format, **delim** indicates the delimiter of the element type and is recorded in the **typdelim** column in the pg_type catalog. Each **val** can be a constant of the array element type or a subarray. For example:

```
gaussdb=# SELECT '{1, 2, 3}'::int[] AS RESULT;
 result
---------
 {1,2,3}
(1 row)

gaussdb=# SELECT '{{1, 2, 3}, {4, 5, 6}, {7, 8, 9}}'::int[] AS RESULT;
         result
-----------------------------
 {{1,2,3},{4,5,6},{7,8,9}}
(1 row)
```

Double quotation marks can be used around any element value, and double quotation marks must be used when the element value contains special characters such as commas or braces.

The following example indicates that there is an array of the varchar type and there are seven varchar elements in total. The elements are as follows:

- Character string containing a space.
- Character string whose value is **"NULL"**.
- Character string whose value is **NULL**.
- Character string containing a backslash (\).
- Character string containing a left brace ({).
- Character string containing a right brace (}).
- Character string containing a comma (,).

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gaussdb=# SELECT '{" ", "NULL", null, "\\", "{", "}", ","}'::varchar[] AS RESULT;
              result
-----------------------------------
 {" ","NULL",NULL,"\\","{","}",","}
(1 row)
```

NOTE

- For array string constant inputs, if the array element value is an empty string, contains braces, delimiters, double quotation marks, backslashes, or spaces, or matches the keyword NULL, these elements are enclosed in double quotation marks. An additional backslash is input if the element value contains double quotation marks or backslashes.
- The keyword NULL is case-insensitive.
- The input spaces not enclosed in double quotation marks are automatically ignored.
- You are advised to use the array constructor instead of string constants to create arrays.

String Outputs of the Array Type

The output of an array value consists of the output of the array element type plus some modifiers indicating the array structure. These modifiers consist of braces ({}) around array values plus delimiters between adjacent items. In a multidimensional array, each dimension has its own level of braces and contains delimiters between adjacent braces at the same level.

The data of the array type contains special characters (in the following description). The following is an example of character string output:

```
gaussdb=# SELECT ARRAY['{', '}', 'hello, world', '"', '\', '  ', NULL] AS RESULT;
                  array
-----------------------------------------------
 {"{","}","hello, world","\"","\\","  ",NULL}
(1 row)
```

NOTE

For array string constant outputs, if the array element value is an empty string or contains braces, delimiters, double quotation marks, backslashes, or spaces, or the element is **NULL**, these element outputs are automatically enclosed in double quotation marks. An additional backslash is output if the element value contains double quotation marks or backslashes.

Use of Array Types

The following is an example of using the array type:

```
-- Create a table with array columns and insert some data.
gaussdb=# CREATE TABLE orders (
  name  varchar,
  items varchar[]
);
gaussdb=# INSERT INTO orders VALUES('a', ARRAY['Apple', 'Orange', 'Pear']);
gaussdb=# INSERT INTO orders VALUES('b', ARRAY['Mineral water', 'Coke', 'Sprite']);
gaussdb=# INSERT INTO orders VALUES('c', ARRAY['Mouse', 'Keyboard', 'Earphone']);
gaussdb=# INSERT INTO orders VALUES('d', '{Cabbage, Potato, Eggplant}');

-- Query data.
gaussdb=# SELECT * FROM orders ORDER BY name;
 name |       items
------+--------------------
 a    | {Apple,Orange,Pear}
 b    | {Mineral water,Coke,Sprite}
 c    | {Mouse,Keyboard,Earphone}
 d    | {Cabbage,Potato,Eggplant}
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
(4 rows)

-- Access array elements.
gaussdb=# SELECT items[1] FROM orders ORDER BY name;
 items
--------
 Apple
 Mineral water
 Mouse
 Cabbage
(4 rows)

-- If the accessed element exceeds the range or the accessed index is NULL, NULL is returned.
gaussdb=# SELECT items[4] FROM orders ORDER BY name;
 items
-------

(4 rows)

gaussdb=# SELECT items[null] FROM orders ORDER BY name;
 items
-------

(4 rows)

-- Access a subarray.
gaussdb=# SELECT items[1:2] FROM orders ORDER BY name;
     items
---------------
 {Apple,Orange}
 {Mineral water,Coke}
 {Mouse,Keyboard}
 {Cabbage,Potato}
(4 rows)

-- Update the entire array.
gaussdb=# UPDATE orders SET items = ARRAY['Banana', 'Watermelon', 'Strawberry'] WHERE name = 'a';
gaussdb=# SELECT items FROM orders WHERE name = 'a';
      items
------------------
 {Banana,Watermelon,Strawberry}
(1 row)

-- Update the elements of an array.
gaussdb=# UPDATE orders SET items[1] = 'Mango' WHERE name = 'a';
gaussdb=# SELECT items FROM orders WHERE name = 'a';
      items
------------------
 {Mango,Watermelon,Strawberry}
(1 row)

-- Update the element fragment of an array.
gaussdb=# UPDATE orders SET items[1:2] = ARRAY['Computer','Phone'] WHERE name = 'c';
gaussdb=# SELECT items FROM orders WHERE name = 'c';
      items
------------------
 {Computer,Mobile phone,Earphone}
(1 row)

-- Add an array element. All unassigned elements between the last element of the original array and the
new element are set to NULL.
gaussdb=# UPDATE orders SET items[4] = 'Display' WHERE name = 'c';
gaussdb=# SELECT items FROM orders WHERE name = 'c';
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
          items
-------------------------
 {Computer,Mobile phone,Earphone,Display}
(1 row)

gaussdb=# UPDATE orders SET items[6] = 'Display 2' WHERE name = 'c';
gaussdb=# SELECT items FROM orders WHERE name = 'c';
                items
--------------------------------------
 {Computer,Mobile phone,Earphone,Display,NULL,Display 2}
(1 row)

-- Drop the table.
gaussdb=# DROP TABLE orders;
```

1.3.22 Data Types Supported by the Vectorized Executor

Table 1-26 lists the data types supported by the vectorized executor.

Table 1-26 Data types supported by the vectorized executor

Category	Data Type	Length
Numeric Types	tinyint [unsigned]	1

	circle[]	-1
Vector Types	floatvector	-1
	boolvector	-1
Other Types	enum	An enum type is a list of several labels. Each label value is a non-empty string, and the string length cannot exceed 63 bytes.

NOTE

Currently, the enum type can be created only in the following mode. For details, see **CREATE TYPE**.

```
CREATE TYPE name AS ENUM (['label' [, ...]]);
```

1.3.23 ROWID Type

The ROWID data type is used to identify a data row in a table and contains key information required for locating the row. In this way, data rows in the table can be quickly located.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

The ROWID data type consists of 29 Base64-encoded characters. **Table 1-27** describes the meaning of each character string.

Table 1-27 Columns of the ROWID type

Column	Description	Character Length	Value Range (Base64 Encoding)
reserve_flag	Reserved flag.	6	**0** (**AAAAAA**) in the current version.
node_slice	Shard ID of a node.	3	The value ranges from 0 (AAA) to 65535 (P//). The actual maximum value is the number of cluster shards.
bucket_id	Bucket ID of the hash bucket table.	3	The value ranges from 0 (AAA) to 32767 (H//). The actual maximum value is the maximum bucket ID of the table. For a non-hash bucket table, the value of this column is fixed at **65535** (**P//**).
table_oid	Table OID.	6	The value ranges from 0 (AAAAAA) to 4294967295 (D/////).
row_no	Row ID.	11	The value ranges from 0 (AAAAAAAAAAA) to 9223372036854775807 (H//////////).

NOTE

The ROWID type does not support the following operations:

- The ROWID type cannot be used as the partitioned key or distribution key of a table.
- The ROWID type does not support HTAP.
- The ROWID type is supported only in Oracle-compatible databases.
- The ROWID type does not support data masking policies.
- The ROWID type cannot be used as the subtype of a user-defined range type. For details, see **Range Types**.
- The ROWID type supports only the JDBC driver.

Examples

```
gaussdb=# CREATE DATABASE ora_test DBCOMPATIBILITY='ORA';
CREATE DATABASE
gaussdb=# \c ora_test
Non-SSL connection (SSL connection is recommended when requiring high-security)
You are now connected to database "ora_test" as user "$user".

-- Create a table.
ora_test=# CREATE TABLE rowid_test(id INT, rwd ROWID) DISTRIBUTE BY HASH(id);
CREATE TABLE

-- Insert data whose value is NULL.
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
ora_test=# INSERT INTO rowid_test VALUES(1, NULL);
INSERT 0 1

-- Insert data that meets the ROWID format.
ora_test=# INSERT INTO rowid_test VALUES(2, 'AAAAAAAAAP//BBBBBAAAAAAAAAAAC');
INSERT 0 1
ora_test=# INSERT INTO rowid_test VALUES(3, 'AAAAAAAAAP//BBBd+AAAAAAAA901/');
INSERT 0 1
ora_test=# INSERT INTO rowid_test VALUES(4, 'AAAAAAAAAP//A12i+AAAAAAAAItn/');
INSERT 0 1
ora_test=# INSERT INTO rowid_test VALUES(5, 'AAAAAAAAAP//CC+uJAAAAAAGASIi9');
INSERT 0 1

-- Insert data that does not meet the ROWID format.
ora_test=# INSERT INTO rowid_test VALUES(6, 'AAAAAAAAAP//BBBd+AAAAAAAA@@@@');
ERROR:  Invalid rowid.
LINE 1: INSERT INTO rowid_test VALUES(6, 'AAAAAAAAAP//BBBd+AAAAAAAA@...
                                         ^
CONTEXT:  referenced column: rwd

-- Insert data that does not meet the ROWID value range.
ora_test=# INSERT INTO rowid_test VALUES(6, 'AAAAAAAAAP/////d+AAAAAAAA901/');
ERROR:  Invalid rowid.
LINE 1: INSERT INTO rowid_test VALUES(6, 'AAAAAAAAAP/////d+AAAAAAAA9...
                                         ^
CONTEXT:  referenced column: rwd

-- View data.
ora_test=# SELECT * FROM rowid_test;
 id |              rwd
----+-------------------------------
  1 |
  2 | AAAAAAAAAP//BBBBBAAAAAAAAAAAC
  3 | AAAAAAAAAP//BBBd+AAAAAAAA901/
  4 | AAAAAAAAAP//A12i+AAAAAAAAItn/
  5 | AAAAAAAAAP//CC+uJAAAAAAGASIi9
(5 rows)

-- Drop the table.
ora_test=# DROP TABLE IF EXISTS rowid_test;
DROP TABLE
ora_test=# \c postgres
Non-SSL connection (SSL connection is recommended when requiring high-security)
You are now connected to database "postgres" as user "$user".
gaussdb=# DROP DATABASE ora_test;
DROP DATABASE
```

Operators

The ROWID type supports comparison operators (=, <>, <, >, <=, and >=). If a comparison operation is performed between the ROWID type and a data type that cannot be implicitly converted to the ROWID type, the error message "Inconsistent datatypes" is displayed. For details about comparison operators, see **Comparison Operators**.

The comparison rules of the ROWID type are as follows: The values of the **node_slice**, **table_oid**, **bucket_id**, and **row_no** columns are compared in sequence.

Examples

```
gaussdb=# CREATE DATABASE ora_test DBCOMPATIBILITY='ORA';
CREATE DATABASE
gaussdb=# \c ora_test
Non-SSL connection (SSL connection is recommended when requiring high-security)
You are now connected to database "ora_test" as user "$user".

-- Compare data of the ROWID type.
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
ora_test=# CREATE OR REPLACE FUNCTION func1 RETURN ROWID AS
ora_test$# DECLARE
ora_test$#     a ROWID;
ora_test$#     b ROWID;
ora_test$# BEGIN
ora_test$#     a := 'AAAAAAAAAP//ABPH//AAAAAAAACAB';
ora_test$#     b := 'AAAAAAAAAP//ABPH//AAAAAAAACAA';
ora_test$#     DBE_OUTPUT.PRINT_LINE((a = b)::text);
ora_test$#     DBE_OUTPUT.PRINT_LINE((a <> b)::text);
ora_test$#     DBE_OUTPUT.PRINT_LINE((a > b)::text);
ora_test$#     DBE_OUTPUT.PRINT_LINE((a < b)::text);
ora_test$#     DBE_OUTPUT.PRINT_LINE((a <= b)::text);
ora_test$#     DBE_OUTPUT.PRINT_LINE((a >= b)::text);
ora_test$#     RETURN a;
ora_test$# END;
ora_test$# /
CREATE FUNCTION

Indexes

Ordinary columns of the ROWID type support B-tree and UB-tree indexes. For details, see **CREATE INDEX**. When ordinary columns of the ROWID type are used for JOIN operations, the HASH JOIN operator is supported. For details, see **Join Queries**.

Examples

```
gaussdb=# CREATE DATABASE ora_test DBCOMPATIBILITY='ORA';
CREATE DATABASE
gaussdb=# \c ora_test
Non-SSL connection (SSL connection is recommended when requiring high-security)
You are now connected to database "ora_test" as user "$user".

ora_test=# CREATE TABLE t1(b ROWID, c INT) WITH (storage_type=ustore);
NOTICE:  The 'DISTRIBUTE BY' clause is not specified. Using 'c' as the distribution column by default.
HINT:  Please use 'DISTRIBUTE BY' clause to specify suitable data distribution column.
CREATE TABLE
ora_test=# CREATE TABLE t2(b ROWID, c INT) WITH (storage_type=astore);
NOTICE:  The 'DISTRIBUTE BY' clause is not specified. Using 'c' as the distribution column by default.
HINT:  Please use 'DISTRIBUTE BY' clause to specify suitable data distribution column.

```

1.3.24 Vector Data Types

Vector data types include floatvector and boolvector.

- The floatvector data type indicates that multidimensional data contains data of the float type, for example, [1.0,3.0,11.0,110.0,62.0,22.0,4.0].

  NOTE

  - The floatvector member supports only single precision. The single-precision range is –3.402E+38 to +3.402E+38, round to six decimal places.
  - The floatvector does not support NULL, NaN, or Inf as elements. If a vector contains NULL values, the database reports an error.
  - The floatvector cannot be NULL. When NULL values are inserted, updated, or converted as vector data, the database reports an error.
  - In some scenarios (when the execution plan is a streaming plan), the numeric precision of floatvector members is controlled by the GUC parameter **extra_float_digits**. This may cause inconsistent calculation results for the same data. Setting **extra_float_digits** to **3** can avoid this problem.

- The boolvector data type indicates that the data contained in multi-dimensional data is of the Boolean type, for example, [0,0,0,0,0,1,0,0,1,0,0,0].

  NOTE

  - Members of the boolvector type can express Boolean data using **t(T)**/**f(F)**, **y(Y)**/**n(N)**, **1**/**0**, **true**/**false**, **yes**/**no**, or **on**/**off**.
  - The boolvector type does not support NULL, NaN, or Inf as elements. If a vector contains NULL values, the database reports an error.
  - The boolvector cannot be NULL. When NULL values are inserted, updated, or converted as vector data, the database reports an error.

Usage of Vector Types

The following is an example of using vector types:

```
-- Create a table that contains vector types and set data dimensions. Dimensions must be specified for vector types during table creation.
gaussdb=# CREATE TABLE t1(id int unique, repr floatvector(4));
gaussdb=# CREATE TABLE t2(id int unique, repr boolvector(3));

-- Insert data.
gaussdb=# INSERT INTO t1 VALUES(0, '[30, 12, 12, 25]');
gaussdb=# INSERT INTO t2 VALUES(1, '[1, 0, 1]');

-- Drop tables.
gaussdb=# DROP TABLE t1;
gaussdb=# DROP TABLE t2;
```

1.4 Character Sets and Collations

A character set provides character encoding rules, and a collation provides character sorting rules. This section describes the character sets and collations in MySQL-compatible GaussDB (that is, **sql_compatibility** is set to **'MYSQL'**). The following character sets, collation rules, and syntax are supported only in MySQL-compatible mode:

For details about the character sets supported by GaussDB, see "ENCODING" in **CREATE DATABASE**. For details about the supported collations, see the PG_COLLATION system catalog.

Some character sets have default collations in MySQL-compatible mode. For details, see **Table 1-398**.

The description of character sets and collations is as follows:

- Each character set has one or more collations and has only one default collation.
- Each collation has only one associated character set.
- The sorting results of the same data may vary according to collations.
- In GaussDB, utf8mb4 and UTF-8 are the same character set.
- When **sql_compatibility** is set to **'MYSQL'**, the binary and SQL_ASCII character sets are the same.
- You are advised to select the same character set for table columns and **server_encoding** to avoid performance loss caused by transcoding.

GaussDB supports the following functions:

- Multiple character sets can be used to store character strings.
- Collations can be used to compare character strings.
- Database-level, schema-level, table-level, and column-level character sets and collations are supported.

  NOTE

  Character strings with different character sets and collations cannot be used in the same server, database, table, or SQL statement.

1.4.1 Character Sets and Collations of the Client Connection

When data containing character set attributes is transmitted between the server and client, encoding conversion is automatically performed. After receiving an SQL statement from a client, the server converts the character set of the SQL statement from the client character set client_encoding to the database character set server_encoding. Before the query result data is sent to the client, the data is encoded and converted to the client_encoding character set of the client.

System parameters:

- **server_encoding**

  Character set specified during database creation. For details, see **CREATE DATABASE**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **client_encoding**

  Character set of the client, which can be modified by using the SET NAMES statement. For details, see **SET**. For details about the parameters, see **client_encoding**.

- **character_set_connection**

  Default character set applied when no character set is specified for character string constants in SQL statements. For details about this parameter, see **character_set_connection**.

- **collation_connection**

  Default collation applied when no collation is specified for character string constants in SQL statements. For details about this parameter, see **collation_connection**.

- **character_set_results**

  Character set of the returned result. For details about this parameter, see **character_set_results**.

  NOTE

  - For an expression that converts a non-character type object to a character type, the result character set and collation are **character_set_connection** and **collation_connection**.
  - By default, the character set and collation number of a bound parameter of the character type are the values of **character_set_connection** and **collation_connection**, respectively. Any value entered for a bound parameter is considered belonging to the preceding character set.
  - During character data conversion, the character encoding is verified. If the character encoding does not meet the requirements, an exception is thrown and an error message is displayed.

1.4.2 Database-level Character Sets and Collations

When creating a database, you can specify the character set sequence of the database. For details about how to create a database, see **CREATE DATABASE**.

```
CREATE DATABASE [IF NOT EXISTS] database_name
        [ ENCODING [=] encoding ] |
        [ LC_COLLATE [=] lc_collate ] |
        [ LC_CTYPE [=] lc_ctype ] |;
```

Parameters:

- **database_name**

  Specifies the database name.

  Value range: a string. It must comply with the identifier naming convention.

- **ENCODING [=] encoding**

  Specifies the character encoding used by the new database. The value can be a string (for example, **SQL_ASCII**) or an integer.

- **LC_COLLATE [=] 'lc_collate'**

  Specifies the character set used by the new database. For example, set this parameter by using **lc_collate = 'zh_CN.gbk'**.

  This parameter affects the sorting behavior of strings (including the sorting result using ORDER BY and the sorting order using indexes on text columns). The default is to use the order rule of the template database.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Value range: character sets supported by the OS.

- **LC_CTYPE [=] 'lc_ctype'**

  Specifies the character type used by the new database. For example, set this parameter by using **lc_ctype = 'zh_CN.gbk'**. The use of this parameter affects the character type, such as uppercase letters, lowercase letters, and digits. By default, the character type of the template database is used.

  Value range: character types supported by the OS.

  NOTE

  - The database-level character set and collation syntax can be used in all schemas. For details about the syntax, see **CREATE DATABASE**.
  - The **LC_COLLATE** and **LC_CTYPE** parameters do not support the collations specific to MySQL-compatible mode. The parameter value range depends on the character sets supported by the local environment. You can run the **locale -a** command to view the parameter value range.

1.4.3 Schema-level Character Sets and Collations

Create a schema and specify the default character set and collation. For details about how to create a schema, see **CREATE SCHEMA**.

```
CREATE SCHEMA schema_name
 [ [DEFAULT] CHARACTER SET | CHARSET [ = ] default_charset ]
 [ [DEFAULT] COLLATE [ = ] default_collation ];
```

Modify the default character set and collation attributes of a schema. For details about how to modify a schema, see **ALTER SCHEMA**.

```
ALTER SCHEMA schema_name
    [ [DEFAULT] CHARACTER SET | CHARSET [ = ] default_charset ] [ [DEFAULT] COLLATE [ = ]
default_collation ];
```

Parameters:

- **schema_name**

  Specifies the schema name.

  Value range: character strings complying with **Identifier Naming Conventions**.

- **default_charset**

  Specifies the default character set of a schema. If you specify this parameter separately, the default collation of the schema will be set to the default collation of the specified character set.

- **default_collation**

  Specifies the default collation of a schema. If you specify this parameter separately, the default character set of the schema will be set to the character set corresponding to the specified collation.

GaussDB selects a character set and collation of a schema in the following ways:

- If both **default_charset** and **default_collation** are specified, character set specified in **default_charset** and the collation specified in **default_collation** will apply. In addition, **default_charset** and **default_collation** must match. Otherwise, an error is reported.
- If only **default_charset** is specified, the character set **default_charset** and its default collation are used.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- If only **default_collation** is specified, the collation **default_collation** and its corresponding character set are used.
- If neither **default_charset** nor **default_collation** is specified, the schema has no default character set or default collation.

NOTE

- If only **default_charset** is specified, it can only be specified to a character set with a default collation. Specifying a character set without a default collation will trigger an error.
- Only the collations in MySQL-compatible mode (**sql_compatibility** is set to **'MYSQL'**) support **default_collation**. If another collation is specified, an error is reported.
- The character set of the new schema must be the same as **server_encoding** of the database.

Examples:

```
-- Set only the character set. The collation is the default collation of the character set.
gaussdb=# CREATE SCHEMA test CHARSET utf8;

-- Set only the collation. The character set is the character set associated with the collation.
gaussdb=# CREATE SCHEMA test COLLATE utf8_bin;

-- Set both the character set and collation. The character set and collation must correspond to each other.
gaussdb=# CREATE SCHEMA test CHARSET utf8 COLLATE utf8_bin;

-- Change the default character set of test to utf8mb4 and the default collation to utf8mb4_bin.
gaussdb=# ALTER SCHEMA test CHARSET utf8mb4 COLLATE utf8mb4_bin;
```

1.4.4 Table-level Character Sets and Collations

Set the default character set and collation of a table. For details about how to create a table, see **CREATE TABLE**.

```
CREATE TABLE table_name (column_list)
    [ [DEFAULT] CHARACTER SET | CHARSET [ = ] default_charset ]
    [ [DEFAULT] COLLATE [ = ] default_collation ]
```

Modify the default character set and default collation of a table. The modification does not affect the existing columns in the table. For details about how to modify a table, see **ALTER TABLE**.

```
ALTER TABLE table_name
    [ [DEFAULT] CHARACTER SET | CHARSET [ = ] default_charset ]
    [ [DEFAULT] COLLATE [ = ] default_collation ]
```

NOTE

Currently, you cannot modify the default character set and default collation of a table to the specified values, set the character set and collation of all columns with character type to the specified value, and convert the data in the column to new character set encoding. The syntax is as follows:

```
ALTER TABLE table_name
    CONVERT TO CHARACTER SET | CHARSET charset [ COLLATE collation ]
```

Parameters

- **table_name**

  Specifies the name of the table.

- **default_charset**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Specifies the default character set of a table. If you specify this parameter separately, the default collation of the table will be set to the default collation of the specified character set.

- **default_collation**

  Specifies the default collation of a table. If you specify this parameter separately, the default character set of the table will be set to the character set corresponding to the specified collation.

GaussDB selects a character set and collation of a table in the following ways:

- If both **default_charset** and **default_collation** are specified, character set specified in **default_charset** and the collation specified in **default_collation** will apply. In addition, **default_charset** and **default_collation** must match. Otherwise, an error is reported.
- If only **default_charset** is specified, the character set **default_charset** and its default collation are used.
- If only **default_collation** is specified, the collation **default_collation** and its corresponding character set are used.
- If neither **default_charset** nor **default_collation** is specified, the default character set and default collation of the schema where the table is located will apply.

NOTE

- If only **default_charset** is specified, it can only be specified to a character set with a default collation. Specifying a character set without a default collation will trigger an error.
- Only the collations in MySQL-compatible mode (**sql_compatibility** is set to **'MYSQL'**) support **default_collation**. If another collation is specified, an error is reported.
- If the default collation of a table is binary, the text types whose collation is not specified in the table are converted to the corresponding binary type, and the collation is set to binary.
- Currently, the default character set of a table must be server_encoding of the database.
- Currently, the data of columns of the character type in the table cannot be converted into encoding.

Example:

```
-- Set only the character set. The collation is the default collation of the character set.
gaussdb=# CREATE TABLE test(c1 text) CHARSET utf8;

-- Set only the collation. The character set is the character set associated with the collation.
gaussdb=# CREATE TABLE test(c1 text) COLLATE utf8_bin;

-- Set both the character set and collation. The character set and collation must correspond to each other.
gaussdb=# CREATE TABLE test(c1 text)  CHARSET utf8 COLLATE utf8_bin;

-- Change the default character set of the table to utf8mb4 and the default collation to utf8mb4_bin.
gaussdb=# ALTER TABLE test CHARSET utf8mb4 COLLATE utf8mb4_bin;

-- Drop the table.
gaussdb=# DROP TABLE test;
```

1.4.5 Column-Level Character Sets and Collations

You can set the column-level character set and collation for each column of the string type (CHAR, VARCHAR, or TEXT).

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
CREATE TABLE table_name (
    column_name data_type
 [ CHARACTER SET | CHARSET charset ]
    [ COLLATE collation ]
);
```

Parameters:

- **table_name**

  Specifies the name of the table.

- **data_type**

  Specifies the data type of a column. The value can only be character set and collation of the string type.

- **CHARACTER SET | CHARSET charset**

  Specifies the character set of a column. If this parameter is specified separately, the collation of the column is set to the default collation of the specified character set.

- **COLLATE collation**

  The COLLATE clause specifies the collation of a column (the data type of the column must support collation). If no collation is specified, the default collation is used.

GaussDB selects a character set and collation of a table column in the following ways:

- If both **charset** and **collation** are specified, **charset** and **collation** are used. **charset** and **collation** must correspond to each other. Otherwise, an error is reported.
- If only **charset** is specified, the character set **charset** and its default collation are used.
- If only **collation** is specified, collation specified in **collation** and its corresponding character set will apply.
- If neither **charset** nor **collation** is specified, the default character set and collation of the table are used.

NOTE

- If only **charset** is specified, it can only be specified to a character set with a default collation. Specifying a character set without a default collation will trigger an error.
- Only the collations in MySQL-compatible mode support **collation**. If another collation is specified, an error is reported.
- If a table column is of the text type and the specified collation is binary, the text type is converted to the corresponding binary type and the collation is the specified binary collation.
- The character set of the partition key of the partitioned table must be the same as that of the database.
- Currently, the default character set of a table column must be server_encoding of the database.

Examples:

```
-- Set only the character set. The collation is the default collation of the character set.
gaussdb=# CREATE TABLE test(c1 text CHARSET utf8);

-- Set only the collation. The character set is the character set associated with the collation.
gaussdb=# CREATE TABLE test(c1 text COLLATE utf8_bin);
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
-- Set both the character set and collation. The character set and collation must correspond to each other.
gaussdb=# CREATE TABLE test(c1 text CHARSET utf8 COLLATE utf8_bin);
```

1.4.6 Character Sets and Collations of Expressions of the String Type

Each expression of the string type contains character sets and collation attributes.

In the MySQL-compatible database (that is, **sql_compatibility** is set to **'MYSQL'**), if **b_format_version** is set to **'5.7'** and **b_format_dev_version** is set to **'s2'**, the default character sets and collations of string constants are determined by the system parameters **character_set_connection** and **collation_connection**. If they are not set, the default character set is the same as **server_encoding** of the database, and the default collation is **default**.

Character set syntax:

GaussDB does not support the character set of string constants specified by the following syntax:

```
[_charset_name]'string'
```

Collation syntax:

You can also specify the collation for expressions of other character string types.

```
EXPRESSION [COLLATE collation_name]
```

Parameter:

COLLATE collation_name

Collation name, which is the collation attribute of the string.

- The data type of the expression must be a data type that supports collations.
- The specified collation must be supported by the character set of the expression.

Example:

```
-- Use the COLLATE statement to specify the collation.
gaussdb=# SELECT 'a' COLLATE utf8mb4_general_ci = 'A';
```

1.4.7 Rules for Combining Character Sets and Collations

In the MySQL-compatible database (that is, **sql_compatibility** is set to **'MYSQL'**), if **b_format_version** is set to **'5.7'** and **b_format_dev_version** is set to **'s2'**, the system processes expressions of different character sets and collations based on the priority to determine the collation and character set of the expression used for string comparison.

Collation priority

The priorities of different expressions in descending order are as follows:

- The COLLATE syntax has the highest priority.
- Expressions with collation conflicts (for example, two character strings with different collations) exist.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- Columns of data types that support collation, user-defined variables, stored procedure parameters, and CASE expressions.
- Specific system functions (such as version() and opengauss_version() function expressions).
- String constants and bound parameters.
- NULL expressions.
- If a data type of an expression does not support collation, the expression has the lowest priority.

When the collations of two expressions are different, the collation of the expression with the highest priority is used.

Example:

```
gaussdb=# CREATE TABLE t_utf8(c1 varchar(16) CHARACTER SET utf8mb4 COLLATE utf8mb4_bin);
gaussdb=# INSERT INTO t_utf8 VALUES('STRING');

-- If the utf8mb4_bin collation is used for comparison, the result is false.
gaussdb=# SELECT c1 = 'string' AS result FROM t_utf8;
 result
--------
 f
(1 row)

-- If the utf8mb4_general_ci collation is used for comparison, the result is true.
gaussdb=# SELECT c1 = 'string' COLLATE utf8mb4_general_ci AS result FROM t_utf8;
 result
--------
 t
(1 row)

-- Define the collation of the bound parameter $1 as collation_connection.
gaussdb=# PREPARE test_collation(text) AS SELECT c1 = $1 AS result FROM t_utf8;

-- The collation of the bound parameter is at the same level as that of the string constant. Even if the input expression contains an explicit collation, the collation of c1 is still used for comparison.
gaussdb=# EXECUTE test_collation('string' COLLATE utf8mb4_general_ci);
 result
--------
 f
(1 row)

-- The CASE expression is at the same level as the c1 column. Even if the expression contains an explicit collation, the collation of the c1 column is still used for comparison. The two collations are different. "same level" is displayed.
gaussdb=# SELECT CASE 'string' COLLATE utf8mb4_general_ci WHEN c1 THEN 'different level' ELSE 'same level' END AS result FROM t_utf8;
   result
------------
 same level
(1 row)

-- The IN subquery has the same level as the c1 column. Even if the expression contains an explicit collation, the collation of c1 is still used for comparison. The two collations are different.
gaussdb=# SELECT c1 FROM t_utf8 WHERE c1 in (SELECT 'string' COLLATE utf8mb4_general_ci);
 c1
----
(0 rows)
```

If the collations of two expressions with the same priority are different, the following processing method is used:

- If the two character sets are the same, the collation suffixed with **_bin** is preferred.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- If the two character sets are the same, the default collation is not preferred.
- If the preceding conditions are not met, the two expressions are marked as a collation conflict, and the collations are marked as invalid.
  - If a conflict occurs because the COLLATE syntax specifies different collations for the same character set, an exception is displayed.
  - If the two conflicting collations are supported in MySQL-compatible mode (**sql_compatibility** is set to **'MYSQL'**), an exception occurs.
  - If the conflicting character set is different from server_encoding of the database, an exception occurs.
  - If an invalid collation is used for sorting operations (such as > and <), an exception occurs.
  - During equality comparison of character strings, if the collation is invalid, the character strings are compared as binary values to determine whether they are equal.

Examples:

```
gaussdb=# CREATE TABLE t_utf8mb4_charset(
    c_utf8_bin varchar(16) character set utf8mb4 collate utf8mb4_bin,
    c_utf8_uni varchar(16) character set utf8mb4 collate utf8mb4_unicode_ci,
    c_utf8_gen varchar(16) character set utf8mb4 collate utf8mb4_general_ci);
gaussdb=# INSERT INTO t_utf8mb4_charset VALUES('STRING', 'String', 'string');

-- The utf8mb4_bin collation is preferentially used for comparison. The result is false.
gaussdb=# SELECT c_utf8_bin = c_utf8_uni FROM t_utf8mb4_charset;

-- Collation conflict. Binary comparison is performed, and the result is false.
gaussdb=# SELECT c_utf8_uni = c_utf8_gen FROM t_utf8mb4_charset;

-- Conflict of the explicitly specified collation. An exception is reported.
gaussdb=# SELECT c_utf8_uni COLLATE utf8mb4_unicode_ci = c_utf8_gen COLLATE utf8mb4_general_ci
FROM t_utf8mb4_charset;
```

NOTE

- Only the character sets of objects and expressions of the string type (excluding char, name, and clob) can be different from those of the database.
- Data types such as ARRAY, XML, JSON, and TSVECTOR contain text data. The character sets in the text data of the objects and expressions of these data types must be the same as the character sets of the database.
- According to the rules for combining character sets and collations, the character sets corresponding to C, POSIX, and DEFAULT collations are server_encoding.

1.5 Constant and macro

Table 1-28 lists the constants and macros that can be used in GaussDB.

Table 1-28 Constant and macro

Parameter	Description	Example
CURRENT_CATALOG	Current database.	testdb=# SELECT CURRENT_CATALOG; current_database ---------- testdb (1 row)

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Description	Example
CURRENT_ROLE	Current user.	gaussdb=# SELECT CURRENT_ROLE; current_user -------------- omm (1 row)
CURRENT_SCHEMA	Current database schema.	gaussdb=# SELECT CURRENT_SCHEMA; current_schema ---------------- public (1 row)
CURRENT_USER	Current user.	gaussdb=# SELECT CURRENT_USER; current_user -------------- omm (1 row)
LOCALTIMESTAMP	Current session time (without time zone).	gaussdb=# SELECT LOCALTIMESTAMP; timestamp ---------------------------- 2015-10-10 15:37:30.968538 (1 row)
NULL	NULL value.	-
SESSION_USER	Current system user.	gaussdb=# SELECT SESSION_USER; session_user -------------- omm (1 row)
SYSDATE	Current system date.	gaussdb=# SELECT SYSDATE; sysdate --------------------- 2015-10-10 15:48:53 (1 row)
USER	Specifies the current user, also called **CURRENT_USER**.	gaussdb=# SELECT USER; current_user -------------- omm (1 row)

1.6 Functions and Operators

An operator can process one or more operands and can be placed before, after, or between operands. Results are returned after the processing.

A function is a set of encapsulated service logic for implementing specific functions. It may or may not have parameters. A function has a return type, and once executed, the result is returned.

Users can modify system functions. However, after the modification, the meaning of the functions may change, which results in disorder in system control. Therefore, users are not allowed to manually modify system functions.

Functions are classified into system functions and syntax functions. Some functions are both system functions and syntax functions. For details, see **Table 1-29**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- System functions: They are registered in the pg_proc system catalog by using the registration mechanism. You can query the pg_proc system catalog to obtain the metadata of system functions.
- Syntax functions: They are directly defined by SQL syntax rules and have dedicated syntax formats. For details about the syntax functions, see **Table 1-29**.

Table 1-29 Syntax functions

Name	ORA-compatible Mode	MySQL-compatible Mode	Other Compatibility Mode
adddate	N/A	Syntax and system functions	Syntax and system functions
cast	Syntax function	Syntax function	Syntax function

year	N/A	System function	N/A

NOTE

When the GUC parameter **behavior_compat_options** includes **'enable_funcname_with_argsname'**, the projection alias displays the complete function.

1.6.1 Logical Operators

Common logical operators include AND, OR, and NOT. The operation result has three values: **TRUE**, **FALSE**, and **NULL**. NULL indicates unknown. Their priorities are NOT > AND > OR.

Table 1-30 lists the calculation rules, where a and b represent logical expressions.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 1-30 Operation rules

a	b	a AND b Result	a OR b Result	NOT a Result
TRUE	TRUE	TRUE	TRUE	FALSE
TRUE	FALSE	FALSE	TRUE	FALSE
TRUE	NULL	NULL	TRUE	FALSE
FALSE	FALSE	FALSE	FALSE	TRUE
FALSE	NULL	FALSE	NULL	TRUE
NULL	NULL	NULL	NULL	NULL

NOTE

- The operators AND and OR are commutative, that is, you can switch the left and right operand without affecting the result.
- Operations on XML data are not supported.

1.6.2 Comparison Operators

Comparison operators are available for the most data types and return Boolean values.

All comparison operators are binary operators. Only data types that are the same or can be implicitly converted can be compared using comparison operators.

Table 1-31 describes comparison operators provided by GaussDB.

Table 1-31 Comparison operations

Operator	Description
<	Less than
>	Greater than
<=	Less than or equal to
>=	Greater than or equal to
=	Equal to
<>, !=, or ^=	Not equal to

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- For comparison operators <=, <>, >=, and ^=, if there is a space between two symbols, it does not affect normal operations. For !=, if there is a space between the exclamation mark (!) and an equal sign (=), the exclamation mark will be identified as factorial, which may cause the result to be inconsistent with the expected result.
- Comparison operators are available for all relevant data types. All comparison operators are binary operators that returned values of Boolean type. The calculation priority of the inequality sign is higher than that of the equality sign. If the entered data type is different and cannot be implicitly converted, the comparison fails. For example, an expression such as **1 < 2 < 3** is invalid because the less-than sign (<) cannot be used to compare Boolean values and 3.
- Each comparison operator has a corresponding function in the PG_PROC system catalog. If the value of the **proleakproof** attribute of the corresponding function is **f**, the function is not used to prevent data leakage. If a user only has the permission on a system view, but does not have the permission on the corresponding table, the query plan may not be optimal when the user queries the system view.
- This operator does not support data of the XML type.
- If the two data types to be compared are different or cannot be implicitly converted to each other, they are first implicitly converted to a third convertible data type before comparison. In this case, the comparison result may be meaningless.

  Example:

```
gaussdb=# EXPLAIN verbose SELECT to_datea('2010-10-10','yyyy-mm-dd') > 1.5;
                                 QUERY PLAN
-----------------------------------------------------------------------------------
 Result  (cost=0.00..0.02 rows=1 width=0)
   Output: ((to_datea('2010-10-10'::text, 'yyyy-mm-dd'::text))::text > '1.5'::text)
(2 rows)
```

1.6.3 Character Processing Functions and Operators

Character processing functions and operators provided by GaussDB are for concatenating strings with each other, concatenating strings with non-strings, and matching the patterns of strings. Except length-related functions, other character processing functions and operators do not support CLOBs larger than 1 GB as parameters.

NOTE

If invalid characters are found in input parameters during character comparison, **false** will be returned by default.

- bin(number)

  Description: Returns a binary string of a given number.

  Parameters: See **Table 1-32**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 1-32 bin parameters

Parameter	Type	Description
number	• Integer types: tinyint, smallint, mediumint, int, and bigint. • Unsigned integer types: tinyint unsigned, smallint unsigned, int unsigned, and bigint unsigned. • Character and text types: char, varchar, tinytext, text, mediumtext, and longtext. Only numeric integer strings are supported, and the integer range is within the bigint range. • Floating-point types: float, real, and double. • Fixed-point types: numeric, decimal, and dec. • Boolean type.	Given number.

Return type: text.

Example:

```
gaussdb=# SELECT bin(5);
  bin
--------
  101
(1 row)
```

NOTE

- The function takes effect only when **sql_compatibility** is set to **'MYSQL'**.
- If the value of the input parameter **number** is a decimal, round it down.
- If the absolute value of the input parameter **number** exceeds the maximum value of the bigint unsigned type, the parameter is converted to the upper limit.

- bit_length(string)

  Description: Returns the number of bits in the input string.

  Return type: int.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Example:

```
gaussdb=# SELECT bit_length('world');
 bit_length
------------
         40
(1 row)
```

- btrim(string text [, characters text])

  Description: Removes the longest string containing only characters specified by **characters** (a space by default) from the start and end of **string**.

  Return type: text.

  Example:

  ```
  gaussdb=# SELECT btrim('sring' , 'ing');
   btrim
  -------
   sr
  (1 row)
  ```

- char_length(string) or character_length(string)

  Description: Specifies the number of characters in a string.

  Return type: int.

  Example:

  ```
  gaussdb=# SELECT char_length('hello');
   char_length
  -------------
             5
  (1 row)
  ```

- dump(expr[, return_fmt [, start_position [, length]]])

  Description: Returns the data type code, byte length, and internal representation of the input expression.

  Parameters: **return_fmt** specifies the number system of the internal representation, **start_position** specifies the byte from which the internal representation starts, and **length** specifies the length of the data to be read.

  Return type: text.

  NOTE

  This function takes effect in ORA-compatible databases where **a_format_version** is **10c** and **a_format_dev_version** is **s2**.

- elt(pos, str1, str2,...)

  Description: Returns a string at a specified position. This function takes multiple string parameters and returns the corresponding string based on the position parameter **pos**.

  Parameters: See **Table 1-33**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 1-33 elt parameters

Parameter	Type	Description
pos	• Integer types: tinyint, smallint, mediumint, int, and bigint. • Unsigned integer types: tinyint unsigned, smallint unsigned, and int unsigned. • Character and text types: char, varchar, tinytext, text, mediumtext, and longtext. Only numeric integer strings are supported, and the integer range is within the bigint range. • Floating-point types: float, real, and double. • Fixed-point types: numeric, decimal, and dec. • Boolean type.	Specified position of the parameter.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Type	Description
str1, str2,...	• Integer types: tinyint, smallint, mediumint, int, and bigint. • Unsigned integer types: tinyint unsigned, smallint unsigned, int unsigned, and bigint unsigned. • Character and text types: char, varchar, tinytext, text, mediumtext, and longtext. • Floating-point types: float, real, and double. • Fixed-point types: numeric, decimal, and dec. • Boolean type. • Large object types: tinyblob, blob, mediumblob, and longblob. • Date types: datetime, timestamp, date, and time.	List of character strings.

Return type: text.

Example:

```
gaussdb=# SELECT elt(3, 'a', 'b', 'c');
 elt
-------
   c
(1 row)
```

NOTE

- The function takes effect only when **sql_compatibility** is set to **'MYSQL'**.
- If the input parameter **pos** is less than 1 or exceeds the number of parameters, **NULL** is returned.

- field(str, str1, str2, str3,...)

  Description: Returns the position number of **str** in the parameter list (for example, **str1**, **str2**, **str3**) using the field function. The position number starts from 1 and increases in ascending order. If no match is found or the value of

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

the **str** parameter is **NULL**, **0** is returned. This function uses different comparison rules based on the types of input parameters.

- If all input parameters are of the numeric type, the comparison is performed based on the numeric rule.
- If all input parameters are of the non-numeric type, the comparison is performed based on the character string rule.
- If the input parameters contain both digits and non-digits, the comparison is performed based on the double type.

Parameters: See **Table 1-34**.

Table 1-34 field parameters

Parameter	Type	Description
str, str1, str2, str3,...	• Integer types: tinyint, smallint, mediumint, int, bigint, tinyint unsigned, smallint unsigned, int unsigned, and bigint unsigned. • Boolean types: true and false. • Floating-point types: float(p), float, real, double, float(m, d), double(m, d), and real(m, d). • Fixed-point types: numeric, decimal, and dec. • Text types: tinytext, text, mediumtext, and longtext. • Character string types: char and varchar. • Large object types: tinyblob, blob, mediumblob, and longblob. • Date types: datetime, timestamp, date, and time.	List of character strings.

Return type: bigint

Example:

```
gaussdb=# SELECT field( 'abc','1',1,'abc','abcd' );
 field
-------
     3
(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- The field function takes effect only when **sql_compatibility** is set to **'MYSQL'**.
- Since the version whose **b_format_version** is set to **'5.7'** and **b_format_dev_version** is set to **'s1'**, the sql_mode parameter **pad_char_to_full_length** specifies whether to add spaces at the end of the char type, which affects the field comparison result. For details, see **Table 1-8**.
- Since the version whose **b_format_version** is set to **'5.7'** and **b_format_dev_version** is set to **'s1'**, the behavior of the character, binary, numeral, and date and time types is M-compatible. This affects the result of field comparison. For details, see **Data Types**. To ensure consistent precision, it is advisable to use the NUMERIC type rather than floating-point (under the numeric type). The use of floating-point may lead to varying precision compared to M-compatible mode, due to differences in connection parameter settings.
- Since the version whose **b_format_version** is set to **'5.7'** and **b_format_dev_version** is set to **'s2'**, characters can be escaped and constant character strings can obtain collations. The collations affect the field comparison result. For details, see the SET NAMES syntax in **SET**. For details about the rules for combining different collations of the character types, see **Rules for Combining Character Sets and Collations**.

- insert(str1, pos, len, str2)

  Description: Returns the processing result of *str1*. The substring starts from *pos* and the number of *len* characters in the character string is replaced with *str2*. If any input parameter is **NULL**, the return value is **NULL**.

  Parameters: See **Table 1-35**.

Table 1-35 insert parameters

Parameter	Type	Description
pos, len	• Integer types: tinyint, smallint, mediumint, int, and bigint. • Unsigned integer types: tinyint unsigned, smallint unsigned, int unsigned, and bigint unsigned. • Character and text types: char, varchar, tinytext, text, mediumtext, and longtext. Only numeric integer strings are supported. • Floating-point types: float, real, and double. • Fixed-point types: numeric, decimal, and dec.	**pos** indicates the parameter in the specified position, and **len** indicates the replacement length.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Type	Description
str1, str2	• NULL. • Integer types: tinyint, smallint, mediumint, int, bigint, tinyint unsigned, smallint unsigned, int unsigned, and bigint unsigned. However, the integer value exceeds the range from 81 negative nines to 81 positive nines, and the return value is different from that of MySQL. This difference between GaussDB and MySQL is inherent and does not result from this function. • Floating-point and fixed-point types: float, real, and double; numeric, decimal, and dec. When using scientific notation, GaussDB displays trailing zeros, unlike MySQL, which does not. This difference between GaussDB and MySQL is inherent and does not result from this function. • Character string types: char and varchar. • Text types: tinytext, text, mediumtext, and longtext. • Large object types: tinyblob, blob, mediumblob, and longblob.	String.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Type	Description
	• Date types: datetime, timestamp, date, and time.	

Return value type: The return value of the function is of the text type (both **s1** and **s2** are of the text type) or bytea type (any of **s1** or **s2** is of the bytea type).

Example:

```
gaussdb=# SELECT INSERT('abcdef',2,3,'gg');
 insert
--------
 aggef
(1 row)
```

NOTE

- The insert function takes effect only when **sql_compatibility** is set to **'MYSQL'**.
- The value range of the input parameter of the Int64 type is limited. If the value exceeds the value range of –9223372036854775808 to 9223372036854775807, an error is reported. MySQL has no restriction on the range of input parameters of the numeric type. If an exception occurs, an alarm is generated and the upper or lower limit is used. Input parameters of the character string are restricted. The maximum length of the input parameter of the text type is 2^30 – 5 bytes, and the maximum length of the input parameter of the bytea type is 2^30 – 512 bytes.

- instr(text, text, int, int)

  Description: Returns the position of the *n*th matched occurrence of the second parameter in the first parameter, starting from the position specified by the third parameter (*n* is the value of the fourth parameter). The third parameter indicates the start position for matching, and the fourth parameter indicates the number of matches.

  Return type: int.

  Example:

  ```
  gaussdb=# SELECT instr( 'abcdabcdabcd', 'bcd', 2, 2 );
   instr
  -------
      6
  (1 row)
  ```

- instrb(text, text, int, int)

  Description: Returns the position of the *n*th matched occurrence of the second parameter in the first parameter, starting from the position specified by the third parameter (*n* is the value of the fourth parameter). The third parameter indicates the start position for matching, and the fourth parameter indicates the number of matches. Different from the instr function, instrb is calculated in bytes and is not affected by the character set in use.

  Return type: int.

  Example:

  ```
  gaussdb=# SELECT instrb( 'abcdabcdabcd', 'bcd', 2, 2 );
   instrb
  -------
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
   6
(1 row)
```

NOTE

- This function takes effect in ORA-compatible databases where **a_format_version** is **10c** and **a_format_dev_version** is **s1**.
- If the values of *int1* and *int2* are decimals, the values are truncated instead of being rounded off.

- lengthb(text/bpchar)

  Description: Obtains the number of bytes of a specified string.

  Return type: int.

  Example:

```
gaussdb=# SELECT lengthb('hello');
 lengthb
---------
       5
(1 row)
```

- lengthc(text/bpchar)

  Description: Returns the length of a specified string, calculated according to Unicode character encoding rules.

  Return type: int.

  Example:

```
gaussdb=# SELECT lengthc('hello');
 lengthc
---------
       5
(1 row)
```

- left(str text, n int)

  Description: Returns the first *n* characters in a string. When *n* is negative, all but the last */n/* characters are returned.

  Return type: text.

  Example:

```
gaussdb=# SELECT left('abcde', 2);
 left
------
 ab
(1 row)
```

- length(string bytea, encoding name)

  Description: Specifies the number of characters in **string** in the given encoding format. In this encoding format, **string** must be valid.

  Return type: int.

  Example:

```
gaussdb=# SELECT length('jose', 'UTF8');
 length
--------
      4
(1 row)
```

NOTE

If the length of the bytea type is queried and UTF-8 encoding is specified, the maximum length can only be **536870888**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- locate(substr, str[, pos])

  Description: Returns the position where *substr* appears for the first time in *str*, starting from *pos* (**1** by default). If *substr* cannot be found in *str*, this function returns **0**.

  Parameters: See **Table 1-36**.

  Table 1-36 locate parameters

Parameter	Type	Description
substr, str	• Integer types: tinyint, smallint, mediumint, int, bigint, tinyint unsigned, smallint unsigned, int unsigned, and bigint unsigned. • Floating-point types: float and double. • Arbitrary precision type: numeric. • Character types: char, varchar, and text. • Binary types: bytea and blob. • Date/Time types: date, time, datetime, and timestamp.	• **substr** (required): substring to be searched for. • **str** (required): character string to be searched for.
pos	• Integer types: tinyint, smallint, mediumint, int, tinyint unsigned, smallint unsigned, int unsigned, and bigint unsigned. • Floating-point types: float and double. • Arbitrary precision type: numeric. • Character types: char, varchar, and text. • Boolean types: true and false.	**pos** (optional): start position of the search.

  Return type: int.

  Example:

```
gaussdb=# SELECT locate( 'b','abcabc');
 locate
--------
      2
(1 row)

gaussdb=# SELECT locate( 'b','abcabc',3);
 locate
--------
      5
(1 row)
```

  NOTE

  The locate function takes effect only when **sql_compatibility** is set to **'MYSQL'**.

- lpad_s(string text, length int [, fill text])

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description: Fills up a string to *length* by appending the characters *fill* (a space by default). If the string is already longer than *length*, an error will be reported.

Return type: text.

NOTE

In ORA-compatible databases where **a_format_version** is **10c** and **a_format_dev_version** is **s1**, this function operates as follows:

- The **length** parameter indicates the display length for character strings. The display length for individual characters is consistent with that in ORA-compatible databases.
- During the function execution, if the remaining length is 1 and the next character is of the full-width type (2 bytes), a space character is added to the left of the string.
- If the value of **length** is a decimal, the value is rounded down instead of being rounded off.
- The **string** and **fill** parameters do not comply with the encoding specifications.

In other cases:

- The **length** parameter indicates the total length of characters in a character string. The length of a single character is fixed to 1.
- If the value of **length** is a decimal, the value is rounded off.
- The **string** and **fill** parameters do not comply with the encoding specifications.

- lpad(string text, length int [, fill text])

  Description: Fills up a string to *length* by appending the characters *fill* (a space by default). If the string is already longer than *length*, it will be truncated from the end.

  Return type: text.

  NOTE

  In ORA-compatible databases where **a_format_version** is **10c** and **a_format_dev_version** is **s1**, this function operates as follows:

  - The **length** parameter indicates the display length for character strings. The display length for individual characters is consistent with that in ORA-compatible databases.
  - During the function execution, if the remaining length is 1 and the next character is of the full-width type (2 bytes), a space character is added to the left of the string.
  - If the value of **length** is a decimal, the value is rounded down instead of being rounded off.
  - The **string** and **fill** parameters do not comply with the encoding specifications.

  In other cases:

  - The **length** parameter indicates the total length of characters in a character string. The length of a single character is fixed to 1.
  - If the value of **length** is a decimal, the value is rounded off.
  - The **string** and **fill** parameters do not comply with the encoding specifications.

- make_set(bits, str1, str2,...)

  Description: **str1** corresponds to bit 0 of the bits input parameter in the bit format, **str2** corresponds to bit 1, and so on. If the lower bit of the corresponding bit form is **1**, the corresponding **str** parameter is appended to the result and returned with a comma as the separator.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameters: See **Table 1-37**.

Table 1-37 make_set parameters

Parameter	Type	Description
bits	The input parameter **bits** supports the following types: • NULL. • Integer types: tinyint, smallint, mediumint, int, bigint, tinyint unsigned, smallint unsigned, int unsigned, and bigint unsigned. • Floating-point and fixed-point types: float, real, and double; numeric, decimal, and dec. • Bit type: bit. GaussDB does not support bits. In the code design, when the input parameter **1** is in hexadecimal format (for example, **x'FFF'**) and the length is an odd number, MySQL reports an error, but GaussDB processes the error in a different way. • Character string types: char and varchar. Only integer strings (within the range of bigint) are supported. For strings containing decimals, the returned results are different because the rounding rule is different from that of MySQL. The character string consisting of digits and letters is not supported. • Text types: tinytext, text, mediumtext, and longtext. Only numeric integer strings (within the range of bigint) are supported. If the integer range is exceeded, the returned result is different from that in MySQL. The returned results of character strings with decimal places are different from those of MySQL due to different rounding rules. The text type combined by digits and letters is not supported. • Large object types: tinyblob, blob, mediumblob, and longblob.	Specifies whether to include the subsequent **str** parameters based on each bit of the binary value corresponding to this parameter.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Type	Description
str1, str2, ...	The input parameter **str** supports the following types: • NULL. • Integer types: tinyint, smallint, mediumint, int, bigint, tinyint unsigned, smallint unsigned, int unsigned, and bigint unsigned. However, the integer value exceeds the range from 81 negative nines to 81 positive nines, and the return value is different from that of MySQL. This difference between GaussDB and MySQL is inherent and does not result from this function. • Floating-point and fixed-point types: float, real, and double for floating-point types; numeric, decimal, and dec for fixed-point types. However, when the value is expressed in scientific notation, the trailing zeros in GaussDB are displayed, and those in MySQL are not displayed. The value is printed in scientific notation. This is an inherent display difference and is not caused by this function. • Character string types: char and varchar. • Text types: tinytext, text, mediumtext, and longtext. • Large object types: tinyblob, blob, mediumblob, and longblob. • Date types: datetime, timestamp, date, and time.	Specifies whether to append some strings of **str1**, **str2**, and so forth to the return result in sequence based on the binary bits of the **bits** parameter.

Return type: text.

Example:

```
gaussdb=# SELECT make_set(7,'a','b','c','d');
 make_set
----------
 a,b,c
(1 row)
gaussdb=# SELECT
make_set(b'10101010101011010101010101101010101010110101010101011010101010101','1','2','3','4','
5','6','7','8','9','10','11','12','13','14','15','16','17','18','19','20','21','22','23','24','25','26','27','28','29','30','31','3
2','33','34','35','36','37','38','39','40','41','42','43','44','45','46','47','48','49','50','51','52','53','54','55','56','57','
58','59','60','61','62','63','64','65','66','67','68','69');
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
                                                  make_set
-----------------------------------------------------------------------------------------------------
 2,4,6,8,10,12,13,15,17,19,21,23,25,26,28,30,32,34,36,38,39,41,43,45,47,49,51,52,54,56,58,60,62,64
(1 row)
```

NOTE

- The make_set function takes effect only when **sql_compatibility** is set to **'MYSQL'**.
- When the **bits** parameter is an integer, the maximum range is int128, which is smaller than the MySQL range.
- When the **bits** parameter is of the date type (datetime, timestamp, date, or time), it is not supported because the conversion from the date type to the integer type is different from that in MySQL, which is not caused by this function.
- GaussDB and MySQL are inherently different in the bit and Boolean types, causing different returned results, which is not caused by this function. When the **bits** input parameter is of the Boolean type, the **str** input parameter of the bit and Boolean types is not supported.

- notlike(bytea, bytea), notlike(name, text), and notlike(text, text)

  Description: This function is an overloaded function and is used to compare whether two input parameters are of different data types.

  Return type: Boolean

  Example:

```
gaussdb=# SELECT notlike(1,2);
   notlike
--------------
          t
(1 row)
gaussdb=# SELECT notlike(1,1);
   notlike
--------------
          f
(1 row)
```

- octet_length(string)

  Description: Specifies the number of bytes in a string.

  Return type: int.

  Example:

```
gaussdb=# SELECT octet_length('jose');
 octet_length
--------------
          4
(1 row)
```

- overlay(string placing string FROM int [for int])

  Description: Replaces substrings. **FROM int** indicates the start position of the replacement in the first string. **for int** indicates the number of characters replaced in the first string.

  Return type: text.

  Example:

```
gaussdb=# SELECT overlay('hello' placing 'world' FROM 2 for 3 );
 overlay
---------
 hworldo
(1 row)
```

- position(substring in string)

  Description: Specifies the position of a substring. Parameters are case-sensitive.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Return type: int. If the character string does not exist, **0** is returned.

Example:

```
gaussdb=# SELECT position('ing' in 'string');
 position
----------
        4
(1 row)
```

- pg_client_encoding()

  Description: Specifies the current client-side encoding name.

  Return type: name

  Example:

  ```
  gaussdb=# SELECT pg_client_encoding();
   pg_client_encoding
  --------------------
   UTF8
  (1 row)
  ```

- quote(str)

  Description: Adds a single quotation mark (') at both ends of the string specified by **str**, and escapes any special characters within the string, such as backslashes (\\), single quotation marks (\'), ASCII NUL (\0), and Control+Z (\Z). If the parameter is **NULL**, the return value is **NULL** without single quotation marks (').

  Parameters: See **Table 1-38**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 1-38 quote parameters

Parameter	Type	Description
str	• NULL. • Integer types: tinyint, smallint, mediumint, int, bigint, tinyint unsigned, smallint unsigned, int unsigned, and bigint unsigned. However, the integer value exceeds the range from 81 negative nines to 81 positive nines, and the return value is different from that of MySQL. This difference between GaussDB and MySQL is inherent and does not result from this function. • Floating-point and fixed-point types: float, real, and double for floating-point types; numeric, decimal, and dec for fixed-point types. However, when the value is expressed in scientific notation, the trailing zeros in GaussDB are displayed, and those in MySQL are not displayed. The value is printed in scientific notation. This is an inherent display difference and is not caused by this function. • Character string types: char and varchar.	Adds a single quotation mark (') at both ends of the string specified by **str**, and escapes any special characters within the string, such as backslashes (\\), single quotation marks (\'), ASCII NUL (\0), and Control+Z (\Z).

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Type	Description
	• Text types: tinytext, text, mediumtext, and longtext. • Large object types: tinyblob, blob, mediumblob, and longblob. • Date types: datetime, timestamp, date, and time.	

Return type: text.

Example:

```
gaussdb=# SELECT quote('hello\' world');
    quote
--------------
 'hello\' world'
(1 row)
```

NOTE

- The function takes effect only when **sql_compatibility** is set to **'MYSQL'**.
- Enable GUC parameters.
  ```
  SET standard_conforming_strings=off;
  SET escape_string_warning=off;
  SET backslash_quote=on;
  ```
- If **str** contains \Z, \r, \%, or _, GaussDB does not escape these characters, unlike MySQL-compatible databases which do escape them. In addition, differences are also observed for slashes followed by certain numbers, such as "\563". These differences are caused by the differences in escape character processing between GaussDB and MySQL, and are not caused by this function.
- The output format of \b in the **str** character string is different from that in MySQL. This difference between GaussDB and MySQL is inherent and does not result from this function.
- If **str** contains "\0", GaussDB cannot recognize it due to the limitations of the UTF-8 character set, leading to input failure. This difference between GaussDB and MySQL is inherent and does not result from this function.
- GaussDB does not support the bit or Boolean type for **str** due to its divergence from MySQL-compatible databases.
- GaussDB supports a maximum data transmission of 1 GB. The input parameter **str** can have a maximum length of 536,870,908, and the returned result string can be up to 1 GB in size.

- quote_ident(string text)

  Description: Returns the given string suitably quoted to be used as an identifier in an SQL statement string (quotation marks are used as required). Quotation marks are added only if necessary (that is, if the string contains non-identifier characters or would be case-folded). The quotation marks embedded in the return value must be written twice.

  Parameter: The input parameter is a string, which will be used as an SQL identifier.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Return type: text.

Example:

```
gaussdb=# SELECT quote_ident('hello world');
 quote_ident
--------------
 "hello world"
(1 row)
```

- quote_literal(string text)

  Description: Returns the given string suitably quoted to be used as text in an SQL statement string (quotation marks are used as required). It supports XML data that is explicitly converted to the character type.

  Return type: text.

  Example:

  ```
  gaussdb=# SELECT quote_literal('hello');
   quote_literal
  ---------------
   'hello'
  (1 row)
  ```

  If a command similar to the following exists, the text will be escaped.

  ```
  gaussdb=# SELECT quote_literal(E'O\'hello');
   quote_literal
  ---------------
   'O''hello'
  (1 row)
  ```

  If a command similar to the following exists, the backslash will be properly doubled.

  ```
  gaussdb=# SELECT quote_literal('O\hello');
   quote_literal
  ---------------
   E'O\\hello'
  (1 row)
  ```

  If the parameter is **NULL**, **NULL** is returned. If the parameter may be null, you are advised to use the quote_nullable function.

  ```
  gaussdb=# SELECT quote_literal(NULL);
   quote_literal
  ---------------

  (1 row)
  ```

- quote_literal(value anyelement)

  Description: Converts the given value to text and then quotes it as a literal.

  Return type: text.

  Example:

  ```
  gaussdb=# SELECT quote_literal(42.5);
   quote_literal
  ---------------
   '42.5'
  (1 row)
  ```

  If a command similar to the following exists, the given value will be escaped.

  ```
  gaussdb=# SELECT quote_literal(E'O\'42.5');
   quote_literal
  ---------------
   '0''42.5'
  (1 row)
  ```

  If a command similar to the following exists, the backslash will be properly doubled.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gaussdb=# SELECT quote_literal('O\42.5');
 quote_literal
---------------
 E'O\\42.5'
(1 row)
```

- quote_nullable(string text)

  Description: Returns the given string suitably quoted to be used as a string in an SQL statement string (quotation marks are used as required). It supports XML data that is explicitly converted to the character type.

  Return type: text.

  Example:

  ```
  gaussdb=# SELECT quote_nullable('hello');
   quote_nullable
  ----------------
   'hello'
  (1 row)
  ```

  If a command similar to the following exists, the text will be escaped.

  ```
  gaussdb=# SELECT quote_nullable(E'O\'hello');
   quote_nullable
  ----------------
   'O''hello'
  (1 row)
  ```

  If a command similar to the following exists, the backslash will be properly doubled.

  ```
  gaussdb=# SELECT quote_nullable('O\hello');
   quote_nullable
  ----------------
   E'O\\hello'
  (1 row)
  ```

  If the parameter is **NULL**, **NULL** is returned.

  ```
  gaussdb=# SELECT quote_nullable(NULL);
   quote_nullable
  ----------------
   NULL
  (1 row)
  ```

- quote_nullable(value anyelement)

  Description: Converts the given value to text and then quotes it as a literal. The input parameter type is anyelement.

  Return type: text.

  Example:

  ```
  gaussdb=# SELECT quote_nullable(42.5);
   quote_nullable
  ----------------
   '42.5'
  (1 row)
  ```

  If a command similar to the following exists, the given value will be escaped.

  ```
  gaussdb=# SELECT quote_nullable(E'O\'42.5');
   quote_nullable
  ----------------
   'O''42.5'
  (1 row)
  ```

  If a command similar to the following exists, the backslash will be properly doubled.

  ```
  gaussdb=# SELECT quote_nullable('O\42.5');
   quote_nullable
  ----------------
  ```

```
 E'O\\42.5'
(1 row)
```

If the parameter is **NULL**, **NULL** is returned.

```
gaussdb=# SELECT quote_nullable(NULL);
 quote_nullable
----------------
 NULL
(1 row)
```

- space(count)

  Description: Returns a string consisting of a specified number of spaces.

  Parameters: See **Table 1-39**.

  Table 1-39 space parameters

Parameter	Type	Description
count	• Integer types: tinyint, smallint, mediumint, int, and bigint. • Unsigned integer types: tinyint unsigned, smallint unsigned, and int unsigned. • Character and text types: char, varchar, tinytext, text, mediumtext, and longtext. Only integer strings are supported, and the integer range is within the bigint range. • Floating-point types: float, real, and double. • Fixed-point types: numeric, decimal, and dec. • Boolean type.	Number of spaces.

  Return type: text.

  Example:

```
gaussdb=# SELECT space(5);
 space
--------

(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- The space function takes effect only when **sql_compatibility** is set to **'MYSQL'**.
- If the input parameter **count** is less than **1073741819** and greater than **0**, a string of *count* spaces is returned. Otherwise, an empty string is returned.
- If the input parameter is of the floating-point or fixed-point type and the parameter value is not an integer, the return value is rounded down.
- If the input parameter is of the Boolean type, the value **true** is converted to **1** and the value **false** is converted to **0**.

- substring_inner(string [from int] [for int])

  Description: Extracts a substring. **from int** indicates the start position of the truncation. **for int** indicates the number of bytes truncated.

  Return type: text.

  Example:

```
gaussdb=# SELECT substring_inner('adcde', 2,3);
 substring_inner
-----------------
 dcd
(1 row)
```

- substring(string [from int] [for int])

  Description: Extracts a substring. **from int** indicates the start position of the truncation. **for int** indicates the number of bytes truncated.

  Return type: text.

  Example:

```
gaussdb=# SELECT substring('Thomas' from 2 for 3);
 substring
-----------
 hom
(1 row)
```

  NOTE

  This function is designed for MySQL-compatible databases. When the GUC parameters **b_format_version** is **'5.7'** and **b_format_dev_version** is **'s1'**, **[from int]** can be a negative number, indicating the character position counted backwards from the end of the string. If these parameters are not set, the result will be empty when **[from int]** is negative.

- substring(string, pos, len)

  Description: Extracts substring.

  Parameters: See **Table 1-40**.

Table 1-40 substring(string, pos, len) parameters

Parameter	Type	Description	Value Range
string	text	Character string to be truncated.	-
pos	Int	Start position of the character string to be truncated.	The absolute value is less than the string length.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Type	Description	Value Range
len	Int	Length of the character string to be truncated.	The value is greater than 0.

Return type: text.

Example:

```
gaussdb=# SELECT substring('substrteststring', -5, 5);
 substring
-----------
 tring
(1 row)
```

NOTE

This function is designed for MySQL-compatible databases. When the GUC parameters **b_format_version** is **'5.7'** and **b_format_dev_version** is **'s1'**, **pos** can be a negative number, indicating the character position counted backwards from the end of the string. If these parameters are not set, the result will be empty when **pos** is negative.

- substring_index(str, split, index)

  Description: Returns the left or right part of the *n*th (specified by *index*) *str* string separated by *split*. If *index* is a positive number, the left part is returned. If *index* is a negative number, the right part is returned.

  Parameters: See **Table 1-41**.

  Table 1-41 substring_index parameters

Parameter	Type	Description
str	text	Source string to be processed.
split	text	Separator to be used.
index	Int	Position index of the separator (starting from 1). A positive number indicates the left side, and a negative number indicates the right side.

  Return type: text.

  Example:

```
gaussdb=# SELECT substring_index('Test1splitTest2splitTest3splitTest4', 'split', 2);
 substring_index
-----------------
 Test1splitTest2
(1 row)

gaussdb=# SELECT substring_index('Test1splitTest2splitTest3splitTest4', 'split', -2);
 substring_index
-----------------
 Test3splitTest4
(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- substring(string FROM pattern)

  Description: Extracts substrings matching the POSIX regular expression. It returns null if there is no match, otherwise the portion of the text that matched the pattern.

  Return type: text.

  Example:

```
gaussdb=# SELECT substring('Thomas' FROM '...$');
 substring
-----------
 mas
(1 row)
gaussdb=# SELECT substring('foobar' FROM 'o(.)b');
 result
--------
 o
(1 row)
gaussdb=# SELECT substring('foobar' FROM '(o(.)b)');
 result
--------
 oob
(1 row)
```

  NOTE

  - If the POSIX regular expression contains any parentheses, the portion of the text that matched the first parenthesized sub-expression (the one whose left parenthesis comes first) is returned. If you want to use parentheses without triggering this behavior, you can put a pair of additional parentheses around the whole expression.
  - When **sql_compatibility** is set to **'MYSQL'**, and the GUC parameters **b_format_version** is set to **'5.7'** and **b_format_dev_version** is set to **'s1'**, this function is used in the same way as **substr(str FROM pos)**. The output result and behavior of this function are the same as those of the **substr(str FROM pos)** function.

- substring(string from pattern for escape)

  Description: Extracts substrings matching the SQL regular expression. The declared schema must match the entire data string; otherwise, the function fails and returns a null value. To indicate the part of the pattern that should be returned on success, the pattern must contain two occurrences of the escape character followed by a double quotation mark ("). The text matching the portion of the pattern between these marks is returned.

  Return type: text.

  Example:

```
gaussdb=# SELECT substring('Thomas' from '%#"o_a#"_' for '#');
 substring
-----------
 oma
(1 row)
```

  NOTE

  When **sql_compatibility** is **'MYSQL'**, and the GUC parameters **b_format_version** is **'5.7'** and **b_format_dev_version** is **'s1'**, this function operates similarly to **substr(str FROM pos FOR len)**. Its output and behavior are identical to those of **substr(str FROM pos FOR len)**.

- rawcat(raw, raw)

  Description: Indicates the string concatenation function.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Return type: raw

Example:

```
gaussdb=# SELECT rawcat('ab','cd');
 rawcat
--------
 ABCD
(1 row)
```

- regexp_substr(string text, pattern text [, position int [, occurrence int [, flags text]]])

  Description: Extracts substrings from a regular expression. Its function is similar to **substr**. When a regular expression contains multiple parallel brackets, it also needs to be processed.

  Parameters:

  - **string**: source character string used for matching.
  - **pattern**: regular expression pattern string used for matching.
  - **position**: start character of the source string used for matching. This parameter is optional. The default value is **1**.
  - **occurrence**: sequence number of the matched substring to be extracted. This parameter is optional. The default value is **1**.
  - **flags**: contains zero or multiple single-letter flags that change the matching behavior of the function. This parameter is optional. **Table 1-42** describes the options supported by **flags** and their meanings.

    Table 1-42 Options supported by flags

Option	Description
'b'	Indicates the BRE matching without extension.
'c'	Indicates the case-sensitive matching.
'e'	Indicates the ERE matching with extension.
'i'	Indicates the case-insensitive matching.
'm'	Indicates the multi-line matching. If **flags** contains **'m'**, use the multi-line matching. Otherwise, use the single-line matching.
'n'	The meaning of **'n'** varies depending on the GUC parameter **behavior_compat_options** and the compatibility mode of the current database. When **sql_compatibility** is set to **'ORA'** or **'MYSQL'** and the GUC parameter **behavior_compat_options** includes **aformat_regexp_match**, the **'n'** option means that "." matches with a newline character (**'\n'**). If **'n'** is not specified in **flags**, "." will not match with a newline character. In other cases, the **'n'** option has the same meaning as the **'m'** option.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Option	Description
'p'	Indicates partial linefeed-sensitive matching, which is similar to the linefeed-sensitive matching (**'m'** or **'n'**) and affects "." and square bracket expression, but does not affect ^ and $.
'q'	Indicates common character matching.
's'	Indicates the single-line matching. The meaning is opposite to those of **'m'** and **'n'**.
't'	Indicates the compact matching. The whitespace characters match themselves.
'w'	Indicates the inverse partial newline-sensitive matching, opposite to **'p'**.
'x'	Indicates the loose matching. The whitespace characters are ignored.

Return type: text.

Example:

```
gaussdb=# SELECT regexp_substr('str','[ac]');
 regexp_substr
---------------

(1 row)

gaussdb=# SELECT regexp_substr('foobarbaz', 'b(..)', 3, 2) AS RESULT;
 result
--------
 baz
(1 row)
```

- regexp_count(string text, pattern text [, position int [, flags text]])

  Description: obtains the number of substrings used for matching.

  Parameters:

  - **string**: source character string used for matching.
  - **pattern**: regular expression pattern string used for matching.
  - **position**: start character of the source string used for matching. This parameter is optional. The default value is **1**.
  - **flags**: contains zero or multiple single-letter flags that change the matching behavior of the function. This parameter is optional. **Table 1-42** describes the options supported by **flags** and their meanings.

  NOTE

  When the function is in an ORA-compatible database, the value of **a_format_version** is **10c**, and the value of **a_format_dev_version** is **s1**, the **pattern** parameter ending with a backslash (\) is valid.

  Return type: int.

  Example:

  ```
  gaussdb=# SELECT regexp_count('foobarbaz','b(..)', 5) AS RESULT;
  result
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
--------
1
(1 row)
```

- regexp_instr(string text, pattern text [, position int [, occurrence int [, return_opt int [, flags text]]]])

  Description: obtains the position (starting from 1) of the substring that meets the matching condition. If no substring is matched, **0** is returned.

  Parameters:

  - **string**: source character string used for matching.
  - **pattern**: regular expression pattern string used for matching.
  - **position**: start character of the source string used for matching. This parameter is optional. The default value is **1**.
  - **occurrence**: sequence number of the matched substring to be obtained. This parameter is optional. The default value is **1**.
  - **return_opt**: specifies whether to return the position of the first or last character of the matched substring. This parameter is optional. If the value is **0**, the position of the first character (starting from 1) of the matched substring is returned. If the value is greater than 0, the position of the next character of the end character of the matched substring is returned. The default value is **0**.
  - **flags**: contains zero or multiple single-letter flags that change the matching behavior of the function. This parameter is optional. **Table 1-42** describes the options supported by **flags** and their meanings.

  Return type: int.

  Example:

```
gaussdb=# SELECT regexp_instr('foobarbaz','b(..)', 1, 1, 0) AS RESULT;
result
--------
4
(1 row)

gaussdb=# SELECT regexp_instr('foobarbaz','b(..)', 1, 2, 0) AS RESULT;
result
--------
7
(1 row)
```

- regexp_matches(string text, pattern text [, flags text])

  Description: Returns all captured substrings resulting from matching a POSIX regular expression against **string**. If there is no match to the pattern, the function returns no rows.

  - If the pattern contains no parenthesized sub-expressions, then each row returned is a single-element text array containing the substring matching the whole pattern.
  - If the pattern contains parenthesized sub-expressions, the function returns a text array whose *n*th element is the substring matching the *n*th parenthesized sub-expression of the pattern.

  Parameter: The optional parameter **flags** contains zero or multiple single-letter flags that change the function's behavior. Flag **i** specifies case-insensitive matching, while flag **g** specifies replacement of each matching substring rather than only the first one.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTICE

If the last parameter is provided but the parameter value is an empty string (''') and the SQL compatibility mode is set to **ORA**, the returned result is an empty set. This is because the ORA compatible mode treats the empty string (''') as **NULL**. To resolve this problem, you can:

- Change the database SQL compatibility mode to **TD**.
- Do not provide the last parameter or do not set the last parameter to an empty string.

Return type: SETOF text[]

Example:

```
gaussdb=# SELECT regexp_matches('foobarbequebaz', '(bar)(beque)');
 regexp_matches
----------------
 {bar,beque}
(1 row)
gaussdb=# SELECT regexp_matches('foobarbequebaz', 'barbeque');
 regexp_matches
----------------
 {barbeque}
(1 row)
gaussdb=# SELECT regexp_matches('foobarbequebazilbarfbonk', '(b[^b]+)(b[^b]+)', 'g');
 regexp_matches
----------------
 {bar,beque}
 {bazil,barf}
(2 rows)
```

- regexp_match(string text, pattern text [, flags text])

  Description: Returns a string array of matching substrings within the first match of a POSIX regular expression pattern. If there is no match to the pattern, the function returns an empty row.

  – If the pattern contains no parenthesized sub-expressions, then each row returned is a single-element text array containing the substring matching the whole pattern.

  – If the pattern contains parenthesized sub-expressions, the function returns a text array whose *n*th element is the substring matching the *n*th parenthesized sub-expression of the pattern.

  Parameter: The **flags** parameter is optional. If **flags** is not specified, tight syntax matching is used by default. The **flags** parameter contains zero or multiple single-letter flags that change the behavior of a function. The following table lists the supported flags.

Table 1-43 flags parameters

Option	Description
'b'	Converts the POSIX regular expression to a BRE.
'c'	Indicates the case-sensitive matching.
'e'	Converts the POSIX regular expression to an ERE.
'i'	Indicates the case-insensitive matching.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Option	Description
'n'	Indicates newline-sensitive matching. A character string is regarded as multiple lines. Caret (^) and dollar sign ($) match the beginning and end of each line. Periods (.) do not match linefeed.
'm'	Indicates newline-sensitive matching. A character string is regarded as multiple lines. Caret (^) and dollar sign ($) match the beginning and end of each line. Periods (.) do not match linefeed. The matching mode of *n* is the same.
'p'	Indicates partial newline-sensitive matching. Periods (.) do not match linefeed. Caret (^) can only match the beginning of the first line and dollar sign ($) can only match the end of the last line.
'q'	Represents the regular expression is a text string, all of which are common characters.
's'	Indicates non-newline-sensitive matching. That is, a character string is regarded as a single line, and caret (^) and dollar sign ($) match the beginning and end of the line, respectively. In this mode, periods (.) in the regular expression can match any character, including the linefeed character.
't'	Indicates the tight syntax matching.
'w'	Indicates inverse partial newline-sensitive matching. In the regular expression, caret (^) matches the beginning of each line, and dollar sign ($) matches only the end of the last line. Period (.) can match any character, including the linefeed character.
'x'	Indicates the extended syntax matching, ignoring whitespace characters and comments in regular expressions. The following three scenarios are excluded: • The whitespace characters or comments starting with the number sign (#) that are prefixed with slashes (\) will be retained. • Whitespace characters or number signs (#) in square brackets will be retained. • The whitespace and comment characters such as (? : are not allowed in multi-character symbols.

NOTICE

If the parameter contains an empty string ('') and the compatibility mode of the database is set to **ORA**, the returned result is **NULL**. This is because the empty string is processed as **NULL** in ORA-compatible mode.

Return type: SETOF text[]

Example:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gaussdb=# SELECT regexp_match('foobarbequebaz', '(bar)(beque)');
 regexp_match
--------------
 {bar,beque}
(1 row)
gaussdb=# SELECT (regexp_match('foobarbequebaz', 'bar.*que'))[1];
 regexp_match
--------------
 barbeque
(1 row)
gaussdb=# SELECT regexp_match('Learning #PostgreSQL', 'R', 'c');
 regexp_match
--------------

(1 row)
gaussdb=# SELECT regexp_match('hello world', 'h e l l o', 'x');
 regexp_match
--------------
 {hello}
(1 row)
```

- regexp_split_to_table(string text, pattern text [, flags text])

  Description: Splits **string** using a POSIX regular expression as the delimiter. If there is no match to the pattern, the function returns the string. When there is at least one match, each match returns the text between the end position of the previous match (or the start position of the string) and the start position of the current match. When there are no more matches, it returns the text from the end of the last match to the end of the string.

  Parameter: The **flags** parameter contains zero or multiple single-letter flags that change the function's behavior. Flag **i** specifies case-insensitive matching. By default, all matching substrings are replaced, not just the first one.

  Return type: SETOF text

  Example:

  ```
  gaussdb=# SELECT regexp_split_to_table('hello world', E'\\s+');
   regexp_split_to_table
  -----------------------
   hello
   world
  (2 rows)
  ```

- regexp_split_to_array(string text, pattern text [, flags text])

  Description: Splits **string** using a POSIX regular expression as the delimiter. This function is similar to the regexp_split_to_table function. However, this function returns the split result as a text array.

  Return type: text[]

  Example:

  ```
  gaussdb=# SELECT regexp_split_to_array('hello world', E'\\s+');
   regexp_split_to_array
  -----------------------
   {hello,world}
  (1 row)
  ```

- repeat(string text, number int)

  Description: Repeats **string** the specified number of times.

  Return type: text.

  Example:

  ```
  gaussdb=# SELECT repeat('Pg', 4);
    repeat
  ----------
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
 PgPgPgPg
(1 row)
```

NOTE

The maximum size of memory allocated at a time cannot exceed 1 GB due to the memory allocation mechanism of the database. Therefore, the maximum value of **number** cannot exceed (1 GB – **x**)/**lengthb** (**string**) – 1. **x** indicates the length of the header information, which is usually greater than 4 bytes. The value varies among different scenarios.

- replace(string text, from text, to text)

  Description: Replaces all occurrences in **string** of substring specified by **from** with substring specified by **to**.

  Return type: text.

  Example:

```
gaussdb=# SELECT replace('abcdefabcdef', 'cd', 'XXX');
    replace
----------------
 abXXXefabXXXef
(1 row)
```

- replace(string, substring)

  Description: Deletes all substrings in a string.

  Parameters: **string** and **substring**, both are of the text type.

  Return type: text.

  Example:

```
gaussdb=# SELECT replace('abcdefabcdef', 'cd');
    replace
----------------
 abefabef
(1 row)
```

- reverse(str)

  Description: Returns a reversed string (by character).

  Return type: text.

  Example:

```
gaussdb=# SELECT reverse('abcde');
 reverse
---------
 edcba
(1 row)
```

- right(str text, n int)

  Description: Returns the last *n* characters in a string. When *n* is negative, all but the first */n/* characters are returned.

  Return type: text.

  Example:

```
gaussdb=# SELECT right('abcde', 2);
 right
-------
 de
(1 row)

gaussdb=# SELECT right('abcde', -2);
 right
-------
 cde
(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- rpad(string text, length int [, fill text])

  Description: Pads a string to a specified length by filling the character specified by **fill** (blank by default). If the string is already longer than *length*, it will be truncated from the end.

  Return type: text.

  NOTE

  In ORA-compatible databases where **a_format_version** is **10c** and **a_format_dev_version** is **s1**, this function operates as follows:

  - The **length** parameter indicates the display length for character strings. The display length for individual characters is consistent with that in the Oracle Database.
  - During the function execution, if the remaining length is 1 and the next character is of the full-width type (2 bytes), a space character is added to the right of the string.
  - If the value of *length* is a decimal, the value is truncated instead of being rounded off.
  - The **string** and **fill** parameters do not comply with the encoding specifications.
  - If the length of the **string** parameter exceeds 1 GB after padding, an error is reported.

  In other cases:

  - The **length** parameter indicates the total length of characters in a character string. The length of a single character is fixed to 1.
  - If the length of the **string** parameter exceeds 1 GB after padding, an error is reported.
  - If the value of **length** is a decimal, the value is rounded off.
  - The **string** and **fill** parameters do not comply with the encoding specifications.

- substrb(text, int, int)

  Description: Extracts substring. The first **int** parameter indicates the start position of the extraction. It can be a positive or negative number. A positive number indicates that the extraction starts from the beginning of the string, and a negative number indicates that the extraction starts from the end of the string. The second **int** parameter indicates the number of characters to be extracted.

  Return type: text.

  Example:

  ```
  gaussdb=# SELECT substrb('string',2,3);
   substrb
  ---------
   tri
  (1 row)
  ```

- substrb(text, int)

  Description: Extracts a substring. **int** indicates the start position of the extraction.

  Return type: text.

  Example:

  ```
  gaussdb=# SELECT substrb('string',2);
   substrb
  ---------
   tring
  (1 row)
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- substr(text, int)/substr(str FROM pos)

  Description: **str** is the target string, and **pos** is the position in the string. The string of **str** from the **pos** position is output to the end of the character.

  Return type: text.

  Example:

```
gaussdb=# SELECT substr('stringtest' FROM 4);
 substr
---------
 ingtest
(1 row)

gaussdb=# SELECT substr('stringtest', 4);
 substr
---------
 ingtest
(1 row)
```

- substr(str FROM pos for len)

  Description: Extracts a substring. The first **int** indicates the start position of the subtraction. The second **int** indicates the number of characters extracted. The value of **pos** can be a negative number. If the value is a negative number, the value is extracted from back to front.

  Return type: text.

  Example:

```
gaussdb=# SELECT substr('teststring' FROM 5 for 2);
 substr
--------
 st
(1 row)
```

- substr(bytea, from, count)

  Description: Extracts a substring from **bytea**. **from** specifies the position where the extraction starts. **count** specifies the length of the extracted substring.

  Return type: text.

  Example:

```
gaussdb=# SELECT substr('string',2,3);
 substr
--------
 tri
(1 row)
```

- string || string

  Description: Concatenates strings.

  Return type: text.

  Example:

```
gaussdb=# SELECT 'MPP'||'DB' AS RESULT;
 result
--------
 MPPDB
(1 row)
```

- string || non-string or non-string || string

  Description: Concatenates strings and non-strings.

  Return type: text.

  Example:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gaussdb=# SELECT 'Value: '||42 AS RESULT;
  result
-----------
 Value: 42
(1 row)
```

- split_part(string text, delimiter text, field int)

  Description: Splits *string* based on *delimiter* and returns the *field*th substring (counting from text of the first appeared delimiter).

  Return type: text.

  Example:

```
gaussdb=# SELECT split_part('abc~@~def~@~ghi', '~@~', 2);
 split_part
------------
 def
(1 row)
```

- strpos(string, substring)

  Description: Specifies the position of a substring. This function is the same as position(substring in string) except that it reverses the parameter order.

  Return type: int.

  Example:

```
gaussdb=# SELECT strpos('source', 'rc');
 strpos
--------
      4
(1 row)
```

- to_hex(number int or bigint)

  Description: Converts a number to a hexadecimal expression.

  Return type: text.

  Example:

```
gaussdb=# SELECT to_hex(2147483647);
  to_hex
----------
 7fffffff
(1 row)
```

- translate(string text, from text, to text)

  Description: Replaces any characters in string that match characters of *from* with the corresponding characters of *to*. If the length of **from** is greater than that of **to**, the characters in **string** that match the characters in **from** (excluding the characters in **to**) will be deleted.

  Return type: text.

  Example:

```
gaussdb=# SELECT translate('12345', '143', 'ax');
 translate
-----------
 a2x5
(1 row)
```

- length(string)

  Description: Obtains the number of characters in a string. When **sql_compatibility** is set to **'MYSQL'**, **b_format_version** is set to **'5.7'**, and **b_format_dev_version** is set to **'s1'**, if the string is of the string or text type, the number of bytes of the string is returned.

  Return type: integer

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- lengthb(string)

  Description: Obtains the number of bytes in a string. The value depends on character sets. For instance, the number of returned bytes varies between GBK and UTF-8.

  Return type: integer

  Example:

  ```
  gaussdb=# SELECT lengthb('ABCDEF');
   lengthb
  ---------
         7
  (1 row)
  ```

- substr(string, from)

  Description: Extracts substrings from **string**. **from** indicates the start position of the extraction.

  - If **from** starts at 0, **1** will be used.
  - If the value of *from* is positive, all characters from *from* to the end are extracted.
  - If the value of *from* is negative, the last *n* characters in the string are extracted, and *n* indicates the absolute value of *from*.

  Return type: text.

  Example:

  - If the value of **from** is positive:

    ```
    gaussdb=# SELECT substr('ABCDEF',2);
     substr
    --------
     BCDEF
    (1 row)
    ```

  - If the value of **from** is negative:

    ```
    gaussdb=# SELECT substr('ABCDEF',-2);
     substr
    --------
     EF
    (1 row)
    ```

- substr(string, from, count)

  Description: Extracts substrings from **string**. **count** indicates the length of the extracted substring, and **from** indicates the start position of the extraction.

  - If **from** starts at 0, **1** will be used.
  - If *from* is a positive number, *count* characters will be extracted, starting from *from*.
  - If *from* is a negative number, *count* characters will be extracted, starting from the *n*th character from the end, where *n* is the absolute value of *from*.
  - If **count** is smaller than 1, **null** will be returned.

  Return type: text.

  Example:

  - If the value of **from** is positive:

    ```
    gaussdb=# SELECT substr('ABCDEF',2,2);
     substr
    --------
     BC
    (1 row)
    ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

  - If the value of **from** is negative:

```
gaussdb=# SELECT substr('ABCDEF',-3,2);
 substr
--------
 DE
(1 row)
```

- substrb(string, from)

  Description: Same as the functionality of the substr(string,from) function, but the calculation unit is byte.

  Return type: text.

  Example:

```
gaussdb=# SELECT substrb('ABCDEF',-2);
 substrb
---------
 EF
(1 row)
```

- substrb(string, from, count)

  Description: Same as the functionality of the substr(string, from, count) function, but the calculation unit is byte.

  Return type: text.

  Example:

```
gaussdb=# SELECT substrb('ABCDEF',2,2);
 substrb
---------
 BC
(1 row)
```

- to_single_byte(char)

  Description: Converts all multi-byte characters in a string to single-byte characters.

  Return type: text.

  NOTE

  This function takes effect in ORA-compatible databases where **a_format_version** is **10c** and **a_format_dev_version** is **s2**.

- to_multi_byte(char)

  Description: Converts all single-byte characters in a string to multi-byte characters.

  Return type: text.

  NOTE

  This function takes effect in ORA-compatible databases where **a_format_version** is **10c** and **a_format_dev_version** is **s2**.

- trim([leading |trailing |both] [characters] FROM string)

  Description: Removes the longest string consisting only of characters in **characters** (a space by default) from the start, end, or both sides of **string**.

  Return type: text.

  Example:

```
gaussdb=# SELECT trim(BOTH 'x' FROM 'xTomxx');
 btrim
-------
 Tom
(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gaussdb=# SELECT trim(LEADING 'x' FROM 'xTomxx');
 ltrim
-------
 Tomxx
(1 row)
gaussdb=# SELECT trim(TRAILING 'x' FROM 'xTomxx');
 rtrim
-------
 xTom
(1 row)
```

- rtrim(string [, characters])

  Description: Removes the longest string consisting only of characters in **characters** (a space by default) from the end of **string**.

  Return type: text.

  Example:

  ```
  gaussdb=# SELECT rtrim('TRIMxxxx','x');
   rtrim
  -------
   TRIM
  (1 row)
  ```

- ltrim(string [, characters])

  Description: Removes the longest string consisting only of characters in **characters** (a space by default) from the start of **string**.

  Return type: text.

  Example:

  ```
  gaussdb=# SELECT ltrim('xxxxTRIM','x');
   ltrim
  -------
   TRIM
  (1 row)
  ```

- upper(string)

  Description: Converts a character string to uppercase.

  Return type: text.

  Example:

  ```
  gaussdb=# SELECT upper('tom');
   upper
  -------
   TOM
  (1 row)
  ```

- lower(string)

  Description: Converts a character string to lowercase.

  Return type: text.

  Example:

  ```
  gaussdb=# SELECT lower('TOM');
   lower
  -------
   tom
  (1 row)
  ```

- nls_upper(string [, nlsparam])

  Description: Converts a character string to uppercase. You can specify a sorting rule to process special uppercase conversions in some languages. The format of **nlsparam** is **'nls_sort=sort_name'**, where **sort_name** is replaced by the specific sorting rule name. When the **nlsparam** parameter is not set, this function is equivalent to **upper**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Return type: text.

Example:

```
gaussdb=# SELECT nls_upper('große');
 nls_upper
-----------
 GROßE
(1 row)
gaussdb=# SELECT nls_upper('große', 'nls_sort = XGerman');
 nls_upper
-----------
 GROSSE
(1 row)
```

NOTE

This function can be used when the value of **a_format_version** is **10c** and that of **a_format_dev_version** is **s2** in an ORA-compatible database.

- nls_lower(string [, nlsparam])

  Description: Converts a character string to lowercase letters. You can specify a sorting rule to process special lowercase conversion rules in some languages. The format of **nlsparam** is **'nls_sort=sort_name'**, where **sort_name** is replaced by the specific sorting rule name. When the **nlsparam** parameter is not set, this function is equivalent to **lower**.

  Return type: text.

  Example:

  ```
  gaussdb=# SELECT nls_lower('INDIVISIBILITY');
    nls_lower
  ----------------
   indivisibility
  (1 row)
  gaussdb=# SELECT nls_lower('INDIVISIBILITY', 'nls_sort = XTurkish');
    nls_lower
  ----------------
   ındıvısıbılıty
  (1 row)
  ```

  NOTE

  This function can be used when the value of **a_format_version** is **10c** and that of **a_format_dev_version** is **s2** in an ORA-compatible database.

- instr(string, substring[,position, occurrence])

  Description: Queries and returns the value of the substring position that occurs the *occurrence* (**1** by default) times from the *position* (**1** by default) in the string.

  – When **position** is **0**, the function will return **0**.
  – When **position** is a negative number, the search starts backwards from the *n*th character counting from the end of the string. *n* represents the absolute value of **position**.

  In this function, the calculation unit is character. One Chinese character is one character.

  Return type: integer

  Example:

  ```
  gaussdb=# SELECT instr('corporate floor','or', 3);
   instr
  -------
       5
  (1 row)
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gaussdb=# SELECT instr('corporate floor','or',-3,2);
 instr
-------
     2
(1 row)
```

- initcap(string)

  Description: Capitalizes the first letter of each word in a string.

  Return type: text.

  Example:

  ```
  gaussdb=# SELECT initcap('hi THOMAS');
    initcap
  -----------
   Hi Thomas
  (1 row)
  ```

  NOTE

  When **a_format_version** is set to **10c** and **a_format_dev_version** is set to **s2**, if a case-insensitive character, such as Chinese, is followed by a case-sensitive character, only the first letter of the case-sensitive character is capitalized. Therefore, you are advised to set **a_format_version** to **10c** and **a_format_dev_version** to **s2**.

- ascii(string)

  Description: Indicates the ASCII code of the first character in the string.

  Return type: integer

  Example:

  ```
  gaussdb=# SELECT ascii('xyz');
   ascii
  -------
    120
  (1 row)
  ```

- ascii2(string)

  Description: Returns the decimal code of the first character of the input string in the database character set.

  Return type: bigint

  NOTE

  This function takes effect in ORA-compatible databases where **a_format_version** is **10c** and **a_format_dev_version** is **s2**.

- asciistr(string)

  Description: Converts non-ASCII characters in the input string to *XXXX*, where *XXXX* indicates the UTF-16 code unit.

  Return type: text.

  NOTE

  This function takes effect in ORA-compatible databases where **a_format_version** is **10c** and **a_format_dev_version** is **s2**.

- unistr(string)

  Description: Converts the coding sequence in a string into the corresponding character. Other characters remain unchanged.

  Return type: text.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- This function takes effect in ORA-compatible databases where **a_format_version** is **10c** and **a_format_dev_version** is **s2**.
- The backslash (\) must be followed by four hexadecimal characters to indicate the coding sequence, or another backslash (\) indicates that a single backslash (\) is entered.
- If the input parameter is of the time type, the time type is implicitly converted to the character string type.

- vsize(expr)

  Description: Returns the number of bytes of the input expression.

  Return type: int.

  NOTE

  This function takes effect in ORA-compatible databases where **a_format_version** is **10c** and **a_format_dev_version** is **s2**.

- replace(string varchar, search_string varchar, replacement_string varchar)

  Description: Replaces all substrings specified by **search_string** in the string with substrings specified by **replacement_string**.

  Return type: text.

  Example:

```
gaussdb=# SELECT replace('jack and jue','j','bl');
    replace
----------------
 black and blue
(1 row)
```

- concat(str1, str2)

  Description: Connects str1 and str2 and returns the string. This function calls the output function of the data type and the return value is uncertain. As a result, the optimizer cannot calculate the result in advance when generating a plan. If there are performance requirements, you are advised to use the operator ||.

  NOTE

  - If **sql_compatibility** is set to **'MYSQL'** and **str1** or **str2** is set to **NULL**, the returned result is **NULL**.
  - The return value of this function is of the variable-length type. When this function is compared with table data, the character string length is lost in the combination result. As a result, the comparison results are different.

  Return type: text.

  Example:

```
gaussdb=# SELECT concat('Hello', ' World!');
    concat
--------------
 Hello World!
(1 row)
gaussdb=# SELECT concat('Hello', NULL);
 concat
--------

(1 row)
gaussdb=# CREATE TABLE test_space(c char(10));
CREATE TABLE
gaussdb=# INSERT INTO test_space values('a');
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
INSERT 0 1
-- After spaces are padded, the character string is still a fixed-length character string. It is expected that the result can be found.
gaussdb=# SELECT * FROM test_space WHERE c = 'a ';
    c
------------
 a
(1 row)
-- The combination result is a variable-length character string. The comparison fails and the result cannot be found.
gaussdb=# SELECT * FROM test_space WHERE c = 'a' || ' ';
 c
---
(0 rows)
```

- chr(integer)

  Description: For the UTF-8 character set, the input is encoded as Unicode and a UTF-8 character is returned. For other character sets, an ASCII character is returned.

  Return type: text.

  NOTE

  - When **a_format_version** is set to **10c** and **a_format_dev_version** is set to **s1** in an ORA-compatible database, the value is truncated instead of being rounded off if the value of *integer* is a decimal.
  - For details about how to set and modify the character set and collation, see **Character Sets and Collations**.

  Example:

```
gaussdb=# SELECT chr(65);
 chr
-----
 A
(1 row)

-- In the case of UTF-8 character set
gaussdb=# SELECT chr(19968);
 chr
-----
 一
(1 row)
```

- chr(cvalue int|bigint)

  Description: Converts **cvalue** into characters with the specified byte sequence.

  Parameter: **cvalue** can be converted to the int or bigint type within the range of [0,2^32 – 1], which matches the range of unsigned int. Depending on the value of **n**, a character array consisting of one to four bytes will be returned. The byte arrays returned in different character sets are the same. However, due to different encoding rules, the result of the returned character string varies depending on the character set encoding. If the character set is single-byte encoded, the corresponding ASCII character is returned after the mod 256 operation is performed on **cvalue**.

  – If a byte in the input *cvalue* is **0**, the output is truncated.
  – If the input does not comply with the encoding rule of the current character set, an error is reported.
  – If the input is **NULL** or **0**, **NULL** is returned.

  Return type: text.

  Example:

```
gaussdb=# SELECT chr(65);
 chr
-----
 A
(1 row)
gaussdb=# CREATE DATABASE gaussdb_o WITH DBCOMPATIBILITY 'ORA';
gaussdb=# \c gaussdb_o
gaussdb_o=# SET a_format_version='10c';
gaussdb_o=# SET a_format_dev_version = 's1';
gaussdb_o=# SELECT chr(16705);
 chr
-----
 AA
(1 row)

-- The output is truncated.
gaussdb_o=# SELECT chr(4259905);
 chr
-----
 A
(1 row)
gaussdb_o=# \c postgres
gaussdb=#  DROP DATABASE gaussdb_o;
```

NOTE

When **a_format_version** is set to **10c** and **a_format_dev_version** is set to **s1** in an ORA-compatible database, the function returns a collation based on the input value. If the current character set for database encoding is a multi-byte character set, the return value contains one to four bytes. If the current character set for database encoding is a single-byte character set, the return value is a single byte obtained by performing the mod 256 operation on the input value. Otherwise, if the current character set for database encoding is UTF-8, the input is encoded as Unicode and a UTF-8 character is returned. For other character sets, an ASCII character is returned.

- nchr(cvalue int|bigint)

  Description: Returns characters (from the national character set) that correspond to the input parameter. The GUC parameter **nls_nchar_characterset** specifies the national character set. Only **AL16UTF16** and **UTF8** are supported.

  – If **nls_nchar_characterset** is set to **AL16UTF16** and the input parameter exceeds two bytes, the input parameter will be truncated, retaining only the lowest two bytes.
  – If **nls_nchar_characterset** is set to **UTF8** and the input parameter exceeds three bytes, the input parameter will be interpreted as **0**.

  This function takes effect in ORA-compatible databases where the GUC parameters **a_format_version** is set to **10c** and **a_format_dev_version** is set to **s4**.

  Parameter: **cvalue** can be converted to the int or bigint type within the range of [0,2^32 – 1], which matches the range of unsigned int. If the input parameter contains the decimal part, the decimal part will be deleted.

  Return type: NVARCHAR2

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- The byte length of the return value of the function is different from that in the Oracle Database.
- The return value of the function is restricted by the database character set. If there is no mapping table for converting UTF-8 to the database character set or the mapping table does not contain the UTF-8 code corresponding to the input parameter, the current database character set does not support the UTF-8 character. In this case, the return value of the function is different from that in the Oracle Database.
- If the current database character set does not support the UTF-8 character corresponding to the input parameter, or the national character set is UTF-8 but the input parameter does not comply with the UTF-8 format, the byte array corresponding to the input parameter is returned. If a single byte is in the range of [0x00,0x7F], an ASCII character is returned. If a single byte is in the range of [0x80,0xFF], a question mark (?) is returned.
- For details about how to set and modify the character set and collation, see **Character Sets and Collations**.

- regexp_substr(source_char, pattern)

  Description: Extracts substrings from a regular expression. If the SQL syntax is ORA- and MySQL-compatible and the value of the GUC parameter **behavior_compat_options** contains **aformat_regexp_match**, the period (.) cannot match the **'\n'** character. However, if **aformat_regexp_match** is not contained, the period (.) matches the **'\n'** character by default.

  Parameters:

  – **source_char**: source character string used for matching.

  – **pattern**: regular expression pattern string used for matching.

  Return type: text.

  Example:

```
gaussdb=# SELECT regexp_substr('500 Hello World, Redwood Shores, CA', ',[^,]+,')
"REGEXPR_SUBSTR";
  REGEXPR_SUBSTR
-------------------
 , Redwood Shores,
(1 row)
```

- regexp_replace(string, pattern, replacement [,flags])

  Description: Replaces any substring matching a POSIX regular expression pattern. The source string is returned if there is no match to the pattern. If there is a match, the matching substring will be replaced by the **replacement** string in the returned string. The string specified by **replacement** can contain **\n**, where **\n** ranges from 1 to 9, to indicate that the substring matching the *n*th parenthesized subexpression of the pattern should be inserted, and it can contain **\&** to indicate that the substring matching the entire pattern should be inserted.

  Parameters:

  – **string**: source character string used for matching.

  – **pattern**: regular expression pattern string used for matching.

  – **flags**: contains zero or multiple single-letter flags that change the matching behavior of the function. This parameter is optional. Flag **g** specifies replacement of each matching substring rather than only the first one. **Table 1-42** describes the options supported by **flags** and their meanings.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Return type: text.

Example:

```
gaussdb=# SELECT regexp_replace('Thomas', '.[mN]a.', 'M');
 regexp_replace
----------------
 ThM
(1 row)
gaussdb=# SELECT regexp_replace('foobarbaz','b(..)', E'X\\1Y', 'g') AS
RESULT;
   result
-------------
 fooXarYXazY
(1 row)
```

- regexp_replace(string text, pattern text [, replacement text [, position int [, occurrence int [, flags text]]]])

  Description: Replaces any substring matching a POSIX regular expression pattern. The source string is returned if there is no match to the pattern. If there is a match, the matching substring will be replaced by the **replacement** string in the returned string.

  Parameters:

  - **string**: source character string used for matching.
  - **pattern**: regular expression pattern string used for matching.
  - **replacement**: character string used to replace the matched substring. This parameter is optional. If no parameter value is specified or the parameter value is null, an empty string is used for replacement.
  - **position**: start character of the source string used for matching. This parameter is optional. The default value is **1**.
  - **occurrence**: sequence number of the matched substring to be replaced. This parameter is optional. The default value is **1**, indicating that the first matched substring is replaced.
  - **flags**: contains zero or multiple single-letter flags that change the matching behavior of the function. This parameter is optional. **Table 1-42** describes the options supported by **flags** and their meanings.

  NOTE

  When **a_format_version** is set to **10c** and **a_format_dev_version** is set to **s1** in an Oracle-compatible database, the default value of **occurrence** is **0**, indicating that all matched substrings are replaced. In addition, the **pattern** parameter that ends with a backslash (\) is valid.

  Return type: text.

  Example:

  ```
  gaussdb=# SELECT regexp_replace('foobarbaz','b(..)', E'X\\1Y', 2, 2, 'n') AS RESULT;
  result
  ------------
  foobarXazY
  (1 row)
  ```

- concat_ws(sep text, str"any" [, str"any" [, ...]])

  Description: Concatenates all but the first parameter, with separators. The first parameter is used as the separator string. Null parameters will be ignored.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTICE

- If the first parameter is **NULL**, the returned result will also be **NULL**.
- If the first parameter is provided but the parameter value is an empty string ('') and the database compatibility mode is set to **ORA**, the returned result is **NULL**. This is because the database interprets the empty string ('') as **NULL** in ORA-compatible mode. To prevent this issue, consider switching to the MySQL-, TD-, or PG-compatible mode.

Return type: text.

Example:

```
gaussdb=# SELECT concat_ws(',', 'ABCDE', 2, NULL, 22);
 concat_ws
------------
 ABCDE,2,22
(1 row)
```

- nlssort(string text, sort_method text)

  Description: Returns the encoding value of a string in the sorting mode specified by **sort_method**. The encoding value can be used for sorting and determines the sequence of the string in the sorting mode. Currently, **sort_method** can be set to **nls_sort=schinese_pinyin_m** or **nls_sort=generic_m_ci**. **nls_sort=generic_m_ci** supports only the case-insensitive order for English characters.

  Parameters: **string** and **sort_method**. Both are of the text type.

  Return type: text.

  Example:

```
gaussdb=# CREATE TABLE test(a text);

gaussdb=# INSERT INTO test(a) VALUES ('abC');

gaussdb=# INSERT INTO test(a) VALUES ('abC');

gaussdb=# INSERT INTO test(a) VALUES ('abc');

gaussdb=# SELECT * FROM test ORDER BY nlssort(a,'nls_sort=schinese_pinyin_m');
   a
--------
 abc
 abC
 abC
(3 rows)

gaussdb=# SELECT * FROM test ORDER BY nlssort(a, 'nls_sort=generic_m_ci');
   a
--------
 abC
 abc
 abC
(3 rows)

gaussdb=# DROP TABLE test;
```

- convert(string bytea, src_encoding name, dest_encoding name)

  Description: Converts the string to **dest_encoding**. **src_encoding** specifies the source encoding scheme. The string must be valid in this encoding scheme.

  Return type: bytea

  Example:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gaussdb=# SELECT convert('text_in_utf8', 'UTF8', 'GBK');
         convert
---------------------------
 \x746578745f696e5f75746638
(1 row)
```

NOTE

If the rule for converting between source to target encoding (for example, GBK and LATIN1) does not exist, the string is returned without conversion. See the PG_CONVERSION system catalog for details. **server_encoding** specifies the character encoding for the database and is specified during database initialization.

Example:

```
gaussdb=# SHOW server_encoding;
 server_encoding
-----------------
 LATIN1
(1 row)

gaussdb=# SELECT convert_from('some text', 'GBK');
 convert_from
--------------
 some text
(1 row)

db_latin1=# SELECT convert_to('some text', 'GBK');
      convert_to
----------------------
 \x736f6d652074657874
(1 row)

db_latin1=# SELECT convert('some text', 'GBK', 'LATIN1');
       convert
----------------------
 \x736f6d652074657874
(1 row)
```

- convert(expr, using transcoding_name)

  Description: Converts a parameter, which can be a character or a number, into a character string of the transcoding_name type, and returns the character string.

  Return type: text.

  Example:

  ```
  gaussdb=# SELECT convert('asdas' using 'gbk');
   convert
  ---------
   asdas
  (1 row)
  ```

  NOTE

  This function takes effect only in databases in MySQL-compatible mode.

- convert_from(string bytea, src_encoding name)

  Description: Converts a string based on the character encoding scheme of the database. **src_encoding** specifies the source encoding scheme. The string must be valid in this encoding scheme.

  Return type: text.

  Example:

  ```
  gaussdb=# SELECT convert_from('text_in_utf8', 'UTF8');
   convert_from
  --------------
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
 text_in_utf8
(1 row)
```

- convert_to(string text, dest_encoding name)

  Description: Converts the string to **dest_encoding**.

  Return type: bytea

  Example:

```
gaussdb=# SELECT convert_to('some text', 'UTF8');
     convert_to
----------------------
 \x736f6d652074657874
(1 row)
```

- string [NOT] LIKE pattern [ESCAPE escape-character]

  Description: Checks whether a match of a pattern occurs.

  – If a pattern does not contain a percentage sign (%) or underscore (_), the pattern represents itself. In this case, the behavior of LIKE is equivalent to the equal operator (=). An underscore (_) in the pattern stands for (matches) any single character; a percent sign (%) can match any sequence of zero or more characters.
  – To match the underscore (_) or percent sign (%), you need to add an escape character before the corresponding character in the pattern. The default escape character is a backslash (\), but you can use the ESCAPE clause to customize an escape character. To match the escape character itself, write two escape characters.

  Return type: Boolean

  Example:

```
gaussdb=# SELECT 'AA_BBCC' LIKE '%A@_B%' ESCAPE '@' AS RESULT;
 result
--------
 t
(1 row)
gaussdb=# SELECT 'AA_BBCC' LIKE '%A@_B%' AS RESULT;
 result
--------
 f
(1 row)
gaussdb=# SELECT 'AA@_BBCC' LIKE '%A@_B%' AS RESULT;
 result
--------
 t
(1 row)
```

- regexp_like(source_string, pattern [, match_parameter])

  Description: Checks whether the source string matches a regular expression pattern. **source_string** specifies the source string, and **pattern** specifies the regular expression pattern to match. **match_parameter** indicates the matching options, which include:

  – **'i'**: case-insensitive.
  – **'c'**: case-sensitive.
  – **'m'**: interprets **source_string** as multiple rows.

  If **match_parameter** is ignored, case-sensitive will be used by default, meaning that "." will not be matched with a newline character and **source_string** will be interpreted as a single row. If an unsupported **match_parameter** option is entered, the message "INFO: illegal argument for function" will be displayed and **false** will be returned in the result.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Return type: Boolean

Example:

```
gaussdb=# SELECT regexp_like('ABC', '[A-Z]');
 regexp_like
-------------
 t
(1 row)
gaussdb=# SELECT regexp_like('ABC', '[D-Z]');
 regexp_like
-------------
 f
(1 row)
gaussdb=# SELECT regexp_like('ABC', '[A-Z]','i');
 regexp_like
-------------
 t
(1 row)
gaussdb=# SELECT regexp_like('ABC', '[A-Z]');
 regexp_like
-------------
 t
(1 row)
```

- format(formatstr text [, str"any" [, ...]])

  Description: Formats a string.

  Return type: text.

  Example:

  ```
  gaussdb=# SELECT format('Hello %s, %1$s', 'World');
        format
  --------------------
   Hello World, World
  (1 row)
  ```

- md5(string)

  Description: Encrypts the string in MD5 mode and returns a value in hexadecimal form.

  NOTE

  The MD5 cryptographic algorithm has lower security and poses security risks. Therefore, you are advised to use a more secure cryptographic algorithm.

  Return type: text.

  Example:

  ```
  gaussdb=# SELECT md5('ABC');
               md5
  ----------------------------------
   902fbdd2b1df0c4f70b4a5d23525e932
  (1 row)
  ```

- sha(string) / sha1(string)

  Description: Encrypts the string using SHA-1 and returns a hexadecimal number. The sha and sha1 functions are the same.

  NOTE

  - The SHA-1 cryptographic algorithm is not recommended because it has lower security and poses security risks.
  - This function is valid only in MySQL-compatible GaussDB (that is, **sql_compatibility** is set to **'MYSQL'**).

  Return type: text.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Example:

```
gaussdb=# SELECT sha('ABC');
                 sha
------------------------------------------
 3c01bdbb26f358bab27f267924aa2c9a03fcfdb8
(1 row)
gaussdb=# SELECT sha1('ABC');
                 sha1
------------------------------------------
 3c01bdbb26f358bab27f267924aa2c9a03fcfdb8
(1 row)
```

- sha2(string, hash_length)

  Description: Encrypts the string in SHA-2 mode and returns a value in hexadecimal form.

  Parameter: **hash_length** corresponds to an SHA-2 algorithm. The value can be **0** (SHA-256), **224** (SHA-224), **256** (SHA-256), **384** (SHA-384), or **512** (SHA-512). For other values, **NULL** is returned.

  NOTE

  - The SHA-224 cryptographic algorithm is not recommended because it has lower security and poses security risks.
  - The SHA2 function records hash plaintext in logs. Therefore, you are advised not to use this function to encrypt sensitive information such as keys.
  - This function is valid only in MySQL-compatible GaussDB (that is, **sql_compatibility** is set to **'MYSQL'**).

  Return type: text.

  Example:

```
gaussdb=# SELECT sha2('ABC',224);
                          sha2
------------------------------------------------------------
 107c5072b799c4771f328304cfe1ebb375eb6ea7f35a3aa753836fad
(1 row)
gaussdb=# SELECT sha2('ABC',256);
                            sha2
------------------------------------------------------------------
 b5d4045c3f466fa91fe2cc6abe79232a1a57cdf104f7a26e716e0a1e2789df78
(1 row)
gaussdb=# SELECT sha2('ABC',0);
                            sha2
------------------------------------------------------------------
 b5d4045c3f466fa91fe2cc6abe79232a1a57cdf104f7a26e716e0a1e2789df78
(1 row)
```

- decode(string text, format text)

  Description: Decodes binary data from textual representation.

  Return type: bytea

  Example:

```
gaussdb=# SELECT decode('MTIzAAE=', 'base64');
   decode
--------------
 \x3132330001
(1 row)
```

- similar_escape(pat text, esc text)

  Description: Converts a regular expression of the SQL:2008 style to the POSIX style.

  Return type: text.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Example:

```
gaussdb=# SELECT similar_escape('\s+ab','2');
 similar_escape
----------------
 ^(?:\\s+ab)$
(1 row)
```

- find_in_set(text, set)

  Description: Finds the position of a given member in a set, counting from 1. If no record is found, 0 is returned. The distributed system does not support the SET data type. An error will be reported when this function is executed.

  Return type: int2.

- find_in_set(str, strlist)

  Description: Queries whether the **strlist** column contains **str**. If the **strlist** column contains **str**, the position of **str** in the **strlist** field is returned. If **str** is not in **strlist** or **strlist** is an empty string, the return value is **0**.

  Parameters: See **Table 1-44**.

  Table 1-44 find_in_set(str, strlist) parameters

Parameter	Type	Description
str	text	**str** indicates the character string to be queried.
strlist	text	**strlist** is a set of character strings separated by commas (,). Different character strings are combined by separators. **strlist** is also a character string.

  Return type: int.

  Example:

```
gaussdb=# SELECT find_in_set('ee','a,ee,c');
 find_in_set
-------------
           2
(1 row)
```

- encode(data bytea, format text)

  Description: Encodes binary data into a textual representation.

  Return type: text.

  Example:

```
gaussdb=# SELECT encode(E'123\\000\\001', 'base64');
  encode
----------
 MTIzAAE=
(1 row)
```

- strcmp(expr1, expr2)

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description: Compares two input strings based on the current character order. If the strings are the same, **0** is returned. If the first string is smaller than the second string, **–1** is returned. Otherwise, **1** is returned.

Parameters: See **Table 1-45**.

Table 1-45 strcmp parameters

Parameter	Type	Description
expr1/expr2	• Character types: CHAR, VARCHAR, NVARCHAR2, and TEXT. • Binary type: BYTEA. • Numeric types: TINYINT [UNSIGNED], SMALLINT [UNSIGNED], INTEGER [UNSIGNED], BIGINT [UNSIGNED], FLOAT4, FLOAT8, and NUMERIC. • Date and time types: DATE, TIME WITHOUT TIME ZONE, DATETIME, and TIMESTAMPTZ.	Character string involved in comparison.

Return type: INTEGER

Example:

```
-- Switch to the MySQL-compatible database.
gaussdb=# CREATE DATABASE gaussdb_m dbcompatibility='MYSQL';
gaussdb=# \c gaussdb_m

-- Set the compatible version control parameter to enable the function of specifying the collation for constant character strings.
gaussdb_m=# SET b_format_version='5.7';
gaussdb_m=# SET b_format_dev_version='s2';

gaussdb_m=# SELECT strcmp('abc', 'ABC');
 strcmp
--------
      0
(1 row)

gaussdb_m=# SELECT strcmp('abc     ', 'abc');
 strcmp
--------
      0
(1 row)

gaussdb_m=# SELECT strcmp('1', 1);
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
 strcmp
--------
      0
(1 row)

gaussdb_m=# SELECT strcmp(123, 2);
 strcmp
--------
     -1
(1 row)
```

NOTE

- The strcmp function is valid only when **sql_compatibility** is set to **'MYSQL'**.
- Since the version whose **b_format_version** is set to **'5.7'** and **b_format_dev_version** is set to **'s1'**, the sql_mode parameter **"pad_char_to_full_length"** specifies whether to add spaces at the end of the char type, which affects the strcmp comparison result. For details, see **Table 1-8**.
- Since the version whose **b_format_version** is set to **'5.7'** and **b_format_dev_version** is set to **'s1'**, the behavior of the character, binary, numeral, and date and time types is M-compatible. This affects the result of strcmp comparison. For details, see **Data Types**. To ensure consistent precision, it is advisable to use the NUMERIC type rather than floating-point (under the numeric type). The use of floating-point may lead to varying precision compared to M-compatible mode, due to differences in connection parameter settings.
- Since the version whose **b_format_version** is set to **'5.7'** and **b_format_dev_version** is set to **'s2'**, character escape and constant character string obtaining collation are supported. The collation affects the strcmp comparison result. For details, see the SET NAMES syntax in **SET**. For details about the rules for combining different collations of the character types, see **Rules for Combining Character Sets and Collations**.

NOTE

- For a string containing linefeed characters, for example, a string consisting of a linefeed character and a space, the values of **LENGTH** and **LENGTHB** in GaussDB are **2**.
- In GaussDB, *n* in the CHAR(n) type indicates the number of characters. Therefore, for multiple-octet coded character sets, the length returned by the LENGTHB function may be longer than *n*.
- GaussDB supports multiple types of databases, including Oracle-, MySQL-, TD-, and PG-compatible. The lexical analyzer of Oracle-compatible database is different from that of the other three databases. In an Oracle-compatible database, an empty string is considered as **NULL**. Therefore, when an Oracle-compatible database is used, if an empty string is used as a parameter in the preceding character operation function, no output is displayed. For example:

  ```
  gaussdb=# SELECT translate('12345','123','');
  translate
  -----------

  (1 row)
  ```

  This is because the database checks whether the input parameter contains **NULL** before calling the corresponding function. If the input parameter contains **NULL**, the kernel does not call the corresponding function. As a result, no output is displayed. In PG-compatible mode, the processing of character strings is the same as that of PG. Therefore, the preceding problem does not occur.

Extension Functions and Operators

- pkg_bpchar_opc()

  Description: Serves as an extension API to add the comparison operator between bpchar and text or between text and bpchar policies, so as to solve

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

the problem that indexes cannot be matched when data of the bpchar and text types is compared. Only the initial user can install extensions.

Example:

- Compare the bpchar type with the text type (initial state, compatible with earlier versions).

```
/*
Create a table and initialize data.
*/
gaussdb=# CREATE TABLE logs_nchar(log_id nchar(16), log_message text);
gaussdb=# INSERT INTO logs_nchar SELECT GENERATE_SERIES(1,100000),MD5(RANDOM());
gaussdb=# INSERT INTO logs_nchar VALUES ('FE306991300002  ','002');
gaussdb=# CREATE INDEX idx_nchar_logid ON logs_nchar(log_id);
gaussdb=# VACUUM ANALYZE logs_nchar;

/*
The purpose is to obtain the detailed execution plan of all nodes.
*/
gaussdb=# SET max_datanode_for_plan = 1;
SET

/*
If no extension is installed, nchar is implicitly converted to text (fixed-length character type to variable-length character type) when nchar and text are compared because the bpchar or text index operator is not available. As a result, the execution plan changes and index cannot be matched.
*/
gaussdb=# EXPLAIN SELECT * FROM logs_nchar WHERE log_id = RPAD(TRIM('FE306991300002
'),16,' ');
                                                 QUERY
PLAN

NOTE

- This solves the problem that data and indexes cannot be properly matched when equality matching is performed between the bpchar type (containing multiple spaces) and the text type.
- UB-tree and B-tree are involved. The comparison operators include >, >=, <, <=, and <>.
- The impact scope involves implicit conversion between character types. For example, when a variable-length data type is compared with a fixed-length data type, the variable-length data type is preferentially converted to the text type instead of the original bpchar type.
- The pkg_bpchar_opc extension is disabled by default. You can query the PG_EXTENSION system catalog to check whether the extension is enabled. If the corresponding record exists, the extension is enabled. If the record does not exist, the extension is not enabled. When the extension is disabled, compatibility with earlier versions is maintained. When the extension is enabled, the ORA-compatible mode is maintained. After the pkg_bpchar_opc extension is enabled, you need to set the **max_datanode_for_plan** parameter as required. This parameter specifies the number of execution plans displayed on DNs when the FQS plan is generated. For example, to set **max_datanode_for_plan** to **64**, run the following command:
  ```
  SET max_datanode_for_plan = 64;
  ```
- In the example, the table definition uses **log_id** as the index and has two columns: **log_id** and **log_message**. The table name is followed by the **log_id** column type. For example, if the table name is **logs_text**, the **log_id** column type is text.

Table 1-46 Functions supported by pkg_bpchar_opc

API	Description
pg_catalog.bpchar_text_lt	Compares the bpchar type with the text type to check whether the value on the left is less than the value on the right.
pg_catalog.bpchar_text_le	Compares the bpchar type with the text type to check whether the value on the left is less than or equal to the value on the right.
pg_catalog.bpchar_text_eq	Compares the bpchar type with the text type to check whether the value on the left is equal to the value on the right.
pg_catalog.bpchar_text_ge	Compares the bpchar type with the text type to check whether the value on the left is greater than or equal to the value on the right.
pg_catalog.bpchar_text_gt	Compares the bpchar type with the text type to check whether the value on the left is greater than the value on the right.
pg_catalog.bpchar_text_ne	Compares the bpchar type with the text type to check whether the value on the left is different from the value on the right.
pg_catalog.bpchar_text_cmp	Specifies that the index of the bpchar and text types supports comparison functions.
pg_catalog.text_bpchar_lt	Compares the text type with the bpchar type to check whether the value on the left is less than the value on the right.
pg_catalog.text_bpchar_le	Compares the text type with the bpchar type to check whether the value on the left is less than or equal to the value on the right.
pg_catalog.text_bpchar_eq	Compares the text type with the bpchar type to check whether the value on the left is equal to the value on the right.
pg_catalog.text_bpchar_ge	Compares the text type with the bpchar type to check whether the value on the left is greater than or equal to the value on the right.
pg_catalog.text_bpchar_gt	Compares the text type with the bpchar type to check whether the value on the left is greater than the value on the right.
pg_catalog.text_bpchar_ne	Compares the text type with the bpchar type to check whether the value on the left is different from the value on the right.
pg_catalog.text_bpchar_cmp	Specifies that the index of the text and bpchar types supports comparison functions.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

API	Description
pg_catalog.hashbpchartext	Specifies that the hash of the bpchar and text types supports comparison functions.
pg_catalog.hashtextbpchar	Specifies that the hash of the text and bpchar types supports comparison functions.

- bpcharlikebpchar(BPCHAR, BPCHAR)

  Description: Specifies whether the BPCHAR character string of the first input parameter is LIKE and whether the BPCHAR character string of the second input parameter is LIKE. It is used to add the BPCHAR type and the LIKE operator of the BPCHAR type. To enable the ~~ operator, ensure that the value of the GUC parameter **behavior_compat_options** contains the **enable_bpcharlikebpchar_compare** configuration item.

  Return type: Boolean. The value range is as follows:

  – **t**: Two parameters of the BPCHAR type are matched.

  – **f**: Two parameters of the BPCHAR type are not matched.

  Example:

```
gaussdb=#  SELECT bpcharlikebpchar('455'::BPCHAR(10), '455  '::BPCHAR);
 bpcharlikebpchar
------------------
 f
(1 row)
gaussdb=#  SELECT bpcharlikebpchar('455 '::BPCHAR(10), '455 '::BPCHAR(10));
 bpcharlikebpchar
------------------
 t
(1 row)
gaussdb=#  SELECT bpcharlikebpchar('455 '::BPCHAR(10), '455'::BPCHAR(10));
 bpcharlikebpchar
------------------
 t
(1 row)
gaussdb=#  SELECT bpcharlikebpchar('455 '::BPCHAR(10), '455'::BPCHAR(11));
 bpcharlikebpchar
------------------
 f

NOTE

- bpcharlikebpchar can be used only when the database compatibility parameter **SQL_COMPATIBILITY** is set to **ORA** and the GUC parameter **behavior_compat_options** contains the **enable_bpcharlikebpchar_compare** column.
- If this feature is enabled, the result set and execution plan for the LIKE pattern matching of the BPCHAR types are affected.
- If the GUC parameter **behavior_compat_options** does not contain the **enable_bpcharlikebpchar_compare** column, this feature is disabled. If the GUC parameter **behavior_compat_options** contains the **enable_bpcharlikebpchar_compare** column, this feature is enabled.
- After the new feature is enabled, fixed-length matching is used (bpchar matches bpchar). The parameter lengths on the left and right sides must be the same. During pattern matching, ensure that the length of the pattern column is the same as the forcible conversion length to avoid the difference between the result and the expected result caused by filling spaces after the length is too long.

- bpcharnlikebpchar(BPCHAR, BPCHAR)

  Description: Specifies whether the first input BPCHAR string is NOT LIKE the second input BPCHAR string. It is used to add a NOT LIKE operator for comparing BPCHAR types. To enable the !~~ operator, ensure that the value of the GUC parameter **behavior_compat_options** contains the **enable_bpcharlikebpchar_compare** configuration item.

  Return type: Boolean. The value range is as follows:

  – **t**: Two BPCHAR parameters do not match.

  – **f**: Two BPCHAR parameters match.

  Example:

```
gaussdb=#  SELECT bpcharnlikebpchar('455 '::BPCHAR(10), '455'::BPCHAR(11));
 bpcharnlikebpchar
-------------------
 t
(1 row)

gaussdb=#  SELECT bpcharnlikebpchar('455 '::BPCHAR(10), '455'::BPCHAR(10));
 bpcharnlikebpchar
-------------------
 f
(1 row)

gaussdb=#  SELECT bpcharnlikebpchar('455 '::BPCHAR(10), '455 '::BPCHAR);
 bpcharnlikebpchar
-------------------
 t
(1 row)
gaussdb=#  CREATE TABLE op_test (
 col BPCHAR(2) DEFAULT NULL
);
CREATE TABLE
gaussdb=#  CREATE INDEX op_index ON op_test(col);
CREATE INDEX
gaussdb=#  INSERT INTO op_test VALUES ('a');
INSERT 0 1
gaussdb=#  INSERT INTO op_test VALUES ('1');

gaussdb=#  INSERT INTO op_test VALUES ('11');
INSERT 0 1
gaussdb=#  INSERT INTO op_test VALUES ('12');
INSERT 0 1
gaussdb=#  INSERT INTO op_test VALUES ('sd');
INSERT 0 1
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gaussdb=#  INSERT INTO op_test VALUES ('aa');
INSERT 0 1
gaussdb=#  SHOW behavior_compat_options;
 behavior_compat_options
-------------------------
(1 row)
-- If behavior_compat_options does not contain enable_bpcharlikebpchar_compare, the latest
bpcharnlikebpchar operator is not enabled and the result set returned by the matching between
bpchars is not the same as expected (no data record is returned in normal cases).
gaussdb=#  SELECT * FROM op_test WHERE col NOT LIKE col::BPCHAR ORDER BY col;
 col
-----
 1
 a
(2 rows)

gaussdb=#  EXPLAIN (COSTS OFF) SELECT * FROM op_test WHERE col NOT LIKE col::BPCHAR ORDER
BY col;
                QUERY PLAN
-------------------------------------------------
 Streaming (type: GATHER)
   Merge Sort Key: col
   Node/s: All datanodes
   ->  Sort
         Sort Key: col
         ->  Seq Scan on op_test
               Filter: (col !~~ (col)::text)
(7 rows)
gaussdb=#  SET behavior_compat_options = 'enable_bpcharlikebpchar_compare';
SET
gaussdb=#  SHOW behavior_compat_options;

NOTE

- bpcharlikebpchar can be used only when the database compatibility parameter **SQL_COMPATIBILITY** is set to **ORA** and the GUC parameter **behavior_compat_options** contains the **enable_bpcharlikebpchar_compare** column.
- If this feature is enabled, the result set and execution plan for the NOT LIKE pattern matching of the BPCHAR types are affected.
- If the GUC parameter **behavior_compat_options** does not contain the **enable_bpcharlikebpchar_compare** column, this feature is disabled. If the GUC parameter **behavior_compat_options** contains the **enable_bpcharlikebpchar_compare** column, this feature is enabled.
- After the new feature is enabled, fixed-length matching is used (bpchar matches bpchar). The parameter lengths on the left and right sides must be the same. During pattern matching, ensure that the length of the pattern column is the same as the forcible conversion length to avoid the difference between the result and the expected result caused by filling spaces after the length is too long.

1.6.4 Binary String Functions and Operators

String Operators

SQL defines some string functions that use keywords, rather than commas, to separate arguments.

- octet_length(string)

  Description: Specifies the number of bytes in a binary string.

  Return type: int

  Example:

  ```
  gaussdb=# SELECT octet_length(E'jo\\000se'::bytea) AS RESULT;
   result
  --------
       5
  (1 row)
  ```

- overlay(string placing string from int [for int])

  Description: Replaces substrings.

  Return type: bytea

  Example:

  ```
  gaussdb=# SELECT overlay(E'Th\\000omas'::bytea placing E'\\002\\003'::bytea from 2 for 3) AS
  RESULT;
      result
  ----------------
   \x5402036d6173
  (1 row)
  ```

- position(substring in string)

  Description: Specifies the position of a specified substring.

  Return type: int

  Example:

  ```
  gaussdb=# SELECT position(E'\\000om'::bytea in E'Th\\000omas'::bytea) AS RESULT;
   result
  --------
       3
  (1 row)
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- substring(string [from int] [for int])

  Description: Truncates a substring.

  Return type: bytea

  Example:

```
gaussdb=# SELECT substring(E'Th\\000omas'::bytea from 2 for 3) AS RESULT;
 result
----------
 \x68006f
(1 row)
```

- substr(bytea [from int] [for int])

  Description: Truncates a substring.

  Return type: bytea

  Example:

```
gaussdb=# SELECT substr(E'Th\\000omas'::bytea,2, 3) AS RESULT;
 result
----------
 \x68006f
(1 row)
```

- trim([both] bytes from string)

  Description: Removes the longest string containing only **bytes** from the start and end of **string**.

  Return type: bytea

  Example:

```
gaussdb=# SELECT trim(E'\\000'::bytea from E'\\000Tom\\000'::bytea) AS RESULT;
 result
----------
 \x546f6d
(1 row)
```

Other Binary String Functions

GaussDB provides common syntax used for calling functions.

- btrim(string bytea, bytes bytea)

  Description: Removes the longest string containing only **bytes** from the start and end of **string**.

  Return type: bytea

  Example:

```
gaussdb=# SELECT btrim(E'\\000trim\\000'::bytea, E'\\000'::bytea) AS RESULT;
  result
------------
 \x7472696d
(1 row)
```

- get_bit(string, offset)

  Description: Extracts bits from a string.

  Return type: int

  Example:

```
gaussdb=# SELECT get_bit(E'Th\\000omas'::bytea, 45) AS RESULT;
 result
--------
      1
(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

> **NOTE**
>
> The first parameter can only be of the bit or bytea type.

- get_byte(string, offset)

  Description: Extracts bytes from a string.

  Return type: int

  Example:

```
gaussdb=# SELECT get_byte(E'Th\\000omas'::bytea, 4) AS RESULT;
 result
--------
    109
(1 row)
```

- set_bit(string, offset, newvalue)

  Description: Sets bits in a string.

  Return type: bytea

  Example:

```
gaussdb=# SELECT set_bit(E'Th\\000omas'::bytea, 45, 0) AS RESULT;
      result
------------------
 \x5468006f6d4173
(1 row)
```

> **NOTE**
>
> The first parameter can only be of the bit or bytea type.

- set_byte(string, offset, newvalue)

  Description: Sets bytes in a string.

  Return type: bytea

  Example:

```
gaussdb=# SELECT set_byte(E'Th\\000omas'::bytea, 4, 64) AS RESULT;
      result
------------------
 \x5468006f406173
(1 row)
```

- rawcmp(raw, raw)

  Description: Specifies the raw data type comparison function.

  Return type: integer

- raweq(raw, raw)

  Description: Specifies the raw data type comparison function.

  Return type: Boolean

- rawge(raw, raw)

  Description: Specifies the raw data type comparison function.

  Return type: Boolean

- rawgt(raw, raw)

  Description: Specifies the raw data type comparison function.

  Return type: Boolean

- rawin(cstring)

  Description: Specifies the raw data type parsing function.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Return type: bytea

- rawle(raw, raw)
  Description: Specifies the raw data type parsing function.
  Return type: Boolean
- rawlike(raw, raw)
  Description: Specifies the raw data type parsing function.
  Return type: Boolean
- rawlt(raw, raw)
  Description: Specifies the raw data type parsing function.
  Return type: Boolean
- rawne(raw, raw)
  Description: Compares whether the raw types are the same.
  Return type: Boolean
- rawnlike(raw, raw)
  Description: Checks whether the raw type matches the pattern.
  Return type: Boolean
- rawout(bytea)
  Description: Specifies the output API of the raw type.
  Return type: cstring
- rawsend(raw)
  Description: Converts the bytea type to the binary type.
  Return type: bytea
- rawtohex(text)
  Description: Converts the raw format to the hexadecimal format.
  Return type: text

1.6.5 Bit String Functions and Operators

Bit String Operators

Aside from the usual comparison operators, the following operators can be used. Bit string operands of **&**, **|**, and **#** must be of equal length. In case of bit shifting, the original length of the bit string is preserved by padding with 0s.

- ||
  Description: Connects bit strings.
  Example:

```
gaussdb=# SELECT B'10001' || B'011' AS RESULT;
  result
----------
 10001011
(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- A field can have a maximum of 180 consecutive internal joins. A field with excessive joins will be split into joined consecutive strings.

  Example: **str1||str2||str3||str4** is split into **(str1||str2)||(str3||str4)**.
- In ORA-compatible mode, if bit strings contain a null string, the null string is ignored and other strings are joined. In other compatibility modes, the null string is returned.

  Take **str1||NULL||str2** as an example. **str1str2** is returned in ORA-compatible mode and **NULL** is returned in other compatibility modes.

- &

  Description: Specifies the AND operation between bit strings.

  Example:

```
gaussdb=# SELECT B'10001' & B'01101' AS RESULT;
 result
--------
 00001
(1 row)
```

- |

  Description: Specifies the OR operation between bit strings.

  Example:

```
gaussdb=# SELECT B'10001' | B'01101' AS RESULT;
 result
--------
 11101
(1 row)
```

- #

  Description: Specifies the OR operation between bit strings if they are inconsistent. If the same positions in the two bit strings are both 1 or 0, the position returns **0**.

  Example:

```
gaussdb=# SELECT B'10001' # B'01101' AS RESULT;
 result
--------
 11100
(1 row)
```

- ~

  Description: Specifies the NOT operation between bit strings.

  Example:

```
gaussdb=# SELECT ~B'10001'AS RESULT;
 result
----------
 01110
(1 row)
```

- <<

  Description: Shifts left in a bit string.

  Example:

```
gaussdb=# SELECT B'10001' << 3 AS RESULT;
 result
----------
 01000
(1 row)
```

- >>

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description: Shifts right in a bit string.

Example:

```
gaussdb=# SELECT B'10001' >> 2 AS RESULT;
 result
----------
 00100
(1 row)
```

The following SQL-standard functions work on bit strings as well as strings: length, bit_length, octet_length, position, substring, and overlay.

The following functions work on bit strings as well as binary strings: get_bit and set_bit. When working with a bit string, these functions number the first (leftmost) bit of the string as bit 0.

In addition, it is possible to convert between integral values and type bit. Example:

```
gaussdb=# SELECT 44::bit(10) AS RESULT;
   result
------------
 0000101100
(1 row)

gaussdb=# SELECT 44::bit(3) AS RESULT;
 result
--------
 100
(1 row)

gaussdb=# SELECT cast(-44 as bit(12)) AS RESULT;
    result
--------------
 111111010100
(1 row)

gaussdb=# SELECT '1110'::bit(4)::integer AS RESULT;
 result
--------
     14
(1 row)

gaussdb=# SELECT substring('10101111'::bit(8), 2);
 substring
-----------
 0101111
(1 row)
```

NOTE

Casting to just "bit" means casting to bit(1), and so will deliver only the least significant bit of the integer.

1.6.6 Pattern Matching Operators

The database provides three independent methods for implementing pattern matching: SQL LIKE operator, SIMILAR TO operator, and POSIX regular expressions. Besides these basic operators, functions can be used to extract or replace matching substrings and to split a string at matching locations.

- LIKE

  Description: Specifies whether the string matches the pattern string following LIKE. The LIKE expression returns true if the string matches the supplied pattern. (As expected, the NOT LIKE expression returns false if LIKE returns true, and vice versa.)

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Matching rules:

- LIKE pattern matching always covers the entire string. Therefore, if it is desired to match a sequence anywhere within a string, the pattern must start and end with a percent sign.
- An underscore (_) represents (matches) any single character. A percent sign (%) represents the wildcard character of any string.
- To match a literal underscore or percent sign, the respective character in the given pattern must be preceded by the escape character. Consequently, the special meanings of metacharacters will be disabled. The default escape character is the backslash but a different one can be selected by using the ESCAPE clause.
- To match the escape character itself, write two escape characters. For example, to write a pattern constant that contains a backslash, you must write two backslashes in the SQL statement.

  NOTE

  - When **standard_conforming_strings** is set to **off**, any backslashes included in literal string constants will undergo dual-writes. Therefore, writing a pattern that actually matches a literal backslash means writing four backslashes in the SQL statement. You can avoid this by selecting a different escape character with ESCAPE; then backslash is not special to LIKE anymore. (But it is still special to the string literal parser, so you still need two of them.)
  - In MySQL-compatible mode, it is also possible to select no escape character by writing **ESCAPE ''**. This effectively disables the escape mechanism, which makes it impossible to disable the special meanings of underscores and percent signs in the pattern.
  - In Oracle-compatible mode, if **standard_conforming_strings** is set to **on**, you can set **behavior_compat_options** to **ignore_like_default_escape**. If **ESCAPE '\'** is not explicitly specified, the special meaning of the backslash (\) is disabled and a single backslash (\) is matched.
    - This option takes effect only for keywords (LIKE, NOT LIKE, ILIKE, and NOT ILIKE) and does not take effect for operators (~~, !~~, ~~*, and !~~*).
    - This option does not take effect when the pattern string contains the ANY, SOME, or ALL clause.
- The keyword ILIKE can be used instead of LIKE to make the matching case-insensitive.
- Operator **~~** is equivalent to LIKE, and operator **~~*** corresponds to ILIKE.

Example:

```
gaussdb=# SELECT 'abc' LIKE 'abc' AS RESULT;
 result
------------
 t
(1 row)
gaussdb=# SELECT 'abc' LIKE 'a%' AS RESULT;
 result
------------
 t
(1 row)
gaussdb=# SELECT 'abc' LIKE '_b_' AS RESULT;
 result
------------
 t
(1 row)
gaussdb=# SELECT 'abc' LIKE 'c' AS RESULT;
 result
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
-----------
 f
(1 row)
```

- SIMILAR TO

  Description: Returns true or false depending on whether the pattern matches the given string. It is similar to LIKE, except that it interprets the pattern using the SQL standard's definition of a regular expression.

  Matching rules:

  – Same as LIKE, this operator succeeds only if its pattern matches the entire string. To match a sequence anywhere within a string, the pattern must start and end with a percent sign (%).

  – An underscore (_) represents (matches) any single character. A percent sign (%) represents the wildcard character of any string.

  – SIMILAR TO supports these pattern-matching metacharacters borrowed from POSIX regular expressions.

Metacharacter	Description
|	Specifies alternation (either of two alternatives).
*	Specifies repetition of the previous item zero or more times.
+	Specifies repetition of the previous item one or more times.
?	Specifies repetition of the previous item zero or one time.
{m}	Specifies repetition of the previous item exactly *m* times.
{m,}	Specifies repetition of the previous item *m* or more times.
{m,n}	Specifies repetition of the previous item at least *m* times and does not exceed *n* times.
()	Combines multiple items into a logical item.
[...]	Specifies a character class which is the same as the POSIX regular expression.

  – A preamble escape character disables the special meaning of any of these metacharacters. The rules for using escape characters are the same as those for LIKE.

  Regular expressions:

  The **substring(string from pattern for escape)** function extracts a substring that matches an SQL regular expression pattern.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Example:

```
gaussdb=# SELECT 'abc' SIMILAR TO 'abc' AS RESULT;
 result
-----------
 t
(1 row)
gaussdb=# SELECT 'abc' SIMILAR TO 'a' AS RESULT;
 result
-----------
 f
(1 row)
gaussdb=# SELECT 'abc' SIMILAR TO '%(b|d)%' AS RESULT;
 result
-----------
 t
(1 row)
gaussdb=# SELECT 'abc' SIMILAR TO '(b|c)%'  AS RESULT;
 result
-----------
 f
(1 row)
```

- POSIX regular expressions

  Description: A regular expression is a character sequence that is an abbreviated definition of a set of strings (a regular set). A string is said to match a regular expression if it is a member of the regular set described by the regular expression. POSIX regular expressions provide a more powerful means for pattern matching than the LIKE and SIMILAR TO operators. **Table 1-47** lists all available operators for pattern matching using POSIX-style regular expressions.

  Table 1-47 Regular expression matching operators

Operator	Description	Example
~	Matches a regular expression, which is case-sensitive.	'thomas' ~ '.*thomas.*'
~*	Matches a regular expression, which is case-insensitive.	'thomas' ~* '.*Thomas.*'
!~	Does not match a regular expression, which is case-sensitive.	'thomas' !~ '.*Thomas.*'
!~*	Does not match a regular expression, which is case-insensitive.	'thomas' !~* '.*vadim.*'

  Matching rules:

  – Unlike LIKE patterns, a regular expression is allowed to match anywhere within a string, unless the regular expression is explicitly anchored to the beginning or end of the string.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- In addition to the metacharacters mentioned above, POSIX regular expressions support the following pattern matching metacharacters.

Metacharacter	Description
^	Specifies the match starting with a string.
$	Specifies the match at the end of a string.
.	Matches any single character.

Regular expression functions: POSIX regular expressions support the following functions:

- The **substring(string from pattern)** function provides a method for extracting a substring that matches a POSIX regular expression pattern.
- The **regexp_count(string text, pattern text [, position int [, flags text]])** function obtains the number of substrings that match a POSIX regular expression pattern.
- The **regexp_instr(string text, pattern text [, position int [, occurrence int [, return_opt int [, flags text]]]])** function obtains the position of a substring that matches a POSIX regular expression pattern.
- The **regexp_substr(string text, pattern text [, position int [, occurrence int [, flags text]]])** function provides a method for extracting a substring that matches a POSIX regular expression pattern.
- The **regexp_replace(string, pattern, replacement [,flags])** function replaces the substring that matches the POSIX regular expression pattern with the new text.
- The **regexp_matches(string text, pattern text [, flags text])** function returns a text array consisting of all captured substrings that match a POSIX regular expression pattern.
- The **regexp_split_to_table(string text, pattern text [, flags text])** function splits a string using a POSIX regular expression pattern as a delimiter.
- The **regexp_split_to_array(string text, pattern text [, flags text])** function behaves the same as regexp_split_to_table, except that regexp_split_to_array returns its result as an array of text.

  NOTE

  The regular expression split functions ignore zero-length matches, which occur at the beginning or end of a string or after the previous match. This is contrary to the strict definition of regular expression matching. The latter is implemented by **regexp_matches**, but the former is usually the most commonly used behavior in practice.

Example:

```
gaussdb=# SELECT 'abc' ~ 'Abc' AS RESULT;
result
--------
 f
(1 row)
gaussdb=# SELECT 'abc' ~* 'Abc' AS RESULT;
 result
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
--------
 t
(1 row)
gaussdb=# SELECT 'abc' !~ 'Abc' AS RESULT;
 result
--------
 t
(1 row)
gaussdb=# SELECT 'abc'!~* 'Abc' AS RESULT;
 result
--------
 f
(1 row)
gaussdb=# SELECT 'abc' ~ '^a' AS RESULT;
 result
--------
 t
(1 row)
gaussdb=# SELECT 'abc' ~ '(b|d)'AS RESULT;
 result
--------
 t
(1 row)
gaussdb=# SELECT 'abc' ~ '^(b|c)'AS RESULT;
 result
--------
 f
(1 row)
```

Although most regular expression searches can be executed quickly, they can still be artificially processed to require any length of time and any amount of memory. Avoid accepting regular expression search patterns from non-security pattern sources. If you have to, consider setting a statement timeout interval. The search with the SIMILAR TO pattern has the same security risks, as SIMILAR TO provides many capabilities that are the same as those of the POSIX regular expression. The LIKE search is much simpler than the other two options. Therefore, it is more secure to accept the non-secure pattern source search.

- [NOT] REGEXP/ [NOT] RLIKE

  Description: The REGEXP operator is used for regular expression matching and complies with POSIX regular expression matching rules. True or false is returned based on whether the pattern matches the given string.

  The following table describes the regular expression operators.

Operator Name	Description	Syntax
REGEXP	Specifies whether the character string matches the regular expression.	expr REGEXP pat
RLIKE	Specifies whether the character string matches the regular expression (same as REGEXP).	expr RLIKE pat

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Operator Name	Description	Syntax
NOT REGEXP	Specifies whether the character string does not match the regular expression.	expr NOT REGEXP pat
NOT RLIKE	Specifies whether the character string does not match the regular expression (same as NOT REGEXP).	expr NOT RLIKE pat

Matching rules:

- A regular expression is allowed to match anywhere within a string, unless the regular expression is explicitly anchored to the beginning or end of the string.
- The pattern matching metacharacters supported by the REGEXP operator are the same as those supported by POSIX regular expressions.
- The operator supports matching the following escape characters.

Escape Character	Description
\b	Backspace key.
\f	Form feed character, for example, C language.
\n	Newline character, for example, C language.
\r	Carriage return character, for example, C language.
\t	Horizontal tab character, for example, C language.
\uwxyz	Character whose hexadecimal value is **0xwxyz**, where **wxyz** is four hexadecimal digits.
\xhhh	Character whose hexadecimal value is **0xhhh**, where **hhh** is any sequence of hexadecimal digits.
\xy	Character whose octal value is **0xy**, where **xy** is two octal digits.
\xyz	Character whose octal value is **0xyz**, where **xyz** is three octal digits.

- In the pattern string **pat**, **[a-dX]** and **[^a-dX]** stand for the range of matching.

  [a-dX] matches any characters of a, b, c, d, and X. **[^a-dX]** matches characters other than a, b, c, d, or X.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

The hyphen (-) between two characters forms a range, indicating that all characters in the range are matched. To include a right square bracket (]), it must follow the left square bracket ([). To include a hyphen (-), it must be after the left square bracket ([) or before the right square bracket (]). Any character that does not have any special meaning enclosed in square brackets ([]) matches itself.

Example:

```
gaussdb=# SELECT 'abd' REGEXP 'a[bc]d' AS RESULT;
 result
--------
 t
(1 row)
gaussdb=# SELECT 'aed' REGEXP 'a[^bc]d' AS RESULT;
 result
--------
 t
(1 row)
gaussdb=# SELECT 'a-' REGEXP 'a[-b]' AS RESULT;
 result
--------
 t
(1 row)
gaussdb=# SELECT 'aX]bc' REGEXP '^[]a-dXYZ]*$' AS RESULT;
 result
--------
 t
(1 row)
```

- In the pattern string **pat**, **[.characters.]** stands for the character sequence of an element. Within a bracket expression (enclosed in []), it matches the character sequence of a collating element. These characters can be individual characters or character names such as **space**. A complete list of character names can be found in the **regex/regc_locale** file.

  Example:

  ```
  gaussdb=# SELECT ' ' REGEXP '[[.space.]]' AS RESULT;
   result
  --------
   t
  (1 row)
  ```

- Character class matching the **[=character_class=]** character in the pattern string pat. It is written in the square bracket expression. **[=character_class=]** indicates the equivalence class. A character matches all characters with the same sort proofreading value, including itself. For example, if o and (+) are of the same class, [[=o=]], [[=(+)=]], and [o(+)] are synonyms. The same class cannot be used as an endpoint of a range.
- Character class matching the **[:character_class:]** character in the pattern string **pat**. It is written in square brackets ([]). **[:character_class:]** is used to match the characters that match the character class. Other class names may be provided for specific regions. The character class cannot be used as an endpoint of a range. The following table lists the standard class names. If the backslash (\) is involved, set the parameters according to the description.

Character Class	Description	Character Range
alnum	Alphanumeric numeric character.	[0-9a-zA-Z]

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Character Class	Description	Character Range
alpha	Alphanumeric character.	[a-zA-Z]
blank	Blank character.	[\t], indicating a blank character
cntrl	Control character.	[\x01-\x1F]
digit	Digit character.	[0-9]
graph	Graphic character.	[^\x01-\x20]
lower	Lowercase character.	[a-z]
print	Graphic character.	[^\x01-\x20]
punct	Punctuation character.	[-!"#$%&'( )*+,./:;<=>?@[\ \]^_`{|}~]
space	Space, tab, new line character, and carriage return.	[\n\r\t\x0B]
upper	Uppercase character.	[A-Z]
xdigit	Hexadecimal numeric character.	[0-9a-fA-F]

Example:

```
gaussdb=# SELECT '\n' REGEXP '[[:space:]]' AS RESULT;
 result
--------
 t
(1 row)
```

- In the pattern string **pat**, [[:<:]] and [[:>:]] match the null string at the start and end positions of a string, respectively.

  Example:

  ```
  gaussdb=# SELECT 'a word a' REGEXP '[[:<:]]word[[:>:]]' AS RESULT;
   result
  --------
   t
  (1 row)
  ```

- To match a text instance with special characters, you need to add two backslashes (\\) before the following special characters: ( ) '' ^ + ? If single quotation marks are used, you need to write **\''** in the source string to match **'\\\''** in the pattern string. If the backslash (\) is involved, set the parameters according to the description.

  Example:

  ```
  gaussdb=# SELECT 'a+b' REGEXP 'a\\+b' AS RESULT;
   result
  --------
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
 t
(1 row)
gaussdb=# SELECT '\" REGEXP '\\\" AS RESULT;
 result
--------
 t
(1 row)
gaussdb=# SELECT '\\' REGEXP '\\\\' AS RESULT;
 result
--------
 t
(1 row)
```

- When the case-sensitive character set and collation are set, regular expression matching is also case-sensitive.

  Example:

```
gaussdb=# SELECT 'abc' REGEXP 'ABC' COLLATE utf8mb4_bin AS RESULT;
 result
--------
 f
(1 row)
```

- If the input parameter **Expr** or **pat** is null, null will be returned.

```
gaussdb=# SELECT NULL REGEXP '*' AS RESULT;
 result
--------

(1 row)
gaussdb=# SELECT '-' REGEXP NULL AS RESULT;
 result
--------

(1 row)
```

NOTE

- This operator is supported only in MySQL-compatible databases, that is, it is valid only when **sql_compatibility** is set to **'MYSQL'**. After **b_format_version** is set to **'5.7'**, the REGEXP operator is equivalent to the ~* operator, and the NOT REGEXP operator is equivalent to the !~* operator.
- When **b_format_dev_version** is set to **s2**, **standard_conforming_strings** is set to **off** and **escape_string_warning** is set to **off** by default. In this case, any backslash written in the string constant must be entered again. Therefore, writing a pattern matching a single backslash is actually going to write four backslashes in the statement.
- This operator supports only the string type, text type, and other data types that can be implicitly converted to the string type and text type. The bytea type is not supported.

1.6.7 Arithmetic Functions and Operators

Arithmetic Operators

- +

  Description: Addition

  Example:

```
gaussdb=# SELECT 2+3 AS RESULT;
 result
--------
      5
(1 row)
```

- -

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description: Subtraction

Example:

```
gaussdb=# SELECT 2-3 AS RESULT;
 result
--------
     -1
(1 row)
```

- *

  Description: Multiplication

  Example:

  ```
  gaussdb=# SELECT 2*3 AS RESULT;
   result
  --------
       6
  (1 row)
  ```

- /

  Description: Division (The result is not rounded.)

  Example:

  ```
  gaussdb=# SELECT 4/2 AS RESULT;
   result
  --------
       2
  (1 row)
  gaussdb=# SELECT 4/3 AS RESULT;
        result
  ------------------
   1.33333333333333
  (1 row)
  ```

- +/-

  Description: Positive/Negative

  Example:

  ```
  gaussdb=# SELECT -2 AS RESULT;
   result
  --------
     -2
  (1 row)
  ```

- %

  Description: Model (to obtain the remainder)

  Example:

  ```
  gaussdb=# SELECT 5%4 AS RESULT;
   result
  --------
       1
  (1 row)
  ```

- @

  Description: Absolute value

  Example:

  ```
  gaussdb=# SELECT @ -5.0 AS RESULT;
   result
  --------
    5.0
  (1 row)
  ```

- ^

  Description: Power (exponent calculation)

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Example:

```
gaussdb=# SELECT 2.0^3.0 AS RESULT;
       result
--------------------
 8.0000000000000000
(1 row)
```

- |/

  Description: Square root

  Example:

```
gaussdb=# SELECT |/ 25.0 AS RESULT;
 result
--------
      5
(1 row)
```

- ||/

  Description: Cubic root

  Example:

```
gaussdb=# SELECT ||/ 27.0 AS RESULT;
 result
--------
      3
(1 row)
```

- !

  Description: Factorial

  Example:

```
gaussdb=# SELECT 5! AS RESULT;
 result
--------
    120
(1 row)
```

- !!

  Description: Factorial (prefix operator)

  Example:

```
gaussdb=# SELECT !!5 AS RESULT;
 result
--------
    120
(1 row)
```

- &

  Description: Binary AND

  Example:

```
gaussdb=# SELECT 91&15  AS RESULT;
 result
--------
     11
(1 row)
```

- |

  Description: Binary OR

  Example:

```
gaussdb=# SELECT 32|3  AS RESULT;
 result
--------
     35
(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- #

  Description: Binary XOR

  Example:

```
gaussdb=# SELECT 17#5  AS RESULT;
 result
--------
     20
(1 row)
```

- ~

  Description: Binary NOT

  Example:

```
gaussdb=# SELECT ~1 AS RESULT;
 result
--------
     -2
(1 row)
```

- <<

  Description: Binary shift left

  Example:

```
gaussdb=# SELECT 1<<4 AS RESULT;
 result
--------
     16
(1 row)
```

- >>

  Description: Binary shift right

  Example:

```
gaussdb=# SELECT 8>>2 AS RESULT;
 result
--------
      2
(1 row)
```

Arithmetic Functions

- abs(x)

  Description: Absolute value

  Return type: same as the input.

  Example:

```
gaussdb=# SELECT abs(-17.4);
 abs
------
 17.4
(1 row)
```

- acos(x)

  Description: Arc cosine

  Return type: double precision

  Example:

```
gaussdb=# SELECT acos(-1);
       acos
------------------
 3.14159265358979
(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- asin(x)

  Description: Arc sine

  Return type: double precision

  Example:

```
gaussdb=# SELECT asin(0.5);
       asin
------------------
 .523598775598299
(1 row)
```

- atan(x)

  Description: Arc tangent

  Return type: double precision

  Example:

```
gaussdb=# SELECT atan(1);
       atan
------------------
 .785398163397448
(1 row)
```

- atan2(y, x)

  Description: Arc tangent of y/x

  Return type: double precision

  Example:

```
gaussdb=# SELECT atan2(2, 1);
      atan2
------------------
 1.10714871779409
(1 row)
```

- bitand(integer, integer)

  Description: Performs the AND (&) operation on two integers.

  Return type: bigint

  Example:

```
gaussdb=# SELECT bitand(127, 63);
 bitand
--------
     63
(1 row)
```

- cbrt(dp)

  Description: Cubic root

  Return type: double precision

  Example:

```
gaussdb=# SELECT cbrt(27.0);
 cbrt
------
    3
(1 row)
```

- ceil(x)

  Description: Minimum integer greater than or equal to the parameter

  Return type: integer

  Example:

```
gaussdb=# SELECT ceil(-42.8);
 ceil
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
------
  -42
(1 row)
```

- ceiling(dp or numeric)

  Description: Minimum integer (alias of ceil) greater than or equal to the parameter

  Return type: same as the input.

  Example:

```
gaussdb=# SELECT ceiling(-95.3);
 ceiling
---------
     -95
(1 row)
```

- cos(x)

  Description: Cosine

  Return type: double precision

  Example:

```
gaussdb=# SELECT cos(-3.1415927);
        cos
-------------------
 -.999999999999999
(1 row)
```

- cosh(x)

  Description: Hyperbolic cosine

  Return type: dp or numeric. If implicit type conversion is not considered, the return type is the same as the input type.

  Example:

```
gaussdb=# SELECT cosh(4);
        cosh
-------------------
 27.3082328360165
(1 row)
```

  NOTE

  This function is valid only when the value of **a_format_version** is **10c** and that of **a_format_dev_version** is **s2** in an ORA-compatible database.

- cot(x)

  Description: Cotangent

  Return type: double precision

  Example:

```
gaussdb=# SELECT cot(1);
       cot
------------------
 .642092615934331
(1 row)
```

- degrees(dp)

  Description: Converts radians to angles.

  Return type: double precision

  Example:

```
gaussdb=# SELECT degrees(0.5);
    degrees
```

```
------------------
 28.6478897565412
(1 row)
```

- div(y numeric, x numeric)

  Description: Integer part of y/x

  Return type: numeric

  Example:

```
gaussdb=# SELECT div(9,4);
 div
-----
   2
(1 row)
```

- exp(x)

  Description: Natural exponent

  Return type: same as the input.

  Example:

```
gaussdb=# SELECT exp(1.0);
        exp
--------------------
 2.7182818284590452
(1 row)
```

- floor(x)

  Description: Not larger than the maximum integer of the parameter

  Return type: same as the input.

  Example:

```
gaussdb=# SELECT floor(-42.8);
 floor
-------
   -43
(1 row)
```

- int1(in)

  Description: Converts the input text parameter into the int1 type and returns the result.

  Return type: int1

  Example:

```
gaussdb=# SELECT int1('123');
 int1
------
 123
(1 row)
gaussdb=# SELECT int1('1.1');
 int1
------
   1
(1 row)
```

- int2(in)

  Description: Converts the input parameter into the int2 type and returns the result. The supported input parameter types include bigint, float4, float8, int16, integer, numeric, real, and text.

  Return type: int2.

  Example:

```
gaussdb=# SELECT int2('1234');
 int2
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
------
 1234
(1 row)
gaussdb=# SELECT int2(25.3);
 int2
------
   25
(1 row)
```

- int4(in)

  Description: Converts the input parameter into the int4 type and returns the result. The supported input parameter types include bit, Boolean, char, double precision, int16, numeric, real, smallint, and text

  Return type: int4

  Example:

```
gaussdb=# SELECT int4('789');
 int4
------
 789
(1 row)
gaussdb=# SELECT int4(99.9);
 int4
------
  100
(1 row)
```

- int8(in)

  Description: Converts the input parameter into the int8 type and returns the result. The supported input parameter types include bit, double precision, int16, integer, numeric, oid, real, smallint, and text.

  Return type: int8

  Example:

```
gaussdb=# SELECT int8('789');
 int8
------
 789
(1 row)
gaussdb=# SELECT int8(99.9);
 int8
------
   99
(1 row)
```

- float4(in)

  Description: Converts the input parameter into the float4 type and returns the result. The supported input parameter types include bigint, double precision, int16, integer, numeric, smallint, and text.

  Return type: float4

  Example:

```
gaussdb=# SELECT float4('789');
 float4
--------
    789
(1 row)

gaussdb=# SELECT float4(99.9);
 float4
--------
   99.9
(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- float8(in)

  Description: Converts the input parameter into the float8 type and returns the result. The supported input parameter types include bigint, int16, integer, numeric, real, smallint, and text.

  Return type: float8

  Example:

```
gaussdb=# SELECT float8('789');
 float8
--------
    789
(1 row)

gaussdb=# SELECT float8(99.9);
 float8
--------
   99.9
(1 row)
```

- int16(in)

  Description: Converts the input parameter into the int16 type and returns the result. The supported input parameter types include bigint, Boolean, double precision, integer, numeric, oid, real, smallint, and tinyint.

  Return type: int16

  Example:

```
gaussdb=# SELECT int16('789');
 int16
--------
    789
(1 row)

gaussdb=# SELECT int16(99.9);
 int16
--------
   100
(1 row)
```

- numeric(in)

  Description: Converts the input parameter into the numeric type and returns the result. The supported input parameter types include bigint, Boolean, double precision, int16, integer, money, real, and smallint.

  Return type: numeric

  Example:

```
gaussdb=# SELECT "numeric"('789');
 numeric
---------
     789
(1 row)

gaussdb=# SELECT "numeric"(99.9);
 numeric
---------
    99.9
(1 row)
```

- oid(in)

  Description: Converts the input parameter into the oid type and returns the result. The supported input parameter types include bigint and int16.

  Return type: oid

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- radians(dp)

  Description: Converts angles to radians.

  Return type: double precision

  Example:

```
gaussdb=# SELECT radians(45.0);
     radians
------------------
 .785398163397448
(1 row)
```

- random()

  Description: Random number between 0.0 and 1.0.

  Return type: double precision

  Example:

```
gaussdb=# SELECT random();
      random
------------------
 .824823560658842
(1 row)
```

  NOTE

  You are advised not to use this function in security scenarios.

- rand([seed])

  Description: The input can be without any parameters or only include a **seed** parameter of the bigint type. Typically, this function returns a random number from 0 to 1. If **seed** is specified, this function will return a random value for **seed**.

  Parameter: a random number seed of the bigint type.

  Return type: double

  Example:

```
b_compatible_db=# SELECT rand();
       rand
------------------
 .327476012520492
(1 row)

b_compatible_db=# SELECT rand(12321);
       rand
------------------
 .326073104515672
(1 row)
```

  NOTE

  - This function takes effect when the database parameter **sql_compatibility** is set to **'MYSQL'**.
  - You are advised not to use this function in security scenarios.

- multiply(x double precision or text, y double precision or text)

  Description: product of x and y.

  Return type: double precision

  Example:

```
gaussdb=# SELECT multiply(9.0, '3.0');
     multiply
------------------
```

```
            27
(1 row)
gaussdb=# SELECT multiply('9.0', 3.0);
   multiply
------------------
            27
(1 row)
```

- ln(x)

  Description: Natural logarithm.

  Return type: same as the input.

  Example:

  ```
  gaussdb=# SELECT ln(2.0);
         ln
  -------------------
   .6931471805599453
  (1 row)
  ```

- log(x)

  Description: Logarithm with 10 as the base.

  Return type: same as the input.

  Example:

  ```
  gaussdb=# SELECT log(100.0);
         log
  --------------------
   2.0000000000000000
  (1 row)
  ```

- log(b numeric, x numeric)

  Description: Logarithm with b as the base.

  Return type: numeric

  Example:

  ```
  gaussdb=# SELECT log(2.0, 64.0);
         log
  --------------------
   6.0000000000000000
  (1 row)
  ```

- log2(x)

  Description: Logarithm with 2 as the base.

  Return type: double precision

  Example:

  ```
  gaussdb=# SELECT log2(2);
   log2
  ------
     1
  (1 row)
  ```

  NOTE

  This function takes effect when the database parameter **sql_compatibility** is set to **'MYSQL'**.

- log10(x)

  Description: Logarithm with 10 as the base.

  Return type: double precision

  Example:

  ```
  gaussdb=# SELECT log10(10);
   log10
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
-------
    1
(1 row)
```

> **NOTE**
>
> This function takes effect when the database parameter **sql_compatibility** is set to **'MYSQL'**.

- mod(x, y)

  Description: Returns the remainder (MOD) of **x**/**y**. If **x** is **0**, the function will return **y**.

  Return type: If the input parameter is of the (text, int) type, the return value is of the NUMERIC type. If the input parameter is of other types, the return type is the same as the parameter type.

  Example:

```
gaussdb=# SELECT mod(9,4);
 mod
-----
   1
(1 row)
gaussdb=# SELECT mod(9,0);
 mod
-----
   9
(1 row)
```

> **NOTE**
>
> In ORA-compatible databases where **a_format_version** is **10c** and **a_format_dev_version** is **s6**, the mod function supports overloading with mod(text, int). When the mod function is called with (text, int) as the input type, mod(text, int) will take precedence.

```
gaussdb=# SET a_format_version='10c';
SET
gaussdb=# SET a_format_dev_version='s6';
SET
gaussdb=# SELECT mod('170141183460469231731687303715884105728', 7);
 mod
-----
   2
(1 row)
```

- pi()

  Description: π constant value.

  Return type: double precision

  Example:

```
gaussdb=# SELECT pi();
        pi
------------------
 3.14159265358979
(1 row)
```

- power(a double precision or numeric, b double precision or numeric)

  Description: b power of a.

  Return type: double precision or numeric. If implicit type conversion is not considered and both input parameters are of the numeric type, the numeric type is returned. If either input parameter is of the double precision type, the double precision type is returned.

  Example:

```
gaussdb=# SELECT power(9.0, 3.0);
       power
---------------------
 729.0000000000000000
(1 row)
```

- remainder(x, y)

  Description: Returns the remainder of **x**/**y**. If **y** is **0**, the function will report an error.

  Return type: same as the input (float4, float8, or numeric).

  Example:

```
gaussdb=# SELECT remainder(11,4);
 remainder
-----------
        -1
(1 row)
gaussdb=# SELECT remainder(9,0);
ERROR: division by zero
CONTEXT:  referenced column: remainder
```

  NOTE

  This function is valid only when the value of **a_format_version** is **10c** and that of **a_format_dev_version** is **s2** in an ORA-compatible database.

- round(x)

  Description: Integer closest to the input parameter.

  Return type: same as the input (double precision or numeric).

  Example:

```
gaussdb=# SELECT round(42.4);
 round
-------
    42
(1 row)

gaussdb=# SELECT round(42.6);
 round
-------
    43
(1 row)
```

  NOTE

  The output of the float/double type may be **-0**. This also occurs in functions such as trunc and ceil. If the value of **a_format_version** is **10c** and that of **a_format_dev_version** is **s1** in an ORA-compatible database, the returned result is **0**. The following is an example:

```
gaussdb=# SELECT round(-0.2::float8);
 round
-------
    -0
(1 row)
```

- round(v numeric, s int)

  Description: The number of *s* digits are kept after the decimal point, and the number is rounded off.

  Return type: numeric

  Example:

```
gaussdb=# SELECT round(42.4382, 2);
 round
-------
```

```
 42.44
(1 row)
```

NOTE

- When the value of **a_format_version** is **10c** and that of **a_format_dev_version** is **s1** in an ORA-compatible database, **s** is truncated to an integer. Otherwise, **s** is rounded off to an integer.
- If the value of **a_format_version** is **10c** and the value of **a_format_dev_version** is **s1**, the round function supports round(timestamp, text) overloading. When **(text, text)** or **(text, '')** is used as the input parameter to call the round function, round (timestamp, text) is preferred.

- setseed(dp)

  Description: Sets a seed, within the range of [–1.0,1.0], for future calls to the random() function.

  Return type: void

  Example:

  ```
  gaussdb=# SELECT setseed(0.54823);
   setseed
  ---------

  (1 row)
  ```

  NOTE

  You are advised not to use this function in security scenarios.

- sign(x)

  Description: Returns symbols of this parameter.

  Return type: **–1** indicates negative numbers. **0** indicates 0, and **1** indicates positive numbers.

  Example:

  ```
  gaussdb=# SELECT sign(-8.4);
   sign
  ------
    -1
  (1 row)
  ```

- sin(x)

  Description: Sine

  Return type: double precision

  Example:

  ```
  gaussdb=# SELECT sin(1.57079);
        sin
  ------------------
   .999999999979986
  (1 row)
  ```

- sinh(x)

  Description: Hyperbolic sine

  Return type: dp or numeric. If implicit type conversion is not considered, the return type is the same as the input type.

  Example:

  ```
  gaussdb=# SELECT sinh(4);
        sinh
  ------------------
   27.2899171971277
  (1 row)
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

> **NOTE**
>
> This function is valid only when the value of **a_format_version** is **10c** and that of **a_format_dev_version** is **s2** in an ORA-compatible database.

- sqrt(x)

  Description: Square root

  Return type: same as the input.

  Example:

```
gaussdb=# SELECT sqrt(2.0);
       sqrt
-------------------
 1.414213562373095
(1 row)
```

> **NOTE**
>
> This function uses the Karatsuba sqrt square root algorithm when the GUC parameter **gs_format_behavior_compat_options** is set to **sqrt_karatsuba**. Otherwise, this function uses the Newton iteration algorithm. The performance of the Karatsuba sqrt square root algorithm is better. In a few scenarios, the precision of the Karatsuba sqrt square root algorithm is different from that of the Newton iteration algorithm.

- tan(x)

  Description: Tangent

  Return type: double precision

  Example:

```
gaussdb=# SELECT tan(20);
       tan
------------------
 2.23716094422474
(1 row)
```

- tanh(x)

  Description: Hyperbolic tangent

  Return type: same as the input (double precision or numeric).

  Example:

```
gaussdb=# SELECT tanh(0.1);
                       tanh
-------------------------------------------
0.099667994624955817118305083678352183538 9
(1 row)
```

> **NOTE**
>
> This function is valid only when the value of **a_format_version** is **10c** and that of **a_format_dev_version** is **s2** in an ORA-compatible database.

- trunc(x)

  Description: Truncation (the integer part is retained).

  Return type: same as the input.

  Example:

```
gaussdb=# SELECT trunc(42.8);
 trunc
-------
    42
(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- trunc(v numeric, s int)

  Description: Truncates the last *s* digits after a decimal point.

  Return type: numeric

  Example:

  ```
  gaussdb=# SELECT trunc(42.4382, 2);
   trunc
  -------
   42.43
  (1 row)
  ```

  NOTE

  This function is valid only when **a_format_version** is set to **10c** and **a_format_dev_version** is set to **s1** in ORA-compatible mode. If the value of **s** is a decimal, the value is truncated instead of being rounded off.

- width_bucket(op numeric, b1 numeric, b2 numeric, count int)

  Description: Returns the SN of the bucket to which the operand would be assigned in the range of [b1,b2], which is divided into *count* equal-sized intervals based on the principle of equal interval bucketing.

  Return type: int.

  Example:

  ```
  gaussdb=# SELECT width_bucket(5.35, 0.024, 10.06, 5);
   width_bucket
  --------------
             3
  (1 row)
  ```

- width_bucket(op dp, b1 dp, b2 dp, count int)

  Description: Returns the SN of the bucket to which the operand would be assigned in the range of [b1,b2], which is divided into *count* equal-sized intervals based on the principle of equal interval bucketing.

  Return type: int.

  Example:

  ```
  gaussdb=# SELECT width_bucket(5.35, 0.024, 10.06, 5);
   width_bucket
  --------------
             3
  (1 row)
  ```

- smgrne(a smgr, b smgr)

  Description: Compares two integers of the smgr type to check whether they are different.

  Return type: Boolean

- smgreq(a smgr, b smgr)

  Description: Compares two integers of the smgr type to check whether they are equivalent.

  Return type: Boolean

- int1abs(tinyint)

  Description: Returns the absolute value of data of the uint8 type.

  Return type: tinyint

- int1and(tinyint, tinyint)

  Description: Returns the bitwise AND result of two data records of the uint8 type.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Return type: tinyint

- int1cmp(tinyint, tinyint)

  Description: Returns the comparison result of two data records of the uint8 type. If the value of the first parameter is greater, **1** is returned. If the value of the second parameter is greater, **-1** is returned. If they are the same, **0** is returned.

  Return type: integer

- int1div(tinyint, tinyint)

  Description: Returns the result of dividing two data records of the uint8 type. The result is of the tinyint type.

  Return type: tinyint

- int1eq(tinyint, tinyint)

  Description: Compares two pieces of data of the uint8 type to check whether they are the same.

  Return type: Boolean

- int1ge(tinyint, tinyint)

  Description: Determines whether the value of the first parameter is greater than or equal to the value of the second parameter in two data records of the uint8 type.

  Return type: Boolean

- int1gt(tinyint, tinyint)

  Description: Checks whether an unsigned 1-byte integer is greater than the other.

  Return type: Boolean

- int1larger(tinyint, tinyint)

  Description: Returns the larger value of unsigned one-byte integers.

  Return type: tinyint

- int1le(tinyint, tinyint)

  Description: Checks whether an unsigned 1-byte integer is less than or equal to the other.

  Return type: Boolean

- int1lt(tinyint, tinyint)

  Description: Checks whether an unsigned 1-byte integer is less than the other.

  Return type: Boolean

- int1smaller(tinyint, tinyint)

  Description: Returns the smaller of two unsigned one-byte integers.

  Return type: tinyint

- int1inc(tinyint)

  Description: Unsigned 1-byte integer plus 1.

  Return type: tinyint

- int1mi(tinyint, tinyint)

  Description: Performs a minus operation on an unsigned 1-byte integer.

  Return type: tinyint

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- int1mod(tinyint, tinyint)

  Description: Performs a MOD operation on unsigned 1-byte integers.

  Return type: tinyint

- int1mul(tinyint, tinyint)

  Description: Performs a multiplication operation on an unsigned 1-byte integer.

  Return type: tinyint

- int1ne(tinyint, tinyint)

  Description: Checks whether an unsigned 1-byte integer is not equal to the other.

  Return type: Boolean

- int1pl(tinyint, tinyint)

  Description: Performs an addition operation on an unsigned 1-byte integer.

  Return type: tinyint

- int1um(tinyint)

  Description: Returns an unsigned 2-byte integer after subtracting the opposite number from the unsigned 1-byte integer.

  Return type: smallint

- int1xor(tinyint, tinyint)

  Description: Performs an XOR operation on an unsigned 1-byte integer.

  Return type: tinyint

- cash_div_int1(money, tinyint)

  Description: Performs a division operation on the money type.

  Return type: money

- cash_mul_int1(money, tinyint)

  Description: Performs a multiplication operation on the money type.

  Return type: money

- int1not(tinyint)

  Description: Reverts binary bits of an unsigned 1-byte integer.

  Return type: tinyint

- int1or(tinyint, tinyint)

  Description: Performs an OR operation on an unsigned 1-byte integer.

  Return type: tinyint

- int1shl(tinyint, integer)

  Description: Shifts an unsigned 1-byte integer leftwards by a specified number of bits.

  Return type: tinyint

- int1shr(tinyint, integer)

  Description: Shifts an unsigned 1-byte integer rightwards by a specified number of bits.

  Return type: tinyint

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- analyze_tgtype_for_type(n smallint)

  Description: Parses **pg_trigger.tgtype**, parses *n* by bit, and returns one of **before each row**, **after each row**, **before statement**, **after statement**, and **instead of**.

  Return type: varchar2(16)

- analyze_tgtype_for_event(n smallint)

  Description: Parses **pg_trigger.tgtype**, parses *n* by bit, and returns one or more of **insert**, **update**, **delete**, and **truncate**.

  Return type: varchar2(246)

- nanvl(n2, n1)

  Description: Two parameters are entered. The parameters must be of the numeric type or a non-numeric type that can be implicitly converted to the numeric type. If the first parameter **n2** is NaN, **n1** is returned. Otherwise, **n2** is returned.

  Return type: double precision > float4 > numeric, depending on the higher priority between the types of the input parameters.

  Example:

  ```
  gaussdb=# SELECT nanvl('NaN', 1.1);
   nanvl
  -------
    1.1
  (1 row)
  ```

  NOTE

  This function is valid only when the value of **a_format_version** is **10c** and that of **a_format_dev_version** is **s2** in an ORA-compatible database.

- numeric_eq_text(numeric, text)

  Description: Checks whether the numeric variable is equal to the numeric value converted from the text variable.

  Return type: Boolean

  Example:

  ```
  gaussdb=# SELECT numeric_eq_text(1, '1');
   numeric_eq_text
  -----------------
   t
  (1 row)
  ```

- numeric_ne_text(numeric, text)

  Description: Checks whether the numeric variable is not equal to the numeric value converted from the text variable.

  Return type: Boolean

- numeric_gt_text(numeric, text)

  Description: Checks whether the numeric variable is greater than the numeric value converted from the text variable.

  Return type: Boolean

- numeric_ge_text(numeric, text)

  Description: Checks whether the numeric variable is greater than or equal to the numeric value converted from the text variable.

  Return type: Boolean

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- numeric_lt_text(numeric, text)

  Description: Checks whether the numeric variable is smaller than the numeric value converted from the text variable.

  Return type: Boolean

- numeric_le_text(numeric, text)

  Description: Checks whether the numeric variable is less than or equal to the numeric value converted from the text variable.

  Return type: Boolean

- text_eq_numeric(text, numeric)

  Description: Checks whether the numeric value converted from a text variable is equal to the numeric variable.

  Return type: Boolean

  Example:

  ```
  gaussdb=# SELECT text_eq_numeric('1', 1);
   text_eq_numeric
  -----------------
   t
  (1 row)
  ```

- text_ne_numeric(text, numeric)

  Description: Checks whether the numeric value converted from a text variable is not equal to the numeric variable.

  Return type: Boolean

- text_gt_numeric(text, numeric)

  Description: Checks whether the numeric value converted from a text variable is greater than the numeric variable.

  Return type: Boolean

- text_ge_numeric(text, numeric)

  Description: Checks whether the numeric value converted from a text variable is greater than or equal to the numeric variable.

  Return type: Boolean

- text_lt_numeric(text, numeric)

  Description: Checks whether the numeric value converted from a text variable is less than the numeric variable.

  Return type: Boolean

- text_le_numeric(text, numeric)

  Description: Checks whether the numeric value converted from a text variable is less than or equal to the numeric variable.

  Return type: Boolean

- bigint_eq_text(bigint, text)

  Description: Checks whether the bigint variable is equal to the bigint value converted from a text variable.

  Return type: Boolean

  ```
  gaussdb=# SELECT bigint_eq_text(1, '1');
   bigint_eq_text
  ----------------
   t
  (1 row)
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- bigint_ne_text(bigint, text)

  Description: Checks whether the bigint variable is not equal to the bigint value converted from a text variable.

  Return type: Boolean

- bigint_gt_text(bigint, text)

  Description: Checks whether the bigint variable is greater than the bigint value converted from a text variable.

  Return type: Boolean

- bigint_ge_text(bigint, text)

  Description: Checks whether the bigint variable is greater than or equal to the bigint value converted from a text variable.

  Return type: Boolean

- bigint_lt_text(bigint, text)

  Description: Checks whether the bigint variable is smaller than the bigint value converted from a text variable.

  Return type: Boolean

- bigint_le_text(bigint, text)

  Description: Checks whether the bigint variable is less than or equal to the bigint value converted from a text variable.

  Return type: Boolean

- text_eq_bigint(text, bigint)

  Description: Checks whether the bigint value converted from a text variable is equal to the bigint variable.

  Return type: Boolean

  Example:

  ```
  gaussdb=# SELECT text_eq_bigint('1', 1);
   text_eq_bigint
  ----------------
   t
  (1 row)
  ```

- text_ne_bigint(text, bigint)

  Description: Checks whether the bigint value converted from a text variable is not equal to the bigint variable.

  Return type: Boolean

- text_gt_bigint(text, bigint)

  Description: Checks whether the bigint value converted from a text variable is greater than the bigint variable.

  Return type: Boolean

- text_ge_bigint(text, bigint)

  Description: Checks whether the bigint value converted from a text variable is greater than or equal to the bigint variable.

  Return type: Boolean

- text_lt_bigint(text, bigint)

  Description: Checks whether the bigint value converted from a text variable is less than the bigint variable.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Return type: Boolean

- text_le_bigint(text, bigint)

  Description: Checks whether the bigint value converted from a text variable is less than or equal to the bigint variable.

  Return type: Boolean

1.6.8 Date and Time Processing Functions and Operators

Time and Date Operators

Table 1-48 describes the time and date operators.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

When working with time and date operators, use explicit type prefixes to modify operands. This will help the database parse the operands correctly according to user expectations and avoid any unexpected results.

Example: Not specifying a data type results in an error.

```
gaussdb=# SELECT date '2001-10-01' - '7' AS RESULT;
ERROR:
GAUSS-10416: invalid input syntax for type timestamp: "7"
SQLSTATE: 22007
LINE 1: SELECT date '2001-10-01' - '7' AS RESULT;
                                   ^
CONTEXT:  referenced column: result
```

In Oracle-compatible mode, the DATEA type supports arithmetic operations with strings of the unspecified types, including integer strings or floating-point strings. The return type of the operation result is DATEA. Only the plus sign (+) and minus sign (-) are supported.

```
gaussdb=# SET nls_date_format='yyyy-mm-dd hh24:mi:ss';
SET
gaussdb=# SELECT '2024-1-2'::DATEA + '0.00000579';
       ?column?
------------------------
 2024-01-02 00:00:01 AD
(1 row)

gaussdb=# SELECT '0.00000579' + '2024-1-2'::DATEA;
       ?column?
------------------------
 2024-01-02 00:00:01 AD
(1 row)

gaussdb=# SELECT '2024-1-2'::DATEA + '1';
       ?column?
------------------------
 2024-01-03 00:00:00 AD
(1 row)

gaussdb=# SELECT '2024-1-2'::DATEA - '0.00000579';
       ?column?
------------------------
 2024-01-01 23:59:59 AD
(1 row)

gaussdb=# SELECT '2' - '2024-1-2'::DATEA;
ERROR:  Invalid data exists in a string for matching date.
LINE 1: SELECT '2' - '2024-1-2'::DATEA;
               ^
```

In ORA-compatible mode, the DATEA type can be subtracted from an unspecified type (complying with the time format).

```
gaussdb=# SET nls_date_format='yyyy-mm-dd hh24:mi:ss';
SET
gaussdb=# SELECT '2024-1-3' - '2024-1-2'::DATEA;
 ?column?
----------
        1
(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 1-48 Time and date operators

Operator	Example
+	gaussdb=# SELECT date '2001-9-28' + integer '7' AS RESULT; result ------------ 2001-10-05 (1 row) **NOTE** In ORA-compatible mode, the query result is 2001-10-05 00:00:00.
	gaussdb=# SELECT date '2001-09-28' + interval '1 hour' AS RESULT; result --------------------- 2001-09-28 01:00:00 (1 row)
	gaussdb=# SELECT date '2001-09-28' + time '03:00' AS RESULT; result --------------------- 2001-09-28 03:00:00 (1 row)
	gaussdb=# SELECT interval '1 day' + interval '1 hour' AS RESULT; result ---------------- 1 day 01:00:00 (1 row)
	gaussdb=# SELECT timestamp '2001-09-28 01:00' + interval '23 hours' AS RESULT; result --------------------- 2001-09-29 00:00:00 (1 row)
	gaussdb=# SELECT time '01:00' + interval '3 hours' AS RESULT; result ---------- 04:00:00 (1 row)
	gaussdb=# SET nls_date_format='yyyy-mm-dd hh24:mi:ss'; SET gaussdb=# SELECT '2024-1-2'::DATEA - '2024-1-1'::DATEA AS RESULT; result -------- 1 (1 row)
-	gaussdb=# SELECT date '2001-10-01' - date '2001-09-28' AS RESULT; result -------- 3 (1 row)
	gaussdb=# SELECT date '2001-10-01' - integer '7' AS RESULT; result --------------------- 2001-09-24 00:00:00 (1 row)

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Operator	Example
	gaussdb=# SELECT date '2001-09-28' - interval '1 hour' AS RESULT; result --------------------- 2001-09-27 23:00:00 (1 row)
	gaussdb=# SELECT time '05:00' - time '03:00' AS RESULT; result ---------- 02:00:00 (1 row)
	gaussdb=# SELECT time '05:00' - interval '2 hours' AS RESULT; result ---------- 03:00:00 (1 row)
	gaussdb=# SELECT timestamp '2001-09-28 23:00' - interval '23 hours' AS RESULT; result --------------------- 2001-09-28 00:00:00 (1 row)
	gaussdb=# SELECT interval '1 day' - interval '1 hour' AS RESULT; result ---------- 23:00:00 (1 row)
	gaussdb=# SELECT timestamp '2001-09-29 03:00' - timestamp '2001-09-27 12:00' AS RESULT; result ---------------- 1 day 15:00:00 (1 row)
	gaussdb=# SET nls_date_format='yyyy-mm-dd hh24:mi:ss'; SET gaussdb=# SELECT '2024-1-2'::DATEA - '2024-1-1'::DATEA AS RESULT; result -------- 1 (1 row) **NOTE** In the scenario where a DATEA type is subtracted from another DATEA type, only 15 valid digits are supported due to the precision issues with the double type. In addition, the 15th digit may be rounded incorrectly due to precision issues with the 16th digit. Example: SELECT '2020-10-02 00:00:00'::datea - '2020-10-01 00:00:34'::datea; The manually calculated result should be: 0.99960648148148148... However, due to the precision issues with double, the actual calculated result becomes 0.999606481481482, where rounding occurs at the 16th digit.
*	gaussdb=# SELECT 900 * interval '1 second' AS RESULT; result ---------- 00:15:00 (1 row)

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Operator	Example
	gaussdb=# SELECT 21 * interval '1 day' AS RESULT; result --------- 21 days (1 row)
	gaussdb=# SELECT double precision '3.5' * interval '1 hour' AS RESULT; result ---------- 03:30:00 (1 row)
/	gaussdb=# SELECT interval '1 hour' / double precision '1.5' AS RESULT; result ---------- 00:40:00 (1 row)

NOTE

In ORA-compatible mode, the following functions are supported:

- The left operand of the DATEA type can be added to the right operand of the TIME WITHOUT TIME ZONE, INTERVAL DAY TO SECOND, INTERVAL DAY, or RELTIME type. The left and right operands can be exchanged.
- The left operand of the DATEA type can be subtracted from the right operand of the TIME WITHOUT TIME ZONE, TIMESTAMP WITH TIME ZONE, INTERVAL DAY TO SECOND, INTERVAL DAY, RELTIME, SMALLDATETIME, or ABSTIME type.
- The left operand of the TIMESTAMP WITHOUT TIME ZONE, TIMESTAMP WITH TIME ZONE, SMALLDATETIME, or ABSTIME type can be subtracted from the right operand of the DATEA type.

Time and Date Functions

- age(timestamp, timestamp)

  Description: Subtracts parameters, producing a result in YYYY-MM-DD format. If the result is negative, the returned result is also negative. The input parameters may or may not contain time zones.

  Return type: interval

  Example:

  ```
  gaussdb=# SELECT age(timestamp '2001-04-10', timestamp '1957-06-13');
           age
  --------------------------
   43 years 9 mons 27 days
  (1 row)
  ```

- age(timestamp)

  Description: Subtracts the parameter value from the system time when the current SQL statement starts to be executed. The input parameters can either both include timezone information or both exclude it.

  Return type: interval

  Example:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gaussdb=# SELECT age(timestamp '1957-06-13');
          age
------------------------
 60 years 2 mons 18 days
(1 row)
```

- clock_timestamp()

  Description: Returns the timestamp of the system time when the current function is called. This volatile function obtains the latest timestamp for each scan. Therefore, the result of each function call in a query is different.

  Return type: timestamp with time zone

  Example:

```
gaussdb=# SELECT clock_timestamp();
       clock_timestamp
-------------------------------
 2017-09-01 16:57:36.636205+08
(1 row)
```

- current_date

  Description: Returns the system date when the current SQL statement starts.

  Return type: date

  Example:

```
gaussdb=# SELECT current_date;
    date
------------
 2017-09-01
(1 row)
-- When the GUC parameter a_format_date_timestamp is enabled in ORA-compatible mode:
gaussdb=# SET a_format_date_timestamp=on;
SET
gaussdb=# SELECT current_date;
    current_date
---------------------
 2023-11-24 11:25:09
(1 row)
-- In ORA-compatible mode, if the GUC parameter mapping_date_to_datea is enabled, the return type is datea.
gaussdb=# SELECT current_date;
      current_date
-------------------------
 2025-05-21 11:31:15 AD
(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

When **sql_compatibility** is **'ORA'**, this function operates as follows:

- If the GUC parameter **mapping_date_to_datea** is set to **on**, the timestamp of the system time when the current SQL statement is started is returned. The return value type is datea, and the column name is **current_date**.
- If the GUC parameter **mapping_date_to_datea** is set to **off**, the following rules are followed:
  - If the GUC parameter **a_format_date_timestamp** is set to **on**, it returns a timestamp that shows the system time when the current SQL statement starts. The return type is timestamp without time zone, accurate to seconds, and the column name is **current_date**.
  - If the GUC parameter **a_format_date_timestamp** is **off**, it returns the system time when the transaction starts. If **a_format_version** is **10c** and **a_format_dev_version** is **s2**, the return type is timestamp without time zone, accurate to seconds, and the column name is **timestamp**. Otherwise, the return type is date, accurate to days, and the column name is **date**.

This function has the following behaviors when **sql_compatibility** is set to **'MYSQL'**, **b_format_version** is set to **5.7**, and **b_format_dev_version** is set to **s1**:

- current_date can be called with parentheses.
- The actually called function of current_date is curdate. You can run the **\df curdate** command to query the detailed input parameters and return values of the function.

- current_time()

  Description: Specifies the system time when the current transaction starts. If **sql_compatibility** is set to **'MYSQL'**, **b_format_version** is set to **'5.7'**, and **b_format_dev_version** is set to **'s1'**, the system time when the current SQL statement starts is returned.

  Return type: time with time zone. When **sql_compatibility** is set to **'MYSQL'**, **b_format_version** is set to **'5.7'**, and **b_format_dev_version** is set to **'s1'**, the return type is time without time zone.

  Example:

```
gaussdb=# SELECT current_time;
      timetz
--------------------
 16:58:07.086215+08
(1 row)
-- When the parameter is enabled in MySQL-compatible mode:
gaussdb_m=# SELECT current_time;
 current_time
--------------
 15:14:00
(1 row)
```

- current_time([precision])

  Description: Returns the system time when the current SQL statement starts.

  Parameter: **precision** indicates the precision (number of decimal places after the second). The value is of the int type and in the range [0,6]. The default value is **0**. If the precision is invalid, an error is reported.

  Return type: time without time zone

  Implementation mode: This function is mapped to the system function curtime.

  Example:

```
gaussdb_m=# SELECT current_time();
 current_time
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
--------------
 15:14:05
(1 row)
gaussdb_m=# SELECT current_time(3);
 current_time
--------------
 15:14:08.433
(1 row)
```

> **NOTE**
>
> This function is valid only when **sql_compatibility** is set to **'MYSQL'**, **b_format_version** is set to **'5.7'**, and **b_format_dev_version** is set to **'s1'**. The actually called function of current_time is curtime. You can run the **\df curtime** command to query the detailed input parameters and return values of the function.

- current_timestamp

  Description: Specifies the current date and time. This is a statement-level timestamp. The returned results within the same statement remain unchanged.

  Return type: timestamp without time zone when **sql_compatibility** is set to **'MYSQL'**, **b_format_version** is set to **'5.7'**, and **b_format_dev_version** is set to **'s1'**, or timestamp with time zone in other scenarios

  Example:

```
gaussdb=# SELECT current_timestamp;
       pg_systimestamp
-------------------------------
 2017-09-01 16:58:19.22173+08
(1 row)

-- When the version is 5.7 in MySQL-compatible database:
gaussdb_m=# SELECT current_timestamp;
     timestamp
---------------------
 2023-08-21 15:08:24
(1 row)
-- When the GUC parameter a_format_date_timestamp is enabled in ORA-compatible mode:
gaussdb=# SET a_format_date_timestamp=on;
SET
gaussdb=# SELECT current_timestamp;
       current_timestamp
-------------------------------
 2023-11-24 11:31:04.895312+08
(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- When **sql_compatibility** is set to **'ORA'**, or **sql_compatibility** is set to **'MYSQL'** and the **b_format_version** and **b_format_dev_version** parameters are not set, the return result is the timestamp of the system time when the latest SQL statement starts to be executed, and the return type is timestamp with time zone. If the GUC parameter **a_format_date_timestamp** is set to **on**, the column name is **current_timestamp**.
- In PL/SQL, a simple assignment statement, such as time1 := current_timestamp, is considered as an expression. Therefore, the return result is the timestamp of the system time when the latest SQL statement is started.
- This function has the following behaviors when **sql_compatibility** is set to **'MYSQL'**, **b_format_version** is set to **5.7**, and **b_format_dev_version** is set to **s1**:
  - The return type is timestamp without time zone.
  - The precision of the returned result is 0.
  - The timestamp of the system time is returned when the current SQL statement starts.
  - This function is implemented through TYPE conversion and has no registered function. Therefore, you can run the **\df+** command of gsql to view the function information in other compatible modes, not the function information in version 5.7 in the MySQL-compatible mode.
  - When the function is called multiple times in an anonymous block, the entire anonymous block is considered as a statement. Therefore, the same result is returned each time the function is called.

- current_timestamp()

  Description: Returns the system time when the current SQL statement starts.

  Return type: timestamp without time zone

  Example:

```
gaussdb=# SELECT current_timestamp();
     timestamp
---------------------
 2023-08-21 14:34:30
(1 row)
```

  NOTE

  This function can be used only when **sql_compatibility** is set to **'MYSQL'**, **b_format_version** is set to **'5.7'**, and **b_format_dev_version** is set to **'s1'**. In addition, this function has the following behavior:

  - The return type is timestamp without time zone.
  - The precision of the returned result is 0.
  - The timestamp of the system time is returned when the current SQL statement starts to be executed.
  - This function is implemented through TYPE conversion and has no registered function. Therefore, you can run the **\df+** command of gsql to view the function information in other modes, not the function information in version 5.7 in the MySQL-compatible mode.

- current_timestamp(precision)

  Description: Obtains the current date and time, and rounds the microseconds of the result to the specified decimal place.

  Parameter: **precision** (number of decimal places after the second). The precision is of the int type, within the range of [0,6] and with a default value of **0**. Setting a value greater than 6 will trigger an alarm and return a time

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

value with the precision of 6. Using any other invalid precision will trigger an error.

Return type: timestamp without time zone when **sql_compatibility** is set to **'MYSQL'**, **b_format_version** is set to **'5.7'**, and **b_format_dev_version** is set to **'s1'**, or timestamp with time zone in other scenarios

Example:

```
gaussdb=# SELECT current_timestamp(1);
      timestamptz
-------------------------------
 2017-09-01 16:58:19.2+08
(1 row)

-- When the version is 5.7 in MySQL-compatible database:
gaussdb_m=# SELECT current_timestamp(1);
      timestamp
-----------------------
 2023-08-21 15:09:35.3
(1 row)

-- When the GUC parameter a_format_date_timestamp is enabled in ORA-compatible mode:
gaussdb=# SET a_format_date_timestamp=on;
SET
gaussdb=# SELECT current_timestamp(6);
      current_timestamp
-------------------------------
 2023-11-24 11:35:57.268592+08
(1 row)
-- If a_format_version is set to 10c and a_format_dev_version is set to s2 in an ORA-compatible database, precision can be an integer of the numeric type.
gaussdb=# SET a_format_version='10c';
SET
gaussdb=# SET a_format_dev_version='s2';
SET
gaussdb=# SELECT current_timestamp(6.0);
     current_timestamp
-------------------------------
 2023-11-25 11:14:48.74763+08
(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- Zeros at the end of microseconds are not displayed. For example, 2017-09-01 10:32:19.212000 is displayed as 2017-09-01 10:32:19.212.
- This function has the following behaviors when **sql_compatibility** is set to **'MYSQL'**, **b_format_version** is set to **5.7**, and **b_format_dev_version** is set to **s1**:
  - The return type is timestamp without time zone.
  - The timestamp of the system time is returned when the current SQL statement starts to be executed.
  - This function is implemented through TYPE conversion and has no registered function. Therefore, you can run the **\df+** command of gsql to view the function information in other modes, not the function information in version 5.7 in the MySQL-compatible mode.
- This function has the following behaviors when **sql_compatibility** is set to **'ORA'** and the GUC parameter **a_format_date_timestamp** is set to **on**:
  - The return value type is timestamp with time zone, and the column name is **current_timestamp**.
  - The timestamp of the system time is returned when the current SQL statement starts to be executed.
  - When **a_format_version** is set to **10c** and **a_format_dev_version** is set to **s2**, the **precision** parameter can be an integer of the numeric type. Otherwise, only the int type is supported.
- When **sql_compatibility** is set to **'ORA'** and the GUC parameter **a_format_date_timestamp** is set to **off**, if the input parameter is an integer without a decimal point, the system date and time when the transaction starts is returned; if the input parameter is an integer with a decimal point, the timestamp of the system time when the current SQL execution starts is returned.

- pg_systimestamp()

  Description: Current date and time (start of the current statement).

  Return type: timestamp with time zone

  Example:

```
gaussdb=# SELECT pg_systimestamp();
       pg_systimestamp
-------------------------------
 2015-10-14 11:21:28.317367+08
(1 row)
```

- systimestamp()

  Description: Gets the date and time of the current system.

  Return type: timestamp with time zone

  Example:

```
gaussdb=# SELECT systimestamp();
        systimestamp
-------------------------------
 2024-04-16 15:55:21.614342+08
(1 row)
-- After the behavior_compat_options parameter is set to sys_function_without_brackets, calling without parentheses is supported.
gaussdb=# SET behavior_compat_options='sys_function_without_brackets';
gaussdb=# SELECT systimestamp;
        systimestamp
-------------------------------
 2024-04-16 15:55:21.614342+08
(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

> **NOTE**
>
> This function takes effect only when **sql_compatibility** is set to **ORA**.

- systimestamp(precision)

  Description: Obtains the date and time of the current system and displays the microsecond part of the result based on the specified precision.

  Parameter: precision (number of decimal places after the second). INT type. Range: [0,6]. The default value is **6**. When the value exceeds 6, a warning message is displayed, the time value is output with precision of 6.

  Return type: timestamp with time zone

  Example:

```
gaussdb=# SELECT systimestamp(6);
        systimestamp
-------------------------------
 2024-04-16 15:55:21.614342+08
(1 row)
gaussdb=# SELECT systimestamp(9);
WARNING:  TIMESTAMP(9) WITH TIME ZONE precision reduced to maximum allowed, 6
CONTEXT:  referenced column: systimestamp
        systimestamp
-------------------------------
 2024-04-16 15:59:49.492505+08
(1 row)
gaussdb=# SELECT systimestamp(5.0);
        systimestamp
-------------------------------
 2024-04-16 16:00:23.48079+08
(1 row)
```

> **NOTE**
>
> This function takes effect only when **sql_compatibility** is set to **ORA**.

- date_part(text, timestamp)

  Description: Retrieves fields such as year or hour from date/time values. It is equivalent to **extract(field from timestamp)**.

  Parameter: **timestamp** of the abstime, date, interval, reltime, time with time zone, time without time zone, timestamp with time zone, timestamp without time zone, datea type (valid only in Oracle-compatible mode).

  Return type: double precision

  Example:

```
gaussdb=# SELECT date_part('hour', timestamp '2001-02-16 20:38:40');
 date_part
-----------
        20
(1 row)
```

- date_part(text, interval)

  Description: Obtains the month. If the value is greater than 12, obtain the remainder after it is divided by 12. It is equivalent to **extract(field from timestamp)**.

  Return type: double precision

  Example:

```
gaussdb=# SELECT date_part('month', interval '2 years 3 months');
 date_part
-----------
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
       3
(1 row)
```

- date_trunc(text, timestamp)

  Description: Truncates to the precision specified by **text**.

  Return type: interval, timestamp with time zone, timestamp without time zone

  Example:

```
gaussdb=# SELECT date_trunc('hour', timestamp  '2001-02-16 20:38:40');
     date_trunc
---------------------
 2001-02-16 20:00:00
(1 row)
```

- trunc(timestamp)

  Description: Truncates to day by default.

  Parameter: **timestamp** can be set to **timestamp with time zone**, **timestamp without time zone**, or **datea** (valid only in Oracle-compatible mode).

  Return type: timestamp without time zone, datea (valid only for ORA compatibility)

  Example:

```
gaussdb=# SELECT trunc(timestamp  '2001-02-16
20:38:40');
                      trunc
---------------------
2001-02-16 00:00:00
(1 row)

gaussdb=# SELECT trunc(timestamp with time zone '2001-02-16 20:38:40');
        trunc
---------------------
 2001-02-16 00:00:00
(1 row)
```

- trunc(arg1, arg2)

  Description: Truncates to the precision specified by **arg2**.

  Parameters:

  – Types of **arg1**: interval, timestamp with time zone, timestamp without time zone, and datea (effective only in ORA-compatible mode).

  – Type of **arg2**: text

  When **arg1** is of the datea type, the units supported by **arg2** are listed in **Table 1-49**.

  When **arg1** is of another supported type, if **sql_compatibility** is set to **'ORA'**, **a_format_version** is set to **10c**, and **a_format_dev_version** is set to **s1**, the units supported by **arg2** are listed in **Table 1-49**. In other cases, the units supported by **arg2** are listed in **Table 1-50**.

Table 1-49 Unit mapping table 1

Unit	Description
cc, scc	Century
syyyy, yyyy, year, syear, yyy, yy, y	Year

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Unit	Description
iyyy, iy, i	The year defined by the ISO 8601 standard, including the calendar week
q	Quarter
month, mon, mm, rm	Month
ww	The date in a given week that corresponds to the same day of the week as the first day of the year
iw	The week that matches the first day of a calendar week defined in the ISO 8601 standard
w	The date in a given week that corresponds to the same day of the week as the first day of the month
ddd, dd, j	Day
day, dy, d	Start date of a week (with Sunday as the first day of the week)
hh, hh12, hh24	Hour
mi	Minute

Table 1-50 Unit mapping table 2

Unit	Description
mil, mils, millennia, millennium	Millennium
c, cc, cent, centuries, century	Century
dec, decade, decades, decs	Decade
y, year, years, yr, yrs, yyyy	Year
q, qtr, quarter	Quarter
mm, mon, mons, month, months	Month
w, week, weeks	Week
j, d, day, days, dd, ddd	Day
h, hh, hour, hours, hr, hrs	Hour
m, mi, min, mins, minute, minutes	Minute
s, sec, second, seconds, secs	Second

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Unit	Description
millisecon, ms, msec, msecond, mseconds, msecs	Millisecond
microsecon, us, usec, usecond, useconds, usecs	Microsecond

Return types: interval, timestamp with time zone, timestamp without time zone, and datea (valid only in Oracle-compatible mode).

Example:

- When **arg1** is of the datea type:

```
-- The first Monday of 2022 is January 3.
gaussdb=# SELECT trunc(to_date('2022-12-30', 'YYYY-MM-
DD'),'iy');
                      trunc
-------------------------
 2022-01-03 00:00:00 AD
(1 row)

-- January 1, 2022 is Saturday. Therefore, the Saturday preceding the following input date is returned:
gaussdb=# SELECT trunc(to_date('2022-12-30', 'YYYY-MM-DD'),'ww');
trunc
-------------------------
 2022-12-24 00:00:00 AD
(1 row)

-- In the week of December 30, 2022, the start date (Monday) of the week is December 26.
gaussdb=# SELECT trunc(to_date('2022-12-30', 'YYYY-MM-DD'),'iw');
trunc
-------------------------
 2022-12-26 00:00:00 AD
(1 row)

-- December 1, 2022 is Thursday. Therefore, the Thursday preceding the following input date is returned:
gaussdb=# SELECT trunc(to_date('2022-12-30', 'YYYY-MM-DD'),'w');
trunc
-------------------------
 2022-12-29 00:00:00 AD
(1 row)

-- In the week of December 30, 2022, the start date (Sunday) of the week is December 25.
gaussdb=# SELECT trunc(to_date('2022-12-30', 'YYYY-MM-DD'),'day');
trunc
-------------------------
 2022-12-25 00:00:00 AD
(1 row)
```

- When **arg1** is of the other supported type:

```
gaussdb=# SELECT trunc(timestamp  '2001-02-16 20:38:40',
'hour');
                      trunc
---------------------
2001-02-16 20:00:00
(1 row)
```

- round(arg1, arg2)

  Description: Rounds off to the precision specified by **arg2**.

  Parameters:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

  - Types of **arg1**: timestamp without time zone, datea (valid only for ORA compatibility)
  - Type of **arg2**: text

  Return type: timestamp without time zone, datea (valid only for ORA compatibility)

  Example:

```
gaussdb=# SELECT round(timestamp  '2001-02-16 20:38:40',
'hour');
                round
---------------------
2001-02-16 21:00:00
(1 row)
-- When the GUC parameter mapping_date_to_datea is enabled in ORA-compatible mode:
gaussdb=# SET nls_date_format = 'YYYY-MM-DD HH24:MI:SS';
gaussdb=# SELECT round(datea '2001-02-16 20:38:40', 'yyyy');
        round
------------------------
 2001-01-01 00:00:00 AD
(1 row)
```

  NOTE

  - This function is valid only when the value of **a_format_version** is **10c** and that of **a_format_dev_version** is **s1** in an ORA-compatible database.
  - When the input parameter **arg1** is of the datea type, units supported by **arg2** are specified in the trunc function. For details, see **Table 1-49**.

- daterange(arg1, arg2)

  Description: Obtains time boundary information.

  Parameters: **arg1** and **arg2** are of the date type.

  Return type: daterange

  Example:

```
gaussdb=# SELECT daterange('2000-05-06','2000-08-08');
       daterange
-------------------------
 [2000-05-06,2000-08-08)
(1 row)
```

  NOTE

  In ORA-compatible mode:

  - After the **mapping_date_to_datea** parameter is enabled, the DATE type is mapped to the DATEA type. The daterange function does not support the DATEA type as an input parameter.
  - After the **mapping_date_to_datea** parameter is disabled, the DATE type is mapped to the TIMESTAMP(0) WITHOUT TIME ZONE type. The daterange function does not support the TIMESTAMP(0) WITHOUT TIME ZONE type as an input parameter.

- daterange(arg1, arg2, text)

  Description: Obtains time boundary information.

  Parameters:

  - **arg1**: start date of the time range. The type is date.
  - **arg2**: end date of the time range. The type is date.
  - **text**: string of boundary symbols. The type is text. The value must be one of the following: **()**, **(]**, **[)**, or **[]**. It is used to specify whether the boundary values are included in the range. **[** indicates that the start date

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

is included, **(** indicates that the start date is not included, **]** indicates that the end date is included, and **)** indicates that the end date is not included.

Return type: daterange

Example:

```
gaussdb=# SELECT daterange('2000-05-06','2000-08-08','[]');
       daterange
-------------------------
 [2000-05-06,2000-08-09)
(1 row)
```

NOTE

In ORA-compatible mode:

- After the **mapping_date_to_datea** parameter is enabled, the DATE type is mapped to the DATEA type. The daterange function does not support the DATEA type as an input parameter.
- After the **mapping_date_to_datea** parameter is disabled, the DATE type is mapped to the TIMESTAMP(0) WITHOUT TIME ZONE type. The daterange function does not support the TIMESTAMP(0) WITHOUT TIME ZONE type as an input parameter.

- isfinite(date)

  Description: Checks whether a date is a finite value. If the date is a finite value, **t** is returned. Otherwise, **f** is returned.

  Return type: Boolean

  Example:

  ```
  gaussdb=# SELECT isfinite(date '2001-02-16');
   isfinite
  ----------
   t
  (1 row)
  gaussdb=# SELECT isfinite(date 'infinity');
   isfinite
  ----------
   f
  (1 row)
  ```

- isfinite(timestamp)

  Description: Checks whether a timestamp is a finite value. If the timestamp is a finite value, **t** is returned. Otherwise, **f** is returned.

  Return type: Boolean

  Example:

  ```
  gaussdb=# SELECT isfinite(timestamp '2001-02-16 21:28:30');
   isfinite
  ----------
   t
  (1 row)
  gaussdb=# SELECT isfinite(timestamp 'infinity');
   isfinite
  ----------
   f
  (1 row)
  ```

- isfinite(interval)

  Description: Checks whether the interval is a finite value. If the interval is a finite value, **t** is returned. Currently, **f** cannot be returned. If **'infinity'** is entered, an error is reported.

  Return type: Boolean

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Example:

```
gaussdb=# SELECT isfinite(interval '4 hours');
 isfinite
----------
 t
(1 row)
```

- justify_days(interval)

  Description: Sets the time interval in months (30 days as a month).

  Return type: interval

  Example:

```
gaussdb=# SELECT justify_days(interval '35 days');
 justify_days
--------------
 1 mon 5 days
(1 row)
```

- justify_hours(interval)

  Description: Sets the time interval in days (24 hours as a day).

  Return type: interval

  Example:

```
gaussdb=# SELECT justify_hours(interval '27 hours');
 justify_hours
---------------
 1 day 03:00:00
(1 row)
```

- justify_interval(interval)

  Description: Adjusts **interval** using **justify_days** and **justify_hours**.

  Return type: interval

  Example:

```
gaussdb=# SELECT justify_interval(interval '1 mon -1 hour');
 justify_interval
------------------
 29 days 23:00:00
(1 row)
```

- localtime()

  Description: Specifies the system time when the current transaction starts. If **sql_compatibility** is set to **'MYSQL'**, **b_format_version** is set to **5.7**, and **b_format_dev_version** is set to **s1**, the system date and time when the current SQL query execution starts is returned.

  Return type: time. If **sql_compatibility** is set to **'MYSQL'**, **b_format_version** is set to **'5.7'**, and **b_format_dev_version** is set to **'s1'**, a timestamp without time zone is returned.

  Example:

```
gaussdb=# SELECT localtime AS RESULT;
     result
----------------
 16:05:55.664681
(1 row)
-- When the parameter is enabled in MySQL-compatible mode:
gaussdb_m=# select localtime;
      localtime
---------------------
 2023-08-21 15:21:57
(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- localtime[([precision])]

  Description: Returns the system date and time when the current SQL statement starts.

  Parameter: **precision** indicates the precision (number of decimal places after the second). The value is of the int type and in the range [0,6]. The default value is **0**. If the value is invalid, an error is reported.

  Return type: timestamp without time zone

  Implementation method: Register the system function localtime.

  Example:

```
gaussdb_m=# SELECT localtime();
     localtime
---------------------
 2023-08-21 15:23:49
(1 row)
gaussdb_m=# SELECT localtime(3);
       localtime
-------------------------
 2023-08-21 15:23:51.965
(1 row)
```

  NOTE

  This function is valid only when **sql_compatibility** is set to **'MYSQL'**, **b_format_version** is set to **'5.7'**, and **b_format_dev_version** is set to **'s1'**.

- localtimestamp

  Description: Specifies the current date and time.

  Return type: timestamp

  Example:

```
gaussdb=# SELECT localtimestamp;
        timestamp
----------------------------
 2017-09-01 17:03:30.781902
(1 row)
-- When the parameter is enabled in MySQL-compatible mode:
gaussdb_m=# SELECT localtimestamp;
     timestamp
---------------------
 2023-08-21 15:27:55
(1 row)
-- When the GUC parameter a_format_date_timestamp is enabled in ORA-compatible mode:
gaussdb=# SET a_format_date_timestamp=on;
SET
gaussdb=# SELECT localtimestamp;
      localtimestamp
----------------------------
 2023-11-24 11:38:25.633231
(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- This function has the following behaviors when **sql_compatibility** is set to **'MYSQL'**, **b_format_version** is set to **5.7**, and **b_format_dev_version** is set to **s1**:
  - It returns the system date and time that indicates when the current SQL statement starts.
  - The return type is timestamp without time zone, and the column name is **timestamp**.
- This function has the following behaviors when **sql_compatibility** is set to **'ORA'** and the GUC parameter **a_format_date_timestamp** is set to **on**:
  - The return value type is timestamp without time zone, and the column name is **localtimestamp**.
  - The timestamp of the system time is returned when the current SQL statement starts to be executed.
  - This prevents the optimizer from obtaining the constant time in advance. As a result, the obtained time is incorrect in the gplan scenario.
- If **sql_compatibility** is set to **'ORA'** and the GUC parameter **a_format_date_timestamp** is set to **off**, this function returns the system date and time when the transaction starts.

- localtimestamp[([precision])]

  Description: Specifies the current date and time.

  Parameter: **precision** (number of decimal places after the second). The precision is of the int type, within the range of [0,6] and with a default value of **0**. Setting a value greater than 6 will trigger an alarm and return a time value with the precision of 6. Using any other invalid precision will trigger an error.

  Return type: timestamp without time zone

  Example:

```
-- Calls with parentheses and without input parameters are supported only in MySQL-compatible mode.
gaussdb_m=# SELECT localtimestamp();
     timestamp
---------------------
 2023-08-21 15:27:59
(1 row)
gaussdb_m=# SELECT localtimestamp(3);
       timestamp
-------------------------
 2023-08-21 15:28:02.445
(1 row)
-- When the GUC parameter a_format_date_timestamp is enabled in ORA-compatible mode:
gaussdb=# SET a_format_date_timestamp=on;
SET
gaussdb=# SELECT localtimestamp(6);
      localtimestamp
----------------------------
 2023-11-24 11:41:14.086227
(1 row)
-- If a_format_version is set to 10c and a_format_dev_version is set to s2 in an ORA-compatible database, precision can be an integer of the numeric type.
gaussdb=# SET a_format_version='10c';
SET
gaussdb=# SET a_format_dev_version='s2';
SET
gaussdb=# SELECT localtimestamp(6.0);
      localtimestamp
----------------------------
 2023-11-24 11:42:45.642167
(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- Zeros at the end of microseconds are not displayed. For example, 2017-09-01 10:32:19.212000 is displayed as 2017-09-01 10:32:19.212.
- When **sql_compatibility** is **'MYSQL'**, **b_format_version** is **5.7**, and **b_format_dev_version** is **s1**, this function returns the system date and time that indicates when the current SQL statement starts. It can be called with parentheses and without input parameters.
- This function has the following behaviors when **sql_compatibility** is set to **'ORA'** and the GUC parameter **a_format_date_timestamp** is set to **on**:
  - It returns a timestamp that shows the system time when the current SQL statement starts.
  - The return value type is timestamp without time zone, and the column name is **localtimestamp**.
  - When **a_format_version** is set to **10c** and **a_format_dev_version** is set to **s2**, the **precision** parameter can be an integer of the numeric type. Otherwise, only the int type is supported.
- If **sql_compatibility** is set to **'ORA'** and the GUC parameter **a_format_date_timestamp** is set to **off**, this function returns the system date and time when the transaction starts.

- maketime(hour, minute, second)

  Description: Generates the time (of the time type) based on the input parameters hour, minute, and second. The three input parameters are of the bigint, bigint, and numeric types, respectively.

  Return type: time

  Example:

```
gaussdb=# SELECT maketime(8, 15, 26.53);
  maketime
-------------
 08:15:26.53
(1 row)

gaussdb=# SELECT maketime(-888, 15, 26.53);
  maketime
------------
 -838:59:59
(1 row)
```

  NOTE

  This function can be used only when **sql_compatibility** is set to **'MYSQL'** and the GUC parameters **b_format_version** and **b_format_dev_version** are set to **'5.7'** and **'s1'**, respectively. In addition, this function has the following behavior:

  - The function returns **NULL** if any of the following conditions is met:
    - The input parameter **minute** is less than 0 or greater than or equal to 60.
    - The input parameter **second** is less than 0 or greater than or equal to 60.
    - The value of any parameter is **NULL**.
  - The returned result of the time type contains six decimal places. If the value of **second** contains more than six decimal places, the value is rounded off.
  - The returned value of the time type is in the range [–838:59:59,838:59:59]. If the value is out of the range, the specified boundary value is returned based on the positive and negative values of **hour**.
  - **maketime** does not support self-nesting.

- now()

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description: Returns the system date and time when the current transaction starts. The results returned in the same transaction are the same. Only when **sql_compatibility** is set to **'MYSQL'**, **b_format_version** is set to **5.7**, and **b_format_dev_version** is set to **s1**, the system date and time when the current SQL query execution starts is returned.

Return type: timestamp with time zone. If **sql_compatibility** is set to **'MYSQL'**, **b_format_version** is set to **5.7**, and **b_format_dev_version** is set to **s1**, a timestamp without time zone is returned.

Example:

```
gaussdb=# SELECT now();
              now
-------------------------------
 2017-09-01 17:03:42.549426+08
(1 row)
-- When the compatibility parameter is enabled and set to 'MYSQL':
gaussdb_m=# SELECT now();
      timestamp
---------------------
 2023-08-21 17:17:42
(1 row)
```

- now(precision)

  Description: Returns the system date and time when the current SQL statement starts.

  Parameter: **precision** (number of decimal places after the second). The precision is of the int type, within the range of [0,6] and with a default value of **0**. Setting a value greater than 6 will trigger an alarm and return a time value with the precision of 6. Using any other invalid precision will trigger an error.

  Return type: timestamp without time zone

  Implementation method: Register the system function now_b.

  Example:

  ```
  gaussdb_m=# SELECT now(3);
        timestamp
  -------------------------
   2023-08-21 17:17:48.819
  (1 row)
  ```

  NOTE

  This function is valid only when **sql_compatibility** is set to **'MYSQL'**, **b_format_version** is set to **'5.7'**, and **b_format_dev_version** is set to **'s1'**.

- now_b(precision)

  Description: Returns the system date and time that indicates when the current SQL statement starts. It is equivalent to the now function but is intended for internal implementation only. It is recommended not to use this function.

  Parameter: **precision** (number of decimal places after the second). The precision is of the int type, within the range of [0,6]. Setting a value greater than 6 will trigger an alarm and return a time value with a precision of 6.

  NOTE

  This function is valid only when **sql_compatibility** is set to **'MYSQL'**, **b_format_version** is set to **'5.7'**, and **b_format_dev_version** is set to **'s1'**.

- timenow()

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description: Returns the system date and time when the current SQL statement starts.

Return type: abstime

Example:

```
gaussdb=# SELECT timenow();
       timenow
------------------------
 2020-06-23 20:36:56+08
(1 row)
```

- dbtimezone

  Description: Time zone of the current database.

  Return type: text

  Example:

  ```
  gaussdb=# SELECT dbtimezone;
         dbtimezone
  ------------------------
   PRC
  (1 row)
  ```

  NOTE

  This function is valid only when the value of **a_format_version** is **10c** and that of **a_format_dev_version** is **s2** in an ORA-compatible database.

- numtodsinterval(num, interval_unit)

  Description: Converts a number to the interval type. **num** is a numeric-typed number. **interval_unit** is a string in the following format: 'DAY' | 'HOUR' | 'MINUTE' | 'SECOND'

  You can set the GUC parameter **intervalstyle** to **oracle** to maintain compatibility with the output format interval.

  Return type: interval

  Example:

  ```
  gaussdb=# SELECT numtodsinterval(100, 'HOUR');
   numtodsinterval
  -----------------
   100:00:00
  (1 row)

  gaussdb=# SET intervalstyle = oracle;
  SET
  gaussdb=# SELECT numtodsinterval(100, 'HOUR');
         numtodsinterval
  -------------------------------
   +000000004 04:00:00.000000000
  (1 row)
  ```

  NOTE

  When **a_format_version** is set to **10c** and **a_format_dev_version** is set to **s2** in an ORA-compatible database, an error is reported if **interval_unit** is set to **'DAY'** and **num** is set to a value greater than **1000000000**.

- numtoyminterval(num, interval_unit)

  Description: Converts a number to the interval type. **num** is a number of the numeric type, and **interval_unit** is a string of the fixed format ('YEAR'|'MONTH').

  You can set the GUC parameter **intervalstyle** to **oracle** to maintain compatibility with the output format interval.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Return type: interval

Example:

```
gaussdb=# \c gaussdb_o;
Non-SSL connection (SSL connection is recommended when requiring high-security)
You are now connected to database "gaussdb_o" as user "omm".
gaussdb_o=# SET a_format_version='10c';
SET
gaussdb_o=# SET a_format_dev_version='s2';
SET
gaussdb=# SELECT numtoyminterval(100, 'MONTH');
 numtoyminterval
-----------------
 8 years 4 mons
(1 row)
gaussdb_o=# SET intervalstyle = oracle;
SET
gaussdb_o=# SELECT numtoyminterval(100, 'MONTH');
 numtoyminterval
-----------------
 8-4
(1 row)

gaussdb_o=# \c postgres
Non-SSL connection (SSL connection is recommended when requiring high-security)
You are now connected to database "postgres" as user "omm".
gaussdb=# DROP DATABASE gaussdb_o;
DROP DATABASE
```

NOTE

This function is valid only when the value of **a_format_version** is **10c** and that of **a_format_dev_version** is **s2** in an ORA-compatible database.

- new_time(date, timezone1,timezone2)

  Description: Returns the date and time of the time zone specified by **timezone2** when the date and time of the time zone specified by **timezone1** are date.

  Return type: timestamp, datea (valid only for ORA compatibility)

  Example:

```
gaussdb=# SELECT new_time('1997-10-10','AST','EST');
      new_time
---------------------
 1997-10-09 23:00:00
(1 row)
gaussdb=# SELECT new_time(to_timestamp ('10-sep-02 14:10:10.123000','dd-mon-rr hh24:mi:ss.ff'),
'ast', 'pst');
        new_time
-------------------------
 2002-09-10 10:10:10.123
(1 row)
-- When the GUC parameter mapping_date_to_datea is enabled in ORA-compatible mode:
gaussdb=# SET nls_date_format = 'YYYY-MM-DD HH24:MI:SS';
gaussdb=# SELECT new_time(datea '2001-02-16 20:38:40', 'AST', 'EST');
        new_time
------------------------
 2001-02-16 19:38:40 AD
(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- When **sql_compatibility** is set to **'ORA'** and the GUC parameter **mapping_date_to_datea** is set to **on**, the database parses the date type in the input parameter to the datea type. In this case, the return value is of the datea type.
- In an Oracle-compatible database, if **a_format_version** is set to **10c**, **a_format_dev_version** is set to **s2**, and the GUC parameter **mapping_date_to_datea** is set to **off**, the database parses the date type in the input parameter to the TIMESTAMP(0) WITHOUT TIME ZONE type. In this case, the return value is of the timestamp type.

- sessiontimezone()

  Description: Returns the time zone of the current session. There is no input parameter.

  Return type: text

  Example:

```
gaussdb=# SELECT sessiontimezone;
 session_time_zone
--------------------
 PST8PDT
(1 row)
gaussdb=# SELECT lower(sessiontimezone);
   lower
-----------
 @ 8 hours
(1 row)
```

  NOTE

  - This function is valid only when the value of **a_format_version** is **10c** and that of **a_format_dev_version** is **s2** in an ORA-compatible database.
  - When **session time zone** is set to **GMT+08:00** or **GMT-08:00**, positive offsets indicate areas west of Greenwich. For example, **GMT+08:00** corresponds to the GMT-8 area, while **GMT-08:00** corresponds to GMT+8.

- sys_extract_utc(timestamp| timestamptz)

  Description: Extracts Coordinated Universal Time (UTC, also formerly known as Greenwich Mean Time) from a date-time value with a time zone offset or time zone region name. If no time zone is specified, the date and time are associated with the session time zone. The input parameter can be in timestamp or timestamptz format.

  Return type: timestamp

  Example:

```
gaussdb=# SELECT sys_extract_utc(timestamp '2000-03-28 11:30:00.00');
   sys_extract_utc
---------------------
 2000-03-28 03:30:00
(1 row)
gaussdb=# SELECT sys_extract_utc(timestamptz '2000-03-28 11:30:00.00 -08:00');
   sys_extract_utc
---------------------
 2000-03-28 19:30:00
(1 row)
```

  NOTE

  This function is valid only when the value of **a_format_version** is **10c** and that of **a_format_dev_version** is **s2** in an ORA-compatible database.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- tz_offset('time_zone_name' | '(+/-)hh:mi' | SESSIONTIMEZONE | DBTIMEZONE)

  Description: Returns the UTC offset of the time zone indicated by the input parameter. The input parameter has the preceding four formats.

  Return type: text

  Example:

```
gaussdb=# SELECT tz_offset('us/pacific');
 tz_offset
-----------
 -08:00
(1 row)
gaussdb=# SELECT tz_offset(sessiontimezone);
 tz_offset
-----------
 +08:00
(1 row)
```

  NOTE

  This function is valid only when the value of **a_format_version** is **10c** and the value of **a_format_dev_version** is **s2** in an ORA-compatible database.

- pg_sleep(seconds)

  Description: Specifies the delay time of the server thread in unit of second. When the database calls this function, it obtains a transaction snapshot that is equivalent to a long transaction. If the time specified in the input parameter is excessively long, **oldestxmin** may not execute successfully, impacting the database's table recycling and query performance.

  Return type: void

  Example:

```
gaussdb=# SELECT pg_sleep(10);
 pg_sleep
----------

(1 row)
```

- statement_timestamp()

  Description: Returns the current date and time (start of the current statement).

  Return type: timestamp with time zone

  Example:

```
gaussdb=# SELECT statement_timestamp();
      statement_timestamp
-------------------------------
 2017-09-01 17:04:39.119267+08
(1 row)
```

- sysdate

  Description: Returns the system date and time when the current SQL statement starts.

  Return type: timestamp, datea (valid only for ORA compatibility)

  Example:

```
gaussdb=# SELECT sysdate;
       sysdate
---------------------
 2017-09-01 17:04:49
(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
-- Result returned when fixed_date is enabled.
gaussdb=# SET fixed_date='2024-05-15 11:47:02';
SET
gaussdb=# SELECT sysdate;
      timestamp
---------------------
 2024-05-15 11:47:02
(1 row)
-- Negative time settings are not supported. To indicate BC time, append BC to the end of the time.
gaussdb=# SET fixed_date = '2012-01-01 00:00:00 BC';
SET
gaussdb=# SELECT sysdate;
      timestamp
------------------------
 2012-01-01 00:00:00 BC
(1 row)
-- In ORA-compatible mode, if the GUC parameter mapping_date_to_datea is enabled, the return type is datea.
gaussdb=# SELECT sysdate;
      sysdate_a
------------------------
 2025-05-21 11:37:26 AD
(1 row)
```

NOTE

When **sql_compatibility** is set to **'ORA'** and the GUC parameter **mapping_date_to_datea** is set to **on**, this function is mapped to the sysdate_a function and the return value is changed to the datea type.

- sysdate([precision])

  Description: Returns the system date and time when a function is executed.

  Parameter: Indicates the time precision. The value is of the int type and in the range [0,6]. The default value is **0**.

  Return type: timestamp without time zone

  Example:

```
gaussdb_m=# SELECT sysdate();
     sysdate()
---------------------
 2023-08-21 17:17:42
(1 row)
gaussdb_m=# SELECT sysdate(3);
       sysdate(3)
-------------------------
 2023-08-21 17:17:48.819
(1 row)
```

NOTE

This function is valid only when **sql_compatibility** is set to **'MYSQL'**, **b_format_version** is set to **'5.7'**, and **b_format_dev_version** is set to **'s1'**.

- current_sysdate()

  Description: Returns the system date and time when the current SQL statement starts.

  Return type: timestamp

  Example:

```
gaussdb=# SELECT current_sysdate();
  current_sysdate
---------------------
 2023-06-20 20:09:02
(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- timeofday()

  Description: Returns the timestamp (such as **clock_timestamp**, but the return type is text) of the system time when the current function is called.

  Return type: text

  Example:

```
gaussdb=# SELECT timeofday();
              timeofday
-------------------------------------
 Fri Sep 01 17:05:01.167506 2017 CST
(1 row)
```

- transaction_timestamp()

  Description: Specifies the system date and time when the current transaction starts.

  Return type: timestamp with time zone. If **sql_compatibility** is set to **'MYSQL'**, **b_format_version** is set to **'5.7'**, and **b_format_dev_version** is set to **'s1'**, a timestamp without time zone is returned.

  Example:

```
gaussdb=# SELECT transaction_timestamp();
     transaction_timestamp
-------------------------------
 2017-09-01 17:05:13.534454+08
(1 row)
-- In MySQL-compatible mode:
gaussdb=#  SELECT transaction_timestamp();
   transaction_timestamp
----------------------------
 2023-09-07 09:32:09.728998
(1 row)
```

- add_months(d,n)

  Description: Returns the time point *d* plus *n* months.

  Parameters:

  – **d**: indicates a value of the timestamp type or a value that can be implicitly converted into the timestamp type.

  – **n**: indicates the value of the INTEGER type and the value that can be implicitly converted to the INTEGER type.

  Return type: timestamp, datea (valid only for ORA compatibility)

  Example:

```
gaussdb=# SELECT add_months(to_date('2017-5-29', 'yyyy-mm-dd'), 11) FROM sys_dummy;
     add_months
---------------------
 2018-04-29 00:00:00
(1 row)
-- When the GUC parameter mapping_date_to_datea is enabled in ORA-compatible mode:
gaussdb=# SET nls_date_format = 'YYYY-MM-DD HH24:MI:SS';
gaussdb=# SELECT add_months(datea '2020-11-12 11:12:13', 3);
       add_months
-------------------------
 2021-02-12 11:12:13 AD
(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- When **sql_compatibility** is set to **'ORA'** and the GUC parameter **mapping_date_to_datea** is set to **on**, the database parses the date type in the input parameter to the datea type. In this case, the return value is of the datea type.
- In this function, if the GUC parameter **mapping_date_to_datea** is set to **off**, the database parses the date type in the input parameter to the TIMESTAMP(0) WITHOUT TIME ZONE type. In this case, the return value is of the timestamp type. When the input parameter type of this function is parsed to TIMESTAMP(0) WITHOUT TIME ZONE, the function has the following behaviors in the Oracle-compatible database where the values of **a_format_version** and **a_format_dev_version** are **10c** and **s1**, respectively:
  - If the returned result is later than 9999, an error is reported.
  - When the input parameter **n** is a decimal, the function does not perform rounding off on the decimal places but truncates them directly.
- When **sql_compatibility** is set to **'ORA'**, if the parameter is of the datea type (for example, in the **add_months(to_datea('2025-2-28', 'yyyy-mm-dd'),1)** scenario), and the value of **behavior_compat_options** contains **end_month_calculate** (that is, **SET behavior_compat_options = 'end_month_calculate'**), the return result is **'2025-03-31 00:00:00 AD'**. Otherwise, the return result is **'2025-03-28 00:00:00 AD'**.

- last_day(d)

  Description: Returns the date of the last day of the month that contains *d*.

  Return type: timestamp, datea (valid only for ORA compatibility)

  Example:

```
gaussdb=# SELECT last_day(to_date('2017-01-01', 'yyyy-mm-dd')) AS cal_result;
    cal_result
---------------------
 2017-01-31 00:00:00
(1 row)
-- When the GUC parameter mapping_date_to_datea is enabled in ORA-compatible mode:
gaussdb=# SET nls_date_format = 'YYYY-MM-DD HH24:MI:SS';
gaussdb=# SELECT last_day(datea '2020-11-12 11:12:13');
       last_day
------------------------
 2020-11-30 11:12:13 AD
(1 row)
```

  NOTE

  - When **sql_compatibility** is set to **'ORA'** and the GUC parameter **mapping_date_to_datea** is set to **on**, the database parses the date type in the input parameter to the datea type. In this case, the return value is of the datea type.
  - When **sql_compatibility** is set to **'MYSQL'**, **b_format_version** is set to **'5.7'**, and **b_format_dev_version** is set to **'s1'**, the last_day function calls the built-in function b_db_last_day. The input parameter type can be TEXT, DATE, DATETIME, or TIME. The return value is of the date type and can be a number in the datetime format.

- months_between(d1, d2)

  Description: Calculates the month difference between time points **d1** and **d2**. If both dates are the end of a month or are the same day, an integer is returned. Otherwise, the return value is a decimal and is calculated as 31 days per month.

  Return type: numeric

  Example:

```
gaussdb=# SELECT months_between(to_date('2022-10-31', 'yyyy-mm-dd'), to_date('2022-09-30',
'yyyy-mm-dd'));
 months_between
----------------
              1
(1 row)

gaussdb=# SELECT months_between(to_date('2022-10-30', 'yyyy-mm-dd'), to_date('2022-09-30',
'yyyy-mm-dd'));
 months_between
----------------
              1
(1 row)

gaussdb=# SELECT months_between(to_date('2022-10-29', 'yyyy-mm-dd'), to_date('2022-09-30',
'yyyy-mm-dd'));
    months_between
-----------------------
 .96774193548387096774
(1 row)
-- In ORA-compatible mode, if the GUC parameter mapping_date_to_datea is enabled, the date type
is mapped to the datea type.
gaussdb=# SET nls_date_format = 'YYYY-MM-DD HH24:MI:SS';
gaussdb=# SELECT months_between('2020-11-12 11:12:13'::date, '2020-11-13 11:12:13'::date);
     months_between
------------------------
 -.03225806451612903226
(1 row)
```

NOTE

- This function is valid only when the value of **a_format_version** is **10c** and that of **a_format_dev_version** is **s1** in an ORA-compatible database.
- When **sql_compatibility** is set to **'ORA'** and the GUC parameter **mapping_date_to_datea** is set to **on**, the database parses the date type in the input parameter to the datea type.

- next_day(x,y)

  Description: Calculates the time of the next week y started from x.

  Return type: timestamp, datea (valid only for ORA compatibility)

  Example:

```
gaussdb=# SELECT next_day(timestamp '2017-05-25 00:00:00','Sunday')AS cal_result;
     cal_result
---------------------
 2017-05-28 00:00:00
(1 row)
gaussdb=# SELECT next_day(timestamp '2024-01-17 00:00:00', 7.9999999);
ERROR:  Week day out of range, the range is 1 ... 7
CONTEXT:  referenced column: next_day
gaussdb=# SET a_format_version='10c';
SET
gaussdb=# SET a_format_dev_version='s1';
SET
gaussdb=# SELECT next_day(timestamp '2024-01-17 00:00:00', 7.9999999);
      next_day
---------------------
 2024-01-20 00:00:00
(1 row)
-- When the GUC parameter mapping_date_to_datea is enabled in ORA-compatible mode:
gaussdb=# SET nls_date_format = 'YYYY-MM-DD HH24:MI:SS';
gaussdb=# SELECT next_day(datea '2020-11-12 11:12:13', 'Monday');
       next_day
------------------------
 2020-11-16 11:12:13 AD
(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- If **a_format_version** is set to **10c**, **a_format_dev_version** is set to **s1**, and the second parameter is a floating-point number, this function discards the decimal part in the ORA-compatible database. Otherwise, this function rounds off the decimal part.
- In an ORA-compatible database, the first parameter can be of the TIMESTAMP WITH TIME ZONE type only when **a_format_version** is set to **10c** and **a_format_dev_version** is set to **s1**.
- When **sql_compatibility** is set to **'ORA'** and the GUC parameter **mapping_date_to_datea** is set to **on**, the database parses the date type in the input parameter to the datea type.
- The second parameter of **next_day** supports abbreviations (case-insensitive), including **SUN**, **MON**, **TUE**, **WED**, **THU**, **THUR**, **FRI**, and **SAT**.

- tinterval(abstime, abstime)

  Description: Creates a time interval with two specific time points.

  Return type: tinterval

  Example:

```
gaussdb=# CALL tinterval(abstime 'May 10, 1947 23:59:12', abstime 'Mon May  1 00:30:30 1995');
                    tinterval
----------------------------------------------------
 ["1947-05-10 23:59:12+08" "1995-05-01 00:30:30+08"]
(1 row)
```

- tintervalend(tinterval)

  Description: Returns the end time of tinterval.

  Return type: abstime

  Example:

```
gaussdb=# SELECT tintervalend('["Sep 4, 1983 23:59:12" "Oct4, 1983 23:59:12"]');
      tintervalend
-------------------------
 1983-10-04 23:59:12+08
(1 row)
```

- tintervalrel(tinterval)

  Description: Calculates and returns the relative time of **tinterval**.

  Return type: reltime

  Example:

```
gaussdb=# SELECT tintervalrel('["Sep 4, 1983 23:59:12" "Oct4, 1983 23:59:12"]');
 tintervalrel
--------------
 1 mon
(1 row)
```

- smalldatetime_ge(smalldatetime, smalldatetime)

  Description: Checks whether the value of the first parameter is greater than or equal to that of the second parameter.

  Return type: Boolean

- smalldatetime_cmp(smalldatetime, smalldatetime)

  Description: Compares two smalldatetime values to check whether they are the same.

  Return type: integer

- smalldatetime_eq(smalldatetime, smalldatetime)

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description: Compares two smalldatetime values to check whether they are the same.

Return type: Boolean

- smalldatetime_gt(smalldatetime, smalldatetime)

  Description: Determines whether the first parameter is greater than the second parameter.

  Return type: Boolean

- smalldatetime_hash(smalldatetime)

  Description: Calculates the hash value corresponding to the smalldatetime value.

  Return type: integer

- smalldatetime_in(cstring, oid, integer)

  Description: Converts the input into a smalldatetime value.

  Return type: smalldatetime

- smalldatetime_larger(smalldatetime, smalldatetime)

  Description: Returns a larger smalldatetime value.

  Return type: smalldatetime

- smalldatetime_le(smalldatetime, smalldatetime)

  Description: Checks whether the value of the first parameter is less than or equal to that of the second parameter.

  Return type: Boolean

- smalldatetime_lt(smalldatetime, smalldatetime)

  Description: Determines whether the first parameter is less than the second parameter.

  Return type: Boolean

- smalldatetime_ne(smalldatetime, smalldatetime)

  Description: Compares two smalldatetime values to check whether they are different.

  Return type: Boolean

- smalldatetime_out(smalldatetime)

  Description: Converts a smalldatetime value to an external string.

  Return type: cstring

- smalldatetime_send(smalldatetime)

  Description: Converts a smalldatetime value to the binary format.

  Return type: bytea

- smalldatetime_smaller(smalldatetime, smalldatetime)

  Description: Returns a smaller smalldatetime.

  Return type: smalldatetime

- smalldatetime_to_abstime(smalldatetime)

  Description: Converts smalldatetime to abstime.

  Return type: abstime

- smalldatetime_to_time(smalldatetime)

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description: Converts smalldatetime to time.
Return type: time without time zone

- smalldatetime_to_timestamp(smalldatetime)
  Description: Converts smalldatetime to timestamp.
  Return type: timestamp without time zone
- smalldatetime_to_timestamptz(smalldatetime)
  Description: Converts smalldatetime to timestamptz.
  Return type: timestamp with time zone
- smalldatetime_to_varchar2(smalldatetime)
  Description: Converts smalldatetime to varchar2.
  Return type: character varying.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

There are multiple methods for obtaining the current time. Select an appropriate API based on the actual service scenario.

- The following APIs return values based on the start time of the current transaction:

```
CURRENT_DATE CURRENT_TIME
CURRENT_TIME(precision)
CURRENT_TIMESTAMP(precision)
LOCALTIME
LOCALTIMESTAMP
LOCALTIME(precision)
LOCALTIMESTAMP(precision)
transaction_timestamp()
now()
```

  The values passed by **CURRENT_TIME** and **CURRENT_TIMESTAMP(precision)** contain time zone information. The values passed by **LOCALTIME** and **LOCALTIMESTAMP** do not contain time zone information. CURRENT_TIME, LOCALTIME, and LOCALTIMESTAMP can specify a precision parameter, which rounds the seconds field of the result to the decimal place. If there is no precision parameter, the result is given the full precision that can be obtained.

  These functions maintain consistent values throughout the transaction by returning results based on the start time of the current transaction. This ensures that the transaction can maintain consistency at the "current" moment and that multiple modifications within the same transaction retain the same timestamp. **transaction_timestamp()** is equivalent to **CURRENT_TIMESTAMP(precision)**, indicating the start time of the transaction where the current statement is located. **now()** is equivalent to **transaction_timestamp()**.

  When a transaction starts, **sql_compatibility** is set to **'ORA'**, and **a_format_date_timestamp** is set to **on**, the results returned by the CURRENT_DATE, CURRENT_TIMESTAMP(precision), LOCALTIMESTAMP and LOCALTIMESTAMP (precision) functions are the timestamp when the current SQL statement starts to be executed. If the GUC parameter **a_format_date_timestamp** is disabled, the returned result is the transaction start date or date and time.

  When **sql_compatibility** is set to **'MYSQL'**, **b_format_version** is set to **'5.7'**, and **b_format_dev_version** is set to **'s1'**, CURDATE, CURRENT_DATE, CURTIME, CURRENT_TIME, CURRENT_TIMESTAMP, NOW, LOCALTIME, LOCALTIMESTAMP, UTC_TIME and UTC_TIMESTAMP all return the start time of SQL statement execution, and SYSDATE returns the start time of function calling. transaction_timestamp() still indicates the transaction start time. The return value type is changed to timestamp without time zone.

- The following APIs return the start time of the current statement:

```
statement_timestamp()
```

  statement_timestamp() returns the start time of the current statement (more accurately, the time when the last instruction is received from the client). The return values of **statement_timestamp()** and **transaction_timestamp()** are the same during the execution of the first instruction of a transaction, but may be different in subsequent instructions.

- The following APIs return the actual current time when the function is called:

```
clock_timestamp()
timeofday()
```

  clock_timestamp() returns the actual current time, and its value changes even in the same SQL statement. Similar to **clock_timestamp()**, **timeofday()** also returns the actual current time. However, the result of **timeofday()** is a formatted text string instead of a timestamp with time zone information.

- convert_tz(dt, from_tz, to_tz)

  Description: Converts the date and time value **dt** from the **from_tz** time zone to the **to_tz** time zone.

  Parameters: See **Table 1-51**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 1-51 convert_tz parameters

Parameter	Type	Description	Value Range
dt	datetime, date, text, and numeric	Time and date value.	[0000-01-01 00:00:00.000000,9999-12-31 23:59:59.999999].
from_tz	text	Source time zone, indicating the time zone to which **dt** belongs.	• The offset format is [–15:59, 5:00], for example, '+08:00'. It indicates the offset from the UTC time. • Named time zone, such as MET and UTC. It indicates the time zone name. For details, see the **PG_TIMEZONE_NAMES** system view.
to_tz	text	Target time zone, indicating the time zone after conversion.	

Return type: datetime

Example:

```
gaussdb=# SET b_format_dev_version = 's1';
SET
gaussdb=# SET b_format_version = '5.7';
SET
gaussdb=# SELECT convert_tz(cast('2023-01-01 10:10:10' as datetime), '+00:00', '+01:00');
    convert_tz
---------------------
 2023-01-01 11:10:10
(1 row)
gaussdb=# SELECT convert_tz(cast('2023-01-01' as date), '+00:00', '+01:00');
    convert_tz
---------------------
 2023-01-01 01:00:00
(1 row)
gaussdb=# SELECT convert_tz('2023-01-01 10:10:10', '+00:00', '+01:00');
    convert_tz
---------------------
 2023-01-01 11:10:10
(1 row)
gaussdb=# SELECT convert_tz('2023-01-01', '+00:00', '+01:00');
    convert_tz
---------------------
 2023-01-01 01:00:00
(1 row)
gaussdb=# SELECT convert_tz(20230101101010, '+00:00', '+01:00');
    convert_tz
---------------------
 2023-01-01 11:10:10
(1 row)
gaussdb=# SELECT convert_tz(20230101, '+00:00', '+01:00');
    convert_tz
---------------------
 2023-01-01 01:00:00
(1 row)
gaussdb=# SELECT convert_tz('2023-01-01 10:10:10', 'UTC', 'PRC');
    convert_tz
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
---------------------
 2023-01-01 18:10:10
(1 row)
```

NOTE

This function is valid only when **sql_compatibility** is set to **'MYSQL'**, **b_format_version** is set to **'5.7'**, and **b_format_dev_version** is set to **'s1'**.

- sec_to_time(seconds)

  Description: Converts the number of seconds into a time of the time type.

  Parameters: See **Table 1-52**.

  Table 1-52 sec_to_time parameters

Parameter	Type	Description	Value Range
seconds	numeric and text	Number of seconds	[–3020399,+3020399], corresponding to the range of the time type [–838:59:59,838:59:59]. An out-of-bounds input will be truncated to the corresponding boundary value.

  Return type: time without time zone

  Example:

```
gaussdb=# SET b_format_dev_version = 's1';
SET
gaussdb=# SET b_format_version = '5.7';
SET
gaussdb=# SELECT sec_to_time(2000);
 sec_to_time
-------------
 00:33:20
(1 row)
gaussdb=# SELECT sec_to_time('-2000');
 sec_to_time
-------------
 -00:33:20
(1 row)
```

  NOTE

  This function is valid only when **sql_compatibility** is set to **'MYSQL'**, **b_format_version** is set to **'5.7'**, and **b_format_dev_version** is set to **'s1'**.

- adddate(date, INTERVAL val unit)

  Description: Returns a new date by adding a certain interval to a date.

  Parameters: See **Table 1-53**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 1-53 adddate(date, INTERVAL val unit) parameters

Parameter	Type	Description	Value Range
date	Expression of the time type, text, datetime, date, or time	Date to be added with an interval.	See the value ranges of the corresponding types.
val	Integer, floating-point number, or character string	Interval to be added.	See the value ranges of the corresponding types.
unit	Keyword	Unit of the interval.	**YEAR**, **QUARTER**, **MONTH**, **WEEK**, **DAY**, **HOUR**, **MINUTE**, **SECOND**, and **MICROSECOND**. For details, see **Time Interval Expressions**.

Return type: TEXT, DATE, DATETIME, or TIME WITHOUT TIMEZONE

Example:

```
gaussdb=# SELECT adddate('2018-05-01', INTERVAL 1 DAY);
  adddate
------------
 2018-05-02
(1 row)
```

NOTE

- This function is valid only when **sql_compatibility** is set to **'MYSQL'**, **b_format_version** is set to **'5.7'**, and **b_format_dev_version** is set to **'s1'**.
- When working with the PREPARE statement, note that the second parameter of the adddate function is an interval expression. If this parameter is replaced by **$1**, you will encounter unexpected results. For example, running **PREPARE p1 AS SELECT adddate('2023-01-01 10:00:00', $1); EXECUTE p1(interval 13 hour);** will yield the unexpected result of **'2023-01-01 10:00:00'**.

- adddate(expr, days)

  Description: Returns a new date by adding a certain number of days to a date.

  Parameters:

  – **expr**: specifies the start date and time. The value type can be expression of the time type, TEXT, DATE, DATETIME, or TIME.

  – **days**: specifies the number of days to be added. The value is of the int type.

  Return type: TEXT, DATE, DATETIME, or TIME WITHOUT TIMEZONE

  Example:

```
gaussdb=# SELECT ADDDATE('2018-05-01', 1);
  adddate
------------
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
 2018-05-02
(1 row)
```

NOTE

This function is valid only when **sql_compatibility** is set to **'MYSQL'**, **b_format_version** is set to **'5.7'**, and **b_format_dev_version** is set to **'s1'**.

- curdate()

  Description: Returns the system date when the local function calling starts. The time zone can be changed within the same connection. The returned date is affected by the time zone.

  Return type: date

  Example:

```
gaussdb=# SELECT curdate();
  curdate
------------
 2023-08-10
(1 row)
```

NOTE

This function is valid only when **sql_compatibility** is set to **'MYSQL'**, **b_format_version** is set to **'5.7'**, and **b_format_dev_version** is set to **'s1'**.

- curtime([precision])

  Description: Returns the system time when the SQL query call starts.

  Parameter: **precision** (number of decimal places after the second). The precision is of the int type, within the range of [0,6] and with a default value of **0**. If the provided value can be converted into an integer within this range, the function will return a time value with the specified precision. Otherwise, the function will report an error.

  Return type: time without time zone

  Implementation method: Register the system function curtime.

  Example:

```
gaussdb=# SELECT curtime(3);
    curtime
--------------
 16:59:57.203
(1 row)
```

NOTE

This function is valid only when **sql_compatibility** is set to **'MYSQL'**, **b_format_version** is set to **'5.7'**, and **b_format_dev_version** is set to **'s1'**.

- date_add(date,INTERVAL val unit)

  Description: Adds a period of time to a specified date and returns the calculation result.

  Parameters: See **Table 1-54**.

Table 1-54 date_add(date,INTERVAL val unit) parameters

Parameter	Type	Description	Value Range
date	Expression of the time type, text, datetime, date, or time	Date to be added with an interval.	See the value ranges of the corresponding types.
val	Integer, floating-point number, or character string	Interval to be added.	See the value ranges of the corresponding types.
unit	Keyword	Unit of the interval.	**YEAR**, **QUARTER**, **MONTH**, **WEEK**, **DAY**, **HOUR**, **MINUTE**, **SECOND**, and **MICROSECOND**. For details, see **Time Interval Expressions**.

Return type: a single return value. For details, see **Table 1-55**.

Table 1-55 Return value types of date_add(date,INTERVAL val unit)

Return Type	Description
TEXT	The **date** input parameter is of the text type.
DATE	The **date** input parameter is of the date type, and the value of the **unit** input parameter is greater than or equal to **day** (for example, **week** or **month**).
TIME WITHOUT TIMEZONE	The **date** input parameter is of the time type.
DATETIME	The **date** input parameter is of the datetime type, or the **date** input parameter and the value of the **unit** input parameter is less than **day** (for example, **hour** or **second**).

Example:

```
gaussdb=#  SELECT date_add('2018-05-01', INTERVAL 1 DAY);
  date_add
------------
 2018-05-02
(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- This function is valid only when **sql_compatibility** is set to **'MYSQL'**, **b_format_version** is set to **'5.7'**, and **b_format_dev_version** is set to **'s1'**.
- When working with the PREPARE statement, note that the second parameter of the date_add function is an interval expression and cannot be replaced by **$1**, for example, **PREPARE p1 AS SELECT date_add('2023-01-01 10:00:00', $1);**.

- date_add(expr, days)

  Description: Returns a new date by adding a certain number of days to a date.

  Parameters:

  – **expr**: specifies the start date and time. The value type can be expression of the time type, TEXT, DATE, DATETIME, or TIME.

  – **days**: specifies the number of days to be added. The value is of the int type.

  Return type: TEXT, DATE, DATETIME, or TIME WITHOUT TIMEZONE

  Example:

```
gaussdb=# SELECT DATE_ADD('2018-05-01', 1);
  date_add
------------
 2018-05-02
(1 row)
```

  NOTE

  This function is valid only when **sql_compatibility** is set to **'MYSQL'**, **b_format_version** is set to **'5.7'**, and **b_format_dev_version** is set to **'s1'**.

- date_format(date, format)

  Description: Outputs the date and time in the specified format.

  Parameters: See **Table 1-56**.

Table 1-56 date_format parameters

Parameter	Type	Description	Value Range
date	Time expression, TEXT, DATETIME, DATE, or TIME	Date to be formatted.	See the value ranges of the corresponding types.
format	text	A formatted string.	For details, see **Table 1-57**.

Table 1-57 lists the format parameters.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 1-57 Values and meanings of format

Value	Meaning
%a	Abbreviation of every day in a week (Sun–Sat).
%b	Abbreviation of every month (Jan–Dec).
%c	Month number (1–12).
%D	Every day in a month with an English prefix (1st, 2nd, 3rd, ...).
%d	Two-digit representation of every day in a month (01–31).
%e	Sequence number of every day in a month (1–31).
%f	Microsecond (000000–999999).
%H	Hour (00–23).
%h	Hour (01–12).
%I	Hour (01–12).
%i	Minutes (00–59).
%j	Every day in a year (001–366).
%k	Hour (0–23).
%l	Hour (1–12).
%M	Month name (January–December).
%m	Two-digit representation of every month (01–12).
%p	AM or PM
%r	12-hour time (hh:mm:ss followed by AM or PM).
%S	Seconds (00–59).
%s	Seconds (00–59).
%T	24-hour time (hh:mm:ss)
%U	Week of a year (00–53). Each week starts from Sunday.
%u	Week of a year (00–53). Each week starts from Monday.
%V	Week of a year (01–53). Each week starts from Sunday.
%v	Week of a year (01–53). Each week starts from Monday.
%W	Name of every day in a week (Sunday–Saturday).

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Value	Meaning
%w	Every day in a week (0–6), where **0** represents Sunday, and **6** represents Saturday.
%X	Week of a year. Each week starts from Sunday. The value is a four-digit number and is used for %V.
%x	Week of a year. Each week starts from Monday. The value is a four-digit number and is used for %v.
%Y	Four-digit year
%y	Two-digit year

Return type: text

Example:

```
gaussdb=# SELECT date_format('2023-10-11 12:13:14.151617','%b %c %M %m');
    date_format
--------------------
 Oct 10 October 10
(1 row)
```

NOTE

This function is valid only when **sql_compatibility** is set to **'MYSQL'**, **b_format_version** is set to **'5.7'**, and **b_format_dev_version** is set to **'s1'**.

- date_sub(date, INTERVAL val unit)

  Description: Returns a new date by subtracting a certain interval from a date.

  Parameters: See **Table 1-58**.

Table 1-58 date_sub(date, INTERVAL val unit) parameters

Parameter	Type	Description	Value Range
date	Expression of the time type, text, datetime, date, or time	Date to be added with an interval.	See the value ranges of the corresponding types.
val	Integer, floating-point number, or character string	Interval to be added.	See the value ranges of the corresponding types.
unit	Keyword	Unit of the interval.	**YEAR**, **QUARTER**, **MONTH**, **WEEK**, **DAY**, **HOUR**, **MINUTE**, **SECOND**, and **MICROSECOND**. For details, see **Time Interval Expressions**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Return type: TEXT, DATE, DATETIME, or TIME WITHOUT TIMEZONE

Example:

```
gaussdb=#  SELECT date_sub('2018-05-01', INTERVAL 1 YEAR);
  date_sub
------------
 2017-05-01
(1 row)
```

NOTE

- This function is valid only when **sql_compatibility** is set to **'MYSQL'**, **b_format_version** is set to **'5.7'**, and **b_format_dev_version** is set to **'s1'**.
- When working with the PREPARE statement, note that the second parameter of the date_sub function is an interval expression and cannot be replaced by **$1**, for example, **PREPARE p1 AS SELECT date_sub('2023-01-01 10:00:00', $1);**.

- date_sub(expr, days)

  Description: Specifies the start date and time and the number of days to be subtracted from the start date and time, and returns the subtraction result.

  Parameters:

  – **expr**: specifies the start date and time. The value type can be expression of the time type, TEXT, DATE, DATETIME, or TIME.

  – **days**: specifies the number of days to be subtracted. The value is of the int type.

  Return type: TEXT, DATE, DATETIME, or TIME WITHOUT TIMEZONE

  Example:

  ```
  gaussdb=#  SELECT date_sub('2023-1-1', 20);
    date_sub
  ------------
   2022-12-12
  (1 row)
  ```

  NOTE

  This function is valid only when **sql_compatibility** is set to **'MYSQL'**, **b_format_version** is set to **'5.7'**, and **b_format_dev_version** is set to **'s1'**.

- datediff(expr1, expr2)

  Description: Returns the number of days between two time expressions.

  Parameter: Expression of the time type, text, datetime, date, or time

  Return type: int.

  Example:

  ```
  gaussdb=#  SELECT datediff('2021-11-12','2021-11-13');
   datediff
  ----------
         -1
  (1 row)
  ```

  NOTE

  This function is valid only when **sql_compatibility** is set to **'MYSQL'**, **b_format_version** is set to **'5.7'**, and **b_format_dev_version** is set to **'s1'**.

- day()/dayofmonth()

  Description: Extracts the number of days in a date and time expression and returns the result. dayofmonth() is the alias of day() and has the same function.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter: The input parameter is the date and time to be extracted, which can be an expression of the time type, or of the text, datetime, date, or time type.

Return type: int.

Example:

```
gaussdb=# SELECT day('2023-01-02');
 day
-----
   2
(1 row)
gaussdb=# SELECT dayofmonth('23-05-22');
 dayofmonth
------------
         22
(1 row)
```

NOTE

This function is valid only when **sql_compatibility** is set to **'MYSQL'**, **b_format_version** is set to **'5.7'**, and **b_format_dev_version** is set to **'s1'**.

- dayname()

  Description: Returns the name of a day in a week.

  Parameter: The input parameter is a time expression, TEXT, DATETIME, DATE, or TIME.

  Return type: text

  Example:

  ```
  gaussdb=# SELECT dayname('2023-10-11');
    dayname
  -----------
   Wednesday
  (1 row)
  ```

  NOTE

  - This function is valid only when **sql_compatibility** is set to **'MYSQL'**, **b_format_version** is set to **'5.7'**, and **b_format_dev_version** is set to **'s1'**.
  - The language used by the return value is specified by the GUC parameter **lc_time_names**.

- dayofweek()

  Description: Returns the working day index of a date (1 = Sunday, 2 = Monday, ..., 7 = Saturday).

  Parameter: Expression of the time type, text, datetime, date, or time

  Return type: bigint

  Example:

  ```
  gaussdb=# SELECT dayofweek('2023-04-16');
   dayofweek
  -----------
           1
  (1 row)
  ```

  NOTE

  This function is valid only when **sql_compatibility** is set to **'MYSQL'**, **b_format_version** is set to **'5.7'**, and **b_format_dev_version** is set to **'s1'**.

- dayofyear()

  Description: Returns the number of a day in the year.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter: The input parameter is a time expression, TEXT, DATETIME, DATE, or TIME.

Return type: int; value range: 1 to 366.

Example:

```
gaussdb=# SELECT dayofyear('2000-12-31');
 dayofyear
-----------
       366
(1 row)
```

NOTE

This function is valid only when **sql_compatibility** is set to **'MYSQL'**, **b_format_version** is set to **'5.7'**, and **b_format_dev_version** is set to **'s1'**.

- extract(unit FROM date)

  Description: Extracts part of the time. This function can be used in other modes, but the behavior varies greatly. When **sql_compatibility** is set to **'MYSQL'**, **b_format_version** is set to **'5.7'**, and **b_format_dev_version** is set to **'s1'**, the function is described as follows:

  Parameters:

  – **unit**: text type. For details about the value types, see **Table 1-59**.

  – **date**: date, time, datetime, text, datea (valid only for ORA compatibility), or other time type expressions.

  Return type: bigint

Table 1-59 Values and meanings of unit

Value of UNIT	Description
MICROSECOND	Microsecond
SECOND	Second
MINUTE	Minute
HOUR	Hour
DAY	Day
WEEK	Week
MONTH	Month
QUARTER	Quarter
YEAR	Year
SECOND_MICROSECOND	Concatenated value of second and microsecond
MINUTE_MICROSECOND	Concatenated value of minute, second, and microsecond
MINUTE_SECOND	Concatenated value of minute and second

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Value of UNIT	Description
HOUR_MICROSECOND	Concatenated value of hour, minute, second, and microsecond
HOUR_SECOND	Concatenated value of hour, minute, and second
HOUR_MINUTE	Concatenated value of hour and minute
DAY_MICROSECOND	Concatenated value of day, hour, minute, second, and microsecond
DAY_SECOND	Concatenated value of day, hour, minute, and second
DAY_MINUTE	Concatenated value of day and minute
DAY_HOUR	Concatenated value of day and hour
YEAR_MONTH	Concatenated value of year and month
EPOCH	Total number of seconds or interval since 1970-01-01 00:00:00-00 UTC

Example:

```
gaussdb=# SELECT extract(YEAR FROM '2023-10-11');
 extract
---------
    2023
(1 row)

gaussdb=# SELECT extract(QUARTER FROM '2023-10-11');
 extract
---------
       4
(1 row)

gaussdb=# SELECT extract(MONTH FROM '2023-10-11');
 extract
---------
      10
(1 row)

gaussdb=# SELECT extract(WEEK FROM '2023-10-11');
 extract
---------
      41
(1 row)

gaussdb=# SELECT extract(DAY FROM '2023-10-11');
 extract
---------
      11
(1 row)

gaussdb=# SELECT extract(HOUR FROM '2023-10-11 12:13:14');
 extract
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
---------
    12
(1 row)
```

NOTE

- When **sql_compatibility** is set to **'MYSQL'**, **b_format_version** is set to **5.7**, and **b_format_dev_version** is set to **s1**, the actually called function is b_extract. In other cases, the actually called function is date_part, which can be queried using commands like **\df b_extract** for detailed input parameters and return values.
- When **sql_compatibility** is set to **'ORA'**:
  - When the GUC parameter **mapping_date_to_datea** is set to **on**, the database parses the date type in the input parameter to the datea type. In this case, the unit can only be year, month, or day. If other units are specified, an error is reported.
  - When the input parameter is of the datea type, the unit can only be year, month, or day regardless of whether the GUC parameter **mapping_date_to_datea** is set to **on** or **off**. If other units are specified, an error is reported.

The GUC parameter **default_week_format** is used to process special week issues. The default value is **0**. For details, see **Table 1-60**.

Table 1-60 default_week_format

default_week_format	First Day of a Week	Range	Which Week is the First Week
0	Sunday	0–53	Week containing Sunday in this year
1	Monday	0–53	Week containing four or more days in this year
2	Sunday	1–53	Week containing Sunday in this year
3	Monday	1–53	Week containing four or more days in this year
4	Sunday	0–53	Week containing four or more days in this year
5	Monday	0–53	Week containing Monday in this year
6	Sunday	1–53	Week containing four or more days in this year
7	Monday	1–53	Week containing Monday in this year

- from_days(days)

  Description: Returns the corresponding date value given a number of days.

  Parameter: The input parameter is a time expression, TEXT, DATETIME, DATE, or TIME.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Return type: date

Example:

```
gaussdb=# SELECT from_days(36524);--0099-12-31
 from_days
------------
 0099-12-31
(1 row)
```

NOTE

- This function is valid only when **sql_compatibility** is set to **'MYSQL'**, **b_format_version** is set to **'5.7'**, and **b_format_dev_version** is set to **'s1'**.
- Null characters and zeros are processed as 0. For input parameters that cannot be correctly converted to bigint, an error is reported.
- If the input parameter is less than **366**, the return date is **0000-00-00**.

- from_unixtime(unix_timestamp[,format])

  Description: Converts a Unix timestamp to the date and time format. A Unix timestamp is the number of seconds from 08:00:00 UTC on January 1, 1970 to a specified time.

  Parameters:

  – **unix_timestamp**: Unix timestamp, which is of the numeric type.

  – **format**: time format. The value is of the text type.

  Return type: text/datetime

  Example:

  ```
  gaussdb=# SELECT from_unixtime(1111885200);
     from_unixtime
  ---------------------
   2005-03-27 09:00:00
  (1 row)
  ```

  NOTE

  This function is valid only when **sql_compatibility** is set to **'MYSQL'**, **b_format_version** is set to **'5.7'**, and **b_format_dev_version** is set to **'s1'**.

- get_format({DATE | TIME | DATETIME | TIMESTAMP}, {'EUR' | 'USA' | 'JIS' | 'ISO' | 'INTERNAL'})

  Description: Obtains the date and time string corresponding to the specified time type under a certain locale standard.

  Parameters:

  – **DATE|TIME|DATETIME|TIMESTAMP**: time types, which are keywords.

  – **'EUR'|'USA'|'JIS'|'ISO'|'INTERNAL'**: five time formats, which are of the text type.

  Return type: text

  Example:

  ```
  gaussdb=# SELECT get_format(date, 'eur');
   get_format
  ------------
   %d.%m.%y
  (1 row)
  gaussdb=# SELECT get_format(date, 'usa');
   get_format
  ------------
   %m.%d.%y
  (1 row)
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- This function is valid only when **sql_compatibility** is set to **'MYSQL'**, **b_format_version** is set to **'5.7'**, and **b_format_dev_version** is set to **'s1'**.
- When working with the PREPARE statement, note that the first parameter of the get_format function is a keyword and cannot be replaced by **$1**, for example, **PREPARE p1 AS SELECT get_format($1, 'usa');**.

- hour()

  Description: Returns the hour part of a time after you enter a time type.

  Parameter: Expression of the time type, text, datetime, date, or time

  Return type: bigint

  Example:

```
gaussdb=# SELECT hour('10:10:10.1');
 hour
------
   10
(1 row)
```

  NOTE

  This function is valid only when **sql_compatibility** is set to **'MYSQL'**, **b_format_version** is set to **'5.7'**, and **b_format_dev_version** is set to **'s1'**.

- makedate(year,dayofyear)

  Description: Returns a date based on the given year and day.

  Parameters:

  – **year**: The parameter type is bigint.

  – **dayofyear**: The parameter type is bigint, indicating the number of days in the year. The value can cross years. If the value is less than or equal to **0**, **null** is returned.

  Return type: date

  Example:

```
gaussdb=# SELECT makedate(2000, 60);
  makedate
------------
 2000-02-29
(1 row)
```

  NOTE

  This function is valid only when **sql_compatibility** is set to **'MYSQL'**, **b_format_version** is set to **'5.7'**, and **b_format_dev_version** is set to **'s1'**.

- microsecond()

  Description: Returns the microsecond part of a time type you enter.

  Parameter: Expression of the time type, text, datetime, date, or time

  Return type: bigint

  Example:

```
gaussdb=# SELECT microsecond('2023-5-5 10:10:10.24485');
 microsecond
-------------
      244850
(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

> **NOTE**
>
> This function is valid only when **sql_compatibility** is set to **'MYSQL'**, **b_format_version** is set to **'5.7'**, and **b_format_dev_version** is set to **'s1'**.

- minute()

  Description: Returns the minute part of a time type you enter.

  Parameter: Expression of the time type, text, datetime, date, or time

  Return type: bigint

  Example:

```
gaussdb=# SELECT minute(time'10:10:10');
 minute
--------
     10
(1 row)
```

  > **NOTE**
  >
  > This function is valid only when **sql_compatibility** is set to **'MYSQL'**, **b_format_version** is set to **'5.7'**, and **b_format_dev_version** is set to **'s1'**.

- month()

  Description: Returns the month of a specified date and time.

  Parameter: The input parameter is the date and time to be extracted, which can be an expression of the time type, or of the TEXT, DATETIME, DATE, or TIME type.

  Return type: int.

  Example:

```
gaussdb=# SELECT month('2021-11-30');
 month
-------
    11
(1 row)
```

  > **NOTE**
  >
  > This function is valid only when **sql_compatibility** is set to **'MYSQL'**, **b_format_version** is set to **'5.7'**, and **b_format_dev_version** is set to **'s1'**.

- monthname()

  Description: Returns the full month name of a date.

  Parameter: The input parameter is a time expression, TEXT, DATETIME, DATE, or TIME.

  Return type: text

  Example:

```
gaussdb=# SELECT monthname('2023-02-28');
 monthname
-----------
 February
(1 row)
```

  > **NOTE**
  >
  > - This function is valid only when **sql_compatibility** is set to **'MYSQL'**, **b_format_version** is set to **'5.7'**, and **b_format_dev_version** is set to **'s1'**.
  > - The language used by the return value is specified by the GUC parameter **lc_time_names**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- period_add(period, month_number)

  Description: Adds a specified number of months to a specified time segment and returns the result as a time segment.

  Parameters:

  – **period**: The parameter type is bigint. The value is a date in *YYYYMM* or *YYMM* format.

  – **month_number**: The parameter type is bigint. The value is the number of months to be added. The value can be a negative number.

  Return type: bigint, which is a date in YYYYMM format.

  Example:

  ```
  gaussdb=# SELECT period_add(202205, -12);
   period_add
  ------------
      202105
  (1 row)
  ```

  NOTE

  This function is valid only when **sql_compatibility** is set to **'MYSQL'**, **b_format_version** is set to **'5.7'**, and **b_format_dev_version** is set to **'s1'**.

- period_diff(p1, p2)

  Description: Calculates the month difference between two time segments.

  Parameters: The parameter type is bigint. The two parameters use the *YYMM* or *YYYYMM* format to indicate the time segment.

  Return type: bigint (month difference)

  Example:

  ```
  gaussdb=# SELECT period_diff('202101', '202102');
   period_diff
  -------------
            -1
  (1 row)
  ```

  NOTE

  This function is valid only when **sql_compatibility** is set to **'MYSQL'**, **b_format_version** is set to **'5.7'**, and **b_format_dev_version** is set to **'s1'**.

- second()

  Description: Returns the second part of a time type you enter.

  Parameter: Expression of the time type, text, datetime, date, or time

  Return type: bigint

  Example:

  ```
  gaussdb=# SELECT second('2023-5-5 10:10:10');
   second
  --------
      10
  (1 row)
  ```

  NOTE

  This function is valid only when **sql_compatibility** is set to **'MYSQL'**, **b_format_version** is set to **'5.7'**, and **b_format_dev_version** is set to **'s1'**.

- quarter()

  Description: Returns the quarter part of a date after you enter a date type.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter: The input parameter is the date and time to be extracted, which can be an expression of the time type, or of the TEXT, DATETIME, DATE, or TIME type.

Return type: bigint

Example:

```
gaussdb=# SELECT quarter('2012-1-1');
 quarter
---------
       1
(1 row)
```

NOTE

This function is valid only when **sql_compatibility** is set to **'MYSQL'**, **b_format_version** is set to **'5.7'**, and **b_format_dev_version** is set to **'s1'**.

- str_to_date(str, format)

  Description: Converts a specified character string to a date/time based on the specified date format.

  Parameters:

  - **str**: character string of the text type, formatted into date.
  - **format**: string of the text type, indicating the target format. **Table 1-61** lists the format parameters.

  Table 1-61 Values and meanings of format

Value	Meaning
%a	Abbreviation of every day in a week (Sun–Sat).
%b	Abbreviation of every month (Jan–Dec).
%c	Month number (1–12).
%D	Every day in a month with an English prefix (1st, 2nd, 3rd, ...).
%d	Two-digit representation of every day in a month (01–31).
%e	Sequence number of every day in a month (1–31).
%f	Microsecond (000000–999999).
%H	Hour (00–23).
%h	Hour (01–12).
%I	Hour (01–12).
%i	Minutes (00–59).
%j	Every day in a year (001–366).
%k	Hour (0–23).

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Value	Meaning
%l	Hour (1–12).
%M	Month name (January–December).
%m	Two-digit representation of every month (01–12).
%p	AM or PM
%r	12-hour time (hh:mm:ss followed by AM or PM).
%S	Seconds (00–59).
%s	Seconds (00–59).
%T	24-hour time (hh:mm:ss)
%U	Week of a year (00–53). Each week starts from Sunday.
%u	Week of a year (00–53). Each week starts from Monday.
%V	Week of a year (01–53). Each week starts from Sunday.
%v	Week of a year (01–53). Each week starts from Monday.
%W	Name of every day in a week (Sunday–Saturday).
%w	Every day in a week (0–6), where **0** represents Sunday, and **6** represents Saturday.
%X	Week of a year. Each week starts from Sunday. The value is a four-digit number and is used for %V.
%x	Week of a year. Each week starts from Monday. The value is a four-digit number and is used for %v.
%Y	Four-digit year
%y	Two-digit year

Return type: text

Example:

```
gaussdb=# SELECT str_to_date('May 1, 2013','%M %d,%Y');--2013-05-01
 str_to_date
-------------
 2013-05-01
(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- This function is valid only when **sql_compatibility** is set to **'MYSQL'**, **b_format_version** is set to **'5.7'**, and **b_format_dev_version** is set to **'s1'**.
- Only the time in YYYY-MM-DD format can be returned.
- If the time contains 0 year, 0 month, and 0 day or contains only hour, minute, and second, an alarm is generated and **NULL** is returned.

- subdate(expr, days)

  Description: Specifies the start date and time and the number of days to be subtracted from the start date and time, and returns the subtraction result.

  Parameters:

  – **expr**: specifies the start date and time. The value type can be expression of the time type, TEXT, DATE, DATETIME, or TIME.

  – **days**: specifies the number of days to be subtracted. The value is of the int type.

  Return type: TEXT, DATE, DATETIME, or TIME WITHOUT TIMEZONE

  Example:

```
gaussdb=# SELECT subdate('2023-1-1', 20);
  subdate
------------
 2022-12-12
(1 row)
```

NOTE

This function is valid only when **sql_compatibility** is set to **'MYSQL'**, **b_format_version** is set to **'5.7'**, and **b_format_dev_version** is set to **'s1'**.

- subdate(expr, INTERVAL val unit)

  Description: Specifies the start date and time and the interval to be subtracted from the start date and time, and returns the subtraction result.

  Parameters: See **Table 1-62**.

Table 1-62 subdate(expr,INTERVAL val unit) parameters

Parameter	Type	Description	Value Range
expr	Expression of the time type, text, datetime, date, or time	Specifies the start date and time.	See the value ranges of the corresponding types.
val	Integer, floating-point number, or character string	Specifies the interval to be subtracted.	See the value ranges of the corresponding types.
unit	Keyword		**YEAR**, **QUARTER**, **MONTH**, **WEEK**, **DAY**, **HOUR**, **MINUTE**, **SECOND**, and **MICROSECOND**. For details, see **Time Interval Expressions**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Return type: TEXT, DATE, DATETIME, or TIME WITHOUT TIMEZONE

Example:

```
gaussdb=# SELECT subdate('2018-05-01', INTERVAL 1 YEAR);
  subdate
------------
 2017-05-01
(1 row)
```

NOTE

- This function is valid only when **sql_compatibility** is set to **'MYSQL'**, **b_format_version** is set to **'5.7'**, and **b_format_dev_version** is set to **'s1'**.
- When working with the PREPARE statement, note that the second parameter of the subdate function is an interval expression. If this parameter is replaced by **$1**, you will encounter unexpected results. For example, running **PREPARE p1 AS SELECT subdate('2023-01-01 10:00:00', $1); EXECUTE p1(interval 13 hour);** will yield the unexpected result of **'2023-01-01 10:00:00'**.

- subtime(expr1, expr2)

  Description: Returns the time difference between **expr1** and **expr2**.

  Parameters: **expr1** is an expression of the TIMESTAMP WITHOUT TIME ZONE or TIME type, and **expr2** is a time expression.

  Return type: TEXT, TIMESTAMP WITHOUT TIME ZONE, or TIME. The return value type is related to the **expr1** type. If the two input parameters are of the TEXT type, the return value type is TEXT. If the two input parameters are parsed as TIMESTAMP WITHOUT TIME ZONE, the return value type is TIMESTAMP WITHOUT TIME ZONE. If the two input parameters are parsed as TIME, the return value type is TIME.

  Example:

  ```
  gaussdb=# SELECT subtime('2000-03-01 20:59:59', '22:58');
        subtime
  ---------------------
   2000-02-29 22:01:59
  (1 row)
  ```

  NOTE

  This function is valid only when **sql_compatibility** is set to **'MYSQL'**, **b_format_version** is set to **'5.7'**, and **b_format_dev_version** is set to **'s1'**.

- addtime(expr1, expr2)

  Description: Returns the sum of **expr1** and **expr2**. The format of the return value is the same as that of **expr1**.

  Parameters: **expr1** is an expression of the timestamp without time zone or time type, and **expr2** is a time expression.

  Return type: text, timestamp without time zone, or time. The return type is determined by the data type of **expr1**. If **expr1** is parsed as timestamp without time zone, the return type will also be timestamp without time zone. If it parsed as time, the return type will also be time.

  Example:

  ```
  gaussdb=# SELECT addtime('2000-03-01 20:59:59', '00:00:01');
        addtime
  ---------------------
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
2000-03-01 21:00:00
(1 row)
```

NOTE

This function is valid only when **sql_compatibility** is set to **'MYSQL'**, **b_format_version** is set to **'5.7'**, and **b_format_dev_version** is set to **'s1'**.

- time_format(time, format)

  Description: Formats the **time** input parameter based on the format specified by **format**.

  Parameters:

  - The value type of **time** is expression of the time type, text, datetime, date, or time
  - **format** is of the text type. **Table 1-63** lists the supported formats.

    Table 1-63 Values and meanings of format

Value	Meaning
%f	Microsecond (000000–999999).
%H	Hour (00–23).
%h, %I	Hour (00–12).
%l	Hour (0–12).
%k	Hour (0–838).
%i	Minutes (00–59).
%p	AM or PM
%r	Time in 12-hour AM or PM format (hh:mm:ss AM/PM)
%S, %s	Seconds (00–59).
%T	Time in 24-hour format (hh:mm:ss)
%a, %b, %D, %j, %M, %U, %u, %V, %v, %W, %w, %X, %x	**NULL**.
%c, %e	0
%d, %m, %y	00
%Y	0000
%*Other characters*|*Other characters*, for example, %A/A	The character itself is returned, for example, A.
%*Single character*+string *s*	%*Single character* is parsed and then concatenated with s.

  Return type: text

  Example:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gaussdb=# SELECT time_format('25:30:30', '%T|%r|%H|%h|%I|%i|%S|%f|%p|%k');
                time_format
-----------------------------------------------
 25:30:30|01:30:30 AM|25|01|01|30|30|000000|AM|25
(1 row)
```

NOTE

This function is valid only when **sql_compatibility** is set to **'MYSQL'**, **b_format_version** is set to **'5.7'**, and **b_format_dev_version** is set to **'s1'**.

- time_to_sec()

  Description: Converts the input parameter of the time type to the number of seconds.

  Parameter: The input parameter is a time expression, TEXT, DATETIME, DATE, or TIME. The time expression is parsed as TIME.

  Return type: int.

  Example:

```
gaussdb=# SELECT time_to_sec('00:00:01');
 time_to_sec
-------------
           1
(1 row)
```

NOTE

This function is valid only when **sql_compatibility** is set to **'MYSQL'**, **b_format_version** is set to **'5.7'**, and **b_format_dev_version** is set to **'s1'**.

- timediff()

  Description: Calculates the difference between two time points and returns an interval.

  Parameters: two parameters, which can be represented as either a time expression or a type such as text, datetime, date, or time.

  Return type: TIME WITHOUT TIMEZONE

  Example:

```
gaussdb=# SELECT timediff(date'2022-12-30',20221229);
 timediff
----------
 24:00:00
(1 row)
```

NOTE

This function is valid only when **sql_compatibility** is set to **'MYSQL'**, **b_format_version** is set to **'5.7'**, and **b_format_dev_version** is set to **'s1'**.

- timestampadd(unit, interval, datetime_expr)

  Description: Returns a new timestamp calculated by adding multiple intervals of a unit to **datetime_expr**.

  Parameters: See **Table 1-64**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 1-64 timestampadd parameters

Parameter	Type	Description	Value Range
unit	Keyword	Unit of the interval.	YEAR, QUARTER, MONTH, WEEK, DAY, HOUR, MINUTE, SECOND, MICROSECOND, Y, MM (month), D, H, M (minute), S, US, YRS, QTR, MON, HRS, MIN, YEARS, WEEKS, or HOURS.
interval	numeric	Interval.	See the value ranges of the corresponding types.
datetime_expr	Expression of the time type, text, datetime, date, or time	Date and time to be changed. If the value is of the text type, the return value type is text. If the value is of the time type, the return value type is time. In other cases, the return value type is datetime.	See the value ranges of the corresponding types.

Return type: DATETIME, TEXT, TIME WITHOUT TIMEZONE

Example:

```
gaussdb=# SELECT timestampadd(DAY,-2,'2022-07-27');
 timestampadd
--------------
 2022-07-25
(1 row)
```

NOTE

- This function is valid only when **sql_compatibility** is set to **'MYSQL'**, **b_format_version** is set to **'5.7'**, and **b_format_dev_version** is set to **'s1'**.
- The actually registered function of timestampadd is timestamp_add. You can run commands such as **\df timestamp_add** to query the detailed input parameter and return value of the function.
- When working with the PREPARE statement, note that the first parameter of the timestampadd function is a keyword and cannot be replaced by **$1**, for example, **PREPARE p1 AS SELECT timestampadd($1, -2, '2023-01-01');**.

- to_days()

  Description: Returns the number of days since January 1, 0000.

  Parameter: The input parameter is a time expression, TEXT, DATETIME, DATE, or TIME. The time expression is parsed as DATE.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Return type: bigint

Example:

```
gaussdb=# SELECT to_days('2000-1-1');
 to_days
---------
  730485
(1 row)
```

NOTE

This function is valid only when **sql_compatibility** is set to **'MYSQL'**, **b_format_version** is set to **'5.7'**, and **b_format_dev_version** is set to **'s1'**.

- to_seconds()

  Description: Returns the number of seconds since the year 0 A.D.

  Parameter: The input parameter is a time expression, TEXT, DATETIME, DATE, or TIME. The time expression is parsed as datetime.

  Return type: bigint

  Example:

  ```
  gaussdb=# SELECT to_seconds('2009-11-29 13:43:32');
   to_seconds
  -------------
   63426721412
  (1 row)
  ```

  NOTE

  This function is valid only when **sql_compatibility** is set to **'MYSQL'**, **b_format_version** is set to **'5.7'**, and **b_format_dev_version** is set to **'s1'**.

- unix_timestamp([date])

  Description: Returns a Unix timestamp representing the number of seconds since "1970-01-01 08:00" UTC. If there is no input parameter, the default value is the datetime timestamp when the function is called.

  Parameter: Expression of the time type, text, datetime, date, or time

  Return type: numeric

  Example:

  ```
  gaussdb=# SELECT unix_timestamp('2022-12-22');
   unix_timestamp
  ----------------
      1671638400
  (1 row)
  ```

  NOTE

  This function is valid only when **sql_compatibility** is set to **'MYSQL'**, **b_format_version** is set to **5.7** and **b_format_dev_version** is set to **s1**.

- utc_date()

  Description: Returns the current UTC date of function execution as a value in YYYY-MM-DD format.

  Return type: date

  Example:

  ```
  gaussdb=# SELECT utc_date();
    utc_date
  ------------
   2023-08-10
  (1 row)
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

> **NOTE**
>
> This function is valid only when **sql_compatibility** is set to **'MYSQL'**, **b_format_version** is set to **5.7** and **b_format_dev_version** is set to **s1**.

- utc_time([precision])

  Description: Returns the current UTC time in the format of *HH:MM:SS* when the function is executed.

  Parameter: Indicates the time precision. The value is of the int type and in the range [0,6]. The default value is **0**.

  Return type: time without time zone

  Example:

```
gaussdb=# SELECT utc_time();
 utc_time
----------
 11:47:53
(1 row)
```

  > **NOTE**
  >
  > This function is valid only when **sql_compatibility** is set to **'MYSQL'**, **b_format_version** is set to **5.7** and **b_format_dev_version** is set to **s1**.

- utc_timestamp([precision])

  Description: Returns the current UTC timestamp in the format of *YYYY-MM-DD HH:MM:SS* when the function is executed.

  Parameter: Indicates the time precision. The value is of the int type and in the range [0,6]. The default value is **0**.

  Return type: timestamp without time zone

  Example:

```
gaussdb=# SELECT utc_timestamp();
    utc_timestamp
---------------------
 2023-08-21 11:51:19
(1 row)
```

  > **NOTE**
  >
  > This function is valid only when **sql_compatibility** is set to **'MYSQL'**, **b_format_version** is set to **5.7** and **b_format_dev_version** is set to **s1**.

- week(date[, mode])

  Description: Returns the week of a date.

  Parameters:

  - **date**: specifies the date and time, which is of the time expression, text, datetime, date, or time type.
  - **Table 1-65** describes the optional parameter **mode**. The default value is **0**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 1-65 Description of mode

mode	First Day of a Week	Range	Which Week is the First Week
0	Sunday	0–53	Week containing Sunday in this year
1	Monday	0–53	Week containing four or more days in this year
2	Sunday	1–53	Week containing Sunday in this year
3	Monday	1–53	Week containing four or more days in this year
4	Sunday	0–53	Week containing four or more days in this year
5	Monday	0–53	Week containing Monday in this year
6	Sunday	1–53	Week containing four or more days in this year
7	Monday	1–53	Week containing Monday in this year

Return type: bigint

Example:

```
gaussdb=# SELECT week(date'2000-01-01', 1);
 week
------
    0
(1 row)

gaussdb=# SELECT week('2000-01-01', 2);
 week
------
   52
(1 row)
```

NOTE

This function is valid only when **sql_compatibility** is set to **'MYSQL'**, **b_format_version** is set to **5.7** and **b_format_dev_version** is set to **s1**.

- weekday()

  Description: Returns the working day index of a date, that is, Monday is 0, Tuesday is 1, Wednesday is 2, Thursday is 3, Friday is 4, Saturday is 5, and Sunday is 6.

  Parameter: Expression of the time type, text, datetime, date, or time

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Return type: bigint

Example:

```
gaussdb=# SELECT weekday('1970-01-01 12:00:00');
 weekday
---------
       3
(1 row)
```

NOTE

This function is valid only when **sql_compatibility** is set to **'MYSQL'**, **b_format_version** is set to **5.7** and **b_format_dev_version** is set to **s1**.

- weekofyear(date)

  Description: Returns the calendar week of the date and time. The value ranges from 1 to 53. This function is equivalent to week(date, 3). For details, see **week(date[, mode])**.

  Parameter: date and time, which can be represented as a time expression or a type such as text, datetime, date, or time.

  Return type: bigint

  Example:

  ```
  gaussdb=# SELECT weekofyear('1970-05-22');
   weekofyear
  ------------
           21
  (1 row)
  ```

  NOTE

  This function is valid only when **sql_compatibility** is set to **'MYSQL'**, **b_format_version** is set to **5.7** and **b_format_dev_version** is set to **s1**.

- year()

  Description: Extracts the year part of the date and time and returns the result.

  Parameter: The input parameter is the date and time to be extracted, which can be an expression of the time type, or of the text, datetime, date, or time type.

  Return type: int.

  Example:

  ```
  gaussdb=# SELECT year('23-05-22');
   year
  ------
   2023
  (1 row)
  ```

  NOTE

  This function is valid only when **sql_compatibility** is set to **'MYSQL'**, **b_format_version** is set to **5.7** and **b_format_dev_version** is set to **s1**.

- yearweek(date[, mode])

  Description: Returns the year and week of a date.

  Parameters:

  - **date**: specifies the date and time, which can be of the DATE, DATETIME, TIMESTAMP, TIME, TEXT, or NUMERIC type.
  - **Table 1-66** describes the optional parameter **mode**. The default value is **0**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 1-66 Description of mode

mode	First Day of a Week	Range	Which Week is the First Week
0	Sunday	0–53	Week containing Sunday in this year
1	Monday	0–53	Week containing four or more days in this year
2	Sunday	1–53	Week containing Sunday in this year
3	Monday	1–53	Week containing four or more days in this year
4	Sunday	0–53	Week containing four or more days in this year
5	Monday	0–53	Week containing Monday in this year
6	Sunday	1–53	Week containing four or more days in this year
7	Monday	1–53	Week containing Monday in this year

Return type: bigint

Example:

```
gaussdb=# SELECT yearweek(datetime'2000-01-01', 3);
 yearweek
----------
   199952
(1 row)
```

NOTE

This function is valid only when **sql_compatibility** is set to **'MYSQL'**, **b_format_version** is set to **5.7** and **b_format_dev_version** is set to **s1**.

Table 1-67 shows the templates for truncating date/time values.

Table 1-67 Truncating date/time values

Item	Format	Description
Microsecond	MICROSECON	Truncates date/time values, accurate to the microsecond (000000–999999).
	US	
	USEC

NOTE

The behaviors of **Table 1-68** are valid only when the value of **a_format_version** is **10c** and that of **a_format_dev_version** is **s1** in an ORA-compatible database.

- timestamp_diff(text, timestamp, timestamp)

  Description: Calculates the difference between two timestamps and truncates the difference to the precision specified by text.

  Return type: bigint

  Example:

```
gaussdb=# SELECT timestamp_diff('year','2018-01-01','2020-04-01');
 timestamp_diff
----------------
              2
(1 row)
gaussdb=# SELECT timestamp_diff('month','2018-01-01','2020-04-01');
 timestamp_diff
----------------
             27
(1 row)
gaussdb=# SELECT timestamp_diff('quarter','2018-01-01','2020-04-01');
 timestamp_diff
----------------
              9
(1 row)
gaussdb=# SELECT timestamp_diff('week','2018-01-01','2020-04-01');
 timestamp_diff
----------------
            117
(1 row)
gaussdb=# SELECT timestamp_diff('day','2018-01-01','2020-04-01');
 timestamp_diff
----------------
            821
(1 row)
gaussdb=# SELECT timestamp_diff('hour','2018-01-01 10:10:10','2018-01-01 12:12:12');
 timestamp_diff
----------------
              2
(1 row)
gaussdb=# SELECT timestamp_diff('minute','2018-01-01 10:10:10','2018-01-01 12:12:12');
 timestamp_diff
----------------
            122
(1 row)
gaussdb=# SELECT timestamp_diff('second','2018-01-01 10:10:10','2018-01-01 10:12:12');
 timestamp_diff
----------------
            122
(1 row)
gaussdb=# SELECT timestamp_diff('microsecond','2018-01-01 10:10:10','2018-01-01 10:12:12');
 timestamp_diff
```

```
----------------
    122000000
(1 row)
```

TIMESTAMPDIFF

TIMESTAMPDIFF(unit , timestamp_expr1, timestamp_expr2)

Description: Returns the result of **timestamp_expr2** – **timestamp_expr1** in the specified unit. This function is equivalent to **timestamp_diff(text, timestamp, timestamp)**.

Parameters: **timestamp_expr1** and **timestamp_expr2** are of the time expression, text, datetime, date, or time type. **unit** specifies the unit of the difference between two dates.

Return type: bigint

NOTE

This function is valid only when the MySQL-compatible database is used (that is, **sql_compatibility** is set to **'MYSQL'**).

- When **b_format_version** is set to **5.7** and **b_format_dev_version** is set to **s1**, the actually called function is b_timestampdiff.
- If the parameters **b_format_version** and **b_format_dev_version** are not set, the actually called function is timestamp_diff. You can run commands such as **\df b_timestampdiff** to query the detailed input parameters and return values of the function.

- year

  Year.

  ```
  gaussdb=# SELECT TIMESTAMPDIFF(YEAR, '2018-01-01', '2020-01-01');
   timestamp_diff
  ----------------
               2
  (1 row)
  ```

- quarter

  Quarter.

  ```
  gaussdb=# SELECT TIMESTAMPDIFF(QUARTER, '2018-01-01', '2020-01-01');
   timestamp_diff
  ----------------
               8
  (1 row)
  ```

- month

  Month.

  ```
  gaussdb=# SELECT TIMESTAMPDIFF(MONTH, '2018-01-01', '2020-01-01');
   timestamp_diff
  ----------------
              24
  (1 row)
  ```

- week

  Week.

  ```
  gaussdb=# SELECT TIMESTAMPDIFF(WEEK, '2018-01-01', '2020-01-01');
   timestamp_diff
  ----------------
             104
  (1 row)
  ```

- day

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Day.

```
gaussdb=# SELECT TIMESTAMPDIFF(DAY, '2018-01-01', '2020-01-01');
 timestamp_diff
----------------
            730
(1 row)
```

- hour

  Hour.

  ```
  gaussdb=# SELECT TIMESTAMPDIFF(HOUR, '2020-01-01 10:10:10', '2020-01-01 11:11:11');
   timestamp_diff
  ----------------
                1
  (1 row)
  ```

- minute

  Minute.

  ```
  gaussdb=# SELECT TIMESTAMPDIFF(MINUTE, '2020-01-01 10:10:10', '2020-01-01 11:11:11');
   timestamp_diff
  ----------------
               61
  (1 row)
  ```

- second

  Second.

  ```
  gaussdb=# SELECT TIMESTAMPDIFF(SECOND, '2020-01-01 10:10:10', '2020-01-01 11:11:11');
   timestamp_diff
  ----------------
             3661
  (1 row)
  ```

- microseconds

  The second field, including fractional parts, is multiplied by 1,000,000.

  ```
  gaussdb=# SELECT TIMESTAMPDIFF(MICROSECOND, '2020-01-01 10:10:10.000000', '2020-01-01
  10:10:10.111111');
   timestamp_diff
  ----------------
           111111
  (1 row)
  ```

EXTRACT

EXTRACT(field FROM source)

Description: The extract function retrieves fields such as year or hour from date/time values.

Parameters:

- **source** is a value expression of type timestamp, time, or interval. (Expressions of type date can be converted to timestamp and can therefore be used as well.)
- **field** is an identifier or string that selects what field to extract from the source value.

Return type: double precision

The following are valid **field** names:

- century

  Century.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

The first century starts at 0001-01-01 00:00:00 A.D. This definition applies to all Gregorian calendar countries. There is no century numbered 0. The century goes from the 1st century B.C. to the 1st century A.D.

```
gaussdb=# SELECT EXTRACT(CENTURY FROM TIMESTAMP '2000-12-16 12:21:13');
 date_part
-----------
        20
(1 row)
```

- day
  - For **timestamp** values, the day (of the month) field (1–31)

    ```
    gaussdb=# SELECT EXTRACT(DAY FROM TIMESTAMP '2001-02-16 20:38:40');
     date_part
    -----------
            16
    (1 row)
    ```

  - For **interval** values, the number of days

    ```
    gaussdb=# SELECT EXTRACT(DAY FROM INTERVAL '40 days 1 minute');
     date_part
    -----------
            40
    (1 row)
    ```

- decade

  Year divided by 10

  ```
  gaussdb=# SELECT EXTRACT(DECADE FROM TIMESTAMP '2001-02-16 20:38:40');
   date_part
  -----------
        200
  (1 row)
  ```

- dow

  Day of the week as Sunday (**0**) to Saturday (**6**)

  ```
  gaussdb=# SELECT EXTRACT(DOW FROM TIMESTAMP '2001-02-16 20:38:40');
   date_part
  -----------
           5
  (1 row)
  ```

- doy

  Day of the year (1–365 or 366)

  ```
  gaussdb=# SELECT EXTRACT(DOY FROM TIMESTAMP '2001-02-16 20:38:40');
   date_part
  -----------
          47
  (1 row)
  ```

- epoch
  - For **timestamp with time zone** values, the number of seconds since 1970-01-01 00:00:00-00 UTC (can be negative).

    For **date** and **timestamp** values, the number of seconds since 1970-01-01 00:00:00-00 local time.

    For **interval** values, the total number of seconds in the interval.

    ```
    gaussdb=# SELECT EXTRACT(EPOCH FROM TIMESTAMP WITH TIME ZONE '2001-02-16
    20:38:40.12-08');
      date_part
    --------------
     982384720.12
    (1 row)
    gaussdb=# SELECT EXTRACT(EPOCH FROM INTERVAL '5 days 3 hours');
     date_part
    -----------
    ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
   442800
(1 row)
```

  - Way to convert an epoch value back to a timestamp

```
gaussdb=# SELECT TIMESTAMP WITH TIME ZONE 'epoch' + 982384720.12 * INTERVAL '1
second' AS RESULT;
          result
----------------------------
 2001-02-17 12:38:40.12+08
(1 row)
```

- hour

  Hour (0–23).

```
gaussdb=# SELECT EXTRACT(HOUR FROM TIMESTAMP '2001-02-16 20:38:40');
 date_part
-----------
        20
(1 row)
```

- isodow

  Day of a week (1–7). Monday is 1 and Sunday is 7.

  NOTE

  The value of **isodow** is identical to **dow** except for Sunday.

```
gaussdb=# SELECT EXTRACT(ISODOW FROM TIMESTAMP '2001-02-18 20:38:40');
 date_part
-----------
         7
(1 row)
```

- isoyear

  The ISO 8601 year that the date falls in (not applicable to intervals).

  The first week of the ISO year starts on Monday and must contain January 4. Therefore, the ISO year corresponding to the date in early January or late December may be different from the calendar year. For details, see **week**.

```
gaussdb=# SELECT EXTRACT(ISOYEAR FROM DATE '2006-01-01');
 date_part
-----------
      2005
(1 row)
gaussdb=# SELECT EXTRACT(WEEK FROM TIMESTAMP '2006-01-01 00:00:40');
 date_part
-----------
        52
(1 row)
gaussdb=# SELECT EXTRACT(ISOYEAR FROM DATE '2006-01-02');
 date_part
-----------
      2006
(1 row)
gaussdb=# SELECT EXTRACT(WEEK FROM TIMESTAMP '2006-01-02 00:00:40');
 date_part
-----------
         1
(1 row)
```

- microseconds

  The second field, including fractional parts, is multiplied by 1,000,000.

```
gaussdb=# SELECT EXTRACT(MICROSECONDS FROM TIME '17:12:28.5');
 date_part
-----------
  28500000
(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- millennium

  Millennium.

  Years in the 1900s are in the second millennium. The third millennium started from January 1, 2001.

  ```
  gaussdb=# SELECT EXTRACT(MILLENNIUM FROM TIMESTAMP '2001-02-16 20:38:40');
   date_part
  -----------
           3
  (1 row)
  ```

- milliseconds

  Second field, including fractional parts, is multiplied by 1000. Note that this includes full seconds.

  ```
  gaussdb=# SELECT EXTRACT(MILLISECONDS FROM TIME '17:12:28.5');
   date_part
  -----------
       28500
  (1 row)
  ```

- minute

  Minute (0–59).

  ```
  gaussdb=# SELECT EXTRACT(MINUTE FROM TIMESTAMP '2001-02-16 20:38:40');
   date_part
  -----------
          38
  (1 row)
  ```

- month

  If **source** is **timestamp**, it represents the number of the month within the year (1–12).

  ```
  gaussdb=# SELECT EXTRACT(MONTH FROM TIMESTAMP '2001-02-16 20:38:40');
   date_part
  -----------
           2
  (1 row)
  ```

  If **source** is **interval**, it represents the number of months, modulo 12 (0–11).

  ```
  gaussdb=# SELECT EXTRACT(MONTH FROM INTERVAL '2 years 13 months');
   date_part
  -----------
           1
  (1 row)
  ```

- quarter

  The quarter of the year (1–4) that the day is in.

  ```
  gaussdb=# SELECT EXTRACT(QUARTER FROM TIMESTAMP '2001-02-16 20:38:40');
   date_part
  -----------
           1
  (1 row)
  ```

- second

  The seconds field, including fractional parts (0–59).

  ```
  gaussdb=# SELECT EXTRACT(SECOND FROM TIME '17:12:28.5');
   date_part
  -----------
        28.5
  (1 row)
  ```

- timezone

  Time zone offset from UTC, measured in seconds. Positive values correspond to time zones east of UTC, negative values to zones west of UTC.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- timezone_hour

  Hour component of the time zone offset.

- timezone_minute

  Minute component of the time zone offset.

- week

  Week number of the date in the year to which the date belongs. By definition (ISO 8601), the first week of a year contains January 4 of that year. (The ISO-8601 week starts on Monday.) In other words, the first Thursday of a year is in week 1 of that year.

  Because of this, it is possible for early January dates to be part of the 52nd or 53rd week of the previous year, and late December dates to be part of the 1st week of the next year. For example, 2006-01-01 is the 52nd week of 2005, and 2006-01-02 is the first week of 2006. You are advised to use the columns **isoyear** and **week** together to ensure consistency.

  ```
  gaussdb=# SELECT EXTRACT(ISOYEAR FROM DATE '2006-01-01');
   date_part
  -----------
       2005
  (1 row)
  gaussdb=# SELECT EXTRACT(WEEK FROM TIMESTAMP '2006-01-01 00:00:40');
   date_part
  -----------
         52
  (1 row)
  gaussdb=# SELECT EXTRACT(ISOYEAR FROM DATE '2006-01-02');
   date_part
  -----------
       2006
  (1 row)
  gaussdb=# SELECT EXTRACT(WEEK FROM TIMESTAMP '2006-01-02 00:00:40');
   date_part
  -----------
          1
  (1 row)
  ```

- year

  Year field.

  ```
  gaussdb=# SELECT EXTRACT(YEAR FROM TIMESTAMP '2001-02-16 20:38:40');
   date_part
  -----------
       2001
  (1 row)
  ```

  NOTE

  When **sql_compatibility** is set to **'ORA'**:

  - When the GUC parameter **mapping_date_to_datea** is set to **on**, the database parses the date type in the input parameter to the datea type. In this case, the unit can only be year, month, or day. If other units are specified, an error is reported.
  - When the input parameter is of the datea type, the unit can only be year, month, or day regardless of whether the GUC parameter **mapping_date_to_datea** is set to **on** or **off**. If other units are specified, an error is reported.

date_part

date_part('field', source)

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description: The date_part function is implemented based on the traditional Ingres function (this function is equivalent to the SQL standard function extract).

Parameter: The **field** parameter is a character string instead of a name. The valid field names are the same as those for **extract**. For details, see **EXTRACT**.

Example:

```
gaussdb=# SELECT date_part('day', TIMESTAMP '2001-02-16 20:38:40');
 date_part
-----------
        16
(1 row)
gaussdb=# SELECT date_part('hour', INTERVAL '4 hours 3 minutes');
 date_part
-----------
         4
(1 row)
```

Table 1-69 specifies the formats for formatting date and time values.

Table 1-69 Formats for formatting date and time

Category	Format	Description
Hour	HH	Hour of a day (01–12).
	HH12	Hour of a day (01–12).
	HH24	Hour of a day (00–23).
Minute	MI	Minute (00–59).
Second	SS	Second (00–59).
	FF	Microsecond (000000–999999).
	FF1	Microsecond (0–9).
	FF2	Microsecond (00–99).
	FF3	Microsecond (000–999).
	FF4	Microsecond (0000–9999).
	FF5	Microsecond (00000–99999).
	FF6	Microsecond (000000–999999).
	SSSSS	Second after midnight (0–86399).
Morning and afternoon	AM or A.M.	Morning identifier
	PM or P.M.	Afternoon identifier
Year	Y,YYY	Year with a comma (with four digits or more)
	SYYYY	Year with four digits BC
	YYYY	Year (with four digits or more)
	YYY	Last three digits of a year

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Category	Format	Description
	YY	Last two digits of a year
	Y	Last one digit of a year
	IYYY	ISO year (with four digits or more)
	IYY	Last three digits of an ISO year
	IY	Last two digits of an ISO year
	I	Last one digit of an ISO year
	RR	Last two digits of a year (A year of the 20th century can be stored in the 21st century.)
	RRRR	Capable of receiving a year with four digits or two digits. If there are 2 digits, the value is the same as the returned value of RR. If there are 4 digits, the value is the same as YYYY.
	• BC or B.C. • AD or A.D.	Era indicator (**BC** or **AD**).
Month	MONTH	Full name of a month in uppercase. (9 characters are filled in if the value is empty.)
	MON	Month in abbreviated format in uppercase (with three characters).
	MM	Month number (01–12).
	RM	Month in Roman numerals (I–XII; I=JAN) and uppercase.
Day	DAY	Full name of a date in uppercase. (9 characters are filled in if the value is empty.)
	DY	Day in abbreviated format in uppercase (with three characters).
	DDD	Day of a year (001–366).
	DD	Day of a month (01–31).
	D	Day of a week (1–7), where **1** represents Sunday.
Week	W	Week of a month (1–5). (The first week starts from the first day of the month.)
	WW	Week of a year (1–53). (The first week starts from the first day of the year.)
	IW	Week in an ISO year (The first Thursday is in the first week.)

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Category	Format	Description
Century	CC	Century (with two digits) (The 21st century starts from 2001-01-01.)
Julian date	J	Julian day (number of days after January 1, 4713 B.C.)
Quarter	Q	Quarter

When **a_format_version** is set to **10c** and **a_format_dev_version** is set to **s1** in an ORA-compatible database, the date and time will be formatted in the specified format.

Table 1-70 New formats for formatting date and time

Item	Format	Description
Century	SCC	Century. A hyphen (-) will be displayed before BC years.
Year	SYYYY	Returns a numeric year. A hyphen (-) will be displayed before BC years.
	RR	Returns the two-digit year of a date.
	RRRR	Returns the four-digit year of a date.
	YEAR	Returns the year of the character type.
	SYEAR	Returns the year of the character type. A hyphen (-) will be displayed before BC years.
Date Format	DL	Returns the date in the specified long date format.
	DS	Returns the date in the specified short date format.
	TS	Returns the time in the specified time format.
Second	FF7	Microsecond (0000000–9999990).
	FF8	Microsecond (00000000–99999900).
	FF9	Microsecond (000000000–999999000).

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- When **sql_compatibility** is set to **'ORA'**:
  - When the GUC parameter **mapping_date_to_datea** is set to **on**, the database parses the date type in the input parameter to the datea type. In this case, the format can only be year, month, or day. If other formats are specified, an error is reported.
  - When the input parameter is of the datea type, the format can only be year, month, or day regardless of whether the GUC parameter **mapping_date_to_datea** is set to **on** or **off**. If other formats are specified, an error is reported.
- In the scenario where this function is in an ORA-compatible database, the value of **a_format_version** is **10c**, and that of **a_format_dev_version** is **s1**:
  - The **to_date** and **to_timestamp** functions support the FX pattern (the input strictly corresponds to a pattern) and the X pattern (decimal point).
  - The input pattern can appear only once, indicating that the patterns of the same information cannot appear at the same time. For example, SYYYY and BC cannot be used together.
  - Formats are case-insensitive.
  - You are advised to use a separator between the input and the format. Otherwise, the behavior may not be compatible with database O.
  - GaussDB uses a strict matching policy. Each format element in the **fmt** string must have a corresponding content in the input string. Otherwise, an error is reported. Oracle Database uses a loose matching policy for optional elements (such as FF) in the format model when converting a string to a date. If the input string does not contain the optional elements, the system automatically skips them and continues to match subsequent elements. This difference affects the behavior of the to_date, to_timestamp, and to_timestamp_tz functions when **fmt** is not specified or contains optional format elements such as FF.
- In the table, the rules for RR to calculate years are as follows:
  - If the range of the input two-digit year is between 00 and 49:

    If the last two digits of the current year are between 00 and 49, the first two digits of the returned year are the same as the first two digits of the current year.

    If the last two digits of the current year are between 50 and 99, the first two digits of the returned year are equal to the first two digits of the current year plus 1.
  - If the range of the input two-digit year is between 50 and 99:

    If the last two digits of the current year are between 00 and 49, the first two digits of the returned year are equal to the first two digits of the current year minus 1.

    If the last two digits of the current year are between 50 and 99, the first two digits of the returned year are the same as the first two digits of the current year.

time_window

time_window(window_width interval, time timestamptz, [origin timestamptz])

Description: Performs modulo operation on the difference between the specified timestamp column and the original timestamp based on the specified time window size.

Parameters: See **Table 1-71**.

Return type: timestamptz

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 1-71 time_window parameters

Parameter	Type	Description
window_width	interval	Time window.
time	timestamp(tz)	Timestamp column.
origin	timestamp(tz)	Original timestamp. The default value is **2000-01-03 00:00:00**.

NOTE

- The unit of **window_width** can be microsecond, millisecond, second, minute, hour, day, week, or a positive number. The default unit is day.
- The values of **window_width** and **time** are correct and cannot be empty.

Example:

```
gaussdb=# SELECT
    time_window(interval '1 min', time),
    time_window(interval '3 min', time,  '2019-07-11 00:02:05'::timestamptz)
        FROM
    (VALUES ('2019-07-12 00:00:00'::timestamptz),
           ('2019-07-12 00:01:01'::timestamptz)) v(time);

     time_window       |      time_window
-------------------------+-------------------------
 2019-07-12 00:00:00+08 | 2019-07-11 23:59:05+08
 2019-07-12 00:01:00+08 | 2019-07-11 23:59:05+08
(2 rows)
```

1.6.9 Type Conversion Functions

Function Type Conversion

- cash_words(money)

  Description: Converts the money type into the text type and then outputs the result.

  Example:

  ```
  gaussdb=# SELECT cash_words('1.23');
              cash_words
  -----------------------------------
   One dollar and twenty three cents
  (1 row)
  ```

- convert(expr, type)

  Description: Converts **expr** into the type specified by **type**.

  Parameters: The first parameter is an arbitrary value, and the second parameter is a type name.

  Return type: the input type.

  Example:

  ```
  gaussdb=# SELECT convert(12.5, text);
   text
  ------
   12.5
  (1 row)
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

> **NOTE**
>
> This function takes effect only in MySQL-compatible mode.

- cast(x as y [DEFAULT z ON CONVERSION ERROR][,fmt])

  Description: Converts **x** into the type specified by **y**. When **sql_compatibility** is **'MYSQL'**, setting **b_format_version** to **'5.7'** and **b_format_dev_version** to **'s1'** will result in **x** being converted into the varchar type when **y** is of the char type.

  Parameters:

  – **x** represents the data to be converted. Its type and value must be convertible into the target type **y**.

  – DEFAULT z ON CONVERSION ERROR, an optional syntax for the first parameter, specifies that if **x** fails to be converted into the type specified by **y**, **z** will be converted into that type instead.

  – The optional parameter **fmt** can be specified when **y** is any of the following types:

    ▪ int1/int2/int4/int8/int16/float4/float8/numeric: The **fmt** parameter has the same effect as the to_number(expr [,fmt]) function.

    ▪ date/timestamp/timestamp with time zone/datea (effective only in ORA-compatible mode): The **fmt** parameter has the same effect as the to_date(string [,fmt]), to_timestamp(string [,fmt]), and to_timestamp_tz(string [,fmt]) functions.

  Example:

```
gaussdb=# SELECT cast('22-oct-1997' as timestamp);
     timestamp
---------------------
 1997-10-22 00:00:00
(1 row)

gaussdb=# SELECT cast('22-ocX-1997' as timestamp DEFAULT '22-oct-1997' ON CONVERSION
ERROR, 'DD-Mon-YYYY');
     timestamp
---------------------
 1997-10-22 00:00:00
(1 row)

gaussdb=# CREATE DATABASE gaussdb_m  WITH dbcompatibility  'MYSQL';
gaussdb=# \c gaussdb_m
-- Set compatible version control parameters.
gaussdb_m=# SET b_format_version='5.7';
gaussdb_m=# SET b_format_dev_version='s1';
gaussdb_m=# SELECT cast('aaa' as char);
 varchar
---------
 aaa
(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- This function supports the optional syntax DEFAULT z ON CONVERSION ERROR and optional parameter **fmt** when **a_format_version** is **10c** and **a_format_dev_version** is **s1**.
- In ORA-compatible databases where the **mapping_date_to_datea** parameter is enabled and **fmt** is not specified, **x** will be converted into the datea type based on **nls_date_format**.
- In ORA-compatible databases where the **mapping_date_to_datea** parameter is enabled and **fmt** is not specified, the datea type will be converted into the character type based on **nls_date_format**.
- When **y** is of the datea type, **x** will only accept the following types: text, bpchar, varchar, clob, nvarchar2, timestamp, and timestamp with time zone.

- cast(x AS {SIGNED | UNSIGNED} [INT | INTEGER])

  Description: Converts **x** into the BIGINT SIGNED or BIGINT UNSIGNED type.

  Parameter: **x** represents the data to be converted. Its type and value must be convertible into the target type INT.

  Return type: BIGINT SIGNED or BIGINT UNSIGNED.

  Example:

```
gaussdb=# SELECT CAST(12 AS UNSIGNED);
 uint8
-------
 12
(1 row)
```

- hextoraw(text)

  Description: Converts a hexadecimal character string into the raw type.

  Return type: raw.

  Example:

```
gaussdb=# SELECT hextoraw('7D');
 hextoraw
----------
 7D
(1 row)
```

- numtoday(numeric)

  Description: Converts a numeric value into a timestamp in the specified format.

  Return type: timestamp.

  Example:

```
gaussdb=# SELECT numtoday(2);
 numtoday
----------
 2 days
(1 row)
```

- rawtohex(string)

  Description: Converts a string in binary format into hexadecimal format. The result is the ASCII code of the input characters in hexadecimal format.

  Return type: varchar.

  Example:

```
gaussdb=# SELECT rawtohex('1234567');
    rawtohex
----------------
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
 31323334353637
(1 row)
```

- to_blob(raw)

  Description: Converts the RAW type into the BLOB type.

  Return type: blob.

  Example:

  ```
  gaussdb=# SELECT to_blob('0AADD343CDBBD'::RAW(10));
     to_blob
  ----------------
   00AADD343CDBBD
  (1 row)
  ```

  NOTE

  The to_blob function is supported when **a_format_version** is **10c** and **a_format_dev_version** is **s2**.

- to_bigint(varchar)

  Description: Converts the character type into the bigint type.

  Return type: bigint.

  Example:

  ```
  gaussdb=# SELECT to_bigint('123364545554455');
     to_bigint
  ----------------
   123364545554455
  (1 row)
  ```

- to_binary_double(expr)

  Description: Converts **expr** into the float8 type.

  Parameter: **expr** accepts numeric values of the number, float4, or float8 type, as well as character strings that can be implicitly converted into numeric values.

  Return type: float8.

  Example:

  ```
  gaussdb=# SELECT to_binary_double('12345678');
   to_binary_double
  ------------------
          12345678
  (1 row)
  ```

  NOTE

  The to_binary_double function is supported when **a_format_version** is **10c** and **a_format_dev_version** is **s2**.

- to_binary_double(expr, fmt)

  Description: Converts **expr** into the float8 type in the format specified by **fmt**.

  Parameters: **expr** and **fmt** accept character strings of the char, nchar, varchar2, or nvarchar2 type. **expr** also accepts numeric values that can be implicitly converted into character strings.

  Return type: float8.

  Example:

  ```
  gaussdb=# SELECT to_binary_double('1,2,3', '9,9,9');
   to_binary_double
  ------------------
                123
  (1 row)
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

> NOTE
>
> The to_binary_double function is supported when **a_format_version** is **10c** and **a_format_dev_version** is **s2**.

- to_binary_double(expr DEFAULT return_value ON CONVERSION ERROR)

  Description: Converts **expr** into the float8 type. On failure, the default value **return_value** will be returned.

  Parameter: **expr** accepts numeric values of the number, float4, or float8 type, as well as numeric values that can be implicitly converted into character strings. If **expr** is not a numeric or string type, an error will be reported.

  Return type: float8.

  Example:

```
gaussdb=# SELECT to_binary_double(1e2 DEFAULT 12 ON CONVERSION ERROR);
 to_binary_double
------------------
              100
(1 row)

gaussdb=# SELECT to_binary_double('aa' DEFAULT 12 ON CONVERSION ERROR);
 to_binary_double
------------------
               12
(1 row)
```

> NOTE
>
> The to_binary_double function is supported when **a_format_version** is **10c** and **a_format_dev_version** is **s2**.

- to_binary_double(expr DEFAULT return_value ON CONVERSION ERROR, fmt)

  Description: Converts **expr** into the float8 type in the format specified by **fmt**. On failure, the default value **return_value** will be returned.

  Parameters: **expr** and **fmt** accept character strings of the char, nchar, varchar2, or nvarchar2 type. **expr** also accepts numeric values that can be implicitly converted into character strings.

  Return type: float8.

  Example:

```
gaussdb=# SELECT to_binary_double('12-' DEFAULT 10 ON CONVERSION ERROR, '99S');
 to_binary_double
------------------
              -12
(1 row)

gaussdb=# SELECT to_binary_double('aa-' DEFAULT 12 ON CONVERSION ERROR, '99S');
 to_binary_double
------------------
               12
(1 row)
```

> NOTE
>
> The to_binary_double function is supported when **a_format_version** is **10c** and **a_format_dev_version** is **s2**.

- to_binary_float(expr)

  Description: Converts **expr** into the float4 type.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter: **expr** accepts numeric values of the number, float4, or float8 type, as well as character strings that can be implicitly converted into numeric values.

Return type: float4.

Example:

```
gaussdb=# SELECT to_binary_float('12345678');
 to_binary_float
------------------
     1.23457e+07
(1 row)
```

NOTE

The to_binary_float function is supported when **a_format_version** is **10c** and **a_format_dev_version** is **s2**.

- to_binary_float(expr, fmt)

  Description: Converts **expr** into the float4 type in the format specified by **fmt**.

  Parameters: **expr** and **fmt** accept character strings of the char, nchar, varchar2, or nvarchar2 type. **expr** also accepts numeric values that can be implicitly converted into character strings.

  Return type: float4.

  Example:

```
gaussdb=# SELECT to_binary_float('1,2,3', '9,9,9');
 to_binary_float
------------------
             123
(1 row)
```

NOTE

The to_binary_float function is supported when **a_format_version** is **10c** and **a_format_dev_version** is **s2**.

- to_binary_float(expr DEFAULT return_value ON CONVERSION ERROR)

  Description: Converts **expr** into the float4 type. On failure, the default value **return_value** will be returned.

  Parameter: **expr** accepts numeric values of the number, float4, or float8 type, as well as numeric values that can be implicitly converted into character strings. If **expr** is not a numeric or string type, an error will be reported.

  Return type: float4.

  Example:

```
gaussdb=# SELECT to_binary_float(1e2 DEFAULT 12 ON CONVERSION ERROR);
 to_binary_float
------------------
             100
(1 row)

gaussdb=# SELECT to_binary_float('aa' DEFAULT 12 ON CONVERSION ERROR);
 to_binary_float
------------------
              12
(1 row)
```

NOTE

The to_binary_float function is supported when **a_format_version** is **10c** and **a_format_dev_version** is **s2**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- to_binary_float(expr DEFAULT return_value ON CONVERSION ERROR, fmt)

  Description: Converts **expr** into the float4 type in the format specified by **fmt**. On failure, the default value **return_value** will be returned.

  Parameters: **expr** and **fmt** accept character strings of the char, nchar, varchar2, or nvarchar2 type. **expr** also accepts numeric values that can be implicitly converted into character strings.

  Return type: float4.

  Example:

```
gaussdb=# SELECT to_binary_float('12-' DEFAULT 10 ON CONVERSION ERROR, '99S');
 to_binary_float
------------------
            -12
(1 row)

gaussdb=# SELECT to_binary_float('aa-' DEFAULT 12 ON CONVERSION ERROR, '99S');
 to_binary_float
------------------
             12
(1 row)
```

  NOTE

  The to_binary_float function is supported when **a_format_version** is **10c** and **a_format_dev_version** is **s2**.

- to_char(datetime/interval [, fmt])

  Description: Converts a DATETIME or INTERVAL value of the DATE, DATEA (effective only in ORA-compatible mode), TIMESTAMP, TIMESTAMP WITH TIME ZONE, or TIMESTAMP WITH LOCAL TIME ZONE type into the TEXT type in the format specified by **fmt** (a template used to format date and time values).

  – The optional parameter **fmt** accepts the following types: date, time, week, quarter, and century. Each type comes with its own distinct template. These templates can be combined as needed. Commonly used templates include HH, MI, SS, YYYY, MM, and DD. For details, see **Table 1-69**.

  – **fmt** can include a modifier, typically "FM", to help identify leading zeros or trailing spaces.

  Return type: text.

  Example:

```
gaussdb=# SELECT to_char(current_timestamp,'HH12:MI:SS');
 to_char
----------
 10:19:26
(1 row)
gaussdb=# SELECT to_char(current_timestamp,'FMHH12:FMMI:FMSS');
 to_char
----------
 10:19:46
(1 row)
-- When mapping_date_to_datea is enabled in ORA-compatible mode, current_date returns the DATEA type.
test_db_a=# SELECT to_char(current_date);
  to_char
------------
 05-11-2024
(1 row)
test_db_a=# SELECT to_char(current_date, 'YYYY-MM-DD HH24:MI:SS AD');
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
      to_char
------------------------
 2024-11-05 14:07:21 AD
(1 row)
```

> **NOTE**
>
> In ORA-compatible databases where the **mapping_date_to_datea** parameter is enabled and **fmt** is not specified, the datea type will be converted into the text type based on **nls_date_format**.

- to_char(double precision/real, text)

  Description: Converts a floating-point value into a character string in the specified format.

  Return type: text.

  Example:

```
gaussdb=# SELECT to_char(125.8::real, '999D99');
 to_char
---------
  125.80
(1 row)
```

- to_char(numeric/smallint/integer/bigint/double precision/real[, fmt])

  Description: Converts an integer or floating-point value into a character string in the specified format.

  - The optional parameter **fmt** accepts the following types: decimal character, digit grouping separator, plus/minus sign, and currency symbol. Each type comes with its own distinct template. These templates can be combined as needed. Commonly used templates include 9, 0, thousands separator (,), and decimal point (.). For details, see **Table 1-72**.
  - A template can include a modifier like "FM". Be aware that if a 0 is specified in the template, "FM" will not be able to identify the 0 in the output.
  - To convert an integer value into a hexadecimal string, you can use the template X or x.

  Return type: text.

  Example:

```
gaussdb=# SELECT to_char(1485,'9,999');
 to_char
---------
  1,485
(1 row)
gaussdb=# SELECT to_char( 1148.5,'9,999.999');
  to_char
------------
  1,148.500
(1 row)
gaussdb=# SELECT to_char(148.5,'990999.909');
   to_char
-------------
    0148.500
(1 row)
gaussdb=# SELECT to_char(123,'XXX');
 to_char
---------
   7B
(1 row)
```

Table 1-72 Formats for the number type

Format	Description
, (comma)	Returns the digit grouping (thousands) separator.
. (period)	Returns the decimal point.
$	Returns the US dollar sign ($) in the specified position.
0	Returns leading zeros.
9	Returns a value with the specified number of digits.
B	Returns blanks when the integer part is 0.
C	Returns the currency symbol (depending on the locale settings).
D	Returns the decimal character (depending on the locale settings).
EEEE	Returns a value in scientific notation.
G	Returns the digit grouping separator (depending on the locale settings).
L	Returns the currency symbol (depending on the locale settings).
MI	Returns the minus sign in the specified position (if the number is less than 0).
PR	Returns a negative value in <angle brackets>.
RN	Returns a Roman numeral (for any input between 1 and 3,999).
S	Returns a signed number (depending on the locale settings).
TM	Returns a value in standard or scientific notation.
TM9	Returns a value in standard or scientific notation.
TME	Returns a value in standard or scientific notation.
U	Returns the dual currency symbol (depending on the locale settings).
V	Shifts the specified number of digits (decimal).

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Format	Description
PL	Returns the plus sign in the specified position (if the number is greater than 0).
SG	Returns the plus/minus sign in the specified position.
TH / th	Returns the suffix for an ordinal number.

NOTE

This function supports the $, C, TM, TM9, TME, and U formats when **a_format_version** is **10c** and **a_format_dev_version** is **s1**. However, it does not support TH, PL, or SG.

- to_char(interval, text)

  Description: Converts a time interval value into a character string in the specified format.

  Return type: text.

  Example:

```
gaussdb=# SELECT to_char(interval '15h 2m 12s', 'HH24:MI:SS');
 to_char
----------
 15:02:12
(1 row)
```

- to_char(integer, text)

  Description: Converts an integer value into a character string in the specified format.

  Return type: text.

  Example:

```
gaussdb=# SELECT to_char(125, '999');
 to_char
---------
  125
(1 row)
```

- to_char(set)

  Description: Converts a value of the SET type into a character string. The SET type is currently unsupported in distributed mode.

  Return type: text.

- to_char(numeric, text)

  Description: Converts a numeric value into a character string in the specified format.

  Return type: text.

  Example:

```
gaussdb=# SELECT to_char(-125.8, '999D99S');
 to_char
---------
 125.80-
(1 row)
```

- to_char(string)

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description: Converts the CHAR, VARCHAR, VARCHAR2, or CLOB type into the TEXT type. If the value to be converted from the CLOB type exceeds the acceptable value range for the target type, an error will be reported.

Return type: text.

Example:

```
gaussdb=# SELECT to_char('01110');
 to_char
---------
 01110
(1 row)
```

- to_nvarchar2(numeric)

  Description: Converts the input into the nvarchar2 type.

  Return type: nvarchar2.

- to_char(timestamp, text)

  Description: Converts a timestamp value into a character string in the specified format.

  Return type: text.

  Example:

  ```
  gaussdb=# SELECT to_char(current_timestamp, 'HH12:MI:SS');
   to_char
  ----------
   10:55:59
  (1 row)
  ```

  NOTE

  - When **a_format_version** is **10c** and **a_format_dev_version** is **s1**, the to_char function will report an error for any incorrect **fmt**.
  - In non-compatible mode, the to_char function will output any unmatched digit in the given **fmt** value as it is. For example, if **fmt** is **FF10**, the function will convert based on the matched **FF1** and output the unmatched digit **0** as it is.

- to_nchar(datetime/interval [, fmt])

  Description: Converts a DATETIME or INTERVAL value of the DATE, DATEA (effective only in ORA-compatible mode), TIMESTAMP, TIMESTAMP WITH TIME ZONE, or TIMESTAMP WITH LOCAL TIME ZONE type into the TEXT type in the format specified by **fmt**.

  – The optional parameter **fmt** accepts the following types: date, time, week, quarter, and century. Each type comes with its own distinct template. These templates can be combined as needed. Commonly used templates include HH, MI, SS, YYYY, MM, and DD. For details, see **Table 1-69**.

  – A template can include a modifier, typically "FM", to help identify leading zeros or trailing spaces.

  Return type: text.

  Example:

  ```
  gaussdb=# SELECT to_nchar(current_timestamp,'HH12:MI:SS');
   to_nchar
  ----------
   10:19:26
  (1 row)
  gaussdb=# SELECT to_nchar(current_timestamp,'FMHH12:FMMI:FMSS');
   to_nchar
  ----------
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
 10:19:46
(1 row)
```

NOTE

- The to_nchar function is supported when **a_format_version** is **10c** and **a_format_dev_version** is **s2**.
- In ORA-compatible databases where the **mapping_date_to_datea** parameter is enabled and **fmt** is not specified, the datea type will be converted into the text type based on **nls_date_format**.

- to_nchar(double precision/real, text)

  Description: Converts a floating-point value into a character string in the specified format.

  Return type: text.

  Example:

```
gaussdb=# SELECT to_nchar(125.8::real, '999D99');
 to_nchar
----------
  125.80
(1 row)
```

- to_nchar(numeric/smallint/integer/bigint/double precision/real[, fmt])

  Description: Converts an integer or floating-point value into a character string in the specified format.

  – The optional parameter **fmt** accepts the following types: decimal character, digit grouping separator, plus/minus sign, and currency symbol. Each type comes with its own distinct template. These templates can be combined as needed. Commonly used templates include 9, 0, thousands separator (,), and decimal point (.). For details, see **Table 1-72**.

  – A template can include a modifier like "FM". Be aware that if a 0 is specified in the template, "FM" will not be able to identify the 0 in the output.

  – To convert an integer value into a hexadecimal string, you can use the template X or x.

  Return type: text.

  Example:

```
gaussdb=# SELECT to_nchar(1485,'9,999');
 to_nchar
----------
  1,485
(1 row)
gaussdb=# SELECT to_nchar( 1148.5,'9,999.999');
  to_nchar
------------
  1,148.500
(1 row)
gaussdb=# SELECT to_nchar(148.5,'990999.909');
   to_nchar
-------------
    0148.500
(1 row)
gaussdb=# SELECT to_nchar(123,'XXX');
 to_nchar
----------
   7B
(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

> **NOTE**
>
> This function takes effect only in ORA-compatible mode (**sql_compatibility = 'ORA'**) when **a_format_version** is **10c** and **a_format_dev_version** is **s2**. When the parameter is enabled, the $, C, TM, TM9, TME, and U formats are supported. However, it does not support TH, PL, or SG.

- to_nchar(interval, text)

  Description: Converts a time interval value into a character string in the specified format.

  Return type: text.

  Example:

```
gaussdb=# SELECT to_nchar(interval '15h 2m 12s', 'HH24:MI:SS');
 to_nchar
----------
 15:02:12
(1 row)
```

- to_nchar(integer, text)

  Description: Converts an integer value into a character string in the specified format.

  Return type: text.

  Example:

```
gaussdb=# SELECT to_nchar(125, '999');
 to_nchar
----------
  125
(1 row)
```

- to_nchar(set)

  Description: Converts a value of the SET type into a character string. The SET type is currently unsupported in distributed mode.

  Return type: text.

- to_nchar(numeric, text)

  Description: Converts a numeric value into a character string in the specified format.

  Return type: text.

  Example:

```
gaussdb=# SELECT to_nchar(-125.8, '999D99S');
 to_nchar
----------
 125.80-
(1 row)
```

- to_nchar(string)

  Description: Converts the CHAR, VARCHAR, VARCHAR2, or CLOB type into the TEXT type. If the value to be converted from the CLOB type exceeds the acceptable value range for the target type, an error will be reported.

  Return type: text.

  Example:

```
gaussdb=# SELECT to_nchar('01110');
 to_nchar
----------
 01110
(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- to_nchar(timestamp, text)

  Description: Converts a timestamp value into a character string in the specified format.

  Return type: text.

  Example:

```
gaussdb=# SELECT to_nchar(current_timestamp, 'HH12:MI:SS');
 to_nchar
----------
 10:55:59
(1 row)
```

  > NOTE
  >
  > The to_nchar function is supported when **a_format_version** is **10c** and **a_format_dev_version** is **s2**.

- to_clob(char/nchar/varchar/varchar2/nvarchar2/text/raw)

  Description: Converts the RAW type or a text character set type (CHAR, NCHAR, VARCHAR, VARCHAR2, NVARCHAR2, or TEXT) into the CLOB type.

  Return type: CLOB.

  Example:

```
gaussdb=# SELECT to_clob('ABCDEF'::RAW(10));
 to_clob
---------
 ABCDEF
(1 row)
gaussdb=# SELECT to_clob('hello111'::CHAR(15));
 to_clob
----------
 hello111
(1 row)
gaussdb=# SELECT to_clob('gauss123'::NCHAR(10));
 to_clob
----------
 gauss123
(1 row)
gaussdb=# SELECT to_clob('gauss234'::VARCHAR(10));
 to_clob
----------
 gauss234
(1 row)
gaussdb=# SELECT to_clob('gauss345'::VARCHAR2(10));
 to_clob
----------
 gauss345
(1 row)
gaussdb=# SELECT to_clob('gauss456'::NVARCHAR2(10));
 to_clob
----------
 gauss456
(1 row)
gaussdb=# SELECT to_clob('World222!'::TEXT);
  to_clob
-----------
 World222!
(1 row)
```

- to_date(text)

  Description: Converts a text value into a timestamp in the specified format. If **a_format_version** is set to **10c**, **a_format_dev_version** is set to **s1**, and **mapping_date_to_datea** is set to **off**, the conversion is performed based on the format specified by the **nls_timestamp_format** parameter. If

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

a_format_version and **a_format_dev_version** are not specified, the conversion is performed based on the fixed format **'YYYY-MM-DD HH24:MI:SS'**.

- Format 1: Date without separators, for example, 20150814. The value must contain the complete year, month, and day.
- Format 2: Date with separators, for example, 2014-08-14. The separator can be any non-digit character.

Return type: timestamp without time zone or datea (effective only in ORA-compatible mode).

Example:

```
-- In ORA-compatible mode, ensure that the input text type adheres to nls_date_format. Otherwise, an error will be reported.
gaussdb=# SELECT to_date('2015-08-14');
      to_date
---------------------
 2015-08-14 00:00:00
(1 row)
```

NOTE

- When **sql_compatibility** is **'ORA'** and the GUC parameter **mapping_date_to_datea** is **on**, this function returns a value of the datea type.
- The to_date function is of the stable rather than immutable type. Therefore, it cannot be used as generated columns/expression indexes.

- to_date(text, text)

  Description: Converts a character-string value into a date in the specified format.

  Return type: timestamp without time zone or datea (effective only in ORA-compatible mode).

  Example:

  ```
  gaussdb=# SELECT to_date('05 Dec 2000', 'DD Mon YYYY');
        to_date
  ---------------------
   2000-12-05 00:00:00
  (1 row)
  ```

  NOTE

  - When **sql_compatibility** is **'ORA'** and the GUC parameter **mapping_date_to_datea** is **on**, this function returns a value of the datea type.
  - The to_date function is of the stable rather than immutable type. Therefore, it cannot be used as generated columns/expression indexes.

- to_date(text [DEFAULT return_value ON CONVERSION ERROR [, fmt]])

  Description: Converts **text** into the DATE type in the format specified by **fmt**. If **fmt** is not specified, the conversion will adhere to **nls_timestamp_format** instead, provided that **a_format_version** is **10c** and **a_format_dev_version** is **s1**. However, if **a_format_version** and **a_format_dev_version** are not specified, the conversion will default to the fixed format **'YYYY-MM-DD HH24:MI:SS'**.

  Parameters:

  - **text**: any expression that can be calculated as CHAR, VARCHAR2, NCHAR, NVARCHAR2, or TEXT string. If the input is null, the function will return null.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **DEFAULT return_value ON CONVERSION ERROR**: This optional parameter specifies that **return_value** will be returned when **text** fails to be converted into the DATE type, provided that **a_format_version** is **10c** and **a_format_dev_version** is **s1**. **return_value** can be an expression or a bind variable that must be convertible into the CHAR, VARCHAR2, NCHAR, NVARCHAR2, or TEXT type. It can also be null. The method of converting **return_value** into the DATE type is the same as converting **text** into the DATE type. If **return_value** fails to be converted into the DATE type, the function will report an error.
- **fmt**: optional parameter. It specifies the date and time format for **string**. If it is not specified, **text** must adhere to the default date format. However, if **fmt** is set to **J**, **text** must be an integer.

Return type: timestamp without time zone or datea (effective only in ORA-compatible mode).

Example:

```
-- In ORA-compatible mode, if the input consists solely of a text type, ensure that the text type
adheres to nls_date_format. Otherwise, an error will be reported.
gaussdb=# SELECT to_date('2015-08-14');
      to_date
---------------------
 2015-08-14 00:00:00
(1 row)
gaussdb=# SELECT to_date('05 Dec 2000', 'DD Mon YYYY');
      to_date
---------------------
 2000-12-05 00:00:00
(1 row)
gaussdb=# SET a_format_version='10c';
SET
gaussdb=# SET a_format_dev_version='s1';
SET
gaussdb=# SHOW nls_timestamp_format;
   nls_timestamp_format
----------------------------
 DD-Mon-YYYY HH:MI:SS.FF AM
(1 row)
gaussdb=# SELECT to_date('12-jan-2022' DEFAULT '12-apr-2022' ON CONVERSION ERROR);
      to_date
---------------------
 2022-01-12 00:00:00
(1 row)
gaussdb=# SELECT to_date('12-ja-2022' DEFAULT '12-apr-2022' ON CONVERSION ERROR);
      to_date
---------------------
 2022-04-12 00:00:00
(1 row)
gaussdb=# SELECT to_date('2022-12-12' DEFAULT '2022-01-01' ON CONVERSION ERROR, 'yyyy-mm-
dd');
      to_date
---------------------
 2022-12-12 00:00:00
(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- When **a_format_version** is **10c** and **a_format_dev_version** is **s1**, inputting a calendar year above 9999 does not necessarily trigger an error. For example, executing to_date('99999-12-12', 'YYYY-MM-DD HH24:MI:SS') will yield 9999-09-12 12:00:00. Any numbers that come after 9999 (the maximum allowed year) will be interpreted as the next **fmt**. This limitation also extends to the to_timestamp function.
- When **sql_compatibility** is **'ORA'** and the GUC parameter **mapping_date_to_datea** is **on**, this function returns a value of the DATEA type. In this case, to_date converts **text** into the DATEA type in the format specified by **fmt**. If **fmt** is not specified, the conversion will adhere to **nls_date_format** instead.
- The to_date function is of the stable rather than immutable type. Therefore, it cannot be used as generated columns/expression indexes.

- to_number(expr [, fmt])

  Description: Converts **expr** into the NUMBER type in the specified format. For details about type conversion formats, see **Table 1-75**. During hexadecimal-to-decimal conversion, only hexadecimal strings with a maximum of 16 bytes can be converted into unsigned numbers. It is important to note that the format value must contain only x or X characters. Otherwise, an error will be reported.

  Return type: number.

  Example:

```
gaussdb=# SELECT to_number('12,454.8-', '99G999D9S');
 to_number
-----------
  -12454.8
(1 row)
```

- to_number(text, text)

  Description: Converts a character-string value into a number in the specified format.

  Return type: numeric.

  Example:

```
gaussdb=# SELECT to_number('12,454.8-', '99G999D9S');
 to_number
-----------
  -12454.8
(1 row)
```

- to_number(expr [DEFAULT return_value ON CONVERSION ERROR [, fmt]])

  Description: Converts **expr** into a numeric value in the format specified by **fmt**. If **fmt** is not specified, **expr** must be directly convertible into a numeric value, such as '123' and '1e2'. For details about type conversion formats, see **Table 1-76**.

  Parameters:

  - **expr**: an expression that can be converted into a CHAR, VARCHAR2, NCHAR, NVARCHAR2, TEXT, INT, or FLOAT string. If the input is null, the function will return null.
  - **DEFAULT return_value ON CONVERSION ERROR**: This optional parameter specifies that **return_value** will be returned when **expr** fails to be converted into the numeric type, provided that **a_format_version** is **10c** and **a_format_dev_version** is **s1**. Similar to **expr**, **return_value** accepts any type that can be converted into a character string. Similar to

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

expr, **return_value** is converted based on **fmt**. If the conversion fails, the function will report an error.

– **fmt**: optional parameter. Specifies the conversion format of **expr**. If any input parameter is null, the function will return null.

Return type: numeric.

Example:

```
gaussdb=# SET a_format_version='10c';
gaussdb=# SET a_format_dev_version='s1';

gaussdb=# SELECT to_number('1e2');
 to_number
-----------
       100
(1 row)

gaussdb=# SELECT to_number('123.456');
 to_number
-----------
   123.456
(1 row)

gaussdb=# SELECT to_number('123', '999');
 to_number
-----------
       123
(1 row)

gaussdb=# SELECT to_number('123-', '999MI');
 to_number
-----------
      -123
(1 row)

gaussdb=# SELECT to_number('123' DEFAULT '456-' ON CONVERSION ERROR, '999MI');
 to_number
-----------
      -456
(1 row)
```

- to_timestamp(double precision)

  Description: Converts a Unix century into a timestamp.

  Return type: timestamp with time zone.

  Example:

  ```
  gaussdb=# SELECT to_timestamp(1284352323);
      to_timestamp
  ------------------------
   2010-09-13 12:32:03+08
  (1 row)
  ```

- to_timestamp(string [,fmt])

  Description: Converts **string** into a timestamp value in the format specified by **fmt**. If **fmt** is not specified, the conversion will adhere to **nls_timestamp_format** instead. In **to_timestamp** in GaussDB:

  – If the input year **YYYY** is 0, the function will report an error.

  – If the input year **YYYY** is less than 0 and **fmt** is set to **SYYYY**, the function will correctly output the absolute value *n* of the BC year.

  Characters in **fmt** must match data/time formats. Otherwise, an error will be reported.

  Return type: timestamp without time zone.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Example:

```
gaussdb=# SHOW nls_timestamp_format;
    nls_timestamp_format
-----------------------------
 DD-Mon-YYYY HH:MI:SS.FF AM
(1 row)

gaussdb=# SELECT to_timestamp('12-sep-2014');
    to_timestamp
---------------------
 2014-09-12 00:00:00
(1 row)
gaussdb=# SELECT to_timestamp('12-Sep-10 14:10:10.123000','DD-Mon-YY HH24:MI:SS.FF');
      to_timestamp
--------------------------
 2010-09-12 14:10:10.123
(1 row)
gaussdb=# SELECT to_timestamp('-1','SYYYY');
      to_timestamp
------------------------
 0001-01-01 00:00:00 BC
(1 row)
gaussdb=# SELECT to_timestamp('98','RR');
    to_timestamp
---------------------
 1998-01-01 00:00:00
(1 row)
gaussdb=# SELECT to_timestamp('01','RR');
    to_timestamp
---------------------
 2001-01-01 00:00:00
(1 row)
```

NOTE

- When **a_format_version** is **10c** and **a_format_dev_version** is **s1**, **fmt** supports FF[7-9]. When FF[7-9] is applied, the number of characters that can be converted from the target position in the string is limited by the number following FF, with only 6 characters ultimately being retained in the conversion result.
- The result returned by the current_timestamp function cannot be used as a string parameter.
- In PG-compatible mode, if a string exceeds the maximum length allowed by **fmt**, as seen in the example with to_timestamp('2024-01-05 14:52:06.694752', 'yyyy-MM-dd hh24:mi:ss'), the string will be automatically truncated to fit within the maximum length allowed by **fmt**, and any excess part will be discarded.
- In PG-compatible databases where the GUC parameter **format_pg_to_timestamp** is enabled, any unsupported formats will be skipped. The current version does not recognize formats such as FF, FF7, FF8, FF9, RR, RRRR, SYYYY, x, and X. However, it supports dates prior to 294277-01-01 00:00:00 and negative years (converted into BC). Milliseconds exceeding precision will be rounded off in FF1 to FF6. When conflicting time and date formats arise, the correctly formatted one will be returned without generating an error. For details about such conflicts, see **Table 1-73**.

Table 1-73 Conflicting formats (fmt) for to_timestamp

Conflict Scenario	Description
SSSSS conflicts with time.	Retain minutes and hours of time and the seconds part of SSSSS.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Conflict Scenario	Description
W and J conflict with time and date.	Priority: Overwrite J, W, and mmdd in sequence. W: Wednesday unless otherwise specified. Default behavior: Overwrite mmdd with W.
SSSSS conflicts with SS.	Retain SS and discard SSSSS.
DDD conflicts with a date.	Discard DDD.

- to_timestamp(text [DEFAULT return_value ON CONVERSION ERROR [, fmt]])

  Description: Converts **text** into the TIMESTAMP type in the format specified by **fmt**. If **fmt** is not specified, the conversion will adhere to **nls_timestamp_format** instead, provided that **a_format_version** is **10c** and **a_format_dev_version** is **s1**. However, if **a_format_version** and **a_format_dev_version** are not specified, the conversion will default to the fixed format '**yyyy-mm-dd hh24-mi-ss**'.

  Parameters:

  - **text**: any expression that can be calculated as CHAR, VARCHAR2, NCHAR, NVARCHAR2, or TEXT string. If the input is null, the function will return null.
  - **DEFAULT return_value ON CONVERSION ERROR**: This optional parameter specifies that **return_value** will be returned when **text** fails to be converted into the TIMESTAMP type, provided that **a_format_version** is **10c** and **a_format_dev_version** is **s1**. **return_value** can be an expression or a bind variable that must be convertible into the CHAR, VARCHAR2, NCHAR, NVARCHAR2, or TEXT type. It can also be null. The method of converting **return_value** into the TIMESTAMP type is the same as converting **text** into the TIMESTAMP type. If **return_value** fails to be converted into the TIMESTAMP type, the function will report an error.
  - **fmt**: optional parameter. It specifies the date and time format for **string**. If it is not specified, **text** must adhere to the default date format. However, if **fmt** is set to **J**, **text** must be an integer.

  Return type: timestamp without time zone.

  Example:

```
gaussdb=# SET a_format_version='10c';
SET
gaussdb=# SET a_format_dev_version='s1';
SET
gaussdb=# SELECT to_timestamp('11-Sep-11' DEFAULT '12-Sep-10 14:10:10.123000' ON
CONVERSION ERROR,'DD-Mon-YY HH24:MI:SS.FF');
    to_timestamp
---------------------
 2011-09-11 00:00:00
(1 row)
gaussdb=# SELECT to_timestamp('12-Sep-10 14:10:10.123000','DD-Mon-YY HH24:MI:SSXFF');
      to_timestamp
-------------------------
 2010-09-12 14:10:10.123
(1 row)
```

- to_timestamp(text, text)

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description: Converts a character-string value into a timestamp in the specified format.

Return type: timestamp.

Example:

```
gaussdb=# SELECT to_timestamp('05 Dec 2000', 'DD Mon YYYY');
    to_timestamp
---------------------
 2000-12-05 00:00:00
(1 row)
```

- to_timestamp_tz(string [DEFAULT return_value ON CONVERSION ERROR] [,fmt])

  Description: Converts **string** into the timestamp with time zone type in the format specified by **fmt**. If **fmt** is not specified, the conversion will adhere to **nls_timestamp_tz_format** instead.

  Parameters:

  – **DEFAULT return_value ON CONVERSION ERROR**: optional parameter. If **string** fails to be converted into the timestamp with time zone type, **return_value** will be converted into that type instead.

  – **fmt**: optional parameter. It specifies the date and time format for **string**.

  Return type: timestamp with time zone.

  Example:

```
gaussdb=# SELECT to_timestamp_tz('05 DeX 2000' DEFAULT '05 Dec 2001' ON CONVERSION ERROR,
'DD Mon YYYY');
    to_timestamp_tz
---------------------------
 2001-12-05 00:00:00+08:00
(1 row)
```

  NOTE

  This function takes effect when **a_format_version** is **10c** and **a_format_dev_version** is **s1**.

- to_timestamp_tz(string [DEFAULT return_value ON CONVERSION ERROR], fmt, nlsparam)

  Description: Converts **string** into the timestamp with time zone type in the format specified by **fmt**. If **string** fails to be converted into the timestamp with time zone type, **return_value** will be converted into that type instead.

  Parameters: See **Table 1-74**.

  Return type: timestamp with time zone.

  Table 1-74 Parameters of to_timestamp_tz(string [DEFAULT return_value ON CONVERSION ERROR], fmt, nlsparam)

Parameter	Type	Description
string	text	Character string to be converted into the timestamp with time zone type.
return_value	text	If **string** fails to be converted into the timestamp with time zone type, **return_value** will be converted into that type instead.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Type	Description
fmt	text	Date and time format for the **string** parameter.
nlsparam	text	Language for month and day names in the specified **string** in the format of '**nls_date_language=***language*'. Currently, *language* can only be **ENGLISH** or **AMERICAN**. Using the **nlsparam** parameter correctly yields the same result as omitting it.

Example:

```
gaussdb=# SELECT to_timestamp_tz('05 DeX 2000' DEFAULT '05 Dec 2001' ON CONVERSION ERROR,
'DD Mon YYYY','nls_date_language=AMERICAN');
    to_timestamp_tz
---------------------------
 2001-12-05 00:00:00+08:00
(1 row)
```

NOTE

This function takes effect when **a_format_version** is **10c** and **a_format_dev_version** is **s4**.

- to_dsinterval(text)

  Description: Converts characters into the interval type. SQL-compatible and ISO formats are supported.

  Return type: interval.

  Example:

  ```
  gaussdb=# SELECT to_dsinterval('12 1:2:3.456');
     to_dsinterval
  ----------------------
   12 days 01:02:03.456
  (1 row)

  gaussdb=# SELECT to_dsinterval('P3DT4H5M6S');
    to_dsinterval
  -----------------
   3 days 04:05:06
  (1 row)
  ```

  NOTE

  This function takes effect when **a_format_version** is **10c** and **a_format_dev_version** is **s2**.

- to_yminterval(text)

  Description: Converts characters into the interval type. SQL-compatible and ISO formats are supported.

  Return type: interval.

  Example:

  ```
  gaussdb=# SELECT to_yminterval('1-1');
   to_yminterval
  -----------------
   1 year 1 mon
  (1 row)
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gaussdb=# SELECT to_yminterval('P13Y3M4DT4H2M5S');
 to_yminterval
-----------------
 13 years 3 mons
(1 row)
```

NOTE

This function takes effect when **a_format_version** is **10c** and **a_format_dev_version** is **s2**.

Table 1-75 Numeric formats

Format	Description
9	Returns a value with the specified number of digits.
0	Returns leading zeros.
. (period)	Returns the decimal point.
, (comma)	Returns the digit grouping (thousands) separator.
PR	Returns a negative value in <angle brackets>.
S	Returns a signed number (depending on the locale settings).
L	Returns the currency symbol (depending on the locale settings).
D	Returns the decimal character (depending on the locale settings).
G	Returns the digit grouping separator (depending on the locale settings).
MI	Returns the minus sign in the specified position (if the number is less than 0).
PL	Returns the plus sign in the specified position (if the number is greater than 0).
SG	Returns the plus/minus sign in the specified position.
RN	Returns a Roman numeral (for any input between 1 and 3,999).
TH / th	Returns the suffix for an ordinal number.
V	Shifts the specified number of digits (decimal).
x / X	Converts a decimal number into its hexadecimal equivalent.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 1-76 Numeric formats for to_number

Format	Description
9	Matches a digit. The digit "9" can occur an equal or greater number of times than the digits in the specified position in **expr**.
0	Strictly matches a digit. The digit "0" must occur the same number of times as the digits in **expr**.
5	Matches the digit "0" or "5".
. (period)	Returns a decimal point in the specified position.
, (comma)	Returns a digit grouping (thousands) separator in the specified position. You can specify multiple commas in **fmt**.
B	Returns leading blanks.
PR	Specifies a negative value in angle brackets (<>), or a positive value with no leading sign.
S	Specifies a negative value with the leading minus sign (–) or a positive value with the leading plus sign (+).
MI	Specifies a negative value with the leading minus sign (–) or a positive value with no leading sign.
$	Returns a value with a leading US dollar sign ($).
L	Returns the local currency symbol.
C	Returns the ISO currency symbol in the specified position.
U	Returns the dual currency symbol.
D	Returns the decimal character (depending on the locale settings).
G	Returns the digit grouping separator (complying with the ISO standard). You can specify multiple commas in **fmt**.
RN / rn	Returns a Roman numeral (for any input between 1 and 3,999). The to_number function does not support this format.
V	The to_number function does not support this format.
X / x	Converts a hexadecimal number into its decimal equivalent.
TM	The to_number function does not support this format.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Format	Description
FM	Removes any leading blanks from the beginning of **fmt** while retaining the placeholder 0. This does not alter the result of the to_number function.
EEEE	Returns a value in scientific notation.

NOTE

Table 1-76 describes the usage of **fmt** in cases where **a_format_version** is **10c** and **a_format_dev_version** is **s1**, while Table 1-75 outlines the usage of **fmt** in all other cases. In Table 1-76, the usage of ISO-related formats is influenced by the **lc_monetary** and **lc_numeric** parameters. Specifically, **lc_monetary** determines the currency symbol, and **lc_numeric** affects the display rules for the decimal point and thousands separator.

- cast_varchar2_to_raw_for_histogram(varchar2)
  Description: Converts the varchar2 type into the raw type.
  Return type: raw.
- abstime_text(abstime)
  Description: Converts the abstime type into the text type.
  Return type: text.
- abstime_to_smalldatetime(abstime)
  Description: Converts the abstime type into the smalldatetime type.
  Return type: smalldatetime.
- bigint_tid(bigint)
  Description: Converts the bigint type into the tid type.
  Return type: tid.
- bool_int1(boolean)
  Description: Converts the Boolean type into the int1 type.
  Return type: tinyint.
- bool_int2(boolean)
  Description: Converts the Boolean type into the int2 type.
  Return type: smallint.
- bool_int8(boolean)
  Description: Converts the Boolean type into the int8 type.
  Return type: bigint.
- bpchar_date(character)
  Description: Converts a character string into a date.
  Return type: date.
- bpchar_float4(character)
  Description: Converts a character string into the float4 type.
  Return type: real.
- bpchar_float8(character)

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description: Converts a character string into the float8 type.

Return type: double precision.

- bpchar_int4(character)

  Description: Converts a character string into the int4 type.

  Return type: integer.

- bpchar_int8(character)

  Description: Converts a character string into the int8 type.

  Return type: bigint.

- bpchar_numeric(character)

  Description: Converts a character string into the numeric type.

  Return type: numeric.

- bpchar_timestamp(character)

  Description: Converts a character string into a timestamp.

  Return type: timestamp without time zone.

- bpchar_to_smalldatetime(character)

  Description: Converts a character string into the smalldatetime type.

  Return type: smalldatetime.

- complex_array_in(cstring, oid, int2vector)

  Description: Converts an external complex_array type into the internal anyarray type.

  Return type: anyarray.

- date_bpchar(date)

  Description: Converts the date type into the bpchar type.

  Return type: character.

- date_text(date)

  Description: Converts the date type into the text type.

  Return type: text.

- date_varchar(date)

  Description: Converts the date type into the varchar type.

  Return type: character varying.

- f4toi1(real)

  Description: Forcibly converts the float4 type into the uint8 type.

  Return type: tinyint.

- f8toi1(double precision)

  Description: Forcibly converts the float8 type into the uint8 type.

  Return type: tinyint.

- float4_bpchar(real)

  Description: Converts the float4 type into the bpchar type.

  Return type: character.

- float4_text(real)

  Description: Converts the float4 type into the text type.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Return type: text.

- float4_varchar(real)
  Description: Converts the float4 type into the varchar type.
  Return type: character varying.
- float8_bpchar(double precision)
  Description: Converts the float8 type into the bpchar type.
  Return type: character.
- float8_interval(double precision)
  Description: Converts the float8 type into the interval type.
  Return type: interval.
- float8_text(double precision)
  Description: Converts the float8 type into the text type.
  Return type: text.
- float8_varchar(double precision)
  Description: Converts the float8 type into the varchar type.
  Return type: character varying.
- i1tof4(tinyint)
  Description: Converts the uint8 type into the float4 type.
  Return type: real.
- i1tof8(tinyint)
  Description: Converts the uint8 type into the float8 type.
  Return type: double precision.
- i1toi2(tinyint)
  Description: Converts the uint8 type into the int16 type.
  Return type: smallint.
- i1toi4(tinyint)
  Description: Converts the uint8 type into the int32 type.
  Parameter: tinyint.
  Return type: integer.
- i1toi8(tinyint)
  Description: Converts the uint8 type into the int64 type.
  Return type: bigint.
- i2toi1(smallint)
  Description: Converts the int16 type into the uint8 type.
  Return type: tinyint.
- i4toi1(integer)
  Description: Converts the int32 type into the uint8 type.
  Parameter: integer.
  Return type: tinyint.
- i8toi1(bigint)
  Description: Converts the int64 type into the uint8 type.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Return type: tinyint.

- int1_avg_accum(bigint[], tinyint)

  Description: Adds the second parameter of the uint8 type to the first parameter. The first parameter is an array of the bigint type.

  Return type: bigint[].

- int1_bool(tinyint)

  Description: Converts the uint8 type into the Boolean type.

  Return type: Boolean.

- int1_bpchar(tinyint)

  Description: Converts the uint8 type into the bpchar type.

  Return type: character.

- int1_mul_cash(tinyint, money)

  Description: Returns the product of an int8 parameter and a money parameter. The return type is money.

  Return type: money.

- int1_numeric(tinyint)

  Description: Converts the uint8 type into the numeric type.

  Return type: numeric.

- int1_nvarchar2(tinyint)

  Description: Converts the uint8 type into the nvarchar2 type.

  Return type: nvarchar2.

- int1_text(tinyint)

  Description: Converts the uint8 type into the text type.

  Return type: text.

- int1_varchar(tinyint)

  Description: Converts the uint8 type into the varchar type.

  Return type: character varying.

- int1in(cstring)

  Description: Converts a character string into an unsigned 1-byte integer.

  Return type: tinyint.

- int1out(tinyint)

  Description: Converts an unsigned 1-byte integer into a character string.

  Return type: cstring.

- int1up(tinyint)

  Description: Converts an integer into an unsigned 1-byte integer.

  Return type: tinyint.

- int2_bool(smallint)

  Description: Converts a signed two-byte integer into the Boolean type.

  Return type: Boolean.

- int2_bpchar(smallint)

  Description: Converts a signed two-byte integer into the bpchar type.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Return type: character.

- int2_text(smallint)
  Description: Converts a signed two-byte integer into the text type.
  Return type: text.
- int2_varchar(smallint)
  Description: Converts a signed two-byte integer into the varchar type.
  Return type: character varying.
- int4_bpchar(integer)
  Description: Converts a signed four-byte integer into the bpchar type.
  Return type: character.
- int4_text(integer)
  Description: Converts a signed four-byte integer into the text type.
  Return type: text.
- int4_varchar(integer)
  Description: Converts a signed four-byte integer into the varchar type.
  Return type: character varying.
- int8_bool(bigint)
  Description: Converts a signed eight-byte integer into the Boolean type.
  Return type: Boolean.
- int8_bpchar(bigint)
  Description: Converts a signed eight-byte integer into the bpchar type.
  Return type: character.
- int8_text(bigint)
  Description: Converts a signed eight-byte integer into the text type.
  Return type: text.
- int8_varchar(bigint)
  Description: Converts a signed eight-byte integer into the varchar type.
  Return type: character varying.
- intervaltonum(interval)
  Description: Converts an internal numeric date into the numeric type.
  Return type: numeric.
- numeric_bpchar(numeric)
  Description: Converts the numeric type into the bpchar type.
  Return type: character.
- numeric_int1(numeric)
  Description: Converts the numeric type into the signed 1-byte integer type.
  Return type: tinyint.
- numeric_text(numeric)
  Description: Converts the numeric type into the text type.
  Return type: text.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- numeric_varchar(numeric)
  Description: Converts the numeric type into the varchar type.
  Return type: character varying.
- nvarchar2in(cstring, oid, integer)
  Description: Converts a cstring into the varchar type.
  Return type: nvarchar2.
- nvarchar2out(nvarchar2)
  Description: Converts the text type into a cstring.
  Return type: cstring.
- nvarchar2send(nvarchar2)
  Description: Converts the varchar type into the binary format.
  Return type: bytea.
- oidvectorin_extend(cstring)
  Description: Converts a character string into the oidvector type.
  Return type: oidvector_extend.
- oidvectorout_extend(oidvector_extend)
  Description: Converts the oidvector type into a character string.
  Return type: cstring.
- oidvectorsend_extend(oidvector_extend)
  Description: Converts the oidvector type into a character string.
  Return type: bytea.
- reltime_text(reltime)
  Description: Converts the reltime type into the text type.
  Return type: text.
- text_date(text)
  Description: Converts the text type into the date type.
  Return type: date.
- text_float4(text)
  Description: Converts the text type into the float4 type.
  Return type: real.
- text_float8(text)
  Description: Converts the text type into the float8 type.
  Return type: double precision.
- text_int1(text)
  Description: Converts the text type into the int1 type.
  Return type: tinyint.
- text_int2(text)
  Description: Converts the text type into the int2 type.
  Return type: smallint.
- text_int4(text)
  Description: Converts the text type into the int4 type.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Return type: integer.

- text_int8(text)
  Description: Converts the text type into the int8 type.
  Return type: bigint.
- text_numeric(text)
  Description: Converts the text type into the numeric type.
  Return type: numeric.
- text_timestamp(text)
  Description: Converts the text type into the timestamp type.
  Return type: timestamp without time zone.
- time_text(time without time zone)
  Description: Converts the time type into the text type.
  Return type: text.
- timestamp_text(timestamp without time zone)
  Description: Converts the timestamp type into the text type.
  Return type: text.
- timestamp_to_smalldatetime(timestamp without time zone)
  Description: Converts the timestamp type into the smalldatetime type.
  Return type: smalldatetime.
- timestamp_varchar(timestamp without time zone)
  Description: Converts the timestamp type into the varchar type.
  Return type: character varying.
- timestamptz_to_smalldatetime(timestamp with time zone)
  Description: Converts the timestamptz type into the smalldatetime type.
  Return type: smalldatetime.
- timestampzone_text(timestamp with time zone)
  Description: Converts the timestamptz type into the text type.
  Return type: text.
- timetz_text(time with time zone)
  Description: Converts the timetz type into the text type.
  Return type: text.
- to_integer(character varying)
  Description: Converts the input into the integer type.
  Return type: integer.
- to_interval(character varying)
  Description: Converts the input into the interval type.
  Return type: interval.
- to_numeric(character varying)
  Description: Converts the input into the numeric type.
  Return type: numeric.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- to_text(smallint)
  Description: Converts the input into the text type.
  Return type: text.
- to_ts(character varying)
  Description: Converts the input into the timestamptz type.
  Return type: timestamp without time zone.
- to_varchar2(timestamp without time zone)
  Description: Converts the input into the varchar2 type.
  Return type: character varying.
- varchar_blob(character varying)
  Description: Converts the varchar type into the blob type.
  Return type: blob.

  NOTICE

  This function is supported only in Oracle-compatible mode. Using it in other modes will result in an error.

- varchar_date(character varying)
  Description: Converts the varchar type into the date type.
  Return type: date.
- varchar_float4(character varying)
  Description: Converts the varchar type into the float4 type.
  Return type: real.
- varchar_float8(character varying)
  Description: Converts the varchar type into the float8 type.
  Return type: double precision.
- varchar_int4(character varying)
  Description: Converts the varchar type into the int4 type.
  Return type: integer.
- varchar_int8(character varying)
  Description: Converts the varchar type into the int8 type.
  Return type: bigint.
- varchar_numeric(character varying)
  Description: Converts the varchar type into the numeric type.
  Return type: numeric.
- varchar_timestamp(character varying)
  Description: Converts the varchar type into the timestamp type.
  Return type: timestamp without time zone.
- varchar2_to_smlldatetime(character varying)
  Description: Converts the varchar2 type into the smlldatetime type.
  Return type: smalldatetime.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- xidout4(xid32)
  Description: Converts the xid type into a 4-byte number.
  Return type: cstring.
- xidsend4(xid32)
  Description: Converts the xid type into the binary format.
  Return type: bytea.
- bytea_blob(any)
  Description: Converts the bytea type into the blob type. Currently, this conversion is limited to the bytea type.
  Return type: blob.
- datea_text(datea)
  Description: Converts the datea type into the text type.
  Return type: text.
- datea_clob(datea)
  Description: Converts the datea type into the clob type.
  Return type: CLOB.
- datea_varchar(datea)
  Description: Converts the datea type into the character varying type.
  Return type: character varying.
- datea_nvarchar2(datea)
  Description: Converts the datea type into the nvarchar2 type.
  Return type: nvarchar2.
- datea_bpchar(datea)
  Description: Converts the datea type into the bpchar type.
  Return type: character.
- text_datea(text)
  Description: Converts the text type into the datea type.
  Return type: datea.
- clob_datea(clob)
  Description: Converts the clob type into the datea type.
  Return type: datea.
- varchar_datea(character varying)
  Description: Converts the character varying type into the datea type.
  Return type: datea.
- bpchar_datea(character)
  Description: Converts the character type into the datea type.
  Return type: datea.
- datea_timestamp(datea)
  Description: Converts the datea type into the timestamp type.
  Return type: timestamp.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- timestamp_datea(timestamp)

  Description: Converts the timestamp type into the datea type.

  Return type: datea.
- datea_timestamptz(datea)

  Description: Converts the datea type into the timestamptz type.

  Return type: timestamptz.
- timestamptz_datea(timestamptz)

  Description: Converts the timestamptz type into the datea type.

  Return type: datea.
- nvarchar2_datea(nvarchar2)

  Description: Converts the nvarchar2 type into the datea type.

  Return type: datea.

  NOTE

  The datea-related conversion functions can be used only in ORA-compatible mode.
- chartorowid(character/character varying/nvarchar2/text)

  Description: Converts the character/character varying/nvarchar2/text type into the rowid type.

  Return type: rowid.
- rowidtobpchar(rowid)

  Description: Converts the rowid type into the character type.

  Return type: character.
- rowidtochar(rowid)

  Description: Converts the rowid type into the character varying type.

  Return type: character varying.
- rowidtonchar(rowid)

  Description: Converts the rowid type into the nvarchar2 type.

  Return type: nvarchar2.
- rowidtotext(rowid)

  Description: Converts the rowid type into the text type.

  Return type: text.

  NOTE

  The rowid-related conversion functions can be used only in Oracle-compatible mode.
- treat(expr AS [JSON | REF] schema.type)

  Description: Converts **expr** into the type (JSON or user-defined type) specified by the keyword after **AS**.

  Return type: JSON or user-defined type.

  Example:

```
gaussdb=# CREATE TABLE json_doc(data CLOB);
gaussdb=# INSERT INTO json_doc VALUES('{"name":"a"}');
gaussdb=# SELECT treat(data as json) FROM json_doc;
    json
--------------
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
 {"name":"a"}
(1 row)
gaussdb=# DROP TABLE json_doc;
DROP TABLE
```

- nesttable_to_array(anynesttable)

  Description: Converts a nest-table collection type into an array type with the same elements.

  Return type: anyarray.

  Example:

```
gaussdb=# CREATE OR REPLACE PROCEDURE p1 IS
gaussdb$#     type t1 IS table of int;
gaussdb$#     v1 t1 := t1(1, 2, 3);
gaussdb$#     v2 int[] := cast(v1 as int[]);
gaussdb$# BEGIN
gaussdb$#     raise info '%', v2;
gaussdb$# END;
gaussdb$# /
CREATE PROCEDURE
gaussdb=# CALL p1();
INFO:  {1,2,3}
 p1
----

(1 row)

gaussdb=# CREATE TYPE t1 is table of int;
CREATE TYPE
gaussdb=# SELECT cast(t1(1, 2, 3) AS int[]) result;
 result
---------
 {1,2,3}
(1 row)
gaussdb=# DROP PROCEDURE p1;
DROP PROCEDURE

gaussdb=# DROP TYPE t1;
DROP TYPE
```

- indexbytableint_to_array(anyindexbytable)

  Description: Converts a collection whose index type is integer into an array type with the same elements.

  Return type: anyarray.

  Example:

```
gaussdb=# CREATE OR REPLACE PACKAGE pkg1 IS
gaussdb$#     type t1 IS table of int index by int;
gaussdb$#     PROCEDURE p1();
gaussdb$# END pkg1;
gaussdb$# /
CREATE PACKAGE
gaussdb=#
gaussdb=# CREATE OR REPLACE PACKAGE BODY pkg1 IS
gaussdb$#     PROCEDURE p1() IS
gaussdb$#         v1 t1 := t1(1 => 1, 2 => 2, 3 => 3);
gaussdb$#         v2 int[];
gaussdb$#     BEGIN
gaussdb$#         v2 := cast(v1 as int[]);
gaussdb$#         RAISE INFO '%', v2;
gaussdb$#     END;
gaussdb$# END pkg1;
gaussdb$# /
CREATE PACKAGE BODY
gaussdb=#
gaussdb=# CALL pkg1.p1();
INFO:  {1,2,3}
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
 p1
----

(1 row)

gaussdb=# SELECT indexbytableint_to_array(pkg1.t1(1 => 1, 2 => 2, 3 => 3));
 indexbytableint_to_array
--------------------------
 {1,2,3}
(1 row)

gaussdb=# DROP PACKAGE pkg1;
DROP PACKAGE
```

Encoding Type Conversion

convert_to_nocase(text, text)

Description: Converts a string into a specified encoding type and then outputs the result.

Return type: bytea.

Example:

```
gaussdb=# SELECT convert_to_nocase('12345', 'GBK');
 convert_to_nocase
-------------------
 \x3132333435
(1 row)
```

1.6.10 Geometric Functions and Operators

Geometric Operators

- +

  Description: Translation

  Example:

  ```
  gaussdb=# SELECT box '((0,0),(1,1))' + point '(2.0,0)' AS RESULT;
     result
  -------------
   (3,1),(2,0)
  (1 row)
  ```

- -

  Description: Translation

  Example:

  ```
  gaussdb=# SELECT box '((0,0),(1,1))' - point '(2.0,0)' AS RESULT;
     result
  ---------------
   (-1,1),(-2,0)
  (1 row)
  ```

- *

  Description: Scaling out/Rotation

  Example:

  ```
  gaussdb=# SELECT box '((0,0),(1,1))' * point '(2.0,0)' AS RESULT;
     result
  -------------
   (2,2),(0,0)
  (1 row)
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- /

  Description: Scaling in/Rotation

  Example:

```
gaussdb=# SELECT box '((0,0),(2,2))' / point '(2.0,0)' AS RESULT;
   result
-------------
 (1,1),(0,0)
(1 row)
```

- #

  Description: Intersection of two figures

  Example:

```
gaussdb=# SELECT box '((1,-1),(-1,1))' # box '((1,1),(-2,-2))' AS RESULT;
 result
---------------
 (1,1),(-1,-1)
(1 row)
```

- #

  Description: Number of paths or polygon vertexes

  Example:

```
gaussdb=# SELECT # path'((1,0),(0,1),(-1,0))' AS RESULT;
 result
--------
      3
(1 row)
```

- @-@

  Description: Length or circumference

  Example:

```
gaussdb=# SELECT @-@ path '((0,0),(1,0))' AS RESULT;
 result
--------
      2
(1 row)
```

- @@

  Description: Center of box

  Example:

```
gaussdb=# SELECT @@ circle '((0,0),10)' AS RESULT;
 result
--------
 (0,0)
(1 row)
```

- <->

  Description: Distance between the two figures

  Example:

```
gaussdb=# SELECT circle '((0,0),1)' <-> circle '((5,0),1)' AS RESULT;
 result
--------
      3
(1 row)
```

- &&

  Description: Overlaps? (One point in common makes this true.)

  Example:

```
gaussdb=# SELECT box '((0,0),(1,1))' && box '((0,0),(2,2))' AS RESULT;
 result
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
--------
 t
(1 row)
```

- <<

  Description: Is strictly left of (no common horizontal coordinate)?

  Example:

```
gaussdb=# SELECT circle '((0,0),1)' << circle '((5,0),1)' AS RESULT;
 result
--------
 t
(1 row)
```

- >>

  Description: Is strictly right of (no common horizontal coordinate)?

  Example:

```
gaussdb=# SELECT circle '((5,0),1)' >> circle '((0,0),1)' AS RESULT;
 result
--------
 t
(1 row)
```

- &<

  Description: Does not extend to the right of?

  Example:

```
gaussdb=# SELECT box '((0,0),(1,1))' &< box '((0,0),(2,2))' AS RESULT;
 result
--------
 t
(1 row)
```

- &>

  Description: Does not extend to the left of?

  Example:

```
gaussdb=# SELECT box '((0,0),(3,3))' &> box '((0,0),(2,2))' AS RESULT;
 result
--------
 t
(1 row)
```

- <<|

  Description: Is strictly below (no common horizontal coordinate)?

  Example:

```
gaussdb=# SELECT box '((0,0),(3,3))' <<| box '((3,4),(5,5))' AS RESULT;
 result
--------
 t
(1 row)
```

- |>>

  Description: Is strictly above (no common horizontal coordinate)?

  Example:

```
gaussdb=# SELECT box '((3,4),(5,5))' |>> box '((0,0),(3,3))' AS RESULT;
 result
--------
 t
(1 row)
```

- &<|

  Description: Does not extend above?

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Example:

```
gaussdb=# SELECT box '((0,0),(1,1))' &<| box '((0,0),(2,2))' AS RESULT;
 result
--------
 t
(1 row)
```

- |&>

  Description: Does not extend below?

  Example:

```
gaussdb=# SELECT box '((0,0),(3,3))' |&> box '((0,0),(2,2))' AS RESULT;
 result
--------
 t
(1 row)
```

- <^

  Description: Is below (allows touching)?

  Example:

```
gaussdb=# SELECT box '((0,0),(-3,-3))' <^ box '((0,0),(2,2))' AS RESULT;
 result
--------
 t
(1 row)
```

- >^

  Description: Is above (allows touching)?

  Example:

```
gaussdb=# SELECT box '((0,0),(2,2))' >^ box '((0,0),(-3,-3))'  AS RESULT;
 result
--------
 t
(1 row)
```

- ?#

  Description: Intersect?

  Example:

```
gaussdb=# SELECT lseg '((-1,0),(1,0))' ?# box '((-2,-2),(2,2))' AS RESULT;
 result
--------
 t
(1 row)
```

- ?-

  Description: Is horizontal?

  Example:

```
gaussdb=# SELECT ?- lseg '((-1,0),(1,0))' AS RESULT;
 result
--------
 t
(1 row)
```

- ?-

  Description: Are horizontally aligned?

  Example:

```
gaussdb=# SELECT point '(1,0)' ?- point '(0,0)' AS RESULT;
 result
--------
 t
(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- ?|

  Description: Is vertical?

  Example:

```
gaussdb=# SELECT ?| lseg '((-1,0),(1,0))' AS RESULT;
 result
--------
 f
(1 row)
```

- ?|

  Description: Are vertically aligned?

  Example:

```
gaussdb=# SELECT point '(0,1)' ?| point '(0,0)' AS RESULT;
 result
--------
 t
(1 row)
```

- ?-|

  Description: Are perpendicular?

  Example:

```
gaussdb=# SELECT lseg '((0,0),(0,1))' ?-| lseg '((0,0),(1,0))' AS RESULT;
 result
--------
 t
(1 row)
```

- ?||

  Description: Are parallel?

  Example:

```
gaussdb=# SELECT lseg '((-1,0),(1,0))' ?|| lseg '((-1,2),(1,2))' AS RESULT;
 result
--------
 t
(1 row)
```

- @>

  Description: Contains?

  Example:

```
gaussdb=# SELECT circle '((0,0),2)' @> point '(1,1)' AS RESULT;
 result
--------
 t
(1 row)
```

- <@

  Description: Contained in or on?

  Example:

```
gaussdb=# SELECT point '(1,1)' <@ circle '((0,0),2)' AS RESULT;
 result
--------
 t
(1 row)
```

- ~=

  Description: Specifies whether two figures are the same.

  Example:

```
gaussdb=# SELECT polygon '((0,0),(1,1))' ~= polygon '((1,1),(0,0))' AS RESULT;
 result
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
--------
 t
(1 row)
```

Geometric Functions

- area(object)

  Description: Area calculation

  Return type: double precision

  Example:

  ```
  gaussdb=# SELECT area(box '((0,0),(1,1))') AS RESULT;
   result
  --------
       1
  (1 row)
  ```

- center(object)

  Description: Figure center calculation

  Return type: point

  Example:

  ```
  gaussdb=# SELECT center(box '((0,0),(1,2))') AS RESULT;
   result
  ---------
   (0.5,1)
  (1 row)
  ```

- diameter(circle)

  Description: Circle diameter calculation

  Return type: double precision

  Example:

  ```
  gaussdb=# SELECT diameter(circle '((0,0),2.0)') AS RESULT;
   result
  --------
       4
  (1 row)
  ```

- height(box)

  Description: Vertical size of box

  Return type: double precision

  Example:

  ```
  gaussdb=# SELECT height(box '((0,0),(1,1))') AS RESULT;
   result
  --------
       1
  (1 row)
  ```

- isclosed(path)

  Description: A closed path?

  Return type: Boolean

  Example:

  ```
  gaussdb=# SELECT isclosed(path '((0,0),(1,1),(2,0))') AS RESULT;
   result
  --------
   t
  (1 row)
  ```

- isopen(path)

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description: An open path?

Return type: Boolean

Example:

```
gaussdb=# SELECT isopen(path '[(0,0),(1,1),(2,0)]') AS RESULT;
 result
--------
 t
(1 row)
```

- length(object)

  Description: Length calculation

  Return type: double precision

  Example:

```
gaussdb=# SELECT length(path '((-1,0),(1,0))') AS RESULT;
 result
--------
      4
(1 row)
```

- npoints(path)

  Description: Number of points in path

  Return type: int

  Example:

```
gaussdb=# SELECT npoints(path '[(0,0),(1,1),(2,0)]') AS RESULT;
 result
--------
      3
(1 row)
```

- npoints(polygon)

  Description: Number of points in polygon

  Return type: int

  Example:

```
gaussdb=# SELECT npoints(polygon '((1,1),(0,0))') AS RESULT;
 result
--------
      2
(1 row)
```

- pclose(path)

  Description: Converts path to closed.

  Return type: path

  Example:

```
gaussdb=# SELECT pclose(path '[(0,0),(1,1),(2,0)]') AS RESULT;
       result
---------------------
 ((0,0),(1,1),(2,0))
(1 row)
```

- popen(path)

  Description: Converts path to open.

  Return type: path

  Example:

```
gaussdb=# SELECT popen(path '((0,0),(1,1),(2,0))') AS RESULT;
       result
---------------------
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
 [(0,0),(1,1),(2,0)]
(1 row)
```

- radius(circle)

  Description: Circle diameter calculation

  Return type: double precision

  Example:

```
gaussdb=# SELECT radius(circle '((0,0),2.0)') AS RESULT;
 result
--------
      2
(1 row)
```

- width(box)

  Description: Horizontal size of box

  Return type: double precision

  Example:

```
gaussdb=# SELECT width(box '((0,0),(1,1))') AS RESULT;
 result
--------
      1
(1 row)
```

Geometric Type Conversion Functions

- box(circle)

  Description: Circle to box

  Return type: box

  Example:

```
gaussdb=# SELECT box(circle '((0,0),2.0)') AS RESULT;
                                result
-----------------------------------------------------------------------
 (1.41421356237309,1.41421356237309),(-1.41421356237309,-1.41421356237309)
(1 row)
```

- box(point, point)

  Description: Points to box

  Return type: box

  Example:

```
gaussdb=# SELECT box(point '(0,0)', point '(1,1)') AS RESULT;
   result
-------------
 (1,1),(0,0)
(1 row)
```

- box(polygon)

  Description: Polygon to box

  Return type: box

  Example:

```
gaussdb=# SELECT box(polygon '((0,0),(1,1),(2,0))') AS RESULT;
   result
-------------
 (2,1),(0,0)
(1 row)
```

- circle(box)

  Description: Box to circle

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Return type: circle

Example:

```
gaussdb=# SELECT circle(box '((0,0),(1,1))') AS RESULT;
            result
-------------------------------
 <(0.5,0.5),0.707106781186548>
(1 row)
```

- circle(point, double precision)

  Description: Center and radius to circle

  Return type: circle

  Example:

  ```
  gaussdb=# SELECT circle(point '(0,0)', 2.0) AS RESULT;
    result
  -----------
   <(0,0),2>
  (1 row)
  ```

- circle(polygon)

  Description: Polygon to circle

  Return type: circle

  Example:

  ```
  gaussdb=# SELECT circle(polygon '((0,0),(1,1),(2,0))') AS RESULT;
                  result
  ------------------------------------------
   <(1,0.333333333333333),0.924950591148529>
  (1 row)
  ```

- lseg(box)

  Description: Box diagonal to line segment

  Return type: lseg

  Example:

  ```
  gaussdb=# SELECT lseg(box '((-1,0),(1,0))') AS RESULT;
      result
  ----------------
   [(1,0),(-1,0)]
  (1 row)
  ```

- lseg(point, point)

  Description: Points to line segment

  Return type: lseg

  Example:

  ```
  gaussdb=# SELECT lseg(point '(-1,0)', point '(1,0)') AS RESULT;
      result
  ----------------
   [(-1,0),(1,0)]
  (1 row)
  ```

- slope(point, point)

  Description: Calculates the slope of a straight line formed by two points.

  Return type: double

  Example:

  ```
  gaussdb=# SELECT slope(point '(1,1)', point '(0,0)') AS RESULT;
   result
  --------
       1
  (1 row)
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- path(polygon)

  Description: Polygon to path

  Return type: path

  Example:

```
gaussdb=# SELECT path(polygon '((0,0),(1,1),(2,0))') AS RESULT;
      result
--------------------
 ((0,0),(1,1),(2,0))
(1 row)
```

- point(double precision, double precision)

  Description: Points

  Return type: point

  Example:

```
gaussdb=# SELECT point(23.4, -44.5) AS RESULT;
   result
--------------
 (23.4,-44.5)
(1 row)
```

- point(box)

  Description: Center of box

  Return type: point

  Example:

```
gaussdb=# SELECT point(box '((-1,0),(1,0))') AS RESULT;
 result
--------
 (0,0)
(1 row)
```

- point(circle)

  Description: Center of circle

  Return type: point

  Example:

```
gaussdb=# SELECT point(circle '((0,0),2.0)') AS RESULT;
 result
--------
 (0,0)
(1 row)
```

- point(lseg)

  Description: Center of a line segment

  Return type: point

  Example:

```
gaussdb=# SELECT point(lseg '((-1,0),(1,0))') AS RESULT;
 result
--------
 (0,0)
(1 row)
```

- point(polygon)

  Description: Center of a polygon

  Return type: point

  Example:

```
gaussdb=# SELECT point(polygon '((0,0),(1,1),(2,0))') AS RESULT;
      result
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
----------------------
 (1,0.333333333333333)
(1 row)
```

- polygon(box)

  Description: Box to 4-point polygon

  Return type: polygon

  Example:

```
gaussdb=# SELECT polygon(box '((0,0),(1,1))') AS RESULT;
          result
---------------------------
 ((0,0),(0,1),(1,1),(1,0))
(1 row)
```

- polygon(circle)

  Description: Circle to 12-point polygon

  Return type: polygon

  Example:

```
gaussdb=# SELECT polygon(circle '((0,0),2.0)') AS RESULT;

result

------------------------------------------------------------------------------------------------------------------------
------------------------------------------------------------------------------------------------------------------------
------------------------------------------------------------
 ((-2,0),(-1.73205080756888,1),(-1,1.73205080756888),(-1.22464679914735e-16,2),
(1,1.73205080756888),(1.73205080756888,1),(2,2.44929359829471e-16),
(1.73205080756888,-0.999999999999999),(1,-1.73205080756888),(3.67394039744206e-16,-2),
(-0.999999999999999,-1.73205080756888),(-1.73205080756888,-1))
(1 row)
```

- polygon(npts, circle)

  Description: Circle to npts-point polygon

  Return type: polygon

  Example:

```
gaussdb=# SELECT polygon(12, circle '((0,0),2.0)') AS RESULT;

result

------------------------------------------------------------------------------------------------------------------------
------------------------------------------------------------------------------------------------------------------------
------------------------------------------------------------
 ((-2,0),(-1.73205080756888,1),(-1,1.73205080756888),(-1.22464679914735e-16,2),
(1,1.73205080756888),(1.73205080756888,1),(2,2.44929359829471e-16),
(1.73205080756888,-0.999999999999999),(1,-1.73205080756888),(3.67394039744206e-16,-2),
(-0.999999999999999,-1.73205080756888),(-1.73205080756888,-1))
(1 row)
```

- polygon(path)

  Description: Path to polygon

  Return type: polygon

  Example:

```
gaussdb=# SELECT polygon(path '((0,0),(1,1),(2,0))') AS RESULT;
      result
--------------------
 ((0,0),(1,1),(2,0))
(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

1.6.11 Network Address Functions and Operators

cidr and inet Operators

The operators **<<**, **<<=**, **>>**, and **>>=** test for subnet inclusion. These operators compare only the network parts of the two addresses (ignoring any host parts) and determine whether one network is identical to or a subnet of the other.

- <

  Description: Is less than

  Example:

```
gaussdb=# SELECT inet '192.168.1.5' < inet '192.168.1.6' AS RESULT;
 result
--------
 t
(1 row)
```

- <=

  Description: Is less than or equals

  Example:

```
gaussdb=# SELECT inet '192.168.1.5' <= inet '192.168.1.5' AS RESULT;
 result
--------
 t
(1 row)
```

- =

  Description: Equals

  Example:

```
gaussdb=# SELECT inet '192.168.1.5' = inet '192.168.1.5' AS RESULT;
 result
--------
 t
(1 row)
```

- >=

  Description: Is greater than or equals

  Example:

```
gaussdb=# SELECT inet '192.168.1.5' >= inet '192.168.1.5' AS RESULT;
 result
--------
 t
(1 row)
```

- >

  Description: Is greater than

  Example:

```
gaussdb=# SELECT inet '192.168.1.5' > inet '192.168.1.4' AS RESULT;
 result
--------
 t
(1 row)
```

- <>

  Description: Does not equal

  Example:

```
gaussdb=# SELECT inet '192.168.1.5' <> inet '192.168.1.4' AS RESULT;
 result
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
--------
 t
(1 row)
```

- <<

  Description: Is contained in

  Example:

```
gaussdb=# SELECT inet '192.168.1.5' << inet '192.168.1/24' AS RESULT;
 result
--------
 t
(1 row)
```

- <<=

  Description: Is contained in or equals

  Example:

```
gaussdb=# SELECT inet '192.168.1/24' <<= inet '192.168.1/24' AS RESULT;
 result
--------
 t
(1 row)
```

- >>

  Description: Contains

  Example:

```
gaussdb=# SELECT inet '192.168.1/24' >> inet '192.168.1.5' AS RESULT;
 result
--------
 t
(1 row)
```

- >>=

  Description: Contains or equals

  Example:

```
gaussdb=# SELECT inet '192.168.1/24' >>= inet '192.168.1/24' AS RESULT;
 result
--------
 t
(1 row)
```

- ~

  Description: Bitwise NOT

  Example:

```
gaussdb=# SELECT ~ inet '192.168.1.6' AS RESULT;
    result
---------------
 63.87.254.249
(1 row)
```

- &

  Description: Performs an AND operation on each bit of the two network addresses.

  Example:

```
gaussdb=# SELECT inet '192.168.1.6' & inet '10.0.0.0' AS RESULT;
 result
---------
 0.0.0.0
(1 row)
```

- |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description: Performs an OR operation on each bit of the two network addresses.

Example:

```
gaussdb=# SELECT inet '192.168.1.6' | inet '10.0.0.0' AS RESULT;
   result
-------------
 202.168.1.6
(1 row)
```

- +

  Description: Addition

  Example:

```
gaussdb=# SELECT inet '192.168.1.6' + 25 AS RESULT;
    result
--------------
 192.168.1.31
(1 row)
```

- -

  Description: Subtraction

  Example:

```
gaussdb=# SELECT inet '192.168.1.43' - 36 AS RESULT;
   result
-------------
 192.168.1.7
(1 row)
```

- -

  Description: Subtraction

  Example:

```
gaussdb=# SELECT inet '192.168.1.43' - inet '192.168.1.19' AS RESULT;
 result
--------
     24
(1 row)
```

cidr and inet Functions

The abbrev, host, and text functions are primarily intended to offer alternative display formats.

- abbrev(inet)

  Description: Abbreviated display format as text

  Return type: text

  Example:

```
gaussdb=# SELECT abbrev(inet '10.1.0.0/16') AS RESULT;
   result
-------------
 10.1.0.0/16
(1 row)
```

- abbrev(cidr)

  Description: Abbreviated display format as text

  Return type: text

  Example:

```
gaussdb=# SELECT abbrev(cidr '10.1.0.0/16') AS RESULT;
 result
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
---------
 10.1/16
(1 row)
```

- broadcast(inet)

  Description: Broadcast address for networks

  Return type: inet

  Example:

```
gaussdb=# SELECT broadcast('192.168.1.5/24') AS RESULT;
      result
------------------
 192.168.1.255/24
(1 row)
```

- family(inet)

  Description: Extracts family of address; **4** for IPv4, **6** for IPv6

  Return type: int

  Example:

```
gaussdb=# SELECT family('127.0.0.1') AS RESULT;
 result
--------
      4
(1 row)
```

- host(inet)

  Description: Extracts IP addresses as text.

  Return type: text

  Example:

```
gaussdb=# SELECT host('192.168.1.5/24') AS RESULT;
   result
-------------
 192.168.1.5
(1 row)
```

- hostmask(inet)

  Description: Constructs the host mask for a network.

  Return type: inet

  Example:

```
gaussdb=# SELECT hostmask('192.168.23.20/30') AS RESULT;
 result
---------
 0.0.0.3
(1 row)
```

- masklen(inet)

  Description: Extracts subnet mask length.

  Return type: int

  Example:

```
gaussdb=# SELECT masklen('192.168.1.5/24') AS RESULT;
 result
--------
     24
(1 row)
```

- netmask(inet)

  Description: Constructs the subnet mask for a network.

  Return type: inet

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Example:

```
gaussdb=# SELECT netmask('192.168.1.5/24') AS RESULT;
    result
---------------
 255.255.255.0
(1 row)
```

- network(inet)

  Description: Extracts the network part of an address.

  Return type: cidr

  Example:

  ```
  gaussdb=# SELECT network('192.168.1.5/24') AS RESULT;
      result
  ----------------
   192.168.1.0/24
  (1 row)
  ```

- set_masklen(inet, int)

  Description: Sets subnet mask length for the **inet** value.

  Return type: inet

  Example:

  ```
  gaussdb=# SELECT set_masklen('192.168.1.5/24', 16) AS RESULT;
      result
  ----------------
   192.168.1.5/16
  (1 row)
  ```

- set_masklen(cidr, int)

  Description: Sets subnet mask length for the **cidr** value.

  Return type: cidr

  Example:

  ```
  gaussdb=# SELECT set_masklen('192.168.1.0/24'::cidr, 16) AS RESULT;
      result
  ----------------
   192.168.0.0/16
  (1 row)
  ```

- text(inet)

  Description: Extracts IP addresses and subnet mask length as text.

  Return type: text

  Example:

  ```
  gaussdb=# SELECT text(inet '192.168.1.5') AS RESULT;
      result
  ----------------
   192.168.1.5/32
  (1 row)
  ```

Any **cidr** value can be cast to **inet** implicitly or explicitly; therefore, the functions shown above as operating on **inet** also work on **cidr** values. An **inet** value can be cast to **cidr**. After the conversion, any bits to the right of the subnet mask are silently zeroed to create a valid **cidr** value. In addition, you can cast a text string to **inet** or **cidr** using normal casting syntax. For example, **inet(expression)** or **colname::cidr**.

macaddr Functions

trunc(macaddr)

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description: Returns a MAC address with the last three bytes set to zero.

Return type: macaddr

Example:

```
gaussdb=# SELECT trunc(macaddr '12:34:56:78:90:ab') AS RESULT;
     result
-------------------
 12:34:56:00:00:00
(1 row)
```

NOTE

The macaddr type also supports the standard relational operators (such as **>** and **<=**) for lexicographical ordering, and the bitwise arithmetic operators (**~**, **&** and **|**) for NOT, AND and OR.

1.6.12 Text Search Functions and Operators

Text Search Operators

- @@

  Description: Specifies whether the tsvector-typed words match the tsquery-typed words.

  Example:

  ```
  gaussdb=# SELECT to_tsvector('fat cats ate rats') @@ to_tsquery('cat & rat') AS RESULT;
   result
  --------
   t
  (1 row)
  ```

- @@@

  Description: Synonym for @@

  Example:

  ```
  gaussdb=# SELECT to_tsvector('fat cats ate rats') @@@ to_tsquery('cat & rat') AS RESULT;
   result
  --------
   t
  (1 row)
  ```

- ||

  Description: Connects two tsvector-typed words.

  Example:

  ```
  gaussdb=# SELECT 'a:1 b:2'::tsvector || 'c:1 d:2 b:3'::tsvector AS RESULT;
            result
  ----------------------------
   'a':1 'b':2,5 'c':3 'd':4
  (1 row)
  ```

- &&

  Description: Performs the AND operation on two tsquery-typed words.

  Example:

  ```
  gaussdb=# SELECT 'fat | rat'::tsquery && 'cat'::tsquery AS RESULT;
            result
  ----------------------------
   ( 'fat' | 'rat' ) & 'cat'
  (1 row)
  ```

- ||

Description: Performs the OR operation on two tsquery-typed words.

Example:

```
gaussdb=# SELECT 'fat | rat'::tsquery || 'cat'::tsquery AS RESULT;
        result
-----------------------
 'fat' | 'rat' | 'cat'
(1 row)
```

- !!

  Description: Not a tsquery-typed word.

  Example:

  ```
  gaussdb=# SELECT !! 'cat'::tsquery AS RESULT;
   result
  --------
   !'cat'
  (1 row)
  ```

- <->

  Description: Performs the PHRASE operation on two tsquery-typed words.

  Example:

  ```
  gaussdb=# SELECT 'fat'::tsquery <-> 'cat'::tsquery AS RESULT;
      result
  ------------------
   'fat' <-> 'cat'
  (1 row)
  ```

- @>

  Description: Specifies whether a tsquery-typed word contains another tsquery-typed word.

  Example:

  ```
  gaussdb=# SELECT 'cat'::tsquery @> 'cat & rat'::tsquery AS RESULT;
   result
  --------
   f
  (1 row)
  ```

- <@

  Description: Specifies whether a tsquery-typed word is contained in another tsquery-typed word.

  Example:

  ```
  gaussdb=# SELECT 'cat'::tsquery <@ 'cat & rat'::tsquery AS RESULT;
   result
  --------
   t
  (1 row)
  ```

In addition to the preceding operators, the ordinary B-tree comparison operators (including = and <) are defined for types tsvector and tsquery.

Text Search Functions

- get_current_ts_config()

  Description: Obtains default text search configurations.

  Return type: regconfig

  Example:

  ```
  gaussdb=# SELECT get_current_ts_config();
   get_current_ts_config
  -----------------------
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
 english
(1 row)
```

- length(tsvector)

  Description: Specifies the number of tsvector-typed words.

  Return type: integer

  Example:

```
gaussdb=# SELECT length('fat:2,4 cat:3 rat:5A'::tsvector);
 length
--------
      3
(1 row)
```

- numnode(tsquery)

  Description: Specifies the number of tsquery-typed words plus operators.

  Return type: integer

  Example:

```
gaussdb=# SELECT numnode('(fat & rat) | cat'::tsquery);
 numnode
---------
       5
(1 row)
```

- plainto_tsquery([config regconfig,] query text)

  Description: Generates tsquery-typed words without punctuations. The AND operator (&) is used as the connection operator.

  Return type: tsquery

  Example:

```
gaussdb=# SELECT plainto_tsquery('english', 'The Fat Rats');
 plainto_tsquery
-----------------
 'fat' & 'rat'
(1 row)
```

- phraseto_tsquery([config regconfig,] query text)

  Description: Generates tsquery-typed words without punctuations. The PHRASE operator (<->) is used as the connection operator. **config** is the token configuration dictionary. For details, see **Dictionaries**.

  Return type: tsquery

  Example:

```
gaussdb=# SELECT phraseto_tsquery('english', 'The Fat Rats');
 phraseto_tsquery
------------------
 'fat' <-> 'rat'
(1 row)
```

- tsquery_phrase(query1 tsquery, query2 tsquery [, distance regdistance])

  Description: Connects tsquery types using the PHRASE operator. **query1** and **query2** can use data of the text type, which will be converted to the tsquery type. **distance** can be used to specify the distance between **query1** and **query2**.

  Return type: tsquery

  Example:

```
-- If the distance is not specified, use the default value 1.
gaussdb=# SELECT tsquery_phrase(to_tsquery('fat'), to_tsquery('cat'));
 tsquery_phrase
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
-----------------
 'fat' <-> 'cat'
(1 row)

-- Specify the distance.
gaussdb=# SELECT tsquery_phrase(to_tsquery('fat'), to_tsquery('cat'), 2);
 tsquery_phrase
-----------------
 'fat' <2> 'cat'
(1 row)
```

- querytree(query tsquery)

  Description: Obtains the indexable part of a tsquery-typed word.

  Return type: text

  Example:

```
gaussdb=# SELECT querytree('foo & ! bar'::tsquery);
 querytree
-----------
 'foo'
(1 row)
```

- setweight(tsvector, "char")

  Description: Assigns weight to each tsvector. The weight value can be **'A'**, **'B'**, **'C'**, or **'D'**.

  Return type: tsvector

  Example:

```
gaussdb=# SELECT setweight('fat:2,4 cat:3 rat:5B'::tsvector, 'A');
           setweight
-------------------------------
 'cat':3A 'fat':2A,4A 'rat':5A
(1 row)
```

- strip(tsvector)

  Description: Removes positions and weights from tsvector.

  Return type: tsvector

  Example:

```
gaussdb=# SELECT strip('fat:2,4 cat:3 rat:5A'::tsvector);
       strip
-------------------
 'cat' 'fat' 'rat'
(1 row)
```

- to_tsquery([config regconfig ,] query text)

  Description: Normalizes words and converts them to tsquery. For details, see **Parsing Queries**.

  Return type: tsquery

  Example:

```
gaussdb=# SELECT to_tsquery('english', 'The & Fat & Rats');
  to_tsquery
---------------
 'fat' & 'rat'
(1 row)
```

- to_tsvector([config regconfig ,] document text)

  Description: Standardizes the document content, removes stop words, sorts the content, deduplicates it, and then regenerates it to the tsvector type.

  Return type: tsvector

  Example:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gaussdb=# SELECT to_tsvector('english', 'The Fat Rats');
   to_tsvector
-----------------
 'fat':2 'rat':3
(1 row)
```

- to_tsvector_for_batch([config regconfig ,] document text)

  Description: Standardizes the document content, removes stop words, sorts the content, deduplicates it, and then regenerates it to the tsvector type.

  Return type: tsvector

  Example:

```
gaussdb=# SELECT to_tsvector_for_batch('english', 'The Fat Rats');
   to_tsvector
-----------------
 'fat':2 'rat':3
(1 row)
```

- ts_headline([config regconfig,] document text, query tsquery [, options text])

  Description: Highlights a query match. For details, see **Highlighting Search Results**.

  Return type: text

  Example:

```
gaussdb=# SELECT ts_headline('x y z', 'z'::tsquery);
 ts_headline
--------------
 x y <b>z</b>
(1 row)
```

- ts_rank([weights float4[],] vector tsvector, query tsquery [, normalization integer])

  Description: Ranks document for query. For details, see **Ranking Search Results**.

  Return type: float4

  Example:

```
gaussdb=# SELECT ts_rank('hello world'::tsvector, 'world'::tsquery);
 ts_rank
----------
 .0607927
(1 row)
```

- ts_rank_cd([weights float4[],] vector tsvector, query tsquery [, normalization integer])

  Description: Ranks document for query using cover density. For details, see **Ranking Search Results**.

  Return type: float4

  Example:

```
gaussdb=# SELECT ts_rank_cd('hello world'::tsvector,'world'::tsquery);
 ts_rank_cd
------------
          0
(1 row)
```

- ts_rewrite(query tsquery, target tsquery, substitute tsquery)

  Description: Replaces tsquery-typed word. For details, see **Rewriting Queries**.

  Return type: tsquery

  Example:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gaussdb=# SELECT ts_rewrite('a & b'::tsquery, 'a'::tsquery, 'foo|bar'::tsquery);
     ts_rewrite
------------------------
 'b' & ( 'foo' | 'bar' )
(1 row)
```

- ts_rewrite(query tsquery, select text)

  Description: Replaces tsquery data in the target with the result of a **SELECT** command. For details, see **Rewriting Queries**.

  Return type: tsquery

  Example:

```
gaussdb=# SELECT ts_rewrite('world'::tsquery, 'select ''world''::tsquery, ''hello''::tsquery');
 ts_rewrite
------------
 'hello'
(1 row)
```

Text Search Debugging Functions

NOTICE

This function is for internal use only. You are advised not to use it.

- ts_debug([config regconfig,] document text, OUT alias text, OUT description text, OUT token text, OUT dictionaries regdictionary[], OUT dictionary regdictionary, OUT lexemes text[])

  Description: Tests a configuration.

  Return type: SETOF record

  Example:

```
gaussdb=# SELECT ts_debug('english', 'The Brightest supernovaes');
                                ts_debug
-------------------------------------------------------------------------------
 (asciiword,"Word, all ASCII",The,{english_stem},english_stem,{})
 (blank,"Space symbols"," ",{},,)
 (asciiword,"Word, all ASCII",Brightest,{english_stem},english_stem,{brightest})
 (blank,"Space symbols"," ",{},,)
 (asciiword,"Word, all ASCII",supernovaes,{english_stem},english_stem,{supernova})
(5 rows)
```

- ts_lexize(dict regdictionary, token text)

  Description: Tests a data dictionary.

  Return type: text[]

  Example:

```
gaussdb=# SELECT ts_lexize('english_stem', 'stars');
 ts_lexize
-----------
 {star}
(1 row)
```

- ts_parse(parser_name text, document text, OUT tokid integer, OUT token text)

  Description: Tests a parser.

  Return type: SETOF record

  Example:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gaussdb=# SELECT ts_parse('default', 'foo - bar');
 ts_parse
-----------
 (1,foo)
 (12," ")
 (12,"- ")
 (1,bar)
(4 rows)
```

- ts_parse(parser_oid oid, document text, OUT tokid integer, OUT token text)

  Description: Tests a parser.

  Return type: SETOF record

  Example:

```
gaussdb=# SELECT ts_parse(3722, 'foo - bar');
 ts_parse
-----------
 (1,foo)
 (12," ")
 (12,"- ")
 (1,bar)
(4 rows)
```

- ts_token_type(parser_name text, OUT tokid integer, OUT alias text, OUT description text)

  Description: Obtains token types defined by a parser.

  Return type: SETOF record

  Example:

```
gaussdb=# SELECT ts_token_type('default');
                      ts_token_type
-----------------------------------------------------------------
 (1,asciiword,"Word, all ASCII")
 (2,word,"Word, all letters")
 (3,numword,"Word, letters and digits")
 (4,email,"Email address")
 (5,url,URL)
 (6,host,Host)
 (7,sfloat,"Scientific notation")
 (8,version,"Version number")
 (9,hword_numpart,"Hyphenated word part, letters and digits")
 (10,hword_part,"Hyphenated word part, all letters")
 (11,hword_asciipart,"Hyphenated word part, all ASCII")
 (12,blank,"Space symbols")
 (13,tag,"XML tag")
 (14,protocol,"Protocol head")
 (15,numhword,"Hyphenated word, letters and digits")
 (16,asciihword,"Hyphenated word, all ASCII")
 (17,hword,"Hyphenated word, all letters")
 (18,url_path,"URL path")
 (19,file,"File or path name")
 (20,float,"Decimal notation")
 (21,int,"Signed integer")
 (22,uint,"Unsigned integer")
 (23,entity,"XML entity")
(23 rows)
```

- ts_token_type(parser_oid oid, OUT tokid integer, OUT alias text, OUT description text)

  Description: Obtains token types defined by a parser.

  Return type: SETOF record

  Example:

```
gaussdb=# SELECT ts_token_type(3722);
                      ts_token_type
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
------------------------------------------------------------
 (1,asciiword,"Word, all ASCII")
 (2,word,"Word, all letters")
 (3,numword,"Word, letters and digits")
 (4,email,"Email address")
 (5,url,URL)
 (6,host,Host)
 (7,sfloat,"Scientific notation")
 (8,version,"Version number")
 (9,hword_numpart,"Hyphenated word part, letters and digits")
 (10,hword_part,"Hyphenated word part, all letters")
 (11,hword_asciipart,"Hyphenated word part, all ASCII")
 (12,blank,"Space symbols")
 (13,tag,"XML tag")
 (14,protocol,"Protocol head")
 (15,numhword,"Hyphenated word, letters and digits")
 (16,asciihword,"Hyphenated word, all ASCII")
 (17,hword,"Hyphenated word, all letters")
 (18,url_path,"URL path")
 (19,file,"File or path name")
 (20,float,"Decimal notation")
 (21,int,"Signed integer")
 (22,uint,"Unsigned integer")
 (23,entity,"XML entity")
(23 rows)
```

- ts_stat(sqlquery text, [weights text,] OUT word text, OUT ndoc integer, OUT nentry integer)

  Description: Obtains statistics of a tsvector column.

  Return type: SETOF record

  Example:

```
gaussdb=# SELECT ts_stat('select ''hello world''::tsvector');
   ts_stat
-------------
 (world,1,1)
 (hello,1,1)
(2 rows)
```

1.6.13 JSON/JSONB Functions and Operators

For details about the JSON/JSONB data type, see **JSON/JSONB Types**. For details about the operator information, see **Table 1-77** and **Table 1-78**.

Table 1-77 Common JSON/JSONB operators

Operators	Left Operand Type	Right Operand Type	Return Type	Description	Example
->	Array-json(b)	int	json(b)	Obtains the **array-json** element. If the index does not exist, **NULL** is returned.	SELECT '[{"a":"foo"},{"b":"bar"},{"c":"baz"}]'::json->2; ?column? ------------- {"c":"baz"} (1 row)
->	object-json(b)	text	json(b)	Obtains the value by a key. If no record is found, **NULL** is returned.	SELECT '{"a": {"b":"foo"}}'::json->'a'; ?column? ------------- {"b":"foo"} (1 row)

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Operators	Left Operand Type	Right Operand Type	Return Type	Description	Example
->>	Array-json(b)	int	text	Obtains JSON array elements. If the index does not exist, **NULL** is returned.	SELECT '[1,2,3]'::json->>2; ?column? ---------- 3 (1 row)
->>	object-json(b)	text	text	Obtains the value by a key. If no record is found, **NULL** is returned.	SELECT '{"a":1,"b":2}'::json->>'b'; ?column? ---------- 2 (1 row)
#>	container-json (b)	text[]	json(b)	Obtains the JSON object in the specified path. If the path does not exist, **NULL** is returned.	SELECT '{"a": {"b":{"c": "foo"}}}'::json #>'{a,b}'; ?column? -------------- {"c": "foo"} (1 row)
#>>	container-json (b)	text[]	text	Obtains the JSON object in the specified path. If the path does not exist, **NULL** is returned.	SELECT '{"a":[1,2,3],"b":[4,5,6]}'::json #>>'{a,2}'; ?column? ---------- 3 (1 row)

CAUTION

For the #> and #>> operators, if no data is found in the specified path, they will return null instead of reporting an error.

Table 1-78 Additional JSONB support for operators

Operators	Right Operand Type	Description	Example
@>	jsonb	Specifies whether the top layer of the JSON on the left contains all items of the top layer of the JSON on the right.	'{"a":1, "b":2}'::jsonb @> '{"b":2}'::jsonb

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Operators	Right Operand Type	Description	Example
<@	jsonb	Specifies whether all items in the JSON file on the left exist at the top layer of the JSON file on the right.	'{"b":2}'::jsonb <@ '{"a":1, "b":2}'::jsonb
?	text	Specifies whether the string of the key or element exists at the top layer of the JSON value.	'{"a":1, "b":2}'::jsonb ? 'b'
?|	text[]	Specifies whether any of these array strings exists as top-layer keys.	'{"a":1, "b":2, "c":3}'::jsonb ?| array['b', 'c']
?&	text[]	Specifies whether all these array strings exist as top-layer keys.	'["a", "b"]'::jsonb ?& array['a', 'b']
=	jsonb	Determines the size between two **JSONB** files, which is the same as the **jsonb_eq** function.	/
<>	jsonb	Determines the size between two **JSONB** files, which is the same as the **jsonb_ne** function.	/
<	jsonb	Determines the size between two **JSONB** files, which is the same as the **jsonb_lt** function.	/
>	jsonb	Determines the size between two **JSONB** files, which is the same as the **jsonb_gt** function.	/

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Operators	Right Operand Type	Description	Example
<=	jsonb	Determines the size between two **JSONB** files, which is the same as the **jsonb_le** function.	/
>=	jsonb	Determines the size between two **JSONB** files, which is the same as the **jsonb_ge** function.	/

NOTE

GIN indexes can be used to effectively search for keys or key-value pairs that appear in a large number of JSONB documents (datums). Two GIN operator classes (jsonb_ops and jsonb_hash_ops) are provided for different performance and flexibility choices.

- The default GIN operator class jsonb_ops supports queries using the @>, ?, ?&, and ?| operators.
- The non-default GIN operator class jsonb_hash_ops supports indexing the @> operator only.

Functions Supported by JSON/JSONB

- array_to_json(anyarray [, pretty_bool])

  Description: Returns the array as JSON. It combines a multi-dimensional array into a JSON array. Line feeds will be added between one-dimensional elements if **pretty_bool** is **true**.

  Return type: json

  Example:

```
gaussdb=# SELECT array_to_json('{{1,5},{99,100}}'::int[]);
  array_to_json
------------------
 [[1,5],[99,100]]
(1 row)
```

- row_to_json(record [, pretty_bool])

  Description: Returns the row as JSON. Line feeds will be added between level-1 elements if **pretty_bool** is **true**.

  Return type: json

  Example:

```
gaussdb=# SELECT row_to_json(row(1,'foo'));
    row_to_json
---------------------
 {"f1":1,"f2":"foo"}
(1 row)
```

- json_array_element(array-json, integer), jsonb_array_element(array-jsonb, integer)

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description: Same as the operator `->`, which returns the element with the specified index in the array.

Return type: json, jsonb

Example:

```
gaussdb=# SELECT json_array_element('[1,true,[1,[2,3]],null]',2);
 json_array_element
--------------------
 [1,[2,3]]
(1 row)
```

- json_array_element_text(array-json, integer), jsonb_array_element_text(array-jsonb, integer)

  Description: Same as the operator `->>`, which returns the element with the specified index in the array.

  Return type: text, text

  Example:

  ```
  gaussdb=# SELECT json_array_element_text('[1,true,[1,[2,3]],null]',2);
  json_array_element_text
  ------------------------
   [1,[2,3]]
  (1 row)
  ```

- json_object_field(object-json, text), jsonb_object_field(object-jsonb, text)

  Description: Same as the operator **`->`**, which returns the value of a specified key in an object.

  Return type: json, json

  Example:

  ```
  gaussdb=# SELECT json_object_field('{"a": {"b":"foo"}}','a');
   json_object_field
  -------------------
   {"b":"foo"}
  (1 row)
  ```

- json_object_field_text(object-json, text), jsonb_object_field_text(object-jsonb, text)

  Description: Same as the operator **`->>`**, which returns the value of a specified key in an object.

  Return type: text, text

  Example:

  ```
  gaussdb=# SELECT json_object_field_text('{"a": {"b":"foo"}}','a');
  json_object_field_text
  ----------------------
   {"b":"foo"}
  (1 row)
  ```

- json_extract_path(json, VARIADIC text[]), jsonb_extract_path((jsonb, VARIADIC text[])

  Description: It is equivalent to the operator `#>`, searches for **json** based on the path specified by the second parameter, and returns the result.

  Return type: json, jsonb

  Example:

  ```
  gaussdb=# SELECT json_extract_path('{"f2":{"f3":1},"f4":{"f5":99,"f6":"stringy"}}', 'f4','f6');
   json_extract_path
  -------------------
   "stringy"
  (1 row)
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- json_extract_path_op(json, text[]), jsonb_extract_path_op(jsonb, text[])

  Description: It is equivalent to the operator `#>`, searches for **json** based on the path specified by the second parameter, and returns the result.

  Return type: json, jsonb

  Example:

```
gaussdb=# SELECT json_extract_path_op('{"f2":{"f3":1},"f4":{"f5":99,"f6":"stringy"}}', ARRAY['f4','f6']);
 json_extract_path_op
----------------------
 "stringy"
(1 row)
```

- json_extract_path_text(json, VARIADIC text[]), jsonb_extract_path_text((jsonb, VARIADIC text[])

  Description: It is equivalent to the operator `#>>`, searches for **json** based on the path specified by the second parameter, and returns the result.

  Return type: text, text

  Example:

```
gaussdb=# SELECT json_extract_path_text('{"f2":{"f3":1},"f4":{"f5":99,"f6":"stringy"}}', 'f4','f6');
 json_extract_path_text
------------------------
 stringy
(1 row)
```

- json_extract_path_text_op(json, text[]), jsonb_extract_path_text_op(jsonb, text[])

  Description: It is equivalent to the operator `#>>`, searches for **json** based on the path specified by the second parameter, and returns the result.

  Return type: text, text

  Example:

```
gaussdb=# SELECT json_extract_path_text_op('{"f2":{"f3":1},"f4":{"f5":99,"f6":"stringy"}}',
ARRAY['f4','f6']);
 json_extract_path_text_op
---------------------------
 stringy
(1 row)
```

- json_array_elements(array-json), jsonb_array_elements(array-jsonb)

  Description: Splits an array. Each element returns a row.

  Return type: json, jsonb

  Example:

```
gaussdb=# SELECT json_array_elements('[1,true,[1,[2,3]],null]');
 json_array_elements
---------------------
 1
 true
 [1,[2,3]]
 null
(4 rows)
```

- json_array_elements_text(array-json), jsonb_array_elements_text(array-jsonb)

  Description: Splits an array. Each element returns a row.

  Return type: text, text

  Example:

```
gaussdb=# SELECT * FROM  json_array_elements_text('[1,true,[1,[2,3]],null]');
   value
-----------
 1
 true
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
 [1,[2,3]]

(4 rows)
```

- json_array_length(array-json), jsonb_array_length(array-jsonb)

  Description: Returns the array length.

  Return type: integer

  Example:

```
gaussdb=# SELECT json_array_length('[1,2,3,{"f1":1,"f2":[5,6]},4,null]');
 json_array_length
-------------------
                 6
(1 row)
```

- json_each(object-json), jsonb_each(object-jsonb)

  Description: Splits each key-value pair of an object into one row and two columns.

  Return type: setof(key text, value json), setof(key text, value jsonb)

  Example:

```
gaussdb=# SELECT * FROM  json_each('{"f1":[1,2,3],"f2":{"f3":1},"f4":null}');
 key |  value
-----+----------
 f1  | [1,2,3]
 f2  | {"f3":1}
 f4  | null
(3 rows)
```

- json_each_text(object-json), jsonb_each_text(object-jsonb)

  Description: Splits each key-value pair of an object into one row and two columns.

  Return type: setof(key text, value text), setof(key text, value text)

  Example:

```
gaussdb=# SELECT * FROM  json_each_text('{"f1":[1,2,3],"f2":{"f3":1},"f4":null}');
 key |  value
-----+----------
 f1  | [1,2,3]
 f2  | {"f3":1}
 f4  |
(3 rows)
```

- json_object_keys(object-json), jsonb_object_keys(object-jsonb)

  Description: Returns all keys at the top layer of the object.

  Return type: SETOF text

  Example:

```
gaussdb=# SELECT json_object_keys('{"f1":"abc","f2":{"f3":"a", "f4":"b"}, "f1":"abcd"}');
 json_object_keys
------------------
 f1
 f2
 f1
(3 rows)
```

```
--The jsonb_object_keys function involves deduplication.
gaussdb=# SELECT jsonb_object_keys('{"f1":"abc","f2":{"f3":"a", "f4":"b"}, "f1":"abcd"}');
 jsonb_object_keys
-------------------
 f1
 f2
(2 rows)
```

- json_populate_record(anyelement, object-json [, bool]), jsonb_populate_record(anyelement, object-jsonb [, bool])

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description: Splits each key-value pair in the second parameter, uses the key as the column name, matches the column name in the first parameter (which must be of the composite type), and fills the value in the format of the first parameter.

Return type: anyelement, anyelement

Example:

```
gaussdb=# CREATE TYPE jpop AS (a text, b int, c bool);
CREATE TYPE
gaussdb=# SELECT * FROM json_populate_record(null::jpop,'{"a":"blurfl","x":43.2}');
   a    | b | c
--------+---+---
 blurfl |   |
(1 row)
```

```
gaussdb=# SELECT * FROM json_populate_record((1,1,null)::jpop,'{"a":"blurfl","x":43.2}');
   a    | b | c
--------+---+---
 blurfl | 1 |
(1 row)
gaussdb=# DROP TYPE jpop;
DROP TYPE
```

- json_populate_recordset(anyelement, array-json [, bool]), jsonb_populate_recordset(anyelement, array-jsonb [, bool])

  Description: Processes each element in the array of the second parameter by utilizing the same method as the json_populate_record and jsonb_populate_record functions. Therefore, each element in the array of the second parameter must be of the object-json type.

  Return type: setof anyelement, setof anyelement

  Example:

```
gaussdb=# CREATE TYPE jpop AS (a text, b int, c bool);
CREATE TYPE
gaussdb=# SELECT * FROM json_populate_recordset(null::jpop, '[{"a":1,"b":2},{"a":3,"b":4}]');
 a | b | c
---+---+---
 1 | 2 |
 3 | 4 |
(2 rows)
gaussdb=# DROP TYPE jpop;
DROP TYPE
```

- json_typeof(json), jsonb_typeof(jsonb)

  Description: Checks the JSON type.

  Return type: text, text

  Example:

```
gaussdb=# SELECT value, json_typeof(value)  FROM (values (json '123.4'), (json '"foo"'), (json 'true'),
(json 'null'), (json '[1, 2, 3]'), (json '{"x":"foo", "y":123}'), (NULL::json))  AS data(value);
         value          | json_typeof
------------------------+-------------
 123.4                  | number
 "foo"                  | string
 true                   | boolean
 null                   | null
 [1, 2, 3]              | array
 {"x":"foo", "y":123} | object
                        |
(7 rows)
```

- json_build_array([VARIADIC "any"])

  Description: Constructs a JSON array from a variable parameter list.

  Return type: array-json

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Example:

```
gaussdb=# SELECT json_build_array('a',1,'b',1.2,'c',true,'d',null,'e',json '{"x": 3, "y": [1,2,3]}','');
                          json_build_array
-------------------------------------------------------------------------------
 ["a", 1, "b", 1.2, "c", true, "d", null, "e", {"x": 3, "y": [1,2,3]}, null]
(1 row)
```

- json_build_object([VARIADIC "any"])

  Description: Constructs a JSON object from a variable parameter list. The number of input parameters must be an even number. Every two input parameters form a key-value pair. Note that the key value cannot be **NULL**.

  Return type: object-json

  Example:

```
gaussdb=# SELECT json_build_object(1,2);
 json_build_object
-------------------
 {"1" : 2}
(1 row)
```

- jsonb_build_object([VARIADIC "any"])

  Description: Constructs a JSONB object from a variable parameter list. The number of input parameters must be an even number. Every two input parameters form a key-value pair. Note that the key value cannot be **NULL**.

  Return type: object-jsonb

NOTICE

- When an element in the variable parameter list contains an empty string (''), if the SQL compatibility mode is Oracle-compatible, the return result of the corresponding element is **NULL**; if the SQL compatibility mode of the database is PG-compatible, the return result of the corresponding element is an empty string. This is because empty strings are treated as **NULL** in ORA-compatible mode.
- If an element in the variable parameter list is of the DATE type, and **mapping_date_to_datea** is disabled in ORA-compatible mode, the DATE type is replaced by the TIMESTAMP (0) WITHOUT TIME ZONE type. When **mapping_date_to_datea** is enabled, the DATE type is replaced by the DATEA type. Therefore, the format of the returned result of the corresponding element position is affected by whether **mapping_date_to_datea** is enabled. In PG-compatible mode, the returned result of the corresponding element position does not contain hour, minute, or second.

Example:

```
gaussdb=# SELECT jsonb_build_object('a',1,'b',1.2,'c',true,'d',null,'e',json '{"x": 3, "y": [1,2,3]}');
                         jsonb_build_object
-------------------------------------------------------------------------------
 {"a": 1, "b": 1.2, "c": true, "d": null, "e": {"x": 3, "y": [1, 2, 3]}}
(1 row)

gaussdb=# SELECT jsonb_build_object();
 jsonb_build_object
--------------------
 {}
(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- json_to_record(object-json, bool), json_to_record(object-json)

  Description: Like all functions that return **record**, the caller must explicitly define the structure of the record with an AS clause. The key-value pairs in **object-json** are split and reassembled. The keys serve as column names to be matched with and populated into the structure of the record explicitly specified by the AS clause. The values of the keys must follow the structure of the relevant data type. The date type is equivalent to TIMESTAMP(0) WITHOUT TIME ZONE in ORA-compatible mode when **mapping_date_to_datea** is disabled. Compared with that in PG-compatible mode, the value also displays the 00:00:00 (hour, minute, and second) character string.

  Parameter: The Boolean input parameter of the first overloaded function specifies whether object nesting is supported. The value **true** indicates that object nesting is supported, and the value **false** indicates that object nesting is not supported. If there is only one input parameter, nesting is supported by default. In this case, the nested JSON object can be converted into a row type and parsed as an array enclosed in square brackets.

  Return type: record

  Example:

  ```
  gaussdb=# SELECT * FROM json_to_record('{"a":1,"b":"foo","c":"bar"}',true) AS x(a int, b text, d text);
    a |  b  | d
   ---+-----+---
    1 | foo |
   (1 row)
  gaussdb=# SELECT * FROM json_to_record('{"a": {"x": 1, "y": 2},"b":"foo","c":[1, 2]}') AS x(a json, b
  text, c int[]);
          a         | b |   c
   -----------------+-----+-------
    {"x": 1, "y": 2} | foo | {1,2}
   (1 row)
  ```

- json_to_recordset(array-json, bool)

  Description: Executes the preceding function on each element in the array by referring to the json_to_record function. Therefore, each element in the array must be object-json. For **bool**, refer to the json_to_record function. **true** indicates that nested objects can be parsed, and **false** indicates that nested objects cannot be parsed, that is, whether the value of an element in a JSON object can be a JSON object.

  Return type: SETOF record

  Example:

  ```
  gaussdb=# SELECT * FROM json_to_recordset('[{"a":1,"b":"foo","d":false},
  {"a":2,"b":"bar","c":true}]',false) AS x(a int, b text, c boolean);
   a |  b  | c
  ---+-----+---
   1 | foo |
   2 | bar | t
  (2 rows)
  ```

- json_object(text[]), json_object(text[], text[])

  Description: Constructs an **object-json** from a text array. This is an overloaded function. When the input parameter is a text array, the array length must be an even number, and members are considered as alternate key-value pairs. When two text arrays are used, the first array is considered as a key, and the second array a value. The lengths of the two arrays must be the same. The value of a key cannot be **NULL**.

  Return type: object-json

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Example:

```
gaussdb=# SELECT json_object('{a,1,b,2,3,NULL,"d e f","a b c"}');
                    json_object
-----------------------------------------------------------
 {"a" : "1", "b" : "2", "3" : null, "d e f" : "a b c"}
(1 row)
gaussdb=# SELECT json_object('{a,b,"a b c"}', '{a,1,1}');
              json_object
---------------------------------------
 {"a" : "a", "b" : "1", "a b c" : "1"}
(1 row)
```

- json_object([VARIADIC "any"])

  Description: Constructs a JSON object from a variable parameter list. The number of input parameters must be an even number. Every two input parameters form a key-value pair. If the key-value pair is null, an error is reported. If the parameter is in the odd format, an error is reported.

  Parameter: variable parameter list. The input parameter is a combination of one or more key-value pairs.

  Return type: json

  Example:

```
gaussdb=# SELECT json_object('d',2,'c','name','b',true,'a',2,'a',NULL,'d',1);
               json_object
-----------------------------------------
 {"a": 2, "b": true, "c": "name", "d": 2}
(1 row)

gaussdb=# SELECT json_object('d',2,true,'name','b',true,'a',2,'aa', current_timestamp);
                                json_object
---------------------------------------------------------------------------
 {"1": "name", "a": 2, "b": true, "d": 2, "aa": "2023-08-12 11:28:13.385958"}
(1 row)
```

  NOTE

  This function takes effect in a MySQL-compatible database when **b_format_version** is set to **'5.7'** and **b_format_dev_version** is set to **'s1'**. When this function takes effect, the original json_object behavior is replaced.

- json_append/json_array_append(json, [VARIADIC "any"])

  Description: Constructs several **json_path**-**value** pairs from a variable-parameter list, appends a value to the path specified in **json**, and returns the modified **json**. json_append is the same as json_array_append. If any parameter is null, **null** is returned. If the JSON format is incorrect, **json_path** is an invalid path expression, or **json_path** contains * or **, an error is reported. If the variable parameter list contains null values and has format error, the exceptions are processed based on the exception sequence. If a null value exists first, **null** is returned first. If a format error occurs first, an error is reported first.

  Parameters: For details, see **Table 1-79**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 1-79 Parameters

Parameter	Type	Description	Value Range
json	JSON, JSONB, CSTRING, TEXT, "char", VARCHAR, BPCHAR, NVARCHAR2	JSON value to be modified. If other non-restricted types are passed, an error will be reported during execution.	The value must be in JSON format.
[VARIADIC "any"]	Variable any array	A variable parameter list, including variable json_path-value pairs. The **json_path**-**value** pair will be constructed from the variable parameter list.	**json_path** must be a valid path expression, and **value** can be any value.

Return type: json

Example:

```
gaussdb=# SELECT json_array_append('[1, [2, 3]]', '$[1]', 4, '$[0]', false, '$[0]', null, '$[0]',
current_timestamp);
                    json_array_append
----------------------------------------------------------------
 [[1, false, null, "2023-08-12 14:27:16.142355+08"], [2, 3, 4]]
(1 row)
```

- json_array([VARIADIC "any"])

  Description: Constructs an array from a variable parameter list and returns a JSON array. If the function does not have any parameters, an empty JSON array is returned.

  Parameter: The input parameter is a variable parameter list. The values in the list can be of any type.

  Return type: json

  Example:

  ```
  -- If no input parameter is entered, an empty JSON array is returned.
  gaussdb=# SELECT json_array();
  ))::numeric >= $0) json_array
  ------------
   []
  (1 row)

  -- The input parameter can be of any type.
  gaussdb=# SELECT json_array(TRUE, FALSE, NULL, 114, 'text', current_timestamp);
                            json_array
  ------------------------------------------------------------------
   [true, false, null, 114, "text", "2023-08-12 15:17:34.979294+08"]
  (1 row)
  ```

- json_array_insert(json, [VARIADIC "any"])

  Description: Constructs one or more **json_path**-**value** pairs from a variable parameter list, inserts a value into the array path specified by the **json_path**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

in **json**, and returns a new JSON value. If there is already an existing value on the specified path, the value is inserted on the path and the existing value is moved backward. If **json** or **json_path** is null, **null** is returned. If the JSON format is incorrect, **json_path** is an invalid path expression, or **json_path** contains * or **, an error is reported. If the variable parameter list contains null values and has format error, the exceptions are processed based on the exception sequence. If a null value exists first, **null** is returned first. If a format error occurs first, an error is reported first.

Parameters: See **Table 1-80**.

Table 1-80 Parameters

Parameter	Type	Description	Value Range
json	JSON, JSONB, CSTRING, TEXT, "char", VARCHAR, BPCHAR, NVARCHAR2	JSON value to be modified. If other non-restricted types are passed, an error will be reported during execution.	The value must be in JSON format.
[VARIADIC "any"]	Variable any array	Variable parameter list, containing one or more json_path-value pairs.	**json_path** must be a valid path expression, and **value** can be any value.

Return type: json

Example:

```
-- Example of containing one json_path-value pair
gaussdb=# SELECT json_array_insert('[1, [2, 3]]', '$[1]', 4);
 json_array_insert
-------------------
 [1, 4, [2, 3]]
(1 row)

-- Example of containing multiple json_path-value pairs
gaussdb=# SELECT json_array_insert('{"x": 1, "y": [1, 2]}', '$.y[0]', NULL, '$.y[0]', 123, '$.y[3]',
current_timestamp);
                        json_array_insert
------------------------------------------------------------------
 {"x": 1, "y": [123, null, 1, "2023-08-14 14:54:12.85087+08", 2]}
(1 row)
```

- json_contains(target_json, candidate_json[, json_path])

  Description: The input parameters are two JSON objects and an optional path specified by **json_path**. If **json_path** is not specified, the system checks whether **target_json** contains **candidate_json**. If **json_path** is specified, the system checks whether **candidate_json** is contained in the JSON path specified by **json_path** in **target_json**. If **json** or **json_path** is null, **null** is returned. If the JSON format is incorrect, **json_path** is an invalid path

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

expression, or **json_path** contains * or **, an error is reported. If the variable parameter list contains null values and has format error, the exceptions are processed based on the exception sequence. If a null value exists first, **null** is returned first. If a format error occurs first, an error is reported first.

Parameters: See **Table 1-81**.

Table 1-81 Parameters

Parameter	Type	Description	Value Range
target_json	JSON, JSONB, CSTRING, TEXT, "char", VARCHAR, BPCHAR, NVARCHAR2	Target JSON object, which is used to check whether **candidate_json** is contained in the JSON object. If other non-restricted types are passed, an error will be reported during execution.	The value must be in JSON format.
candidate_json	JSON, JSONB, CSTRING, TEXT, "char", VARCHAR, BPCHAR, NVARCHAR2	JSON subobject, which is used to check whether it is contained in **target_json**. If other non-restricted types are passed, an error will be reported during execution.	The value must be in JSON format.
json_path	text	Specified JSON path. This parameter is optional. If this parameter is specified, the path specified by **json_path** in **target_json** is used to determine the inclusion relationship.	**json_path** must be a valid path expression.

Return type: bigint. If there is an inclusion relationship, **1** is returned. If there is no inclusion relationship, **0** is returned.

Example:

```
-- No path is specified.
gaussdb=# SELECT json_contains('[1, 2, {"x": 3}]', '{"x":3}');
 json_contains
---------------
             1
(1 row)

-- A path is specified.
gaussdb=# SELECT json_contains('[1, 2, {"x": 3},[1,2,3,4]]', '2','$[1]');
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
 json_contains
---------------
             1
(1 row)

gaussdb=# SELECT json_contains('[1, 2, {"x": 3},[1,2,3,4]]', '1','$[1]');
 json_contains
---------------
             0
(1 row)
```

- json_contains_path(json, mode_str, [VARIADIC text])

  Description: Checks whether a JSON object has a value on the specified path. There can be multiple paths. The first input parameter is a JSON object, and the second input parameter can be **one** or **all**, specifying whether to check all paths. The third input parameter is a variable parameter list. All JSON paths are constructed from the variable parameter list. According to the mode, if a path value exists, **1** is returned. If no path value exists, **0** is returned. If **json** or **json_path** is null, **null** is returned. If the JSON format is incorrect, or **json_path** is an invalid path expression, an error is reported. If the variable parameter list contains null values and has format error, the exceptions are processed based on the exception sequence. If a null value exists first, **null** is returned first. If a format error occurs first, an error is reported first.

  Parameters: See **Table 1-82**.

Table 1-82 Parameters

Parameter	Type	Description	Value Range
json	JSON, JSONB, CSTRING, TEXT, "char", VARCHAR, BPCHAR, NVARCHAR2	JSON object to be specified. If other non-restricted types are passed, an error will be reported during execution.	The value must be in JSON format.
mode_str	text	The value can be **one** or **all**. If the value is **one** and one path exists, **1** is returned; otherwise, **0** is returned. If the value is **all** and all paths exist, **1** is returned; otherwise, **0** is returned.	The value must be **one** or **all**, which is case-insensitive.
[VARIADIC text]	Variable text array	Variable parameter list from which all JSON paths are constructed.	**json_path** must be a valid path expression.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Return type: bigint

Example:

```
-- In the all scenario, all paths must exist.
gaussdb=# SELECT json_contains_path('[1, 2, {"x": 3}]', 'all', '$[0]', '$[1]', '$[2]');
 json_contains_path
--------------------
                  1
(1 row)

gaussdb=# SELECT json_contains_path('[1, 2, {"x": 3}]', 'all', '$[0]', '$[1]', '$[6]');
 json_contains_path
--------------------
                  0
(1 row)

-- In the one scenario, at least one path must exist.
gaussdb=# SELECT json_contains_path('[1, 2, {"x": 3}]', 'one', '$[0]', '$[1]', '$[5]');
 json_contains_path
--------------------
                  1
(1 row)
```

- json_depth(json)

  Description: Returns the maximum depth of the input JSON object. If the input parameter is null, **null** is returned.

  Parameter: The input parameter is a JSON object whose depth needs to be queried. Only the JSON, JSONB, CSTRING, TEXT, "char", VARCHAR, BPCHAR, and NVARCHAR2 types are supported. If other non-restricted types or an invalid JSON object is passed, an error will be reported during execution.

  Return type: int

  Example:

  ```
  -- The depth of an empty array is 1.
  gaussdb=# SELECT json_depth('[]');
   json_depth
  ------------
           1
  (1 row)

  gaussdb=# SELECT json_depth('{"s":1, "x":2,"y":[1]}');
   json_depth
  ------------
           3
  (1 row)
  ```

- json_extract(json, [VARIADIC text])

  Description: Extracts the data of JSON paths from a JSON object, merges this data into a JSON array, and returns the array. These JSON paths are built out of the variable-parameter list. Both the JSON paths and JSON object are specified in the input parameters. If **json** or **json_path** is null, **null** is returned. If the JSON format is incorrect, or **json_path** is an invalid path expression, an error is reported. If the variable parameter list contains null values and has format error, the exceptions are processed based on the exception sequence. If a null value exists first, **null** is returned first. If a format error occurs first, an error is reported first.

  Parameters: See **Table 1-83**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 1-83 Parameters

Parameter	Type	Description	Value Range
json	JSON, JSONB, CSTRING, TEXT, "char", VARCHAR, BPCHAR, NVARCHAR2	JSON value from which paths are to be extracted. If other non-restricted types are passed, an error will be reported during execution.	The value must be in JSON format.
[VARIADIC text]	Variable text array	Variable parameter list, containing one or more JSON paths.	**json_path** must be a valid path expression.

Return type: json

Example:

```
-- One path is extracted.
gaussdb=# SELECT json_extract('[1, 2, {"x": 3}]', '$[2]');
 json_extract
--------------
 {"x": 3}
(1 row)

-- Multiple paths are extracted.
gaussdb=# SELECT json_extract('["a", ["b", "c"], "d"]', '$[1]', '$[2]', '$[3]');
   json_extract
-------------------
 [["b", "c"], "d"]
(1 row)
```

- json_insert(json, [VARIADIC any])

  Description: Inserts a value at the position specified by **json_path** in a JSON object. The insertion operation is performed only when the path does not exist. The input parameter is a JSON object, several JSON paths, and the value to be inserted. Each JSON path must be paired with a value. If **json** or **json_path** is null, **null** is returned. In addition, **json_path** cannot contain wildcard characters * or **. Otherwise, an error is reported. If the variable parameter list contains null values and has format error, the exceptions are processed based on the exception sequence. If a null value exists first, **null** is returned first. If a format error occurs first, an error is reported first.

  Parameters: See **Table 1-84**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 1-84 Parameters

Parameter	Type	Description	Value Range
json	JSON, JSONB, CSTRING, TEXT, "char", VARCHAR, BPCHAR, NVARCHAR2	JSON value to be inserted. If other non-restricted types are passed, an error will be reported during execution.	The value must be in JSON format.
[VARIADIC any]	Variable any array	Variable parameter list, containing one or more json_path-value pairs.	**json_path** must be a valid path expression, and **value** can be any value.

Return type: json

Example:

```
gaussdb=# SELECT json_insert('[1, [2, 3], {"a": [4, 5]}]', '$[3]', 2);
          json_insert
-------------------------------
 [1, [2, 3], {"a": [4, 5]}, 2]
(1 row)

gaussdb=# SELECT json_insert('[1, [2, 3], {"a": [4, 5]}]', '$[10]', 10,'$[5]', 5);
            json_insert
-----------------------------------
 [1, [2, 3], {"a": [4, 5]}, 10, 5]
(1 row)
```

- json_keys(json[, json_path])

  Description: The input parameters are a JSON object and an optional JSON path. If no JSON path is specified, this function returns a JSON array of member key values of the top-layer object in the JSON object. If a JSON path is specified, this function returns the JSON array of the top-layer member key values in the JSON object corresponding to the path. If **json** or **json_path** is null, **null** is returned. If the JSON format is incorrect, **json_path** is an invalid path expression, or **json_path** contains * or **, an error is reported.

  Parameters: See **Table 1-85**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 1-85 Parameters

Parameter	Type	Description	Value Range
json	JSON, JSONB, CSTRING, TEXT, "char" , VARCHAR, BPCHAR, NVARCHAR2	A JSON value. If other non-restricted types are passed, an error will be reported during execution.	The value must be in JSON format.
json_path	text	A JSON path, which is optional.	**json_path** must be a valid path expression.

Return type: json

Example:

```
gaussdb=# SELECT json_keys('{"x": 1, "y": 2, "z": 3}');
    json_keys
-----------------
 ["x", "y", "z"]
(1 row)

gaussdb=# SELECT json_keys('[1,2,3,{"name":"Tom"}]','$[3]');
 json_keys
-----------
 ["name"]
(1 row)
```

- json_length(json[, json_path])

  Description: The input parameters are a JSON object and an optional JSON path. If no JSON path is specified, this function returns the length of the specified JSON object. If a JSON path is specified, this function returns the length of the JSON object corresponding to the path. If **json** or **json_path** is null, **null** is returned. If the JSON format is incorrect, **json_path** is an invalid path expression, or **json_path** contains * or **, an error is reported.

  Parameters: See **Table 1-86**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 1-86 Parameters

Parameter	Type	Description	Value Range
json	JSON, JSONB, CSTRING, TEXT, "char", VARCHAR, BPCHAR, NVARCHAR2	A JSON value. If other non-restricted types are passed, an error will be reported during execution.	The value must be in JSON format.
json_path	text	A JSON path, which is optional.	**json_path** must be a valid path expression.

Return type: int

Example:

```
gaussdb=# SELECT json_length('[1,2,3,4,5]');
 json_length
-------------
           5
(1 row)

gaussdb=# SELECT json_length('{"name":"Tom", "age":24, "like":"football"}');
 json_length
-------------
           3
(1 row)
```

- json_merge([VARIADIC any])

  Description: Combines all JSON objects passed to this function and returns the combined result. If the input parameter is null, **null** is returned. If the variable parameter list contains null values and has format error, the exceptions are processed based on the exception sequence. If a null value exists first, **null** is returned first. If a format error occurs first, an error is reported first.

  Parameter: a variable parameter list used to construct multiple JSON objects. The input parameter consists of multiple JSON objects. Only the JSON, JSONB, CSTRING, TEXT, "char", VARCHAR, BPCHAR, and NVARCHAR2 types are supported. If other non-restricted types are passed, an error will be reported during execution.

  Return type: json

  Example:

```
gaussdb=# SELECT json_merge('[1, 2]','[2]');
 json_merge
------------
 [1, 2, 2]
(1 row)

gaussdb=# SELECT json_merge('{"b":"2"}','{"a":"1"}','[1,2]');
          json_merge
------------------------------
 [{"a": "1", "b": "2"}, 1, 2]
(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- json_quote(json)

  Description: Uses double quotation marks ("") to enclose the input parameter into a JSON string and returns the string.

  Parameter: The input parameter is a JSON object. Only the JSON, JSONB, CSTRING, TEXT, "char", VARCHAR, BPCHAR, and NVARCHAR2 types are supported. If other non-restricted types are passed, an error will be reported during execution.

  Return type: json

  Example:

  ```
  gaussdb=# SELECT json_quote('gauss');
   json_quote
  ------------
   "gauss"
  (1 row)
  ```

- json_unquote(json)

  Description: Cancels the enclosure of the input parameter using quotation marks and returns the character string.

  Parameter: The input parameter is a JSON object. Only the JSON, JSONB, CSTRING, TEXT, "char", VARCHAR, BPCHAR, and NVARCHAR2 types are supported. If other non-restricted types are passed, an error will be reported during execution.

  Return type: text

  Example:

  ```
  gaussdb=# SELECT json_unquote('"gauss"');
   json_unquote
  --------------
   gauss
  (1 row)
  ```

- json_remove(json, [VARIADIC text])

  Description: The input parameters are a JSON object and several JSON paths to be deleted. These JSON paths are constructed from the variable parameter list. This function deletes the value of **json_path** in the JSON object and returns the modified JSON object. If **json** or **json_path** is null, **null** is returned. If the JSON format is incorrect, **json_path** is an invalid path expression, or **json_path** contains * or **, an error is reported. If the variable parameter list contains null values and has format error, the exceptions are processed based on the exception sequence. If a null value exists first, **null** is returned first. If a format error occurs first, an error is reported first.

  Parameters: See **Table 1-87**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 1-87 Parameters

Parameter	Type	Description	Value Range
json	JSON, JSONB, CSTRING, TEXT, "char", VARCHAR, BPCHAR, NVARCHAR2	A JSON value. If other non-restricted types are passed, an error will be reported during execution.	The value must be in JSON format.
[VARIADIC text]	Variable text array	Variable parameter list, containing one or more JSON paths.	**json_path** must be a valid path expression.

Return type: json

Example:

```
gaussdb=# SELECT json_remove('[0, 1, 2, [3, 4]]', '$[0]', '$[2]');
 json_remove
-------------
 [1, 2]
(1 row)

gaussdb=# SELECT json_remove('[0, 1, 2, [3, 4]]', '$[0]', '$[0]','$[0]');
 json_remove
-------------
 [[3, 4]]
(1 row)
```

- json_replace(json, [VARIADIC any])

  Description: Replaces data in a path specified by **json_path** in a JSON object with a specified value and returns the modified JSON object. The input parameter is a JSON object, multiple JSON paths, and values to be replaced. The JSON paths and values must be in pairs. If **json** or **json_path** is null, **null** is returned. If the JSON format is incorrect, **json_path** is an invalid path expression, or **json_path** contains * or **, an error is reported. If the variable parameter list contains null values and has format error, the exceptions are processed based on the exception sequence. If a null value exists first, **null** is returned first. If a format error occurs first, an error is reported first.

  Parameters: See **Table 1-88**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 1-88 Parameters

Parameter	Type	Description	Value Range
json	JSON, JSONB, CSTRING, TEXT, "char", VARCHAR, BPCHAR, NVARCHAR2	A JSON value. If other non-restricted types are passed, an error will be reported during execution.	The value must be in JSON format.
[VARIADIC any]	Variable any input parameter	Variable parameter list, containing one or more json_path-value pairs.	**json_path** must be a valid path expression, and **value** can be any value.

Return type: json

Example:

```
gaussdb=# SELECT json_replace('{"x": 1}', '$.x', 'true');
 json_replace
---------------
 {"x": "true"}
(1 row)

gaussdb=# SELECT json_replace('{"x": 1}', '$.x', true, '$.x', 123, '$.x', 'asd', '$.x', null);
 json_replace
--------------
 {"x": null}
(1 row)
```

- json_search(json, mode_str, search_str, escape_char, json_path)

  Description: Returns the path of a given string in a JSON object. It returns a path string or an array of multiple paths. If any of **json**, **search_str**, and **json_path** is null, **null** is returned. If the JSON format is incorrect or **json_path** is not a valid path expression, an error is reported. If the variable parameter list contains null values and has format error, the exceptions are processed based on the exception sequence. If a null value exists first, **null** is returned first. If a format error occurs first, an error is reported first.

  Parameters: See **Table 1-89**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 1-89 Parameters

Parameter	Type	Description	Value Range
json	JSON, JSONB, CSTRING, TEXT, "char", VARCHAR, BPCHAR, NVARCHAR2	Target JSON object. If other non-restricted types are passed, an error will be reported during execution.	The value must be in JSON format.
mode_str	text	The value can be **one** or **all**. If the value is **one**, only the first matched path is obtained. If the value is **all**, all matched paths are obtained.	The value must be **one** or **all**, which is case-insensitive.
search_str	text	Character string to be searched for. In normal cases, the entire character string is matched. However, the wildcard % can be used to match any number of characters, and _ can be used to match any character.	-
escape_char	text	If **search_str** contains a wildcard, this parameter is defined as an escape character for the wildcard. This parameter is optional. The default value is **'\'**. If the character is added before the wildcard, the wildcard is not considered as a wildcard.	The value can be any single character.
json_path	text	If **json_path** is specified, the search is performed in the path. This parameter is optional.	**json_path** must be a valid path expression.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Return type: text

Example:

```
-- In the all mode:
gaussdb=# SELECT json_search('{"a":"abc","b":"abc"}','all','abc');
 json_search
----------------
 ["$.a", "$.b"]
(1 row)

-- In the one mode:
gaussdb=# SELECT json_search('{"a":"abc","b":"abc"}','one','abc');
 json_search
-------------
 "$.a"
(1 row)

-- The default escape character is used.
gaussdb=# SELECT json_search('{"a":"abc","b":"a%c"}','one','a\%c');
 json_search
-------------
 "$.b"
(1 row)
```

- json_set(json, [VARIADIC any])

  Description: Uses the specified value to update the data in the path specified by **json_path** in a JSON object and returns the modified JSON object. If the specified path does not have any value, the value is inserted into the corresponding path. The input parameter is a JSON object, multiple JSON paths, and values to be set. The JSON paths and values must be in pairs. If **json** or **json_path** is null, **null** is returned. If the JSON format is incorrect, **json_path** is an invalid path expression, or **json_path** contains * or **, an error is reported. If the variable parameter list contains null values and has format error, the exceptions are processed based on the exception sequence. If a null value exists first, **null** is returned first. If a format error occurs first, an error is reported first.

  Parameters: See **Table 1-90**.

Table 1-90 Parameters

Parameter	Type	Description	Value Range
json	JSON, JSONB, CSTRING, TEXT, "char", VARCHAR, BPCHAR, NVARCHAR2	A JSON value. If other non-restricted types are passed, an error will be reported during execution.	The value must be in JSON format.
[VARIADIC any]	Variable any array	Variable parameter list, containing one or more json_path-value pairs.	**json_path** must be a valid path expression, and **value** can be any value.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Return type: json

Example:

```
gaussdb=# SELECT json_set('{"s":3}','$.s','d');
  json_set
------------
 {"s": "d"}
(1 row)

gaussdb=# SELECT json_set('{"s":3}','$.a','d','$.a','1');
      json_set
--------------------
 {"a": "1", "s": 3}
(1 row)
```

- json_type(json)

  Description: Returns a string representing the type of the given JSON object. If the input parameter is null, **null** is returned.

  Parameter: a JSON object. Only the JSON, JSONB, CSTRING, TEXT, "char", VARCHAR, BPCHAR, and NVARCHAR2 types are supported. If other non-restricted types are passed, an error will be reported during execution.

  Return type: text. For details, see **Table 1-91**.

  Table 1-91 Return value of json_type

JSON Element Type	Return Value
Array	ARRAY
Object	OBJECT
String	STRING
Numeric	NUMBER
Boolean	BOOLEAN
NULL	NULL

  Example:

```
gaussdb=# SELECT json_type('{"w":{"2":3},"2":4}');
 json_type
-----------
 OBJECT
(1 row)

gaussdb=# SELECT json_type('[1,2,2,3,3,4,4,4,4,4,4,4,4]');
 json_type
-----------
 ARRAY
(1 row)
```

- json_valid(json)

  Description: Returns **0** or **1** to indicate whether the given parameter is a valid JSON object. If the input parameter is null, **null** is returned.

  Parameter: The input parameter is a JSON object. Only the JSON, JSONB, CSTRING, TEXT, "char", VARCHAR, BPCHAR, and NVARCHAR2 types are supported. If a non-null value of a restricted type is passed, **0** is always returned.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Return type: bigint

Example:

```
gaussdb=# SELECT json_valid('{"name":"Tom"}');
 json_valid
------------
          1
(1 row)

gaussdb=# SELECT json_valid('[1,23,4,5,5]');
 json_valid
------------
          1
(1 row)

gaussdb=# SELECT json_valid('[1,23,4,5,5]}');
 json_valid
------------
          0
(1 row)
```

- json_agg(any)

  Description: Aggregates values into a JSON array.

  Return type: array-json

  Example:

```
gaussdb=# CREATE TABLE classes(name varchar, score int);
CREATE TABLE
gaussdb=# INSERT INTO classes VALUES('A',2);
INSERT 0 1
gaussdb=# INSERT INTO classes VALUES('A',3);
INSERT 0 1
gaussdb=# INSERT INTO classes VALUES('D',5);
INSERT 0 1
gaussdb=# INSERT INTO classes VALUES('D',null);
INSERT 0 1
gaussdb=# SELECT * FROM classes;
 name | score
------+-------
 A    |     2
 A    |     3
 D    |     5
 D    |
(4 rows)

gaussdb=# SELECT name, json_agg(score) score FROM classes GROUP BY name ORDER BY name;
 name |   score
------+-----------
 A    | [2, 3]
 D    | [5, null]
(2 rows)

gaussdb=# DROP TABLE classes;
DROP TABLE
```

- json_object_agg(any, any)

  Description: Aggregates values into a JSON object.

  Return type: object-json

  Example:

```
gaussdb=# CREATE TABLE classes(name varchar, score int);
CREATE TABLE
gaussdb=# INSERT INTO classes VALUES('A',2);
INSERT 0 1
gaussdb=# INSERT INTO classes VALUES('A',3);
INSERT 0 1
gaussdb=# INSERT INTO classes VALUES('D',5);
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
INSERT 0 1
gaussdb=# INSERT INTO classes VALUES('D',null);
INSERT 0 1
gaussdb=# SELECT * FROM classes;
 name | score
------+-------
 A    |     2
 A    |     3
 D    |     5
 D    |
(4 rows)

gaussdb=# SELECT json_object_agg(name, score) FROM classes GROUP BY name ORDER BY name;
     json_object_agg
-------------------------
 { "A" : 2, "A" : 3 }
 { "D" : 5, "D" : null }
(2 rows)

gaussdb=# DROP TABLE classes;
DROP TABLE
```

- jsonb_contained(jsonb, jsonb)

  Description: Same as the operator `<@`, determines whether all elements in the first parameter exist at the top layer of the second parameter.

  Return type: Boolean

  Example:

  ```
  gaussdb=# SELECT jsonb_contained('[1,2,3]', '[1,2,3,4]');
   jsonb_contained
  -----------------
    t
   (1 row)
  ```

- jsonb_contains(jsonb, jsonb)

  Description: Same as the operator `@>`, determines whether all elements in the second parameter exist at the top layer of the first parameter.

  Return type: Boolean

  Example:

  ```
  gaussdb=# SELECT jsonb_contains('[1,2,3,4]', '[1,2,3]');
   jsonb_contains
  ----------------
   t
  (1 row)
  ```

- jsonb_exists(jsonb, text)

  Description: Same as the operator `?`, checks whether the second parameter in the string exists at the top layer of the first parameter in the format of key/elem/scalar.

  Return type: Boolean

  Example:

  ```
  gaussdb=# SELECT jsonb_exists('["1",2,3]', '1');
   jsonb_exists
  --------------
   t
  (1 row)
  ```

- jsonb_exists_all(jsonb, text[])

  Description: Same as the operator `?&`, checks whether all elements of the second parameter in the string array exist at the top layer of the first parameter in the format of key/elem/scalar.

  Return type: Boolean

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Example:

```
gaussdb=# SELECT jsonb_exists_all('["1","2",3]', '{1, 2}');
 jsonb_exists_all
------------------
 t
(1 row)
```

- jsonb_exists_any(jsonb, text[])

  Description: Similar to the `?|` operator, it determines whether any element in parameter 2 exists at the top level of parameter 1 in the form of key/elem/scalar.

  Return type: Boolean

  Example:

```
gaussdb=# SELECT jsonb_exists_any('["1","2",3]', '{1, 2, 4}');
 jsonb_exists_any
------------------
 t
(1 row)
```

- jsonb_cmp(jsonb, jsonb)

  Description: Compares values. A positive value indicates greater than, a negative value indicates less than, and **0** indicates equal.

  Return type: integer

  Example:

```
gaussdb=# SELECT jsonb_cmp('["a", "b"]', '{"a":1, "b":2}');
 jsonb_cmp
-----------
     -1
(1 row)
```

- jsonb_eq(jsonb, jsonb)

  Description: Same as the operator `=`, compares two values to check whether they are equal.

  Return type: Boolean

  Example:

```
gaussdb=# SELECT jsonb_eq('["a", "b"]', '{"a":1, "b":2}');
 jsonb_eq
----------
 f
(1 row)
```

- jsonb_ne(jsonb, jsonb)

  Description: Same as the operator `<>`, compares two values to check whether they are not equal.

  Return type: Boolean

  Example:

```
gaussdb=# SELECT jsonb_ne('["a", "b"]', '{"a":1, "b":2}');
 jsonb_ne
----------
 t
(1 row)
```

- jsonb_gt(jsonb, jsonb)

  Description: Same as the operator `>`, compares whether the value of the first parameter is greater than that of the second parameter.

  Return type: Boolean

  Example:

```
gaussdb=# SELECT jsonb_gt('["a", "b"]', '{"a":1, "b":2}');
 jsonb_gt
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
----------
 f
(1 row)
```

- jsonb_ge(jsonb, jsonb)

  Description: Same as the operator `>=`, compares whether the value of the first parameter is greater than or equal to that of the second parameter.

  Return type: Boolean

  Example:

```
gaussdb=# SELECT jsonb_ge('["a", "b"]', '{"a":1, "b":2}');
 jsonb_ge
----------
 f
(1 row)
```

- jsonb_lt(jsonb, jsonb)

  Description: Same as the operator `<`, compares whether the value of the first parameter is less than that of the second parameter.

  Return type: Boolean

  Example:

```
gaussdb=# SELECT jsonb_lt('["a", "b"]', '{"a":1, "b":2}');
 jsonb_lt
----------
 t
(1 row)
```

- jsonb_le(jsonb, jsonb)

  Description: Same as the operator `<=`, compares whether the value of the first parameter is less than or equal to that of the second parameter.

  Return type: Boolean

  Example:

```
gaussdb=# SELECT jsonb_le('["a", "b"]', '{"a":1, "b":2}');
 jsonb_le
----------
 t
(1 row)
```

- to_json(anyelement)

  Description: Converts the input parameter into the `json` type.

  Return type: json

  Example:

```
gaussdb=# SELECT to_json('{1,5}'::text[]);
  to_json
-----------
 ["1","5"]
(1 row)
```

- to_jsonb(anyelement)

  Description: Converts the input anyelement parameter to the JSONB type.

  Return type: jsonb

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTICE

- When the parameter is an empty string (''), if the SQL compatibility mode of the database is Oracle-compatible, **NULL** is returned; if the SQL compatibility mode of the database is PG-compatible, an empty string is returned. This is because empty strings are treated as NULL in ORA-compatible mode.
- When the parameter is of the DATE type, if the database SQL compatibility mode is Oracle-compatible, the returned result contains hour, minute, and second; if the database SQL compatibility mode is PG-compatible, the returned result does not contain hour, minute, and second. This is because DATE will be replaced by TIMESTAMP(0) WITHOUT TIME ZONE in ORA-compatible mode when **mapping_date_to_datea** is disabled.

Example:

```
gaussdb=# SELECT to_jsonb(ARRAY[1, 2, 3, 4]);
   to_jsonb
--------------
 [1, 2, 3, 4]
(1 row)
```

- jsonb_hash(jsonb)

  Description: Performs the hash operation on JSONB.

  Return type: integer

  Example:

```
gaussdb=# SELECT jsonb_hash('[1,2,3]');
 jsonb_hash
------------
 -559968547
(1 row)
```

- Other Functions

  Description: Internal functions used by JSON and JSONB aggregate functions.

```
json_agg_transfn
json_agg_finalfn
json_object_agg_transfn
json_object_agg_finalfn
```

1.6.14 HLL Functions and Operators

Hash Functions

- hll_hash_boolean(bool)

  Description: Hashes data of the Boolean type.

  Return type: hll_hashval

  Example:

```
gaussdb=# SELECT hll_hash_boolean(FALSE);
  hll_hash_boolean
---------------------
 -5451962507482445012
(1 row)
```

- hll_hash_boolean(bool, int32)

  Description: Configures a hash seed (that is, changes the hash policy) and hashes data of the Boolean type.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Return type: hll_hashval

Example:

```
gaussdb=# SELECT hll_hash_boolean(FALSE, 10);
 hll_hash_boolean
--------------------
 -1169037589280886076
(1 row)
```

- hll_hash_smallint(smallint)

  Description: Hashes data of the smallint type.

  Return type: hll_hashval

  Example:

  ```
  gaussdb=# SELECT hll_hash_smallint(100::smallint);
   hll_hash_smallint
  --------------------
   962727970174027904
  (1 row)
  ```

  NOTE

  If parameters with the same numeric value are hashed using different data types, the data will differ, because hash functions select different calculation policies for each type.

- hll_hash_smallint(smallint, int32)

  Description: Configures a hash seed (that is, changes the hash policy) and hashes data of the smallint type.

  Return type: hll_hashval

  Example:

  ```
  gaussdb=# SELECT hll_hash_smallint(100::smallint, 10);
   hll_hash_smallint
  --------------------
   -9056177146160443041
  (1 row)
  ```

- hll_hash_integer(integer)

  Description: Hashes data of the integer type.

  Return type: hll_hashval

  Example:

  ```
  gaussdb=# SELECT hll_hash_integer(0);
    hll_hash_integer
  ----------------------
   5156626420896634997
  (1 row)
  ```

- hll_hash_integer(integer, int32)

  Description: Hashes data of the integer type and configures a hash seed (that is, changes the hash policy).

  Return type: hll_hashval

  Example:

  ```
  gaussdb=# SELECT hll_hash_integer(0, 10);
   hll_hash_integer
  --------------------
   -5035020264353794276
  (1 row)
  ```

- hll_hash_bigint(bigint)

  Description: Hashes data of the bigint type.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Return type: hll_hashval

Example:

```
gaussdb=# SELECT hll_hash_bigint(100::bigint);
   hll_hash_bigint
---------------------
 -2401963681423227794
(1 row)
```

- hll_hash_bigint(bigint, int32)

  Description: Hashes data of the bigint type and configures a hash seed (that is, changes the hash policy).

  Return type: hll_hashval

  Example:

  ```
  gaussdb=# SELECT hll_hash_bigint(100::bigint, 10);
     hll_hash_bigint
  ---------------------
   -2305749404374433531
  (1 row)
  ```

- hll_hash_bytea(bytea)

  Description: Hashes data of the bytea type.

  Return type: hll_hashval

  Example:

  ```
  gaussdb=# SELECT hll_hash_bytea(E'\\x');
   hll_hash_bytea
  ----------------
   0
  (1 row)
  ```

- hll_hash_bytea(bytea, int32)

  Description: Hashes data of the bytea type and configures a hash seed (that is, changes the hash policy).

  Return type: hll_hashval

  Example:

  ```
  gaussdb=# SELECT hll_hash_bytea(E'\\x', 10);
     hll_hash_bytea
  ---------------------
   7233188113542599437
  (1 row)
  ```

- hll_hash_text(text)

  Description: Hashes data of the text type.

  Return type: hll_hashval

  Example:

  ```
  gaussdb=# SELECT hll_hash_text('AB');
     hll_hash_text
  ---------------------
   -5666002586880275174
  (1 row)
  ```

- hll_hash_text(text, int32)

  Description: Hashes data of the text type and configures a hash seed (that is, changes the hash policy).

  Return type: hll_hashval

  Example:

  ```
  gaussdb=# SELECT hll_hash_text('AB', 10);
  hll_hash_text
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
---------------------
-2215507121143724132
(1 row)
```

- hll_hash_any(anytype)

  Description: Hashes data of any type.

  Return type: hll_hashval

  Example:

```
gaussdb=# SELECT hll_hash_any(1);
    hll_hash_any
----------------------
 -1316670585935156930
(1 row)

gaussdb=# SELECT hll_hash_any('08:00:2b:01:02:03'::macaddr);
    hll_hash_any
----------------------
 -3719950434455589360
(1 row)
```

- hll_hash_any(anytype, int32)

  Description: Hashes data of any type and configures a hash seed (that is, changes the hash policy).

  Return type: hll_hashval

  Example:

```
gaussdb=# SELECT hll_hash_any(1, 10);
    hll_hash_any
----------------------
 7048553517657992351
(1 row)
```

- hll_hashval_eq(hll_hashval, hll_hashval)

  Description: Compares two pieces of data of the hll_hashval type to check whether they are the same.

  Return type: Boolean

  Example:

```
gaussdb=# SELECT hll_hashval_eq(hll_hash_integer(1), hll_hash_integer(1));
 hll_hashval_eq
----------------
 t
(1 row)
```

- hll_hashval_ne(hll_hashval, hll_hashval)

  Description: Compares two pieces of data of the hll_hashval type to check whether they are different.

  Return type: Boolean

  Example:

```
gaussdb=# SELECT hll_hashval_ne(hll_hash_integer(1), hll_hash_integer(1));
 hll_hashval_ne
----------------
 f
(1 row)
```

Log Functions

There are three HLL modes: explicit, sparse, and full. When the data size is small, the explicit mode is used. In this mode, distinct values are calculated without errors. As the number of distinct values increases, the HLL mode is switched to the

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

sparse and full modes in sequence. The two modes have no difference in the calculation result, but vary in the calculation efficiency of HLL functions and the storage space of HLL objects. The following functions can be used to view some HLL parameters.

- hll_print(hll)

  Description: Prints some debugging parameters of an HLL.

  Example:

```
gaussdb=# SELECT hll_print(hll_empty());
                                hll_print
-------------------------------------------------------------------------------
 type=1(HLL_EMPTY), log2m=14, log2explicit=10, log2sparse=12, duplicatecheck=0
(1 row)
```

- hll_type(hll)

  Description: Checks the type of the current HLL.

  The return values are described as follows:

  – **0** indicates HLL_UNINIT, which is an uninitialized HLL object.
  – **1** indicates HLL_EMPTY, which is an empty HLL object.
  – **2** indicates HLL_EXPLICIT, which is an HLL object in explicit mode.
  – **3** indicates HLL_SPARSE, which is an HLL object in sparse mode.
  – **4** indicates HLL_FULL, which is an HLL object in full mode.
  – **5** indicates HLL_UNDEFINED, which is an invalid HLL object.

  Example:

```
gaussdb=# SELECT hll_type(hll_empty());
 hll_type
----------
        1
(1 row)
```

- hll_log2m(hll)

  Description: Checks the value of **log2m** in the current HLL data structure. **log2m** is the logarithm of the number of buckets. This value affects the error rate of calculating distinct values by HLL. The error rate = ±1.04/√(2^log2m). When the value of **log2m** is explicitly set to a value ranging from 10 to 16, HLL sets the number of buckets to 2^{log2m}. When the value of **log2explicit** is explicitly set to **–1**, the built-in default value is used.

  Example:

```
gaussdb=# SELECT hll_log2m(hll_empty());
 hll_log2m
-----------
        14
(1 row)

gaussdb=# SELECT hll_log2m(hll_empty(10));
 hll_log2m
-----------
        10
(1 row)

gaussdb=# SELECT hll_log2m(hll_empty(-1));
 hll_log2m
-----------
        14
(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- hll_log2explicit(hll)

  Description: Queries the value of **log2explicit** in the current HLL data structure. Generally, the HLL changes from the explicit mode to the sparse mode and then to the full mode. This process is called the promotion hierarchy policy. You can change the value of **log2explicit** to change the policy. For example, if the value of **log2explicit** is **0**, the explicit mode will be skipped and the sparse mode is directly entered. When the value of **log2explicit** is explicitly set to a value ranging from 1 to 12, the HLL will switch to the sparse mode when the length of the data segment exceeds $2^{log2explicit}$. When the value of **log2explicit** is explicitly set to **–1**, the built-in default value is used.

  Example:

```
gaussdb=# SELECT hll_log2explicit(hll_empty());
 hll_log2explicit
------------------
               10
(1 row)

gaussdb=# SELECT hll_log2explicit(hll_empty(12, 8));
 hll_log2explicit
------------------
                8
(1 row)

gaussdb=# SELECT hll_log2explicit(hll_empty(12, -1));
 hll_log2explicit
------------------
               10
(1 row)
```

- hll_log2sparse(hll)

  Description: Queries the value of **log2sparse** in the current HLL data structure. Generally, the HLL changes from the explicit mode to the sparse mode and then to the full mode. This process is called the promotion hierarchy policy. You can adjust the value of **log2sparse** to change the policy. For example, if the value of **log2sparse** is **0**, the system skips the sparse mode and directly enters the full mode. If the value of **log2sparse** is explicitly set to a value ranging from 1 to 14, the HLL will switch to the full mode when the length of the data segment exceeds $2^{log2sparse}$. When the value of **log2sparse** is explicitly set to **–1**, the built-in default value is used.

  Example:

```
gaussdb=# SELECT hll_log2sparse(hll_empty());
 hll_log2sparse
----------------
             12
(1 row)

gaussdb=# SELECT hll_log2sparse(hll_empty(12, 8, 10));
 hll_log2sparse
----------------
             10
(1 row)

gaussdb=# SELECT hll_log2sparse(hll_empty(12, 8, -1));
 hll_log2sparse
----------------
             12
(1 row)
```

- hll_duplicatecheck(hll)

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description: Specifies whether duplicate check is enabled. **0**: disable; **1**: enable. This function is disabled by default. If there are many duplicate values, you can enable this function to improve efficiency. When the value of **duplicatecheck** is explicitly set to **–1**, the built-in default value is used.

Example:

```
gaussdb=# SELECT hll_duplicatecheck(hll_empty());
 hll_duplicatecheck
--------------------
                  0
(1 row)

gaussdb=# SELECT hll_duplicatecheck(hll_empty(12, 8, 10, 1));
 hll_duplicatecheck
--------------------
                  1
(1 row)

gaussdb=# SELECT hll_duplicatecheck(hll_empty(12, 8, 10, -1));
 hll_duplicatecheck
--------------------
                  0
(1 row)
```

Functional Functions

- hll_empty()

  Description: Creates an empty HLL.

  Return type: HLL

  Example:

  ```
  gaussdb=# SELECT hll_empty();
                                                          hll_empty
  ------------------------------------------------------------------
   \x484c4c00000000002b050000000000000000000000000000000000000000
  (1 row)
  ```

- hll_empty(int32 log2m)

  Description: Creates an empty HLL and sets the **log2m** parameter. The parameter value ranges from 10 to 16. If the input is **–1**, the built-in default value is used.

  Return type: HLL

  Example:

  ```
  gaussdb=# SELECT hll_empty(10);
                                                          hll_empty
  ------------------------------------------------------------------
   \x484c4c00000000002b040000000000000000000000000000000000000000
  (1 row)

  gaussdb=# SELECT hll_empty(-1);
                                                          hll_empty
  ------------------------------------------------------------------
   \x484c4c00000000002b050000000000000000000000000000000000000000
  (1 row)
  ```

- hll_empty(int32 log2m, int32 log2explicit)

  Description: Creates an empty HLL and sets the **log2m** and **log2explicit** parameters in sequence. The value of **log2explicit** ranges from 0 to 12. The value **0** indicates that the explicit mode is skipped. This parameter is used to set the threshold of the explicit mode. When the length of the data segment reaches $2^{log2explicit}$, the mode is switched to the sparse or full mode. If the input is **–1**, the built-in default value of **log2explicit** is used.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Return type: HLL

Example:

```
gaussdb=# SELECT hll_empty(10, 4);
                    hll_empty
--------------------------------------------------------------
 \x484c4c0000000000130400000000000000000000000000000000000000
(1 row)

gaussdb=# SELECT hll_empty(10, -1);
                    hll_empty
--------------------------------------------------------------
 \x484c4c00000000002b040000000000000000000000000000000000000000
(1 row)
```

- hll_empty(int32 log2m, int32 log2explicit, int64 log2sparse)

  Description: Creates an empty HLL and sets the **log2m**, **log2explicit** and **log2sparse** parameters in sequence. The value of **log2sparse** ranges from 0 to 14. The value **0** indicates that the sparse mode is skipped. This parameter is used to set the threshold of the sparse mode. When the length of the data segment reaches $2^{log2sparse}$, the mode is switched to the full mode. If the input is **–1**, the built-in default value of **log2sparse** is used.

  Return type: HLL

  Example:

  ```
  gaussdb=# SELECT hll_empty(10, 4, 8);
                      hll_empty
  --------------------------------------------------------------
   \x484c4c0000000000120400000000000000000000000000000000000000
  (1 row)

  gaussdb=# SELECT hll_empty(10, 4, -1);
                      hll_empty
  --------------------------------------------------------------
   \x484c4c0000000000130400000000000000000000000000000000000000
  (1 row)
  ```

- hll_empty(int32 log2m, int32 log2explicit, int64 log2sparse, int32 duplicatecheck)

  Description: Creates an empty HLL and sets the **log2m**, **log2explicit**, **log2sparse**, and **duplicatecheck** parameters in sequence. The value of **duplicatecheck** is **0** or **1**, indicating whether the duplicate check mode is enabled. By default, this mode is disabled. If the input is **–1**, the built-in default value of **duplicatecheck** is used.

  Return type: HLL

  Example:

  ```
  gaussdb=# SELECT hll_empty(10, 4, 8, 0);
                      hll_empty
  --------------------------------------------------------------
   \x484c4c0000000000120400000000000000000000000000000000000000
  (1 row)

  gaussdb=# SELECT hll_empty(10, 4, 8, -1);
                      hll_empty
  --------------------------------------------------------------
   \x484c4c0000000000120400000000000000000000000000000000000000
  (1 row)
  ```

- hll_add(hll, hll_hashval)

  Description: Adds hll_hashval to an HLL.

  Return type: HLL

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Example:

```
gaussdb=# SELECT hll_add(hll_empty(), hll_hash_integer(1));
                                hll_add
-------------------------------------------------------------------------------
 \x484c4c08000002002b0900000000000000f03f3e2921ff133fbaed3e2921ff133fbaed00
(1 row)
```

- hll_add_rev(hll_hashval, hll)

  Description: Adds **hll_hashval** to an HLL. This function works the same as **hll_add**, except that the positions of parameters are switched.

  Return type: HLL

  Example:

```
gaussdb=# SELECT hll_add_rev(hll_hash_integer(1), hll_empty());
                               hll_add_rev
-------------------------------------------------------------------------------
 \x484c4c08000002002b0900000000000000f03f3e2921ff133fbaed3e2921ff133fbaed00
(1 row)
```

- hll_eq(hll, hll)

  Description: Compares two HLLs to check whether they are the same.

  Return type: Boolean

  Example:

```
gaussdb=# SELECT hll_eq(hll_add(hll_empty(), hll_hash_integer(1)), hll_add(hll_empty(),
hll_hash_integer(2)));
 hll_eq
--------
 f
(1 row)
```

- hll_ne(hll, hll)

  Description: Compares two HLLs to check whether they are different.

  Return type: Boolean

  Example:

```
gaussdb=# SELECT hll_ne(hll_add(hll_empty(), hll_hash_integer(1)), hll_add(hll_empty(),
hll_hash_integer(2)));
 hll_ne
--------
 t
(1 row)
```

- hll_cardinality(hll)

  Description: Calculates the number of distinct values of an HLL.

  Return type: int

  Example:

```
gaussdb=# SELECT hll_cardinality(hll_empty() || hll_hash_integer(1));
 hll_cardinality
-----------------
               1
(1 row)
```

- hll_union(hll, hll)

  Description: Performs the UNION operation on two HLL data structures to obtain one HLL.

  Return type: HLL

  Example:

```
gaussdb=# SELECT hll_union(hll_add(hll_empty(), hll_hash_integer(1)), hll_add(hll_empty(),
hll_hash_integer(2)));
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
                                    hll_union
-----------------------------------------------------------------------------------------------

\x484c4c10002000002b090000000000000000040000000000000000b3ccc49320cca1ae3e2921ff133fba
ed00
(1 row)
```

Aggregate Functions

- hll_add_agg(hll_hashval)

  Description: Groups hashed data into HLL.

  Return type: HLL

  Example:

```
-- Prepare data:
gaussdb=# CREATE TABLE t_id(id int);
gaussdb=# INSERT INTO t_id VALUES(generate_series(1,500));
gaussdb=# CREATE TABLE t_data(a int, c text);
gaussdb=# INSERT INTO t_data SELECT mod(id,2), id FROM t_id;

-- Create a table and specify an HLL column:
gaussdb=# CREATE TABLE t_a_c_hll(a int, c hll);

-- Use GROUP BY on column a to group data, and insert the data to the HLL:
gaussdb=# INSERT INTO t_a_c_hll SELECT a, hll_add_agg(hll_hash_text(c)) FROM t_data GROUP BY a;

-- Calculate the number of distinct values for each group in the HLL:
gaussdb=# SELECT a, #c AS cardinality FROM t_a_c_hll ORDER BY a;
 a |   cardinality
---+------------------
 0 | 247.862354346299
 1 | 250.908710610377
(2 rows)
```

- hll_add_agg(hll_hashval, int32 log2m)

  Description: Groups hashed data into HLL and specifies the **log2m** parameter. The value ranges from 10 to 16. If the input is **–1** or **NULL**, the built-in default value is used.

  Return type: HLL

  Example:

```
gaussdb=# SELECT hll_cardinality(hll_add_agg(hll_hash_text(c), 12)) FROM t_data;
 hll_cardinality
------------------
 497.965240179228
(1 row)
```

- hll_add_agg(hll_hashval, int32 log2m, int32 log2explicit)

  Description: Groups hashed data into HLL and specifies the **log2m** and **log2explicit** parameters in sequence. The value of **log2explicit** ranges from 0 to 12. The value **0** indicates that the explicit mode is skipped. This parameter is used to set the threshold of the explicit mode. When the length of the data segment reaches $2^{log2explicit}$, the mode is switched to the sparse or full mode. If the input is **–1** or **NULL**, the built-in default value of **log2explicit** is used.

  Return type: HLL

  Example:

```
gaussdb=# SELECT hll_cardinality(hll_add_agg(hll_hash_text(c), NULL, 1)) FROM t_data;
 hll_cardinality
------------------
 498.496062953313
(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- hll_add_agg(hll_hashval, int32 log2m, int32 log2explicit, int64 log2sparse)

  Description: Groups hashed data into HLL and sets the **log2m**, **log2explicit**, and **log2sparse** parameters in sequence. The value of **log2sparse** ranges from 0 to 14. The value **0** indicates that the sparse mode is skipped. This parameter is used to set the threshold of the sparse mode. When the length of the data segment reaches $2^{log2sparse}$, the mode is switched to the full mode. If the input is **–1** or **NULL**, the built-in default value of **log2sparse** is used.

  Return type: HLL

  Example:

  ```
  gaussdb=# SELECT hll_cardinality(hll_add_agg(hll_hash_text(c), NULL, 6, 10)) FROM t_data;
   hll_cardinality
  ------------------
   498.496062953313
  (1 row)
  ```

- hll_add_agg(hll_hashval, int32 log2m, int32 log2explicit, int64 log2sparse, int32 duplicatecheck)

  Description: Groups hashed data into HLL and specifies the **log2m**, **log2explicit**, **log2sparse**, and **duplicatecheck** parameters. The value of **duplicatecheck** can be **0** or **1**, indicating whether to enable this mode. By default, this mode is disabled. If the input is **–1** or **NULL**, the built-in default value of **duplicatecheck** is used.

  Return type: HLL

  Example:

  ```
  gaussdb=# SELECT hll_cardinality(hll_add_agg(hll_hash_text(c), NULL, 6, 10, -1)) FROM t_data;
   hll_cardinality
  ------------------
   498.496062953313
  (1 row)
  ```

- hll_union_agg(hll)

  Description: Performs the UNION operation on multiple pieces of data of the HLL type to obtain one HLL.

  Return type: HLL

  Example:

  ```
  -- Perform the UNION operation on data of the HLL type in each group to obtain one HLL, and calculate the number of distinct values:
  gaussdb=# SELECT #hll_union_agg(c) AS cardinality FROM t_a_c_hll;
    cardinality
  ------------------
   498.496062953313
  (1 row)

  -- Drop tables.
  gaussdb=# DROP TABLE t_id;
  gaussdb=# DROP TABLE t_data;
  gaussdb=# DROP TABLE t_a_c_hll;
  ```

  NOTE

  To perform the UNION operation on data in multiple HLLs, ensure that the HLLs have the same precision. Otherwise, **UNION** cannot be performed. This constraint also applies to the **hll_union(hll, hll)** function.

Obsolete Functions

Some old HLL functions are deprecated due to version upgrade. You can replace them with similar functions.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- hll_schema_version(hll)

  Description: Checks the schema version in the current HLL. In earlier versions, the schema version is fixed at **1**, which is used to verify the header of the HLL field. After refactoring, the HLL field is added to the header for verification. The schema version is no longer used.

- hll_regwidth(hll)

  Description: Queries the bucket size in the HLL data structure. In earlier versions, the value of **regwidth** ranges from 1 to 5, which has a large error and limits the upper limit of the cardinality estimation. After refactoring, the value of **regwidth** is fixed at **6** and the variable is not used.

- hll_expthresh(hll)

  Description: Obtains the value of **expthresh** in the current HLL. The hll_log2explicit(hll) function is used to replace similar functions.

- hll_sparseon(hll)

  Description: Specifies whether the sparse mode is enabled. Use hll_log2sparse(hll) to replace similar functions. The value **0** indicates that the sparse mode is disabled.

Built-In Functions

HLL has a series of built-in functions for internal data processing. Generally, users do not need to know how to use these functions. For details, see **Table 1-92**.

Table 1-92 Built-in functions

Function	Description
hll_in	Receives HLL data in string format.
hll_out	Sends HLL data in string format.
hll_recv	Receives HLL data in bytea format.
hll_send	Sends HLL data in bytea format.
hll_trans_in	Receives hll_trans_type data in string format.
hll_trans_out	Sends hll_trans_type data in string format.
hll_trans_recv	Receives hll_trans_type data in bytea format.
hll_trans_send	Sends hll_trans_type data in bytea format.
hll_typmod_in	Receives typmod data.
hll_typmod_out	Sends typmod data.
hll_hashval_in	Receives hll_hashval data.
hll_hashval_out	Sends hll_hashval data.
hll_add_trans0	Works similar to hll_add. No input parameter is specified during initialization. It is usually used in the first phase of DNs in distributed aggregation operations.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Function	Description
hll_add_trans1	Works similar to hll_add. An input parameter is specified during initialization. It is usually used in the first phase of DNs in distributed aggregation operations.
hll_add_trans2	Works similar to hll_add. Two input parameters are specified during initialization. It is usually used in the first phase of DNs in distributed aggregation operations.
hll_add_trans3	Works similar to hll_add. Three input parameters are specified during initialization. It is usually used in the first phase of DNs in distributed aggregation operations.
hll_add_trans4	Works similar to hll_add. Four input parameters are specified during initialization. It is usually used in the first phase of DNs in distributed aggregation operations.
hll_union_trans	Works similar to hll_union and is used on the first phase of DNs in distributed aggregation operations.
hll_union_collect	Works similar to hll_union and is used on the second phase of CNs in distributed aggregation operations to summarize the results of each DN.
hll_pack	Is used on the third phase of CNs in distributed aggregation operations to convert a user-defined type hll_trans_type to the HLL type.
hll	Converts an HLL type to another HLL type. Input parameters can be specified.
hll_hashval	Converts the bigint type to the hll_hashval type.
hll_hashval_int4	Converts the int4 type to the hll_hashval type.

Operators

- =

  Description: Compares the values of the HLL or hll_hashval type to check whether they are the same.

  Return type: Boolean

  Example:

```
--hll
gaussdb=# SELECT (hll_empty() || hll_hash_integer(1)) = (hll_empty() || hll_hash_integer(1));
 ?column?
----------
 t
(1 row)

--hll_hashval
gaussdb=# SELECT hll_hash_integer(1) = hll_hash_integer(1);
 ?column?
----------
 t
(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- <> or !=

  Description: Compares the values of the HLL or hll_hashval type to check whether they are different.

  Return type: Boolean

  Example:

```
--hll
gaussdb=# SELECT (hll_empty() || hll_hash_integer(1)) <> (hll_empty() || hll_hash_integer(2));
 ?column?
----------
 t
(1 row)

--hll_hashval
gaussdb=# SELECT hll_hash_integer(1) <> hll_hash_integer(2);
 ?column?
----------
 t
(1 row)
```

- ||

  Description: Represents the functions of hll_add, hll_union, and hll_add_rev.

  Return type: HLL

  Example:

```
--hll_add
gaussdb=# SELECT hll_empty() || hll_hash_integer(1);
                                ?column?
--------------------------------------------------------------------------------
 \x484c4c08000002002b0900000000000000f03f3e2921ff133fbaed3e2921ff133fbaed00
(1 row)

--hll_add_rev
gaussdb=# SELECT hll_hash_integer(1) || hll_empty();
                                ?column?
--------------------------------------------------------------------------------
 \x484c4c08000002002b0900000000000000f03f3e2921ff133fbaed3e2921ff133fbaed00
(1 row)

--hll_union
gaussdb=# SELECT (hll_empty() || hll_hash_integer(1)) || (hll_empty() || hll_hash_integer(2));
                                    ?column?
-----------------------------------------------------------------------------------------------

\x484c4c10002000002b0900000000000000004000000000000000000b3ccc49320cca1ae3e2921ff133fba
ed00
(1 row)
```

- #

  Description: Calculates the number of distinct values of an HLL. It works the same as the hll_cardinality function.

  Return type: int

  Example:

```
gaussdb=# SELECT #(hll_empty() || hll_hash_integer(1));
 ?column?
----------
        1
(1 row)
```

1.6.15 SEQUENCE Functions

The sequence functions provide a simple method to ensure security of multiple users for users to obtain sequence values from sequence objects.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- nextval(regclass)

  Description: Specifies an increasing sequence and returns a new value.

  NOTE

  - To avoid blocking of concurrent transactions that obtain numbers from the same sequence, a nextval operation is never rolled back; that is, once a value is fetched, it is considered used, even if the transaction that did the nextval later aborts. This means that aborted transactions may leave unused "holes" in the sequence of assigned values. Therefore, the GaussDB sequence object cannot be used to obtain "holeless" sequences.
  - If the nextval function is pushed to DNs, each DN will automatically connect to the GTM and requests the next value. For example, in the **insert into t1 select** *xxx* statement, a column in table **t1** needs to call the nextval function. If the maximum number of connections on the GTM is 8192, this type of pushed statements occupies too many GTM connections. Therefore, the number of concurrent connections for these statements is limited to 7000 divided by the number of cluster DNs. The other connections are reserved for other statements.
  - If an insert statement contains both a set returning function (SRF) and an auto-increment sequence column, the sequence value will skip one increment. The following uses the generate_series function as an example:

    ```
    CREATE TABLE t1 (a int, b serial);
    INSERT INTO t1(a) VALUES(generate_series(1,1)); -- Insert data with column b as 1.
    INSERT INTO t1(a) VALUES(generate_series(1,1));  -- Insert data with column b as 3, skipping 2.
    ```

  - For the sequence of the **rowid** system column, nextval() can be operated only in maintenance mode.

  Return type: numeric

  The nextval function can be called in either of the following ways (In example 2, the ORA syntax is supported. Currently, the sequence name cannot contain a dot.):

  ```
  gaussdb=# CREATE SEQUENCE seqDemo;

  -- Example 1:
  gaussdb=# SELECT nextval('seqDemo');
   nextval
  ---------
        1
  (1 row)

  -- Example 2:
  gaussdb=# SELECT seqDemo.nextval;
   nextval
  ---------
        2
  (1 row)
  gaussdb=# DROP SEQUENCE seqDemo;
  ```

- currval(regclass)

  Description: Returns the last value of **nextval** in the current session. If nextval has not been called for the specified sequence in the current session, an error is reported when currval is called. By default, **currval** is disabled. To enable it, set **enable_beta_features** to **true**. After **enable_beta_features** is set to **true**, **nextval** will not be pushed down.

  Return type: numeric

  The currval function can be called in either of the following ways (In example 2, the ORA syntax is supported. Currently, the sequence name cannot contain a dot.):

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gaussdb=# CREATE SEQUENCE seq1;
gaussdb=# SELECT nextval('seq1');
gaussdb=# SET enable_beta_features = true;

-- Example 1:
gaussdb=# SELECT currval('seq1');
 currval
---------
       1
(1 row)

-- Example 2:
gaussdb=# SELECT seq1.currval seq1;
 seq1
------
    1
(1 row)
gaussdb=# DROP SEQUENCE seq1;
gaussdb=# SET enable_beta_features = false;
```

- lastval()

  Description: Returns the last value of **nextval** in the current session. This function is equivalent to currval, except that it does not use sequence names as parameters. It fetches the sequence used by nextval last time in the current session. If nextval has not been called in the current session, an error is reported when lastval is called.

  By default, lastval is disabled. To enable it, set **enable_beta_features** or **lastval_supported** to **true**. After lastval is enabled, nextval() will not be pushed down.

  Return type: numeric

  Example:

  ```
  gaussdb=# CREATE SEQUENCE seq1;
  gaussdb=# SELECT nextval('seq1');
  gaussdb=# SET enable_beta_features = true;
  gaussdb=# SELECT lastval();
   lastval
  ---------
         1
  (1 row)
  gaussdb=# DROP SEQUENCE seq1;
  gaussdb=# SET enable_beta_features = false;
  ```

- setval(regclass, bigint)

  Description: Sets the current value of a sequence.

  Return type: numeric

  Example:

  ```
  gaussdb=# CREATE SEQUENCE seqDemo;
  gaussdb=# SELECT nextval('seqDemo');
  gaussdb=# SELECT setval('seqDemo',3);
   setval
  --------
       3
  (1 row)
  gaussdb=# DROP SEQUENCE seqDemo;
  ```

- setval(regclass, numeric, Boolean)

  Sets the current value of a sequence and the is_called sign.

  Return type: numeric

  Example:

  ```
  gaussdb=# CREATE SEQUENCE seqDemo;
  gaussdb=# SELECT nextval('seqDemo');
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gaussdb=# SELECT setval('seqDemo',5,true);
 setval
--------
      5
(1 row)
gaussdb=# DROP SEQUENCE seqDemo;
```

NOTE

- After this function is used, the new value takes effect immediately on the GTM. If the cache value is greater than the **session_sequence_cache** value, the current session continues to obtain the cache until the cache value is used up. If the cache value is less than or equal to the **session_sequence_cache** value, the new value takes effect immediately in the current session. However, if other sessions have cached sequence values, the new value takes effect only after the cached values are used up. To avoid sequence value conflicts, exercise caution when using this function.
- Changes made by this function will not be undone if a transaction is rolled back, as the sequence is non-transactional.
- For sequences of the **rowid** system column, this function can be used only in maintenance mode.

- pg_sequence_last_value(sequence_oid oid, OUT cache_value int16, OUT last_value int16)

  Description: Obtains the parameters of a specified sequence, including the cache value and current value.

  Return type: int16, int16

- gs_get_sequence_parameters(sequence_oid, OUT start_value int16, OUT minimum_value int16, OUT maximum_value int16, OUT increment int16, OUT cycle_option Boolean, OUT order_option Boolean)

  Description: Obtains the parameter information about a specified sequence, including the start value, minimum value, maximum value, increment, cycling option, and order option.

  Return type: int16, int16, int16, int16, boolean, boolean

- gs_get_sequence_last_value(sequence_oid oid, OUT cache_value int16, OUT last_value int16)

  Description: Obtains the parameters of a specified sequence, including the cache value and current value.

  Return type: int16, int16

- get_global_last_value_from_gtm(sequence_regclass regclass, OUT is_called boolean, OUT last_value numeric)

  Description: Obtains the flag indicating whether a sequence has been called and the latest value of the requested sequence from GTM.

  Parameter: name or OID of a sequence to be queried.

  Return types: Boolean and numeric

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- For upgrade from a version that does not support get_global_last_value_from_gtm to a version that supports get_global_last_value_from_gtm, this function cannot be used during the upgrade observation period.
- The get_global_last_value_from_gtm function requires communication with the GTM each time it is called; therefore, it is not recommended to execute it frequently.
- The latest value that has been requested for a sequence does not necessarily indicate the maximum value that has been used. If the sequence's cache is greater than 1 and the sequence values requested by the node are not used up, this will leave unused "holes."

1.6.16 Array Functions and Operators

Array Operators

- =

  Description: Specifies whether two arrays are equal.

  Example:

```
gaussdb=# SELECT ARRAY[1.1,2.1,3.1]::int[] = ARRAY[1,2,3] AS RESULT ;
 result
--------
 t
(1 row)
```

- <>

  Description: Specifies whether two arrays are not equal.

  Example:

```
gaussdb=# SELECT ARRAY[1,2,3] <> ARRAY[1,2,4] AS RESULT;
 result
--------
 t
(1 row)
```

- <

  Description: Specifies whether an array is less than another.

  Example:

```
gaussdb=# SELECT ARRAY[1,2,3] < ARRAY[1,2,4] AS RESULT;
 result
--------
 t
(1 row)
```

- >

  Description: Specifies whether an array is greater than another.

  Example:

```
gaussdb=# SELECT ARRAY[1,4,3] > ARRAY[1,2,4] AS RESULT;
 result
--------
 t
(1 row)
```

- <=

  Description: Specifies whether an array is less than or equal to another.

  Example:

```
gaussdb=# SELECT ARRAY[1,2,3] <= ARRAY[1,2,3] AS RESULT;
 result
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
--------
 t
(1 row)
```

- >=

  Description: Specifies whether an array is greater than or equal to another.

  Example:

```
gaussdb=# SELECT ARRAY[1,4,3] >= ARRAY[1,4,3] AS RESULT;
 result
--------
 t
(1 row)
```

- @>

  Description: Specifies whether an array contains another.

  Example:

```
gaussdb=# SELECT ARRAY[1,4,3] @> ARRAY[3,1] AS RESULT;
 result
--------
 t
(1 row)
```

- <@

  Description: Specifies whether an array is contained in another.

  Example:

```
gaussdb=# SELECT ARRAY[2,7] <@ ARRAY[1,7,4,2,6] AS RESULT;
 result
--------
 t
(1 row)
```

- &&

  Description: Specifies whether an array overlaps another (have common elements).

  Example:

```
gaussdb=# SELECT ARRAY[1,4,3] && ARRAY[2,1] AS RESULT;
 result
--------
 t
(1 row)
```

- ||

  Description: Array-to-array concatenation.

  Example:

```
gaussdb=# SELECT ARRAY[1,2,3] || ARRAY[4,5,6] AS RESULT;
    result
---------------
 {1,2,3,4,5,6}
(1 row)
gaussdb=# SELECT ARRAY[1,2,3] || ARRAY[[4,5,6],[7,8,9]] AS RESULT;
          result
---------------------------
 {{1,2,3},{4,5,6},{7,8,9}}
(1 row)
```

- ||

  Description: Element-to-array concatenation.

  Example:

```
gaussdb=# SELECT 3 || ARRAY[4,5,6] AS RESULT;
  result
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
-----------
 {3,4,5,6}
(1 row)
```

- ||

  Description: Array-to-element concatenation.

  Example:

```
gaussdb=# SELECT ARRAY[4,5,6] || 7 AS RESULT;
  result
-----------
 {4,5,6,7}
(1 row)
```

Array comparisons compare the array contents element-by-element, using the default B-tree comparison function for the element data type. In multidimensional arrays, the elements are accessed in row-major order. If the contents of two arrays are equal but the dimensionality is different, the first difference in the dimensionality information determines the sort order.

Array Functions

- array_append(anyarray, anyelement)

  Description: Appends an element to the end of an array, and only supports one-dimensional arrays.

  Return type: anyarray

  Example:

```
gaussdb=# SELECT array_append(ARRAY[1,2], 3) AS RESULT;
 result
---------
 {1,2,3}
(1 row)
```

- array_prepend(anyelement, anyarray)

  Description: Appends an element to the beginning of an array, and only supports one-dimensional arrays.

  Return type: anyarray

  Example:

```
gaussdb=# SELECT array_prepend(1, ARRAY[2,3]) AS RESULT;
 result
---------
 {1,2,3}
(1 row)
```

- array_cat(anyarray, anyarray)

  Description: Concatenates two arrays, and supports multi-dimensional arrays.

  Return type: anyarray

  Example:

```
gaussdb=# SELECT array_cat(ARRAY[1,2,3], ARRAY[4,5]) AS RESULT;
   result
-------------
 {1,2,3,4,5}
(1 row)

gaussdb=# SELECT array_cat(ARRAY[[1,2],[4,5]], ARRAY[6,7]) AS RESULT;
      result
--------------------
 {{1,2},{4,5},{6,7}}
(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- array_union(anyarray, anyarray)

  Description: Concatenates two arrays. Only one-dimensional arrays are supported. If an input parameter is **NULL**, another input parameter is returned.

  Return type: anyarray

  Example:

```
gaussdb=# SELECT array_union(ARRAY[1,2,3], ARRAY[3,4,5]) AS RESULT;
   result
-------------
 {1,2,3,3,4,5}
(1 row)

gaussdb=# SELECT array_union(ARRAY[1,2,3], NULL) AS RESULT;
 result
---------
 {1,2,3}
(1 row)
```

- array_union_distinct(anyarray, anyarray)

  Description: Concatenates two arrays and deduplicates them. Only one-dimensional arrays are supported. If an input parameter is **NULL**, the other input parameter is returned. Make sure that the returned input parameter contains only one-dimensional arrays. For multi-dimensional arrays, an error is reported.

  Return type: anyarray

  Example:

```
gaussdb=# SELECT array_union_distinct(ARRAY[1,2,3], ARRAY[3,4,5]) AS RESULT;
   result
-------------
 {1,2,3,4,5}
(1 row)

gaussdb=# SELECT array_union_distinct(ARRAY[1,2,3], NULL) AS RESULT;
 result
---------
 {1,2,3}
(1 row)
```

- array_intersect(anyarray, anyarray)

  Description: Intersects two arrays. Only one-dimensional arrays are supported. If any input parameter is **NULL**, **NULL** is returned.

  Return type: anyarray

  Example:

```
gaussdb=# SELECT array_intersect(ARRAY[1,2,3], ARRAY[3,4,5]) AS RESULT;
   result
-------------
 {3}
(1 row)

gaussdb=# SELECT array_intersect(ARRAY[1,2,3], NULL) AS RESULT;
 result
--------

(1 row)
```

- array_intersect_distinct(anyarray, anyarray)

  Description: Intersects two arrays and deduplicates them. Only one-dimensional arrays are supported. If any input parameter is **NULL**, **NULL** is returned.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Return type: anyarray

Example:

```
gaussdb=# SELECT array_intersect_distinct(ARRAY[1,2,2], ARRAY[2,2,4,5]) AS RESULT;
  result
-------------
 {2}
(1 row)

gaussdb=# SELECT array_intersect_distinct(ARRAY[1,2,3], NULL) AS RESULT;
 result
--------

(1 row)
```

- array_except(anyarray, anyarray)

  Description: Calculates the difference between two arrays. Only one-dimensional arrays are supported. If the first input parameter is **NULL**, **NULL** is returned. If the second input parameter is **NULL**, the first input parameter is returned.

  Return type: anyarray

  Example:

```
gaussdb=# SELECT array_except(ARRAY[1,2,3], ARRAY[3,4,5]) AS RESULT;
  result
-------------
 {1,2}
(1 row)

gaussdb=# SELECT array_except(ARRAY[1,2,3], NULL) AS RESULT;
 result
---------
 {1,2,3}
(1 row)

gaussdb=# SELECT array_except(NULL, ARRAY[3,4,5]) AS RESULT;
 result
--------

(1 row)
```

- array_except_distinct(anyarray, anyarray)

  Description: Calculates the difference between two arrays and deduplicates them. Only one-dimensional arrays are supported. If the first input parameter is **NULL**, **NULL** is returned. If the second input parameter is **NULL**, the first input parameter is returned. The first input parameter can contain only one-dimensional arrays. For multi-dimensional arrays, an error is reported.

  Return type: anyarray

  Example:

```
gaussdb=# SELECT array_except_distinct(ARRAY[1,2,2,3], ARRAY[3,4,5]) AS RESULT;
  result
-------------
 {1,2}
(1 row)

gaussdb=# SELECT array_except_distinct(ARRAY[1,2,3], NULL) AS RESULT;
 result
---------
 {1,2,3}
(1 row)

gaussdb=# SELECT array_except_distinct(NULL, ARRAY[3,4,5]) AS RESULT;
 result
--------
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
(1 row)
```

- array_ndims(anyarray)

  Description: Returns the number of dimensions of an array.

  Return type: int

  Example:

  ```
  gaussdb=# SELECT array_ndims(ARRAY[[1,2,3], [4,5,6]]) AS RESULT;
   result
  --------
       2
  (1 row)
  ```

- array_dims(anyarray)

  Description: Returns the lower and upper bounds of each dimension of an array.

  Return type: text

  Example:

  ```
  gaussdb=# SELECT array_dims(ARRAY[[1,2,3], [4,5,6]]) AS RESULT;
    result
  ------------
   [1:2][1:3]
  (1 row)
  ```

- array_length(anyarray, int)

  Description: Returns the length of the requested array dimension.

  Return type: int

  Example:

  ```
  gaussdb=# SELECT array_length(array[1,2,3], 1) AS RESULT;
   result
  --------
       3
  (1 row)
  ```

- array_lower(anyarray, int)

  Description: Returns lower bound of the requested array dimension.

  Return type: int

  Example:

  ```
  gaussdb=# SELECT array_lower('[0:2]={1,2,3}'::int[], 1) AS RESULT;
   result
  --------
       0
  (1 row)
  ```

- array_sort(anyarray)

  Description: Returns an array in ascending order. Only one-dimensional array of the anyarray type supports sorting. Multidimensional arrays return **NULL**. Currently, the record, XML, XMLtype, and JSON arrays cannot be sorted.

  Return type: anyarray

  Example:

  ```
  gaussdb=# SELECT array_sort(ARRAY[5,1,3,6,2,7]) AS RESULT;
   result
  -------------
  {1,2,3,5,6,7}
  (1 row)
  gaussdb=# SELECT array_sort(array[array[1,23], array[1,34]]);
   array_sort
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
-------------
 {NULL,NULL}
(1 row)
```

- array_upper(anyarray, int)

  Description: Returns upper bound of the requested array dimension.

  Return type: int

  Example:

```
gaussdb=# SELECT array_upper(ARRAY[1,8,3,7], 1) AS RESULT;
 result
--------
      4
(1 row)
```

- array_to_string(anyarray, text [, text])

  Description: Uses the first **text** as the new delimiter and the second **text** to replace **NULL** values.

  Return type: text

  Example:

```
gaussdb=# SELECT array_to_string(ARRAY[1, 2, 3, NULL, 5], ',', '*') AS RESULT;
  result
-----------
 1,2,3,*,5
(1 row)
```

- array_delete(anyarray)

  Description: Clears elements in an array and returns an empty array of the same type.

  Return type: anyarray

  Example:

```
gaussdb=# SELECT array_delete(ARRAY[1,8,3,7]) AS RESULT;
 result
--------
 {}
(1 row)
```

- array_deleteidx(anyarray, int)

  Description: Deletes specified index elements from an array and returns an array consisting of the remaining elements.

  Return type: anyarray

  Example:

```
gaussdb=# SELECT array_deleteidx(ARRAY[1,2,3,4,5], 1) AS RESULT;
  result
-----------
 {2,3,4,5}
(1 row)
```

  NOTE

  array_deleteidx(anyarray, int): This function is disabled when the value of **a_format_version** is **10c** and the value of **a_format_dev_version** is **s1**.

- array_extendnull(anyarray, int)

  Description: Adds a specified number of null elements to the end of an array.

  Return type: anyarray

  Example:

```
gaussdb=# SELECT array_extendnull(ARRAY[1,8,3,7],1) AS RESULT;
   result
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
--------------
{1,8,3,7,null}
(1 row)
```

- array_extendnull(anyarray, int, int)

  Description: Adds a specified number of elements with a specified index to the end of an array.

  Return type: anyarray

  Example:

```
gaussdb=# SELECT array_extendnull(ARRAY[1,8,3,7],2,2) AS RESULT;
   result
--------------
{1,8,3,7,8,8}
(1 row)
```

  NOTE

  array_extendnull(anyarray, int, int): This function takes effect when the value of **a_format_version** is **10c** and the value of **a_format_dev_version** is **s1**.

- array_trim(anyarray, int)

  Description: Removes a specified number of elements from the end of an array.

  Return type: anyarray

  Example:

```
gaussdb=# SELECT array_trim(ARRAY[1,8,3,7],1) AS RESULT;
 result
---------
 {1,8,3}
(1 row)
```

- array_exists(anyarray, int)

  Description: Checks whether the second parameter is a valid index of an array.

  Return type: Boolean

  Example:

```
gaussdb=# SELECT array_exists(ARRAY[1,8,3,7],1) AS RESULT;
 result
--------
 t
(1 row)
```

- array_next(anyarray, int)

  Description: Returns the index of the element following a specified index in an array based on the second input parameter.

  Return type: int

  Example:

```
gaussdb=# SELECT array_next(ARRAY[1,8,3,7],1) AS RESULT;
 result
--------
      2
(1 row)
```

- array_prior(anyarray, int)

  Description: Returns the index of the element followed by a specified index in an array based on the second input parameter.

  Return type: int

  Example:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gaussdb=# SELECT array_prior(ARRAY[1,8,3,7],2) AS RESULT;
 result
--------
  1
(1 row)
```

- string_to_array(text, text, [text])

  Description: Uses the second **text** as the new delimiter and the third **text** as the substring to be replaced by **NULL** values. A substring can be replaced by **NULL** values only when it is the same as the third **text**.

  Return type: text[]

  Example:

```
gaussdb=# SELECT string_to_array('xx~^~yy~^~zz', '~^~', 'yy') AS RESULT;
    result
--------------
 {xx,NULL,zz}
(1 row)
gaussdb=# SELECT string_to_array('xx~^~yy~^~zz', '~^~', 'y') AS RESULT;
   result
------------
 {xx,yy,zz}
(1 row)
```

  In **string_to_array**, if the delimiter parameter is **NULL**, each character in the input string will become a separate element in the resulting array. If the delimiter is an empty string, then the entire input string is returned as a one-element array. Otherwise, the input string is split at each occurrence of the delimiter string.

  In **string_to_array**, if the null-string parameter is omitted or **NULL**, none of the substrings of the input will be replaced by **NULL**.

  In **array_to_string**, if the null-string parameter is omitted or **NULL**, any null elements in the array are simply skipped and not represented in the output string.

- unnest(anyarray)

  Description: Expands an array to a set of rows.

  Return type: setof anyelement

  Example:

```
gaussdb=# SELECT unnest(ARRAY[1,2]) AS RESULT;
 result
--------
      1
      2
(2 rows)
```

- _pg_keysequal

  Description: Checks whether two smallint arrays are the same.

  Parameter: smallint[], smallint[]

  Return type: Boolean

  > **NOTE**
  >
  > This function exists in the information_schema namespace.

- cardinality(anyarray)

  Description: Returns the total number of elements in each dimension of an array. If the array is empty, **0** is returned.

  Return type: integer

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Example:

```
gaussdb=# SELECT cardinality(array[[1, 2], [3, 4]]);
 cardinality
-------------
           4
(1 row)
```

- array_positions(anyarray, anyelement)

  Description: Returns an array of indexes of all second parameters that appear in the array given as the first parameter.

  Return type: int[]

  Example:

```
gaussdb=# SELECT array_positions(array[1, 2, 3, 1], 1) AS RESULT;
 result
--------
 {1,4}
(1 row)
```

  NOTE

  - The array must be one-dimensional.
  - The second parameter can be set to **NULL**.
  - If no second parameter is found in the array, an empty array is returned.

1.6.17 Range Functions and Operators

Range Operators

- =

  Description: Equals

  Example:

```
gaussdb=# SELECT int4range(1,5) = '[1,4]'::int4range AS RESULT;
 result
--------
 t
(1 row)
```

- <>

  Description: Does not equal

  Example:

```
gaussdb=# SELECT numrange(1.1,2.2) <> numrange(1.1,2.3) AS RESULT;
 result
--------
 t
(1 row)
```

- <

  Description: Is less than

  Example:

```
gaussdb=# SELECT int4range(1,10) < int4range(2,3) AS RESULT;
 result
--------
 t
(1 row)
```

- >

  Description: Is greater than

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Example:

```
gaussdb=# SELECT int4range(1,10) > int4range(1,5) AS RESULT;
 result
--------
 t
(1 row)
```

- <=

  Description: Is less than or equals

  Example:

  ```
  gaussdb=# SELECT numrange(1.1,2.2) <= numrange(1.1,2.2) AS RESULT;
   result
  --------
   t
  (1 row)
  ```

- >=

  Description: Greater than or equal

  Example:

  ```
  gaussdb=# SELECT numrange(1.1,2.2) >= numrange(1.1,2.0) AS RESULT;
   result
  --------
   t
  (1 row)
  ```

- @>

  Description: Contains range

  Example:

  ```
  gaussdb=# SELECT int4range(2,4) @> int4range(2,3) AS RESULT;
   result
  --------
   t
  (1 row)
  ```

- @>

  Description: Contains element

  Example:

  ```
  gaussdb=# SELECT '[2011-01-01,2011-03-01)'::tsrange @> '2011-01-10'::timestamp AS RESULT;
   result
  --------
   t
  (1 row)
  ```

- <@

  Description: Range is contained by

  Example:

  ```
  gaussdb=# SELECT int4range(2,4) <@ int4range(1,7) AS RESULT;
   result
  --------
   t
  (1 row)
  ```

- <@

  Description: Element is contained by

  Example:

  ```
  gaussdb=# SELECT 42 <@ int4range(1,7) AS RESULT;
   result
  --------
   f
  (1 row)
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- &&

  Description: Overlap (have points in common)

  Example:

```
gaussdb=# SELECT int8range(3,7) && int8range(4,12) AS RESULT;
 result
--------
 t
(1 row)
```

- <<

  Description: Strictly left of

  Example:

```
gaussdb=# SELECT int8range(1,10) << int8range(100,110) AS RESULT;
 result
--------
 t
(1 row)
```

- >>

  Description: Strictly right of

  Example:

```
gaussdb=# SELECT int8range(50,60) >> int8range(20,30) AS RESULT;
 result
--------
 t
(1 row)
```

- &<

  Description: Does not extend to the right of

  Example:

```
gaussdb=# SELECT int8range(1,20) &< int8range(18,20) AS RESULT;
 result
--------
 t
(1 row)
```

- &>

  Description: Does not extend to the left of

  Example:

```
gaussdb=# SELECT int8range(7,20) &> int8range(5,10) AS RESULT;
 result
--------
 t
(1 row)
```

- -|-

  Description: Is adjacent to

  Example:

```
gaussdb=# SELECT numrange(1.1,2.2) -|- numrange(2.2,3.3) AS RESULT;
 result
--------
 t
(1 row)
```

- +

  Description: Union

  Example:

```
gaussdb=# SELECT numrange(5,15) + numrange(10,20) AS RESULT;
 result
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
--------
 [5,20)
(1 row)
```

- *

  Description: Intersection

  Example:

```
gaussdb=# SELECT int8range(5,15) * int8range(10,20) AS RESULT;
 result
---------
 [10,15)
(1 row)
```

- -

  Description: Difference

  Example:

```
gaussdb=# SELECT int8range(5,15) - int8range(10,20) AS RESULT;
 result
--------
 [5,10)
(1 row)
```

The simple comparison operators **<**, **>**, **<=**, and **>=** compare the lower bounds first, and only if those are equal, compare the upper bounds.

The **<<**, **>>**, and **-|-** operators always return false when an empty range is involved; that is, an empty range is not considered to be either before or after any other range.

The union and difference operators will fail if the resulting range would need to contain two disjoint sub-ranges.

Range Functions

The lower and upper functions return null if the range is empty or the requested bound is infinite. The lower_inc, upper_inc, lower_inf, and upper_inf functions all return false for an empty range.

- numrange(numeric, numeric, [text])

  Description: Specifies a range.

  Return type: range's element type

  Example:

```
gaussdb=# SELECT numrange(1.1,2.2) AS RESULT;
 result
--------
[1.1,2.2)
(1 row)
gaussdb=# SELECT numrange(1.1,2.2, '()') AS RESULT;
 result
--------
(1.1,2.2)
(1 row)
```

- lower(anyrange)

  Description: Lower bound of range

  Return type: range's element type

  Example:

```
gaussdb=# SELECT lower(numrange(1.1,2.2)) AS RESULT;
 result
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
--------
   1.1
(1 row)
```

- upper(anyrange)

  Description: Specifies the upper bound of a range.

  Return type: range's element type

  Example:

  ```
  gaussdb=# SELECT upper(numrange(1.1,2.2)) AS RESULT;
   result
  --------
     2.2
  (1 row)
  ```

- isempty(anyrange)

  Description: Specifies whether a range is empty.

  Return type: Boolean

  Example:

  ```
  gaussdb=# SELECT isempty(numrange(1.1,2.2)) AS RESULT;
   result
  --------
   f
  (1 row)
  ```

- lower_inc(anyrange)

  Description: Specifies whether the lower bound is inclusive.

  Return type: Boolean

  Example:

  ```
  gaussdb=# SELECT lower_inc(numrange(1.1,2.2)) AS RESULT;
   result
  --------
   t
  (1 row)
  ```

- upper_inc(anyrange)

  Description: Specifies whether the upper bound is inclusive.

  Return type: Boolean

  Example:

  ```
  gaussdb=# SELECT upper_inc(numrange(1.1,2.2)) AS RESULT;
   result
  --------
   f
  (1 row)
  ```

- lower_inf(anyrange)

  Description: Specifies whether the lower bound is infinite.

  Return type: Boolean

  Example:

  ```
  gaussdb=# SELECT lower_inf('(,)'::daterange) AS RESULT;
   result
  --------
   t
  (1 row)
  ```

- upper_inf(anyrange)

  Description: Specifies whether the upper bound is infinite.

  Return type: Boolean

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Example:

```
gaussdb=# SELECT upper_inf('(,)'::daterange) AS RESULT;
 result
--------
 t
(1 row)
```

- elem_contained_by_range(anyelement, anyrange)

  Description: Determines whether an element is within the range.

  Return type: Boolean

  Example:

  ```
  gaussdb=# SELECT elem_contained_by_range('2', numrange(1.1,2.2));
   elem_contained_by_range
  -------------------------
   t
  (1 row)
  ```

  NOTE

  In Oracle-compatible mode, after the **mapping_date_to_datea** parameter is enabled, the date type is mapped to the datea type. The datea type does not support being used as a range type, and this function does not support the datea type as an input parameter.

- in_range_int16_int16(int16, int16, int16, boolean, boolean)

  Description: Checks whether the first parameter is within the range of the second parameter plus or minus the third parameter.

  Parameters:

  – First parameter: It specifies the number to be checked against the given range.

  – The second parameter: It specifies the start value of the current range.

  – Third parameter: It is a range value, which must be a positive number.

  – Fourth parameter: It specifies whether the current operation is a subtraction or addition operation.

    ▪ TRUE: Compare the second parameter minus the third parameter with the first parameter.

    ▪ FALSE: Compare the second parameter plus the third parameter with the first parameter.

  – Fifth parameter: It compares the operation result of the second and third parameters with the first parameter.

    ▪ TRUE: Check whether the result is greater than the first parameter. If the result is greater than or equal to the first parameter, the return value of the function is TRUE. Otherwise, the return value of the function is FALSE.

    ▪ FALSE: Check whether the result is less than or equal to the first parameter. If the result is less than or equal to the first parameter, the return value of the function is TRUE. Otherwise, the return value of the function is FALSE.

  Return type: Boolean

  Example:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gaussdb=# SELECT in_range_int16_int16(1::int16, 1::int16, 1::int16, true, true);
 in_range_int16_int16
----------------------
 f
(1 row)

gaussdb=# SELECT in_range_int16_int16(1::int16, 4::int16, 2::int16, true, true);
 in_range_int16_int16
----------------------
 t
(1 row)
```

- in_range_int8_int16(int8, int8, int16, boolean, boolean)

  Description: Checks whether the first parameter is within the range of the second parameter plus or minus the third parameter.

  Parameters:

  – First parameter: It specifies the number to be checked against the given range.

  – The second parameter: It specifies the start value of the current range.

  – Third parameter: It is a range value, which must be a positive number.

  – Fourth parameter: It specifies whether the current operation is a subtraction or addition operation.

    ▪ TRUE: Compare the second parameter minus the third parameter with the first parameter.

    ▪ FALSE: Compare the second parameter plus the third parameter with the first parameter.

  – Fifth parameter: It compares the operation result of the second and third parameters with the first parameter.

    ▪ TRUE: Check whether the result is greater than the first parameter. If the result is greater than or equal to the first parameter, the return value of the function is TRUE. Otherwise, the return value of the function is FALSE.

    ▪ FALSE: Check whether the result is less than or equal to the first parameter. If the result is less than or equal to the first parameter, the return value of the function is TRUE. Otherwise, the return value of the function is FALSE.

  Return type: Boolean

  Example:

```
gaussdb=# SELECT in_range_int8_int16(1::int8, 1::int8, 1::int16, true, true);
 in_range_int8_int16
---------------------
 f
(1 row)

gaussdb=# SELECT in_range_int8_int16(1::int8, 4::int8, 2::int16, true, true);
 in_range_int8_int16
---------------------
 t
(1 row)
```

- in_range_int4_int16(int4, int4, int16, boolean, boolean)

  Description: Checks whether the first parameter is within the range of the second parameter plus or minus the third parameter.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameters:

- First parameter: It specifies the number to be checked against the given range.
- The second parameter: It specifies the start value of the current range.
- Third parameter: It specifies a range value, which must be a positive number.
- Fourth parameter: It specifies whether the current operation is a subtraction or addition operation.
  - **TRUE**: The function compares the second parameter minus the third parameter with the first parameter.
  - **FALSE**: The function compares the second parameter plus the third parameter with the first parameter.
- Fifth parameter: It compares the operation result of the second and third parameters with the first parameter.
  - **TRUE**: The function checks whether the result is greater than the first parameter. If the result is greater than or equal to the first parameter, the return value of the function is **TRUE**. Otherwise, the return value of the function is **FALSE**.
  - **FALSE**: The function checks whether the result is less than or equal to the first parameter. If the result is less than or equal to the first parameter, the return value of the function is **TRUE**. Otherwise, the return value of the function is **FALSE**.

Return type: Boolean

Example:

```
gaussdb=# SELECT in_range_int4_int16(1::int4, 1::int4, 1::int16, true, true);
 in_range_int4_int16
---------------------
 f
(1 row)

gaussdb=# SELECT in_range_int4_int16(1::int4, 4::int4, 2::int16, true, true);
 in_range_int4_int16
---------------------
 t
(1 row)
```

- in_range_int2_int16(int2, int2, int16, boolean, boolean)

  Description: Checks whether the first parameter is within the range of the second parameter plus or minus the third parameter.

  Parameters:

  - First parameter: It specifies the number to be checked against the given range.
  - The second parameter: It specifies the start value of the current range.
  - Third parameter: It specifies a range value, which must be a positive number.
  - Fourth parameter: It specifies whether the current operation is a subtraction or addition operation.
    - **TRUE**: The function compares the second parameter minus the third parameter with the first parameter.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

    - **FALSE**: The function compares the second parameter plus the third parameter with the first parameter.
  - Fifth parameter: It compares the operation result of the second and third parameters with the first parameter.
    - **TRUE**: The function checks whether the result is greater than the first parameter. If the result is greater than or equal to the first parameter, the return value of the function is **TRUE**. Otherwise, the return value of the function is **FALSE**.
    - **FALSE**: The function checks whether the result is less than or equal to the first parameter. If the result is less than or equal to the first parameter, the return value of the function is **TRUE**. Otherwise, the return value of the function is **FALSE**.

  Return type: Boolean

  Example:

```
gaussdb=# SELECT in_range_int2_int16(1::int2, 1::int2, 1::int16, true, true);
 in_range_int2_int16
---------------------
 f
(1 row)

gaussdb=# SELECT in_range_int2_int16(1::int2, 4::int2, 2::int16, true, true);
 in_range_int2_int16
---------------------
 t
```

- in_range_int1_int16(int1, int1, int16, boolean, boolean)

  Description: Checks whether the first parameter is within the range of the second parameter plus or minus the third parameter.

  Parameters:

  - First parameter: It specifies the number to be checked against the given range.
  - The second parameter: It specifies the start value of the current range.
  - Third parameter: It specifies a range value, which must be a positive number.
  - Fourth parameter: It specifies whether the current operation is a subtraction or addition operation.
    - **TRUE**: The function compares the second parameter minus the third parameter with the first parameter.
    - **FALSE**: The function compares the second parameter plus the third parameter with the first parameter.
  - Fifth parameter: It compares the operation result of the second and third parameters with the first parameter.
    - **TRUE**: The function checks whether the result is greater than the first parameter. If the result is greater than or equal to the first parameter, the return value of the function is **TRUE**. Otherwise, the return value of the function is **FALSE**.
    - **FALSE**: The function checks whether the result is less than or equal to the first parameter. If the result is less than or equal to the first

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

parameter, the return value of the function is **TRUE**. Otherwise, the return value of the function is **FALSE**.

Return type: Boolean

```
gaussdb=# SELECT in_range_int1_int16(1::int1, 1::int1, 1::int16, true, true);
 in_range_int1_int16
---------------------
 f
(1 row)

gaussdb=# SELECT in_range_int1_int16(1::int1, 4::int1, 2::int16, true, true);
 in_range_int1_int16
---------------------
 t
(1 row)
```

- in_range_float8_float8(float8, float8, float8, boolean, boolean)

  Description: Checks whether the first parameter is within the range of the second parameter plus or minus the third parameter.

  Parameters:

  – First parameter: It specifies the number to be checked against the given range.

  – The second parameter: It specifies the start value of the current range.

  – Third parameter: It specifies a range value, which must be a positive number.

  – Fourth parameter: It specifies whether the current operation is a subtraction or addition operation.

    ▪ **TRUE**: The function compares the second parameter minus the third parameter with the first parameter.

    ▪ **FALSE**: The function compares the second parameter plus the third parameter with the first parameter.

  – Fifth parameter: It compares the operation result of the second and third parameters with the first parameter.

    ▪ **TRUE**: The function checks whether the result is greater than the first parameter. If the result is greater than or equal to the first parameter, the return value of the function is **TRUE**. Otherwise, the return value of the function is **FALSE**.

    ▪ **FALSE**: The function checks whether the result is less than or equal to the first parameter. If the result is less than or equal to the first parameter, the return value of the function is **TRUE**. Otherwise, the return value of the function is **FALSE**.

  Return type: Boolean

  Example:

```
gaussdb=# SELECT in_range_float8_float8(1.0::float8, 1.9::float8, 1.0::float8, true, true);
 in_range_float8_float8
------------------------
 f
(1 row)
```

- in_range_float4_float8(float4, float4, float8, boolean, boolean)

  Description: Checks whether the first parameter is within the range of the second parameter plus or minus the third parameter.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameters:

- First parameter: It specifies the number to be checked against the given range.
- The second parameter: It specifies the start value of the current range.
- Third parameter: It specifies a range value, which must be a positive number.
- Fourth parameter: It specifies whether the current operation is a subtraction or addition operation.
  - **TRUE**: The function compares the second parameter minus the third parameter with the first parameter.
  - **FALSE**: The function compares the second parameter plus the third parameter with the first parameter.
- Fifth parameter: It compares the operation result of the second and third parameters with the first parameter.
  - **TRUE**: The function checks whether the result is greater than the first parameter. If the result is greater than or equal to the first parameter, the return value of the function is **TRUE**. Otherwise, the return value of the function is **FALSE**.
  - **FALSE**: The function checks whether the result is less than or equal to the first parameter. If the result is less than or equal to the first parameter, the return value of the function is **TRUE**. Otherwise, the return value of the function is **FALSE**.

Return type: Boolean

Example:

```
gaussdb=# SELECT in_range_float4_float8(1.0::float4, 1.9::float4, 1.0::float8, true, true);
 in_range_float4_float8
------------------------
 f
(1 row)
```

- in_range_numeric_numeric(numeric, numeric, numeric, boolean, boolean)

  Description: Checks whether the first parameter is within the range of the second parameter plus or minus the third parameter.

  Parameters:

  - First parameter: It specifies the number to be checked against the given range.
  - The second parameter: It specifies the start value of the current range.
  - Third parameter: It specifies a range value, which must be a positive number.
  - Fourth parameter: It specifies whether the current operation is a subtraction or addition operation.
    - **TRUE**: The function compares the second parameter minus the third parameter with the first parameter.
    - **FALSE**: The function compares the second parameter plus the third parameter with the first parameter.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

  - Fifth parameter: It compares the operation result of the second and third parameters with the first parameter.
    - **TRUE**: The function checks whether the result is greater than the first parameter. If the result is greater than or equal to the first parameter, the return value of the function is **TRUE**. Otherwise, the return value of the function is **FALSE**.
    - **FALSE**: The function checks whether the result is less than or equal to the first parameter. If the result is less than or equal to the first parameter, the return value of the function is **TRUE**. Otherwise, the return value of the function is **FALSE**.

  Return type: Boolean

  Example:

```
gaussdb=# SELECT in_range_numeric_numeric(1.0::numeric(10,4), 1.9::numeric(10,4),
1.0::numeric(10,4), true, true);
 in_range_numeric_numeric
--------------------------
 f
(1 row)
```

- in_range_interval_interval(interval, interval, interval, boolean, boolean)

  Description: Checks whether the first parameter is within the range of the second parameter plus or minus the third parameter.

  Parameters:

  - First parameter: It specifies the number to be checked against the given range.
  - The second parameter: It specifies the start value of the current range.
  - Third parameter: It specifies a range value, which must be a positive number.
  - Fourth parameter: It specifies whether the current operation is a subtraction or addition operation.
    - **TRUE**: The function compares the second parameter minus the third parameter with the first parameter.
    - **FALSE**: The function compares the second parameter plus the third parameter with the first parameter.
  - Fifth parameter: It compares the operation result of the second and third parameters with the first parameter.
    - **TRUE**: The function checks whether the result is greater than the first parameter. If the result is greater than or equal to the first parameter, the return value of the function is **TRUE**. Otherwise, the return value of the function is **FALSE**.
    - **FALSE**: The function checks whether the result is less than or equal to the first parameter. If the result is less than or equal to the first parameter, the return value of the function is **TRUE**. Otherwise, the return value of the function is **FALSE**.

  Return type: Boolean

  Example:

```
gaussdb=# SELECT in_range_interval_interval(interval '13' hour, interval '10' hour, interval '3' hour,
false, true);
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
 in_range_interval_interval
----------------------------
 t
(1 row)
```

- in_range_timestamp_interval(timestamp, timestamp, interval, boolean, boolean)

  Description: Checks whether the first parameter is within the range of the second parameter plus or minus the third parameter.

  Parameters:

  – First parameter: It specifies the number to be checked against the given range.

  – The second parameter: It specifies the start value of the current range.

  – Third parameter: It specifies a range value, which must be a positive number.

  – Fourth parameter: It specifies whether the current operation is a subtraction or addition operation.

    ▪ **TRUE**: The function compares the second parameter minus the third parameter with the first parameter.

    ▪ **FALSE**: The function compares the second parameter plus the third parameter with the first parameter.

  – Fifth parameter: It compares the operation result of the second and third parameters with the first parameter.

    ▪ **TRUE**: The function checks whether the result is greater than the first parameter. If the result is greater than or equal to the first parameter, the return value of the function is **TRUE**. Otherwise, the return value of the function is **FALSE**.

    ▪ **FALSE**: The function checks whether the result is less than or equal to the first parameter. If the result is less than or equal to the first parameter, the return value of the function is **TRUE**. Otherwise, the return value of the function is **FALSE**.

  Return type: Boolean

```
gaussdb=# SELECT in_range_timestamp_interval('12-10-2010 11:25:00', '10-11-2010 11:26:00', interval
'60' day, false, true);
 in_range_timestamp_interval
-----------------------------
 t
(1 row)
```

- in_range_timestamptz_interval(timestamptz, timestamptz, interval, boolean, boolean)

  Description: Checks whether the first parameter is within the range of the second parameter plus or minus the third parameter.

  Parameters:

  – First parameter: It specifies the number to be checked against the given range.

  – The second parameter: It specifies the start value of the current range.

  – Third parameter: It specifies a range value, which must be a positive number.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

  - Fourth parameter: It specifies whether the current operation is a subtraction or addition operation.
    - **TRUE**: The function compares the second parameter minus the third parameter with the first parameter.
    - **FALSE**: The function compares the second parameter plus the third parameter with the first parameter.
  - Fifth parameter: It compares the operation result of the second and third parameters with the first parameter.
    - **TRUE**: The function checks whether the result is greater than the first parameter. If the result is greater than or equal to the first parameter, the return value of the function is **TRUE**. Otherwise, the return value of the function is **FALSE**.
    - **FALSE**: The function checks whether the result is less than or equal to the first parameter. If the result is less than or equal to the first parameter, the return value of the function is **TRUE**. Otherwise, the return value of the function is **FALSE**.

  Return type: Boolean

  Example:

```
gaussdb=# SELECT in_range_timestamptz_interval('12-10-2010 11:25:00+00', '10-11-2010
11:26:00+00', interval '60' day, false, true);
 in_range_timestamptz_interval
-------------------------------
 t
(1 row)
```

- in_range_time_interval(time, time, interval, boolean, boolean)

  Description: Checks whether the first parameter is within the range of the second parameter plus or minus the third parameter.

  Parameters:

  - First parameter: It specifies the number to be checked against the given range.
  - The second parameter: It specifies the start value of the current range.
  - Third parameter: It specifies a range value, which must be a positive number.
  - Fourth parameter: It specifies whether the current operation is a subtraction or addition operation.
    - **TRUE**: The function compares the second parameter minus the third parameter with the first parameter.
    - **FALSE**: The function compares the second parameter plus the third parameter with the first parameter.
  - Fifth parameter: It compares the operation result of the second and third parameters with the first parameter.
    - **TRUE**: The function checks whether the result is greater than the first parameter. If the result is greater than or equal to the first parameter, the return value of the function is **TRUE**. Otherwise, the return value of the function is **FALSE**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

    - **FALSE**: The function checks whether the result is less than or equal to the first parameter. If the result is less than or equal to the first parameter, the return value of the function is **TRUE**. Otherwise, the return value of the function is **FALSE**.

  Return type: Boolean

  Example:

```
gaussdb=# SELECT in_range_time_interval('00:00:00', '12:00:00', interval '13' hour, true, true);
 in_range_time_interval
------------------------
 f
(1 row)
```

- in_range_timetz_interval(timetz, timetz, interval, boolean, boolean)

  Description: Checks whether the first parameter is within the range of the second parameter plus or minus the third parameter.

  Parameters:

  - First parameter: It specifies the number to be checked against the given range.
  - The second parameter: It specifies the start value of the current range.
  - Third parameter: It specifies a range value, which must be a positive number.
  - Fourth parameter: It specifies whether the current operation is a subtraction or addition operation.
    - **TRUE**: The function compares the second parameter minus the third parameter with the first parameter.
    - **FALSE**: The function compares the second parameter plus the third parameter with the first parameter.
  - Fifth parameter: It compares the operation result of the second and third parameters with the first parameter.
    - **TRUE**: The function checks whether the result is greater than the first parameter. If the result is greater than or equal to the first parameter, the return value of the function is **TRUE**. Otherwise, the return value of the function is **FALSE**.
    - **FALSE**: The function checks whether the result is less than or equal to the first parameter. If the result is less than or equal to the first parameter, the return value of the function is **TRUE**. Otherwise, the return value of the function is **FALSE**.

  Return type: Boolean

  Example:

```
gaussdb=# SELECT in_range_timetz_interval('00:00:00+00', '12:00:00+00', interval '13' hour, true, true);
 in_range_timetz_interval
--------------------------
 f
(1 row)
```

- in_range_int8_numeric(int8, int8, numeric, boolean, boolean)

  Description: Checks whether the first parameter is within the range of the second parameter plus or minus the third parameter.

  Parameters:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

  - First parameter: It specifies the number to be checked against the given range.
  - The second parameter: It specifies the start value of the current range.
  - Third parameter: It specifies a range value, which must be a positive number.
  - Fourth parameter: It specifies whether the current operation is a subtraction or addition operation.
    - **TRUE**: The function compares the second parameter minus the third parameter with the first parameter.
    - **FALSE**: The function compares the second parameter plus the third parameter with the first parameter.
  - Fifth parameter: It compares the operation result of the second and third parameters with the first parameter.
    - **TRUE**: The function checks whether the result is greater than the first parameter. If the result is greater than or equal to the first parameter, the return value of the function is **TRUE**. Otherwise, the return value of the function is **FALSE**.
    - **FALSE**: The function checks whether the result is less than or equal to the first parameter. If the result is less than or equal to the first parameter, the return value of the function is **TRUE**. Otherwise, the return value of the function is **FALSE**.

  Return type: Boolean

  Example:

```
gaussdb=# SELECT in_range_int8_numeric(1::int8, 2::int8, 0.9::numeric(10,4), true, true);
 in_range_int8_numeric
-----------------------
 t
(1 row)
```

- in_range_int4_numeric(int4, int4, numeric, boolean, boolean)

  Description: Checks whether the first parameter is within the range of the second parameter plus or minus the third parameter.

  Parameters:

  - First parameter: It specifies the number to be checked against the given range.
  - The second parameter: It specifies the start value of the current range.
  - Third parameter: It specifies a range value, which must be a positive number.
  - Fourth parameter: It specifies whether the current operation is a subtraction or addition operation.
    - **TRUE**: The function compares the second parameter minus the third parameter with the first parameter.
    - **FALSE**: The function compares the second parameter plus the third parameter with the first parameter.
  - Fifth parameter: It compares the operation result of the second and third parameters with the first parameter.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

    - **TRUE**: The function checks whether the result is greater than the first parameter. If the result is greater than or equal to the first parameter, the return value of the function is **TRUE**. Otherwise, the return value of the function is **FALSE**.
    - **FALSE**: The function checks whether the result is less than or equal to the first parameter. If the result is less than or equal to the first parameter, the return value of the function is **TRUE**. Otherwise, the return value of the function is **FALSE**.

  Return type: Boolean

  Example:

```
gaussdb=# SELECT in_range_int4_numeric(1::int4, 2::int4, 0.9::numeric(10,4), true, true);
 in_range_int4_numeric
-----------------------
 t
(1 row)
```

- in_range_int2_numeric(int2, int2, numeric, boolean, boolean)

  Description: Checks whether the first parameter is within the range of the second parameter plus or minus the third parameter.

  Parameters:

  – First parameter: It specifies the number to be checked against the given range.
  – The second parameter: It specifies the start value of the current range.
  – Third parameter: It specifies a range value, which must be a positive number.
  – Fourth parameter: It specifies whether the current operation is a subtraction or addition operation.
    - **TRUE**: The function compares the second parameter minus the third parameter with the first parameter.
    - **FALSE**: The function compares the second parameter plus the third parameter with the first parameter.
  – Fifth parameter: It compares the operation result of the second and third parameters with the first parameter.
    - **TRUE**: The function checks whether the result is greater than the first parameter. If the result is greater than or equal to the first parameter, the return value of the function is **TRUE**. Otherwise, the return value of the function is **FALSE**.
    - **FALSE**: The function checks whether the result is less than or equal to the first parameter. If the result is less than or equal to the first parameter, the return value of the function is **TRUE**. Otherwise, the return value of the function is **FALSE**.

  Return type: Boolean

  Example:

```
gaussdb=# SELECT in_range_int2_numeric(1::int2, 2::int2, 0.9::numeric(10,4), true, true);
 in_range_int2_numeric
-----------------------
 t
(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- in_range_int1_numeric(int1, int1, numeric, boolean, boolean)

  Description: Checks whether the first parameter is within the range of the second parameter plus or minus the third parameter.

  Parameters:

  - First parameter: It specifies the number to be checked against the given range.
  - The second parameter: It specifies the start value of the current range.
  - Third parameter: It specifies a range value, which must be a positive number.
  - Fourth parameter: It specifies whether the current operation is a subtraction or addition operation.
    - **TRUE**: The function compares the second parameter minus the third parameter with the first parameter.
    - **FALSE**: The function compares the second parameter plus the third parameter with the first parameter.
  - Fifth parameter: It compares the operation result of the second and third parameters with the first parameter.
    - **TRUE**: The function checks whether the result is greater than the first parameter. If the result is greater than or equal to the first parameter, the return value of the function is **TRUE**. Otherwise, the return value of the function is **FALSE**.
    - **FALSE**: The function checks whether the result is less than or equal to the first parameter. If the result is less than or equal to the first parameter, the return value of the function is **TRUE**. Otherwise, the return value of the function is **FALSE**.

  Return type: Boolean

  Example:

  ```
  gaussdb=# SELECT in_range_int1_numeric(1::int1, 2::int1, 0.9::numeric(10,4), true, true);
   in_range_int1_numeric
  -----------------------
   t
  (1 row)
  ```

- in_range_numeric_float4(numeric, numeric, float4, boolean, boolean)

  Description: Checks whether the first parameter is within the range of the second parameter plus or minus the third parameter.

  Parameters:

  - First parameter: It specifies the number to be checked against the given range.
  - The second parameter: It specifies the start value of the current range.
  - Third parameter: It specifies a range value, which must be a positive number.
  - Fourth parameter: It specifies whether the current operation is a subtraction or addition operation.
    - **TRUE**: The function compares the second parameter minus the third parameter with the first parameter.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

        - **FALSE**: The function compares the second parameter plus the third parameter with the first parameter.
    - Fifth parameter: It compares the operation result of the second and third parameters with the first parameter.
        - **TRUE**: The function checks whether the result is greater than the first parameter. If the result is greater than or equal to the first parameter, the return value of the function is **TRUE**. Otherwise, the return value of the function is **FALSE**.
        - **FALSE**: The function checks whether the result is less than or equal to the first parameter. If the result is less than or equal to the first parameter, the return value of the function is **TRUE**. Otherwise, the return value of the function is **FALSE**.

    Return type: Boolean

    Example:

    ```
    gaussdb=# SELECT in_range_numeric_float4(1.0::numeric(10,4), 1.9::numeric(10,4), 1.0::float4, true, true);
     in_range_numeric_float4
    -------------------------
     f
    (1 row)
    ```

- in_range_numeric_float8(numeric, numeric, float8, boolean, boolean)

    Description: Checks whether the first parameter is within the range of the second parameter plus or minus the third parameter.

    Parameters:

    - First parameter: It specifies the number to be checked against the given range.
    - The second parameter: It specifies the start value of the current range.
    - Third parameter: It specifies a range value, which must be a positive number.
    - Fourth parameter: It specifies whether the current operation is a subtraction or addition operation.
        - **TRUE**: The function compares the second parameter minus the third parameter with the first parameter.
        - **FALSE**: The function compares the second parameter plus the third parameter with the first parameter.
    - Fifth parameter: It compares the operation result of the second and third parameters with the first parameter.
        - **TRUE**: The function checks whether the result is greater than the first parameter. If the result is greater than or equal to the first parameter, the return value of the function is **TRUE**. Otherwise, the return value of the function is **FALSE**.
        - **FALSE**: The function checks whether the result is less than or equal to the first parameter. If the result is less than or equal to the first parameter, the return value of the function is **TRUE**. Otherwise, the return value of the function is **FALSE**.

    Return type: Boolean

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Example:

```
gaussdb=# SELECT in_range_numeric_float8(1.0::numeric(10,4), 1.9::numeric(10,4), 1.0::float8, true,
true);
 in_range_numeric_float8
-------------------------
 f
(1 row)
```

- in_range_int8_float8(int8, int8, float8, boolean, boolean)

  Description: Checks whether the first parameter is within the range of the second parameter plus or minus the third parameter.

  Parameters:

  - First parameter: It specifies the number to be checked against the given range.
  - The second parameter: It specifies the start value of the current range.
  - Third parameter: It specifies a range value, which must be a positive number.
  - Fourth parameter: It specifies whether the current operation is a subtraction or addition operation.
    - **TRUE**: The function compares the second parameter minus the third parameter with the first parameter.
    - **FALSE**: The function compares the second parameter plus the third parameter with the first parameter.
  - Fifth parameter: It compares the operation result of the second and third parameters with the first parameter.
    - **TRUE**: The function checks whether the result is greater than the first parameter. If the result is greater than or equal to the first parameter, the return value of the function is **TRUE**. Otherwise, the return value of the function is **FALSE**.
    - **FALSE**: The function checks whether the result is less than or equal to the first parameter. If the result is less than or equal to the first parameter, the return value of the function is **TRUE**. Otherwise, the return value of the function is **FALSE**.

  Return type: Boolean

  Example:

  ```
  gaussdb=# SELECT in_range_int8_float8(1::int8, 2::int8, 0.9::float8, true, true);
   in_range_int8_float8
  ----------------------
   t
  (1 row)
  ```

- in_range_int4_float8(int4, int4, float8, boolean, boolean)

  Description: Checks whether the first parameter is within the range of the second parameter plus or minus the third parameter.

  Parameters:

  - First parameter: It specifies the number to be checked against the given range.
  - The second parameter: It specifies the start value of the current range.
  - Third parameter: It specifies a range value, which must be a positive number.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

  - Fourth parameter: It specifies whether the current operation is a subtraction or addition operation.
    - **TRUE**: The function compares the second parameter minus the third parameter with the first parameter.
    - **FALSE**: The function compares the second parameter plus the third parameter with the first parameter.
  - Fifth parameter: It compares the operation result of the second and third parameters with the first parameter.
    - **TRUE**: The function checks whether the result is greater than the first parameter. If the result is greater than or equal to the first parameter, the return value of the function is **TRUE**. Otherwise, the return value of the function is **FALSE**.
    - **FALSE**: The function checks whether the result is less than or equal to the first parameter. If the result is less than or equal to the first parameter, the return value of the function is **TRUE**. Otherwise, the return value of the function is **FALSE**.

  Return type: Boolean

  Example:

```
gaussdb=# SELECT in_range_int4_float8(1::int4, 2::int4, 0.9::float8, true, true);
 in_range_int4_float8
----------------------
 t
(1 row)
```

- in_range_int2_float8(int2, int2, float8, boolean, boolean)

  Description: Checks whether the first parameter is within the range of the second parameter plus or minus the third parameter.

  Parameters:

  - First parameter: It specifies the number to be checked against the given range.
  - The second parameter: It specifies the start value of the current range.
  - Third parameter: It specifies a range value, which must be a positive number.
  - Fourth parameter: It specifies whether the current operation is a subtraction or addition operation.
    - **TRUE**: The function compares the second parameter minus the third parameter with the first parameter.
    - **FALSE**: The function compares the second parameter plus the third parameter with the first parameter.
  - Fifth parameter: It compares the operation result of the second and third parameters with the first parameter.
    - **TRUE**: The function checks whether the result is greater than the first parameter. If the result is greater than or equal to the first parameter, the return value of the function is **TRUE**. Otherwise, the return value of the function is **FALSE**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

        - **FALSE**: The function checks whether the result is less than or equal to the first parameter. If the result is less than or equal to the first parameter, the return value of the function is **TRUE**. Otherwise, the return value of the function is **FALSE**.

    Return type: Boolean

    Example:

```
gaussdb=# SELECT in_range_int2_float8(1::int2, 2::int2, 0.9::float8, true, true);
 in_range_int2_float8
----------------------
 t
(1 row)
```

- in_range_int1_float8(int1, int1, float8, boolean, boolean)

    Description: Checks whether the first parameter is within the range of the second parameter plus or minus the third parameter.

    Parameters:

    - First parameter: It specifies the number to be checked against the given range.
    - The second parameter: It specifies the start value of the current range.
    - Third parameter: It specifies a range value, which must be a positive number.
    - Fourth parameter: It specifies whether the current operation is a subtraction or addition operation.
        - **TRUE**: The function compares the second parameter minus the third parameter with the first parameter.
        - **FALSE**: The function compares the second parameter plus the third parameter with the first parameter.
    - Fifth parameter: It compares the operation result of the second and third parameters with the first parameter.
        - **TRUE**: The function checks whether the result is greater than the first parameter. If the result is greater than or equal to the first parameter, the return value of the function is **TRUE**. Otherwise, the return value of the function is **FALSE**.
        - **FALSE**: The function checks whether the result is less than or equal to the first parameter. If the result is less than or equal to the first parameter, the return value of the function is **TRUE**. Otherwise, the return value of the function is **FALSE**.

    Return type: Boolean

    Example:

```
gaussdb=# SELECT in_range_int1_float8(1::int1, 2::int1, 0.9::float8, true, true);
 in_range_int1_float8
----------------------
 t
(1 row)
```

- in_range_float8_int16(float8, float8, int16, boolean, boolean)

    Description: Checks whether the first parameter is within the range of the second parameter plus or minus the third parameter.

    Parameters:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

  - First parameter: It specifies the number to be checked against the given range.
  - The second parameter: It specifies the start value of the current range.
  - Third parameter: It specifies a range value, which must be a positive number.
  - Fourth parameter: It specifies whether the current operation is a subtraction or addition operation.
    - **TRUE**: The function compares the second parameter minus the third parameter with the first parameter.
    - **FALSE**: The function compares the second parameter plus the third parameter with the first parameter.
  - Fifth parameter: It compares the operation result of the second and third parameters with the first parameter.
    - **TRUE**: The function checks whether the result is greater than the first parameter. If the result is greater than or equal to the first parameter, the return value of the function is **TRUE**. Otherwise, the return value of the function is **FALSE**.
    - **FALSE**: The function checks whether the result is less than or equal to the first parameter. If the result is less than or equal to the first parameter, the return value of the function is **TRUE**. Otherwise, the return value of the function is **FALSE**.

  Return type: Boolean

  Example:

```
gaussdb=# SELECT in_range_float8_int16(1.0::float8, 1.9::float8, 1::int16, true, true);
 in_range_float8_int16
-----------------------
 f
(1 row)
```

- in_range_float4_int16(float4, float4, int16, boolean, boolean)

  Description: Checks whether the first parameter is within the range of the second parameter plus or minus the third parameter.

  Parameters:

  - First parameter: It specifies the number to be checked against the given range.
  - The second parameter: It specifies the start value of the current range.
  - Third parameter: It specifies a range value, which must be a positive number.
  - Fourth parameter: It specifies whether the current operation is a subtraction or addition operation.
    - **TRUE**: The function compares the second parameter minus the third parameter with the first parameter.
    - **FALSE**: The function compares the second parameter plus the third parameter with the first parameter.
  - Fifth parameter: It compares the operation result of the second and third parameters with the first parameter.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

    - **TRUE**: The function checks whether the result is greater than the first parameter. If the result is greater than or equal to the first parameter, the return value of the function is **TRUE**. Otherwise, the return value of the function is **FALSE**.
    - **FALSE**: The function checks whether the result is less than or equal to the first parameter. If the result is less than or equal to the first parameter, the return value of the function is **TRUE**. Otherwise, the return value of the function is **FALSE**.

  Return type: Boolean

  Example:

```
gaussdb=# SELECT in_range_float4_int16(1.0::float4, 1.9::float4, 1::int16, true, true);
 in_range_float4_int16
-----------------------
 f
(1 row)
```

- in_range_float8_int8(float8, float8, int8, boolean, boolean)

  Description: Checks whether the first parameter is within the range of the second parameter plus or minus the third parameter.

  Parameters:

  - First parameter: It specifies the number to be checked against the given range.
  - The second parameter: It specifies the start value of the current range.
  - Third parameter: It specifies a range value, which must be a positive number.
  - Fourth parameter: It specifies whether the current operation is a subtraction or addition operation.
    - **TRUE**: The function compares the second parameter minus the third parameter with the first parameter.
    - **FALSE**: The function compares the second parameter plus the third parameter with the first parameter.
  - Fifth parameter: It compares the operation result of the second and third parameters with the first parameter.
    - **TRUE**: The function checks whether the result is greater than the first parameter. If the result is greater than or equal to the first parameter, the return value of the function is **TRUE**. Otherwise, the return value of the function is **FALSE**.
    - **FALSE**: The function checks whether the result is less than or equal to the first parameter. If the result is less than or equal to the first parameter, the return value of the function is **TRUE**. Otherwise, the return value of the function is **FALSE**.

  Return type: Boolean

  Example:

```
gaussdb=# SELECT in_range_float8_int8(1.0::float8, 1.9::float8, 1::int8, true, true);
 in_range_float8_int8
----------------------
 f
(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- in_range_float4_int8(float4, float4, int8, boolean, boolean)

  Description: Checks whether the first parameter is within the range of the second parameter plus or minus the third parameter.

  Parameters:

  - First parameter: It specifies the number to be checked against the given range.
  - The second parameter: It specifies the start value of the current range.
  - Third parameter: It specifies a range value, which must be a positive number.
  - Fourth parameter: It specifies whether the current operation is a subtraction or addition operation.
    - **TRUE**: The function compares the second parameter minus the third parameter with the first parameter.
    - **FALSE**: The function compares the second parameter plus the third parameter with the first parameter.
  - Fifth parameter: It compares the operation result of the second and third parameters with the first parameter.
    - **TRUE**: The function checks whether the result is greater than the first parameter. If the result is greater than or equal to the first parameter, the return value of the function is **TRUE**. Otherwise, the return value of the function is **FALSE**.
    - **FALSE**: The function checks whether the result is less than or equal to the first parameter. If the result is less than or equal to the first parameter, the return value of the function is **TRUE**. Otherwise, the return value of the function is **FALSE**.

  Return type: Boolean

  Example:

  ```
  gaussdb=# SELECT in_range_float4_int8(1.0::float4, 1.9::float4, 1::int8, true, true);
   in_range_float4_int8
  ----------------------
   f
  (1 row)
  ```

- in_range_float8_int4(float8, float8, int4, boolean, boolean)

  Description: Checks whether the first parameter is within the range of the second parameter plus or minus the third parameter.

  Parameters:

  - First parameter: It specifies the number to be checked against the given range.
  - The second parameter: It specifies the start value of the current range.
  - Third parameter: It specifies a range value, which must be a positive number.
  - Fourth parameter: It specifies whether the current operation is a subtraction or addition operation.
    - **TRUE**: The function compares the second parameter minus the third parameter with the first parameter.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

        - **FALSE**: The function compares the second parameter plus the third parameter with the first parameter.
    - Fifth parameter: It compares the operation result of the second and third parameters with the first parameter.
        - **TRUE**: The function checks whether the result is greater than the first parameter. If the result is greater than or equal to the first parameter, the return value of the function is **TRUE**. Otherwise, the return value of the function is **FALSE**.
        - **FALSE**: The function checks whether the result is less than or equal to the first parameter. If the result is less than or equal to the first parameter, the return value of the function is **TRUE**. Otherwise, the return value of the function is **FALSE**.

    Return type: Boolean

    Example:

    ```
    gaussdb=# SELECT in_range_float8_int4(1.0::float8, 1.9::float8, 1::int4, true, true);
     in_range_float8_int4
    ----------------------
     f
    (1 row)
    ```

- in_range_float4_int4(float4, float4, int4, boolean, boolean)

    Description: Checks whether the first parameter is within the range of the second parameter plus or minus the third parameter.

    Parameters:

    - First parameter: It specifies the number to be checked against the given range.
    - The second parameter: It specifies the start value of the current range.
    - Third parameter: It specifies a range value, which must be a positive number.
    - Fourth parameter: It specifies whether the current operation is a subtraction or addition operation.
        - **TRUE**: The function compares the second parameter minus the third parameter with the first parameter.
        - **FALSE**: The function compares the second parameter plus the third parameter with the first parameter.
    - Fifth parameter: It compares the operation result of the second and third parameters with the first parameter.
        - **TRUE**: The function checks whether the result is greater than the first parameter. If the result is greater than or equal to the first parameter, the return value of the function is **TRUE**. Otherwise, the return value of the function is **FALSE**.
        - **FALSE**: The function checks whether the result is less than or equal to the first parameter. If the result is less than or equal to the first parameter, the return value of the function is **TRUE**. Otherwise, the return value of the function is **FALSE**.

    Return type: Boolean

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Example:

```
gaussdb=# SELECT in_range_float4_int4(1.0::float4, 1.9::float4, 1::int4, true, true);
 in_range_float4_int4
----------------------
 f
(1 row)
```

- in_range_float8_int2(float8, float8, int2, boolean, boolean)

  Description: Checks whether the first parameter is within the range of the second parameter plus or minus the third parameter.

  Parameters:

  - First parameter: It specifies the number to be checked against the given range.
  - The second parameter: It specifies the start value of the current range.
  - Third parameter: It specifies a range value, which must be a positive number.
  - Fourth parameter: It specifies whether the current operation is a subtraction or addition operation.
    - **TRUE**: The function compares the second parameter minus the third parameter with the first parameter.
    - **FALSE**: The function compares the second parameter plus the third parameter with the first parameter.
  - Fifth parameter: It compares the operation result of the second and third parameters with the first parameter.
    - **TRUE**: The function checks whether the result is greater than the first parameter. If the result is greater than or equal to the first parameter, the return value of the function is **TRUE**. Otherwise, the return value of the function is **FALSE**.
    - **FALSE**: The function checks whether the result is less than or equal to the first parameter. If the result is less than or equal to the first parameter, the return value of the function is **TRUE**. Otherwise, the return value of the function is **FALSE**.

  Return type: Boolean

  Example:

  ```
  gaussdb=# SELECT in_range_float8_int2(1.0::float8, 1.9::float8, 1::int2, true, true);
   in_range_float8_int2
  ----------------------
   f
  (1 row)
  ```

- in_range_float4_int2(float4, int2, int2, boolean, boolean)

  Description: Checks whether the first parameter is within the range of the second parameter plus or minus the third parameter.

  Parameters:

  - First parameter: It specifies the number to be checked against the given range.
  - The second parameter: It specifies the start value of the current range.
  - Third parameter: It specifies a range value, which must be a positive number.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

  - Fourth parameter: It specifies whether the current operation is a subtraction or addition operation.
    - **TRUE**: The function compares the second parameter minus the third parameter with the first parameter.
    - **FALSE**: The function compares the second parameter plus the third parameter with the first parameter.
  - Fifth parameter: It compares the operation result of the second and third parameters with the first parameter.
    - **TRUE**: The function checks whether the result is greater than the first parameter. If the result is greater than or equal to the first parameter, the return value of the function is **TRUE**. Otherwise, the return value of the function is **FALSE**.
    - **FALSE**: The function checks whether the result is less than or equal to the first parameter. If the result is less than or equal to the first parameter, the return value of the function is **TRUE**. Otherwise, the return value of the function is **FALSE**.

  Return type: Boolean

  Example:

```
gaussdb=# SELECT in_range_float4_int2(1.0::float4, 1.9::float4, 1::int2, true, true);
 in_range_float4_int2
----------------------
 f
(1 row)
```

- in_range_float8_int1(float8, float8, int1, boolean, boolean)

  Description: Checks whether the first parameter is within the range of the second parameter plus or minus the third parameter.

  Parameters:

  - First parameter: It specifies the number to be checked against the given range.
  - The second parameter: It specifies the start value of the current range.
  - Third parameter: It specifies a range value, which must be a positive number.
  - Fourth parameter: It specifies whether the current operation is a subtraction or addition operation.
    - **TRUE**: The function compares the second parameter minus the third parameter with the first parameter.
    - **FALSE**: The function compares the second parameter plus the third parameter with the first parameter.
  - Fifth parameter: It compares the operation result of the second and third parameters with the first parameter.
    - **TRUE**: The function checks whether the result is greater than the first parameter. If the result is greater than or equal to the first parameter, the return value of the function is **TRUE**. Otherwise, the return value of the function is **FALSE**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

    - **FALSE**: The function checks whether the result is less than or equal to the first parameter. If the result is less than or equal to the first parameter, the return value of the function is **TRUE**. Otherwise, the return value of the function is **FALSE**.

  Return type: Boolean

  Example:

```
gaussdb=# SELECT in_range_float8_int1(1.0::float8, 1.9::float8, 1::int1, true, true);
 in_range_float8_int1
----------------------
 f
(1 row)
```

- in_range_float4_int1(float4, float4, int1, boolean, boolean)

  Description: Checks whether the first parameter is within the range of the second parameter plus or minus the third parameter.

  Parameters:

  – First parameter: It specifies the number to be checked against the given range.
  – The second parameter: It specifies the start value of the current range.
  – Third parameter: It specifies a range value, which must be a positive number.
  – Fourth parameter: It specifies whether the current operation is a subtraction or addition operation.
    - **TRUE**: The function compares the second parameter minus the third parameter with the first parameter.
    - **FALSE**: The function compares the second parameter plus the third parameter with the first parameter.
  – Fifth parameter: It compares the operation result of the second and third parameters with the first parameter.
    - **TRUE**: The function checks whether the result is greater than the first parameter. If the result is greater than or equal to the first parameter, the return value of the function is **TRUE**. Otherwise, the return value of the function is **FALSE**.
    - **FALSE**: The function checks whether the result is less than or equal to the first parameter. If the result is less than or equal to the first parameter, the return value of the function is **TRUE**. Otherwise, the return value of the function is **FALSE**.

  Return type: Boolean

  Example:

```
gaussdb=# SELECT in_range_float4_int1(1.0::float4, 1.9::float4, 1::int1, true, true);
 in_range_float4_int1
----------------------
 f
(1 row)
```

- in_range_float8_float4(float8, float8, float4, boolean, boolean)

  Description: Checks whether the first parameter is within the range of the second parameter plus or minus the third parameter.

  Parameters:

  - First parameter: It specifies the number to be checked against the given range.
  - The second parameter: It specifies the start value of the current range.
  - Third parameter: It specifies a range value, which must be a positive number.
  - Fourth parameter: It specifies whether the current operation is a subtraction or addition operation.
    - **TRUE**: The function compares the second parameter minus the third parameter with the first parameter.
    - **FALSE**: The function compares the second parameter plus the third parameter with the first parameter.
  - Fifth parameter: It compares the operation result of the second and third parameters with the first parameter.
    - **TRUE**: The function checks whether the result is greater than the first parameter. If the result is greater than or equal to the first parameter, the return value of the function is **TRUE**. Otherwise, the return value of the function is **FALSE**.
    - **FALSE**: The function checks whether the result is less than or equal to the first parameter. If the result is less than or equal to the first parameter, the return value of the function is **TRUE**. Otherwise, the return value of the function is **FALSE**.

  Return type: Boolean

  Example:

```
gaussdb=# SELECT in_range_float8_float4(1.0::float8, 1.9::float8, 1.0::float4, true, true);
 in_range_float8_float4
------------------------
 f
(1 row)
```

- in_range_float4_float4(float4, float4, float4, boolean, boolean)

  Description: Checks whether the first parameter is within the range of the second parameter plus or minus the third parameter.

  Parameters:

  - First parameter: It specifies the number to be checked against the given range.
  - The second parameter: It specifies the start value of the current range.
  - Third parameter: It specifies a range value, which must be a positive number.
  - Fourth parameter: It specifies whether the current operation is a subtraction or addition operation.
    - **TRUE**: The function compares the second parameter minus the third parameter with the first parameter.
    - **FALSE**: The function compares the second parameter plus the third parameter with the first parameter.
  - Fifth parameter: It compares the operation result of the second and third parameters with the first parameter.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

    - **TRUE**: The function checks whether the result is greater than the first parameter. If the result is greater than or equal to the first parameter, the return value of the function is **TRUE**. Otherwise, the return value of the function is **FALSE**.
    - **FALSE**: The function checks whether the result is less than or equal to the first parameter. If the result is less than or equal to the first parameter, the return value of the function is **TRUE**. Otherwise, the return value of the function is **FALSE**.

  Return type: Boolean

  Example:

```
gaussdb=# SELECT in_range_float4_float4(1.0::float4, 1.9::float4, 1.0::float4, true, true);
 in_range_float4_float4
------------------------
 f
(1 row)
```

- in_range_float8_numeric(float8, float8, numeric, boolean, boolean)

  Description: Checks whether the first parameter is within the range of the second parameter plus or minus the third parameter.

  Parameters:

  - First parameter: It specifies the number to be checked against the given range.
  - The second parameter: It specifies the start value of the current range.
  - Third parameter: It specifies a range value, which must be a positive number.
  - Fourth parameter: It specifies whether the current operation is a subtraction or addition operation.
    - **TRUE**: The function compares the second parameter minus the third parameter with the first parameter.
    - **FALSE**: The function compares the second parameter plus the third parameter with the first parameter.
  - Fifth parameter: It compares the operation result of the second and third parameters with the first parameter.
    - **TRUE**: The function checks whether the result is greater than the first parameter. If the result is greater than or equal to the first parameter, the return value of the function is **TRUE**. Otherwise, the return value of the function is **FALSE**.
    - **FALSE**: The function checks whether the result is less than or equal to the first parameter. If the result is less than or equal to the first parameter, the return value of the function is **TRUE**. Otherwise, the return value of the function is **FALSE**.

  Return type: Boolean

  Example:

```
gaussdb=# SELECT in_range_float8_numeric(1.0::float8, 1.9::float8, 1.0::numeric(10,4), true, true);
 in_range_float8_numeric
-------------------------
 f
(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- in_range_float4_numeric(float4, float4, numeric, boolean, boolean)

  Description: Checks whether the first parameter is within the range of the second parameter plus or minus the third parameter.

  Parameters:

  - First parameter: It specifies the number to be checked against the given range.
  - The second parameter: It specifies the start value of the current range.
  - Third parameter: It specifies a range value, which must be a positive number.
  - Fourth parameter: It specifies whether the current operation is a subtraction or addition operation.
    - **TRUE**: The function compares the second parameter minus the third parameter with the first parameter.
    - **FALSE**: The function compares the second parameter plus the third parameter with the first parameter.
  - Fifth parameter: It compares the operation result of the second and third parameters with the first parameter.
    - **TRUE**: The function checks whether the result is greater than the first parameter. If the result is greater than or equal to the first parameter, the return value of the function is **TRUE**. Otherwise, the return value of the function is **FALSE**.
    - **FALSE**: The function checks whether the result is less than or equal to the first parameter. If the result is less than or equal to the first parameter, the return value of the function is **TRUE**. Otherwise, the return value of the function is **FALSE**.

  Return type: Boolean

  Example:

  ```
  gaussdb=# SELECT in_range_float4_numeric(1.0::float4, 1.9::float4, 1.0::numeric(10,4), true, true);
   in_range_float4_numeric
  -------------------------
   f
  (1 row)
  ```

- in_range_numeric_int16(numeric, numeric, int16, boolean, boolean)

  Description: Checks whether the first parameter is within the range of the second parameter plus or minus the third parameter.

  Parameters:

  - First parameter: It specifies the number to be checked against the given range.
  - The second parameter: It specifies the start value of the current range.
  - Third parameter: It specifies a range value, which must be a positive number.
  - Fourth parameter: It specifies whether the current operation is a subtraction or addition operation.
    - **TRUE**: The function compares the second parameter minus the third parameter with the first parameter.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

        - **FALSE**: The function compares the second parameter plus the third parameter with the first parameter.
    - Fifth parameter: It compares the operation result of the second and third parameters with the first parameter.
        - **TRUE**: The function checks whether the result is greater than the first parameter. If the result is greater than or equal to the first parameter, the return value of the function is **TRUE**. Otherwise, the return value of the function is **FALSE**.
        - **FALSE**: The function checks whether the result is less than or equal to the first parameter. If the result is less than or equal to the first parameter, the return value of the function is **TRUE**. Otherwise, the return value of the function is **FALSE**.

    Return type: Boolean

    Example:

    ```
    gaussdb=# SELECT in_range_numeric_int16(1.0::numeric(10,4), 1.9::numeric(10,4), 1.0::int16, true, true);
     in_range_numeric_int16
    ------------------------
     f
    (1 row)
    ```

- in_range_numeric_int8(numeric, numeric, int8, boolean, boolean)

    Description: Checks whether the first parameter is within the range of the second parameter plus or minus the third parameter.

    Parameters:

    - First parameter: It specifies the number to be checked against the given range.
    - The second parameter: It specifies the start value of the current range.
    - Third parameter: It specifies a range value, which must be a positive number.
    - Fourth parameter: It specifies whether the current operation is a subtraction or addition operation.
        - **TRUE**: The function compares the second parameter minus the third parameter with the first parameter.
        - **FALSE**: The function compares the second parameter plus the third parameter with the first parameter.
    - Fifth parameter: It compares the operation result of the second and third parameters with the first parameter.
        - **TRUE**: The function checks whether the result is greater than the first parameter. If the result is greater than or equal to the first parameter, the return value of the function is **TRUE**. Otherwise, the return value of the function is **FALSE**.
        - **FALSE**: The function checks whether the result is less than or equal to the first parameter. If the result is less than or equal to the first parameter, the return value of the function is **TRUE**. Otherwise, the return value of the function is **FALSE**.

    Return type: Boolean

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Example:

```
gaussdb=# SELECT in_range_numeric_int8(1.0::numeric(10,4), 1.9::numeric(10,4), 1.0::int8, true, true);
 in_range_numeric_int8
-----------------------
 f
(1 row)
```

- in_range_numeric_int4(numeric, numeric, int4, boolean, boolean)

  Description: Checks whether the first parameter is within the range of the second parameter plus or minus the third parameter.

  Parameters:

  - First parameter: It specifies the number to be checked against the given range.
  - The second parameter: It specifies the start value of the current range.
  - Third parameter: It specifies a range value, which must be a positive number.
  - Fourth parameter: It specifies whether the current operation is a subtraction or addition operation.
    - **TRUE**: The function compares the second parameter minus the third parameter with the first parameter.
    - **FALSE**: The function compares the second parameter plus the third parameter with the first parameter.
  - Fifth parameter: It compares the operation result of the second and third parameters with the first parameter.
    - **TRUE**: The function checks whether the result is greater than the first parameter. If the result is greater than or equal to the first parameter, the return value of the function is **TRUE**. Otherwise, the return value of the function is **FALSE**.
    - **FALSE**: The function checks whether the result is less than or equal to the first parameter. If the result is less than or equal to the first parameter, the return value of the function is **TRUE**. Otherwise, the return value of the function is **FALSE**.

  Return type: Boolean

  Example:

  ```
  gaussdb=# SELECT in_range_numeric_int4(1.0::numeric(10,4), 1.9::numeric(10,4), 1.0::int4, true, true);
   in_range_numeric_int4
  -----------------------
   f
  (1 row)
  ```

- in_range_numeric_int1(numeric, numeric, int1, boolean, boolean)

  Description: Checks whether the first parameter is within the range of the second parameter plus or minus the third parameter.

  Parameters:

  - First parameter: It specifies the number to be checked against the given range.
  - The second parameter: It specifies the start value of the current range.
  - Third parameter: It specifies a range value, which must be a positive number.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

  - Fourth parameter: It specifies whether the current operation is a subtraction or addition operation.
    - **TRUE**: The function compares the second parameter minus the third parameter with the first parameter.
    - **FALSE**: The function compares the second parameter plus the third parameter with the first parameter.
  - Fifth parameter: It compares the operation result of the second and third parameters with the first parameter.
    - **TRUE**: The function checks whether the result is greater than the first parameter. If the result is greater than or equal to the first parameter, the return value of the function is **TRUE**. Otherwise, the return value of the function is **FALSE**.
    - **FALSE**: The function checks whether the result is less than or equal to the first parameter. If the result is less than or equal to the first parameter, the return value of the function is **TRUE**. Otherwise, the return value of the function is **FALSE**.

  Return type: Boolean

  Example:

```
gaussdb=# SELECT in_range_numeric_int1(1.0::numeric(10,4), 1.9::numeric(10,4), 1.0::int1, true, true);
 in_range_numeric_int1
-----------------------
 f
(1 row)
```

- in_range_int8_int8(int8, int8, int8, boolean, boolean)

  Description: Checks whether the first parameter is within the range of the second parameter plus or minus the third parameter.

  Parameters:

  - First parameter: It specifies the number to be checked against the given range.
  - The second parameter: It specifies the start value of the current range.
  - Third parameter: It specifies a range value, which must be a positive number.
  - Fourth parameter: It specifies whether the current operation is a subtraction or addition operation.
    - **TRUE**: The function compares the second parameter minus the third parameter with the first parameter.
    - **FALSE**: The function compares the second parameter plus the third parameter with the first parameter.
  - Fifth parameter: It compares the operation result of the second and third parameters with the first parameter.
    - **TRUE**: The function checks whether the result is greater than the first parameter. If the result is greater than or equal to the first parameter, the return value of the function is **TRUE**. Otherwise, the return value of the function is **FALSE**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

        - **FALSE**: The function checks whether the result is less than or equal to the first parameter. If the result is less than or equal to the first parameter, the return value of the function is **TRUE**. Otherwise, the return value of the function is **FALSE**.

    Return type: Boolean

    Example:

```
gaussdb=# SELECT in_range_int8_int8(1::int8, 1::int8, 1::int8, true, true);
 in_range_int8_int8
--------------------
 f
(1 row)
```

- in_range_int4_int8(int4, int4, int8, boolean, boolean)

    Description: Checks whether the first parameter is within the range of the second parameter plus or minus the third parameter.

    Parameters:

    - First parameter: It specifies the number to be checked against the given range.
    - The second parameter: It specifies the start value of the current range.
    - Third parameter: It specifies a range value, which must be a positive number.
    - Fourth parameter: It specifies whether the current operation is a subtraction or addition operation.
        - **TRUE**: The function compares the second parameter minus the third parameter with the first parameter.
        - **FALSE**: The function compares the second parameter plus the third parameter with the first parameter.
    - Fifth parameter: It compares the operation result of the second and third parameters with the first parameter.
        - **TRUE**: The function checks whether the result is greater than the first parameter. If the result is greater than or equal to the first parameter, the return value of the function is **TRUE**. Otherwise, the return value of the function is **FALSE**.
        - **FALSE**: The function checks whether the result is less than or equal to the first parameter. If the result is less than or equal to the first parameter, the return value of the function is **TRUE**. Otherwise, the return value of the function is **FALSE**.

    Return type: Boolean

    Example:

```
gaussdb=# SELECT in_range_int4_int8(1::int4, 1::int4, 1::int8, true, true);
 in_range_int4_int8
--------------------
 f
(1 row)
```

- in_range_int2_int8(int2, int2, int8, boolean, boolean)

    Description: Checks whether the first parameter is within the range of the second parameter plus or minus the third parameter.

    Parameters:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

  - First parameter: It specifies the number to be checked against the given range.
  - The second parameter: It specifies the start value of the current range.
  - Third parameter: It specifies a range value, which must be a positive number.
  - Fourth parameter: It specifies whether the current operation is a subtraction or addition operation.
    - **TRUE**: The function compares the second parameter minus the third parameter with the first parameter.
    - **FALSE**: The function compares the second parameter plus the third parameter with the first parameter.
  - Fifth parameter: It compares the operation result of the second and third parameters with the first parameter.
    - **TRUE**: The function checks whether the result is greater than the first parameter. If the result is greater than or equal to the first parameter, the return value of the function is **TRUE**. Otherwise, the return value of the function is **FALSE**.
    - **FALSE**: The function checks whether the result is less than or equal to the first parameter. If the result is less than or equal to the first parameter, the return value of the function is **TRUE**. Otherwise, the return value of the function is **FALSE**.

  Return type: Boolean

  Example:

```
gaussdb=# SELECT in_range_int2_int8(1::int2, 1::int2, 1::int8, true, true);
 in_range_int2_int8
--------------------
 f
(1 row)
```

- in_range_int1_int8(int1, int1, int8, boolean, boolean)

  Description: Checks whether the first parameter is within the range of the second parameter plus or minus the third parameter.

  Parameters:

  - First parameter: It specifies the number to be checked against the given range.
  - The second parameter: It specifies the start value of the current range.
  - Third parameter: It specifies a range value, which must be a positive number.
  - Fourth parameter: It specifies whether the current operation is a subtraction or addition operation.
    - **TRUE**: The function compares the second parameter minus the third parameter with the first parameter.
    - **FALSE**: The function compares the second parameter plus the third parameter with the first parameter.
  - Fifth parameter: It compares the operation result of the second and third parameters with the first parameter.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

    - **TRUE**: The function checks whether the result is greater than the first parameter. If the result is greater than or equal to the first parameter, the return value of the function is **TRUE**. Otherwise, the return value of the function is **FALSE**.
    - **FALSE**: The function checks whether the result is less than or equal to the first parameter. If the result is less than or equal to the first parameter, the return value of the function is **TRUE**. Otherwise, the return value of the function is **FALSE**.

  Return type: Boolean

  Example:

```
gaussdb=# SELECT in_range_int1_int8(1::int1, 1::int1, 1::int8, true, true);
 in_range_int1_int8
--------------------
 f
(1 row)
```

- in_range_int8_int4(int8, int8, int4, boolean, boolean)

  Description: Checks whether the first parameter is within the range of the second parameter plus or minus the third parameter.

  Parameters:

  – First parameter: It specifies the number to be checked against the given range.
  – The second parameter: It specifies the start value of the current range.
  – Third parameter: It specifies a range value, which must be a positive number.
  – Fourth parameter: It specifies whether the current operation is a subtraction or addition operation.
    - **TRUE**: The function compares the second parameter minus the third parameter with the first parameter.
    - **FALSE**: The function compares the second parameter plus the third parameter with the first parameter.
  – Fifth parameter: It compares the operation result of the second and third parameters with the first parameter.
    - **TRUE**: The function checks whether the result is greater than the first parameter. If the result is greater than or equal to the first parameter, the return value of the function is **TRUE**. Otherwise, the return value of the function is **FALSE**.
    - **FALSE**: The function checks whether the result is less than or equal to the first parameter. If the result is less than or equal to the first parameter, the return value of the function is **TRUE**. Otherwise, the return value of the function is **FALSE**.

  Return type: Boolean

  Example:

```
gaussdb=# SELECT in_range_int8_int4(1::int8, 1::int8, 1::int4, true, true);
 in_range_int8_int4
--------------------
 f
(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- in_range_int4_int4(int4, int4, int4, boolean, boolean)

  Description: Checks whether the first parameter is within the range of the second parameter plus or minus the third parameter.

  Parameters:

  - First parameter: It specifies the number to be checked against the given range.
  - The second parameter: It specifies the start value of the current range.
  - Third parameter: It specifies a range value, which must be a positive number.
  - Fourth parameter: It specifies whether the current operation is a subtraction or addition operation.
    - **TRUE**: The function compares the second parameter minus the third parameter with the first parameter.
    - **FALSE**: The function compares the second parameter plus the third parameter with the first parameter.
  - Fifth parameter: It compares the operation result of the second and third parameters with the first parameter.
    - **TRUE**: The function checks whether the result is greater than the first parameter. If the result is greater than or equal to the first parameter, the return value of the function is **TRUE**. Otherwise, the return value of the function is **FALSE**.
    - **FALSE**: The function checks whether the result is less than or equal to the first parameter. If the result is less than or equal to the first parameter, the return value of the function is **TRUE**. Otherwise, the return value of the function is **FALSE**.

  Return type: Boolean

  Example:

  ```
  gaussdb=# SELECT in_range_int4_int4(1::int4, 1::int4, 1::int4, true, true);
   in_range_int4_int4
  --------------------
   f
  (1 row)
  ```

- in_range_int2_int4(int2, int2, int4, boolean, boolean)

  Description: Checks whether the first parameter is within the range of the second parameter plus or minus the third parameter.

  Parameters:

  - First parameter: It specifies the number to be checked against the given range.
  - The second parameter: It specifies the start value of the current range.
  - Third parameter: It specifies a range value, which must be a positive number.
  - Fourth parameter: It specifies whether the current operation is a subtraction or addition operation.
    - **TRUE**: The function compares the second parameter minus the third parameter with the first parameter.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

    - **FALSE**: The function compares the second parameter plus the third parameter with the first parameter.
  - Fifth parameter: It compares the operation result of the second and third parameters with the first parameter.
    - **TRUE**: The function checks whether the result is greater than the first parameter. If the result is greater than or equal to the first parameter, the return value of the function is **TRUE**. Otherwise, the return value of the function is **FALSE**.
    - **FALSE**: The function checks whether the result is less than or equal to the first parameter. If the result is less than or equal to the first parameter, the return value of the function is **TRUE**. Otherwise, the return value of the function is **FALSE**.

  Return type: Boolean

  Example:

```
gaussdb=# SELECT in_range_int2_int4(1::int2, 1::int2, 1::int4, true, true);
 in_range_int2_int4
--------------------
 f
(1 row)
```

- in_range_int1_int4(int1, int1, int4, boolean, boolean)

  Description: Checks whether the first parameter is within the range of the second parameter plus or minus the third parameter.

  Parameters:

  - First parameter: It specifies the number to be checked against the given range.
  - The second parameter: It specifies the start value of the current range.
  - Third parameter: It specifies a range value, which must be a positive number.
  - Fourth parameter: It specifies whether the current operation is a subtraction or addition operation.
    - **TRUE**: The function compares the second parameter minus the third parameter with the first parameter.
    - **FALSE**: The function compares the second parameter plus the third parameter with the first parameter.
  - Fifth parameter: It compares the operation result of the second and third parameters with the first parameter.
    - **TRUE**: The function checks whether the result is greater than the first parameter. If the result is greater than or equal to the first parameter, the return value of the function is **TRUE**. Otherwise, the return value of the function is **FALSE**.
    - **FALSE**: The function checks whether the result is less than or equal to the first parameter. If the result is less than or equal to the first parameter, the return value of the function is **TRUE**. Otherwise, the return value of the function is **FALSE**.

  Return type: Boolean

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Example:

```
gaussdb=# SELECT in_range_int1_int4(1::int1, 1::int1, 1::int4, true, true);
 in_range_int1_int4
--------------------
 f
(1 row)
```

- in_range_int8_int2(int8, int8, int2, boolean, boolean)

  Description: Checks whether the first parameter is within the range of the second parameter plus or minus the third parameter.

  Parameters:

  – First parameter: It specifies the number to be checked against the given range.

  – The second parameter: It specifies the start value of the current range.

  – Third parameter: It specifies a range value, which must be a positive number.

  – Fourth parameter: It specifies whether the current operation is a subtraction or addition operation.

    ▪ **TRUE**: The function compares the second parameter minus the third parameter with the first parameter.

    ▪ **FALSE**: The function compares the second parameter plus the third parameter with the first parameter.

  – Fifth parameter: It compares the operation result of the second and third parameters with the first parameter.

    ▪ **TRUE**: The function checks whether the result is greater than the first parameter. If the result is greater than or equal to the first parameter, the return value of the function is **TRUE**. Otherwise, the return value of the function is **FALSE**.

    ▪ **FALSE**: The function checks whether the result is less than or equal to the first parameter. If the result is less than or equal to the first parameter, the return value of the function is **TRUE**. Otherwise, the return value of the function is **FALSE**.

  Return type: Boolean

  Example:

  ```
  gaussdb=# SELECT in_range_int8_int2(1::int8, 1::int8, 1::int2, true, true);
   in_range_int8_int2
  --------------------
   f
  (1 row)
  ```

- in_range_int4_int2(int4, int4, int2, boolean, boolean)

  Description: Checks whether the first parameter is within the range of the second parameter plus or minus the third parameter.

  Parameters:

  – First parameter: It specifies the number to be checked against the given range.

  – The second parameter: It specifies the start value of the current range.

  – Third parameter: It specifies a range value, which must be a positive number.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

  - Fourth parameter: It specifies whether the current operation is a subtraction or addition operation.
    - **TRUE**: The function compares the second parameter minus the third parameter with the first parameter.
    - **FALSE**: The function compares the second parameter plus the third parameter with the first parameter.
  - Fifth parameter: It compares the operation result of the second and third parameters with the first parameter.
    - **TRUE**: The function checks whether the result is greater than the first parameter. If the result is greater than or equal to the first parameter, the return value of the function is **TRUE**. Otherwise, the return value of the function is **FALSE**.
    - **FALSE**: The function checks whether the result is less than or equal to the first parameter. If the result is less than or equal to the first parameter, the return value of the function is **TRUE**. Otherwise, the return value of the function is **FALSE**.

  Return type: Boolean

  Example:

```
gaussdb=# SELECT in_range_int4_int2(1::int4, 1::int4, 1::int2, true, true);
 in_range_int4_int2
--------------------
 f
(1 row)
```

- in_range_int2_int2(int2, int2, int2, boolean, boolean)

  Description: Checks whether the first parameter is within the range of the second parameter plus or minus the third parameter.

  Parameters:

  - First parameter: It specifies the number to be checked against the given range.
  - The second parameter: It specifies the start value of the current range.
  - Third parameter: It specifies a range value, which must be a positive number.
  - Fourth parameter: It specifies whether the current operation is a subtraction or addition operation.
    - **TRUE**: The function compares the second parameter minus the third parameter with the first parameter.
    - **FALSE**: The function compares the second parameter plus the third parameter with the first parameter.
  - Fifth parameter: It compares the operation result of the second and third parameters with the first parameter.
    - **TRUE**: The function checks whether the result is greater than the first parameter. If the result is greater than or equal to the first parameter, the return value of the function is **TRUE**. Otherwise, the return value of the function is **FALSE**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

    - **FALSE**: The function checks whether the result is less than or equal to the first parameter. If the result is less than or equal to the first parameter, the return value of the function is **TRUE**. Otherwise, the return value of the function is **FALSE**.

  Return type: Boolean

  Example:

```
gaussdb=# SELECT in_range_int2_int2(1::int2, 1::int2, 1::int2, true, true);
 in_range_int2_int2
--------------------
 f
(1 row)
```

- in_range_int1_int2(int1, int1, int2, boolean, boolean)

  Description: Checks whether the first parameter is within the range of the second parameter plus or minus the third parameter.

  Parameters:

  - First parameter: It specifies the number to be checked against the given range.
  - The second parameter: It specifies the start value of the current range.
  - Third parameter: It specifies a range value, which must be a positive number.
  - Fourth parameter: It specifies whether the current operation is a subtraction or addition operation.
    - **TRUE**: The function compares the second parameter minus the third parameter with the first parameter.
    - **FALSE**: The function compares the second parameter plus the third parameter with the first parameter.
  - Fifth parameter: It compares the operation result of the second and third parameters with the first parameter.
    - **TRUE**: The function checks whether the result is greater than the first parameter. If the result is greater than or equal to the first parameter, the return value of the function is **TRUE**. Otherwise, the return value of the function is **FALSE**.
    - **FALSE**: The function checks whether the result is less than or equal to the first parameter. If the result is less than or equal to the first parameter, the return value of the function is **TRUE**. Otherwise, the return value of the function is **FALSE**.

  Return type: Boolean

  Example:

```
gaussdb=# SELECT in_range_int1_int2(1::int1, 1::int1, 1::int2, true, true);
 in_range_int1_int2
--------------------
 f
(1 row)
```

- in_range_int8_int1(int8, int8, int1, boolean, boolean)

  Description: Checks whether the first parameter is within the range of the second parameter plus or minus the third parameter.

  Parameters:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

  - First parameter: It specifies the number to be checked against the given range.
  - The second parameter: It specifies the start value of the current range.
  - Third parameter: It specifies a range value, which must be a positive number.
  - Fourth parameter: It specifies whether the current operation is a subtraction or addition operation.
    - **TRUE**: The function compares the second parameter minus the third parameter with the first parameter.
    - **FALSE**: The function compares the second parameter plus the third parameter with the first parameter.
  - Fifth parameter: It compares the operation result of the second and third parameters with the first parameter.
    - **TRUE**: The function checks whether the result is greater than the first parameter. If the result is greater than or equal to the first parameter, the return value of the function is **TRUE**. Otherwise, the return value of the function is **FALSE**.
    - **FALSE**: The function checks whether the result is less than or equal to the first parameter. If the result is less than or equal to the first parameter, the return value of the function is **TRUE**. Otherwise, the return value of the function is **FALSE**.

  Return type: Boolean

  Example:

```
gaussdb=# SELECT in_range_int8_int1(1::int8, 1::int8, 1::int1, true, true);
 in_range_int8_int1
--------------------
 f
(1 row)
```

- in_range_int4_int1(int4, int4, int1, boolean, boolean)

  Description: Checks whether the first parameter is within the range of the second parameter plus or minus the third parameter.

  Parameters:

  - First parameter: It specifies the number to be checked against the given range.
  - The second parameter: It specifies the start value of the current range.
  - Third parameter: It specifies a range value, which must be a positive number.
  - Fourth parameter: It specifies whether the current operation is a subtraction or addition operation.
    - **TRUE**: The function compares the second parameter minus the third parameter with the first parameter.
    - **FALSE**: The function compares the second parameter plus the third parameter with the first parameter.
  - Fifth parameter: It compares the operation result of the second and third parameters with the first parameter.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

  - **TRUE**: The function checks whether the result is greater than the first parameter. If the result is greater than or equal to the first parameter, the return value of the function is **TRUE**. Otherwise, the return value of the function is **FALSE**.
  - **FALSE**: The function checks whether the result is less than or equal to the first parameter. If the result is less than or equal to the first parameter, the return value of the function is **TRUE**. Otherwise, the return value of the function is **FALSE**.

Return type: Boolean

Example:

```
gaussdb=# SELECT in_range_int4_int1(1::int4, 1::int4, 1::int1, true, true);
 in_range_int4_int1
--------------------
 f
(1 row)
```

- in_range_int2_int1(int2, int2, int1, boolean, boolean)

  Description: Checks whether the first parameter is within the range of the second parameter plus or minus the third parameter.

  Parameters:

  – First parameter: It specifies the number to be checked against the given range.
  – The second parameter: It specifies the start value of the current range.
  – Third parameter: It specifies a range value, which must be a positive number.
  – Fourth parameter: It specifies whether the current operation is a subtraction or addition operation.
    - **TRUE**: The function compares the second parameter minus the third parameter with the first parameter.
    - **FALSE**: The function compares the second parameter plus the third parameter with the first parameter.
  – Fifth parameter: It compares the operation result of the second and third parameters with the first parameter.
    - **TRUE**: The function checks whether the result is greater than the first parameter. If the result is greater than or equal to the first parameter, the return value of the function is **TRUE**. Otherwise, the return value of the function is **FALSE**.
    - **FALSE**: The function checks whether the result is less than or equal to the first parameter. If the result is less than or equal to the first parameter, the return value of the function is **TRUE**. Otherwise, the return value of the function is **FALSE**.

  Return type: Boolean

  Example:

```
gaussdb=# SELECT in_range_int2_int1(1::int2, 1::int2, 1::int1, true, true);
 in_range_int2_int1
--------------------
 f
(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- in_range_int1_int1(int1, int1, int1, boolean, boolean)

  Description: Checks whether the first parameter is within the range of the second parameter plus or minus the third parameter.

  Parameters:

  - First parameter: It specifies the number to be checked against the given range.
  - The second parameter: It specifies the start value of the current range.
  - Third parameter: It specifies a range value, which must be a positive number.
  - Fourth parameter: It specifies whether the current operation is a subtraction or addition operation.
    - **TRUE**: The function compares the second parameter minus the third parameter with the first parameter.
    - **FALSE**: The function compares the second parameter plus the third parameter with the first parameter.
  - Fifth parameter: It compares the operation result of the second and third parameters with the first parameter.
    - **TRUE**: The function checks whether the result is greater than the first parameter. If the result is greater than or equal to the first parameter, the return value of the function is **TRUE**. Otherwise, the return value of the function is **FALSE**.
    - **FALSE**: The function checks whether the result is less than or equal to the first parameter. If the result is less than or equal to the first parameter, the return value of the function is **TRUE**. Otherwise, the return value of the function is **FALSE**.

  Return type: Boolean

  Example:

  ```
  gaussdb=# SELECT in_range_int1_int1(1::int1, 1::int1, 1::int1, true, true);
   in_range_int1_int1
  --------------------
   f
  (1 row)
  ```

- in_range_int8_float4(int8, int8, float4, boolean, boolean)

  Description: Checks whether the first parameter is within the range of the second parameter plus or minus the third parameter.

  Parameters:

  - First parameter: It specifies the number to be checked against the given range.
  - The second parameter: It specifies the start value of the current range.
  - Third parameter: It specifies a range value, which must be a positive number.
  - Fourth parameter: It specifies whether the current operation is a subtraction or addition operation.
    - **TRUE**: The function compares the second parameter minus the third parameter with the first parameter.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

        - **FALSE**: The function compares the second parameter plus the third parameter with the first parameter.
    - Fifth parameter: It compares the operation result of the second and third parameters with the first parameter.
        - **TRUE**: The function checks whether the result is greater than the first parameter. If the result is greater than or equal to the first parameter, the return value of the function is **TRUE**. Otherwise, the return value of the function is **FALSE**.
        - **FALSE**: The function checks whether the result is less than or equal to the first parameter. If the result is less than or equal to the first parameter, the return value of the function is **TRUE**. Otherwise, the return value of the function is **FALSE**.

    Return type: Boolean

    Example:

```
gaussdb=# SELECT in_range_int8_float4(1::int8, 2::int8, 0.9::float4, true, true);
 in_range_int8_float4
----------------------
 t
(1 row)
```

- in_range_int4_float4(int4, int4, float4, boolean, boolean)

  Description: Checks whether the first parameter is within the range of the second parameter plus or minus the third parameter.

  Parameters:

  - First parameter: It specifies the number to be checked against the given range.
  - The second parameter: It specifies the start value of the current range.
  - Third parameter: It specifies a range value, which must be a positive number.
  - Fourth parameter: It specifies whether the current operation is a subtraction or addition operation.
    - **TRUE**: The function compares the second parameter minus the third parameter with the first parameter.
    - **FALSE**: The function compares the second parameter plus the third parameter with the first parameter.
  - Fifth parameter: It compares the operation result of the second and third parameters with the first parameter.
    - **TRUE**: The function checks whether the result is greater than the first parameter. If the result is greater than or equal to the first parameter, the return value of the function is **TRUE**. Otherwise, the return value of the function is **FALSE**.
    - **FALSE**: The function checks whether the result is less than or equal to the first parameter. If the result is less than or equal to the first parameter, the return value of the function is **TRUE**. Otherwise, the return value of the function is **FALSE**.

  Return type: Boolean

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Example:

```
gaussdb=# SELECT in_range_int4_float4(1::int4, 2::int4, 0.9::float4, true, true);
 in_range_int4_float4
----------------------
 t
(1 row)
```

- in_range_int2_float4(int2, int2, float4, boolean, boolean)

  Description: Checks whether the first parameter is within the range of the second parameter plus or minus the third parameter.

  Parameters:

  - First parameter: It specifies the number to be checked against the given range.
  - The second parameter: It specifies the start value of the current range.
  - Third parameter: It specifies a range value, which must be a positive number.
  - Fourth parameter: It specifies whether the current operation is a subtraction or addition operation.
    - **TRUE**: The function compares the second parameter minus the third parameter with the first parameter.
    - **FALSE**: The function compares the second parameter plus the third parameter with the first parameter.
  - Fifth parameter: It compares the operation result of the second and third parameters with the first parameter.
    - **TRUE**: The function checks whether the result is greater than the first parameter. If the result is greater than or equal to the first parameter, the return value of the function is **TRUE**. Otherwise, the return value of the function is **FALSE**.
    - **FALSE**: The function checks whether the result is less than or equal to the first parameter. If the result is less than or equal to the first parameter, the return value of the function is **TRUE**. Otherwise, the return value of the function is **FALSE**.

  Return type: Boolean

  Example:

  ```
  gaussdb=# SELECT in_range_int2_float4(1::int2, 2::int2, 0.9::float4, true, true);
   in_range_int2_float4
  ----------------------
   t
  (1 row)
  ```

- in_range_int1_float4(int1, int1, float4, boolean, boolean)

  Description: Checks whether the first parameter is within the range of the second parameter plus or minus the third parameter.

  Parameters:

  - First parameter: It specifies the number to be checked against the given range.
  - The second parameter: It specifies the start value of the current range.
  - Third parameter: It specifies a range value, which must be a positive number.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

  - Fourth parameter: It specifies whether the current operation is a subtraction or addition operation.
    - **TRUE**: The function compares the second parameter minus the third parameter with the first parameter.
    - **FALSE**: The function compares the second parameter plus the third parameter with the first parameter.
  - Fifth parameter: It compares the operation result of the second and third parameters with the first parameter.
    - **TRUE**: The function checks whether the result is greater than the first parameter. If the result is greater than or equal to the first parameter, the return value of the function is **TRUE**. Otherwise, the return value of the function is **FALSE**.
    - **FALSE**: The function checks whether the result is less than or equal to the first parameter. If the result is less than or equal to the first parameter, the return value of the function is **TRUE**. Otherwise, the return value of the function is **FALSE**.

  Return type: Boolean

  Example:

```
gaussdb=# SELECT in_range_int1_float4(1::int1, 2::int1, 0.9::float4, true, true);
 in_range_int1_float4
----------------------
 t
(1 row)
```

1.6.18 Aggregate Functions

Aggregate Functions

- sum(expression)

  Description: Sum of expression across all input values

  Return type:

  Generally, same as the argument data type. In the following cases, type conversion occurs:

  - BIGINT for SMALLINT or INT arguments
  - NUMBER for BIGINT arguments
  - DOUBLE PRECISION for floating-point arguments

  Example:

```
gaussdb=# CREATE TABLE tab(a int);
CREATE TABLE
gaussdb=# INSERT INTO tab VALUES(1);
INSERT 0 1
gaussdb=# INSERT INTO tab VALUES(2);
INSERT 0 1
gaussdb=# SELECT sum(a) FROM tab;
 sum
-----
   3
(1 row)
gaussdb=# DROP TABLE tab;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- max(expression)

  Description: Specifies the maximum value of expression across all input values.

  Parameter type: any array, number, character string, date/time, or ROWID.

  Return type: same as the parameter type

  Example:

```
gaussdb=# CREATE TABLE max_t1(a int, b int);

gaussdb=# INSERT INTO max_t1 VALUES(1,2),(2,3),(3,4),(4,5);

gaussdb=# SELECT MAX(a) FROM max_t1;
 max
-----
   4
(1 row)

gaussdb=# DROP TABLE max_t1;
```

- min(expression)

  Description: Minimum value of expression across all input values

  Parameter type: any array, number, character string, date/time, or ROWID.

  Return type: same as the parameter type

  Example:

```
gaussdb=# CREATE TABLE min_t1(a int, b int);

gaussdb=# INSERT INTO min_t1 VALUES(1,2),(2,3),(3,4),(4,5);

gaussdb=# SELECT MIN(a) FROM min_t1;
 min
-----
   1
(1 row)

gaussdb=# DROP TABLE min_t1;
```

- avg(expression)

  Description: Average (arithmetic mean) of all input values

  Return type:

  – For any input parameter of the integer type or that can be implicitly converted to the integer type, the return type is NUMBER.
  – For any input parameter of the floating-point type or that can be implicitly converted to the floating-point type, the return type is DOUBLE PRECISION.
  – In other cases, the data type is the same as that of the input parameter.

  Example:

```
gaussdb=# CREATE TABLE avg_t1(a int, b int);

gaussdb=# INSERT INTO avg_t1 VALUES(1,2),(2,3),(3,4),(4,5);

gaussdb=# SELECT AVG(a) FROM avg_t1;
        avg
--------------------
 2.5000000000000000
(1 row)

gaussdb=# DROP TABLE avg_t1;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- count(expression)

  Description: Returns the number of input rows for which the value of expression is not null.

  Return type: bigint

  Operations on XML data are supported.

  Example:

```
gaussdb=# CREATE TABLE count_t1(a int, b int);

gaussdb=# INSERT INTO count_t1 VALUES (NULL,1),(1,2),(2,3),(3,4),(4,5);

gaussdb=# SELECT COUNT(a) FROM count_t1;
 count
-------
     4
(1 row)

gaussdb=# DROP TABLE count_t1;
```

- count(*)

  Description: Returns the number of input rows.

  Return type: bigint

  Operations on XML data are supported.

  Example:

```
gaussdb=# CREATE TABLE count_t1(a int, b int);

gaussdb=# INSERT INTO count_t1 VALUES (NULL,1),(1,2),(2,3),(3,4),(4,5);

gaussdb=# SELECT COUNT(*) FROM count_t1;
 count
-------
     5
(1 row)

gaussdb=# DROP TABLE count_t1;
```

- KEEP(DENSE_RANK { FIRST | LAST } ORDER BY expr)

  Description: Sorts data rows in a query result based on specified rules and returns the first or last group of values. This can be used in aggregate or window functions.

  Syntax:

```
aggregate_function KEEP ( DENSE_RANK { FIRST | LAST }  ORDER BY expr [ DESC | ASC ] [ NULLS { FIRST | LAST } ]
     [, expr [ DESC | ASC ] [ NULLS { FIRST | LAST } ]]...)
```

  Return type: data type of the specified column in aggregate_function.

  NOTE

  - aggregate_function is an aggregate function. Currently, only MIN, MAX, SUM, AVG, COUNT, VARIANCE, and STDDEV are supported.
  - The KEEP keyword is used for clearer semantics and is limited to aggregate functions and window functions.
  - DENSE_RANK FIRST and DENSE_RANK LAST indicate that only rows after the minimum (FIRST) and maximum (LAST) dense ranking are aggregated, respectively.
  - Vectorized plans cannot be generated for execution.

  Example:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gaussdb=# CREATE TABLE keep_t1(a int, b int, c int);

gaussdb=# INSERT INTO keep_t1 values(2, 111, 333), (2, 11, 33), (2, 11, 3), (1, 22, 55), (1, 2, 5);

gaussdb=#  SELECT MIN(b) KEEP(DENSE_RANK FIRST ORDER BY a) MIN_FIRST,
        MIN(b) KEEP(DENSE_RANK LAST ORDER BY a) MIN_LAST,
        MAX(b) KEEP(DENSE_RANK FIRST ORDER BY a) MAX_FIRST,
        MAX(b) KEEP(DENSE_RANK LAST ORDER BY a) MAX_LAST FROM keep_t1;
 min_first | min_last | max_first | max_last
-----------+----------+-----------+----------
         2 |       11 |        22 |      111
(1 row)

gaussdb=# DROP TABLE keep_t1;
```

- default(column_name)

  Description: Obtains the default value of a table column.

  Return type: text

  Example:

```
-- Create a MySQL-compatible database.
gaussdb=# CREATE DATABASE gaussdb_m WITH DBCOMPATIBILITY 'MYSQL';

gaussdb=# \c gaussdb_m

gaussdb_m=# CREATE TABLE t1(id int DEFAULT 100, name varchar(20) DEFAULT 'tt');

gaussdb_m=# INSERT INTO t1 VALUES(1,'test');

-- Execute the query.
gaussdb_m=# SELECT default(id), default(name) FROM t1;
 default | default
---------+---------
     100 | tt
(1 row)

-- Delete the database.
gaussdb_m=# \c postgres
gaussdb=# DROP DATABASE gaussdb_m;
```

  NOTE

  - The default function takes effect only when **sql_compatibility** is set to **'MYSQL'**.
  - If a table column does not have a default value, the default function returns a null value.
  - If a table column is a hidden column (such as **xmin** or **cmin**), the default function returns a null value.
  - If a table column is an auto-increment column, the default function returns **0**.
  - GaussDB supports default values of partitioned tables, temporary tables, and multi-table join query.
  - GaussDB supports the query of nodes whose column names contain character string values (indicating names) and A_Star nodes (indicating that asterisks (*) appear), for example, **default(tt.t4.id)** and **default(tt.t4.*)**.
  - When the default value of a column is created in GaussDB, the range of the column type is not verified. As a result, an error may be reported when the default function is used.
  - If the default value of a column is a function expression, the default function of GaussDB will return the calculated value of the default expression set for the column during table creation.

- array_agg(expression)

  Description: Input values, including nulls, concatenated into an array

  Return type: array of the parameter type

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Operations on XML data are supported.

Example:

```
gaussdb=# CREATE TABLE array_agg_t1(a int, b int);

gaussdb=# INSERT INTO array_agg_t1 VALUES (NULL,1),(1,2),(2,3),(3,4),(4,5);

gaussdb=# SELECT ARRAY_AGG(a) FROM array_agg_t1;
  array_agg
----------------
 {NULL,1,2,3,4}
(1 row)

gaussdb=# DROP TABLE array_agg_t1;
```

- string_agg(expression, delimiter)

  Description: Input values concatenated into a string, separated by delimiter

  Return type: same as the parameter data type.

  Operations on XML data that is explicitly converted to the character type are supported.

  Example:

```
gaussdb=# CREATE TABLE string_agg_t1(a int, b int);

gaussdb=# INSERT INTO string_agg_t1 VALUES (NULL,1),(1,2),(2,3),(3,4),(4,5);

gaussdb=# SELECT STRING_AGG(a,';') FROM string_agg_t1;
 string_agg
------------
 1;2;3;4
(1 row)

gaussdb=# DROP TABLE string_agg_t1;
```

- listagg([DISTINCT | ALL] expression [, delimiter]) [WITHIN GROUP(ORDER BY order-list)]

  Description: Aggregation column data sorted according to the mode specified by WITHIN GROUP, and concatenated to a string using the specified delimiter

  - **DISTINCT**: Optional. It deduplicates the result after each row is concatenated. Only the ORA-compatible mode is supported.
  - **expression**: Required. It specifies an aggregation column name or a column-based, valid expression. It does not support the VARIADIC parameters.
  - **delimiter**: Optional. It specifies a delimiter, which can be a string constant or a deterministic expression based on a group of columns. The default value is empty.
  - **order-list**: Optional. It specifies the sorting mode in a group.

  Return type: text

  > **NOTE**
  >
  > listagg is a column-to-row aggregate function, compatible with Oracle Database 11g Release 2. You can specify the OVER clause as a window function. When listagg is used as a window function, the OVER clause does not support the window sorting or framework of ORDER BY, to avoid different meanings or behaviors in listagg and ORDER BY of the WITHIN GROUP clause.

  Example:

  The aggregation column is of the text character set type.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gaussdb=# CREATE TABLE listagg_t1(a int, b text);

gaussdb=# INSERT INTO listagg_t1 VALUES (NULL,'a1'),(1,'b2'),(1,'c3'),(2,'d4'),(2,'e5'),(3,'f6');

gaussdb=# SELECT a,LISTAGG(b,';') WITHIN GROUP(ORDER BY b) FROM listagg_t1 GROUP BY a
ORDER BY a;
 a | listagg
---+---------
 1 | b2;c3
 2 | d4;e5
 3 | f6
   | a1
(4 rows)

gaussdb=# SELECT a,LISTAGG(b,';') FROM listagg_t1 GROUP BY a ORDER BY a;
 a | listagg
---+---------
 1 | b2;c3
 2 | d4;e5
 3 | f6
   | a1
(4 rows)

gaussdb=# DROP TABLE listagg_t1;
```

The aggregation column is of the integer type.

```
gaussdb=# CREATE TABLE listagg_t1(a int, b int);

gaussdb=# INSERT INTO listagg_t1 VALUES (NULL,1),(1,2),(1,3),(2,4),(2,5),(3,6);

gaussdb=# SELECT a,LISTAGG(b,';') WITHIN GROUP(ORDER BY b) FROM listagg_t1 GROUP BY a
ORDER BY a;

- group_concat([DISTINCT | ALL] expression [,expression ...] [ORDER BY { expression [[ASC | DESC | USING operator] | nlssort_expression_clause] [NULLS { FIRST | LAST }] } [,...]] [SEPARATOR str_val])

  Description: The number of parameters is not fixed. Multiple columns can be concatenated. Aggregation columns are sorted based on the value of **ORDER**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

BY and concatenated into a character string using the specified separator. This function cannot be used as a window function.

- **DISTINCT**: Optional. It deduplicates the results after each row is concatenated.
- **expression**: Required. It specifies the aggregation column name or a valid column-based expression.
- **ORDER BY**: Optional. It is followed by a variable number of expressions and sorting rule. The group_concat function does not support the (ORDER BY + number) format.
- **SEPARATOR**: Optional. It is followed by a character or string. This separator is used to concatenate the expression results of two adjacent lines in a group. If it is not specified, the comma (,) is used by default.
- When both DISTINCT and ORDER BY are specified, all ORDER BY expressions must be in DISTINCT expressions. Otherwise, an error is reported.
- Parameter **group_concat_max_len** is used to limit the maximum length of **GROUP_CONCAT**. If the length exceeds the maximum, the system truncates the length. Currently, the maximum length that can be returned is 1073741823.

Return type: text

Example:

Set **separator** to **';'**.

```
gaussdb=# CREATE TABLE group_concat_t1(a int, b int);

gaussdb=# INSERT INTO group_concat_t1 VALUES (NULL,1),(1,2),(1,3),(2,4),(2,5),(3,6);

gaussdb=# SELECT a,group_concat(b separator ';') FROM group_concat_t1 GROUP BY a ORDER BY a;
 a | group_concat
---+--------------
 1 | 2;3
 2 | 4;5
 3 | 6
   | 1
(4 rows)

gaussdb=# DROP TABLE group_concat_t1;
```

By default, the separator is a comma (,).

```
gaussdb=# CREATE TABLE group_concat_t1(a int, b int);

gaussdb=# INSERT INTO group_concat_t1 VALUES (NULL,1),(1,2),(1,3),(2,4),(2,5),(3,6);

(4 rows)

gaussdb=# DROP TABLE group_concat_t1;
```

- wm_concat(expression)

  Description: Concatenates the expression data of a specified column or columns into a character string by commas (,) for output.

  Return type: text

  Example:

```
gaussdb=# CREATE TABLE wm_concat_t1(a int, b interval);
CREATE TABLE
gaussdb=# INSERT INTO wm_concat_t1 VALUES (NULL,'1 days'),(1,'2 days'),(1,'3 days'),(2,'4 days'),
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
(2,'5 days'),(3,'6 days');
INSERT 0 6
gaussdb=# SELECT wm_concat(a) FROM wm_concat_t1;
 wm_concat
-----------
 1,1,2,2,3
(1 row)
gaussdb=# SELECT wm_concat(b) FROM wm_concat_t1;
              wm_concat
-------------------------------------------
 1 day,2 days,3 days,4 days,5 days,6 days
(1 row)
gaussdb=# DROP TABLE wm_concat_t1;
```

NOTE

The return value of this function is text, and the combined result is unordered.

- covar_pop(Y, X)

  Description: Overall covariance

  Return type: double precision

  Example:

```
gaussdb=# CREATE TABLE covar_pop_t1(a int, b int);

gaussdb=# INSERT INTO covar_pop_t1 VALUES (NULL,11),(11,21),(11,31),(21,41),(21,51),(31,61);

gaussdb=# SELECT COVAR_POP(a,b) FROM covar_pop_t1;
 covar_pop
-----------
       100
(1 row)

gaussdb=# DROP TABLE covar_pop_t1;
```

- covar_samp(Y, X)

  Description: Sample covariance

  Return type: double precision

  Example:

```
gaussdb=# CREATE TABLE covar_samp_t1(a int, b int);

gaussdb=# INSERT INTO covar_samp_t1 VALUES (NULL,11),(11,21),(11,31),(21,41),(21,51),(31,61);

gaussdb=# SELECT COVAR_SAMP(a,b) FROM covar_samp_t1;
 covar_samp
------------
        125
(1 row)

gaussdb=# DROP TABLE covar_samp_t1;
```

- stddev_pop(expression)

  Description: Overall standard difference

  Return type: DOUBLE PRECISION for floating-point arguments, otherwise NUMERIC

  Example:

```
gaussdb=# CREATE TABLE stddev_pop_t1(a int, b int);

gaussdb=# INSERT INTO stddev_pop_t1 VALUES (NULL,11),(11,21),(11,31),(21,41),(21,51),(31,61);

gaussdb=# SELECT STDDEV_POP(a) FROM stddev_pop_t1;
    stddev_pop
--------------------
```

```
 7.4833147735478828
(1 row)

gaussdb=# DROP TABLE stddev_pop_t1;
```

- stddev_samp(expression)

  Description: Sample standard deviation of the input values

  Return type: DOUBLE PRECISION for floating-point arguments, otherwise NUMERIC

  Example:

```
gaussdb=# CREATE TABLE stddev_samp_t1(a int, b int);

gaussdb=# INSERT INTO stddev_samp_t1 VALUES (NULL,11),(11,21),(11,31),(21,41),(21,51),(31,61);

gaussdb=# SELECT STDDEV_SAMP(a) FROM stddev_samp_t1;
   stddev_samp
--------------------
 8.3666002653407555
(1 row)

gaussdb=# DROP TABLE stddev_samp_t1;
```

- var_pop(expression)

  Description: Specifies the population variance of the input values (square of the population standard deviation).

  Return type: DOUBLE PRECISION for floating-point arguments, otherwise NUMERIC

  Example:

```
gaussdb=# CREATE TABLE var_pop_t1(a int, b int);

gaussdb=# INSERT INTO var_pop_t1 VALUES (NULL,11),(11,21),(11,31),(21,41),(21,51),(31,61);

gaussdb=# SELECT VAR_POP(a) FROM var_pop_t1;
      var_pop
--------------------
 56.0000000000000000
(1 row)

gaussdb=# DROP TABLE var_pop_t1;
```

- var_samp(expression)

  Description: Specifies the sample variance of the input values (square of the sample standard deviation).

  Return type: DOUBLE PRECISION for floating-point arguments, otherwise NUMERIC

  Example:

```
gaussdb=# CREATE TABLE var_samp_t1(a int, b int);

gaussdb=# INSERT INTO var_samp_t1 VALUES (NULL,11),(11,21),(11,31),(21,41),(21,51),(31,61);

gaussdb=# SELECT VAR_SAMP(a) FROM var_samp_t1;
     var_samp
--------------------
 70.0000000000000000
(1 row)

gaussdb=# DROP TABLE var_samp_t1;
```

- bit_and(expression)

  Description: The bitwise AND of all non-null input values, or null if none

  Return type: same as the parameter data type.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Example:

```
gaussdb=# CREATE TABLE bit_and_t1(a int, b int);

gaussdb=# INSERT INTO bit_and_t1 VALUES (NULL,11),(1,2),(1,3),(2,4),(2,5),(3,6);

gaussdb=# SELECT BIT_AND(a) FROM bit_and_t1;
 bit_and
---------
       0
(1 row)

gaussdb=# DROP TABLE bit_and_t1;
```

- bit_or(expression)

  Description: The bitwise OR of all non-null input values, or null if none

  Return type: same as the parameter data type.

  Example:

```
gaussdb=# CREATE TABLE bit_or_t1(a int, b int);

gaussdb=# INSERT INTO bit_or_t1 VALUES (NULL,11),(1,2),(1,3),(2,4),(2,5),(3,6);

gaussdb=# SELECT BIT_OR(a) FROM bit_or_t1;
 bit_or
--------
      3
(1 row)

gaussdb=# DROP TABLE bit_or_t1;
```

- bool_and(expression)

  Description: Its value is **true** if all input values are **true**, otherwise **false**.

  Return type: Boolean

  Example:

```
gaussdb=# SELECT bool_and(100 <2500);
 bool_and
----------
 t
(1 row)
```

- bool_or(expression)

  Description: Its value is **true** if at least one input value is **true**, otherwise **false**.

  Return type: Boolean

  Example:

```
gaussdb=# SELECT bool_or(100 <2500);
 bool_or
----------
 t
(1 row)
```

- corr(Y, X)

  Description: Specifies the correlation coefficient.

  Return type: double precision

  Example:

```
gaussdb=# CREATE TABLE corr_t1(a int, b int);

gaussdb=# INSERT INTO corr_t1 VALUES (NULL,11),(1,2),(1,3),(2,4),(2,5),(3,6);

gaussdb=# SELECT CORR(a,b) FROM corr_t1;
      corr
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
------------------
 .944911182523068
(1 row)

gaussdb=# DROP TABLE corr_t1;
```

- every(expression)

  Description: Equivalent to **bool_and**

  Return type: Boolean

  Example:

```
gaussdb=# SELECT every(100 <2500);
 every
-------
 t
(1 row)
```

- rank(expression)

  Description: The tuples in different groups are sorted non-consecutively by **expression**.

  Return type: bigint

  Example:

```
gaussdb=# CREATE TABLE rank_t1(a int, b int);

gaussdb=# INSERT INTO rank_t1 VALUES(NULL,1),(1, 2),(1, 3),(2, 4),(2, 5),(3,6);

gaussdb=# SELECT a,b,RANK() OVER(PARTITION BY a ORDER BY b) FROM rank_t1;
 a | b | rank
---+---+------
 1 | 2 |    1
 1 | 3 |    2
 2 | 4 |    1
 2 | 5 |    2
 3 | 6 |    1
   | 1 |    1
(6 rows)

gaussdb=# DROP TABLE rank_t1;
```

- regr_avgx(Y, X)

  Description: Specifies the average of the independent variable (**sum(X)/Y**).

  Return type: double precision

  Example:

```
gaussdb=# CREATE TABLE regr_t1(a int, b int);

gaussdb=# INSERT INTO regr_t1 VALUES (NULL,11),(1,2),(1,3),(2,4),(2,5),(3,6);

gaussdb=# SELECT REGR_AVGX(a,b) FROM regr_t1;
 regr_avgx
-----------
         4
(1 row)

gaussdb=# DROP TABLE regr_t1;
```

- regr_avgy(Y, X)

  Description: Specifies the average of the dependent variable (**sum(Y)/X**).

  Return type: double precision

  Example:

```
gaussdb=# CREATE TABLE regr_avgy_t1(a int, b int);
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gaussdb=# INSERT INTO regr_avgy_t1 VALUES (NULL,11),(1,2),(1,3),(2,4),(2,5),(3,6);

gaussdb=# SELECT REGR_AVGY(a,b) FROM regr_avgy_t1;
 regr_avgy
-----------
       1.8
(1 row)

gaussdb=# DROP TABLE regr_avgy_t1;
```

- regr_count(Y, X)

  Description: Specifies the number of input rows in which both expressions are non-null.

  Return type: bigint

  Example:

```
gaussdb=# CREATE TABLE regr_count_t1(a int, b int);

gaussdb=# INSERT INTO regr_count_t1 VALUES (NULL,11),(1,2),(1,3),(2,4),(2,5),(3,6);

gaussdb=# SELECT REGR_COUNT(a,b) FROM regr_count_t1;
 regr_count
------------
          5
(1 row)

gaussdb=# DROP TABLE regr_count_t1;
```

- regr_intercept(Y, X)

  Description: y-intercept of the least-squares-fit linear equation determined by the (X, Y) pairs

  Return type: double precision

  Example:

```
gaussdb=# CREATE TABLE regr_intercept_t1(a int, b int);

gaussdb=# INSERT INTO regr_intercept_t1 VALUES (NULL,11),(1,2),(1,3),(2,4),(2,5),(3,6);

gaussdb=# SELECT REGR_INTERCEPT(b,a) FROM regr_intercept_t1;
  regr_intercept
------------------
 .785714285714286
(1 row)

gaussdb=# DROP TABLE regr_intercept_t1;
```

- regr_r2(Y, X)

  Description: Specifies the square of the correlation coefficient.

  Return type: double precision

  Example:

```
gaussdb=# CREATE TABLE regr_r2_t1(a int, b int);

gaussdb=# INSERT INTO regr_r2_t1 VALUES (NULL,11),(1,2),(1,3),(2,4),(2,5),(3,6);

gaussdb=# SELECT REGR_R2(b,a) FROM regr_r2_t1;
     regr_r2
------------------
 .892857142857143
(1 row)

gaussdb=# DROP TABLE regr_r2_t1;
```

- regr_slope(Y, X)

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description: Slope of the least-squares-fit linear equation determined by the (X, Y) pairs

Return type: double precision

Example:

```
gaussdb=# CREATE TABLE regr_slope_t1(a int, b int);

gaussdb=# INSERT INTO regr_slope_t1 VALUES (NULL,11),(1,2),(1,3),(2,4),(2,5),(3,6);

gaussdb=# SELECT REGR_SLOPE(b,a) FROM regr_slope_t1;
    regr_slope
------------------
 1.78571428571429
(1 row)

gaussdb=# DROP TABLE regr_slope_t1;
```

- regr_sxx(Y, X)

  Description: **sum(Y^2) – sum(X)^2/N** (sum of squares of the independent variables)

  Return type: double precision

  Example:

```
gaussdb=# CREATE TABLE regr_sxx_t1(a int, b int);

gaussdb=# INSERT INTO regr_sxx_t1 VALUES (NULL,11),(1,2),(1,3),(2,4),(2,5),(3,6);

gaussdb=# SELECT REGR_SXX(b,a) FROM regr_sxx_t1;
 regr_sxx
----------
      2.8
(1 row)

gaussdb=# DROP TABLE regr_sxx_t1;
```

- regr_sxy(Y, X)

  Description: **sum(X*Y) – sum(X) * sum(Y)/N** (sum of products of independent times dependent variable)

  Return type: double precision

  Example:

```
gaussdb=# CREATE TABLE regr_sxy_t1(a int, b int);

gaussdb=# INSERT INTO regr_sxy_t1 VALUES (NULL,11),(1,2),(1,3),(2,4),(2,5),(3,6);

gaussdb=# SELECT REGR_SXY(b,a) FROM regr_sxy_t1;
 regr_sxy
----------
        5
(1 row)

gaussdb=# DROP TABLE regr_sxy_t1;
```

- regr_syy(Y, X)

  Description: **sum(Y^2) – sum(X)^2/N** ("sum of squares" of the dependent variable)

  Return type: double precision

  Example:

```
gaussdb=# CREATE TABLE regr_syy_t1(a int, b int);

gaussdb=# INSERT INTO regr_syy_t1 VALUES (NULL,11),(1,2),(1,3),(2,4),(2,5),(3,6);

gaussdb=# SELECT REGR_SYY(b,a) FROM regr_syy_t1;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
 regr_syy
----------
       10
(1 row)

gaussdb=# DROP TABLE regr_syy_t1;
```

- stddev(expression)

  Description: Alias of **stddev_samp**

  Return type: DOUBLE PRECISION for floating-point arguments, otherwise NUMERIC

  Example:

```
gaussdb=# CREATE TABLE stddev_t1(a int, b int);

gaussdb=# INSERT INTO stddev_t1 VALUES (NULL,11),(1,2),(1,3),(2,4),(2,5),(3,6);

gaussdb=# SELECT STDDEV(a) FROM stddev_t1;
        stddev
----------------------
 .83666002653407554798
(1 row)

gaussdb=# DROP TABLE stddev_t1;
```

- variance(expression,expression)

  Description: Alias of **var_samp**

  Return type: DOUBLE PRECISION for floating-point arguments, otherwise NUMERIC

  Example:

```
gaussdb=# CREATE TABLE variance_t1(a int, b int);

gaussdb=# INSERT INTO variance_t1 VALUES (NULL,11),(1,2),(1,3),(2,4),(2,5),(3,6);

gaussdb=# SELECT VARIANCE(a) FROM variance_t1;
       variance
----------------------
 .70000000000000000000
(1 row)

gaussdb=# DROP TABLE variance_t1;
```

- spread()

  Description: Calculates the difference between the maximum value and minimum value in a certain period.

  Parameters: real type. For details, see **Table 1-93**.

  Return type: real

  Table 1-93 Parameters of the spread function

Parameter	Type	Description
field	Numeric	Column to be calculated.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- If there are fewer than two tuples in each group, the returned result is **0**. Do not use this function with the over statement.
- The spread function cannot be pushed down and requires data to be pulled from the CN for calculation. If the data volume is large, data will be flushed to disk, affecting performance.

Example:

```
gaussdb=# SELECT
gaussdb-#       SPREAD(value)
gaussdb-# FROM
gaussdb-#       (VALUES ('2019-07-12 00:00:00'::timestamptz, 1),('2019-07-12 00:01:00'::timestamptz,
2),('2019-07-12 00:02:00'::timestamptz, 3)) v(time,value);
 spread
--------
      2
(1 row)
```

- pivot_func(anyelement)

  Description: Returns the only non-null value in a column. If there are two or more non-null values, an error is reported. **value** is an input parameter and can be of any type.

  Return type: same as the input parameter type

  NOTE

  This aggregate function is mainly used inside the pivot syntax.

```
gaussdb=# CREATE TABLE pivot_func_t1(a int, b int);

gaussdb=# INSERT INTO pivot_func_t1 VALUES (NULL,11),(1,2);

gaussdb=# SELECT PIVOT_FUNC(a) FROM pivot_func_t1;
 pivot_func
------------
          1
(1 row)

gaussdb=# DROP TABLE pivot_func_t1;
```

- checksum(expression)

  Description: Returns the CHECKSUM value of all input values. This function can be used to check whether the data in the tables is the same before and after the backup, restoration, or migration of GaussDB (databases other than GaussDB are not supported). Before and after database backup, database restoration, or data migration, you need to manually run SQL commands to obtain the execution results. Compare the obtained execution results to check whether the data in the tables before and after the backup or migration is the same.

  NOTE

  - For large tables, the execution of CHECKSUM function may take a long time.
  - If the CHECKSUM values of two tables are different, it indicates that the contents of the two tables are different. Using the hash function in the CHECKSUM function may incur conflicts. There is low possibility that two tables with different contents may have the same CHECKSUM value. The same problem may occur when CHECKSUM is used for columns.
  - If the time type is timestamp, timestamptz, or smalldatetime, ensure that the time zone settings are the same when calculating the CHECKSUM value.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

  - If the CHECKSUM value of a column is calculated and the column type can be changed to TEXT by default, set *expression* to the column name.
  - If the CHECKSUM value of a column is calculated and the column type cannot be converted to TEXT by default, set *expression* to *Column name*::**TEXT**.
  - If the CHECKSUM value of all columns is calculated, set *expression* to *Table name*::**TEXT**.

  The following types of data can be converted into the TEXT type by default: char, name, int8, int2, int1, int4, raw, pg_node_tree, float4, float8, bpchar, varchar, nvarchar2, date, datea (valid only for ORA compatibility), timestamp, timestamptz, numeric, and smalldatetime. Other types (for example, XML) need to be forcibly converted to TEXT.

  Return type: numeric

  Example:

  The following shows the CHECKSUM value of a column that can be converted to the TEXT type by default:

```
gaussdb=# CREATE TABLE checksum_t1(a int, b int);

gaussdb=# INSERT INTO checksum_t1 VALUES (NULL,11),(1,2),(1,3),(2,4),(2,5),(3,6);

gaussdb=# SELECT CHECKSUM(a) FROM checksum_t1;
  checksum
-------------
 18126842830
(1 row)

gaussdb=# DROP TABLE checksum_t1;
```

  The following shows the CHECKSUM value of a column that cannot be converted to the TEXT type by default. Note that the CHECKSUM parameter is set to *Column name*::**TEXT**.

```
gaussdb=# CREATE TABLE checksum_t1(a int, b int);

gaussdb=# INSERT INTO checksum_t1 VALUES (NULL,11),(1,2),(1,3),(2,4),(2,5),(3,6);

gaussdb=# SELECT CHECKSUM(a::TEXT) FROM checksum_t1;
  checksum
-------------
 18126842830
(1 row)

gaussdb=# DROP TABLE checksum_t1;
```

  The following shows the CHECKSUM value of all columns in a table. Note that the CHECKSUM parameter is set to *Table name*::**TEXT**. The table name is not modified by its schema.

```
gaussdb=# CREATE TABLE checksum_t1(a int, b int);

gaussdb=# INSERT INTO checksum_t1 VALUES (NULL,11),(1,2),(1,3),(2,4),(2,5),(3,6);

gaussdb=# SELECT CHECKSUM(checksum_t1::TEXT) FROM checksum_t1;
  checksum
-------------
 11160522226
(1 row)

gaussdb=# DROP TABLE checksum_t1;
```

- sample(value_array anyarray, N int)

  Description: Returns *N* random values for a given column.

Parameter: See **Table 1-94**.

Return type: anyelement

Table 1-94 Parameters of the sample function

Parameter	Type	Description
value_array	anyarray	Array of the queried column.
N	int	Number of random samples.

NOTE

- The value of *N* must be a positive number and the length cannot be greater than that of **value_array**.
- This function cannot be used together with the OVER clause.
- Arrays with data volumes exceeding the value range of the int8 type cannot be used.

Example:

```
gaussdb=# SELECT
gaussdb-#     sample(array_agg(value), 1)
gaussdb-# FROM
gaussdb-#     (VALUES ('2019-07-12 00:00:00'::timestamptz, 1),('2019-07-12 00:01:00'::timestamptz,
2),('2019-07-12 00:02:00'::timestamptz, 3)) v(time,value);
 sample
--------
      3
(1 row)
```

- mode() within group (order by value anyelement)

  Description: Returns the value with the highest occurrence frequency for a given column. If multiple values have the same frequency, this function returns the smallest value among these values.

  Parameter: See **Table 1-95**.

  Return type: anyelement

  Table 1-95 Parameters of the mode function

Parameter	Type	Description
value	anyelement	Queried column.

  NOTE

  - This function must be used together with the WITHIN GROUP statement. If the WITHIN GROUP statement does not exist, an error is reported. Parameters of this function are placed after ORDER BY of the group.
  - This function cannot be used together with the OVER clause.

  Example:

```
gaussdb=# SELECT
gaussdb-#     mode() within group (order by value)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gaussdb-# FROM
gaussdb-#     (VALUES ('2019-07-12 00:00:00'::timestamptz, 1),('2019-07-12 00:01:00'::timestamptz,
2),('2019-07-12 00:02:00'::timestamptz, 3)) v(time,value);
 mode
------
    1
(1 row)
```

- integral(time_array timestamptz[], value_array double precision[], unit interval)

  Description: Returns the trapezoidal area integral for a given column at a given time.

  Parameter: See **Table 1-96**.

  Return type: float

  Table 1-96 Parameters of the integral function

Parameter	Type	Description
time_array	timestamptz[]	Queried time array.
value_array	double precision[]	Array of the queried column.
unit	interval	Time unit.

  NOTE

  - The length of the time array must be the same as that of the value array. Otherwise, an error is reported.
  - This function cannot be used together with the OVER clause.
  - Arrays with data volumes exceeding the value range of the int type cannot be used.

  Example:

```
gaussdb=# SELECT
gaussdb-#     integral(array_agg(time), array_agg(value), interval '1 second')
gaussdb-# FROM
gaussdb-#     (VALUES ('2019-07-12 00:00:00'::timestamptz, 1),('2019-07-12 00:01:00'::timestamptz,
2),('2019-07-12 00:02:00'::timestamptz, 3)) v(time,value);
    integral
------------------
 239.999999999999
(1 row)
```

Aggregate Function Nesting

Description: Performs another aggregate function operation on the grouping calculation result of the aggregate function.

Generally, it can be described as follows:

```
SELECT AGG1(AGG2(column_name1)) FROM table_name GROUP BY column_name2;
```

It is equivalent to:

```
SELECT AGG1(value) FROM (SELECT AGG2(column_name1) value FROM table_name GROUP BY
column_name2);
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

In the preceding information:

- **AGG1()**: outer aggregate function.
- **AGG2()**: inner aggregate function.
- **table_name**: table name.
- **column_name1** and **column_name2**: column names.
- **value**: alias of the result of the inner aggregate function.

The overall meaning can be described as follows: The grouping calculation result of the inner aggregate function AGG2() is used as the input of the outer aggregate function AGG1() for recalculation.

NOTE

1. The nested aggregate function is located between SELECT and FROM. Otherwise, it is meaningless.
2. The SELECT statement that uses a nested aggregate function contains a GROUP BY clause.
3. Only the nested aggregate functions or constant expressions can be selected together with another nested aggregate function. The constant expression does not support the CASE WHEN expression or functions logically equivalent to CASE WHEN (such as the DECODE function, NVL2 function in ORA-compatible mode, and IF function in MySQL-compatible mode).
4. The aggregate function supports only one nesting operation.
5. Currently, the following aggregate functions can be nested: avg, max, min, sum, var_pop, var_samp, variance, stddev_pop, stddev_samp, stddev, median, regr_sxx, regr_syy, regr_sxy, regr_avgx, regr_avgy, regr_r2, regr_slope, regr_intercept, covar_pop, covar_samp, corr, and listagg.
6. The return type of the inner aggregate function must comply with the parameter type of the outer aggregate function.

Example:

```
gaussdb=# CREATE TABLE test1 (id INT,val INT);
CREATE TABLE
gaussdb=# INSERT INTO test1 VALUES (1, 1);
INSERT 0 1
gaussdb=# INSERT INTO test1 VALUES (1, null);
INSERT 0 1
gaussdb=# INSERT INTO test1 VALUES (2, 10);
INSERT 0 1
gaussdb=# INSERT INTO test1 VALUES (2, 55);
INSERT 0 1

gaussdb=# SELECT SUM(MIN(val)) FROM test1 GROUP BY id;
 sum
-----
  11
(1 row)

gaussdb=# DROP TABLE test1;
DROP TABLE
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

1.6.19 Window Functions

Window Functions

Window functions and the **OVER** clause are used together. The OVER clause is used for grouping data and sorting the elements in a group. Window functions are used for generating sequence numbers for the values in the group.

NOTE

order by in a window function must be followed by a column name. If it is followed by a number, the number is processed as a constant value and the target column is not ranked.

If a parent query contains filter criteria of a window function in a subquery, the filter criteria in the parent query can be pushed down to the subquery.

CAUTION

1. Only the <, <=, and = filter criteria of window functions in parent queries can be pushed down to subqueries.
2. The upper boundary of a restriction condition range can be a constant, constant expression, parameter, non-VOLATILE function, or non-correlated sublink.
3. Only the **ROW_NUMBER()**, **RANK()**, and **DENSE_RANK()** window functions are supported.

Example:

```
-- Create a table.
gaussdb=# CREATE TABLE t2 (c1 INT, c2 INT);
-- Import data.
gaussdb=# INSERT INTO t2 SELECT generate_series, generate_series FROM generate_series(1, 1000000);
-- Execute the query. The query is normal, no error is reported, and the execution result is correct.
gaussdb=# EXPLAIN ANALYZE SELECT nc1 FROM (
SELECT row_number() over() rid,
t2.c1 nc1
FROM t2
) WHERE rid BETWEEN 1 AND (1 + 10 - 1);
                                                  QUERY PLAN
-------------------------------------------------------------------------------------------------------------------------
Streaming (type: GATHER)  (cost=0.12..10.64 rows=5 width=4) (actual time=10.201..12.766 rows=10
loops=1)
  Node/s: All datanodes
  ->  Subquery Scan on __unnamed_subquery__  (cost=0.00..10.45 rows=5 width=4) (actual
time=[5.310,6.092]..[5.310,6.092], rows=10)
        Filter: (__unnamed_subquery__.rid >= 1)
        ->  WindowAgg  (cost=0.00..10.25 rows=16 width=4) (actual time=[5.262,5.873]..[5.262,5.873],
rows=10)
              row_number_filter: (row_number() OVER () <= 10)
              ->  Streaming(type: BROADCAST)  (cost=0.00..10.29 rows=32 width=4) (actual
time=[5.162,5.682]..[5.162,5.682], rows=11)
                    Spawn on: All datanodes
                    ->  WindowAgg  (cost=0.00..10.25 rows=16 width=4) (actual time=[1.759,1.815]..
[1.786,1.844], rows=20)
                          row_number_filter: (row_number() OVER () <= 10)
                          ->  Seq Scan on t2  (cost=0.00..13.13 rows=20 width=4) (actual time=[1.711,1.716]..
[1.743,1.747], rows=22)
 Total runtime: 13.428 ms
(12 rows)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
-- Clear the environment to prevent data leakage.
gaussdb=# DROP TABLE t2;
```

- RANK()

  Description: The RANK function is used for generating non-consecutive sequence numbers for the values in each group. The same values have the same sequence number.

  Return type: bigint

  Example:

```
gaussdb=# CREATE TABLE rank_t1(a int, b int);

gaussdb=# INSERT INTO rank_t1 VALUES(1,1),(1,1),(1, 2),(1, 3),(2, 4),(2, 5),(3,6);

gaussdb=# SELECT a,b,RANK() OVER(PARTITION BY a ORDER BY b) FROM rank_t1;
 a | b | rank
---+---+------
 1 | 1 |    1
 1 | 1 |    1
 1 | 2 |    3
 1 | 3 |    4
 2 | 4 |    1
 2 | 5 |    2
 3 | 6 |    1
(7 rows)

gaussdb=# DROP TABLE rank_t1;
```

- ROW_NUMBER()

  Description: The ROW_NUMBER function is used for generating consecutive sequence numbers for the values in each group. The same values have different sequence numbers.

  Return type: bigint

  Example:

```
gaussdb=# CREATE TABLE row_number_t1(a int, b int);

gaussdb=# INSERT INTO row_number_t1 VALUES(1,1),(1,1),(1, 2),(1, 3),(2, 4),(2, 5),(3,6);

gaussdb=# SELECT a,b,ROW_NUMBER() OVER(PARTITION BY a ORDER BY b) FROM row_number_t1;
 a | b | row_number
---+---+------------
 1 | 1 |          1
 1 | 1 |          2
 1 | 2 |          3
 1 | 3 |          4
 2 | 4 |          1
 2 | 5 |          2
 3 | 6 |          1
(7 rows)

gaussdb=# DROP TABLE row_number_t1;
```

- DENSE_RANK()

  Description: The DENSE_RANK function is used for generating consecutive sequence numbers for the values in each group. The same values have the same sequence number.

  Return type: bigint

  Example:

```
gaussdb=# CREATE TABLE dense_rank_t1(a int, b int);

gaussdb=# INSERT INTO dense_rank_t1 VALUES(1,1),(1,1),(1, 2),(1, 3),(2, 4),(2, 5),(3,6);
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gaussdb=# SELECT a,b,DENSE_RANK() OVER(PARTITION BY a ORDER BY b) FROM dense_rank_t1;
 a | b | dense_rank
---+---+------------
 1 | 1 |          1
 1 | 1 |          1
 1 | 2 |          2
 1 | 3 |          3
 2 | 4 |          1
 2 | 5 |          2
 3 | 6 |          1
(7 rows)

gaussdb=# DROP TABLE dense_rank_t1;
```

- PERCENT_RANK()

  Description: The PERCENT_RANK function is used for generating corresponding sequence numbers for the values in each group. That is, the function calculates the value according to the formula: Sequence number = (**rank** – 1) / (**totalrows** – 1). **rank** is the corresponding sequence number generated based on the **RANK** function for the value and **totalrows** is the total number of elements in a group.

  Return type: double precision

  Example:

```
gaussdb=# CREATE TABLE percent_rank_t1(a int, b int);

gaussdb=# INSERT INTO percent_rank_t1 VALUES(1,1),(1,1),(1, 2),(1, 3),(2, 4),(2, 5),(3,6);

gaussdb=# SELECT a,b,PERCENT_RANK() OVER(PARTITION BY a ORDER BY b) FROM percent_rank_t1;
 a | b |    percent_rank
---+---+-----------------
 1 | 1 |                0
 1 | 1 |                0
 1 | 2 | .666666666666667
 1 | 3 |                1
 2 | 4 |                0
 2 | 5 |                1
 3 | 6 |                0
(7 rows)

gaussdb=# DROP TABLE percent_rank_t1;
```

- CUME_DIST()

  Description: The CUME_DIST function is used for generating accumulative distribution sequence numbers for the values in each group. That is, the function calculates the value according to the following formula: Sequence number = Number of rows preceding or peer with current row/Total rows.

  Return type: double precision

  Example:

```
gaussdb=# CREATE TABLE cume_dist_t1(a int, b int);

gaussdb=# INSERT INTO cume_dist_t1 VALUES(1,1),(1,1),(1, 2),(1, 3),(2, 4),(2, 5),(3,6);

gaussdb=# SELECT a,b,CUME_DIST() OVER(PARTITION BY a ORDER BY b) FROM cume_dist_t1;
 a | b | cume_dist
---+---+-----------
 1 | 1 |        .5
 1 | 1 |        .5
 1 | 2 |       .75
 1 | 3 |         1
 2 | 4 |        .5
 2 | 5 |         1
 3 | 6 |         1
(7 rows)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gaussdb=# DROP TABLE cume_dist_t1;
```

- NTILE(num_buckets integer)

  Description: The NTILE function is used for equally allocating sequential data sets to the buckets whose quantity is specified by **num_buckets** according to **num_buckets integer** and allocating the bucket number to each row. Divide the partition as evenly as possible.

  Return type: integer

  Example:

```
gaussdb=# CREATE TABLE ntile_t1(a int, b int);

gaussdb=# INSERT INTO ntile_t1 VALUES(1,1),(1,1),(1, 2),(1, 3),(2, 4),(2, 5),(3,6);

gaussdb=# SELECT a,b,NTILE(2) OVER(PARTITION BY a ORDER BY b) FROM ntile_t1;
 a | b | ntile
---+---+-------
 1 | 1 |     1
 1 | 1 |     1
 1 | 2 |     2
 1 | 3 |     2
 2 | 4 |     1
 2 | 5 |     2
 3 | 6 |     1
(7 rows)

gaussdb=# DROP TABLE ntile_t1;
```

- LAG

  Description: The LAG function is used for generating lag values for the corresponding values in each group. That is, the value of the row obtained by moving forward the row corresponding to the current value by **offset** (integer) is the sequence number. If the row does not exist after the moving, the result value is the default value. If not specified, **offset** defaults to **1** and **default** to **NULL**. The value of **default** must be of the same type as **value**.

  Syntax:

```
LAG(value any [, offset integer [, default any ]])
LAG(value any ignore|respect nulls [, offset integer [, default any ]])
LAG(value any [, offset integer [, default any ]]) ignore|respect nulls
```

Figure 1-1 LAG syntax diagram

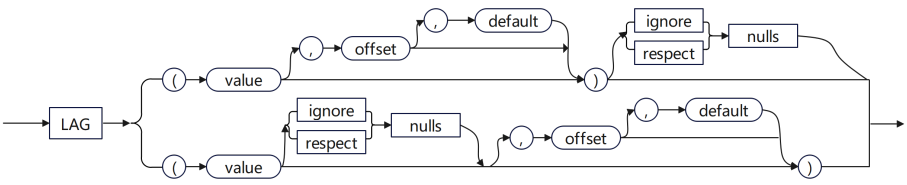

Figure 1-1 shows the syntax diagram for the LAG function. **ignore|respect nulls** determines whether NULL is included in the forward offset value. If not specified, the default value **respect nulls** is used. If **ignore nulls** is specified and the **value** is set to **NULL**, NULL is not included in the forward offset value. If **ignore nulls** is specified, the function performance deteriorates.

Return type: same as the parameter type

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Example 1: Disable **ignore nulls** and set **offset** to **3** and **default** to **null**.

```
-- Create a table and insert data into the table.
gaussdb=# CREATE TABLE ta1 (hire_date date, last_name varchar(20), department_id int);
CREATE TABLE
gaussdb=# INSERT INTO ta1 values('07-DEC-02', 'Raphaely', 30);
INSERT 0 1
gaussdb=# INSERT INTO ta1 values('24-JUL-05', 'Tobias',  30);
INSERT 0 1
gaussdb=# INSERT INTO ta1 values('24-DEC-05', 'Baida',  30);
INSERT 0 1
gaussdb=# INSERT INTO ta1 values('18-MAY-03', 'Khoo', 30);
INSERT 0 1
gaussdb=# INSERT INTO ta1 values('15-NOV-06', 'Himuro',  30);
INSERT 0 1
gaussdb=# INSERT INTO ta1 values('10-AUG-07', 'Colmenares',  30);
INSERT 0 1
gaussdb=# INSERT INTO ta1 values('10-MAY-07', 'yq',  11);
INSERT 0 1
gaussdb=# INSERT INTO ta1 values('10-MAY-08', 'zi',  11);
INSERT 0 1
gaussdb=# INSERT INTO ta1 values('', 'yq1',  30);
INSERT 0 1
gaussdb=# INSERT INTO ta1 values(null, 'yq2',  30);
INSERT 0 1
gaussdb=# INSERT INTO ta1 values('10-DEC-07', 'yq3',  30);
INSERT 0 1
gaussdb=# INSERT INTO ta1 values(null, null,  11);
INSERT 0 1
gaussdb=# INSERT INTO ta1 values(null, null,  11);
INSERT 0 1

-- Call LAG and set offset to 3 and default to null.
gaussdb=# SELECT hire_date, last_name, department_id, lag(hire_date, 3, null)  OVER (PARTITION BY
department_id ORDER BY last_name) AS "NextHired" FROM ta1 ORDER BY department_id;
     hire_date      | last_name  | department_id |      NextHired
--------------------+------------+---------------+---------------------
 2007-05-10 00:00:00 | yq         |            11 |
 2008-05-10 00:00:00 | zi         |            11 |
                     |            |            11 |
                     |            |            11 | 2007-05-10 00:00:00
 2005-12-24 00:00:00 | Baida      |            30 |
 2007-08-10 00:00:00 | Colmenares |            30 |
 2006-11-15 00:00:00 | Himuro     |            30 |
 2003-05-18 00:00:00 | Khoo       |            30 | 2005-12-24 00:00:00
 2002-12-07 00:00:00 | Raphaely   |            30 | 2007-08-10 00:00:00
 2005-07-24 00:00:00 | Tobias     |            30 | 2006-11-15 00:00:00
                     | yq1        |            30 | 2003-05-18 00:00:00
                     | yq2        |            30 | 2002-12-07 00:00:00
 2007-12-10 00:00:00 | yq3        |            30 | 2005-07-24 00:00:00
(13 rows)
```

Example 2: Enable the **ignore nulls** and set **offset** to **3** and **default** to **'01-JAN-00'**.

```
gaussdb=# SELECT hire_date, last_name, department_id, lag(hire_date, 3, '01-JAN-00') ignore nulls
OVER (PARTITION BY department_id ORDER BY last_name) AS "NextHired"
 FROM ta1 ORDER BY department_id;

-- Drop the table.
gaussdb=# DROP TABLE ta1;
DROP TABLE
```

- LEAD

  Description: The LEAD function is used for generating leading values for the corresponding values in each group. That is, the value of the row obtained by moving backward the row corresponding to the current value by **offset** (integer) is the sequence number. If the row after the moving exceeds the total number of rows for the current group, the result value is the default value. If omitted, **offset** defaults to **1** and **default** to **NULL**. The value of **default** must be of the same type as **value**.

  Syntax:

```
LEAD(value any [, offset integer [, default any ]])
LEAD(value any ignore|respect nulls [, offset integer [, default any ]])
LEAD(value any [, offset integer [, default any ]]) ignore|respect nulls
```

Figure 1-2 LEAD syntax diagram

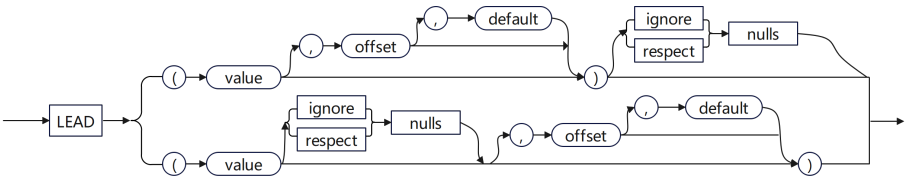

Figure 1-2 shows the syntax diagram for the LEAD function. **ignore|respect nulls** determines whether NULL is included in the backward offset value. If not specified, the default value **respect nulls** is used. If **ignore nulls** is specified and the **value** is set to **NULL**, NULL is not included in the backward offset value. If **ignore nulls** is specified, the function performance deteriorates.

Return type: same as the parameter type

Example 1: Disable **ignore nulls**, set **offset** to **2**, and do not specify **default**.

```

-- Drop the table.
gaussdb=# DROP TABLE ta1;
DROP TABLE
```

- FIRST_VALUE()

  Description: Returns the first value of each group.

  Return type: same as the parameter type

  Syntax:

  ```
  LAST_VALUE(value any)
  LAST_VALUE(value any IGNORE|RESPECT NULLS)
  LAST_VALUE(value any) IGNORE|RESPECT NULLS
  ```

  IGNORE|RESPECT NULLS: specifies whether to ignore NULL values. **RESPECT NULLS** is the default value. If **IGNORE NULLS** is enabled and the first value in

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

the group is NULL, the system continues to query the group until a non-NULL value is found. If the last value of the current group is still **NULL**, **NULL** is returned.

Example 1: If **IGNORE NULLS** is disabled, **NULL** values are not ignored by default.

```
gaussdb=# CREATE TABLE first_value_t1(a int, b int);

gaussdb=# INSERT INTO first_value_t1 VALUES(1, NULL),(1,1),(1,1),(1, 2),(1, 3),(2, 4),(2, 5),(3,6);

gaussdb=# SELECT a,b,FIRST_VALUE(b) OVER(PARTITION BY a ORDER BY b) FROM first_value_t1;
 a | b | first_value
---+---+-------------
 1 | 1 |           1
 1 | 1 |           1

 1 |   |
 1 | 3 |
 1 | 2 |
 1 | 1 |
 1 | 1 |
 2 | 5 |           5
 2 | 4 |           5
 3 | 6 |           6
(8 rows)

gaussdb=# DROP TABLE first_value_t1;
```

- LAST_VALUE()

  Description: Returns the last value of each group.

  Return type: same as the parameter type

  Syntax:

  ```
  LAST_VALUE(value any)
  LAST_VALUE(value any IGNORE|RESPECT NULLS)
  LAST_VALUE(value any) IGNORE|RESPECT NULLS
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

IGNORE|RESPECT NULLS specifies whether to ignore **NULL** values. **RESPECT NULLS** is the default value. If **IGNORE NULLS** is enabled and the last value in the group is NULL, the system continues to query the group until a non-NULL value is found. If the first value of the current group is still **NULL**, **NULL** is returned.

Example 1: If **IGNORE NULLS** is disabled, **NULL** values are not ignored by default.

```
gaussdb=# CREATE TABLE last_value_t1(a int, b int);

gaussdb=# INSERT INTO last_value_t1 VALUES(1, NULL),(1,1),(1,1),(1, 2),(1, 3),(2, 4),(2, 5),(3,6);

gaussdb=# SELECT a,b,LAST_VALUE(b) OVER(PARTITION BY a ORDER BY b) FROM last_value_t1;
 a | b | last_value
---+---+------------
 1 | 1 |          1
 1 | 1 |          1
 1 | 2 |          2
 1 | 3 |          3
 1 |   |
 2 | 4 |          4
 2 | 5 |          5
 3 | 6 |          6
(8 rows)
gaussdb=# DROP TABLE last_value_t1;
```

Example 2: **IGNORE NULLS** is enabled.

```
gaussdb=# CREATE TABLE last_value_t1(a int, b int);

gaussdb=# INSERT INTO last_value_t1 VALUES(1, NULL),(1,1),(1,1),(1, 2),(1, 3),(2, 4),(2, 5),(3,6);

gaussdb=# SELECT a,b,LAST_VALUE(b) IGNORE NULLS OVER(PARTITION BY a ORDER BY b) FROM
last_value_t1;
 a | b | last_value
---+---+------------
 1 | 1 |          1
 1 | 1 |          1
 1 | 2 |          2
 1 | 3 |          3
 1 |   |          3
 2 | 4 |          4
 2 | 5 |          5
 3 | 6 |          6
(8 rows)

gaussdb=# DROP TABLE last_value_t1;
```

- NTH_VALUE(value any, nth integer)

  Description: Returns the *n*th row for a group. If the row does not exist, **NULL** is returned by default.

  Return type: same as the parameter type

  Syntax:

  ```
  NTH_VALUE(value any, nth integer)
  NTH_VALUE(value any, nth integer) IGNORE|RESPECT NULLS
  ```

  IGNORE|RESPECT NULLS specifies whether to ignore **NULL** values. **RESPECT NULLS** is the default value. If **IGNORE NULLS** is enabled, the system searches for non-NULL values in each group until the *n*th non-NULL value is found. If no *n*th non-NULL value is found until end of the current group, **NULL** is returned.

  Example 1: If **IGNORE NULLS** is disabled, **NULL** values are not ignored by default.

gaussdb=# DROP TABLE nth_value_t1;
```

- delta()

  Description: Returns the difference between the current row and the previous row.

  Parameter: numeric, as shown in **Table 1-97**.

  Return type: numeric

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 1-97 Parameters of the delta function

Parameter	Type	Description
field	Numeric	Column to be calculated.

NOTE

- When the delta() function is used as a window function, it must be used together with the over() statement, and the rows statement in the over() statement does not change the result of the delta() function. For example, the results returned by delta(value) over(order by time rows 1 preceding) and delta(value) over(order by time rows 3 preceding) are the same.
- The delta() function supports only numeric types that can be calculated; it does not support character string types.
- In the delta() function, **rows 1 preceding** in over() specifies the difference with the previous row. For other cases, the format is as follows:
  1. If the user uses the ORDER BY clause within over(), the calculation is for each sorted row compared to the first row.
  2. If the user uses the PARTITION BY clause within over(), the calculation is for the last row of each group compared to the first row of that group.
- The delta() function cannot be pushed down and requires data to be pulled from the CN for calculation. If the data volume is large, data will be flushed to disk, affecting performance.

Example:

```
gaussdb=# SELECT
gaussdb-#       delta(value) over (rows 1 preceding)
gaussdb-# FROM
gaussdb-#       (VALUES ('2019-07-12 00:00:00'::timestamptz, 1),('2019-07-12 00:01:00'::timestamptz,
2),('2019-07-12 00:02:00'::timestamptz, 3)) v(time,value);
 delta
-------
     0
     1
     1
(3 rows)
```

- RATIO_TO_REPORT(column_name)

  Description: Calculates the ratio of the value in a column to the total value in the group to which the column belongs.

  Parameter: numeric type, or any type that can be implicitly converted to the numeric type.

  Return type: For input parameter types float4 and float8, the return type is of the same value type. For other input parameter types, the return type is numeric.

  NOTE

  When RATIO_TO_REPORT(column_name) is used together with OVER(), the input parameters of OVER() support only **PARTITION BY** and **NULL**.

  Example 1:

```
gaussdb=# CREATE TABLE ratio_to_report_t1(a int, b int);

gaussdb=# INSERT INTO ratio_to_report_t1 VALUES(1,1),(1,1),(1, 2),(1, 3),(2, 4),(2, 5),(3,6);

gaussdb=# SELECT a,b,RATIO_TO_REPORT(b) OVER(PARTITION BY a) FROM ratio_to_report_t1;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
 a | b |    ratio_to_report
---+---+-----------------------
 1 | 1 |  .14285714285714285714
 1 | 1 |  .14285714285714285714

 ratio_to_report_proc
----------------------

(1 row)

gaussdb=# DROP PROCEDURE ratio_to_report_proc;

gaussdb=# DROP TABLE ratio_to_report_t1;
```

- KEEP(DENSE_RANK { FIRST | LAST } ORDER BY expr)

  Description: Sorts data rows in a query result based on specified rules and returns the first or last group of values. This can be used in aggregate or window functions.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Syntax:

```
aggregate_function KEEP ( DENSE_RANK { FIRST | LAST }  ORDER BY expr [ DESC | ASC ] [ NULLS
{ FIRST | LAST } ]
    [, expr [ DESC | ASC ] [ NULLS { FIRST | LAST } ]]...)
OVER ( [query_partition_clause] ) ]
```

Return type: data type of the specified column in aggregate_function.

NOTE

- aggregate_function indicates an aggregate function. Currently, only MIN, MAX, SUM, AVG, COUNT, VARIANCE, and STDDEV are supported.
- The KEEP keyword is used for clearer semantics and is limited to aggregate functions and window functions.
- DENSE_RANK FIRST and DENSE_RANK LAST indicate that only rows after the minimum (FIRST) and maximum (LAST) dense ranking are aggregated, respectively.
- Vectorized plans cannot be generated for execution.

Example:

```
gaussdb=# CREATE TABLE keep_t1(a int, b int, c int, d int);

gaussdb=# INSERT INTO keep_t1 values(2, 111, 333, 10), (2, 11, 33, 10), (2, 11, 3, 1), (1, 22, 55, 10),
(1, 2, 5, 100);

gaussdb=#  SELECT MIN(d) KEEP(DENSE_RANK FIRST ORDER BY b) OVER (PARTITION BY a)
MIN_FIRST,
   MIN(b) KEEP(DENSE_RANK LAST ORDER BY b) OVER (PARTITION BY a) MIN_LAST,
   MAX(b) KEEP(DENSE_RANK FIRST ORDER BY b) OVER (PARTITION BY a) MAX_FIRST,
   MAX(b) KEEP(DENSE_RANK LAST ORDER BY b) OVER (PARTITION BY a) MAX_LAST FROM keep_t1;
 min_first | min_last | max_first | max_last
-----------+----------+-----------+----------
       100 |       22 |         2 |       22
       100 |       22 |         2 |       22
         1 |      111 |        11 |      111
         1 |      111 |        11 |      111
         1 |      111 |        11 |      111
(5 rows)
gaussdb=# DROP TABLE keep_t1;
```

- fill(value anyelement)

  Description: Performs interpolation on each group of empty data and supplements the empty values in the existing data. The rules are as follows:

  – If the current value is empty, the previous non-empty value is returned.

  – If the current data is not empty, the current value is returned.

  Parameters: See **Table 1-98**.

  Return type: anyelement

Table 1-98 Parameters of the fill function

Parameter	Type	Description
Value	anyelement	Value to be filled.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- The fill function must be used together with the OVER clause.
- The core algorithm is implemented through the COALESCE function. For details, see **Conditional Expression Functions**.

Example:

```
gaussdb=# SELECT
gaussdb-#    time,
gaussdb-#    CASE WHEN value is not null THEN value else fill(value) over(partition by time) END
gaussdb-# FROM
gaussdb-#    (VALUES ('2019-07-12 00:00:00'::timestamptz, 1),
gaussdb(#            ('2019-07-12 00:00:00'::timestamptz, NULL),
gaussdb(#            ('2019-07-12 00:02:00'::timestamptz, 3)) v(time,value);
         time          | fill
-----------------------+------
 2019-07-12 00:00:00+08 |    1
 2019-07-12 00:00:00+08 |    1
 2019-07-12 00:02:00+08 |    3
(3 rows)
```

1.6.20 Security Functions

Security Functions

- gs_encrypt_aes128(encryptstr,keystr)

  Description: Encrypts **encryptstr** strings using the key derived from **keystr** and returns encrypted strings. The value of **keystr** ranges from 8 to 16 bytes and contains at least three types of the following characters: uppercase letters, lowercase letters, digits, and special characters. Currently, the following types of data can be encrypted: numerals supported in the database; character type; RAW in binary type; and DATE, TIMESTAMP, and SMALLDATETIME in date/time type.

  Return type: text

  Length of the return value: At least 92 bytes and no more than (4*[*Len*/3]+68) bytes, where *Len* indicates the length of the data before encryption (unit: byte).

  Example:

  ```
  gaussdb=# SELECT gs_encrypt_aes128('MPPDB','1234@abc');
                                  gs_encrypt_aes128
  ----------------------------------------------------------------------------------------------
   OF1g3+70oeqFfyKiWlpxfYxPnpeitNc6+7nAe02Ttt37fZF8Q+bbEYhdw/YG+0c9tHKRWM6OcTzlB3HnqvX
  +1d8Bflo=
  (1 row)
  ```

  NOTE

  An encryption password is required during the execution of this function. For security purposes, the gsql tool does not record the SQL statements containing the function name in the execution history. That is, the execution history of this function cannot be found in **gsql** by paging up and down.

- gs_decrypt_aes128(decryptstr,keystr)

  Description: Decrypts **decryptstr** strings using the key derived from **keystr** and returns decrypted strings. The **keystr** used for decryption must be consistent with that used for encryption. **keystr** cannot be empty.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

> **NOTE**
>
> This function needs to be used with the **gs_encrypt_aes128** encryption function.

Return type: text

Example:

```
gaussdb=# SELECT gs_decrypt_aes128('OF1g3+70oeqFfyKiWlpxfYxPnpeitNc6+7nAe02Ttt37fZF8Q
+bbEYhdw/YG+0c9tHKRWM6OcTzlB3HnqvX+1d8Bflo=','1234@abc');
 gs_decrypt_aes128
-------------------
 MPPDB
(1 row)
```

> **NOTE**
>
> An encryption password is required during the execution of this function. For security purposes, the gsql tool does not record the SQL statements containing the function name in the execution history. That is, the execution history of this function cannot be found in gsql by paging up and down.

- aes_encrypt(str, key_str, init_vector)

  Description: Encrypts the string **str** using the encryption password **key_str** and initialization vector **init_vector** based on the AES algorithm.

  Parameters in the command above are as follows:

  - **str**: character string to be encrypted. If **str** is set to **NULL**, the function returns **NULL**.
  - **key_str**: encryption password. If **key_str** is set to **NULL**, the function returns **NULL**. For security purposes, you are advised to use a 128-bit, 192-bit, or 256-bit secure random number as the key character string if the key length is 128 bits, 192 bits, or 256 bits (determined by the value of **block_encryption_mode**).
  - **init_vector**: An initialization variable is provided for the required block encryption mode. The length is greater than or equal to 16 bytes. Bytes greater than 16 bytes are automatically ignored. If neither **str** nor **key_str** is **NULL**, this parameter cannot be **NULL**. Otherwise, an error is reported. For security purposes, you are advised to ensure that the IV for each encryption is unique in OFB mode and that the IV for each encryption is unpredictable in CBC or CFB mode.

  Return type: text

  Example:

```
gaussdb=# SELECT aes_encrypt('huwei123','123456vfhex4dyu,vdaladhjsadad','1234567890123456');
 aes_encrypt
-------------
 u*8\x05c?0
(1 row)
```

NOTE

- This function is valid only when GaussDB is compatible with MySQL (that is, **sql_compatibility** is set to **'MYSQL'**).
- An encryption password is required during the execution of this function. For security purposes, the gsql tool does not record the SQL statements containing the function name in the execution history. That is, the execution history of this function cannot be found in gsql by paging up and down.
- Do not call this function during operations related to stored procedures, preventing the risk of sensitive information disclosure. In addition, when using the stored procedure that contains the function, you are advised to filter the parameter information of the function before providing the information for external maintenance personnel to locate the fault. Delete the logs after using them.
- Do not call the function when **debug_print_plan** is set to **on**, preventing the risk of sensitive information disclosure. You are advised to filter parameter information of the function in the log files generated when **debug_print_plan** is set to **on** before providing the log files to external maintenance engineers for fault locating. After you finish using the logs, delete them as soon as possible.
- The SQL_ASCII setting performs quite differently from other settings. If the character set of the server is SQL_ASCII, the server interprets the byte values 0 to 127 according to the ASCII standard. The byte values 128 to 255 are regarded as the characters that cannot be parsed. If this parameter is set to SQL_ASCII, no code conversion occurs. When this function calls the third-party OpenSSL library, the returned data is non-ASCII data. Therefore, when the character set of the database server is set to SQL_ASCII, the encoding of the client must also be set to SQL_ASCII. Otherwise, an error is reported. The database does not convert or verify non-ASCII characters.

- aes_decrypt(pass_str, key_str, init_vector)

  Description: Decrypts the string **str** using the decryption password **key_str** and initialization vector **init_vector** based on the AES algorithm.

  Parameters in the command above are as follows:

  – **pass_str**: character string to be decrypted. If **pass_str** is set to **NULL**, the function returns **NULL**.

  – **key_str**: decryption password. If **key_str** is set to **NULL**, the function returns **NULL**. For security purposes, you are advised to use a 128-bit, 192-bit, or 256-bit secure random number as the key character string if the key length is 128 bits, 192 bits, or 256 bits (determined by the value of **block_encryption_mode**).

  – **init_vector**: An initialization variable is provided for the required block decryption mode. The length is greater than or equal to 16 bytes. Bytes greater than 16 bytes are automatically ignored. If neither **pass_str** nor **key_str** is **NULL**, this parameter cannot be **NULL**. Otherwise, an error is reported. For security purposes, you are advised to ensure that the IV for each encryption is unique in OFB mode and that the IV for each encryption is unpredictable in CBC or CFB mode.

  Return type: text

  Example:

```
gaussdb=# SELECT
aes_decrypt(aes_encrypt('huwei123','123456vfhex4dyu,vdaladhjsadad','1234567890123456'),'123456vf
hex4dyu,vdaladhjsadad','1234567890123456');
 aes_decrypt
-------------
 huwei123
(1 row)
```

NOTE

- This function is valid only when GaussDB is compatible with MySQL (that is, **sql_compatibility** is set to **'MYSQL'**).
- A decryption password is required during the execution of this function. For security purposes, the gsql tool does not record the SQL statements containing the function name in the execution history. That is, the execution history of this function cannot be found in gsql by paging up and down.
- Do not call this function during operations related to stored procedures, preventing the risk of sensitive information disclosure. In addition, when using the stored procedure that contains the function, you are advised to filter the parameter information of the function before providing the information for external maintenance personnel to locate the fault. Delete the logs after using them.
- Do not call the function when **debug_print_plan** is set to **on**, preventing the risk of sensitive information disclosure. You are advised to filter parameter information of the function in the log files generated when **debug_print_plan** is set to **on** before providing the log files to external maintenance engineers for fault locating. After you finish using the logs, delete them as soon as possible.
- To ensure successful decryption, ensure that the values of **block_encryption_mode**, **key_str** and IV are the same as those during encryption.
- Due to encoding differences, encrypted data cannot be directly copied from the gsql client for decryption. In this scenario, the decryption result may not be the character string before encryption.
- The SQL_ASCII setting performs quite differently from other settings. If the character set of the server is SQL_ASCII, the server interprets the byte values 0 to 127 according to the ASCII standard. The byte values 128 to 255 are regarded as the characters that cannot be parsed. If this parameter is set to SQL_ASCII, no code conversion occurs. When this function calls the third-party OpenSSL library, the returned data is non-ASCII data. Therefore, when the character set of the database server is set to SQL_ASCII, the encoding of the client must also be set to SQL_ASCII. Otherwise, an error is reported. The database does not convert or verify non-ASCII characters.

- gs_digest(input_string, hash_algorithm)

  Description: Hashes the input string using the specified hash algorithm and returns a hexadecimal number.

  Parameters in the command above are as follows:

  – **input_string**: character string to be hashed. The value cannot be **NULL**.

  – **hash_algorithm**: specifies the hash algorithm. Currently, SHA-256, SHA-384, SHA-512, and SM3 are supported. Both uppercase and lowercase letters are supported. If an unsupported hash algorithm is used, an error is reported.

  Return type: text

  Example:

```
gaussdb=# SELECT pg_catalog.gs_digest('gaussdb', 'sha256');
                            gs_digest
------------------------------------------------------------------
 4dc50d746f4e04f9b446986b34a0050e358fbfb8bc1fba314c54b52a417b0b8e
(1 row)
```

- gs_password_deadline()

  Description: Indicates the number of remaining days before the password of the current user expires.

  Return type: interval

  Example:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gaussdb=# SELECT gs_password_deadline();
 gs_password_deadline
------------------------
 83 days 17:44:32.196094
(1 row)
```

- gs_password_notifytime()

  Description: Specifies the number of days prior to password expiration that a user will receive a reminder.

  Return type: int32

- gs_password_lifetime(roleName)

  Description: Displays the remaining time before the account password expires.

  Parameter: name of the account to be queried. If no parameter is passed, the current login account is used by default.

  Return type: string

  Example:

  If the account has no password expiration set, the following information is displayed:

  ```
  gaussdb=# SELECT gs_password_lifetime('user2');
   gs_password_lifetime
  ------------------------
   -
  (1 row)
  ```

  If the account has a password expiration set, the following information is displayed:

  ```
  gaussdb=# SELECT gs_password_lifetime('user1');
   gs_password_lifetime
  ------------------------
   9 days 23:38:30.509614
  (1 row)
  ```

  NOTE

  gs_password_deadline() queries the password expiration time set in **password_effect_time**, and gs_password_lifetime() queries the expiration time set for the account password.

- login_audit_messages(BOOLEAN)

  Description: Queries login information about a login user.

  Return type: tuple

  Example:

  – Check the date, time, and IP address of the last successful login.

    ```
    gaussdb=> SELECT * FROM login_audit_messages(true);
     username | database |       logintime        |    mytype     | result | client_conninfo
    ----------+----------+------------------------+---------------+--------+-----------------
     omm      | postgres | 2020-06-29 21:56:40+08 | login_success | ok     | gsql@[local]
    (1 row)
    ```

  – Check the number, date, and time of failed attempts since the previous successful login.

    ```
    gaussdb=>  SELECT * FROM login_audit_messages(false);
     username | database |       logintime        |    mytype    | result |  client_conninfo
    ----------+----------+------------------------+--------------+--------+-------------------
     omm      | postgres | 2020-06-29 21:57:55+08 | login_failed | failed | [unknown]@[local]
     omm      | postgres | 2020-06-29 21:57:53+08 | login_failed | failed | [unknown]@[local]
    (2 rows)
    ```

- login_audit_messages_pid()

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description: Queries login information about a login user. Different from **login_audit_messages**, this function queries login information based on **backendid**. Information about subsequent logins of the same user does not alter the query result of previous logins and cannot be found using this function.

Return type: tuple

NOTE

When the thread pool is enabled, the **backendid** obtained in the same session may change due to thread switchover. As a result, the return values are different when the function is called for multiple times. You are advised not to call this function when the thread pool is enabled.

Example:

– Check the date, time, and IP address of the last successful login.

```
gaussdb=> SELECT * FROM login_audit_messages_pid(true);
 username | database |       logintime        |    mytype     | result | client_conninfo |    backendid
----------+----------+------------------------+---------------+--------+-----------------+-----------------
 omm      | postgres | 2020-06-29 21:56:40+08 | login_success | ok     | gsql@[local]    |
139823109633792
(1 row)
```

– Check the number, date, and time of failed attempts since the previous successful login.

```
gaussdb=> SELECT * FROM login_audit_messages_pid(false);
 username | database |       logintime        |    mytype    | result |  client_conninfo  |    backendid
----------+----------+------------------------+--------------+--------+-------------------+-----------------
 omm      | postgres | 2020-06-29 21:57:55+08 | login_failed | failed | [unknown]@[local] |
139823109633792
 omm      | postgres | 2020-06-29 21:57:53+08 | login_failed | failed | [unknown]@[local] |
139823109633792
(2 rows)
```

- inet_server_addr()

  Description: Displays the server IP address.

  Return type: inet

  Example:

```
gaussdb=# SELECT inet_server_addr();
 inet_server_addr
------------------
 10.10.0.13
(1 row)
```

  NOTE

  - The client IP address 10.10.0.50 and server IP address 10.10.0.13 are used as an example.
  - If a local connection is used, the value is empty.

- inet_client_addr()

  Description: Displays the client IP address.

  Return type: inet

  Example:

```
gaussdb=# SELECT inet_client_addr();
 inet_client_addr
------------------
 10.10.0.50
(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- The client IP address 10.10.0.50 and server IP address 10.10.0.13 are used as an example.
- If a local connection is used, the value is empty.

- gs_query_audit(starttime, endtime, audit_log)

  Description: Queries the traditional audit logs of the current CN.

  Parameters: **timestamptz starttime** and **timestamptz endtime[,audit_log]**

  Return type: record

  Table 1-99 describes the return fields.

  Table 1-99 Fields returned by gs_query_audit

Name	Type	Description
time	timestamp with time zone	Operation time
type	text	Operation
result	text	Operation result
userid	oid	User ID
username	text	Name of the user who performs the operation
database	text	Database name
client_conninfo	text	Client connection information
object_name	text	Object name
detail_info	text	Operation details
node_name	text	Node name
thread_id	text	Thread ID
local_port	text	Local port
remote_port	text	Remote port

  Example:

```
gaussdb=# SELECT * FROM gs_query_audit('2025-01-14 11:35:41','2025-01-14 11:35:42');
          time          |     type      | result | userid | username | database | client_conninfo | object_name
|                        detail_info                         |  node_name   |            thread_id
        | local_port | remote_port
------------------------+---------------+--------+--------+----------+----------+-----------------+-------------
+------------------------------------------------------------+--------------+-----------------------
---------+------------+-------------
 2025-01-14 11:35:41+08 | login_success | ok     | 10     |  omm     | postgres | gsql@[local]    |

(3 rows)
```

- pg_query_audit(starttime, endtime, audit_log)

  Description: Queries the traditional audit logs of the current CN.

  Parameters: **timestamptz starttime** and **timestamptz endtime[,audit_log]**

  Return type: record

  Table 1-100 describes the return fields.

  Table 1-100 Fields returned by pg_query_audit

Name	Type	Description
time	timestamp with time zone	Operation time
type	text	Operation
result	text	Operation result
userid	oid	User ID
username	text	Name of the user who performs the operation
database	text	Database name
client_conninfo	text	Client connection information
object_name	text	Object name
detail_info	text	Operation details
node_name	text	Node name
thread_id	text	Thread ID
local_port	text	Local port
remote_port	text	Remote port

  Example:

```
gaussdb=# SELECT * FROM pg_query_audit('2025-01-14 11:35:41','2025-01-14 11:35:42');
          time          |     type      | result | userid | username | database | client_conninfo | object_name
|                       detail_info                        |  node_name   |           thread_id     | local_port |
remote_port

139779518232320@790140941809559 | 45002      | null
(3 rows)
```

- gs_query_audit_dist(starttime, endtime)

  Description: Queries the traditional audit logs of all CNs. The return fields of this function are the same as those of the gs_query_audit function.

  Parameters: **timestamptz starttime** and **timestamptz endtime**

  Return type: record

  Example:

```
gaussdb=# SELECT * FROM gs_query_audit_dist('2025-01-14 11:35:41','2025-01-14 11:35:42');
          time          |     type      | result | userid | username | database | client_conninfo | object_name
|                       detail_info                        |  node_name   |           thread_id       | local_port |
remote_port

- pgxc_query_audit(starttime, endtime)

  Description: Queries the traditional audit logs of all CNs. The return fields of this function are the same as those of the gs_query_audit function.

  Parameters: **timestamptz starttime** and **timestamptz endtime**

  Return type: record

  Example:

```
gaussdb=# SELECT * FROM pgxc_query_audit('2025-01-14 11:35:41','2025-01-14 11:35:42');
          time          |     type      | result | userid | username | database | client_conninfo | object_name
|                       detail_info                        |  node_name   |           thread_id       | local_port |

- gs_query_unified_audit(starttime, endtime, audit_log)

  Description: Queries the unified audit logs of all CNs.

  Parameters: **timestamptz starttime** and **timestamptz endtime[,audit_log text]**

  Return type: record

  The following table describes the returned columns.

  Table 1-101 Unified audit log parameters

Name	Description
time	Operation time.
type	Operation type.
result	Operation result.
userid	User ID.
username	Name of the user who performs the operation.
database	Database name.
client_conninfo	Client connection information.
object_name	Operation object name.
detail_info	Operation details.
node_name	Node name.
thread_id	Thread ID.
local_port	Local port.
remote_port	Remote port.
policy_id	Unified audit policy ID.
unified_audit_type	Unified audit policy type.
unified_audit_policy	Unified audit policy information.

  Example:

```
gaussdb=# SELECT * FROM gs_query_unified_audit(sysdate-1,sysdate+1) WHERE type='audit_policy';
          time          |     type     | result | userid | username | database | client_conninfo |
object_name              |                        detail_info                         |  node_name   |
```

(6 rows)
```

- gs_delete_audit(starttime, endtime)

  Description: Deletes audit logs in a specified period.

  Parameters: **timestamptz starttime** and **timestamptz endtime**

  Return type: void

  Example:

  ```
  gaussdb=# SELECT * FROM gs_delete_audit('2025-01-14 00:00:00','2025-01-14 00:01:00');
   gs_delete_audit
  -----------------

  (1 row)
  ```

- pg_delete_audit(starttime, endtime)

  Description: Deletes audit logs in a specified period.

  Parameters: **timestamptz starttime** and **timestamptz endtime**

  Return type: void

  Example:

  ```
  gaussdb=# SELECT * FROM pg_delete_audit('2025-01-14 00:00:00','2025-01-14 00:01:00');
   pg_delete_audit
  -----------------

  (1 row)
  ```

- alldigitsmasking()

  Description: Specifies the internal function of the masking policy, which is used to anonymize all characters.

  Parameter: col text, letter character default '0'

  Return type: text

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- creditcardmasking()

  Description: Specifies the internal function of the masking policy, which is used to anonymize all credit card information.

  Parameter: col text, letter character default 'x'

  Return type: text

- randommasking()

  Description: Specifies the internal function of the masking policy. The random policy is used.

  Parameter: col text

  Return type: text

- fullemailmasking()

  Description: Specifies the internal function of the masking policy, which is used to anonymize the text before the last period (.) except the at sign (@).

  Parameter: col text, letter character default 'x'

  Return type: text

- basicemailmasking()

  Description: Specifies the internal function of the masking policy, which is used to anonymize the text before the first at sign (@).

  Parameter: col text, letter character default 'x'

  Return type: text

- shufflemasking()

  Description: Specifies the internal function of the masking policy, which is used to sort characters out of order.

  Parameter: col text

  Return type: text

- regexpmasking()

  Description: Specifies the internal function of the masking policy, which is used to replace characters using a regular expression.

  Parameter: col text, reg text, replace_text text, pos INTEGER default 0, reg_len INTEGER default -1

  Return type: text

- gs_encrypt(encryptstr, keystr, encrypttype)

  Description: Encrypts **encryptstr** strings using **keystr** as the key and returns encrypted strings based on **encrypttype**.

  Return type: text

Parameter	Type	Description	Value Range
encryptstr	text	Data to be encrypted	-

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Type	Description	Value Range
keystr	text	Encryption password	The value ranges from 8 to 16 bytes and contains at least three types of the following characters: uppercase letters, lowercase letters, digits, and special characters.
encrypttype	text	Encryption/ Decryption type (case-insensitive)	aes128, sm4, aes128_cbc_sha256, aes256_cbc_sha256, aes128_gcm_sha256, aes256_gcm_sha256, and sm4_ctr_sm3

Example:

```
gaussdb=#  SELECT gs_encrypt('MPPDB', 'Asdf1234', 'sm4');
       gs_encrypt
------------------------------
 ZBzOmaGA4Bb+coyucJ0B8AkIShqc
(1 row)
```

NOTE

An encryption password is required during the execution of this function. For security purposes, the gsql tool does not record the SQL statements containing the function name in the execution history. That is, the execution history of this function cannot be found in **gsql** by paging up and down.

aes128 and **sm4** are compatible with earlier versions. The **aes128** encryption and decryption algorithm in CBC mode is used for AES-128 encryption and decryption, and **SHA1** is used for integrity check. The **sm4** encryption and decryption algorithm uses the SM4 CTR mode and does not perform integrity check.

- gs_decrypt(decryptstr, keystr, decrypttype)

  Description: Decrypts **decryptstr** strings using **keystr** as the decryption password and returns decrypted strings based on **decrypttype**. The **decrypttype** and **keystr** used for decryption must be consistent with **encrypttype** and **keystr** used for encryption. **keystr** cannot be empty.

  This function needs to be used with the **gs_encrypt** encryption function.

  Return type: text

Parameter	Type	Description	Value Range
decryptstr	text	Data to be decrypted	-
keystr	text	Decryption password	The value ranges from 8 to 16 bytes and contains at least three types of the following characters: uppercase letters, lowercase letters, digits, and special characters.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Type	Description	Value Range
decrypttype	text	Encryption/Decryption type (case-insensitive)	aes128, sm4, aes128_cbc_sha256, aes256_cbc_sha256, aes128_gcm_sha256, aes256_gcm_sha256, and sm4_ctr_sm3

Example:

```
gaussdb=# SELECT gs_decrypt('ZBzOmaGA4Bb+coyucJ0B8AkIShqc', 'Asdf1234', 'sm4');
 gs_decrypt
------------
 MPPDB
(1 row)
```

NOTE

A decryption password is required during the execution of this function. For security purposes, the gsql tool does not record the SQL statements containing the function name in the execution history. That is, the execution history of this function cannot be found in gsql by paging up and down.

aes128 and **sm4** are compatible with earlier versions. The **aes128** encryption and decryption algorithm in CBC mode is used for AES-128 encryption and decryption, and **SHA1** is used for integrity check. The **sm4** encryption and decryption algorithm uses the SM4 CTR mode and does not perform integrity check.

- gs_encrypt_bytea(encryptstr, keystr, encrypttype)

  Description: Encrypts **encryptstr** strings using **keystr** as the encryption password and returns encrypted strings based on **encrypttype**.

  Return type: bytea

Parameter	Type	Description	Value Range
encryptstr	text	Data to be encrypted	-
keystr	text	Encryption password	The value ranges from 8 to 16 bytes and contains at least three types of the following characters: uppercase letters, lowercase letters, digits, and special characters.
encrypttype	text	Encryption/Decryption type (case-insensitive)	aes128_cbc_sha256, aes256_cbc_sha256, aes128_gcm_sha256, aes256_gcm_sha256, and sm4_ctr_sm3

Example:

```
gaussdb=#  SELECT gs_encrypt_bytea('MPPDB', 'Asdf1234', 'sm4_ctr_sm3');
                                gs_encrypt_bytea
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```

\x90e286971c2c70410def0a2814af4ac44c737926458b66271d9d1547bc937395ca018d7755672fa9dc3c
dc6ec4a76001dc0e137f3bc5c8a5c51143561f1d09a848bfdebfec5e
(1 row)
```

NOTE

An encryption password is required during the execution of this function. For security purposes, the gsql tool does not record the SQL statements containing the function name in the execution history. That is, the execution history of this function cannot be found in gsql by paging up and down.

- gs_decrypt_bytea(decryptstr, keystr, decrypttype)

  Description: Decrypts **decryptstr** strings using **keystr** as the decryption password and returns decrypted strings based on **decrypttype**. The **decrypttype** and **keystr** used for decryption must be consistent with **encrypttype** and **keystr** used for encryption. **keystr** cannot be empty.

  This function needs to be used with the **gs_encrypt_bytea** encryption function.

  Return type: text

Parameter	Type	Description	Value Range
decryptstr	bytea	Data to be decrypted	-
keystr	text	Decryption password	The value ranges from 8 to 16 bytes and contains at least three types of the following characters: uppercase letters, lowercase letters, digits, and special characters.
decrypttype	text	Encryption/ Decryption type (case-insensitive)	aes128_cbc_sha256, aes256_cbc_sha256, aes128_gcm_sha256, aes256_gcm_sha256, and sm4_ctr_sm3

  Example:

```
gaussdb=# SELECT
gs_decrypt_bytea('\x90e286971c2c70410def0a2814af4ac44c737926458b66271d9d1547bc937395ca018
d7755672fa9dc3cdc6ec4a76001dc0e137f3bc5c8a5c51143561f1d09a848bfdebfec5e', 'Asdf1234',
'sm4_ctr_sm3');
 gs_decrypt_bytea
------------------
 MPPDB
(1 row)
```

NOTE

A decryption password is required during the execution of this function. For security purposes, the gsql tool does not record the SQL statements containing the function name in the execution history. That is, the execution history of this function cannot be found in gsql by paging up and down.

1.6.21 Ledger Database Functions

- get_dn_hist_relhash(text, text)

  Description: Returns the hash value of table-level data in a specified tamper-proof user table. This function can be called only between distributed nodes or through EXECUTE DIRECT ON. A message indicating insufficient permission is displayed when all users call this function.

  Parameter type: text

  Return type: hash16

- ledger_hist_check(text, text)

  Description: Verifies the consistency between the hash value of table-level data in a specified tamper-proof user table and that in the corresponding history table.

  Parameter type: text

  Return type: Boolean

  Example:

  ```
  -- Create a schema.
  gaussdb=# CREATE SCHEMA ledgernsp WITH BLOCKCHAIN;
  -- Create a table.
  gaussdb=# CREATE TABLE ledgernsp.tab(a int, b text);
  -- Insert data.
  gaussdb=# INSERT INTO ledgernsp.tab values(generate_series(1, 10000), 'test');
  gaussdb=# SELECT ledger_hist_check('ledgernsp','tab');
   ledger_hist_check
  -------------------
   t
  (1 row)
  ```

- ledger_hist_repair(text, text)

  Description: Restores the hash value of the history table corresponding to the specified tamper-proof user table to be the same as that of the user table, and returns the hash difference.

  Parameter type: text

  Return type: hash16

  Example:

  ```
  gaussdb=# SELECT ledger_hist_repair('ledgernsp','tab');
   ledger_hist_repair
  --------------------
   0000000000000000
  (1 row)
  ```

- ledger_hist_archive(text, text)

  Description: Archives the history table corresponding to a specified tamper-proof user table to the **hist_back** folder in the audit log directory. If the name of a user history table contains a slash (/), the slash (/) is replaced with an underscore (_) in the name of the file generated during archiving.

  Parameter type: text

  Return type: Boolean

  Example:

  ```
  gaussdb=# EXECUTE DIRECT ON (datanode1) 'select pg_catalog.ledger_hist_archive(''ledgernsp'',
  ''tab'');';
   ledger_hist_archive
  ---------------------
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
 t
(1 row)
```

- ledger_gchain_check(text, text)

  Description: Verifies the consistency between the history table hash corresponding to the specified tamper-proof user table and the relhash corresponding to the global history table.

  Parameter type: text

  Return type: Boolean

  Example:

  ```
  gaussdb=# SELECT ledger_gchain_check('ledgernsp','tab');
   ledger_gchain_check
  ---------------------
   t
  (1 row)
  ```

- ledger_gchain_repair(text, text)

  Description: Restores relhash of a specified tamper-proof user table in the global history table so that the hash is the same as that in the history table, and returns the total hash value of the specified table.

  Parameter type: text

  Return type: hash16

  Example:

  ```
  gaussdb=# SELECT ledger_gchain_repair('ledgernsp','tab');
   ledger_gchain_repair
  ----------------------
   da30c1260af5be50
  (1 row)
  ```

- ledger_gchain_archive(void)

  Description: Archives global history tables to the **hist_back** folder in the audit log directory.

  Parameter type: void

  Return type: Boolean

  Example:

  ```
  gaussdb=# SELECT ledger_gchain_archive();
   ledger_gchain_archive
  -----------------------
   t
  (1 row)
  -- Clean the environment.
  gaussdb=# DROP TABLE ledgernsp.tab;
  gaussdb=# DROP SCHEMA ledgernsp;
  ```

- hash16in(cstring)

  Description: Converts the input hexadecimal string into the internal hash16 format.

  Parameter type: cstring

  Return type: hash16

- hash16out(hash16)

  Description: Converts internal hash16 data to hexadecimal cstring data.

  Parameter type: hash16

  Return type: cstring

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- hash32in(cstring)

  Description: Converts the input hexadecimal string (32 characters) into the internal type hash32.

  Parameter type: cstring

  Return type: hash32
- hash32out(hash32)

  Description: Converts internal hash32 data to hexadecimal cstring data.

  Parameter type: hash32

  Return type: cstring

1.6.22 Encrypted Functions and Operators

- byteawithoutorderwithequalcolin(cstring)

  Description: Converts input data to the internal byteawithoutorderwithequalcol format.

  Parameter type: cstring

  Return type: byteawithoutorderwithequalcol
- byteawithoutorderwithequalcolout(byteawithoutorderwithequalcol)

  Description: Converts internal data of the byteawithoutorderwithequalcol type to data of the cstring type.

  Parameter type: byteawithoutorderwithequalcol

  Return type: cstring
- byteawithoutorderwithequalcolsend(byteawithoutorderwithequalcol)

  Description: Converts data of the byteawithoutorderwithequalcol type to data of the bytea type.

  Parameter type: byteawithoutorderwithequalcol

  Return type: bytea
- byteawithoutorderwithequalcolrecv(internal)

  Description: Converts data of the internal type to data of the byteawithoutorderwithequalcol type.

  Parameter type: internal

  Return type: byteawithoutorderwithequalcol
- byteawithoutorderwithequalcoltypmodin(cstring[])

  Description: Converts data of the cstring[] type to data of the byteawithoutorderwithequalcol type.

  Parameter type: cstring[]

  Return type: int4
- byteawithoutorderwithequalcoltypmodout(int4)

  Description: Converts data of the int4 type into data of the cstring type.

  Parameter type: int4

  Return type: cstring
- byteawithoutordercolin(cstring)

  Description: Converts input data to the internal byteawithoutordercolin format.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter type: cstring

Return type: byteawithoutordercol

- byteawithoutordercolout(byteawithoutordercol)

  Description: Converts internal data of the byteawithoutordercol type to data of the cstring type.

  Parameter type: byteawithoutordercol

  Return type: cstring

- byteawithoutordercolsend(byteawithoutordercol)

  Description: Converts data of the byteawithoutordercol type to data of the bytea type.

  Parameter type: byteawithoutordercol

  Return type: bytea

- byteawithoutordercolrecv(internal)

  Description: Converts data of the internal type to data of the byteawithoutordercol type.

  Parameter type: internal

  Return type: byteawithoutordercol

- byteawithoutorderwithequalcolcmp(byteawithoutorderwithequalcol, byteawithoutorderwithequalcol)

  Description: Compares two byteawithoutorderwithequalcol data sizes. If the first data size is smaller than the second one, **-1** is returned. If the first data size is equal to the second one, **0** is returned. If the first data size is larger than the second one, **1** is returned.

  Parameter type: byteawithoutorderwithequalcol, byteawithoutorderwithequalcol

  Return type: int4

- byteawithoutorderwithequalcolcmpbytear(byteawithoutorderwithequalcol, bytea)

  Description: Compares the byteawithoutorderwithequalcol and bytea data sizes. If the first data size is smaller than the second one, **-1** is returned. If the first data size is equal to the second one, **0** is returned. If the first data size is larger than the second one, **1** is returned.

  Parameter type: byteawithoutorderwithequalcol, bytea

  Return type: int4

- byteawithoutorderwithequalcolcmpbyteal(bytea, byteawithoutorderwithequalcol)

  Description: Compares the bytea and byteawithoutorderwithequalcol data sizes. If the first data size is smaller than the second one, **-1** is returned. If the first data size is equal to the second one, **0** is returned. If the first data size is larger than the second one, **1** is returned.

  Parameter type: bytea, byteawithoutorderwithequalcol

  Return type: int4

- byteawithoutorderwithequalcoleq(byteawithoutorderwithequalcol, byteawithoutorderwithequalcol)

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description: Compares two byteawithoutorderwithequalcol data records. If they are the same, **true** is returned. Otherwise, **false** is returned.

Parameter type: byteawithoutorderwithequalcol, byteawithoutorderwithequalcol

Return type: Boolean

- byteawithoutorderwithequalcoleqbyteal(bytea, byteawithoutorderwithequalcol)

  Description: Compares the bytea and byteawithoutorderwithequalcol data records. If they are the same, **true** is returned. Otherwise, **false** is returned.

  Parameter type: bytea, byteawithoutorderwithequalcol

  Return type: Boolean

- byteawithoutorderwithequalcoleqbytear(byteawithoutorderwithequalcol, bytea)

  Description: Compares the byteawithoutorderwithequalcol and bytea data records. If they are the same, **true** is returned. Otherwise, **false** is returned.

  Parameter type: byteawithoutorderwithequalcol, bytea

  Return type: Boolean

- byteawithoutorderwithequalcolne(byteawithoutorderwithequalcol, byteawithoutorderwithequalcol)

  Description: Compares two byteawithoutorderwithequalcol data records. If they are different, **true** is returned. Otherwise, **false** is returned.

  Parameter type: byteawithoutorderwithequalcol, byteawithoutorderwithequalcol

  Return type: Boolean

- byteawithoutorderwithequalcolnebyteal(bytea, byteawithoutorderwithequalcol)

  Description: Compares the bytea and byteawithoutorderwithequalcol data records. If they are the same, **true** is returned. Otherwise, **false** is returned.

  Parameter type: bytea, byteawithoutorderwithequalcol

  Return type: Boolean

- byteawithoutorderwithequalcolnebytear(byteawithoutorderwithequalcol, bytea)

  Description: Compares the byteawithoutorderwithequalcol and bytea data records. If they are the same, **true** is returned. Otherwise, **false** is returned.

  Parameter type: byteawithoutorderwithequalcol, bytea

  Return type: Boolean

- hll_hash_byteawithoutorderwithequalcol(byteawithoutorderwithequalcol)

  Description: Returns the hll hash value of byteawithoutorderwithequalcol.

  Parameter type: byteawithoutorderwithequalcol

  Return type: hll_hashval

- tee_sortsupport(internal)

  Description: Function used to support sorting, which is internally called during sorting and cannot be called by users.

  Parameter type: internal

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Return type: void

- teegtsel(internal, oid, internal, integer)

  Description: Selectivity of ciphertext greater than and greater than or equal to. The default value **0.3333333333333333** is returned. It cannot be called by common users.

  Parameter type: internal, oid, internal, integer

  Return type: double precision

- teeltsel(internal, oid, internal, integer)

  Description: Selectivity of ciphertext less than and less than or equal to. The default value **0.3333333333333333** is returned. It cannot be called by common users.

  Parameter type: internal, oid, internal, integer

  Return type: double precision

- teelikesel(internal, oid, internal, integer)

  Description: Selectivity of ciphertext fuzzy match. The default value **0.005** is returned. It cannot be called by common users.

  Parameter type: internal, oid, internal, integer

  Return type: double precision

- teenlikesel(internal, oid, internal, integer)

  Description: Selectivity of ciphertext non-fuzzy-match. The default value **0.005** is returned. It cannot be called by common users.

  Parameter type: internal, oid, internal, integer

  Return type: double precision

- sum(byteawithoutorderwithequalcol)

  Description: Aggregates the ciphertext sum.

  Parameter type: byteawithoutorderwithequalcol

  Return type: byteawithoutorderwithequalcol

- avg(byteawithoutorderwithequalcol)

  Description: Aggregates the ciphertext average value.

  Parameter type: byteawithoutorderwithequalcol

  Return type: byteawithoutorderwithequalcol

- min(byteawithoutorderwithequalcol)

  Description: Aggregates the ciphertext minimum value.

  Parameter type: byteawithoutorderwithequalcol

  Return type: byteawithoutorderwithequalcol

- max(byteawithoutorderwithequalcol)

  Description: Aggregates the ciphertext maximum value.

  Parameter type: byteawithoutorderwithequalcol

  Return type: byteawithoutorderwithequalcol

- stddev_samp(byteawithoutorderwithequalcol)

  Description: Aggregates the standard deviation of ciphertext samples.

  Parameter type: byteawithoutorderwithequalcol

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Return type: byteawithoutorderwithequalcol

- stddev_pop(byteawithoutorderwithequalcol)

  Description: Aggregates the total standard deviation of ciphertext.

  Parameter type: byteawithoutorderwithequalcol

  Return type: byteawithoutorderwithequalcol

- var_samp(byteawithoutorderwithequalcol)

  Description: Aggregates the variance of ciphertext samples.

  Parameter type: byteawithoutorderwithequalcol

  Return type: byteawithoutorderwithequalcol

- var_pop(byteawithoutorderwithequalcol)

  Description: Aggregates the total variance of ciphertext.

  Parameter type: byteawithoutorderwithequalcol

  Return type: byteawithoutorderwithequalcol

- tee_trans(byteawithoutorderwithequalcol, byteawithoutorderwithequalcol)

  Description: Aggregates the internal processing function for ciphertext. It cannot be called by common users.

  Parameter type: byteawithoutorderwithequalcol, byteawithoutorderwithequalcol

  Return type: byteawithoutorderwithequalcol

- tee_collect(byteawithoutorderwithequalcol, byteawithoutorderwithequalcol)

  Description: Aggregates the internal processing function for ciphertext. It cannot be called by common users.

  Parameter type: byteawithoutorderwithequalcol, byteawithoutorderwithequalcol

  Return type: byteawithoutorderwithequalcol

- tee_final(byteawithoutorderwithequalcol)

  Description: Aggregates the internal processing function for ciphertext. It cannot be called by common users.

  Parameter type: byteawithoutorderwithequalcol

  Return type: byteawithoutorderwithequalcol

- ce_encrypt_deterministic(text, oid)

  Description: Encrypts the plaintext of the TEXT type to the encrypted equivalent structure. The key OID is the value of **column_key_distributed_id** in the gs_column_keys system catalog. This function is not supported in the current version.

  Parameter type: text, oid

  Return type: byteawithoutorderwithequalcol

- ce_encrypt_deterministic(int1, oid)

  Description: Encrypts the plaintext of the int1 type to the encrypted equivalent structure. The key OID is the value of **column_key_distributed_id** in the gs_column_keys system catalog. This function is not supported in the current version.

  Parameter type: int1, oid

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Return type: byteawithoutorderwithequalcol

- ce_encrypt_deterministic(int2, oid)

  Description: Encrypts the plaintext of the int2 type to the encrypted equivalent structure. The key OID is the value of **column_key_distributed_id** in the gs_column_keys system catalog. This function is not supported in the current version.

  Parameter type: int2, oid

  Return type: byteawithoutorderwithequalcol

- ce_encrypt_deterministic(int4, oid)

  Description: Encrypts the plaintext of the int4 type to the encrypted equivalent structure. The key OID is the value of **column_key_distributed_id** in the gs_column_keys system catalog. This function is not supported in the current version.

  Parameter type: int4, oid

  Return type: byteawithoutorderwithequalcol

- ce_encrypt_deterministic(int8, oid)

  Description: Encrypts the plaintext of the int8 type to the encrypted equivalent structure. The key OID is the value of **column_key_distributed_id** in the gs_column_keys system catalog. This function is not supported in the current version.

  Parameter type: int8, oid

  Return type: byteawithoutorderwithequalcol

- ce_encrypt_deterministic(float4, oid)

  Description: Encrypts the plaintext of the float4 type to the encrypted equivalent structure. The key OID is the value of **column_key_distributed_id** in the gs_column_keys system catalog. This function is not supported in the current version.

  Parameter type: float4, oid

  Return type: byteawithoutorderwithequalcol

- ce_encrypt_deterministic(float8, oid)

  Description: Encrypts the plaintext of the float8 type to the encrypted equivalent structure. The key OID is the value of **column_key_distributed_id** in the gs_column_keys system catalog. This function is not supported in the current version.

  Parameter type: float8, oid

  Return type: byteawithoutorderwithequalcol

- ce_encrypt_deterministic(numeric, oid)

  Description: Encrypts the plaintext of the numeric type to the encrypted equivalent structure. The key OID is the value of **column_key_distributed_id** in the gs_column_keys system catalog. This function is not supported in the current version.

  Parameter type: numeric, oid

  Return type: byteawithoutorderwithequalcol

- ce_encrypt_deterministic(clob, oid)

  Description: Encrypts the plaintext of the CLOB type to the encrypted equivalent structure. The key OID is the value of **column_key_distributed_id**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

in the gs_column_keys system catalog. This function is not supported in the current version.

Parameter type: clob, oid

Return type: byteawithoutorderwithequalcol

- ce_encrypt_deterministic(varchar, oid)

  Description: Encrypts the plaintext of the varchar type to the encrypted equivalent structure. The key OID is the value of **column_key_distributed_id** in the gs_column_keys system catalog. This function is not supported in the current version.

  Parameter type: varchar, oid

  Return type: byteawithoutorderwithequalcol

- ce_encrypt_deterministic(nvarchar2, oid)

  Description: Encrypts the plaintext of the nvarchar2 type to the encrypted equivalent structure. The key OID is the value of **column_key_distributed_id** in the gs_column_keys system catalog. This function is not supported in the current version.

  Parameter type: nvarchar2, oid

  Return type: byteawithoutorderwithequalcol

- ce_encrypt_deterministic(bpchar, oid)

  Description: Encrypts the plaintext of the bpchar type to the encrypted equivalent structure. The key OID is the value of **column_key_distributed_id** in the gs_column_keys system catalog. This function is not supported in the current version.

  Parameter type: bpchar, oid

  Return type: byteawithoutorderwithequalcol

- ce_encrypt_deterministic(bytea, oid)

  Description: Encrypts the plaintext of the bytea type to the encrypted equivalent structure. The key OID is the value of **column_key_distributed_id** in the gs_column_keys system catalog. This function is not supported in the current version.

  Parameter type: bytea, oid

  Return type: byteawithoutorderwithequalcol

- ce_decrypt_deterministic(byteawithoutorderwithequalcol, oid)

  Description: Decrypts the ciphertext of the encrypted equivalent structure to the plaintext data of the text type. The key OID is the value of **column_key_distributed_id** in the gs_column_keys system catalog. This function is not supported in the current version.

  Parameter type: byteawithoutorderwithequalcol, oid

  Return type: text

NOTE

The following functions starting with ce_encrypt/ce_decrypt exist in the pg_catalog namespace.

- ce_encrypt_text(text, int4, boolean, int4, internal)

  Description: Encryption function for fully-encrypted type conversion. It cannot be called by common users.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter type: text, int4, Boolean, int4, internal

Return type: byteawithoutorderwithequalcol

- ce_encrypt_varchar(varchar, int4, boolean, int4, internal)

  Description: Encryption function for fully-encrypted type conversion. It cannot be called by common users.

  Parameter type: varchar, int4, Boolean, int4, internal

  Return type: byteawithoutorderwithequalcol

- ce_encrypt_nvarchar2(nvarchar2, int4, boolean, int4, internal)

  Description: Encryption function for fully-encrypted type conversion. It cannot be called by common users.

  Parameter type: nvarchar2, int4, Boolean, int4, internal

  Return type: byteawithoutorderwithequalcol

- ce_encrypt_bpchar(bpchar, int4, boolean, int4, internal)

  Description: Encryption function for fully-encrypted type conversion. It cannot be called by common users.

  Parameter type: bpchar, int4, Boolean, int4, internal

  Return type: byteawithoutorderwithequalcol

- ce_encrypt_int1(int1, int4, boolean, int4, internal)

  Description: Encryption function for fully-encrypted type conversion. It cannot be called by common users.

  Parameter type: int1, int4, Boolean, int4, internal

  Return type: byteawithoutorderwithequalcol

- ce_encrypt_int2(int2, int4, boolean, int4, internal)

  Description: Encryption function for fully-encrypted type conversion. It cannot be called by common users.

  Parameter type: int2, int4, Boolean, int4, internal

  Return type: byteawithoutorderwithequalcol

- ce_encrypt_int4(int4, int4, boolean, int4, internal)

  Description: Encryption function for fully-encrypted type conversion. It cannot be called by common users.

  Parameter type: int4, int4, Boolean, int4, internal

  Return type: byteawithoutorderwithequalcol

- ce_encrypt_int8(int8, int4, boolean, int4, internal)

  Description: Encryption function for fully-encrypted type conversion. It cannot be called by common users.

  Parameter type: int8, int4, Boolean, int4, internal

  Return type: byteawithoutorderwithequalcol

- ce_encrypt_float4(float4, int4, boolean, int4, internal)

  Description: Encryption function for fully-encrypted type conversion. It cannot be called by common users.

  Parameter type: float4, int4, Boolean, int4, internal

  Return type: byteawithoutorderwithequalcol

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- ce_encrypt_float8(float8, int4, boolean, int4, internal)

  Description: Encryption function for fully-encrypted type conversion. It cannot be called by common users.

  Parameter type: float8, int4, Boolean, int4, internal

  Return type: byteawithoutorderwithequalcol
- ce_encrypt_numeric(numeric, int4, boolean, int4, internal)

  Description: Encryption function for fully-encrypted type conversion. It cannot be called by common users.

  Parameter type: numeric, int4, Boolean, int4, internal

  Return type: byteawithoutorderwithequalcol
- ce_encrypt_bytea(bytea, int4, boolean, int4, internal)

  Description: Encryption function for fully-encrypted type conversion. It cannot be called by common users.

  Parameter type: bytea, int4, Boolean, int4, internal

  Return type: byteawithoutorderwithequalcol
- ce_encrypt_clob(clob, int4, boolean, int4, internal)

  Description: Encryption function for fully-encrypted type conversion. It cannot be called by common users.

  Parameter type: clob, int4, Boolean, int4, internal

  Return type: byteawithoutorderwithequalcol
- ce_decrypt_text(byteawithoutorderwithequalcol, int4, boolean, int4, internal)

  Description: Decryption function for fully-encrypted type conversion. It cannot be called by common users.

  Parameter type: byteawithoutorderwithequalcol, int4, Boolean, int4, internal

  Return type: text
- ce_decrypt_varchar(byteawithoutorderwithequalcol, int4, boolean, int4, internal)

  Description: Decryption function for fully-encrypted type conversion. It cannot be called by common users.

  Parameter type: byteawithoutorderwithequalcol, int4, Boolean, int4, internal

  Return type: varchar
- ce_decrypt_nvarchar2(byteawithoutorderwithequalcol, int4, boolean, int4, internal)

  Description: Decryption function for fully-encrypted type conversion. It cannot be called by common users.

  Parameter type: byteawithoutorderwithequalcol, int4, Boolean, int4, internal

  Return type: nvarchar2
- ce_decrypt_bpchar(byteawithoutorderwithequalcol, int4, boolean, int4, internal)

  Description: Decryption function for fully-encrypted type conversion. It cannot be called by common users.

  Parameter type: byteawithoutorderwithequalcol, int4, Boolean, int4, internal

  Return type: bpchar

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- ce_decrypt_int1(byteawithoutorderwithequalcol, int4, boolean, int4, internal)

  Description: Decryption function for fully-encrypted type conversion. It cannot be called by common users.

  Parameter type: byteawithoutorderwithequalcol, int4, Boolean, int4, internal

  Return type: int1
- ce_decrypt_int2(byteawithoutorderwithequalcol, int4, boolean, int4, internal)

  Description: Decryption function for fully-encrypted type conversion. It cannot be called by common users.

  Parameter type: byteawithoutorderwithequalcol, int4, Boolean, int4, internal

  Return type: int2
- ce_decrypt_int4(byteawithoutorderwithequalcol, int4, boolean, int4, internal)

  Description: Decryption function for fully-encrypted type conversion. It cannot be called by common users.

  Parameter type: byteawithoutorderwithequalcol, int4, Boolean, int4, internal

  Return type: int4
- ce_decrypt_int8(byteawithoutorderwithequalcol, int4, boolean, int4, internal)

  Description: Decryption function for fully-encrypted type conversion. It cannot be called by common users.

  Parameter type: byteawithoutorderwithequalcol, int4, Boolean, int4, internal

  Return type: int8
- ce_decrypt_float4(byteawithoutorderwithequalcol, int4, boolean, int4, internal)

  Description: Decryption function for fully-encrypted type conversion. It cannot be called by common users.

  Parameter type: byteawithoutorderwithequalcol, int4, Boolean, int4, internal

  Return type: float4
- ce_decrypt_float8(byteawithoutorderwithequalcol, int4, boolean, int4, internal)

  Description: Decryption function for fully-encrypted type conversion. It cannot be called by common users.

  Parameter type: byteawithoutorderwithequalcol, int4, Boolean, int4, internal

  Return type: float8
- ce_decrypt_numeric(byteawithoutorderwithequalcol, int4, boolean, int4, internal)

  Description: Decryption function for fully-encrypted type conversion. It cannot be called by common users.

  Parameter type: byteawithoutorderwithequalcol, int4, Boolean, int4, internal

  Return type: numeric
- ce_decrypt_bytea(byteawithoutorderwithequalcol, int4, boolean, int4, internal)

  Description: Decryption function for fully-encrypted type conversion. It cannot be called by common users.

  Parameter type: byteawithoutorderwithequalcol, int4, Boolean, int4, internal

  Return type: bytea

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- ce_decrypt_clob(byteawithoutorderwithequalcol, int4, boolean, int4, internal)

  Description: Decryption function for fully-encrypted type conversion. It cannot be called by common users.

  Parameter type: byteawithoutorderwithequalcol, int4, Boolean, int4, internal

  Return type: CLOB

Examples

Encrypted equality functions such as byteawithoutorderwithequalcolin and byteawithoutorderwithequalcolout are read/write format conversion functions such as in, out, send, and recv specified by the data type byteawithoutorderwithequalcol in the database kernel. For details, see the byteain and byteaout functions of the bytea type. However, the local CEK is verified, and the function can be successfully executed only when the encrypted column contains a cekoid that exists on the localhost.

```
-- For example, use an encrypted client to connect to the database and create an encrypted table int_type.
int_col2 is the encrypted column.
gaussdb=# \key_info keyType=user_token,password=*********
gaussdb=# CREATE CLIENT MASTER KEY MyCMK WITH (KEY_STORE = user_token, ALGORITHM =
AES_256_CBC);
gaussdb=# CREATE COLUMN ENCRYPTION KEY cek1 WITH VALUES (CLIENT_MASTER_KEY = MyCMK,
ALGORITHM = AEAD_AES_256_CBC_HMAC_SHA256);
gaussdb=# CREATE TABLE IF NOT EXISTS int_type (
id INT,
int_col1 TINYINT,
int_col2 smallint ENCRYPTED WITH (COLUMN_ENCRYPTION_KEY = cek1, ENCRYPTION_TYPE =
DETERMINISTIC)
);
CREATE TABLE
gaussdb=# INSERT INTO int_type VALUES (2, 100, 200);
INSERT 0 1

-- Use a non-encrypted client to connect to the database and query the ciphertext of the encrypted column.
gaussdb=# SELECT int_col2 FROM int_type;
                                                
```

```
gaussdb=# SELECT * FROM
byteawithoutorderwithequalcolsend('\x907219912381298461289346129'::byteawithoutorderwithequalcol);
ERROR:  cek with OID 596711794 not found
LINE 1: SELECT * FROM byteawithoutorderwithequalcolsend('\x907219912...
                                                        ^
gaussdb=# SELECT * FROM byteawithoutordercolout('\x907219019999999999999123812984612893461 29');

```

1.6.23 Set Return Functions

NOTE

- If the input parameters of any function are set return functions (SRFs), expressions in the input parameter list of that function will be verified, and an error will be reported upon detecting multiple SRFs.

  Taking **SELECT div(srf(n,1),srf(m,2));** as an example:

- If the target list of the SELECT statement includes **srf**, multiple rows of data will be returned.
- If the target list of the SELECT statement includes multiple layers of nested SRFs, such as **srf(n, srf(m, 1))**, $n \times m$ rows of data will be returned. Even if strict functions are utilized, they will not be optimized as long as they are not SRFs.

  For example, **SELECT srf(n, div(srf(m, 1), NULL));div** is a strict function. If the input parameters of the function do not include **srf** but include **NULL**, the function will return **NULL**. If the input parameters include **srf**, the strict function will not be optimized and will return *m* rows of **NULL**.
- If the input parameters of an SRF include an expression whose return value is **NULL**, the SRF will return 0 rows if it is strict, and return the designated number of rows of **NULL** if it is not strict.

  For example, **srf(10, 'a')** indicates that 10 rows of **'a'** need to be returned. If **srf(10, NULL)** is passed, a strict SRF will return 0 rows, whereas a non-strict SRF will return 10 rows of **NULL**.

Series Generating Functions

- generate_series(start, stop)

  Description: Generates a series of values, from **start** to **stop** with a step size of one.

  Parameter types: int, bigint, and numeric.

  Return types: setof int, setof bigint, and setof numeric (same as the parameter types).

- generate_series(start, stop, step)

  Description: Generates a series of values, from **start** to **stop** with a step size of **step**.

  Parameter types: int, bigint, and numeric.

  Return types: setof int, setof bigint, and setof numeric (same as the parameter types).

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- generate_series(start, stop, step interval)

  Description: Generates a series of values, from **start** to **stop** with a step size of **step**.

  Parameter type: timestamp or timestamp with time zone.

  Return type: setof timestamp or setof timestamp with time zone (same as the parameter type).

When **step** is positive, zero rows are returned if **start** is greater than **stop**. Conversely, when **step** is negative, zero rows are returned if **start** is less than **stop**. Zero rows are also returned for **NULL** inputs. It is an error for **step** to be zero.

Example:

```
gaussdb=# SELECT * FROM generate_series(2,4);
 generate_series
-----------------
               2
               3
               4
(3 rows)

gaussdb=# SELECT * FROM generate_series(5,1,-2);
 generate_series
-----------------
               5
               3
               1
(3 rows)

gaussdb=# SELECT * FROM generate_series(4,3);
 generate_series
-----------------
(0 rows)

-- This example applies to the date-plus-integer operator.
gaussdb=# SELECT current_date + s.a AS dates FROM generate_series(0,14,7) AS s(a);
   dates
------------

```

- gs_search_function_with_name(funcname)

  Description: Obtains the OID of the funcname function.

  Parameter type: cstring.

  Return type: setof oid.

  ```
  -- Basic usage
  CREATE OR REPLACE FUNCTION proc_plpgsql(a int,b int, c int)
  RETURNS int AS $BODY$
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
DECLARE
BEGIN
RETURN $1 + $2;
END;

Index Generating Functions

- generate_subscripts(array anyarray, dim int)

  Description: Generates a series comprising the given array's indexes.

  Return type: setof int.

- generate_subscripts(array anyarray, dim int, reverse boolean)

  Description: Generates a series comprising the given array's indexes. When **reverse** is true, the series is returned in reverse order.

  Return type: setof int.

generate_subscripts is a function that generates the set of valid indexes for the specified dimension of the given array. Zero rows are returned for arrays that do not have the requested dimension, or for NULL arrays (but valid indexes are returned for NULL array elements). Example:

```
-- Basic usage
gaussdb=# SELECT generate_subscripts('{NULL,1,NULL,2}'::int[], 1) AS s;
 s
---
 1
 2
 3
 4
(4 rows)
-- Unnest a 2D array.
gaussdb=# CREATE OR REPLACE FUNCTION unnest2(anyarray)
RETURNS SETOF anyelement AS $$
SELECT $1[i][j]
   FROM generate_subscripts($1,1) g1(i),
        generate_subscripts($1,2) g2(j);
$$ LANGUAGE sql IMMUTABLE;

gaussdb=# SELECT * FROM unnest2(ARRAY[[1,2],[3,4]]);
 unnest2
---------
       1
       2
       3
       4
(4 rows)

-- Delete the function.
gaussdb=# DROP FUNCTION unnest2;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

1.6.24 Overloaded Query Functions

- gs_search_function_with_name_and_arg(funcname_and_argtypes cstring)

  Description: Returns the information about the overloaded function that is actually called based on the function name and input parameter type.

  Return type: text

  NOTE

  - This function is supported only in Oracle-compatible mode.
  - To query the overloading information of a function whose input parameter contains **NULL**, replace **NULL** with **UNKNOWN**.
  - If the input parameter of the function is a window function, add **over()** at the end.
  - Some functions are implemented using syntax keywords and cannot be queried using this function. For details about the mapping, see **Table 1-102**.
  - If the function to be searched for is changed or the function selection logic is changed, the result of the function may change. For details about the function selection logic, see **Functions**.

Table 1-102 Internal function calling relationship of syntax functions

Syntax Function	Internal Function
CURRENT_CATALOG	current_database()
CURRENT_DATE	The matching priority is from top to bottom. • When **a_format_date_timestamp** is set to **on** and **mapping_date_to_datea** is set to **off**, pg_systimestamp()::timestamp(0) is used. • When **mapping_date_to_datea** is set to **on**, pg_systimestamp()::datea is used. • When **a_format_version** is set to **10c** and **a_format_dev_version** is set to **s2** or later version, 'now'::text::timestamp(0) is used. • In other scenarios, text_date('now'::text) is used.
CURRENT_ROLE	current_user()
CURRENT_SCHEMA	current_schema()
CURRENT_TIME[(n)]	'now'::text::timetz[(n)]

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Syntax Function	Internal Function
CURRENT_TIMESTAMP	• For CURRENT_TIMESTAMP, pg_systimestamp() is used. • CURRENT_TIMESTAMP(int) – When **a_format_date_timestamp** is set to **on**, pg_systimestamp()::timestamptz(int) is used. – When **a_format_date_timestamp** is set to **off**, 'now'::text::timestamptz(int) is used. • For CURRENT_TIMESTAMP(float), current_timestamp(numeric) is used only when **a_format_version** is set to **'10c'** and **a_format_dev_version** is set to **'s2'** or later version.
CURRENT_USER	current_user()
DBTIMEZONE	Supported only when **a_format_version** is set to **'10c'** and **a_format_dev_version** is set to **'s2'** or later version. In this case, dbtimezone() is used.
DECODE	• If the number of parameters is 2, DECODE(A, B) corresponds to decode(A, B). • If the number of parameters is greater than 2, a case is constructed. For details, see **UNION, CASE, and Related Constructs**.
EXTRACT (field FROM source)	date_part(field, source)
GROUP_CONCAT(arg1[, …] SEPARATOR s)	group_concat(s, arg1[, …])
LOCALTIME[(n)]	'now'::text::time[(n)]

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Syntax Function	Internal Function
LOCALTIMESTAMP	• LOCALTIMESTAMP – When **a_format_date_timestamp** is set to **on**, pg_systimestamp()::timestamp is used. – When **a_format_date_timestamp** is set to **off**, 'now'::text::timestamp is used. • LOCALTIMESTAMP(int) – When **a_format_date_timestamp** is set to **on**, pg_systimestamp()::timestamp(int) is used. – When **a_format_date_timestamp** is set to **off**, 'now'::text::timestamp(int) is used. • LOCALTIMESTAMP(float) is supported only when **a_format_version** is set to **'10c'** and **a_format_dev_version** is set to **'s2'** or a later version. – When **a_format_date_timestamp** is set to **on**, current_timestamp(numeric)::timestamp is used. – When **a_format_date_timestamp** is set to **off**, there is no mapping.
NOW()	now()
OVERLAY	• OVERLAY(A PLACING B FROM C FOR D) corresponds to overlay(A, B, C, D). • OVERLAY(A PLACING B FROM C) corresponds to overlay(A, B, C).
POSITION (A IN B)	position(B, A)
SESSION_USER	session_user()
SESSIONTIMEZONE	session_time_zone()

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Syntax Function	Internal Function
SUBSTR	• SUBSTR(str, pos) corresponds to substr(str, pos). • SUBSTR(str FROM pos) corresponds to substr(str, pos). • SUBSTR(str, pos, len) corresponds to substr(str, pos, len). • SUBSTR(str FROM pos FOR len) corresponds to substr(str, pos, len). • SUBSTR(str FOR len FROM pos) corresponds to substr(str, pos, len). • SUBSTR(str FOR len) corresponds to substr(str, 1::int4, len::int4).
SUBSTRING	• SUBSTRING(str, pos) corresponds to substring(str, pos). • SUBSTRING(str FROM pos) corresponds to substring(str, pos). • SUBSTRING(str, pos, len) corresponds to substring(str, pos, len). • SUBSTRING(str FROM pos FOR len) corresponds to substring(str, pos, len). • SUBSTRING(str FOR len FROM pos) corresponds to substring(str, pos, len). • SUBSTRING(str FOR len) corresponds to substring(str, 1::int4, len::int4).
SYSDATE	• When **mapping_date_to_datea** is set to **off**, current_sysdate() is used. • When **mapping_date_to_datea** is set to **on**, sysdate_a() is used.
TRIM(BOTH [A | A [FROM]] B)	btrim(B[, A])
TRIM(LEADING [A | A [FROM]] B)	ltrim(B[, A])
TRIM(TRAILING [A | A [FROM]] B)	rtrim(B[, A])
USER	current_user()
XMLEXISTS(A PASSING [BY REF] B [BY REF])	xmlexists(A, B)

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

> **NOTE**
>
> For a syntax function that has an internal mapping function, the projection alias in the query result actually displays the name of the implementation function internally called, not the syntax keyword itself.

```
-- Basic usage.
gaussdb=# SELECT gs_search_function_with_name_and_arg('abs(int)');
     gs_search_function_with_name_and_arg
-----------------------------------------------
 pg_catalog.int4 pg_catalog.abs(pg_catalog.int4)
(1 row)

gaussdb=# SELECT gs_search_function_with_name_and_arg('pg_catalog.avg(int16)');
       gs_search_function_with_name_and_arg
-------------------------------------------------------
 pg_catalog.float8 pg_catalog.avg(pg_catalog.float8)
(1 row)

gaussdb=# SELECT gs_search_function_with_name_and_arg('lag(datea, int, unknown) over()');
                              gs_search_function_with_name_and_arg
-------------------------------------------------------------------------------------------------------------
 pg_catalog.anyelement pg_catalog.lag(pg_catalog.anyelement, pg_catalog.int4,
pg_catalog.anyelement)
(1 row)
```

- gs_search_operator_with_name_and_arg(ltype cstring, opname cstring, rtype cstring)

  Description: Returns the information about the overloaded operator that is actually called based on the operator name and the data types of the left and right operands.

  Return type: text

  > **NOTE**
  >
  > - This function is supported only in Oracle-compatible mode.
  > - Only binary operators can be queried.
  > - To query the overloading information of an operator whose input parameter contains **NULL**, replace **NULL** with **UNKNOWN**.
  > - To query the overloading information of the != or ^= operator, use <> instead.
  > - If the operator to be searched for is changed or the operator selection logic is changed, the result of the function may change. For details about the operator selection logic, see **Operators**.

```
-- Basic usage.
gaussdb=# SELECT gs_search_operator_with_name_and_arg('int', '+', 'int');
            gs_search_operator_with_name_and_arg
-------------------------------------------------------------
 pg_catalog.int4 (pg_catalog.int4 pg_catalog.+ pg_catalog.int4)
(1 row)

gaussdb=# SELECT gs_search_operator_with_name_and_arg('int', '+', 'float4');
               gs_search_operator_with_name_and_arg
-----------------------------------------------------------------------
 pg_catalog.float8 (pg_catalog.float8 pg_catalog.+ pg_catalog.float4)
(1 row)
```

1.6.25 Conditional Expression Functions

Conditional Expression Functions

- coalesce(expr1, expr2, ..., exprn)

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description: Returns the first non-NULL value in the parameter list. **COALESCE(expr1, expr2)** is equivalent to **CASE WHEN expr1 IS NOT NULL THEN expr1 ELSE expr2 END**.

Example:

```
gaussdb=# SELECT coalesce(NULL,'hello');
 coalesce
----------
 hello
(1 row)
```

Note:

- **NULL** is returned only if all parameters are **NULL**.
- It is often used to replace **NULL** with the default value.
- Like a **CASE** expression, **COALESCE** only evaluates the parameters that are needed to determine the result. That is, parameters to the right of the first non-NULL parameter are not evaluated.

- decode(base_expr, compare1, value1, compare2,value2, ... default)

  Description: Compares **base_expr** with each **compare(n)** and returns **value(n)** if they are matched. If no match occurs, **default** is returned.

  Example:

  ```
  gaussdb=# SELECT decode('A','A',1,'B',2,0);
   case
  ------
   1
  (1 row)
  ```

  Note: Operations on the XML data are not supported.

- nullif(expr1, expr2)

  Description: Returns **NULL** only when **expr1** is equal to **expr2**. Otherwise, **expr1** is returned. This function is logically equivalent to CASE WHEN expr1 = expr2 THEN NULL ELSE expr1 END.

  NOTE

  The nullif(expr1, expr2) function is a mapping function. Therefore, the corresponding function definition cannot be found in the pg_proc system catalog.

  Example:

  ```
  gaussdb=# SELECT nullif('hello','world');
   nullif
  --------
   hello
  (1 row)
  ```

  Note: Operations on the XML data are not supported.

  Assume the two parameter data types are different:

  - If implicit conversion exists between the two data types, implicitly convert the parameter of lower priority to this data type using the data type of higher priority. If the conversion succeeds, computation is performed. Otherwise, an error is reported. Example:

    ```
    gaussdb=# SELECT nullif('1234'::VARCHAR,123::INT4);
     nullif
    --------
       1234
    (1 row)
    gaussdb=# SELECT nullif('1234'::VARCHAR,'2012-12-24'::DATE);
    ERROR:  invalid input syntax for type timestamp: "1234"
    ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

  - If implicit conversion is not applied between two data types, an error is displayed. Example:

```
gaussdb=# SELECT nullif(1::bit, '1'::MONEY);
ERROR:  operator does not exist: bit = money
LINE 1: SELECT nullif(1::bit, '1'::MONEY);
                  ^
HINT:  No operator matches the given name and argument type(s). You might need to add explicit type casts.
CONTEXT:  referenced column: nullif
```

- nvl(expr1 , expr2)

  Description:

  - If the value of **expr1** is **NULL**, the value of **expr2** is returned.
  - If the value of **expr1** is not **NULL**, the value of **expr1** is returned.

  Example:

```
gaussdb=# SELECT nvl('hello','world');
  nvl
-------
 hello
(1 row)
```

  Note: **expr1** and **expr2** can be of any data type. If they have different data types, the NVL function will check whether **expr2** can be implicitly converted into **expr1**. If **expr2** can be implicitly converted into **expr1**, the function will return the data type of **expr1**. If **expr2** cannot be implicitly converted into **expr1** but **expr1** can be implicitly converted into **expr2**, the function will return the data type of **expr2**. If no implicit type conversion exists between the two parameters and the parameters are different data types, an error is reported.

- nvl2(expr1, expr2, expr3)

  Description:

  - If *expr1* is **NULL**, *expr3* is returned.
  - If *expr1* is not **NULL**, *expr2* is returned.

    NOTE

    This function takes effect in ORA-compatible databases where **a_format_version** is **10c** and **a_format_dev_version** is **s1**.

  Example:

```
gaussdb=# SELECT nvl2('hello','world','other');
  case
-------
 world
(1 row)
```

  Note: The *expr2* and *expr3* parameters can be of any type. If the last two parameters of NVL2 are of different types, check whether *expr3* can be implicitly converted to *expr2*. If *expr3* cannot be implicitly converted to *expr2*, an error is returned. If the first parameter is of the numeric type, the function converts this parameter and other parameters to the numeric type, and then compares them. If the parameters cannot be converted, an error message is displayed. If the first parameter is of another type, the function converts other parameters to the type of the first parameter for comparison. If the parameters cannot be converted, an error message is displayed.

- greatest(expr1 [, ...])

  Description: Selects the largest value from a list of any number of expressions.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Example:

```
gaussdb=# SELECT greatest(1*2,2-3,4-1);
 greatest
----------
        3
(1 row)
gaussdb=# SELECT greatest('HARRY', 'HARRIOT', 'HAROLD');
 greatest
----------
 HARRY
(1 row)
```

Note: Operations on the XML data are not supported.

NOTE

In ORA-compatible mode, when **a_format_version** is set to **10c** and **a_format_dev_version** is set to **s1**:

1. If the value of any parameter is null, the function returns null.
2. If the first parameter is of the numeric type, the function converts this parameter and other parameters to the numeric type, and then compares them. If the parameters cannot be converted, an error message is displayed. If the first parameter is of another type, the function converts other parameters to the type of the first parameter for comparison. If the parameters cannot be converted, an error message is displayed.

- least(expr1 [, ...])

  Description: Selects the smallest value from a list of any number of expressions.

  Example:

```
gaussdb=# SELECT least(1*2,2-3,4-1);
 least
-------
    -1
(1 row)
gaussdb=# SELECT least('HARRY','HARRIOT','HAROLD');
 least
--------
 HAROLD
(1 row)
```

  Note: Operations on the XML data are not supported.

  NOTE

  In ORA-compatible mode, when **a_format_version** is set to **10c** and **a_format_dev_version** is set to **s1**:

  1. If the value of any parameter is null, the function returns null.
  2. If the first parameter is of the numeric type, the function converts this parameter and other parameters to the numeric type, and then compares them. If the parameters cannot be converted, an error message is displayed. If the first parameter is of another type, the function converts other parameters to the type of the first parameter for comparison. If the parameters cannot be converted, an error message is displayed.

- EMPTY_BLOB()

  Description: Initiates a BLOB variable in an INSERT or an UPDATE statement to a **NULL** value.

  Return type: BLOB

  Example:

```
-- Create a table.
gaussdb=# CREATE TABLE blob_tb(b blob,id int) DISTRIBUTE BY REPLICATION;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
-- Insert data.
gaussdb=# INSERT INTO blob_tb VALUES (empty_blob(),1);
-- Drop the table.
gaussdb=# DROP TABLE blob_tb;
```

Note: The length is 0 obtained using DBE_LOB.GET_LENGTH.

- EMPTY_CLOB()

  Description: Initiates a CLOB variable in an INSERT or UPDATE statement to a null value.

  > NOTE
  >
  > This function is valid in ORA-compatible mode only when **a_format_version** is set to **10c** and **a_format_dev_version** is set to **s1**.

  Return type: CLOB

  Example:

```
-- Create a table.
gaussdb=# CREATE TABLE clob_tb(c clob,id int);
-- Insert data.
gaussdb=# INSERT INTO clob_tb VALUES (empty_clob(),1);
-- Drop the table.
gaussdb=# DROP TABLE clob_tb;
```

  Note: The length is 0 obtained using DBE_LOB.GET_LENGTH.

- lnnvl(condition)

  Description: Checks the condition in the WHERE clause of a query statement. If the condition is true, **false** is returned. If the condition is unknown or false, **true** is returned.

  condition: The value must be a logical expression. However, it cannot be used in composite conditions with keywords such as AND, OR, and BETWEEN.

  Return type: Boolean

  Example:

```
-- Create a table.
gaussdb=# CREATE TABLE student_demo (name VARCHAR2(20), grade  NUMBER(10,2));
CREATE TABLE

-- Insert data.
gaussdb=# INSERT INTO student_demo VALUES ('name0',0);
INSERT 0 1
gaussdb=# INSERT INTO student_demo VALUES ('name1',1);
INSERT 0 1
gaussdb=# INSERT INTO student_demo VALUES ('name2',2);
INSERT 0 1

-- Call lnnvl.
gaussdb=# SELECT * FROM student_demo WHERE LNNVL(name = 'name1');
 name  | grade
-------+-------
 name0 |  0.00
 name2 |  2.00
(2 rows)

-- Drop the table.
gaussdb=# drop table student_demo;
DROP TABLE
```

  > NOTE
  >
  > The lnnvl function is supported in ORA-compatible mode only when **a_format_version** is set to **10c** and **a_format_dev_version** is set to **s2**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- isnull(expr)

  Description: Checks whether **expr** is **NULL**. If **expr** is **NULL**, **true** is returned. Otherwise, **false** is returned. The isnull function is compatible in full mode.

  Parameter: Any type of input is supported.

  Return type: Boolean

  Example:

```
gaussdb=# SELECT isnull(null);
 isnull
--------
 t
(1 row)

gaussdb=# SELECT isnull(1);
 isnull
--------
 f
(1 row)
```

- if(expr1, expr2, expr3)

  Description: Checks the value of **expr1**. If **expr1** is **true**, **expr2** is returned. Otherwise, **expr3** is returned. This function is logically equivalent to CASE WHEN expr1 THEN expr2 ELSE expr3 END.

  Parameters: See **Table 1-103**.

  Table 1-103 Parameter types

Parameter	Valid Input Parameter Type	Description
expr1	Boolean	Determines the return value of the if() function.
expr2	Any type	If **expr1** is **true**, **expr2** is returned.
expr3	Any type	If **expr1** is **false**, **expr3** is returned.

  Return value type: related to the input parameter type. For details about the output rules, see the description.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- if(expr1, expr2, expr3) is supported only in MySQL-compatible mode.
- When the compatibility parameters **b_format_version** is set to **''** and **b_format_dev_version** is set to **''**, the output result type of the if(expr1, expr2, expr3) function is the same as that of the CASE WHEN expr1 THEN expr2 ELSE expr3 END function. When the compatibility parameters **b_format_version** is set to **'5.7'** and **b_format_dev_version** is set to **'s1'**, the return value type is deduced according to the following rules in descending order:
  - If the two input parameters are of the same type, the return value type is the same as the input parameter type.
  - If one of the input parameters is of the SET type, the return value is of the TEXT type.
  - If one of the input parameters is of the BLOB type, the return value is of the BLOB type.
  - If one of the input parameters is of the TEXT type, the return value is of the TEXT type.
  - If one of the input parameters is of the STRING type, the return value is of the TEXT type.
  - If the two input parameters are of the time type, the return value is of the TIMESTAMPTZ type; if one of the input parameters is of the time type but the other is not, the return value is of the TEXT type.
  - If both input parameters are signed integers and one input parameter is of the BIGINT type, the return value is of the BIGINT type; otherwise, the return value is of the INT type.
  - If both input parameters are unsigned integers and one input parameter is of the UNSIGNED BIGINT type, the return value is of the UNSIGNED BIGINT type; otherwise, the return value is of the UNSIGNED INT type.
  - If the two input parameters are of the floating-point type and integer type respectively, the return value is of the floating-point type.
  - Except the preceding NUMERIC type combinations, the return value for other NUMERIC type combinations is of the NUMERIC type.
  - If no implicit conversion function exists between the input parameter type and return value type, an error is reported.
- If the input parameter **expr1** is **NULL**, the returned result is the same as that when **expr1** is **FALSE**.
- The if(expr1, expr2, expr3) function is a mapping function. Therefore, the corresponding function definition cannot be found in the pg_proc system catalog.

Example:

```
-- expr1 is an expression.
gaussdb=# select if(2>3, 'true', 'false');
 case
-------
 false
(1 row)

-- If the input parameter expr1 is NULL, the result is the same as that when expr1 is false, and the value of expr3 is returned.
gaussdb=# select if(null, 'not null', 'is null');
  case
---------
 is null
(1 row)
```

- ifnull(expr1, expr2)

  Description: Returns the value of **expr2** if **expr1** is **NULL**; otherwise, returns the value of **expr1**. This function is logically equivalent to nvl(expr1, expr2).

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter: any type.

Return value type: related to the input parameter type. For details about the output rules, see the description.

NOTE

- ifnull(expr1, expr2) is supported only in MySQL-compatible mode.
- When the compatibility parameters **b_format_version** is set to **''** and **b_format_dev_version** is set to **''**, the output result type of the ifnull(expr1, expr2) function is the same as that of the nvl(expr1, expr2) function. When the compatibility parameters **b_format_version** is set to **'5.7'** and **b_format_dev_version** is set to **'s1'**, the return value type is deduced according to the following rules in descending order:
  - If the two input parameters are of the same type, the return value type is the same as the input parameter type.
  - If one of the input parameters is of the SET type, the return value is of the TEXT type.
  - If one of the input parameters is of the BLOB type, the return value is of the BLOB type.
  - If one of the input parameters is of the TEXT type, the return value is of the TEXT type.
  - If one of the input parameters is of the STRING type, the return value is of the TEXT type.
  - If the two input parameters are of the time type, the return value is of the TIMESTAMPTZ type; if one of the input parameters is of the time type but the other is not, the return value is of the TEXT type.
  - If one input parameter is of the FLOAT4 type and the other is of any numeric type, the return type is DOUBLE.
  - If both input parameters are of the NUMERIC type, the return value is of the type with higher precision. For example, if the input parameter types are TINYINT and INT, the return value type is INT.
  - If no implicit conversion function exists between the input parameter type and return value type, an error is reported.
- If both input parameters are **NULL**, the return value is **NULL**; otherwise, the first value that is not **NULL** is returned.
- The ifnull(expr1, expr2) function is a mapping function. Therefore, the corresponding function definition cannot be found in the pg_proc system catalog.

Example:

```
-- If the input parameter is an empty string, the output is an empty string instead of NULL.
gaussdb=# SELECT ifnull('', null) is null as a;
 a
---
 f
(1 row)

-- If both input parameters are NULL, the output is NULL.
gaussdb=# SELECT ifnull(null, null) is null as a;
 a
---
 t
(1 row)

-- If the input parameters are NULL and a character string, the output is the first non-null value.
gaussdb=# SELECT ifnull(null, 'A') as a;
 a
---
 A
(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

1.6.26 System Information Functions

Session Information Functions

- SYS_CONTEXT()

  Description: Returns the value of the parameter associated with the context namespace at the current time. This function has the same function as **USERENV()** when the first input parameter is **userenv**.

  Currently, the following parameters can be used as the second input parameter.

  'current_edition_name', 'current_schema', 'current_sql', 'current_user', 'current_userid', 'database_role', 'ip_address', 'is_apply_server', 'isdba', 'nls_currency', 'nls_date_format', 'nls_date_language', 'server_host', 'service_name', 'session_user', 'session_userid', 'db_name', 'db_unique_name', 'instance', 'instance_name', 'current_edition_id', 'current_schemaid', 'lang', 'language', and 'sid'

  Return type: text.

  Example:

  ```
  gaussdb=# SELECT SYS_CONTEXT('userenv','NLS_CURRENCY');
   sys_context
  -------------
   $
  (1 row)

  gaussdb=# SELECT SYS_CONTEXT('userenv','NLS_DATE_FORMAT');
    sys_context
  ---------------
   ISO, MDY
  (1 row)

  gaussdb=# SELECT SYS_CONTEXT('userenv','NLS_DATE_LANGUAGE');
   sys_context
  -------------
   en_US.UTF-8
  (1 row)
  ```

- USERENV()

  Description: Returns the value of the parameter associated with the context namespace at the current time. This function has the same function as **SYS_CONTEXT()** when the first input parameter is **userenv**.

  Currently, the following input parameters are supported:

  'current_edition_name', 'current_schema', 'current_sql', 'current_user', 'current_userid', 'database_role', 'ip_address', 'is_apply_server', 'isdba', 'nls_currency', 'nls_date_format', 'nls_date_language', 'server_host', 'service_name', 'session_user', 'session_userid', 'db_name', 'db_unique_name', 'instance', 'instance_name', 'current_edition_id', 'current_schemaid', 'lang', 'language', and 'sid'

  Currently, the following input parameters are not supported:

  'action', 'is_application_root', 'is_application_pdb', 'audited_cursorid', 'authenticated_identity', 'authentication_data', 'authentication_method', 'cdb_domain', 'cdb_name', 'client_identifier', 'con_id', 'con_name', 'current_sql_length', 'db_domain', 'db_supplemental_log_level', 'dblink_info', 'drain_status', 'entryid', 'enterprise_identity', 'fg_job_id', 'global_uid', 'identification_type', 'is_dg_rolling_upgrade', 'ldap_server_type', 'module',

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

'network_protocol', 'nls_calendar', 'nls_sort', 'nls_territory', 'oracle_home', 'os_user', 'platform_slash', 'policy_invoker', 'proxy_enterprise_identity', 'proxy_user', 'proxy_userid', 'scheduler_job', 'session_edition_id', 'session_edition_name', 'sessionid', 'statementid', 'terminal', 'unified_audit_sessionid', 'session_default_collation', 'client_info', 'bg_job_id', 'client_program_name', 'current_bind', 'global_context_memory', 'host', and 'current_sqln'

Return type: text.

Example:

```
gaussdb=# SELECT USERENV('sid');
 userenv
---------
 955
(1 row)

gaussdb=# SELECT USERENV('instance');
 userenv
---------
 14524
(1 row)

gaussdb=# SELECT USERENV('action');
 userenv
---------

(1 row)

gaussdb=# SELECT USERENV('actijj');
ERROR:  The configuration parameter actijj cannot be identified.
CONTEXT:  PL/pgSQL function userenv(text) line 114 at RETURN
referenced column: userenv
```

NOTE

If the input parameter is not supported, NULL is returned. If the input parameter is invalid, an error is reported.

- current_catalog()

  Description: Name of the current database (called "catalog" in the SQL standard)

  Return type: name.

  Example:

  ```
  testdb=# SELECT current_catalog;
   current_database
  ------------------
   testdb
  (1 row)
  ```

- current_database()

  Description: Name of the current database

  Return type: name.

  Example:

  ```
  testdb=# SELECT current_database();
   current_database
  ------------------
   testdb
  (1 row)
  ```

- current_query()

  Description: Text of the currently executing query committed by the client (which might contain more than one statement)

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Return type: text.

Example:

```
gaussdb=# SELECT current_query();
      current_query
--------------------------
 SELECT current_query();
(1 row)
```

- current_schema[()]

  Description: Name of the current schema

  Return type: name.

  Example:

  ```
  gaussdb=# SELECT current_schema();
   current_schema
  ----------------
   public
  (1 row)
  ```

  Note: **current_schema** returns the first valid schema name in the search path. (If the search path is empty or contains no valid schema name, **NULL** is returned.) This is the schema that will be used for any tables or other named objects that are created without specifying a target schema.

- current_schemas(Boolean)

  Description: Name of a schema in the search path

  Return type: name[].

  Example:

  ```
  gaussdb=# SELECT current_schemas(true);
    current_schemas
  ---------------------
   {pg_catalog,public}
  (1 row)
  ```

  Note:

  current_schemas(Boolean) returns an array of the names of all schemas in the search path. The Boolean option specifies whether implicitly included system schemas such as **pg_catalog** are included in the returned search path.

  NOTE

  The search path can be altered at runtime. The command is as follows:

  ```
  SET search_path TO schema [, schema, ...]
  ```

- database()

  Description: Returns the name of the current schema.

  Return type: name.

  Example:

  ```
  gaussdb=# SELECT database();
   database
  ----------
   public
  (1 row)
  ```

  NOTE

  This function is valid in a MySQL-compatible database when the GUC parameters **b_format_version** and **b_format_dev_version** are set to **'5.7'** and **'s1'**, respectively.

- current_user()

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description: Username in the current operating environment.

Return type: name.

Example:

```
gaussdb=# SELECT current_user;
 current_user
--------------
 omm
(1 row)
```

Note: **current_user** is the user identifier used for permission check. Generally, it indicates a session user, which can be modified by **SET ROLE**. During function execution, it is affected by the SECURITY DEFINER attribute.

- definer_current_user()

  Description: Username in the current operating environment.

  Return type: name.

  Example:

  ```
  gaussdb=# SELECT definer_current_user();
   definer_current_user
  ----------------------
   omm
  (1 row)
  ```

  Note: Generally, the results of **definer_current_user** and **current_user** are the same. However, when this function is executed in a stored procedure, the name of user who defines the current stored procedure is returned.

- pg_current_sessionid()

  Description: Session ID in the current operating environment.

  Return type: text.

  Example:

  ```
  gaussdb=# SELECT pg_current_sessionid();
      pg_current_sessionid
  ----------------------------
   1579228402.140190434944768
  (1 row)
  ```

  Note: pg_current_sessionid() is used to obtain the session ID in the current operating environment. The format of the value is *Timestamp.Session ID*. When **enable_thread_pool** is disabled, the actual session ID is the thread ID.

- pg_current_sessid()

  Description: Session ID in the current operating environment.

  Return type: text.

  Example:

  ```
  gaussdb=# select pg_current_sessid();
  pg_current_sessid
  -------------------
  140308875015936
  (1 row)
  ```

  Note: In thread pool mode, the session ID of the current session is obtained. In non-thread pool mode, the background thread ID of the current session is obtained.

- pg_current_userid()

  Description: Current user ID.

  Return type: text.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Example:

```
gaussdb=# SELECT pg_current_userid();
pg_current_userid
-------------------
10
(1 row)
```

- tablespace_oid_name(oid)

  Description: Queries the tablespace name based on the tablespace OID.

  Return type: text.

  Example:

  ```
  gaussdb=# select tablespace_oid_name(1663);
   tablespace_oid_name
  ---------------------
   pg_default
  (1 row)
  ```

- inet_client_addr()

  Description: Remote connection address. **inet_client_addr** returns the IP address of the current client.

  > NOTE
  >
  > This function takes effect only in remote connection mode.

  Return type: inet.

  Example:

  ```
  gaussdb=# SELECT inet_client_addr();
   inet_client_addr
  ------------------
   10.10.0.50
  (1 row)
  ```

- inet_client_port()

  Description: Remote connection port. **inet_client_port** returns the port number of the current client.

  > NOTE
  >
  > This function takes effect only in remote connection mode.

  Return type: int.

  Example:

  ```
  gaussdb=# SELECT inet_client_port();
   inet_client_port
  ------------------
            33143
  (1 row)
  ```

- inet_server_addr()

  Description: Local connection address. **inet_server_addr** returns the IP address on which the server accepts the current connection.

  > NOTE
  >
  > This function takes effect only in remote connection mode.

  Return type: inet.

  Example:

  ```
  gaussdb=# SELECT inet_server_addr();
   inet_server_addr
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
------------------
 10.10.0.13
(1 row)
```

- inet_server_port()

  Description: Local connection port. **inet_server_port** returns the number of the port receiving the current connection. All these functions return **NULL** if the current connection is via a UDS.

  > NOTE
  >
  > This function takes effect only in remote connection mode.

  Return type: int.

  Example:

```
gaussdb=# SELECT inet_server_port();
 inet_server_port
------------------
             8000
(1 row)
```

- pg_backend_pid()

  Description: ID of the worker thread connected to the current session.

  Return type: int.

  Example:

```
gaussdb=# SELECT pg_backend_pid();
 pg_backend_pid
-----------------
 140229352617744
(1 row)
```

- pg_conf_load_time()

  Description: Configures load time. **pg_conf_load_time** returns the timestamp when the server configuration files were last loaded.

  Return type: timestamp with time zone.

  Example:

```
gaussdb=# SELECT pg_conf_load_time();
      pg_conf_load_time
-------------------------------
 2017-09-01 16:05:23.89868+08
(1 row)
```

- pg_my_temp_schema()

  Description: OID of the temporary schema of a session. The value is **0** if the OID does not exist.

  Return type: oid.

  Example:

```
gaussdb=# SELECT pg_my_temp_schema();
 pg_my_temp_schema
-------------------
                 0
(1 row)
```

  Note: **pg_my_temp_schema** returns the OID of the current session's temporary schema, or **0** if it has no temporary schemas (because no temporary tables are created). **pg_is_other_temp_schema** returns **true** if the given OID is the OID of another session's temporary schema.

- pg_is_other_temp_schema(oid)

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description: Specifies whether the schema is the temporary schema of another session.

Return type: Boolean

Example:

```
gaussdb=# SELECT pg_is_other_temp_schema(25356);
 pg_is_other_temp_schema
-------------------------
 f
(1 row)
```

- pg_listening_channels()

  Description: Name of the channel that the session is currently listening on.

  Return type: setof text.

  Example:

  ```
  gaussdb=# SELECT pg_listening_channels();
   pg_listening_channels
  -----------------------
  (0 rows)
  ```

  Note: **pg_listening_channels** returns a set of names of channels that the current session is currently listening on.

- pg_postmaster_start_time()

  Description: Server start time. **pg_postmaster_start_time** returns the timestamp with time zone when the server is started.

  Return type: timestamp with time zone.

  Example:

  ```
  gaussdb=# SELECT pg_postmaster_start_time();
    pg_postmaster_start_time
  ------------------------------
   2017-08-30 16:02:54.99854+08
  (1 row)
  ```

- sessionid2pid()

  Description: Obtains PID information from a session ID (for example, the **sessid** column in **pv_session_stat**).

  Return type: int8

  Example:

  ```
  gaussdb=# select sessionid2pid(sessid::cstring) from pv_session_stat limit 2;
    sessionid2pid
  -----------------
   139973107902208
   139973107902208
  (2 rows)
  ```

- session_context('namespace' , 'parameter')

  Description: Obtains and returns the parameter values of a specified namespace.

  Return type: VARCHAR.

  Example:

  ```
  gaussdb=# SELECT session_context('USERENV', 'CURRENT_SCHEMA');
   session_context
  -----------------
   public
  (1 row)
  ```

  The result varies according to the current actual schema.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Note: Currently, only the SESSION_CONTEXT('USERENV', 'CURRENT_SCHEMA') and SESSION_CONTEXT('USERENV', 'CURRENT_USER') formats are supported.

- pg_trigger_depth()

  Description: Nesting level of triggers.

  Return type: int.

  Example:

```
gaussdb=# SELECT pg_trigger_depth();
 pg_trigger_depth
------------------
                0
(1 row)
```

- opengauss_version()

  Description: Referenced openGauss kernel version.

  Return type: text.

  The following is an example. Replace *x.x.x* in the query result with the actual value.

```
gaussdb=# SELECT opengauss_version();
 opengauss_version
--------------------
 x.x.x
(1 row)
```

- gs_deployment()

  Description: Deployment mode of the current system. For a distributed system, **Distribute** is returned.

  Return type: text.

  Example:

```
gaussdb=# SELECT gs_deployment();
 gs_deployment
---------------
 Distribute
(1 row)
```

- session_user

  Description: Session username.

  Return type: name.

  Example:

```
gaussdb=# SELECT session_user;
 session_user
--------------
 omm
(1 row)
```

  Note: **session_user** usually specifies the initial user connected to the current database, but system administrators can change this setting by using **SET SESSION AUTHORIZATION**.

- user

  Description: Equivalent to current_user.

  Return type: name.

  Example:

```
gaussdb=# SELECT user;
 current_user
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
--------------
 omm
(1 row)

-- Create an ORA-compatible database and set the GUC parameter a_format_func_col_name to
'user'.
gaussdb=# SET a_format_func_col_name = 'user';
SET

gaussdb=# SELECT user;
 user
------
 omm
(1 row)
```

> **NOTE**
>
> In ORA-compatible mode, if the GUC parameter **a_format_func_col_name** is set to **'user'**, the projection column name returned by the user function is **user**.

- get_shard_oids_byname()

  Description: Returns the OID of the node when the node name is entered.

  Return type: oid.

  Example:

```
gaussdb=# SELECT get_shard_oids_byname('datanode1');
 get_shard_oids_byname
-----------------------
 {16385}
(1 row)
```

- getpgusername()

  Description: Obtains the database username.

  Return type: name.

  Example:

```
gaussdb=# SELECT getpgusername();
 getpgusername
---------------
 GaussDB_userna
(1 row)
```

- getdatabaseencoding()

  Description: Obtains the database encoding mode.

  Return type: name.

  Example:

```
gaussdb=# SELECT getdatabaseencoding();
 getdatabaseencoding
---------------------
 SQL_ASCII
(1 row)
```

- version()

  Description: Version information. **version** returns a string describing a server's version.

  Return type: text.

  Example:

```
gaussdb=# SELECT version();
                                                
```

```
release
(1 row)
```

- working_version_num()

  Description: Version number. It returns a version number related to system compatibility.

  Return type: int.

  Example:

```
gaussdb=# SELECT working_version_num();
 working_version_num
---------------------
               92231
(1 row)
```

- get_hostname()

  Description: Returns the host name of the current node.

  Return type: text.

  Example:

```
gaussdb=# SELECT get_hostname();
 get_hostname
--------------
 linux-user
(1 row)
```

- get_nodename()

  Description: Returns the name of the current node.

  Return type: text.

  Example:

```
gaussdb=# SELECT get_nodename();
 get_nodename
--------------
 coordinator1
(1 row)
```

- get_nodeinfo(text)

  Description: Returns the value of the corresponding node information based on the search attribute. Currently, the search attributes include **node_name** and **node_type**.

  Return type: text.

  Example:

```
gaussdb=# SELECT get_nodeinfo('node_type');
 get_nodeinfo
--------------
 DIS_CN
(1 row)
gaussdb=# SELECT get_nodeinfo('node_name');
 get_nodeinfo
--------------
 coordinator1
(1 row)
```

- get_schema_oid(cstring)

  Description: Returns the OID of the queried schema.

  Return type: oid.

  Example:

```
gaussdb=# SELECT get_schema_oid('public');
 get_schema_oid
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
----------------
          2200
(1 row)
```

- pgxc_parse_clog(OUT xid int8, OUT nodename text, OUT status text)

  Description: Returns the status of all transactions in the current cluster.

  Return type: SETOF record

  Example:

  ```
  gaussdb=# SELECT pgxc_parse_clog();
   pgxc_parse_clog
  ----------------
  (0,dn_6004_6005_6006,INPROGRESS)
  (1,dn_6004_6005_6006,COMMITTED)
  (2,dn_6004_6005_6006,INPROGRESS)
  (3 row)
  ```

- pgxc_parse_clog(IN int2 bucketid, OUT xid int8, OUT nodename text, OUT status text)

  Description: Returns the statuses of all transactions with the specified bucket IDs in the current cluster. The input parameter is the bucket IDs of the hash bucket table. The value range is [–1,1023]. For an ordinary table, the value is **–1**.

  Return type: SETOF record

  Example:

  ```
  gaussdb=# SELECT pgxc_parse_clog('-1');
   pgxc_parse_clog
  ----------------
  (0,dn_6004_6005_6006,INPROGRESS)
  (1,dn_6004_6005_6006,COMMITTED)
  (2,dn_6004_6005_6006,INPROGRESS)
  (3 row)
  ```

- pgxc_prepared_xact()

  Description: Returns the list of transaction GIDs at the prepared stage in the cluster.

  Return type: set of text

  Example:

  ```
  gaussdb=# SELECT pgxc_prepared_xact();
   pgxc_prepared_xact
  --------------------
  (0 row)
  ```

- pgxc_xacts_iscommitted()

  Description: Returns the status of the transaction with the specified XID in the cluster. **t** indicates the committed state, **f** indicates the aborted state, and **null** indicates other states. Users must have the SYSADMIN or MONADMIN permission.

  Return type: SETOF record

  Example:

  ```
  gaussdb=# SELECT pgxc_xacts_iscommitted(1);
   pgxc_xacts_iscommitted
  --------------------
  (dn_6004_6005_6006,t)
  (cn_5001,t)
  (cn_5002,t)
  (dn_6001_6002_6003,t)
  (4 row)
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- pgxc_total_memory_detail()

  Description: Displays the memory usage in the cluster. Users must have the SYSADMIN or MONADMIN permission.

  > **NOTE**
  >
  > If the GUC parameter **enable_memory_limit** is set to **off**, this function cannot be used.

  Return type: set of pv_total_memory_detail

  Example:

```
gaussdb=# SELECT pgxc_total_memory_detail();
pgxc_total_memory_detail
--------------------
(dn_6004_6005_6006,max_process_memory,81920)
(dn_6004_6005_6006,process_used_memory,72747)
(dn_6004_6005_6006,max_dynamic_memory,12096)
(dn_6004_6005_6006,dynamic_used_memory,1530)
(4 row)
```

- pv_total_memory_detail()

  Description: Collects statistics on memory usage of the current database node in the unit of MB.

  > **NOTE**
  >
  > If the GUC parameter **enable_memory_limit** is set to **off**, this function cannot be used.

  Return type: record.

  Table 1-104 Return values

Name	Type	Description
nodename	text	Node name.

Name	Type	Description
memorytype	text	Memory type. The value must be one of the following: • **max_process_memory**: memory occupied by a GaussDB cluster instance • **process_used_memory**: memory occupied by a GaussDB thread • **max_dynamic_memory**: maximum dynamic memory • **dynamic_used_memory**: used dynamic memory • **dynamic_peak_memory**: dynamic peak memory • **dynamic_used_shrctx**: maximum dynamic shared memory context • **dynamic_peak_shrctx**: dynamic peak value of the shared memory context • **max_shared_memory**: maximum shared memory • **shared_used_memory**: used shared memory • **high_backend_thread_memory**: memory used by high-priority threads. This is valid only when **enable_threads_memory_reserve** is set to **on**. • **high_backend_thread_max_memory**: memory reserved for high-priority threads. This is valid only when **enable_threads_memory_reserve** is set to **on**. • **medium_backend_thread_memory**: memory used by medium-priority threads. This is valid only when **enable_threads_memory_reserve** is set to **on**. • **medium_backend_thread_max_memory**: memory reserved for medium-priority threads. This is valid only when **enable_threads_memory_reserve** is set to **on**. • **low_backend_thread_memory**: memory used by low-priority threads. This is valid only when **enable_threads_memory_reserve** is set to **on**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Name	Type	Description
		• **low_backend_thread_max_memory**: memory reserved for low-priority threads. This is valid only when **enable_threads_memory_reserve** is set to **on**. • **max_sctpcomm_memory**: maximum memory allowed for the communications library. • **sctpcomm_used_memory**: memory used by the communications library. • **sctpcomm_peak_memory**: memory peak of the communications library. • **other_used_memory**: other used memory
memorymbytes	integer	Size of allocated memory-typed memory

- get_client_info()

  Description: Returns client information.

  Return type: record.

- pv_session_memory_detail()

  Description: Collects session memory usage by the MemoryContext node.

  Return type: record.

Table 1-105 Return values

Name	Type	Description
sessid	text	• When the thread pool is disabled (**enable_thread_pool = off**), this column indicates the thread start time+session ID (string: **timestamp.sessionid**). • When the thread pool is enabled (**enable_thread_pool = on**): If the memory context is at the thread level, this column indicates the thread start time +thread ID (string: **timestamp.threadid**). If the memory context is at the session level, the column indicates the thread start time +session ID (string: **timestamp.sessionid**).
threadid	bigint	Thread ID bound to a session.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Name	Type	Description
contextname	text	Name of the memory context.
level	smallint	Hierarchy of the memory context.
parent	text	Name of the parent memory context.
totalsize	bigint	Total size of the memory context, in bytes.
freesize	bigint	Total size of released memory in the memory context, in bytes.
usedsize	bigint	Size of used memory in the memory context, in bytes. For **TempSmallContextGroup**, this parameter specifies the number of collected memory contexts.

Access Permission Query Functions

Permissions on DDL statements, including ALTER, DROP, COMMENT, INDEX, and VACUUM, are inherent permissions implicitly owned by the owner.

NOTE

For the preceding implicitly owned permissions, the owner and users who inherit the owner's permissions cannot directly obtain them through the following access permission query functions. However, the actual owner and users who inherit the owner's permissions have these permissions, and the execution is not affected. To obtain permissions through the following query functions, you need to explicitly grant the permissions using GRANT before querying.

The following access permission query function only specifies whether a user has a certain permission on an object. That is, the permission on the object recorded in the **acl** column of the system catalog is returned.

- has_any_column_privilege(user, table, privilege)

  Description: Queries whether a specified user has permission to access any column in a table.

  Table 1-106 Parameter type description

Parameter	Valid Input Parameter Type	Description	Value Range
user	name, oid	A specific user	Username or ID

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Valid Input Parameter Type	Description	Value Range
table	text, oid	Tables	Table name or ID
privilege	text	Permission	• **SELECT**: allows the SELECT statement to be executed on any column of a specified table. • **INSERT**: allows the INSERT statement to be executed on any column of a specified table. • **UPDATE**: allows the UPDATE statement to be executed on any column of a specified table. • **REFERENCES**: allows a foreign key constraint (not supported in distributed mode). • **COMMENT**: allows the COMMENT statement to be executed on any column of a specified table.

Return type: Boolean

Example:

```
gaussdb=# CREATE USER test_user PASSWORD '********';
gaussdb=# CREATE TABLE test_table(col int);
gaussdb=# SELECT has_any_column_privilege('test_user','test_table','INSERT');
has_any_column_privilege
--------------------------
f
(1 row)

gaussdb=# DROP USER test_user;
```

- has_any_column_privilege(table, privilege)

  Description: Queries whether the current user has the permission to access any column of a table. For details about the valid parameter types, see **Table 1-106**.

  Return type: Boolean

  Note: **has_any_column_privilege** checks whether a user can access any column of a table in a particular way. Its parameter possibilities are analogous to those of **has_table_privilege**, except that the desired access permission type must be some combination of SELECT, INSERT, UPDATE, or REFERENCES.

  Example:

```
gaussdb=# SELECT has_any_column_privilege('test_table','INSERT');
has_any_column_privilege
--------------------------
t
(1 row)

gaussdb=# DROP TABLE test_table;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

> **NOTE**
>
> Note that having any of these permissions at the table level indicates that the permission is implicitly granted for each column of the table. Therefore, **has_any_column_privilege** always returns **true** if **has_table_privilege** has the same parameters. A success message is also returned if a column-level permission is granted for at least one column.

- has_column_privilege(user, table, column, privilege)

  Description: Queries whether a specified user has permission to access columns.

  Table 1-107 Parameter type description

Parameter	Valid Input Parameter Type	Description	Value Range
user	name, oid	A specific user	Username or ID.
table	text, oid	Table name	Table name or ID.
column	text, smallint	Column name	Column name or attribute number.
privilege	text	Permission	• **SELECT**: allows the SELECT statement to be executed on specified columns of a table. • **INSERT**: allows the INSERT statement to be executed on specified columns of a table. • **UPDATE**: allows the UPDATE statement to be executed on specified columns of a table. • **REFERENCES**: allows a foreign key constraint (not supported in distributed mode). • **COMMENT**: allows the COMMENT statement to be executed on specified columns of a table.

  Return type: Boolean

- has_column_privilege(table, column, privilege)

  Description: Queries whether the current user has permission to access columns. For details about the valid parameter types, see **Table 1-107**.

  Return type: Boolean

  has_column_privilege checks whether a user can access a column in a particular way. Its parameter possibilities are analogous to those of

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

has_table_privilege, with the addition that the column can be specified either by name or attribute number. The desired access permission type must be some combination of SELECT, INSERT, UPDATE, or REFERENCES.

NOTE

Note that having any of these permissions at the table level indicates that the permission is implicitly granted for each column of the table.

- has_cek_privilege(user, cek, privilege)

  Description: Specifies whether a specified user has permission on CEKs.

  Table 1-108 Parameter type description

Parameter	Valid Input Parameter Type	Description	Value Range
user	name, oid	A specific user	Username or ID
cek	text, oid	CEK	Name or ID of a CEK
privilege	text	Permission	• **USAGE**: allows users to use the specified CEK. • **DROP**: allows users to delete the specified CEK.

  Return type: Boolean.

- has_cmk_privilege(user, cmk, privilege)

  Description: Specifies whether a specified user has permission on CMKs.

  Table 1-109 Parameter type description

Parameter	Valid Input Parameter Type	Description	Value Range
user	name, oid	A specific user	Username or ID
cmk	text, oid	CMK	Name or ID of the CMK
privilege	text	Permission	• **USAGE**: allows users to use the specified CMK. • **DROP**: allows users to delete the specified CMK.

  Return type: Boolean.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- has_database_privilege(user, database, privilege)

  Description: Queries whether a specified user has permission to access databases.

  Table 1-110 Parameter type description

Parameter	Valid Input Parameter Type	Description	Value Range
user	name, oid	A specific user	Username or ID
database	text, oid	Database	Database name or ID
privilege	text	Permission	• **CREATE**: For databases, allows new schemas to be created within the database. • **TEMPORARY**: allows users to create temporary tables when the database is used. • **TEMP**: allows users to create temporary tables when the database is used. • **CONNECT**: allows users to access specified databases. • **ALTER**: allows users to modify the attributes of a specified object. • **DROP**: allows users to delete a specified object. • **COMMENT**: allows users to define or modify comments of a specified object.

  Return type: Boolean

- has_database_privilege(database, privilege)

  Description: Queries whether the current user has the permission to access a database. For details about valid parameter types, see **Table 1-110**.

  Return type: Boolean

  Note: **has_database_privilege** checks whether a user can access a database in a particular way. Its parameter possibilities are analogous to those of **has_table_privilege**. The desired access permission type must be some combination of CREATE, CONNECT, TEMPORARY, or TEMP (which is equivalent to TEMPORARY).

- has_directory_privilege(user, directory, privilege)

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 1-111 Parameter type description

Parameter	Valid Input Parameter Type	Description	Value Range
user	name, oid	A specific user	Username or ID
directory	text, oid	Directory	Directory name or OID
privilege	text	Permission	• **READ**: allows read operations on the directory. • **WRITE**: allows write operations on the directory.

Description: Specifies whether a specified user has permission on directories.

Return type: Boolean

- has_directory_privilege(directory, privilege)

  Description: Queries whether the current user has the permission to access a directory. For details about valid parameter types, see **Table 1-111**.

  Return type: Boolean

- has_foreign_data_wrapper_privilege(user, fdw, privilege)

Table 1-112 Parameter type description

Parameter	Valid Input Parameter Type	Description	Value Range
user	name, oid	A specific user	Username or ID
fdw	text, oid	Foreign data wrapper	Name or ID of the foreign data wrapper
privilege	text	Permission	**USAGE**: allows access to the foreign data wrapper.

Description: Queries whether a specified user has permission to access foreign data wrappers.

Return type: Boolean

- has_foreign_data_wrapper_privilege(fdw, privilege)

  Description: Queries whether the current user has permissions on foreign data wrappers. For details about valid parameter types, see **Table 1-112**.

  Return type: Boolean

  Note: **has_foreign_data_wrapper_privilege** checks whether a user can access a foreign data wrapper in a particular way. Its parameter possibilities are

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

analogous to those of **has_table_privilege**. The desired access permission type must be **USAGE**.

- has_function_privilege(user, function, privilege)

  Table 1-113 Parameter type description

Parameter	Valid Input Parameter Type	Description	Value Range
user	name, oid	A specific user	Username or ID
function	text, oid	Function	Function name or ID
privilege	text	Permission	**EXECUTE**: allows users to use specified functions and the operators that are realized by the functions. • **ALTER**: allows users to modify the attributes of a specified object. • **DROP**: allows users to delete a specified object. • **COMMENT**: allows users to define or modify comments of a specified object.

  Description: Queries whether a specified user has permission to access functions.

  Return type: Boolean

- has_function_privilege(function, privilege)

  Description: Queries whether the current user has permission to access functions. For details about valid parameter types, see **Table 1-113**.

  Return type: Boolean

  Note: **has_function_privilege** checks whether a user can access a function in a particular way. Its parameter possibilities are analogous to those of **has_table_privilege**. When a function is specified by a text string rather than by an OID, the allowed input is the same as that for the regprocedure data type (see **OID Types**). The desired access permission type must be EXECUTE.

- has_language_privilege(user, language, privilege)

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 1-114 Parameter type description

Parameter	Valid Input Parameter Type	Description	Value Range
user	name, oid	A specific user	Username or ID
language	text, oid	Language	Language name or ID
privilege	text	Permission	**USAGE**: allows users to specify a procedural language when creating a function.

Description: Queries whether a specified user has permission to access languages.

Return type: Boolean

- has_language_privilege(language, privilege)

  Description: Queries whether the current user has permission to access languages. For details about valid parameter types, see **Table 1-114**.

  Return type: Boolean

  Note: **has_language_privilege** checks whether a user can access a procedural language in a particular way. Its parameter possibilities are analogous to those of **has_table_privilege**. The desired access permission type must be **USAGE**.

- has_nodegroup_privilege(user, nodegroup, privilege)

  Description: Checks whether a user has permission to access a cluster node.

  Return type: Boolean

Table 1-115 Parameter type description

Parameter	Valid Input Parameter Type	Description	Value Range
user	name, oid	A specific user	Existing username or ID.
nodegroup	text, oid	Cluster node	Existing cluster node.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Valid Input Parameter Type	Description	Value Range
privilege	text	Permission	• **USAGE**: For sub-clusters, allows users who can access objects contained in the schema to access tables in the sub-cluster. • **CREATE**: For sub-clusters, allows users to create tables within the sub-cluster. • **COMPUTE**: allows elastic computing in the sub-cluster. • **ALTER**: allows users to modify the attributes of a specified object. • **DROP**: allows users to delete a specified object.

- has_nodegroup_privilege(nodegroup, privilege)

  Description: Checks whether a user has permission to access a cluster node.

  Return type: Boolean

- has_schema_privilege(user, schema, privilege)

  Description: Queries whether a specified user has permission to access schemas.

  Return type: Boolean

- has_schema_privilege(schema, privilege)

  Description: Queries whether the current user has permission to access schemas.

  Return type: Boolean

  Note: **has_schema_privilege** checks whether a user can access a schema in a particular way. Its parameter possibilities are analogous to those of **has_table_privilege**. The desired access permission type must be a combination among CREATE, USAGE, ALTER, DROP, and COMMENT. If the check type contains the CREATE permission and the checked schema is a schema with the same name as the user, the function returns **TRUE** only when the user has the OWNER permission on the schema due to the special constraint of the schema with the same name.

- has_sequence_privilege(user, sequence, privilege)

  Description: Queries whether a specified user has permissions on sequences.

  Return type: Boolean

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 1-116 Parameter type description

Parameter	Valid Input Parameter Type	Description	Value Range
user	name, oid	A specific user	Existing username or ID.
sequence	text, oid	Sequence	Existing sequence name or ID.
privilege	text	Permission	• **USAGE**: For sequences, allows users to use the nextval function. • **SELECT**: allows users to create a sequence. • **UPDATE**: allows users to execute the **UPDATE** statement. • **ALTER**: allows users to modify the attributes of a specified object. • **DROP**: allows users to delete a specified object. • **COMMENT**: allows users to define or modify comments of a specified object.

- has_sequence_privilege(sequence, privilege)

  Description: Queries whether the current user has permissions on sequences.

  Return type: Boolean
- has_server_privilege(user, server, privilege)

  Description: Queries whether a specified user has permission to access foreign servers.

  Return type: Boolean
- has_server_privilege(server, privilege)

  Description: Queries whether the current user has permission to access foreign servers.

  Return type: Boolean

  Note: **has_server_privilege** checks whether a user can access a foreign server in a particular way. Its parameter possibilities are analogous to those of **has_table_privilege**. The access permission type must be **USAGE**, **ALTER**, **DROP**, or **COMMENT**.
- has_table_privilege(user, table, privilege)

  Description: Queries whether a specified user has permission to access tables.

  Return type: Boolean
- has_table_privilege(table, privilege)

  Description: Queries whether the current user has permission to access tables.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Return type: Boolean

Note: **has_table_privilege** checks whether a user can access a table in a particular way. The user can be specified by name or by OID (**pg_authid.oid**), or be set to **public** which indicates public pseudo roles. If this parameter is omitted, **current_user** is used. The table can be specified by name or by OID. When it is specified by name, the name can be schema-qualified if necessary. If the desired access permission type is specified by a text string, the text string must be one of the values **SELECT**, **INSERT**, **UPDATE**, **DELETE**, **TRUNCATE**, **REFERENCESTRIGGER**, **ALTER**, **DROP**, **COMMENT**, **INDEX**, or **VACUUM**. Optionally, **WITH GRANT OPTION** can be added to a permission type to test whether the permission is held with the grant option. Also, multiple permission types can be separated by commas (,), in which case the result will be **true** if any of the listed permissions is held.

Example:

```
gaussdb=# CREATE SCHEMA tpcds;
gaussdb=# CREATE TABLE tpcds.web_site(col int);
gaussdb=# CREATE USER test_user PASSWORD '********';
gaussdb=# SELECT has_table_privilege('tpcds.web_site', 'select');
 has_table_privilege
---------------------
 t
(1 row)

gaussdb=# SELECT has_table_privilege('test_user', 'tpcds.web_site', 'select,INSERT WITH GRANT
OPTION ');
 has_table_privilege
---------------------
 f
(1 row)

gaussdb=# DROP USER test_user;
gaussdb=# DROP TABLE tpcds.web_site;
gaussdb=# DROP SCHEMA tpcds;
```

- has_tablespace_privilege(user, tablespace, privilege)

  Description: Queries whether a specified user has permission to access tablespaces.

  Return type: Boolean

- has_tablespace_privilege(tablespace, privilege)

  Description: Queries whether the current user has permission to access tablespaces.

  Return type: Boolean

  Note: **has_tablespace_privilege** checks whether a user can access a tablespace in a particular way. Its parameter possibilities are analogous to those of **has_table_privilege**. The access permission type must be **CREATE**, **ALTER**, **DROP**, or **COMMENT**.

- pg_has_role(user, role, privilege)

  Description: Queries whether a specified user has permission on roles.

  Return type: Boolean

- pg_has_role(role, privilege)

  Description: Queries whether the current user has permission to access a role.

  Return type: Boolean

  Note: **pg_has_role** checks whether a user can access a role in a particular way. Its parameter possibilities are analogous to those of **has_table_privilege**,

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

except that **public** cannot be used as a username. The desired access permission type must be some combination of **MEMBER** or **USAGE**. **MEMBER** denotes direct or indirect membership in the role (that is, permission **SET ROLE**), while **USAGE** denotes the usage permission on the role that is available without the **SET ROLE** permission.

- has_any_privilege(user, privilege)

  Description: Queries whether a specified user has certain ANY permission. If multiple permissions are queried at the same time, **true** is returned as long as one permission is obtained.

  Return type: Boolean

  Table 1-117 Parameter type description

Parameter	Valid Input Parameter Type	Description	Value Range
user	name	A specific user	Existing username

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Valid Input Parameter Type	Description	Value Range
privilege	text	ANY permission	The options are as follows: • CREATE ANY TABLE [WITH ADMIN OPTION] • ALTER ANY TABLE [WITH ADMIN OPTION] • DROP ANY TABLE [WITH ADMIN OPTION] • SELECT ANY TABLE [WITH ADMIN OPTION] • INSERT ANY TABLE [WITH ADMIN OPTION] • UPDATE ANY TABLE [WITH ADMIN OPTION] • DELETE ANY TABLE [WITH ADMIN OPTION] • TRUNCATE ANY TABLE [WITH ADMIN OPTION] • CREATE ANY SEQUENCE [WITH ADMIN OPTION] • CREATE ANY INDEX [WITH ADMIN OPTION] • CREATE ANY FUNCTION [WITH ADMIN OPTION] • EXECUTE ANY FUNCTION [WITH ADMIN OPTION] • CREATE ANY PACKAGE [WITH ADMIN OPTION] • EXECUTE ANY PACKAGE [WITH ADMIN OPTION] • CREATE ANY TYPE [WITH ADMIN OPTION]

Schema Visibility Query Functions

Each function performs the visibility check on one type of database objects. For functions and operators, an object in the search path is visible if there is no object of the same name and parameter data type earlier in the path. For operator classes, both name and associated index access methods are considered.

All these functions require OIDs to identify the objects to be checked. If you want to test an object by name, it is convenient to use the OID alias type (regclass, regtype, regprocedure, regoperator, regconfig, or regdictionary).

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

For example, a table is said to be visible if the schema where the table is located is in the search path and no table of the same name appears earlier in the search path. This is equivalent to the statement that the table can be referenced by name without explicit schema qualification. To list the names of all visible tables, run the following command:

```
gaussdb=# SELECT relname FROM pg_class WHERE pg_table_is_visible(oid);
```

- pg_collation_is_visible(collation_oid)

  Description: Queries whether the collation is visible in search path.

  Return type: Boolean
- pg_conversion_is_visible(conversion_oid)

  Description: Queries whether the conversion is visible in the search path.

  Return type: Boolean
- pg_function_is_visible(function_oid)

  Description: Queries whether the function is visible in the search path.

  Return type: Boolean
- pg_opclass_is_visible(opclass_oid)

  Description: Queries whether the operator class is visible in the search path.

  Return type: Boolean
- pg_operator_is_visible(operator_oid)

  Description: Queries whether the operator is visible in the search path.

  Return type: Boolean
- pg_opfamily_is_visible(opclass_oid)

  Description: Queries whether the operator family is visible in the search path.

  Return type: Boolean
- pg_table_is_visible(table_oid)

  Description: Queries whether the table is visible in the search path.

  Return type: Boolean
- pg_ts_config_is_visible(config_oid)

  Description: Queries whether the text search configuration is visible in the search path.

  Return type: Boolean
- pg_ts_dict_is_visible(dict_oid)

  Description: Queries whether the text search dictionary is visible in the search path.

  Return type: Boolean
- pg_ts_parser_is_visible(parser_oid)

  Description: Queries whether the text search parser is visible in the search path.

  Return type: Boolean
- pg_ts_template_is_visible(template_oid)

  Description: Queries whether the text search template is visible in the search path.

  Return type: Boolean

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- pg_type_is_visible(type_oid)

  Description: Queries whether the type (or domain) is visible in the search path.

  Return type: Boolean

System Catalog Information Functions

- format_type(type_oid, typemod)

  Description: Obtains the SQL name of a data type.

  Return type: text.

  Note: **format_type** returns the SQL name of a data type based on the OID of the data type and possible modifiers. If the specific modifier is unknown, pass **NULL** at the position of the modifier. Modifiers are generally meaningful only for data types with length restrictions. The SQL name returned by **format_type** contains the length of the data type, which can be calculated by taking sizeof(int32) from actual storage length [actual storage len – sizeof(int32)] in the unit of bytes. 32-bit space is required to store the customized length set by users. Therefore, the actual storage length contains 4 bytes more than the customized length. In the following example, the SQL name returned by **format_type** is character varying(6), indicating the length of the varchar type is 6 bytes. Therefore, the actual storage length of the varchar type is 10 bytes.

  ```
  gaussdb=# SELECT format_type((SELECT oid FROM pg_type WHERE typname='varchar'), 10);
      format_type
  ----------------------
   character varying(6)
  (1 row)
  ```

- pg_check_authid(role_oid)

  Description: Checks whether a role name with given OID exists.

  Return type: Boolean.

  ```
  gaussdb=# select pg_check_authid(1);
  pg_check_authid
  -----------------
  f
  (1 row)
  ```

- pg_describe_object(catalog_id, object_id, object_sub_id)

  Description: Obtains the description of a database object.

  Return type: text.

  Note: **pg_describe_object** returns the description of a database object specified by a catalog OID, an object OID, and a (possibly zero) sub-object ID. This is useful to determine the identity of an object stored in the **pg_depend** catalog.

- pg_get_constraintdef(constraint_oid)

  Description: Obtains definition of a constraint.

  Return type: text.

- pg_get_constraintdef(constraint_oid, pretty_bool)

  Description: Obtains definition of a constraint.

  Return type: text.

  Note: **pg_get_constraintdef** and **pg_get_indexdef** respectively reconstruct the creation command for a constraint and an index.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- pg_get_expr(pg_node_tree, relation_oid)

  Description: Decompiles internal form of an expression, assuming that any Vars in it refer to the relationship indicated by the second parameter.

  Return type: text.

- pg_get_expr(pg_node_tree, relation_oid, pretty_bool)

  Description: Decompiles internal form of an expression, assuming that any Vars in it refer to the relationship indicated by the second parameter.

  Return type: text.

  Note: **pg_get_expr** decompiles the internal form of an individual expression, such as the default value of a column. This helps to check the content of system catalogs. If the expression contains keywords, specify the OID of the relationship that the keywords refer to as the second parameter; if no keywords are contained, use zero.

- pg_get_functiondef(func_oid)

  Description: Obtains the definition of a function.

  Return type: text.

  Example:

```
gaussdb=# SELECT * FROM pg_get_functiondef(598);
 headerlines |                    definition
-------------+-----------------------------------------------------
           4 | CREATE OR REPLACE FUNCTION pg_catalog.abbrev(inet)+
             |  RETURNS text                                     +
             |  LANGUAGE internal                                +
             |  IMMUTABLE STRICT NOT FENCED NOT SHIPPABLE        +
             | AS $function$inet_abbrev$function$                +
             |
(1 row)
```

- pg_get_function_arguments(func_oid)

  Description: Obtains argument list of function's definition (with default values).

  Return type: text.

  Note: **pg_get_function_arguments** returns the parameter list of a function, in the form it would need to appear in **CREATE FUNCTION**.

- pg_get_function_identity_arguments(func_oid)

  Description: Obtains the parameter list to identify a function (without default values).

  Return type: text.

  Note: **pg_get_function_identity_arguments** returns the parameter list required to identify a function, in the form it would need to appear in **ALTER FUNCTION**. This form omits default values.

- pg_get_function_result(func_oid)

  Description: Obtains the RETURNS clause for a function.

  Return type: text.

  Note: **pg_get_function_result** returns the appropriate **RETURNS** clause for the function.

- pg_get_indexdef(index_oid)

  Description: Obtains the **CREATE INDEX** command for an index.

  Return type: text.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Example:

```
gaussdb=# CREATE TABLE test3 (a int, b int);
gaussdb=# CREATE INDEX test3_b_index ON test3 USING btree(b) TABLESPACE pg_default;
gaussdb=# SELECT pg_get_indexdef(oid) FROM (SELECT oid FROM pg_class WHERE relname =
'test3_b_index') tmp;
                                        pg_get_indexdef
-----------------------------------------------------------------------------------------------------
 CREATE INDEX test3_b_index ON test3 USING ubtree (b) WITH (storage_type=USTORE) TABLESPACE
pg_default
(1 row)
```

- pg_get_indexdef(index_oid, dump_schema_only)

  Description: Obtains the **CREATE INDEX** command for indexes in dump scenarios. In the current version, the value of **dump_schema_only** does not affect the function output.

  Return type: text.

  Example:

```
gaussdb=# SELECT pg_get_indexdef(oid, true) FROM (SELECT oid FROM pg_class WHERE relname =
'test3_b_index') tmp;
                                        pg_get_indexdef
-----------------------------------------------------------------------------------------------------
 CREATE INDEX test3_b_index ON test3 USING ubtree (b) WITH (storage_type=USTORE) TABLESPACE
pg_default
(1 row)
```

- pg_get_indexdef(index_oid, column_no, pretty_bool)

  Description: Obtains the **CREATE INDEX** command for an index, or definition of just one index column when the value of **column_no** is not zero.

  Return type: text.

  Example:

```
gaussdb=# SELECT pg_get_indexdef(oid, 0, false) FROM (SELECT oid FROM pg_class WHERE relname
= 'test3_b_index') tmp;
                                        pg_get_indexdef
-----------------------------------------------------------------------------------------------------
 CREATE INDEX test3_b_index ON test3 USING ubtree (b) WITH (storage_type=USTORE) TABLESPACE
pg_default
(1 row)

gaussdb=# SELECT pg_get_indexdef(oid, 1, false) FROM (SELECT oid FROM pg_class WHERE relname
= 'test3_b_index') tmp;
 pg_get_indexdef
-----------------
 b
(1 row)

gaussdb=# DROP INDEX test3_b_index;
gaussdb=# DROP TABLE test3;
```

  Note: pg_get_idexdef returns a complete CREATE OR REPLACE INDEX statement for a function.

- pg_get_keywords()

  Description: Obtains the list of SQL keywords and their categories.

  Return type: SETOF record.

  Note: **pg_get_keywords** returns a set of records describing the SQL keywords recognized by the server. The **word** column contains the keywords. The **catcode** column contains a category code: **U** for unreserved, **C** for column name, **T** for type or function name, or **R** for reserved. The **catdesc** column contains a possibly-localized string describing the category. The keyword range and type vary depending on the compatibility mode, and the return

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

result of pg_get_keywords also varies. The records returned by the pg_get_keywords function do not contain the options configured in the **disable_keyword_options** parameter. For details about the **disable_keyword_options** parameter, see **Platform and Client Compatibility**.

- pg_get_ruledef(rule_oid)

  Description: Obtains the **CREATE RULE** command for a rule.

  Return type: text.

- pg_get_ruledef(rule_oid, pretty_bool)

  Description: Obtains the **CREATE RULE** command for a rule.

  Return type: text.

- pg_get_userbyid(role_oid)

  Description: Obtains the role name with a given OID.

  Return type: name.

  Note: **pg_get_userbyid** extracts a role's name given its OID.

- pg_check_authid(role_id)

  Description: Checks whether a user exists based on **role_id**.

  Return type: text.

  ```
  gaussdb=# SELECT pg_check_authid(20);
  pg_check_authid
  -----------------
  f
  (1 row)
  ```

- pg_get_viewdef(view_name)

  Description: Obtains the underlying **SELECT** command for a view.

  Return type: text.

- pg_get_viewdef(view_name, pretty_bool)

  Description: Obtains the underlying **SELECT** command for a view. Lines with columns are wrapped to 80 columns if **pretty_bool** is set to **true**.

  Return type: text.

  Note: **pg_get_viewdef** reconstructs the SELECT query that defines a view. Most of these functions come in two forms. When the function has the **pretty_bool** parameter and the value is **true**, it can optionally "pretty-print" the result. The pretty-printed format is more readable. The other one is the default format which is more likely to be interpreted in the same way by future versions. Avoid using pretty-printed output for dump purposes. Passing **false** to the pretty-print parameter generates the same result as a variant without this parameter.

- pg_get_viewdef(view_oid)

  Description: Obtains the underlying SELECT command for a view.

  Return type: text.

- pg_get_viewdef(view_oid, pretty_bool)

  Description: Obtains the underlying **SELECT** command for a view. Lines with columns are wrapped to 80 columns if **pretty_bool** is set to **true**.

  Return type: text.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- pg_get_viewdef(view_oid, wrap_column_int)

  Description: Obtains the underlying **SELECT** command for a view. Lines with columns are wrapped to the specified number of columns and printing is implicit.

  Return type: text.

- pg_get_tabledef(table_oid)

  Description: Obtains the definition of a table based on **table_oid**.

  Return type: text.

  Example:

```
gaussdb=# CREATE TABLE t1 (c1 serial);
gaussdb=# SELECT pg_get_tabledef(oid) FROM (SELECT oid FROM pg_class WHERE relname = 't1')
tmp;
                          pg_get_tabledef
------------------------------------------------------------------------------
 SET search_path = public;                                                   +
 CREATE TABLE t1 (                                                           +
     c1 integer DEFAULT nextval('t1_c1_seq1790791646'::regclass) NOT NULL+
 )                                                                           +
 WITH (orientation=row, compression=no, storage_type=USTORE, segment=off)+
 DISTRIBUTE BY HASH(c1)                                                      +
 TO GROUP group_version1;
(1 row)
```

- pg_get_tabledef(table_name)

  Description: Obtains the definition of a table based on **table_name**.

  Return type: text.

  Example:

```
gaussdb=# SELECT * FROM pg_get_tabledef('t1');
                          pg_get_tabledef
------------------------------------------------------------------------------
 SET search_path = public;                                                   +
 CREATE TABLE t1 (                                                           +
     c1 integer DEFAULT nextval('t1_c1_seq1790791646'::regclass) NOT NULL+
 )                                                                           +
 WITH (orientation=row, compression=no, storage_type=USTORE, segment=off)+
 DISTRIBUTE BY HASH(c1)                                                      +
 TO GROUP group_version1;
(1 row)
```

  Note: **pg_get_tabledef** reconstructs the CREATE statement of the definition of the table, including the table definition, index information, comments, and ILM policy. You need to create the group, schema, tablespace, and server information on which the table object depends. If the ILM policy is inherited from the parent object, pg_get_tabledef does not return the ILM policy creation statement of the data object.

- pg_options_to_table(reloptions)

  Description: Obtains the set of storage option name/value pairs.

  Return type: SETOF record.

  Note: **pg_options_to_table** returns the set of storage option name/value pairs (**option_name**/**option_value**) when **pg_class.reloptions** or **pg_attribute.attoptions** is passed.

- pg_tablespace_databases(tablespace_oid)

  Description: Obtains the set of database OIDs that have objects in the specified tablespace.

  Return type: SETOF oid.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Note: **pg_tablespace_databases** allows a tablespace to be checked. It returns the set of OIDs of databases that have objects stored in the tablespace. If this function returns any rows of data, the tablespace is not empty and cannot be dropped. To display the specific objects in the tablespace, you need to connect to the databases identified by **pg_tablespace_databases** and query the pg_class system catalogs.

- pg_tablespace_location(tablespace_oid)

  Description: Obtains the path in the file system that this tablespace is located in.

  Return type: text.

- pg_typeof(any)

  Description: Obtains the data type of any value.

  Return type: regtype.

  Note: pg_typeof returns the OID of the data type of the value that is passed to it. This can be helpful for troubleshooting or dynamically constructing SQL queries. It is declared that the function returns regtype, which is an OID alias type (see **OID Types**). This means that it is the same as an OID for comparison purposes but displays as a type name.

  Example:

```
gaussdb=# SELECT pg_typeof(33);
 pg_typeof
-----------
 integer
(1 row)

gaussdb=# SELECT typlen FROM pg_type WHERE oid = pg_typeof(33);
 typlen
--------
      4
(1 row)
```

- collation for (any)

  Description: Obtains the collation of the parameter.

  Return type: text.

  Note: The expression **collation for** returns the collation of the value that is passed to it. Example:

```
gaussdb=# SELECT collation for (description) FROM pg_description LIMIT 1;
 pg_collation_for
------------------
 "default"
(1 row)
```

  The value might be quoted and schema-qualified. If no collation is derived for the parameter expression, then a null value is returned. If the argument is not of a collatable data type, then an error message is displayed.

- getdistributekey(table_name)

  Description: Obtains a distribution key for a hash table.

  Return type: text.

  Example:

```
gaussdb=# SELECT getdistributekey('t1');
 getdistributekey
------------------
 c1
(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- pg_extension_update_paths(name)

  Description: Returns the version update path of the specified extension. This function can be called only by system administrators.

  Return type: text (source text), text (target text), text (path text)

- pg_get_serial_sequence(tablename, colname)

  Description: Obtains the sequence of the corresponding table name and column name.

  Return type: text.

  Example:

```
gaussdb=# SELECT * FROM pg_get_serial_sequence('t1', 'c1');
   pg_get_serial_sequence
----------------------------
 public.t1_c1_seq1790791646
(1 row)
```

- pg_sequence_parameters(sequence_oid, OUT start_value int16, OUT minimum_value int16, OUT maximum_value int16, OUT increment int16, OUT cycle_option Boolean, OUT order_option Boolean)

  Description: Obtains the parameters of a specified sequence, including the start value, minimum value, maximum value, increment, cycle option, and order option.

  Return type: int16, int16, int16, int16, Boolean, Boolean.

  Example:

```
-- Use the name of the sequence automatically generated when the t1 table is created.
gaussdb=# SELECT oid FROM pg_class WHERE relname = 't1_c1_seq1790791646';
  oid
-------
 17120
(1 row)

-- Use the OID obtained from the preceding query.
gaussdb=# SELECT * FROM  pg_sequence_parameters(17120);
 start_value | minimum_value |     maximum_value     | increment | cycle_option | order_option
-------------+---------------+-----------------------+-----------+--------------+--------------
           1 |             1 | 9223372036854775807 |         1 | f            | f
(1 row)
```

- pgxc_get_variable_info()

  Description: Obtains variable values on the node, including **nodeName**, **nextOid**, **nextXid**, **oldestXid**, **xidVacLimit**, **oldestXidDB**, **lastExtendCSNLogpage**, **startExtendCSNLogpage**, **nextCommitSeqNo**, **latestCompleteXid**, and **startupMaxXid**.

  Return type: set of pg_variable_info

  Example:

```
gaussdb=# SELECT pgxc_get_variable_info( );
                        pgxc_get_variable_info
-----------------------------------------------------------------------
(dn_6004_6005_6006,25617,141396349,2073,20000002073,15808,138111,0,127154152,141396348,104
433004)
(1 row)
```

- gs_get_index_status(schema_name, index_name)

  Description: Obtains the index status information on all nodes, including whether an index can be inserted and whether an index is available. This function is mainly used to check the index status during online index creation or when the index creation fails. The return values include **node_name**, **indisready**, and **indisvalid**. Only when **indisready** and **indisvalid** of indexes

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

on all nodes are set to **true** and the index state is not changed to unusable, the current index is available.

Return type: text, Boolean, Boolean

Example:

```
gaussdb=# CREATE INDEX index1 ON t1(c1);
gaussdb=# SELECT * FROM gs_get_index_status('public', 'index1');
   node_name    | indisready | indisvalid
----------------+------------+------------
 datanode1      | t          | t
 datanode2      | t          | t
 coordinator1   | t          | t
(3 row)

gaussdb=# DROP INDEX index1;
gaussdb=# DROP TABLE t1;
```

Comment Information Functions

- col_description(table_oid, column_number)

  Description: Obtains the comment for a table column.

  Return type: text.

  Note: **col_description** returns the comment for a table column, which is specified by the OID of its table and its column number.

- obj_description(object_oid, catalog_name)

  Description: Obtains the comment for a database object.

  Return type: text.

  Note: The two-parameter form of **obj_description** returns the comment for a database object specified by its OID and the name of the system catalog to which it belongs. For example, **obj_description(123456,'pg_class')** would retrieve the comment for the table with OID 123456. The one-parameter form of **obj_description** requires only the OID.

  obj_description cannot be used for table columns since columns do not have OIDs of their own.

- obj_description(object_oid)

  Description: Obtains the comment for a database object.

  Return type: text.

- shobj_description(object_oid, catalog_name)

  Description: Obtains the comment for a shared database object.

  Return type: text.

  Note: **shobj_description** is used just like **obj_description**, except that the former is used for shared objects. Some system catalogs are global to all databases in the cluster, and the comments for objects in them are stored globally as well.

XIDs and Snapshots

Internal XIDs are 64 bits. **txid_snapshot**, data type used by these functions, stores information about XID visibility at a particular moment in time. **Table 1-118** describes the components.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 1-118 Snapshot components

Name	Description
xmin	Earliest XID (**txid**) that is still active. All earlier transactions will either be committed and visible, or rolled back.
xmax	First as-yet-unassigned **txid**. All **txids** greater than or equal to this are not yet started as of the time of the snapshot, so they are invisible.
xip_list	Active **txids** at the time of the snapshot. The list includes only those active **txids** between **xmin** and **xmax**; there might be active **txids** higher than **xmax**. A **txid** that is greater than or equal to **xmin** and less than **xmax** and that is not in this list was already completed at the time of the snapshot, and is either visible or rolled back according to its commit status. The list does not include **txids** of subtransactions.

The textual representation of **txid_snapshot** is **xmin:xmax:xip_list**.

For example, **10:20:10,14,15** means **xmin=10, xmax=20, xip_list=10, 14, 15**.

The following functions provide server transaction information in an exportable form. These functions are mainly used to determine which transactions were committed between two snapshots.

- pgxc_is_committed(transaction_id)

  Description: Specifies whether the given XID is committed or ignored. **NULL** indicates the unknown status (it can be running, ready, frozen, or other status). In maintenance mode (when the GUC parameter **xc_maintenance_mode** is set to **on**), the statuses of all transactions with the specified bucket IDs and ordinary tables are traversed. If a status conflict occurs, for example, the status of the same transaction is **committed** in bucket 1 and **rolled back** in bucket 2, an error is reported. Exercise caution when enabling the mode. It is used by maintenance engineers for troubleshooting. Common users should not use the mode.

  Return type: Boolean.

- pgxc_is_committed(transaction_id, bucketid)

  Description: Commits or ignores the given transaction (gxid) if **bucketid** is specified. **NULL** indicates that the status is unknown (running, ready, or frozen). **bucketid** is the physical bucket ID of the hash bucket table. The value is **–1** for an ordinary table. In maintenance mode (when the GUC parameter **xc_maintenance_mode** is set to **on**), if **bucketid** is set to **–1**, the statuses of all transactions with the specified bucket IDs and ordinary tables are traversed. If a status conflict occurs, for example, the status of the same transaction is **committed** in bucket 1 and **rolled back** in bucket 2, an error is reported. Exercise caution when enabling the mode. It is used by maintenance engineers for troubleshooting. Common users should not use the mode.

  Return type: Boolean.

- txid_current()

  Description: Obtains the current XID.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Return type: bigint.

- gs_txid_oldestxmin()

  Description: Obtains the minimum XID (specified by **oldestxmin**).

  Return type: bigint.

- txid_current_snapshot()

  Description: Obtains the current snapshot.

  Return type: txid_snapshot.

- txid_snapshot_xip(txid_snapshot)

  Description: Obtains in-progress XIDs in a snapshot.

  Return type: setof bigint.

- txid_snapshot_xmax(txid_snapshot)

  Description: Obtains **xmax** of snapshots.

  Return type: bigint.

- txid_snapshot_xmin(txid_snapshot)

  Description: Obtains **xmin** of snapshots.

  Return type: bigint.

- txid_visible_in_snapshot(bigint, txid_snapshot)

  Description: Specifies whether the XID is visible in a snapshot (do not use subtransaction IDs).

  Return type: Boolean

- get_local_prepared_xact()

  Description: Obtains the two-phase residual transaction information of the current node, including the XID, GID of the two-phase transaction, prepared time, owner OID, database OID, and node name of the current node.

  Return types: xid, text, timestamptz, oid, and text.

- get_remote_prepared_xacts()

  Description: Obtains the two-phase residual transaction information of all remote nodes, including the XID, GID of the two-phase transaction, prepared time, owner name, database name, and node name.

  Return types: xid, text, timestamptz, name, and text.

- global_clean_prepared_xacts(text, text)

  Description: Concurrently cleans two-phase residual transactions. Only the gs_clean tool can call this function for cleaning. In other situations, **false** is returned.

  Return type: Boolean

- pgxc_stat_get_wal_senders()

  Description: Returns the sent logs of all primary DNs and the received logs of their corresponding standby DNs in the cluster. Only users with the system admin or monitor admin permission can use this function.

  Return values: See **Table 1-119**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 1-119 pgxc_stat_get_wal_senders parameters

Column	Description
nodename	Instance name.
sender_pid	PID of the thread for sending logs.
local_role	Instance role.
peer_role	Role of the instance on the receiver.
peer_state	Status of the instance on the receiver.
state	Synchronization status between instances.
sender_sent_location	Location where the sender sends logs.
sender_write_location	Location where the sender writes logs.
sender_flush_location	Location where the sender flushes logs to disk.
sender_replay_location	Log location of the current instance. If the DN is a primary DN, the location is the value of **sender_flush_location**. Otherwise, the location where the current instance log is replayed is used.
receiver_received_location	Location where the receiver receives logs.
receiver_write_location	Location where the receiver writes logs.
receiver_flush_location	Location where the receiver flushes logs to disk.
receiver_replay_location	Location where the receiver replays logs.

- pgxc_stat_get_wal_senders_status()

  Description: Returns the receiving status of transaction logs on all nodes. Only users with the system admin or monitor admin permission can use this function.

  Return values: See **Table 1-120**.

Table 1-120 pgxc_stat_get_wal_senders_status parameters

Column	Description
nodename	Name of the primary node.
source_ip	IP address of the primary node.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Column	Description
source_port	Port of the primary node.
dest_ip	IP address of the standby node.
dest_port	Port of the standby node.
sender_pid	PID of the sending thread.
local_role	Type of the primary node.
peer_role	Type of the standby node.
peer_state	Status of the standby node.
state	WAL sender status.
sender_sent_location	Sending position of the primary node.
sender_write_location	Writing position of the primary node.
sender_replay_location	Redo position of the primary node.
receiver_received_location	Receiving position of the standby node.
receiver_write_location	Writing position of the standby node.
receiver_flush_location	Flushing location of the standby node.
receiver_replay_location	Redo location of the standby node.

- gs_get_next_xid_csn()

  Description: Returns the values of **next_xid** and **next_csn** on all nodes globally.

  For details about the return values, see **Table 1-121**.

  Table 1-121 gs_get_next_xid_csn columns

Column	Description
nodename	Node name.
next_xid	ID of the next transaction on the current node.
next_csn	Next CSN of the current node.

- pg_control_system()

  Description: Returns the status of the system control file.

  Return type: SETOF record.

- pg_control_checkpoint()

  Description: Returns the system checkpoint status.

  Return type: SETOF record.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- get_prepared_pending_xid()

  Description: Returns **nextxid** when restoration is complete.

  Return type: text.

- pg_clean_region_info()

  Description: Clears the region map.

  Return type: character varying

- pg_get_replication_slot_name()

  Description: Obtains the slot name.

  Return type: text.

- pg_get_running_xacts()

  Description: Obtains running **xact**.

  Return type: handle integer, gxid xid, state tinyint, node text, xmin xid, vacuum Boolean, timeline bigint, prepare_xid xid, pid bigint, next_xid xid, dbid oid

- pg_get_variable_info()

  Description: Obtains the shared memory variable cache.

  Return type: node_name text, nextOid oid, nextXid xid, oldestXid xid, xidVacLimit xid, oldestXidDB oid, lastExtendCSNLogpage xid, startExtendCSNLogpage xid, nextCommitSeqNo xid, latestCompletedXid xid, and startupMaxXid xid

- pg_get_xidlimit()

  Description: Obtains XID information from the shared memory.

  Return type: nextXid xid, oldestXid xid, xidVacLimit xid, xidWarnLimit xid, xidStopLimit xid, xidWrapLimit xid, oldestXidDB oid

- pg_relation_compression_ratio(text)

  Description: Queries the compression ratio of a table. By default, **1.0** is returned.

  Parameter: text.

  Return type: real.

- pg_relation_with_compression(text)

  Description: Specifies whether a table is compressed.

  Parameter: text.

  Return type: Boolean.

- pg_stat_file_recursive(location text[, get_turbo_info boolean])

  Description: Lists all files in a directory. Only the initial user can execute this function.

  Parameter: **location text[, get_turbo_info boolean]**.

  Return types: path text, filename text, size bigint, and isdir boolean[, isturbocompress boolean].

- pg_stat_get_activity_for_temptable()

  Description: Returns records of background threads related to the temporary table.

  Return type: datid oid, timelineid integer, tempid integer, and sessionid bigint

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- pg_stat_get_activity_ng(pid bigint)

  Description: Returns records of background threads related to nodegroup.

  Parameter: pid bigint

  Return type: datid oid, pid bigint, sessionid bigint, and node_group text
- pg_stat_get_cgroup_info()

  Description: Returns Cgroup information.

  Return type: cgroup_name text, percent integer, usage_percent integer, shares bigint, usage bigint, cpuset text, relpath text, valid text, node_group text
- pg_stat_get_realtime_info_internal(oid, oid, bigint, cstring, oid)

  Description: Returns real-time information. Currently, this API is unavailable. **FailedToGetSessionInfo** is returned.

  Parameter: oid, oid, bigint, cstring, oid

  Return type: text.
- pg_stat_get_wlm_session_iostat_info()

  Description: Returns the session load I/O information.

  Return types: threadid bigint, maxcurr_iops integer, mincurr_iops integer, maxpeak_iops integer, minpeak_iops integer, iops_limits integer, io_priority integer, and curr_io_limits integer.
- pg_test_err_contain_err(integer)

  Description: Tests the error type and return information.

  Parameter: integer

  Return type: void
- pv_session_memory_detail_tp()

  Description: Returns the memory usage of the session. For details, see **pv_session_memory_detail**.

  Return types: sessid text, sesstype text, contextname text, level smallint, parent text, totalsize bigint, freesize bigint, and usedsize bigint.
- gs_get_table_distribution(table_name text, schema_name text)

  Description: Returns the distribution of table data on each DN.

  Parameter: table_name text, schema_name text

  Return type: text.
- pv_builtin_functions()

  Description: Displays information about all built-in system functions.

  Return types: proname name, pronamespace oid, proowner oid, prolang oid, procost real, prorows real, provariadic oid, protransform regproc, proisagg boolean, proiswindow boolean, prosecdef boolean, proleakproof boolean, proisstrict boolean, proretset boolean, provolatile "char", pronargs smallint, pronargdefaults smallint, prorettype oid, proargtypes oidvector, proallargtypes integer[], proargmodes "char"[], proargnames text[], proargdefaults pg_node_tree, prosrc text, probin text, proconfig text[], proacl aclitem[], prodefaultargpos int2vector, fencedmode boolean, proshippable boolean, propackage boolean, and oid oid.
- pv_thread_memory_detail()

  Description: Returns the memory information of each thread.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Return types: threadid text, tid bigint, thrdtype text, contextname text, level smallint, parent text, totalsize bigint, freesize bigint, and usedsize bigint.

- pg_shared_memory_detail()

  Description: Returns usage information about all generated shared memory contexts. For details about each column, see **DBE_PERF.SHARED_MEMORY_DETAIL**.

  Return types: contextname text, level smallint, parent text, totalsize bigint, freesize bigint, and usedsize bigint.

- pgxc_get_running_xacts()

  Description: Returns information about running transactions on each node in the cluster. The column content is the same as that in the PGXC_RUNNING_XACTS view (see **PGXC_RUNNING_XACTS**). Only users with the system admin or monitor admin permission can view the information.

  Return type: SETOF record

- pgxc_snapshot_status()

  Description: Returns the status of key memory information in the GTM in GTM mode for fault locating. GTM-Free and GTM-Lite do not support this function.

  Return type: xmin xid, xmax xid, xcnt int, oldestxmin xid, next_xid xid, timeline int, active_thread_num int, max_active_thread_num int, snapshot_num int, snapshot_totalsize bigint

  For details about the return values, see **Table 1-122**.

Table 1-122 pgxc_snapshot_status return parameters

Column	Description
xmin	Minimum active XID in the GTM.
xmax	Largest XID committed in the GTM plus 1. Transactions whose IDs are greater than or equal to this value are active.
xcnt	Number of active transactions in the GTM.
oldestxmin	ID of the earliest accessed transaction in the GTM.
next_xid	ID of the next transaction allocated by the GTM.
timeline	Current timeline in the GTM.
active_thread_num	Number of active worker threads in the GTM.
max_active_thread_num	Peak number of worker threads in the GTM within one minute.
snapshot_num	Number of snapshots delivered by the GTM within one minute.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Column	Description
snapshot_totalsize	Total size of snapshots delivered by the GTM within one minute.

- get_gtm_lite_status()

  Description: Returns the backup XID and CSN in the GTM for fault locating. This system function is not supported in GTM-Free mode.

  Return values: See **Table 1-123**.

  Table 1-123 get_gtm_lite_status return parameters

Column	Description
backup_xid	Backup XID in the GTM.
csn	Latest CSN issued by the GTM.

- adm_hist_snapshot_func()

  Description: Returns information about the snapshot execution time. To access this function, set the **enable_wdr_snapshot** parameter to **on** and obtain the permission to access the **snapshot schema**, **snapshot table**, and **tables_snap_timestamp** tables.

  Return types: snap_id bigint, dbid oid, begin_interval_time timestamp(3), end_interval_time timestamp(3), flush_elapsed interval day(5) to second(1), begin_interval_time_tz timestamp(3) with time zone, and end_interval_time_tz timestamp(3) with time zone.

- global_sql_patch_func()

  Description: SQL patch information on each global node, which is used to return the result of the global_sql_patch view.

  Return values: See **Table 1-124**.

  Table 1-124 global_sql_patch_func return parameters

Name	Type	Description
node_name	text	Name of the node where the SQL patch is located.
patch_name	name	Patch name.
unique_sql_id	bigint	Global unique query ID.
owner	oid	ID of the user who creates the patch.
enable	Boolean	Determines whether the patch takes effect.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Name	Type	Description
status	"char"	Specifies whether the SQL patch is created based on the unique SQL ID (value: **'d'**) or SQL hash value (value: **'h'**).
abort	Boolean	Determines whether the value is **AbortHint**.
hint_string	text	Hint text.
description	text	Patch description.
parent_unique_sql_id	bigint	Globally unique ID of the outer statement of the SQL statement for which the patch takes effect. The value of this parameter is **0** for statements outside a stored procedure. For statements inside the stored procedure, the value of this parameter is the globally unique ID of the statement that calls the stored procedure.
original_query	text	Original statement.

- gs_get_current_version()

  Description: Returns the current compilation mode based on the current compilation macro. **'M'** is returned.

  Return type: char.

- gs_get_kernel_info()

  Description: Global transaction information on each primary CN and DN.

  Return values: See **Table 1-125**.

Table 1-125 gs_get_kernel_info columns

Name	Type	Description
node_name	text	Node name.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Name	Type	Description
module	text	Module name, including: • **XACT** (transaction module) • **STANDBY** (standby module) • **UNDO** (undo module) • **HOTPATH** (hot patch module) • **FULL_SQL** • **LOCK** (lock module) • **SQL** • **SEC** (security module)

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Name	Type	Description
name	text	Name of the key data in the memory state, including: • **startup_max_xid** (maximum XID when a thread is started) • **recent_local_xmin** (minimum XID of a local active transaction) **recent_global_xmin** (minimum XID of a global active transaction) • **standby_xmin** (minimum XID of active transactions on the standby node) • **standby_redo_cleanup_xmin** (minimum XID of cleanup logs during redo on the standby node) • **standby_redo_cleanup_xmin_lsn** (LSN of the minimum XID of cleanup logs during redo on the standby node) • **local_csn_min** (minimum CSN of local active transactions) • **replication_slot_xmin** (minimum XID of replication slots) • **replication_slot_catalog_xmin** (minimum XID of catalog replication slots) • **global_recycle_xid** (minimum XID of global undo recycling transactions) • **global_frozen_xid** (minimum XID of global frozen transactions) • **recent_xmin** (minimum XID of active transactions in the current session) • **next_csn** (CSN of the next transaction) • **hotpatch_additional_info** (reserved column for hot patches) • **stmt_session_discard_records** (data volume discarded by full SQL statements due to full slots supported by the kernel) • **stmt_shm_flush_discard_records** (data volume discarded by full SQL statements due to full ringbuf supported by the kernel) • **idle_in_trans_timeout_records** (accumulated data volume of idle transaction timeout counts supported by the kernel) • **total_lock_usage** (**LOCK**: number of locks applied for through the primary lock table)

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Name	Type	Description
		• **total_lock_usage_rate** (**LOCK**: usage of the prim+ary lock tablespace) • **fastpath_strong_relation_locks_count** (**LOCK**: partition where FASTPATH strong lock conflicts exist and the number of strong locks corresponding to the partition) • **fastpath_failure_rate** (**LOCK**: percentage of locks that cannot be applied for through FASTPATH due to strong lock conflicts in the corresponding partition) • **lock_acquire_lack_fastpath_count** (**LOCK**: total number of times that locks fail to be applied for through FASTPATH because FASTPATH slots are used up) • **n_soft_parse** (**SQL**: number of soft parsing times) • **n_hard_parse** (**SQL**: number of hard parsing times) • **hsm_access_success_count** (**SEC**: number of successful accesses to the KMS) • **hsm_access_failure_count** (**SEC**: number of failed accesses to the KMS)
value	text	Value of the key data in the memory state.

Example:

```
gaussdb=# SELECT * FROM gs_get_kernel_info();
  node_name   | module  |              name                      |  value

- gs_get_single_node_group(object_type, object_name1, object_name2, queryonly)

  Description: Obtains the default single-node information of the target table or schema.

  Parameters: See **Table 1-126**.

  Return type: text.

  Table 1-126 gs_get_single_node_group parameters

Parameter	Type	Description	Value Range
object_type	text	Object type.	• **schema** • **table**
object_name1	text	Schema name.	Name of an existing schema.
object_name2	text	Table name.	• Table name. • **NULL** (default).
queryonly	bool	Specifies whether to query only.	• **true** (default). • **false**.

  Example:

```
gaussdb=# CREATE SCHEMA s1 SET NODE GROUP sys_single_group1;

gaussdb=# CREATE TABLE single_table(c1 int, c2 int) TO GROUP sys_single_group2;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gaussdb=# SELECT gs_get_single_node_group('schema', 's1');
 gs_get_single_node_group
--------------------------
 sys_single_group1
(1 row)

gaussdb=# SELECT gs_get_single_node_group('table', 'public', 'single_table');
 gs_get_single_node_group
--------------------------
 sys_single_group2
(1 row)

gaussdb=# DROP TABLE single_table;
DROP TABLE
gaussdb=# DROP SCHEMA s1 CASCADE;
DROP SCHEMA
```

1.6.27 System Administration Functions

1.6.27.1 Configuration Setting Functions

Configuration setting functions are used for querying and modifying GUC parameters.

- current_setting(setting_name)

  Description: Obtains the current value of **setting_name** by query. It is equivalent to the SQL statement SHOW.

  Return type: text

  Example:

  ```
  gaussdb=# SELECT current_setting('datestyle');

   current_setting
  -----------------
   ISO, MDY
  (1 row)
  ```

- set_working_grand_version_num_manually(tmp_version)

  Description: Upgrades new features of GaussDB by switching the authorization version.

  Return type: void

- shell_in(type)

  Description: Processes the input route of the shell type (that is, the type that has not been filled).

  Return type: void

- shell_out(type)

  Description: Processes the output route of the shell type (that is, the type that has not been filled).

  Return type: void

- set_config(setting_name, new_value, is_local)

  Description: Sets a specified configuration parameter and returns the parameter value. This function does not allow you to set the **ROLE** parameter.

  Parameters:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

  - **setting_name**: name of the parameter to be set.
  - **new_value**: value of the parameter to be set.
  - **is_local**: application scope of the parameter value.
    - If **is_local** is **true**, the **new_value** applies only to the current transaction.
    - If **is_local** is **false**, the **new_value** applies to the current session, which is equivalent to the SQL statement SET.

  Return type: text

  Example:

```
gaussdb=# SELECT set_config('log_statement_stats', 'off', false);

 set_config
------------
 off
(1 row)
```

1.6.27.2 Universal File Access Functions

Universal file access functions provide local access APIs for files on a database server. Only files in the database cluster directory and the **log_directory** directory can be accessed. A relative path is used for files in the cluster directory, and a path matching the **log_directory** configuration setting is used for log files. Only the database initial user can use these functions.

- pg_ls_dir(dirname text)

  Description: Lists files in a directory.

  Return type: setof text

  Note: pg_ls_dir returns all the names in the specified directory, except the special entries "." and "..".

  Example:

```
gaussdb=# SELECT pg_ls_dir('./');
      pg_ls_dir
----------------------
 .gaussdb.conf.swp
 gaussdb.conf
 pg_tblspc
 PG_VERSION
 gs_ident.conf
 core
 server.crt
 pg_serial
 pg_twophase
 gaussdb.conf.lock
 pg_stat_tmp
 pg_notify
 pg_subtrans
 pg_ctl.lock
 pg_xlog
 pg_clog
 base
 pg_snapshots
 postmaster.opts
 postmaster.pid
 server.key.rand
 server.key.cipher
 pg_multixact
 pg_errorinfo
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
 server.key
 gs_hba.conf
 pg_replslot
 .gs_hba.conf.swp
 cacert.pem
 gs_hba.conf.lock
 global
 gaussdb.state
(32 rows)
```

- pg_read_file(filename text, offset bigint, length bigint)

  Description: Returns the content of a text file. It can return a maximum of length bytes from *offset*. The actual value is smaller than the length if the end of the file is reached at first. If *offset* is negative, it is the length rolled back from the file end. If *offset* and *length* are omitted, the entire file is returned.

  Return type: text

  Example:

```
gaussdb=# SELECT pg_read_file('postmaster.pid',0,100);
           pg_read_file
----------------------------------------
 53078                            +
/srv/BigData/testdir/data1/coordinator+
 1500022474                       +
 8000                            +
 /var/run/FusionInsight           +
 localhost                        +
  2
(1 row)
```

- pg_read_binary_file(filename text [, offset bigint, length bigint,missing_ok boolean[, compress boolean]])

  Description: Returns the content of a binary file. The function is similar to pg_read_file, but the return value is of the bytea type. Therefore, no encoding check is performed. This function can be used with the convert_from function to read a file in a specified encoding.

  Return type: bytea

```
gaussdb=# SELECT convert_from(pg_read_binary_file('filename'), 'UTF8');
```

- pg_read_binary_file_blocks(path text, block_begin bigint, block_count bigint, bitmap bigint)

  Description: Reads the binary content of a specified page area in a cross-page transparent compression file. This function can be called only by the initial database user.

  Return type: bytea

- pg_stat_file(filename text)

  Description: Returns a record with the status information of the text file, including the file size, last access timestamp, last modification timestamp, last file status change timestamp, and a **Boolean** value indicating if it is a directory.

  Return type: record

  Typical usages are as follows:

```
gaussdb=# SELECT * FROM pg_stat_file('filename');
gaussdb=# SELECT (pg_stat_file('filename')).modification;
```

  Example:

```
gaussdb=# SELECT convert_from(pg_read_binary_file('postmaster.pid'), 'UTF8');
           convert_from
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
---------------------------------------
 4881                                 +
 /srv/BigData/gaussdb/data1/coordinator+
 1496308688                           +
 25108                                +
 /opt/huawei/Bigdata/gaussdb/gaussdb_tmp +
 *                                    +
  25108001  43352069                  +

(1 row)
gaussdb=# SELECT * FROM pg_stat_file('postmaster.pid');

 size |         access         |       modification       |         change
| creation | isdir
------+------------------------+--------------------------+--------------------------
+----------+-------
  117 | 2017-06-05 11:06:34+08 | 2017-06-01 17:18:08+08 | 2017-06-01 17:18:08+08
|          | f
(1 row)
gaussdb=# SELECT (pg_stat_file('postmaster.pid')).modification;
      modification
-------------------------
 2017-06-01 17:18:08+08
(1 row)
```

1.6.27.3 Server Signal Functions

Server signal functions send control signals to other server threads. Only the system administrator has the permission to execute the following functions:

- pg_cancel_backend(pid int)

  Description: Cancels a statement that is being executed by a backend thread.

  Return type: Boolean

  Note: pg_cancel_backend sends a query cancellation (SIGINT) signal to the backend thread identified by **pid**. The PID of an active backend thread can be found in the **pid** column of the PG_STAT_ACTIVITY view (see **PG_STAT_ACTIVITY**), or can be found by listing the database thread using **ps** on the server. A user with the SYSADMIN permission, the owner of the database connected to the backend thread, the owner of the backend thread, or a user who inherits permissions of the built-in role gs_role_signal_backend can use this function.

- pg_cancel_session(pid bigint, sessionid bigint)

  Description: Cancels the statement that is being executed by an active session in thread pool mode.

  Return type: Boolean

  Note: The input parameters of pg_cancel_session can be queried using the **pid** and **sessionid** columns in pg_stat_activity. The input parameters can be used to cancel the statements that are being executed by active sessions in thread pool mode. When the input parameters **pid** and **sessionid** are the same and both are thread IDs, the function of pg_cancel_backend is the same as that of pg_cancel_backend.

- pg_cancel_invalid_query()

  Description: Cancels the invalid query of a backend.

  Return type: Boolean

  Note: Only the system administrator has the permission to cancel queries that are running in the backend of a degraded GTM.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- pg_reload_conf()

  Description: Sends a SIGHUP signal to the server to trigger all server threads to reload their configuration files.

  Return type: Boolean

- pg_rotate_logfile()

  Description: Rotates the log files of the server.

  Return type: Boolean

  Note: pg_rotate_logfile sends a signal to the log file manager, instructing the manager to immediately switch to a new output file. This function works only when redirect_stderr is used for log output. Otherwise, no log file manager sub-thread is generated.

- pg_terminate_session(pid bigint, sessionid bigint)

  Description: Terminates a backend session in thread pool mode.

  Return type: Boolean

  Note: The input parameters of this function can be queried using the **pid** and **sessionid** fields in pg_stat_activity. A user with the SYSADMIN permission, the owner of the database connected to the session, the owner of the session, or a user who inherits permissions of the built-in role gs_role_signal_backend has the permission to use this function. If the target session fails to be terminated after this function is executed, the socket connection between the session and the client is forcibly closed.

  NOTICE

  - This function has two execution modes based on the relationship between the input parameters **pid** and **sessionid**. The details are as follows:
    - If the parameter values are the same (**pid** = **sessionid**, and the value is the thread ID), the function terminates threads by thread. Non-thread pool threads and active thread pool threads can be terminated, but inactive thread pool threads cannot be terminated.
    - If the parameter values are different (**pid** ≠ **sessionid**), the function terminates sessions by session. Active sessions can be terminated, and inactive sessions and their client socket connections can be cleared.
  - In the following scenarios, the target thread or session may not be terminated immediately after this function is executed:
    - The thread or session is waiting for a lock.
    - The thread or session is blocked or does not respond due to a hardware fault (for example, a storage exception, network interruption, or resource unavailability).
    - The session is in the network I/O (for example, **recv/send**) state.
    - The session is in the idle state when the system CPU load is high or the thread pool is full.

- pg_terminate_active_session_socket(pid int64, sessionid int64)

  Description: Closes the socket connection between an active session and the client.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Return type: Boolean

Note: Each of these functions returns **true** if they are successful and **false** otherwise. A user with the SYSADMIN permission, the owner of the database connected to the backend thread, the owner of the backend thread, or a user who inherits permissions of the built-in role gs_role_signal_backend can use this function.

- pg_terminate_backend(pid int)

  Description: Terminates a backend thread. Only the system administrator and thread owner can use this function.

  Return type: Boolean

  Note: Each of these functions returns **true** if they are successful and **false** otherwise. A user with the SYSADMIN permission, the owner of the database connected to the backend thread, the owner of the backend thread, or a user who inherits permissions of the built-in role gs_role_signal_backend can use this function. If the target session fails to be terminated after this function is executed, the socket connection between the session and the client is forcibly closed.

  NOTICE

  - This function can terminate non-thread pool threads and active thread pool threads, but cannot terminate inactive thread pool threads.
  - In the following scenarios, the target thread may not be terminated immediately after this function is executed:
    - The thread is waiting for a lock.
    - The thread is blocked or does not respond due to a hardware fault (for example, a disk exception or resource unavailability).

  Example:

```
gaussdb=# SELECT pid from pg_stat_activity;
       pid
-----------------
 140657876268816
(1 rows)

gaussdb=# SELECT pg_terminate_backend(140657876268816);
 pg_terminate_backend
----------------------
 t
(1 row)
```

- gs_cancel_invalid_gtm_query(cstring)

  Description: Disconnects all sessions connected to the GTM with a specified address. The function parameter is a comma-separated string. The format of each separated substring is IP[:port] (Content in square parentheses ([]) is optional.).

  Return type: void

  Remarks: Only the system administrator has the permission to execute this function. This function is automatically called by the CM component in a specific process. You are advised not to manually call this function.

- terminate_session_has_temp_file()

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description: Interrupts all sessions where temporary files are being opened.

Return type: void

Remarks: Only the system administrator has the permission to execute this function. This function is automatically called by the CM component in a specific process. You are advised not to manually call this function.

1.6.27.4 Backup and Restoration Control Functions

Backup Control Functions

Backup control functions help with online backup.

- pg_create_restore_point(name text)

  Description: Creates a named point for performing a restore (requires an administrator role).

  Return type: text

  Note: pg_create_restore_point creates a named transaction log record that can be used as a restoration target, and returns the corresponding transaction log location. The given name can then be used with **recovery_target_name** to specify the point up to which restoration will proceed. Avoid creating multiple restoration points with the same name, since restoration will stop at the first one whose name matches the restoration target.

- pg_current_xlog_location()

  Description: Obtains the write position of the current transaction log.

  Return type: text

  Note: pg_current_xlog_location displays the write position of the current transaction log in the same format as those of the previous functions. Read-only operations do not require SYSADMIN permissions.

- pg_current_xlog_insert_location()

  Description: Obtains the insert position of the current transaction log.

  Return type: text

  Note: pg_current_xlog_insert_location displays the insert position of the current transaction log. The insertion point is the logical end of the transaction log at any instant, while the write location is the end of what has been written out from the server's internal buffers. The write position is the end that can be detected externally from the server. This operation can be performed to archive only some of completed transaction log files. The insert position is mainly used for commissioning the server. Read-only operations do not require SYSADMIN permissions.

- gs_current_xlog_insert_end_location()

  Description: Obtains the insert position of the current transaction log.

  Return type: text

  Note: **gs_current_xlog_insert_end_location** displays the insert position of the current transaction log.

- pg_start_backup(label text [, fast boolean])

  Description: Starts to perform online backup. (An administrator, replication role, or O&M administrator must enable **operation_mode**.) Label strings

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

starting with **gs_roach** are reserved and can be used only by the internal backup tool GaussRoach.

Return type: text

Note: pg_start_backup receives a user-defined backup label (usually the name of the position where the backup dump file is stored). This function writes a backup label file to the data directory of the database cluster and then returns the starting position of backed up transaction logs in text mode. This function must be used together with pg_stop_backup(). If this function is called independently, backup_label remains. During WAL replay, the checkpoint is read based on backup_label. If the WAL file corresponding to the checkpoint has been reclaimed, the database cannot be started.

```
gaussdb=# SELECT pg_start_backup('label_goes_here',true);
 pg_start_backup
-----------------
 0/3000020
(1 row)
```

- pg_stop_backup()

  Description: Completes online backup. **operation_mode** must be enabled by an administrator role, replication role, or OPRADMIN.

  Return type: text

  Note: pg_stop_backup deletes the label file created by pg_start_backup and creates a backup history file in the transaction log archive area. The history file includes the label given to pg_start_backup, the start and end transaction log locations for the backup, and the start and end time of the backup. The return value is the backup's ending transaction log location. After the end position is calculated, the insert position of the current transaction log automatically goes ahead to the next transaction log file. The ended transaction log file can be immediately archived so that backup is complete.

- pg_switch_xlog()

  Description: Switches to a new transaction log file An administrator or O&M administrator must enable **operation_mode**.

  Return type: text

  Note: pg_switch_xlog moves to the next transaction log file so that the current log file can be archived (if continuous archive is used). The return value is the ending transaction log location + 1 within the just-completed transaction log file. If there has been no transaction log activity since the last transaction log switchover, pg_switch_xlog does not move but returns the start location of the transaction log file currently in use.

- pg_xlogfile_name(location text)

  Description: Converts the position string in a transaction log to a file name.

  Return type: text

  Note: pg_xlogfile_name extracts only the transaction log file name. If the given transaction log position is the transaction log file border, a transaction log file name will be returned for both the two functions. This is usually the desired behavior for managing transaction log archiving, since the preceding file is the last one that currently needs to be archived.

- pg_xlogfile_name_offset(location text)

  Description: Converts the position string in a transaction log to a file name and returns the byte offset in the file.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Return type: text, integer

Note: pg_xlogfile_name_offset can extract transaction log file names and byte offsets from the returned results of the preceding functions. Example:

```
gaussdb=# SELECT * FROM pg_xlogfile_name_offset(pg_stop_backup());
NOTICE:  pg_stop_backup cleanup done, waiting for required WAL segments to be archived
NOTICE:  pg_stop_backup complete, all required WAL segments have been archived
        file_name         | file_offset
--------------------------+-------------
000000010000000000000003 |         272
(1 row)
```

- pg_xlog_location_diff(location text, location text)

  Description: Calculates the difference in bytes between two transaction log locations.

  Return type: numeric

- pg_cbm_start_tracked_location()

  Description: Queries the start LSN parsed by CBM.

  Return type: text

- pg_cbm_tracked_location()

  Description: Queries the LSN parsed by CBM.

  Return type: text

- pg_cbm_get_merged_file(startLSNArg text, endLSNArg text)

  Description: Combines CBM files within the specified LSN range into one and returns the name of the combined file.

  Return type: text

  Note: Only SYSADMIN or OPRADMIN can obtain the CBM combination file.

- pg_cbm_get_changed_block(startLSNArg text, endLSNArg text)

  Description: Merges CBM files within the specified LSN range into a table and returns records in this table.

  Return type: records

  Note: The table columns returned by pg_cbm_get_changed_block include the start LSN, end LSN, tablespace OID, database OID, table relfilenode, table fork number, whether the table is a system catalog, whether the table is dropped, whether the table is created, whether the table is truncated, number of pages in the truncated table, number of modified pages, and list of modified page numbers.

- gs_cbm_get_changed_block(startLSNArg text, endLSNArg text)

  Description: Merges CBM files within the specified LSN range into a table and returns records in this table.

  Return type: records

  Note: The table columns returned by gs_cbm_get_changed_block include the LSNs where the merge starts and ends, tablespace OID, database OID, relfilenode of the table, fork number of the table, whether the table is a system catalog, whether the table is dropped, whether the table is created, whether the table is truncated, number of pages after the table is truncated, number of modified pages, list of modified page numbers, and XID of the relevant transaction (only for the operations of creating and dropping databases or tablespaces).

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- pg_cbm_recycle_file(targetLSNArg text)

  Description: Deletes the CBM files that are no longer used and returns the first LSN after the deletion.

  Return type: text

- pg_cbm_force_track(targetLSNArg text,timeOut int)

  Description: Forcibly executes the CBM trace to the specified Xlog position and returns the Xlog position of the actual trace end point.

  Return type: text

- pg_enable_delay_ddl_recycle()

  Description: Enables DDL delay and returns the Xlog position of the enabling point. An administrator or O&M administrator must enable **operation_mode**.

  Return type: text

- pg_disable_delay_ddl_recycle(barrierLSNArg text, isForce bool)

  Description: Disables DDL delay and returns the Xlog range where DDL delay takes effect. An administrator or O&M administrator must enable **operation_mode**.

  Return type: records

- pg_enable_delay_xlog_recycle()

  Description: Enables the Xlog recycling delay function for CN recovery. An administrator or O&M administrator must enable **operation_mode**.

  Return type: void

- pg_disable_delay_xlog_recycle()

  Description: Disables the Xlog recycling delay function for CN recovery. An administrator or O&M administrator must enable **operation_mode**.

  Return type: void

- pg_cbm_rotate_file(rotate_lsn text)

  Description: Forcibly switches the file after the CBM parses **rotate_lsn**. This function is called during the build process.

  Return type: void

- gs_roach_stop_backup(backupid text)

  Description: Stops a backup started by the internal backup tool GaussRoach. It is similar to the **pg_stop_backup system** function but is more lightweight.

  Return type: text. The content is the insertion position of the current log.

  Note: To call this function, users must possess the SYSADMIN or OPRADMIN permission. In the case of OPRADMIN, **operation_mode** must be enabled.

- gs_roach_enable_delay_ddl_recycle(backupid name)

  Description: Enables DDL delay and returns the log position of the enabling point. It is similar to the pg_enable_delay_ddl_recycle system function but is more lightweight. In addition, different **backupid** values can be used to concurrently enable DDL statements with delay. **backupid** values that start with "gs_roach" are reserved for the internal backup tool, GaussRoach. To use them, you need to set **application_name** to '**gs_roach**'.

  Return type: text. The content is the log location of the start point.

- gs_roach_disable_delay_ddl_recycle(backupid text)

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description: Disables DDL delay and returns the log range where DDL delay takes effect. It is similar to the pg_enable_delay_ddl_recycle system function but is more lightweight. In addition, different **backupid** values can be used to concurrently disable DDL statements with delay. **backupid** values that start with "gs_roach" are reserved for the internal backup tool, GaussRoach. To use them, you need to set **application_name** to **'gs_roach'**.

Return type: records. The content is the range of logs for which DDL delay takes effect.

- gs_roach_switch_xlog(request_ckpt bool)

  Description: Switches the currently used log segment file and triggers a full checkpoint if **request_ckpt** is set to **true**.

  Return type: text. The content is the location of the segment log.

  Note: To call this function, users must possess the SYSADMIN or OPRADMIN permission. In the case of OPRADMIN, **operation_mode** must be enabled.

- gs_block_dw_io(timeout int, identifier text)

  Description: Blocks doublewrite page flushing.

  Parameters:

  – timeout

    Block duration.

    Value range: [0,3600], in seconds. The value **0** indicates that the block duration is 0s.

  – identifier

    ID of the operation.

    Value range: a string, supporting only uppercase letters, lowercase letters, digits, and underscores (_).

  Return type: Boolean

  Note: To call this function, users must possess the SYSADMIN or OPRADMIN permission. In the case of OPRADMIN, **operation_mode** must be enabled.

- gs_is_dw_io_blocked()

  Description: Checks whether disk flushing on the current doublewrite page is blocked. If disk flushing is blocked, **true** is returned.

  Return type: Boolean

  Note: To call this function, users must possess the SYSADMIN or OPRADMIN permission. In the case of OPRADMIN, **operation_mode** must be enabled.

- gs_pitr_advance_last_updated_barrier()

  Description: In PITR mode, forcibly updates the global maximum archived recovery point uploaded to OBS/NAS last time to the current point. No input parameter is required.

  Return type: text

  Note: To call this function, users must possess the SYSADMIN or OPRADMIN permission. In the case of OPRADMIN, **operation_mode** must be enabled. This parameter is valid only on the first normal CN in a distributed system. The return value is the latest local maximum archived recovery point.

- gs_pitr_clean_local_barrier_files('delete_timestamp')

  Description: Clears locally cached barrier record files.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Value range: The **delete_timestamp** parameter is of the text type. It is a Linux timestamp and contains 10 characters.

Return type: text

Note: To call this function, users must possess the SYSADMIN or OPRADMIN permission. In the case of OPRADMIN, **operation_mode** must be enabled. The returned result is the start timestamp of the earliest barrier file on the localhost after the deletion.

- gs_get_barrier_lsn(barrier_name text)

  Description: Obtains the LSN corresponding to the barrier created using a backup.

  Return type: text

  Note: Currently, only **gs_roach_full** and **gs_roach_inc** are supported. To call this function, the user must have the SYSADMIN or OPRADMIN permission. An O&M administrator must enable **operation_mode**.

- gs_gbr_relation_associated_filenode(schemaName name, tableName name)

  Description: Returns the relfilenode of all indexes, sequences, partitions, TOASTs, and TOAST indexes related to the input table.

  Return type: records

  Note: The table columns returned by gs_gbr_relation_associated_filenode include the file type relkind, namespace where the file is located, relation name corresponding to the file, OID of the database where the file is located, OID of the tablespace where the file is located, and relfilenode of the file.

- gs_pitr_stop_archive_manually(archive_slot_name cstring)

  Description: Stops an ongoing archiving task on a single CN/DN (valid only for remote media). The function returns whether the archiving task is stopped successfully.

  Return type: text

  Note: To call this function, the user must have the SYSADMIN or OPRADMIN permission. An O&M administrator must enable **operation_mode**. This is an internal function and cannot be called by users.

- pg_create_physical_replication_slot_extern(slotname text, dummy_standby bool, extra_content text, need_recycle_xlog bool)

  Description: Creates an OBS or NAS archive slot or backup slot. For an archive slot, **slotname** indicates the name of the archive slot or recovery slot. The primary and standby slots must use the same slot name. **dummy_standby** is a reserved parameter. **extra_content** contains some information about the archive slot. For an OBS archive slot, the format is **OBS;obs_server_ip;obs_bucket_name;obs_ak;obs_sk;archive_path;is_recovery;is_vote_replicate**, in which **OBS** indicates the archive media of the archive slot, **obs_server_ip** indicates the IP address of OBS, **obs_bucket_name** indicates the bucket name, **obs_ak** indicates the AK of OBS, **obs_sk** indicates the SK of OBS, **archive_path** indicates the archive path, and **is_recovery** specifies whether the slot is an archive slot or a recovery slot (**0**: archive slot; **1**: recovery slot). **is_vote_replicate** specifies whether the voting copy is archived first. The value **0** indicates that the synchronous standby node is archived first, and the value **1** indicates that the voting copy is archived first. This column is reserved in the current version and is not adapted yet. For a NAS archive slot, the format is

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NAS;archive_path;is_recovery;is_vote_replicate. Compared with the OBS archive slot, the NAS archive slot does not have the OBS configuration information, while the meanings of other fields are the same.

If the media is not OBS or NAS, the OBS archive slot is used by default. The **extra_content** format is **obs_server_ip;obs_bucket_name;obs_ak;obs_sk;archive_path;is_recovery;is_vote_replicate**.

need_recycle_xlog specifies whether to recycle old archive logs when creating an archive slot. The value **true** indicates that old archive logs are recycled, and the value **false** indicates that old archive logs are not recycled.

For a backup slot, **slotname** starts with **gs_roach_** and is usually created by the backup process. **dummy_standby** is a reserved parameter. The value of **extra_content** can be **NULL** or a valid LSN character string. **need_recycle_xlog** does not affect the function of the backup slot. If the value of **extra_content** is **NULL**, the checkpoint redo point is used as the initial position of the backup slot. If the value of **extra_content** is a valid LSN character string and the LSN is smaller than the current checkpoint redo point, the LSN is used as the initial position of the backup slot. If the character string is an invalid LSN, the creation fails.

Return type: records, including slotname and xlog_position.

Note: Users who call this function must have the SYSADMIN permission or the REPLICATION permission, or inherit permissions of the built-in role gs_role_replication. Currently, multiple archive slots cannot be created.

Example:

Create an OBS archive slot.

In the following command, *obs_server_ip*, *obs_bucket_name*, *obs_ak*, and *obs_sk* indicate the OBS IP address, bucket name, AK, and SK, respectively. **gaussdb_uuid/dn1** indicates the log archive path in the OBS bucket. Replace it with the actual path as required.

```
gaussdb=# SELECT * FROM pg_create_physical_replication_slot_extern('uuid', false,
'OBS;obs_server_ip;obs_bucket_name;obs_ak;obs_sk;gaussdb_uuid/dn1;0;0', false);
 slotname | xlog_position
----------+---------------
 uuid     |
(1 row)
```

Create a NAS archive slot.

In the following command, **/data/nas/media/gaussdb_uuid/dn1** indicates the log archive path on the NAS. Replace it with the actual path as required.

```
gaussdb=# SELECT * FROM pg_create_physical_replication_slot_extern('uuid', false, 'NAS;/data/nas/
media/gaussdb_uuid/dn1;0;0', false);
 slotname | xlog_position
----------+---------------
 uuid     |
```

Create a backup slot.

Before using the pg_create_physical_replication_slot_extern function to create a backup slot, run the **set application_name='gs_roach'** command. This function is used for backup-related O&M operations. You are advised not to use it directly.

```
gaussdb=# SELECT * FROM pg_catalog.pg_create_physical_replication_slot_extern('gs_roach_full',
false, NULL, false);
   slotname    | xlog_position
---------------+---------------
 gs_roach_full | 0/3F883530
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- gs_set_obs_delete_location(delete_location text)

  Description: Sets the location where OBS archive logs can be deleted. The value of **delete_location** is an LSN. The logs before this location have been replayed and flushed to disks and can be deleted on OBS.

  Return type: xlog_file_name text, indicating the file name of the logs that can be deleted. The value of this parameter is returned regardless of whether OBS is deleted successfully.

  Note: To call this function, users must possess the SYSADMIN or OPRADMIN permission. In the case of OPRADMIN, **operation_mode** must be enabled.

  ```
  gaussdb=# SELECT gs_set_obs_delete_location('0/54000000');
   gs_set_obs_delete_location
  ----------------------------
   000000010000000000000054_00
  (1 row)
  ```

- gs_set_obs_delete_location_with_slotname(cstring, cstring)

  Description: Sets the location where OBS archive logs in a specified archived slot can be deleted. The first parameter indicates the LSN. The logs before this location have been replayed and flushed to disks and can be deleted on OBS. The second parameter indicates the name of the archive slot.

  Return type: xlog_file_name text, indicating the file name of the logs that can be deleted. The value of this parameter is returned regardless of whether OBS is deleted successfully.

  Note: To call this function, users must possess the SYSADMIN or OPRADMIN permission. In the case of OPRADMIN, **operation_mode** must be enabled.

- gs_get_global_barrier_status()

  Description: gs_get_global_barrier_status is used to query the latest global barrier archived in OBS.

  Return type: text

  global_barrier_id: globally latest barrier ID.

  global_achive_barrier_id: globally latest archived barrier ID.

  Note: To call this function, users must possess the SYSADMIN or OPRADMIN permission. In the case of OPRADMIN, **operation_mode** must be enabled.

- gs_get_global_barriers_status()

  Description: gs_get_global_barriers_status is used to query the latest global barrier archived in OBS.

  Return type: text

  slot_name: slot name.

  global_barrier_id: globally latest barrier ID.

  global_achive_barrier_id: globally latest archived barrier ID.

  Note: To call this function, users must possess the SYSADMIN or OPRADMIN permission. In the case of OPRADMIN, **operation_mode** must be enabled.

- gs_set_archive_standby_name_on_primary(text)

  Description: gs_set_archive_standby_name_on_primary is used to specify the standby node for archiving. After the setting, the specified standby node performs the archive operation. In DCF mode, the standby node cannot be specified. The input is the name of a standby node, for example, **dn_6002**.

  Return type: Boolean

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

The value **true** indicates that the setting is successful, while the value **false** indicates that the setting fails.

Restoration Control Functions

Restoration control functions provide information about the status of standby nodes. These functions may be executed both during restoration and in normal running.

- pg_is_in_recovery()

  Description: Returns **true** if restoration is still in progress.

  Return type: Boolean

- pg_last_xlog_receive_location()

  Description: Obtains the last transaction log location received and synchronized to disk by streaming replication. While streaming replication is in progress, this will increase monotonically. If restoration has been completed, then this value will remain static at the value of the last WAL record received and synchronized to disk during restoration. If streaming replication is disabled or if it has not yet started, the function returns a null value.

  Return type: text

- pg_last_xlog_replay_location()

  Description: Obtains last transaction log location replayed during restoration. If restoration is still in progress, this will increase monotonically. If restoration has been completed, then this value will remain static at the value of the last WAL record received during that restoration. When the server has been started normally without restoration, the function returns a null value.

  Return type: text

- pg_last_xact_replay_timestamp()

  Description: Obtains the timestamp of last transaction replayed during restoration. This is the time to commit a transaction or abort a WAL record on the primary node. If no transactions have been replayed during restoration, this function will return a null value. If restoration is still in progress, this will increase monotonically. If restoration has been completed, then this value will remain static at the value of the last WAL record received during that restoration. If the server normally starts without manual intervention, this function will return a null value.

  Return type: timestamp with time zone

Restoration control functions control restoration threads. These functions may be executed only during restoration.

- pg_is_xlog_replay_paused()

  Description: Returns **true** if restoration is paused.

  Return type: Boolean

- pg_xlog_replay_pause()

  Description: Pauses restoration immediately.

  Return type: void

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- pg_xlog_replay_resume()

  Description: Restarts restoration if it was paused.

  Return type: void

- gs_get_active_archiving_standby()

  Description: Queries information about archive standby nodes in the same shard. The standby node name, archive location, and number of archive logs are returned.

  Return type: text, int

- gs_pitr_get_warning_for_xlog_force_recycle()

  Description: Checks whether logs are recycled because a large number of logs are stacked in the archive slot after archiving is enabled.

  Return type: Boolean

- gs_pitr_clean_history_global_barriers(stop_barrier_timestamp cstring)

  Description: Clears all barrier records generated before the specified time. The earliest barrier record is returned. The input parameter is of the cstring type and is a Linux timestamp. You need to perform this operation as an administrator or O&M administrator.

  Return type: text

- gs_pitr_archive_slot_force_advance(stop_barrier_timestamp cstring)

  Description: Forcibly updates the archive slot and clears unnecessary barrier records. The new archive slot location is returned. The input parameter is of the cstring type and is a Linux timestamp. You need to perform this operation as an administrator or O&M administrator.

  Return type: text

- gs_recent_barrier_buffer_info(start_time text, end_time text)

  Description: Queries barrier information based on the time range entered by the user to obtain time_stamp, CSN, LSN, and standard_time.

  Return type: records

  Note: To call this function, you must have the SYSADMIN or OPRADMIN permission. The input parameters **start_time** and **end_time** are in the format of year-month-day time, where the time is in the clock format. The maximum query time span is one day. If the time span exceeds the limit, the end time is automatically converted to the limit boundary based on the query start time. Example:

```
gaussdb=# SELECT * FROM gs_recent_barrier_buffer_info('2024-01-15 23:27:50', '2024-01-15
23:28:00');
 timestamp |       lsn        |   csn   |    standard_time
-----------+------------------+---------+---------------------
 1705332470 | 00000000/15FFBBA0 | 41020421 | 2024-01-15 23:27:50
 1705332471 | 00000000/15FFBDF0 | 41020422 | 2024-01-15 23:27:51
 1705332472 | 00000000/15FFC058 | 41020423 | 2024-01-15 23:27:52
 1705332472 | 00000000/15FFC0F8 | 41020424 | 2024-01-15 23:27:52
 1705332473 | 00000000/15FFC348 | 41020425 | 2024-01-15 23:27:53
 1705332474 | 00000000/15FFC598 | 41020426 | 2024-01-15 23:27:54
 1705332475 | 00000000/15FFC638 | 41020427 | 2024-01-15 23:27:55

```

- gs_show_obs_media_files(slot_name cstring, src cstring, offset int32, limit int32)

  Description: Queries the OBS file list based on the archive slot (**slot_name**) and OBS directory address (**src**) entered by the user.

  Return type: records

  Note: To call this function, you must have the SYSADMIN or OPRADMIN permission. **offset** indicates the query result offset, and **limit** indicates the maximum number of output lines. All files in **src** are queried. Example:

```
gaussdb=# SELECT gs_show_obs_media_files('ssh','cn_5001/pg_xlog',1, 5);
                                gs_show_obs_media_files
-----------------------------------------------------------------------------------------------
 (wstdist_ssh/archive/cn_5001/pg_xlog/
000000010000000000000010_01_01_00000000_00000000_00000003)
 (wstdist_ssh/archive/cn_5001/pg_xlog/
000000010000000000000010_02_01_00000000_00000000_00000003)
 (wstdist_ssh/archive/cn_5001/pg_xlog/
000000010000000000000010_03_01_00000000_00000000_00000003)
 (wstdist_ssh/archive/cn_5001/pg_xlog/
000000010000000000000011_00_01_00000000_00000000_00000003)
 (wstdist_ssh/archive/cn_5001/pg_xlog/
000000010000000000000011_01_01_00000000_00000000_00000003)
(5 rows)
```

- gs_upload_obs_media_file(slot_name cstring, src cstring, dest cstring, is_forced bool)

  Description: Uploads OBS files based on the archive slot (**slot_name**), source address (**src**), OBS address (**dest**), and whether to forcibly upload files (**is_forced**).

  Return type: void

  Note: To call this function, you must have the SYSADMIN or OPRADMIN permission. The original file directory must be the directory specified by *$GAUSSLOG*. Example:

```
gaussdb=# SELECT * FROM gs_upload_obs_media_file('ssh', '/data/gauss/log/stwang/test/
000000010000000000000019_02_01_00000000_00000000_00000003', 'cn_5001/pg_xlog/
000000010000000000000019_02_01_00000000_00000000_00000003', true);
 gs_upload_obs_media_file
--------------------------

(1 row)
```

- gs_download_obs_media_file(slot_name cstring, src cstring, dest cstring)

  Description: Downloads OBS files based on the archive slot (**slot_name**), download source address (**src**), and local destination address (**dest**).

  Return type: void

  Note: To call this function, you must have the SYSADMIN or OPRADMIN permission. The download directory must be the directory specified by *$GAUSSLOG*. Example:

```
gaussdb=# SELECT * FROM gs_download_obs_media_file('ssh','cn_5001/pg_xlog/
000000010000000000000019_02_01_00000000_00000000_00000003','/data/gauss/log/stwang/test');
 gs_download_obs_media_file
----------------------------

(1 row)
```

While restoration is paused, no further database changes are applied. In hot standby mode, all new queries will see the same consistent snapshot of the

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

database, and no further query conflicts will be generated until restoration is resumed.

If streaming replication is disabled, the paused state may continue indefinitely without problem. While streaming replication is in progress, WAL records will continue to be received, which will eventually fill available disk space. This progress depends on the duration of the pause, the rate of WAL generation, and available disk space.

1.6.27.5 Dual-Cluster DR Control Functions

- gs_streaming_dr_in_switchover()

  Description: Truncates services during a planned switchover in the primary cluster in streaming replication-based remote DR solutions.

  Return type: Boolean, indicating whether the service truncation is successful and whether the switchover process can be performed normally.

- gs_set_dr_dest_name()

  Description: Configures the IDs of all log receiver clusters in the log sender cluster. The input parameter is a character string consisting of the IDs of all log receiver clusters directly connected to the log sender cluster. The IDs are separated by commas (,). If the setting is successful, **t** is returned. Otherwise, **f** is returned.

  Input parameter type: text. If the input parameter is **0**, the instance ID of the log receiver cluster is not configured. This parameter is automatically set during the DR process. You are advised not to change the value.

  NOTICE

  The instance ID of the log receiver cluster cannot be **invalid_cluster_uuid** and can contain a maximum of 36 characters.

  Return type: Boolean

  Example

  ```
  gaussdb=# SELECT * FROM gs_set_dr_dest_name('cluster1,cluster2');
   gs_set_dr_dest_name
  ---------------------
   t
  (1 row)
  ```

- gs_get_dr_dest_name()

  Description: Queries all instance IDs of the log receiver cluster configured using **gs_set_dr_dest_name**.

  Return type: text. If the return value is **0**, the configured instance ID of the log receiver cluster is empty.

  Example

  ```
  gaussdb=# SELECT * FROM gs_get_dr_dest_name();
   gs_get_dr_dest_name
  ---------------------
   cluster1,cluster2
  (1 row)
  ```

- gs_set_hadr_link_info()

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description: Sets the DR link information. The input parameter is a text in JSON format. If the setting is successful, **"success"** is returned. If the setting fails, **"failed"** is returned. This parameter is automatically set during the DR process. You are advised not to change the value.

Return type: text.

Table 1-127 gs_set_hadr_link_info parameters

Parameter	Type	Description
meta_version	string	Version number of the DR link in JSON format.
version	string	Version number of the DR link information.
replication_info	string	Stores DR link information, which is a JSON array containing information about multiple links.
dest_name	string	ID of the standby cluster instance for DR.
dest_type	string	Types of DR links. Value type: enumerated value Value range: **physical_standby_cluster**, **logical_standby_cluster**, and **gaussstor** Default value: **physical_standby_cluster**
mode	string	Log synchronization mode of DR links. Value type: enumerated value Value range: • **sync**: The link waits for the standby node at the log receiving end to persist redo logs to disks to ensure that no data is lost. This affects the host performance. • **semisync**: The link is preferentially synchronized. If the link is disconnected or the RPO is abnormal, the link is degraded to asynchronous. • **async**: The asynchronous transmission is performed, preferentially ensuring host performance. Default value: **async**
net_timeout	string	Timeout threshold in semi-synchronous mode. Value range: [0,*max*] Unit: second Default value: **0**
rpo_threshold	int	RPO threshold in semi-synchronous mode. Value range: [0,*max*] Unit: second Default value: **0**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Type	Description
compression	string	Specifies whether to enable compression. Value type: enumerated value Value range: **enable** and **disable** Default value: **enable**
compression_algo_setting	string	Compression algorithm. Currently, this parameter cannot be modified and the default value **"lz4,1"** is used.
replication_rate_limit	int/ string	Speed limit of the DR link. The unit can be **K**, **M**, or **G** for example, **1024K**, **1M**, **10M**, and **2048G**. Unit: byte Value range: **-1**, **0**, and 1 MB to 2 TB ● Integer: **-1**, **0**, and 1048576 to 2199023255552 ● String: **-1**, **0**, and 1048576 to 2199023255552 Default value: **-1**
rate_burst	int	Maximum size of a data packet that can be sent at a time. The value is a multiple of **replication_rate_limit**. Value range: [1,5] Default value: **2**
conn_info	string	Connection string and access permission information. For details, see the following example.

Example

```
gaussdb=# SELECT gs_set_hadr_link_info('{"meta_version":"1","version":"3","replication_info":
[{"dest_name":"clusterb","dest_type":"physical_standby_cluster","mode":"async","net_timeout":0,"rpo_t

                        |
```

- gs_get_hadr_link_version()

  Description: Obtains the version number of the DR link information.

  Return type: int8

  Example

```
gaussdb=# SELECT * FROM gs_get_hadr_link_version();
 link_info_version
-------------------
               100
(1 row)
```

- gs_get_hadr_sync_status()

  Description: Displays the log synchronization status of all DR links.

  Return type: record

Table 1-128 gs_get_hadr_sync_status parameters

Category	Parameter	Type	Description
Output parameter	dest_name	text	ID of the cluster that receives logs over the DR link.
Output parameter	sync_state	text	Actual synchronization status of the current DR link.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Category	Parameter	Type	Description
Output parameter	current_rpo	int	RPO time of the current DR link, in seconds.
Output parameter	sender_sent_location	text	Location where the DR link log sender sends logs.
Output parameter	sender_write_location	text	Location where the DR link log sender writes logs to the file system.
Output parameter	sender_flush_location	text	Location of the flush disk of the DR link log sender.
Output parameter	sender_replay_location	text	Location of the replay log of the DR link log sender.
Output parameter	receiver_received_location	text	Location of the received log of the DR link log receiver.
Output parameter	receiver_flush_location	text	Location of the log flush disk of the DR link log receiver.
Output parameter	last_disconnect_time	timestamptz	Latest DR link disconnection time.
Output parameter	last_upgrade_to_sync_time	timestamptz	Time when the semi-synchronous mode is upgraded to the synchronous mode for the last time.
Output parameter	last_downgrade_to_async_time	timestamptz	Time when the semi-synchronous mode is downgraded to the asynchronous mode for the last time.
Output parameter	mode	text	Value of the log synchronization mode of the DR link.
Output parameter	net_timeout	text	Timeout threshold of the semi-synchronous mode of the DR link.
Output parameter	rpo_threshold	text	RPO threshold of the semi-synchronous mode of the DR link.

Example

```

- gs_stat_get_replication_limit()

  Description: Queries the parameter values of flow control for all links of the current cluster and the average bandwidth usage in the last 1s, 5s, and 60s.

  Return type: record

  Table 1-129 gs_stat_get_replication_limit parameters

Category	Parameter	Type	Description
Output parameter	dest_name	text	Name of the target cluster of the sending link.
Output parameter	replication_rate_limit	text	Maximum bandwidth configured for the link.
Output parameter	rate_burst	text	Maximum burst traffic configured for the link, which is a multiple of the maximum bandwidth.
Output parameter	current_usage	text	Average bandwidth used by the link in the last 1s, in byte/s.
Output parameter	average_usage_5s	text	Average bandwidth used by the link in the last 5s, in byte/s.
Output parameter	average_usage_60s	text	Average bandwidth used by the link in the last 60s, in byte/s.

  Example

```
gaussdb=# SELECT * FROM gs_stat_get_replication_limit();
-[ RECORD 1 ]----------+---------
dest_name              | clusterb
replication_rate_limit | -1
rate_burst             | 2
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```

average_usage_5s       | 0
average_usage_60s      | 0
-[ RECORD 2 ]----------+---------
dest_name              | clusterc
replication_rate_limit | -1
rate_burst             | 2
current_usage          | 0
average_usage_5s       | 0
average_usage_60s      | 0
```

1.6.27.6 Dual-Cluster DR Query Functions

- gs_get_local_barrier_status()

  Description: If the streaming replication-based remote DR feature is enabled, the primary cluster and standby cluster for DR synchronize logs. The barrier log is flushed to disk in the primary cluster, and replayed in the standby cluster for DR to determine the archive log progress of the primary cluster and the log replay progress of the standby cluster for DR. **gs_get_local_barrier_status** is used to query the current log replay status of each node in the standby cluster for DR.

  Return type: text.

  barrier_id: latest barrier ID of a node in the standby cluster for DR.

  barrier_lsn: LSN of the latest barrier ID returned by a node in the standby cluster for DR.

  archive_lsn: location of archive logs obtained by a node in the standby cluster for DR. This parameter does not take effect currently.

  flush_lsn: location of logs that have been flushed to disks on a node in the standby cluster for DR.

- gs_hadr_in_recovery()

  Description: Checks whether the current node is in barrier-based log restoration if the streaming replication-based remote DR feature is enabled. If it is in restoration, **true** is returned. Only after the log restoration is complete, can the standby cluster for DR be promoted to the production cluster during the switchover process. This operation must be performed by system administrators.

  Return type: Boolean

  > **NOTE**
  >
  > This function is used only when a planned switchover is performed in the standby cluster for DR.

- gs_streaming_dr_get_switchover_barrier()

  Description: Checks whether the CN and main standby DN in the standby cluster for DR have received the switchover barrier logs and replayed the logs in the streaming replication-based remote DR solution. If it has, **true** is returned. In the standby cluster for DR, the procedure for promoting the standby database instance for DR to the production database instance in the switchover process can be started only after the switchover barrier logs of all DNs are replayed (the SYSADMIN permission is required).

  Return type: Boolean

  Note: This function is used only when a planned switchover is performed in the standby database instance in streaming DR solutions.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- gs_streaming_dr_service_truncation_check()

  Description: Checks whether the CN and primary DN in the primary cluster has sent the switchover barrier logs in the streaming replication-based remote DR solution. If it has, **true** is returned. The procedure for demoting the production database instance to the standby database instance in the switchover process can be started only after the logs are sent (restricted to system administrators).

  Return type: Boolean

  Note: This function is used only when a planned switchover is performed in the standby database instance for DR.

- gs_hadr_local_rto_and_rpo_stat()

  Description: Displays the log flow control information of the local database instance and standby database instance for streaming DR. (If this command is executed on a node that does not participate in streaming DR, for example, a standby DN or a CN, no information may be returned.)

  The return value type is record. The types and meanings of the columns are as described in **Table 1-130**.

Table 1-130 gs_hadr_local_rto_and_rpo_stat parameters

Parameter	Type	Description
hadr_sender_node_name	text	Node name, including the primary database instance and the main standby node of the standby database instance.
hadr_receiver_node_name	text	Name of the main standby node of the standby database instance.
source_ip	text	IP address of the primary DN of the primary database instance.
source_port	int	Communication port of the primary DN of the primary database instance.
dest_ip	text	IP address of the main standby DN of the standby database instance.
dest_port	int	Communication port of the main standby DN of the standby database instance.
current_rto	int	Flow control information, that is, log RTO time of the current primary and standby database instances (unit: second).
target_rto	int	Flow control information, that is, the RTO time between the target primary and standby database instances (unit: second).
current_rpo	int	Flow control information, that is, log RPO time of the current primary and standby database instances (unit: second).

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Type	Description
target_rpo	int	Flow control information, that is, the RPO time between the target primary and standby database instances (unit: second).
rto_sleep_time	int	RTO flow control information, that is, expected sleep time (unit: μs) required by WAL sender on the host to reach the specified RTO.
rpo_sleep_time	int	RPO flow control information, that is, the expected sleep time (unit: μs) required by xlogInsert on the host to reach the specified RPO.

- gs_hadr_remote_rto_and_rpo_stat()

  Description: Displays the log flow control information of all other shards or CN database instances and DR database instances for streaming DR. (Generally, this command is executed on CNs. If this command is executed on DNs, no information may be returned.)

  The return value type is record. The types and meanings of the columns are as described in **Table 1-131**.

  Table 1-131 gs_hadr_remote_rto_and_rpo_stat

Parameter	Type	Description
hadr_sender_node_name	text	Node name, including the primary database instance and the main standby node of the standby database instance.
hadr_receiver_node_name	text	Name of the main standby node of the standby database instance.
source_ip	text	IP address of the primary DN of the primary database instance.
source_port	int	Communication port of the primary DN of the primary database instance.
dest_ip	text	IP address of the main standby DN of the standby database instance.
dest_port	int	Communication port of the main standby DN of the standby database instance.
current_rto	int	Flow control information, that is, log RTO time of the current primary and standby database instances (unit: second).
target_rto	int	Flow control information, that is, the RTO time between the target primary and standby database instances (unit: second).

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Type	Description
current_rpo	int	Flow control information, that is, log RPO time of the current primary and standby database instances (unit: second).
target_rpo	int	Flow control information, that is, the RPO time between the target primary and standby database instances (unit: second).
rto_sleep_time	int	RTO flow control information, that is, expected sleep time (unit: μs) required by WAL sender on the host to reach the specified RTO.
rpo_sleep_time	int	RPO flow control information, that is, the expected sleep time (unit: μs) required by xlogInsert on the host to reach the specified RPO.

- gs_is_wal_truncate_complete()

  Description: Queries whether online log truncation is complete when the standby cluster for DR is promoted to primary. If online log truncation is complete, **true** is returned. The value is reset each time the query is complete.

  Return type: Boolean

  Remarks: This function is used only when the standby cluster for DR is promoted to primary.

- gs_hadr_local_replay_delay_stat()

  Description: Displays the barrier receiving, barrier replay, and delay time of the standby cluster for DR when the standby cluster for DR delays replay.

  Return type: record.

  Table 1-132 gs_hadr_local_replay_delay_stat return parameters

Parameter	Type	Description
node_name	text	Specifies the instance name.
receive_barrier	text	Receives logs that carry timestamps.
receive_barrier_lsn	text	Receives the LSN of the log with the timestamp.
receive_time	timestamp with time zone	Parses the received timestamp.
replay_barrier	text	Replays logs that carry timestamps.
replay_barrier_lsn	text	Replays the LSN of the log that carries the timestamp.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Type	Description
replay_time	timestamp with time zone	Parses the replay timestamp.
delay_replay	int8	Specifies the replay delay.
current_remain_interval	int8	Indicates the actual delay interval.

Example:

```
gaussdb=# SELECT * FROM gs_hadr_local_replay_delay_stat();
  node_name   |             receive_barrier             | receive_barrier_lsn |        receive_time        |
replay_barrier              | replay_barrier_lsn |        replay_time         | delay_replay |
current_remain_interval
--------------+-----------------------------------------+---------------------+----------------------------
+-----------------------------------------+--------------------+----------------------------+--------------
+-------------------------

16:32:11.492+08 |            0 |                         4
(1 row)
```

- disaster_cluster_run_mode()

  Description: Queries whether the primary cluster or standby cluster for DR is connected during connection. When this function is queried, **0** is returned for the primary cluster and **1** is returned for the standby cluster for DR.

  Return type: int.

  Example:

  ```
  gaussdb=# SELECT pg_catalog.disaster_cluster_run_mode();
  ----------------
               0
  (1 row)
  ```

- pgxc_disaster_read_node()

  Description: Returns the cluster information related to the standby cluster for DR during connection.

  The return value type is record. The types and meanings of the columns are as described in **Table 1-133**.

  Note: An error is reported when the primary cluster is queried. This function is used only for the standby cluster for DR.

Table 1-133 pgxc_disaster_read_node

Parameter	Type	Description
node_name	name	Node name.
node_type	char	Node type. **D** represents the main standby DN, **S** represents the cascaded standby DN, and **C** represents the query node.
node_host	name	Communication IP address of a node.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Type	Description
node_port	int	Communication port of a node.
node_host1	name	Virtual communication IP address of a node.
node_port1	int	Virtual communication port of a node.
nodeis_active	boolean	Node status. **true** indicates normal, and **false** indicates abnormal.

Example:

```
gaussdb=# SELECT * from pg_catalog.pgxc_disaster_read_node();
  node_name   | node_type | node_host  | node_port | node_host1 | node_port1 | nodeis_active

(10 rows)
```

1.6.27.7 Snapshot Synchronization Functions

Snapshot synchronization functions save the current snapshot and return its identifier.

- pg_export_snapshot()

  Description: Saves the snapshot system information of the current transaction and returns the snapshot ID to the client.

  Return type: text

  Note: **pg_export_snapshot** saves the current snapshot and returns a text string identifying the snapshot. This string must be passed to clients that want to import the snapshot. A snapshot can be imported when the **set transaction snapshot snapshot_id;** command is executed. Doing so is possible only when the transaction is set to the **SERIALIZABLE** or **REPEATABLE READ** isolation level. Currently, GaussDB does not support the two isolation levels. The output of the function cannot be used as the input of **set transaction snapshot**.

- pg_export_snapshot_and_csn()

  Description: Saves the snapshot system information of the current transaction and returns the snapshot ID and the corresponding CSN to the client. Compared with **pg_export_snapshot()**, **pg_export_snapshot()** returns a CSN, indicating the CSN of the current snapshot.

  Return type: text.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

1.6.27.8 Database Object Functions

Database Object Size Functions

Database object size functions calculate the actual disk space used by database objects.

- pg_column_size(any)

  Description: Specifies the number of bytes used to store a particular value (possibly compressed).

  Return type: int.

  Note: **pg_column_size** displays the space for storing an independent data value.

  ```
  gaussdb=# SELECT pg_column_size(1);
   pg_column_size
  ----------------
               4
  (1 row)
  ```

- pg_database_size(oid)

  Description: Specifies the disk space used by the database with a specified OID.

  Return type: bigint

- pg_database_size(name)

  Description: Specifies the disk space used by the database with a specified name.

  Return type: bigint

  Note: **pg_database_size** receives the OID or name of a database and returns the disk space used by the corresponding object.

  Example:

  ```
  gaussdb=# CREATE DATABASE testdb;
  gaussdb=# SELECT pg_database_size('testdb');
   pg_database_size
  ------------------
          51590112
  (1 row)
  gaussdb=# DROP DATABASE testdb;
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

The query time of the pg_database_size(oid/name) function is linearly related to the number of object files in the database corresponding to the OID/name. To evaluate the time required, perform the following steps:

1. Since the time required is related to the software and hardware environments, the test result of a certain database (the number of object files in the selected database should not be too large) is used as the benchmark. Calculate the time consumed by a single object file (**database_size_t**) based on the query time and the number of object files in the database.
2. Obtain the OID of the database to be queried using the command **SELECT oid, * FROM pg_database WHERE datname = 'database';**. In the **base** and **pg_tblspc** tablespace directories, count the total number of files (**database_obj_num**) in the directory corresponding to the OID. If the directory contains subdirectories, you need to enter it to view the number of object files. You can run **ls | wc -l** to query the number of files in the directory.
3. Calculate the estimated total time consumption based on **database_size_t** (time consumption of a single file) and **database_obj_num** (number of all object files in the database) in the benchmark test result. The total time consumption is equal to **database_size_t** multiplied by **database_obj_num**. If the estimated latency is too long, consider adjusting the execution timeout threshold to avoid unnecessary alarms.

- get_db_source_datasize()

  Description: Estimates the total size of non-compressed data in the current database.

  Return type: bigint

  Note: ANALYZE must be performed before this function is called.

  Example:

```
gaussdb=# analyze;
ANALYZE
gaussdb=# SELECT get_db_source_datasize();
 get_db_source_datasize
------------------------
            35384925667
(1 row)
```

- pg_relation_size(relation regclass, fork text)

  Description: Specifies the disk space used by the specified bifurcating tree ('main', 'fsm', or 'vm') of a certain table or index.

  Return type: bigint

- pg_relation_size(relation regclass)

  Description: Is an abbreviation of **pg_relation_size(..., 'main')**.

  Return type: bigint

  Note: **pg_relation_size** receives the OID or name of a table, an index, or a compressed table, and returns the size.

- pg_partition_size(oid, oid)

  Description: Specifies the disk space used by the partition with a specified OID. The first **oid** is the OID of the table and the second **oid** is the OID of the partition.

  Return type: bigint

- pg_partition_size(text, text)

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description: Specifies the disk space used by the partition with a specified name. The first **text** is the table name and the second **text** is the partition name.

Return type: bigint

- pg_partition_indexes_size(oid, oid)

  Description: Specifies the disk space used by the index of the partition with a specified OID. The first **oid** is the OID of the table and the second **oid** is the OID of the partition.

  Return type: bigint

- pg_partition_indexes_size(text, text)

  Description: Specifies the disk space used by the index of the partition with a specified name. The first **text** is the table name and the second **text** is the partition name.

  Return type: bigint

- pg_indexes_size(regclass)

  Description: Specifies the total disk space used by the index appended to the specified table.

  Return type: bigint

- pg_size_pretty(bigint)

  Description: Converts a size in bytes expressed as a 64-bit integer into a human-readable format with size units.

  Return type: text.

- pg_size_pretty(numeric)

  Description: Converts a size in bytes expressed as a numeric value into a human-readable format with size units.

  Return type: text.

  Note: **pg_size_pretty** formats the results of other functions into a human-readable format. KB, MB, GB, and TB can be used.

- pg_table_size(regclass)

  Description: Specifies the disk space used by the specified table, excluding indexes (but including TOAST, free space mapping, and visibility mapping).

  Return type: bigint

- pg_tablespace_size(oid)

  Description: Specifies the disk space used by the tablespace with a specified OID.

  Return type: bigint

- pg_tablespace_size(name)

  Description: Specifies the disk space used by the tablespace with a specified name.

  Return type: bigint

  Note:

  pg_tablespace_size receives the OID or name of a database and returns the disk space used by the corresponding object.

- pg_total_relation_size(regclass)

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description: Specifies the total disk space used by the specified table, including all indexes and TOAST data.

Return type: bigint

- dist_relation_size(nspname name, relname name)

  Description: Specifies the number of relpages of ordinary tables in a specified schema on each DN.

  Return type: float8.

  Table 1-134 Parameters

Input Parameter	Type	Description
nspname	name	Schema name of a table.
relname	name	Table name.

  In the 1 CN+6 DN database environment, you can view the number of relpages on the 6 DNs.

```
gaussdb=# CREATE TABLE tab(col int);
-- The value of node_name must be the same as the node name in the current environment.
gaussdb=# SELECT * FROM dist_relation_size('public','tab');
 node_name | relpages
-----------+----------
 datanode1 |        0
 datanode2 |        0
 datanode3 |        0
 datanode4 |        0
 datanode6 |        0
 datanode5 |        0
(6 rows)

gaussdb=# DROP TABLE tab;
```

  NOTE

  - This function cannot be used during the upgrade observation period.
  - This function cannot be called on DNs.

- dist_partition_size(nspname name, relname name, subname name)

  Description: Specifies the number of relpages of a specified partition in a partitioned table in a specified schema on each DN.

  Return type: float8.

  Table 1-135 Parameters

Input Parameter	Type	Description
nspname	name	Schema name of a table.
relname	name	Table name.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Input Parameter	Type	Description
subname	name	Name of the partition to be queried.

In the 1 CN+6 DN database environment, you can view the number of relpages on the 6 DNs.

```
gaussdb=# CREATE TABLE test_part_table(col int)
PARTITION BY RANGE(col)
(
    PARTITION p1 VALUES LESS THAN (10),
    PARTITION p2 VALUES LESS THAN (20),
    PARTITION p3 VALUES LESS THAN (MAXVALUE)
);
-- The value of node_name must be the same as the node name in the current environment.
gaussdb=# SELECT * FROM dist_partition_size('public','test_part_table','p1') ORDER BY node_name;
 node_name | relpages
-----------+----------
 datanode1 |        0
 datanode2 |        0
 datanode3 |        0
 datanode4 |        0
 datanode5 |        0
 datanode6 |        0
(6 rows)

gaussdb=# DROP TABLE test_part_table;
```

NOTE

- This function cannot be used during the upgrade observation period.
- This function cannot be called on DNs.

- datalength(any)

  Description: Specifies the number of bytes used by an expression of a specified data type (data management space, data compression, or data type conversion is not considered).

  Return type: int.

  Note: **datalength** is used to calculate the space of an independent data value.

  Example:

  ```
  gaussdb=# SELECT datalength(1);
  datalength
  ------------
  4
  (1 row)
  ```

  The following table lists the supported data types and calculation methods.

Data Type			Storage Space
Numeric data types	Integer types	TINYINT	1
		SMALLINT	2
		INTEGER	4
		BINARY_INTEGER	4

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Data Type			Storage Space
		BIGINT	8
	Arbitrary precision types	DECIMAL	Every four decimal digits occupy two bytes. The digits before and after the decimal point are calculated separately.
		NUMERIC	Every four decimal digits occupy two bytes. The digits before and after the decimal point are calculated separately.
		NUMBER	Every four decimal digits occupy two bytes. The digits before and after the decimal point are calculated separately.
	Sequence integer	SMALLSERIAL	2
		SERIAL	4
		BIGSERIAL	8
	Floating-point types	FLOAT4	4
		DOUBLE PRECISION	8
		FLOAT8	8
		BINARY_DOUBLE	8
		FLOAT[(p)]	Every four decimal digits occupy two bytes. The digits before and after the decimal point are calculated separately.
		DEC[(p[,s])]	Every four decimal digits occupy two bytes. The digits before and after the decimal point are calculated separately.
		INTEGER[(p[,s])]	Every four decimal digits occupy two bytes. The digits before and after the decimal point are calculated separately.
Boolean data types	Boolean type	BOOLEAN	1

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Data Type			Storage Space
Character data types	Character types	CHAR	1
		CHAR(n)	n
		CHARACTER(n)	n
		NCHAR(n)	n
		VARCHAR(n)	Actual number of bytes of a character
		CHARACTER VARYING(n)	Actual number of bytes of a character
		VARCHAR2(n)	Actual number of bytes of a character
		NVARCHAR2(n)	Actual number of bytes of a character
		TEXT	Actual number of bytes of a character
		CLOB	Actual number of bytes of a character
Time data types	Time types	DATE	8
		DATEA (supported only in ORA-compatible mode)	8
		TIME	8
		TIMETZ	12
		TIMESTAMP	8
		TIMESTAMPTZ	8
		SMALLDATETIME	8
		INTERVAL DAY TO SECOND	16
		INTERVAL	16
		RELTIME	4
		ABSTIME	4
		TINTERVAL	12
ROWID type	ROWID type	ROWID	24

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Database Object Position Functions

- pg_relation_filenode(relation regclass)

  Description: Specifies the number of filenodes in a specified relationship.

  Return type: oid

  Note: **pg_relation_filenode** receives the OID or name of a table, an index, a sequence, or a compressed table, and returns the number of **filenode** allocated to it. **filenode** is the basic component of the file name used by the relationship. For most tables, the result is the same as that of **pg_class.relfilenode**. For the specified system directory, **relfilenode** is **0** and this function must be used to obtain the correct value. If a relationship that is not stored is transmitted, such as a view, this function returns a null value.

- pg_relation_filepath(relation regclass)

  Description: Specifies the name of a file path with the specified relationship. It can be used only for non-segment-page relationships.

  Return type: text.

  Description: pg_relation_filepath is similar to pg_relation_filenode, except that pg_relation_filepath returns the whole file path name for the relationship (relative to the data directory *PGDATA* of the database cluster).

  For segment-page relationships, you are advised to use functions or views. For example:

  ```
  SELECT e.*, f.file_name
  FROM gs_seg_extents e, gs_seg_datafiles f
  WHERE e.tablespace_name = f.tablespace_name AND e.bucketnode = f.bucketnode AND e.file_id =
  f.file_id AND e.forknum = f.forknum;
  ```

- get_large_table_name(relfile_node text, threshold_size_gb int8)

  Description: Queries whether the table size (in GB) exceeds the threshold (**threshold_size_gb**) based on the table file code (**relfile_node**). If the size exceeds the threshold, the schema name and table name (in *schemaname*.*tablename* format) are returned, otherwise, **null** is returned.

  Return type: text.

- pg_filenode_relation(tablespace oid, filenode oid)

  Description: Obtains the table names corresponding to the tablespace and relfilenode.

  Return type: regclass

- pg_partition_filenode(partition_oid)

  Description: Obtains **filenode** corresponding to the OID lock of a specified partitioned table.

  Return type: oid

- pg_partition_filepath(partition_oid)

  Description: Specifies the file path name of a specified partition. It can be used only for non-segment-page relationships.

  Return type: text.

  Note: For segment-page relationships, you are advised to use functions or views. For example:

  ```
  SELECT e.*, f.file_name
  FROM gs_seg_extents e, gs_seg_datafiles f
  WHERE e.tablespace_name = f.tablespace_name AND e.bucketnode = f.bucketnode AND e.file_id =
  f.file_id AND e.forknum = f.forknum;
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Recycle Bin Object Functions

- gs_is_recycle_object(classid, objid, objname)

  Description: Determines whether an object is in the recycle bin. This function is not supported in distributed mode.

  Return type: Boolean

- gs_is_recycle_obj(classid, objid, objname)

  Description: Determines whether an object is in the recycle bin. **classid** indicates the OID of the system catalog where the object is located, **objid** indicates the OID of the object, and **objname** indicates the name of the object.

  Return type: Boolean

1.6.27.9 Advisory Lock Functions

Advisory lock functions manage advisory locks.

- pg_advisory_lock(key bigint)

  Description: Obtains an exclusive session-level advisory lock.

  Return type: void

  Note: **pg_advisory_lock** locks resources defined by an application. The resources can be identified using a 64-bit or two nonoverlapped 32-bit key values. If another session locks the resources, the function blocks the resources until they can be used. The lock is exclusive. Multiple locking requests are pushed into the stack. Therefore, if the same resource is locked three times, it must be unlocked three times so that it is released to another session.

- pg_advisory_lock(key1 int, key2 int)

  Description: Obtains an exclusive session-level advisory lock.

  Return type: void

  Note: Only users with the SYSADMIN permission can add session-level exclusive advisory locks to the key-value pair (65535, 65535).

- pg_advisory_lock(lock_id int4, lock_id int4, database_name Name)

  Description: Obtains the exclusive advisory lock of a specified database by inputting the lock ID and database name.

  Return type: void

- pg_advisory_lock_shared(key bigint)

  Description: Obtains a shared session-level advisory lock.

  Return type: void

- pg_advisory_lock_shared(key1 int, key2 int)

  Description: Obtains a shared session-level advisory lock.

  Return type: void

  Note: **pg_advisory_lock_shared** works in the same way as **pg_advisory_lock**, except that **pg_advisory_lock_shared** obtains an advisory lock shared with other sessions requesting the lock, while **pg_advisory_lock** obtains an exclusive advisory lock.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- pg_advisory_unlock(key bigint)

  Description: Releases an exclusive session-level advisory lock.

  Return type: Boolean

- pg_advisory_unlock(key1 int, key2 int)

  Description: Releases an exclusive session-level advisory lock.

  Return type: Boolean

  Note: **pg_advisory_unlock** releases the obtained exclusive advisory lock. If the release is successful, the function returns **true**. If the lock was not held, it will return **false**. In addition, an SQL warning will be reported by the server.

- pg_advisory_unlock(lock_id int4, lock_id int4, database_name Name)

  Description: Releases the exclusive advisory lock of a specified database by inputting the lock ID and database name.

  Return type: Boolean

  Note: If the release is successful, **true** is returned. If no lock is held, **false** is returned.

- pg_advisory_unlock_shared(key bigint)

  Description: Releases a shared session-level advisory lock.

  Return type: Boolean

- pg_advisory_unlock_shared(key1 int, key2 int)

  Description: Releases a shared session-level advisory lock.

  Return type: Boolean

  Note: **pg_advisory_unlock_shared** works in the same way as **pg_advisory_unlock**, except that it releases a shared session-level advisory lock.

- pg_advisory_unlock_all()

  Description: Releases all advisory locks owned by the current session.

  Return type: void

  Note: **pg_advisory_unlock_all** releases all advisory locks owned by the current session. The function is implicitly called when the session ends even if the client is abnormally disconnected.

- pg_advisory_xact_lock(key bigint)

  Description: Obtains an exclusive transaction-level advisory lock.

  Return type: void

- pg_advisory_xact_lock(key1 int, key2 int)

  Description: Obtains an exclusive transaction-level advisory lock.

  Return type: void

  Note: pg_advisory_xact_lock works in the same way as pg_advisory_lock, except the lock is automatically released at the end of the current transaction and cannot be released explicitly. Only users with the SYSADMIN permission can add transaction-level exclusive advisory locks to the key-value pair (65535, 65535).

- pg_advisory_xact_lock_shared(key bigint)

  Description: Obtains a shared transaction-level advisory lock.

  Return type: void

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- pg_advisory_xact_lock_shared(key1 int, key2 int)

  Description: Obtains a shared transaction-level advisory lock.

  Return type: void

  Note: pg_advisory_xact_lock_shared works in the same way as pg_advisory_lock_shared, except the lock is automatically released at the end of the current transaction and cannot be released explicitly.

- pg_try_advisory_lock(key bigint)

  Description: Obtains an exclusive session-level advisory lock if available.

  Return type: Boolean

  Note: **pg_try_advisory_lock** is similar to **pg_advisory_lock**, except **pg_try_advisory_lock** does not block the resource until the resource is released. It either immediately obtains the lock and returns **true** or returns **false**, which indicates the lock cannot be performed currently.

- pg_try_advisory_lock(key1 int, key2 int)

  Description: Obtains an exclusive session-level advisory lock if available.

  Return type: Boolean

  Note: Only users with the SYSADMIN permission can add session-level exclusive advisory locks to the key-value pair (65535, 65535).

- pg_try_advisory_lock_shared(key bigint)

  Description: Obtains a shared session-level advisory lock if available.

  Return type: Boolean

- pg_try_advisory_lock_shared(key1 int, key2 int)

  Description: Obtains a shared session-level advisory lock if available.

  Return type: Boolean

  Note: **pg_try_advisory_lock_shared** works in the same way as **pg_try_advisory_lock**, except that **pg_try_advisory_lock_shared** attempts to obtain a shared lock instead of an exclusive lock.

- pg_try_advisory_xact_lock(key bigint)

  Description: Obtains an exclusive transaction-level advisory lock if available.

  Return type: Boolean

- pg_try_advisory_xact_lock(key1 int, key2 int)

  Description: Obtains an exclusive transaction-level advisory lock if available.

  Return type: Boolean

  Note: pg_try_advisory_xact_lock works in the same way as pg_try_advisory_lock, except that the lock, if acquired, is automatically released at the end of the current transaction and cannot be released explicitly. Only users with the SYSADMIN permission can add transaction-level exclusive advisory locks to the key-value pair (65535, 65535).

- pg_try_advisory_xact_lock_shared(key bigint)

  Description: Obtains a shared transaction-level advisory lock if available.

  Return type: Boolean

- pg_try_advisory_xact_lock_shared(key1 int, key2 int)

  Description: Obtains a shared transaction-level advisory lock if available.

  Return type: Boolean

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Note: pg_try_advisory_xact_lock_shared works in the same way as pg_try_advisory_lock_shared, except the lock, if acquired, is automatically released at the end of the current transaction and cannot be released explicitly.

- lock_cluster_ddl()

  Description: Attempts to obtain a session-level exclusive advisory lock for all active CNs in the cluster.

  Return type: Boolean

  Note: Only users with the SYSADMIN permission can call this function.

- unlock_cluster_ddl()

  Description: Attempts to add a session-level exclusive advisory lock on the CN.

  Return type: Boolean

  Note: Only users with the SYSADMIN permission can call this function.

- pg_rel_advisory_lock(schema_name cstring, relname cstring)

  Description: Obtains a session-level advisory lock on a table.

  Return type: void

  Note: pg_rel_advisory_lock is for internal use only. You are advised not to use it.

- pg_rel_advisory_unlock(schema_name cstring, relname cstring)

  Description: Releases a session-level advisory lock on a table.

  Return type: void

  Note: pg_rel_advisory_unlock is for internal use only. You are advised not to use it.

1.6.27.10 Logical Replication Functions

NOTE

When using the logical replication functions, set the GUC parameter **wal_level** to **logical**. For details, see "Feature Usage Guidelines > Logical Replication > Logical Decoding (Non-Multi-Primary) > Logical Decoding by SQL Functions" in *Developer Guide*.

- pg_create_logical_replication_slot('slot_name', 'plugin_name', 'output_order')

  Description: Creates a logical replication slot.

  Parameters:

  - slot_name

    Indicates the name of the streaming replication slot.

    Value range: character strings, which can only consist of lowercase letters, digits, underscores (_), question marks (?), hyphens (-), and periods (.). One or two periods alone cannot be used as the replication slot name.

  - plugin_name

    Indicates the name of the plug-in.

    Value range: a string. The value can be:

    - General plug-ins: **mppdb_decoding** or **sql_decoding**.
    - Supporting only for parallel decoding: **parallel_binary_decoding**, **parallel_json_decoding**, or **parallel_text_decoding**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

– output_order

Indicates the output sequence of the replication slot decoding results. This parameter is optional.

Valid value: **0** or **1**. The default value is **0** on DNs and **1** on CNs.

- **0**: The replication slot decoding results are sorted by transaction COMMIT LSN. In this case, the value of **confirmed_csn** of the replication slot is **0**. This replication slot is called an LSN-based replication slot.
- **1**: The replication slot decoding results are sorted by transaction CSN. In this case, the value of **confirmed_csn** of the replication slot is not **0**. This replication slot is called a CSN-based replication slot, and the **confirmed_flush** value of such replication slot is meaningless.

NOTE

- The CSN-based replication slot is used only for distributed strong consistency decoding. The LSN-based replication slot is required for non-distributed strong consistency decoding.
- When a replication slot is created, if the value of **output_order** is a decimal, the value is rounded off to an integer.

Return types: name and text.

Example:

```
gaussdb=# SELECT * FROM pg_create_logical_replication_slot('slot_lsn','mppdb_decoding',0);
 slotname | xlog_position
----------+---------------
 slot_lsn | 0/6D08B58
(1 row)

gaussdb=# SELECT * FROM pg_create_logical_replication_slot('slot_csn','mppdb_decoding',1);
 slotname | xlog_position
----------+---------------
 slot_csn | 0/59AD800
(1 row)
```

Note: The first return value is the slot name, and the second one has different meanings in LSN-based replication slots and CSN-based replication slots. For an LSN-based replication slot, the value is **confirmed_flush** of the replication slot, indicating that transactions whose commit LSN is less than or equal to the value will not be decoded and output. For a CSN-based replication slot, the value is **confirmed_csn** of the replication slot, indicating that transactions whose CSN is less than or equal to the value will not be decoded and output. Users who call this function must have the SYSADMIN permission or the REPLICATION permission, or inherit permissions of the built-in role gs_role_replication. Currently, this function can be called only on the CN or primary DNs.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

CAUTION

When this function is executed on a CN, if **output_order** is set to **1**, a replication slot with the same name will be created on all CNs and primary DNs. If a replication slot with the same name already exists on some DNs, a CSN-based logical replication slot will be created on other CNs and primary DNs that do not have a replication slot with the same name. In addition, an error message is displayed, indicating that the replication slot already exists. In this case, you need to delete the existing replication slot with the same name on other CNs and primary DN (if the replication slot is an LSN-based logical replication slot, you need to manually delete it on the corresponding node) and create a replication slot on the CN. If you set **output_order** to **0** when creating a replication slot on a CN, no replication slot will be created on DNs. Replication slots created on CNs are only used to identify whether related replication slots exist on DNs.

- pg_create_physical_replication_slot('slot_name', 'isDummyStandby')

  Description: Creates a physical replication slot.

  Parameters:

  – slot_name

    Indicates the name of the streaming replication slot.

    Value range: character strings, which can only consist of lowercase letters, digits, underscores (_), question marks (?), hyphens (-), and periods (.). One or two periods alone cannot be used as the replication slot name. Replication slots that start with "gs_roach" are reserved for the internal backup tool, GaussRoach. To use them, you need to set **application_name** to **'gs_roach'**.

  – isDummyStandby

    Reserved parameter.

    Type: Boolean.

  Return types: name and text.

  NOTE

  - Users who call this function must have the SYSADMIN permission or the REPLICATION permission, or inherit permissions of the built-in role gs_role_replication.
  - The physical replication slot created by this function does not have **restart_lsn**. Therefore, the slot is considered invalid and will be automatically deleted when the checkpoint is performed.

- pg_drop_replication_slot('slot_name')

  Description: Deletes a streaming replication slot.

  Parameters:

  – slot_name

    Indicates the name of the streaming replication slot.

    Value range: character strings, which can only consist of lowercase letters, digits, underscores (_), question marks (?), hyphens (-), and periods (.). One or two periods alone cannot be used as the replication slot name. Replication slots that start with "gs_roach" are reserved for the internal

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

backup tool, GaussRoach. To use them, you need to set **application_name** to **'gs_roach'**.

Return type: void.

NOTE

- Users who call this function must have the SYSADMIN permission or the REPLICATION permission, or inherit permissions of the built-in role gs_role_replication.
- When a database is deleted, the logical replication slots on the database are not deleted. You need to manually delete the logical replication slots on the database. Otherwise, historical versions of Xlogs and system catalogs cannot be reclaimed.
- When a logical replication slot is deleted from a CN, if the logical replication slot is an LSN-based logical replication slot, only the replication slot of the current node is deleted. Replication slots with the same name on other nodes are not affected. When a CSN-based logical replication slot with the same name exists on other nodes, no error is reported because some nodes do not have replication slots. In addition, replication slots with the same name on all nodes are successfully deleted. If no replication slot exists on any node, an error is reported.
- If an LSN-based logical replication slot remains on the current CN and a CSN-based logical replication slot with the same name remains on other nodes, deleting the replication slot on the current CN will delete only the local LSN-based logical replication slot. After the deletion is complete, perform the deletion operation again to delete the CSN-based logical replication slots with the same name on other nodes.

- pg_logical_slot_peek_changes('slot_name', 'upto_lsn', upto_nchanges, 'options_name', 'options_value')

  Description: Performs decoding but does not go to the next streaming replication slot. (The decoded result will be returned again during the next decoding.)

  Parameters:

  – slot_name

    Indicates the name of the streaming replication slot.

    Value range: character strings, which can only consist of lowercase letters, digits, underscores (_), question marks (?), hyphens (-), and periods (.). One or two periods alone cannot be used as the replication slot name.

  – upto_lsn

    For the CSN-based logical replication slot, the decoding is complete until the transaction whose CSN is less than or equal to the value is decoded (a transaction whose CSN is greater than the specified CSN may be decoded). For the LSN-based replication slot, the decoding is complete until the first transaction whose COMMIT LSN is greater than or equal to the value is decoded.

    Value range: a string, for example, **'1/2AAFC60'**, **'0/A060'**, or **'3A/0'** (a hexadecimal uint64 value containing two uint32 values separated by a slash (/); if any uint32 value is **0**, **0** is displayed.) **NULL** indicates that the end position of decoding is not specified.

  – upto_nchanges

    Indicates the number of decoded records (including the **begin** and **commit** timestamps). Assume that there are three transactions, which involve 3, 5, and 7 records, respectively. If **upto_nchanges** is set to **4**, 8 records of the first two transactions will be decoded. Specifically,

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

decoding is stopped when the number of decoded records surpasses the value of **upto_nchanges** after decoding in the first two transactions is finished.

Value range: non-negative integers.

NOTE

If any of the **upto_lsn** and **upto_nchanges** values is reached, decoding ends.

- **options**: Specifies optional parameters, consisting of **options_name** and **options_value**.
  - include-xids

    Specifies whether the decoded **data** column includes XIDs.

    Value range: Boolean. The default value is **true**.
    - **false**: The decoded **data** column does not contain XID information.
    - **true**: The decoded **data** column contains XID information.
  - skip-empty-xacts

    Specifies whether to ignore empty transactions during decoding.

    Value range: Boolean. The default value is **false**.
    - **false**: The empty transaction information is not ignored during decoding.
    - **true**: The empty transaction information is ignored during decoding.
  - include-timestamp

    Specifies whether the decoded information includes commit timestamps.

    Value range: Boolean. The default value is **true**.
    - **false**: The decoded information does not contain the **commit** timestamp.
    - **true**: The decoded information contains the **commit** timestamp.
  - only-local

    Specifies whether to decode only local logs.

    Value range: Boolean. The default value is **true**.
    - **false**: Non-local logs and local logs are decoded.
    - **true**: Only local logs are decoded.
  - force-binary

    Specifies whether to output the decoding result in binary format.

    Value range: Boolean. The default value is **false**.
    - **false**: The decoding result is output in text format.
    - The value cannot be set to **true** currently.
  - white-table-list

    Whitelist parameter, including the schema and table name to be decoded.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Value range: a string that contains table names in the whitelist. Different tables are separated by commas (,). An asterisk (*) is used to fuzzily match all tables. Schema names and table names are separated by periods (.). No space character is allowed. The following is an example:

```
SELECT * FROM pg_logical_slot_peek_changes('slot1', NULL, 4096, 'white-table-list',
'public.t1,public.t2');
```

- skip-xid-list

  Specifies the blacklist of transactions (represented by their XIDs) to be skipped during decoding. Transactions cannot be skipped during the upgrade observation period.

  Value range: A character string that contains XIDs, separated by slashes (/). No whitespace characters are allowed. Valid XIDs range from 3 to 18446744073709551615 (that is, the maximum value of uint64). The following is an example:

  ```
  SELECT * FROM pg_logical_slot_peek_changes('slot1', NULL, 4096, 'skip-xid-list',
  '1234/2345');
  ```

- max-txn-in-memory

  Memory control parameter. The unit is MB. If the memory occupied by a single transaction is greater than the value of this parameter, data is flushed to disk.

  Value range: integers from 0 to 100. The default value is **0** (disabled).

- **max-reorderbuffer-in-memory**:

  Memory control parameter. The unit is GB. If the total memory (including the cache) of transactions being concatenated in the sender thread is greater than the value of this parameter, the current decoding transaction is flushed to disk.

  Value range: integers from 0 to 100. The default value is **0** (disabled).

- **desc-memory-limit**:

  A memory control parameter, in MB. When the total memory of table metadata maintained by a logical decoding task is greater than the value of this parameter, some table metadata will be evicted.

  Value range: an integer ranging from 10 to 1048576. The default value is **200**.

- include-user

  Specifies whether the BEGIN logical log of a transaction records the username of the transaction.

  Value range: Boolean. The default value is **false**.

  - **false**: The BEGIN logical log of a transaction does not record the username of the transaction.
  - **true**: The BEGIN logical log of a transaction records the username of the transaction.

- exclude-userids

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Lists the OIDs of blacklisted users.

Value range: OIDs of blacklisted users. Multiple OIDs are separated by commas (,). The system does not verify the existence of the specified OIDs.

- exclude-users

  Specifies the name of a blacklisted user.

  Value range: names of blacklisted users. Multiple names are separated by commas (,). **dynamic-resolution** specifies whether to dynamically parse and identify usernames. If the decoding is interrupted because the user does not exist and the corresponding blacklisted user does not exist at the time when logs are generated, you can set **dynamic-resolution** to **true** or delete the username from the blacklist to start decoding and continue to obtain logical logs.

- enable-ddl-decoding

  (Logical decoding control parameter) Specifies whether to enable logical decoding for DDL statements.

  Value range: Boolean. The default value is **false**.

  - **false**: Logical decoding of DDL statements is disabled.
  - **true**: Logical decoding of DDL statements is enabled.

- enable-ddl-json-format

  (Logical decoding control parameter) Specifies the DDL reverse parsing process and output format.

  Value range: Boolean. The default value is **false**.

  - **false**: The DDL statement reverse parsing result is output in text format.
  - **true**: The DDL statement reverse parsing result is output in JSON format.

- **skip-generated-columns**:

  (Logical decoding control parameter) Specifies whether to skip generating decoding results for stored generated columns. This parameter remains ineffective on old tuples (those that have undergone an UPDATE or DELETE operation), meaning that decoding results will still be generated for their stored generated columns. Currently, the generated column syntax is not supported in distributed mode. This option is not supported for CN decoding.

  Value range: Boolean. The default value is **false** or **off**.

  - **true**/**on**: The decoding result of stored generated columns is not output.
  - **false**/**off**: The decoding result of stored generated columns is output.

  Virtual generated columns are not controlled by this parameter. DML decoding results will not be generated for virtual generated columns.

- dynamic-resolution

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Specifies whether to dynamically parse the names of blacklisted users.

Value range: Boolean. The default value is **true**.

- **false**: An error is reported and the logical decoding exits when the decoding detects that a user does not exist in blacklist **exclude-users**.
- **true**: Decoding continues when it detects that a user does not exist in blacklist **exclude-users**.

- **decode-sequence**:

  (Logical decoding control parameter) Specifies whether to generate decoding results for logs that record sequence value changes.

  Value range: Boolean. The default value is **false**.

  - The value cannot be set to **true** currently.
  - **false**: The decoding result of the change log of the sequence value is not output.

  NOTICE

  Currently, **decode-sequence** can only be set to **false**. If **decode-sequence** is set to **true**, an error is reported when decoding is started and the decoding process exits.

- **enable-decode-position**:

  (Logical decoding control parameter) Specifies whether to send decoding position logs when the logs are read during logical decoding.

  Value range: Boolean. The default value is **false**.

  - **true**: Position logs are generated.
  - **false**: Position logs are not generated.

- enable-rowno:

  (Logical decoding control parameter) Specifies whether to output the **rowno** system column for new and old tuples in INSERT/UPDATE/DELETE operations when decoding a primary key–free table that includes the **rowid** system column and has the **REPLICA IDENTITY** option set to **FULL** or any other value equivalent to **FULL**. When using this option to output the **rowno** system column, ensure that the target database contains columns with the same name and type. Otherwise, logical decoding logs may fail to be replayed. If you have any questions, contact Huawei technical support.

  Value range: Boolean

  - **true**: The **rowno** system column is output.
  - **false**: The **rowno** system column is not output.

  Default value: **false**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTICE

- This option is ineffective for the sql_decoding plug-in.
- The actual effect of the **REPLICA IDENTITY** option is equivalent to **FULL**. Currently, it refers to the **NOTHING** and **DEFAULT** options of the Ustore table. For details, see the option description in **REPLICA IDENTITY { DEFAULT | USING INDEX index_name | FULL | NOTHING }**.

NOTE

For details about other options, see "Feature Usage Guidelines > Logical Replication > Logical Decoding (Non-Multi-Primary) > Logical Decoding Options" in *Developer Guide*.

Return types: text, xid, and text.

Example:

```
gaussdb=# EXECUTE DIRECT ON (datanode1) 'SELECT * FROM
pg_logical_slot_peek_changes(''slot_lsn'',NULL,4096,''skip-empty-xacts'',''on'')';
 location  |  xid  |                                                
```

Note: In the preceding function example, **datanode1** is the name of the DN to be decoded, and **slot_lsn** and **slot_csn** are the names of the logical replication slots.

The decoding result returned by the function contains three columns, corresponding to the preceding return value types, which are the LSN (for an LSN-based replication slot) or CSN (for a CSN-based replication slot), XID, and decoded content, respectively. If the **location** column indicates the CSN, the value of the **location** column is updated only when the commit logs are decoded. Users who call this function must have the SYSADMIN permission or the REPLICATION permission, or inherit permissions of the built-in role gs_role_replication.

NOTE

On the CN, this function cannot be executed in a CSN-based replication slot (**confirmed_csn** is not **0**).

- pg_logical_slot_get_changes('slot_name', 'upto_lsn', upto_nchanges, 'options_name', 'options_value')

  Description: Performs decoding and goes to the next streaming replication slot.

  Parameter description: Same as that for **pg_logical_slot_peek_changes**. For details, see **pg_logical_slot_peek_changes('slot_name', 'upto_lsn', upto_nchanges, 'options_name', 'options_value')**.

  Note: Users who call this function must have the SYSADMIN permission or the REPLICATION permission, or inherit permissions of the built-in role gs_role_replication.

  NOTE

  On the CN, this function cannot be executed in a CSN-based replication slot (**confirmed_csn** is not **0**). When this function is called on the standby DN, the corresponding logical replication slot on the primary DN is updated synchronously. If this function is executed on the standby DN, a WAL sender of the primary DN is occupied when the replication slot number on the primary DN is updated. The logical decoding function reserves a WAL sender for each logical replication slot. Therefore, if this function is executed in normal scenarios, the logical replication slot number on the primary DN is updated normally. If this function is executed continuously in a short period of time, the primary DN fails to update the slot number and no error is reported.

- pg_logical_slot_peek_binary_changes('slot_name', 'upto_lsn', upto_nchanges, 'options_name', 'options_value')

  Description: Performs decoding in binary mode and does not go to the next streaming replication slot. (The decoded data can be obtained again during the next decoding.)

  Parameters:

  – slot_name

    Indicates the name of the streaming replication slot.

    Value range: character strings, which can only consist of lowercase letters, digits, underscores (_), question marks (?), hyphens (-), and periods (.). One or two periods alone cannot be used as the replication slot name.

  – upto_lsn

    For the CSN-based logical replication slot, the decoding is complete until the transaction whose CSN is less than or equal to the value is decoded

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

(a transaction whose CSN is greater than the specified CSN may be decoded). For the LSN-based replication slot, the decoding is complete until the first transaction whose COMMIT LSN is greater than or equal to the value is decoded.

Value range: a string, for example, **'1/2AAFC60'**, **'0/A060'**, or **'3A/0'** (a hexadecimal uint64 value containing two uint32 values separated by a slash (/); if any uint32 value is **0**, **0** is displayed.) **NULL** indicates that the end position of decoding is not specified.

- upto_nchanges

  Indicates the number of decoded records (including the **begin** and **commit** timestamps). Assume that there are three transactions, which involve 3, 5, and 7 records, respectively. If **upto_nchanges** is set to **4**, 8 records of the first two transactions will be decoded. Specifically, decoding is stopped when the number of decoded records surpasses the value of **upto_nchanges** after decoding in the first two transactions is finished.

  Value range: non-negative integers.

  NOTE

  If any of the **upto_lsn** and **upto_nchanges** values is reached, decoding ends.

- **options**: Specifies optional parameters, consisting of **options_name** and **options_value**.

  - include-xids

    Specifies whether the decoded **data** column includes XIDs.

    Value range: Boolean. The default value is **true**.

    - **false**: The decoded **data** column does not contain XID information.
    - **true**: The decoded **data** column contains XID information.

  - skip-empty-xacts

    Specifies whether to ignore empty transactions during decoding.

    Value range: Boolean. The default value is **false**.

    - **false**: The empty transaction information is not ignored during decoding.
    - **true**: The empty transaction information is ignored during decoding.

  - include-timestamp

    Specifies whether the decoded information includes commit timestamps.

    Value range: Boolean. The default value is **true**.

    - **false**: The decoded information does not contain the **commit** timestamp.
    - **true**: The decoded information contains the **commit** timestamp.

  - only-local

    Specifies whether to decode only local logs.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Value range: Boolean. The default value is **true**.

- **false**: Non-local logs and local logs are decoded.
- **true**: Only local logs are decoded.

- force-binary

  This parameter is useless for the function.

  Value range: Boolean. The result is output in binary format.

- white-table-list

  Specifies the whitelist of schemas and tables to be decoded.

  Value range: a string that contains table names in the whitelist. Different tables are separated by commas (,). An asterisk (*) is used to fuzzily match all tables. Schema names and table names are separated by periods (.). No space character is allowed. Example: **select * from pg_logical_slot_peek_binary_changes('slot1', NULL, 4096, 'white-table-list', 'public.t1,public.t2');**

- skip-xid-list

  Specifies the blacklist of transactions (represented by their XIDs) to be skipped during decoding. Transactions cannot be skipped during the upgrade observation period.

  Value range: A character string that contains XIDs, separated by slashes (/). No whitespace characters are allowed. Valid XIDs range from 3 to 18446744073709551615 (that is, the maximum value of uint64). The following is an example:

  ```
  SELECT * FROM pg_logical_slot_peek_changes('slot1', NULL, 4096, 'skip-xid-list', '1234/2345');
  ```

- max-txn-in-memory

  Memory control parameter. The unit is MB. If the memory occupied by a single transaction is greater than the value of this parameter, data is flushed to disk.

  Value range: integers from 0 to 100. The default value is **0** (disabled).

- **max-reorderbuffer-in-memory**:

  Memory control parameter. The unit is GB. If the total memory (including the cache) of transactions being concatenated in the sender thread is greater than the value of this parameter, the current decoding transaction is flushed to disk.

  Value range: integers from 0 to 100. The default value is **0** (disabled).

- **desc-memory-limit**:

  A memory control parameter, in MB. When the total memory of table metadata maintained by a logical decoding task is greater than the value of this parameter, some table metadata will be evicted.

  Value range: an integer ranging from 10 to 1048576. The default value is **200**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- include-user

  Specifies whether the BEGIN logical log of a transaction records the username of the transaction.

  Value range: Boolean. The default value is **false**.

  - **false**: The BEGIN logical log of a transaction does not record the username of the transaction.
  - **true**: The BEGIN logical log of a transaction records the username of the transaction.

- exclude-userids

  Lists the OIDs of blacklisted users.

  Value range: OIDs of blacklisted users. Multiple OIDs are separated by commas (,). The system does not verify the existence of the specified OIDs.

- exclude-users

  Specifies the name of a blacklisted user.

  Value range: names of blacklisted users. Multiple names are separated by commas (,). **dynamic-resolution** specifies whether to dynamically parse and identify usernames. If the decoding is interrupted because the user does not exist and the corresponding blacklisted user does not exist at the time when logs are generated, you can set **dynamic-resolution** to **true** or delete the username from the blacklist to start decoding and continue to obtain logical logs.

- dynamic-resolution

  Specifies whether to dynamically parse the names of blacklisted users.

  Value range: Boolean. The default value is **true**.

  - **false**: An error is reported and the logical decoding exits when the decoding detects that a user does not exist in blacklist **exclude-users**.
  - **true**: Decoding continues when it detects that a user does not exist in blacklist **exclude-users**.

- **decode-sequence**:

  (Logical decoding control parameter) Specifies whether to generate decoding results for logs that record sequence value changes.

  Value range: Boolean. The default value is **false**.

  - The value cannot be set to **true** currently.
  - **false**: The decoding result of the change log of the sequence value is not output.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTICE

Currently, **decode-sequence** can only be set to **false**. If **decode-sequence** is set to **true**, an error is reported when decoding is started and the decoding process exits.

- **enable-decode-position**:

  (Logical decoding control parameter) Specifies whether to send decoding position logs when the logs are read during logical decoding.

  Value range: Boolean. The default value is **false**.

  - **true**: Position logs are generated.
  - **false**: Position logs are not generated.

- enable-rowno:

  (Logical decoding control parameter) Specifies whether to output the **rowno** system column for new and old tuples in INSERT/UPDATE/DELETE operations when decoding a primary key–free table that includes the **rowid** system column and has the **REPLICA IDENTITY** option set to **FULL** or any other value equivalent to **FULL**. When using this option to output the **rowno** system column, ensure that the target database contains columns with the same name and type. Otherwise, logical decoding logs may fail to be replayed. If you have any questions, contact Huawei technical support.

  Value range: Boolean

  - **true**: The **rowno** system column is output.
  - **false**: The **rowno** system column is not output.

  Default value: **false**.

NOTICE

- This option is ineffective for the sql_decoding plug-in.
- The actual effect of the **REPLICA IDENTITY** option is equivalent to **FULL**. Currently, it refers to the **NOTHING** and **DEFAULT** options of the Ustore table. For details, see the option description in **REPLICA IDENTITY { DEFAULT | USING INDEX index_name | FULL | NOTHING }**.

NOTE

Some configuration options can be configured in functions but do not take effect. For details, see "Feature Usage Guidelines > Logical Replication > Logical Decoding (Non-Multi-Primary) > Logical Decoding Options" in *Developer Guide*.

Return types: text, xid, and bytea.

Note: The function returns the decoding results. Each decoding result contains three columns, corresponding to the above return types and indicating the LSN position, XID, and decoded content in binary format, respectively. Users who call this function must have the SYSADMIN permission or the

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

REPLICATION permission, or inherit permissions of the built-in role gs_role_replication.

NOTE

On the CN, this function cannot be executed in a CSN-based replication slot (**confirmed_csn** is not **0**).

- pg_logical_slot_get_binary_changes('slot_name', 'upto_lsn', upto_nchanges, 'options_name', 'options_value')

  Description: Performs decoding in binary mode and does not go to the next streaming replication slot.

  Parameters: same as **pg_logical_slot_peek_binary_changes**.

  Note: Users who call this function must have the SYSADMIN permission or the REPLICATION permission, or inherit permissions of the built-in role gs_role_replication.

  NOTE

  On the CN, this function cannot be executed in a CSN-based replication slot (**confirmed_csn** is not **0**). This function cannot be executed on the standby DN.

- pg_replication_slot_advance ('slot_name', 'upto_lsn')

  Description: Directly goes to the streaming replication slot for a specified CSN (for CSN-based logical replication slots) or LSN (for LSN-based replication slots), without outputting any decoded result.

  Parameters:

  – slot_name

    Indicates the name of the streaming replication slot.

    Value range: character strings, which can only consist of lowercase letters, digits, underscores (_), question marks (?), hyphens (-), and periods (.). One or two periods alone cannot be used as the replication slot name.

  – upto_lsn

    For the CSN-based logical replication slot, it indicates the target CSN before which logs are decoded. During the next decoding, only the transaction results whose CSN is greater than this value will be output. If the input CSN is smaller than the value of **confirmed_csn** recorded in the current streaming replication slot, the input CSN is used. If the input CSN is greater than the latest CSN that can be obtained, the latest CSN is directly used. If the input CSN is smaller than the CSN of the latest physical log, the logs before first CSN greater than the input CSN are decoded.

    For the LSN-based logical replication slot, it indicates the target LSN before which logs are decoded. During the next decoding, only the transaction results whose LSN is greater than this value will be output. If the input LSN is smaller than the LSN before which logs are decoded in the current streaming replication slot, an error is reported. If the input LSN is greater than the LSN of the latest physical log, the LSN of the latest physical log is directly used. If the input LSN is smaller than the LSN of the latest physical log, the logs before first LSN greater than the input LSN are decoded.

    Value range: a string, for example, **'1/2AAFC60'**, **'0/A060'**, or **'3A/0'** (a hexadecimal uint64 value containing two uint32 values separated by a

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

slash (/); if any uint32 value is **0**, **0** is displayed.) **NULL** indicates that the end position of decoding is not specified.

Return types: name and text.

NOTE

- The return value corresponds to **slot_name** and the actual position (CSN or LSN). Users who call this function must have the SYSADMIN permission or the REPLICATION permission, or inherit permissions of the built-in role gs_role_replication.
- On the CN, this function cannot be executed in a CSN-based replication slot (**confirmed_csn** is not **0**). This function can be executed on the backup replication slot on the standby DN. This function can be executed on the logical replication slot on the standby DN and the corresponding logical replication slot on the primary DN is updated synchronously. If this function is executed on the standby DN, a WAL sender of the primary DN is occupied when the replication slot number on the primary DN is updated. The logical decoding function reserves a WAL sender for each logical replication slot. Therefore, if this function is executed in normal scenarios, the logical replication slot number on the primary DN is updated normally. If this function is executed continuously in a short period of time, the primary DN fails to update the slot number and no error is reported.

- pg_get_replication_slots()

  Description: Obtains the replication slot list.

  Table 1-136 Return values

Column	Data Type	Description
slot_name	text	Name of the replication slot.
plugin	text	Name of the output plug-in corresponding to the logical replication slot.
slot_type	text	Replication slot type. • **physical**: physical replication slot. • **logical**: logical replication slot.
datoid	oid	OID of the database where the replication slot resides.
active	Boolean	Specifies whether the replication slot is activated. • **f**: not activated. • **t**: activated.
xmin	xid	XID of the earliest transaction that the database must reserve for the replication slot.
catalog_xmin	xid	XID of the earliest system catalog-involved transaction that the database must reserve for the logical replication slot.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Column	Data Type	Description
restart_lsn	text	Physical location of the earliest Xlog required by the replication slot.
dummy_standby	Boolean	Reserved parameter.
confirmed_flush	text	Location of the received log confirmed by the client (dedicated for logical replication slots).
confirmed_csn	xid	CSN corresponding to the last transaction in the received log confirmed by the client (dedicated for logical replication slots).
dictionary_csn_min	xid	CSN of the earliest dictionary table-involved transaction that the database must reserve for the logical replication slot.
slot_dictionary_type	text	Type of the logical replication slot.
intra_cluster	Boolean	Specifies whether the replication slot needs to synchronize data between clusters. • **true**: no. • **false**: yes.
remote_stream	Boolean	Specifies whether the replication slot is decoding the remote log stream.

Example:

```
Run the following command on the DN:
gaussdb=# SELECT * FROM pg_get_replication_slots();
 slot_name |     plugin     | slot_type | datoid | active | xmin | catalog_xmin | restart_lsn |
dummy_standby | confirmed_flush | confirmed_csn | dictionary_csn_min | slot_dictionary_type |
intra_cluster | remote_stream
-----------+----------------+-----------+--------+--------+------+--------------+-------------+---------------
+-----------------+--------------+--------------------+----------------------
 dn_6002   |              | physical |      0 | t      |      |              | 0/3622B528  | f             |

NOTICE

When a query is performed on a DN, the **confirmed_csn** query result of the LSN-based logical replication slot is empty, and the **confirmed_flush** query result of the CSN-based logical replication slot is empty. When a query is performed on the CN, **catalog_xmin**, **restart_lsn**, **confirmed_flush**, and **confirmed_csn** of the CSN-based logical replication slot are not displayed and the query result is empty.

- pg_logical_get_area_changes('start_lsn', 'upto_lsn', upto_nchanges, 'decoding_plugin', 'xlog_path', 'options_name', 'options_value')

  Description: Specifies an LSN range or an Xlog file for decoding.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

The constraints are as follows:

- The current network and hardware environment are normal.
- It is recommended that the size of a single tuple be less than or equal to 500 MB. If the size ranges from 500 MB to 1 GB, an error is reported.
- Log decoding is not supported for operations that are not recorded in Xlogs, such as data page replication.
- When making API calls, set **wal_level** to **logical**. The system can only parse the log files generated when **wal_level** is **logical**. If the Xlog file being used is not at the logical level, an error will occur, and the file will not be decoded.
- To successfully parse Xlog files, use a copy of a fully homogeneous DN and avoid performing any DDL operations or VACUUM FULL in the database so that the system can find the meta information associated with data.
- Do not read an excessive number of Xlog files at a time. When selecting range decoding instead of file decoding, it is advisable to read one Xlog file each time. Decoding an Xlog file typically requires two to three times the memory of the file size.
- Logs before VACUUM FULL cannot be decoded.
- Xlog files generated before scale-out cannot be decoded.
- When **enable-ddl** is disabled, columns of the TOAST, CLOB, and BLOB types cannot be decoded. When enable-ddl is enabled, columns of related types can be decoded.
- This mode decodes content based on the data stored in Xlog text rather than transactions. Therefore, data that is not in the Xlog cannot be decoded. If related Xlogs are missing, the missing logs cannot be decoded.
- When **enable-ddl** is disabled: If no file is specified for decoding from the decoding point, the system will check for DDL operations between the decoding start point and the latest redo value. If any DDL operation is detected, no decoding will take place. If a file is specified for decoding, the system will check for DDL operations between the start point and the last readable content of that file, as well as between the start point of Xlogs in the data directory and the latest redo value. If any DDL operation is detected, decoding for all tables will be deactivated.
- When **enable-ddl** is disabled, columns of the TOAST, CLOB, and BLOB types cannot be decoded. When enable-ddl is enabled, columns of related types can be decoded.
- When **enable-ddl** is enabled, decoding of DDL statements is supported in the range and DDL statements can be output. For details about the output DDL statement range, see "Feature Usage Guidelines > Logical Replication > Logical Decoding (Non-Multi-Primary) > Logical Decoding of DDL Statements" in *Developer Guide*.
- To parse the UPDATE and DELETE statements of a table, you need to configure the **REPLICA IDENTITY** attribute for the table. If the table does not have a primary key, set **REPLICA IDENTITY** to **FULL**. For details, see the **REPLICA IDENTITY { DEFAULT | USING INDEX index_name | FULL | NOTHING }** column in **ALTER TABLE**.
- In M-compatible mode, the decoded data value of the float4 type is output as the actual stored value, which is displayed differently from that of the SQL query.

Note: When separation-of-duties is enabled, only the initial database user can call the function. When separation-of-duties is disabled, the SYSADMIN permission is required.

Parameters:

– start_lsn

  Specifies the LSN at the start of decoding.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Value range: character strings in the format of *xlogid*/*xrecoff*, for example, '1/2AAFC60'. **NULL** indicates that the start position of decoding logs is not limited.

– upto_lsn

Specifies the LSN at the end of decoding.

Value range: character strings in the format of *xlogid*/*xrecoff*, for example, '1/2AAFC60'. **NULL** indicates that the end position of decoding is not specified.

– upto_nchanges

Indicates the number of decoded records (including the **begin** and **commit** timestamps). Assume that there are three transactions, which involve 3, 5, and 7 records, respectively. If **upto_nchanges** is set to **4**, 8 records of the first two transactions will be decoded. Specifically, decoding is stopped when the number of decoded records surpasses the value of **upto_nchanges** after decoding in the first two transactions is finished.

Value range: non-negative integers.

NOTE

If any of the **LSN** and **upto_nchanges** values are reached, decoding ends.

– decoding_plugin

Decoding plug-in, which is a .so plug-in that specifies the output format of the decoded content.

Value range: **mppdb_decoding** and **sql_decoding**.

– xlog_path

Decoding plug-in, which specifies the Xlog absolute path of the decoding file.

Value range: **NULL** or a character string of the absolute path of the Xlog file.

– **options**: This parameter is optional and consists of multiple pairs of **options_name** and **options_value**. You can retain the default values.

  ▪ include-xids

  Specifies whether the decoded **data** column includes XIDs.

  Value range: Boolean. The default value is **true**.

  false: The decoded **data** column does not contain XID information.

  true: The decoded **data** column contains XID information.

  ▪ include-timestamp

  Specifies whether the decoded information includes commit timestamps.

  Value range: Boolean. The default value is **true**.

  false: The decoded information does not contain the **commit** timestamp.

  true: The decoded information contains the **commit** timestamp.

  ▪ only-local

  Specifies whether to decode only local logs.

  Value range: Boolean. The default value is **true**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

false: Non-local logs and local logs are decoded.

true: Only local logs are decoded.

- force-binary

  Specifies whether to output the decoding result in binary format.

  Value range: Boolean. The default value is **false**.

  false: The decoding result is output in text format.

  The value cannot be set to **true** currently.

- white-table-list

  Specifies the whitelist of schemas and tables to be decoded. Value range: a string that contains table names in the whitelist. Different tables are separated by commas (,). An asterisk (*) is used to fuzzily match all tables. Schema names and table names are separated by periods (.). No space character is allowed.

- white-database-list

  Whitelist parameter, including names of databases to be decoded. Value range: a character string that contains database names in the whitelist. Different database names are separated by commas (,). No space character is allowed. If **white-database-list** is not set, only the database Xlogs of the current connection are decoded. If **white-database-list** is set, only the database Xlogs specified in **white-database-list** are decoded. If the system database is decoded, ordinary table data in the system database can be retrieved.

- enable-ddl

  Decoding that contains DDL syntax is supported. If the DDL syntax exists between the start position and the latest log, the function is not affected. The value can be **0** or **1**.

  If this parameter is set to **1**: enable-ddl is enabled. This function supports decoding of xlog areas containing DDL syntax.

  If this parameter is set to **0**, enable-ddl is disabled by default. This function does not support decoding of xlog areas containing DDL syntax. If a DDL statement is detected, the function exits directly.

  If a column has been deleted from the table definition, the column name of the decoded data will be replaced by the UNDEFINED placeholder when **enable-ddl** is enabled.

- **data-limit**:

  Specifies the amount of output data after decoding. The unit is KB.

  Value range: an integer greater than or equal to 0. The default value is **0**, indicating that the size of the decoding result is not limited.

  The input parameter **data-limit** of this function is used together with the GUC parameter **data-limit**. The decoding stops if it exceeds either of the **data-limit** values.

  Rules:

  1) If the GUC parameter **data-limit** is set to **0**, and **data-limit** for function decoding is not set or is set to **0**, the decoding result has no upper limit.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

2) If the GUC parameter **data-limit** is not set, and **data-limit** for function decoding is set to **0**, the upper limit of the decoding result is 10 GB.
3) If the GUC parameter **data-limit** is set, and **data-limit** for function decoding is not set or is set to **0**, the upper limit of the decoding result is the value of the GUC parameter **data-limit**.
4) If both the GUC parameter **data-limit** and **data-limit** of the function are set, the smaller value is used as the upper limit of the decoding result.

- xlog_dir

  The archive log folder can be decoded, and the folder name is the same as the first eight digits of the WAL file. Decoding can be performed only when **enable-ddl** is set to **1** and the input **start_lsn** and **upto_lsn** are valid intervals. Value range: full path of the folder.

  For details, see "Feature Usage Guidelines > Logical Replication > Logical Decoding (Non-Multi-Primary) > Data Restoration by Logical Decoding" in *Developer Guide*.

  ```
  gaussdb=# SELECT * FROM pg_logical_get_area_changes('1/F9FC24C8', '1/FA67B2A0', NULL, 'sql_decoding', NULL ,'enable-ddl','1','xlog_dir','/base/username/xlog_dir/00000000');
  ```

- **decode-sequence**:

  (Logical decoding control parameter) Specifies whether to generate decoding results for logs that record sequence value changes.

  Value range: Boolean. The default value is **false**.

  - The value cannot be set to **true** currently.
  - **false**: The decoding result of the change log of the sequence value is not output.

  NOTICE

  Currently, **decode-sequence** can only be set to **false**. If **decode-sequence** is set to **true**, an error is reported when decoding is started.

- enable-rowno:

  (Logical decoding control parameter) Specifies whether to output the **rowno** system column for new and old tuples in INSERT/UPDATE/DELETE operations when decoding a primary key–free table that includes the **rowid** system column and has the **REPLICA IDENTITY** option set to **FULL** or any other value equivalent to **FULL**. When using this option to output the **rowno** system column, ensure that the target database contains columns with the same name and type. Otherwise, logical decoding logs may fail to be replayed. If you have any questions, contact Huawei technical support.

  Value range: Boolean

  - **true**: The **rowno** system column is output.
  - **false**: The **rowno** system column is not output.

  Default value: **false**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTICE

- This option is ineffective for the sql_decoding plug-in.
- The actual effect of the **REPLICA IDENTITY** option is equivalent to **FULL**. Currently, it refers to the **NOTHING** and **DEFAULT** options of the Ustore table. For details, see the option description in **REPLICA IDENTITY { DEFAULT | USING INDEX index_name | FULL | NOTHING }**.

NOTE

pg_logical_get_area_changes takes effect only for the preceding parameters. It does not take effect for the other parameters such as **max-txn-in-memory**, **include-user**, **exclude-userids**, **exclude-users** and **dynamic-resolution** (for details, see pg_logical_slot_peek_changes).

Return type: text, xid, text

Example:

```
- Perform DML operations on a CN. You can query the DML operations executed on the current DN.
gaussdb=# SELECT * FROM pg_logical_get_area_changes('0/502E418', NULL, NULL, 'sql_decoding',
NULL);
 location  |  xid  |                                 data
-----------+-------+--------------------------------------------------------------------------------
 0/502E448 | 17365 | insert into public.t1 values (1, 1);
 0/502E5A0 | 17365 | COMMIT 17365 (at 2023-11-01 11:28:43.92526+08) 2010016
 0/502E5D0 | 17366 | delete from public.t1 where a = 1;insert into public.t1 values (1, 2);
 0/502E6D8 | 17366 | COMMIT 17366 (at 2023-11-01 11:28:45.889283+08) 2010017
 0/502E7B8 | 17367 | delete from public.t1 where a = 1;
 0/502E8B0 | 17367 | COMMIT 17367 (at 2023-11-01 11:28:48.301307+08) 2010018
(6 rows)
```

Note: The function returns the decoding results. Each decoding result contains three columns, corresponding to the above return types and indicating the LSN, XID, and decoded content, respectively.

- gs_get_parallel_decode_status()

  Description: Monitors the lengths of the read log queue and decoding result queue of each decoder thread to identify performance bottlenecks in parallel decoding.

  Return type: text, int, text, text, text, int64, int64, TimestampTz

  Example:

```
gaussdb=# SELECT * FROM gs_get_parallel_decode_status();
 slot_name | parallel_decode_num | read_change_queue_length  | decode_change_queue_length |
reader_lsn | working_txn_cnt | working_txn_memory |      decoded_time
-----------+---------------------+---------------------------+----------------------------+------------
+-----------------+--------------------+------------------------
 slot1     |                   2 | queue0: 1005, queue1: 320 | queue0: 63, queue1: 748    | 0/1DCE2578
|              42 |          192927504 | 2023-01-10 11:18:22+08
(1 row)
```

  Note: In the return values, **slot_name** indicates the replication slot name, **parallel_decode_num** indicates the number of parallel decoder threads in the replication slot, **read_change_queue_length** indicates the current length of the log queue read by each decoder thread, **decode_change_queue_length** indicates the current length of the decoding result queue of each decoder thread, **reader_lsn** indicates the log location read by the reader thread, **working_txn_cnt** indicates the number of transactions being concatenated in the current sender thread, **working_txn_memory** indicates the total memory (in bytes) occupied by the concatenation transactions in the sender thread,

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

and **decoded_time** indicates the time of the latest WAL decoded by the replication slot.

NOTICE

The value of **decoded_time** comes from checkpoint logs and transaction commit logs, which has a certain error. If no log containing the time is decoded, "2000-01-01 08:00:00+08" (depending on the time zone set in the database) is displayed.

- gs_get_slot_decoded_wal_time(slot_name)

  Description: Queries the time of the latest WAL decoded by a replication slot.

  Parameters:

  – slot_name

    Specifies the name of the replication slot to be queried.

    Value range: a string, supporting only letters, digits, underscores (_), question marks (?), hyphens (-), and periods (.).

  Example:

```
gaussdb=# SELECT * FROM gs_get_slot_decoded_wal_time('replication_slot');
 gs_get_slot_decoded_wal_time
------------------------------
 2023-01-10 11:25:22+08
(1 row)
```

  Note: The returned values indicate the time of the latest WAL decoded by the replication slot.

NOTICE

- The returned time is extracted from checkpoint logs and transaction commit logs, with a certain margin of error. If no log containing the time is decoded, "2000-01-01 08:00:00+08" (depending on the time zone set in the database) is displayed. When you query the time of the most recent decoded WAL at a non-existent logical replication slot, NULL will be returned. In gsql, you can use **\pset null 'null'** to customize how NULL is displayed.
- Serial decoding is not supported.

- gs_logical_parallel_decode_status('slot_name')

  Description: Obtains the decoding statistics of active replication slots for parallel logical decoding, including 29 rows of metrics.

  The descriptions of the metrics are listed in the following table.

```
Record - (stat_id int, stat_name TEXT, value TEXT)
```

Table 1-137 Metrics

Metric	Description
slot_name	Name of the logical replication slot.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Metric	Description
reader_lsn	Location of the logical logs to be decoded.
wal_read_total_time	Time required for loading the log module, in microseconds.
wal_wait_total_time	Time required for waiting for the log module, in microseconds.
parser_total_time	Time required for the reader thread to process data, in microseconds.
decoder_total_time	Total processing duration of all decoder threads, in microseconds.
sender_total_time	Time required for the sender thread to process data, in microseconds.
net_send_total_time	Time required for the network to send logical logs, in microseconds.
net_wait_total_time	Time required for the network to wait for sending logical logs, in microseconds.
net_send_total_bytes	Number of bytes of logical logs sent by the network.
transaction_count	Number of transactions.
big_transaction_count	Number of large transactions.
max_transaction_tuples	Maximum number of transaction operation tuples.
sent_transaction_count	Number of transactions sent (by the local database).
spill_disk_transaction_count	Number of flushed transactions.
spill_disk_bytes	Total number of bytes flushed to disk.
spill_disk_count	Number of disk flushing times.
input_queue_full_count	Total number of times that the input queues of all decoder threads are full.
output_queue_full_count	Total number of times that the output queues of all decoder threads are full.
dml_count	Total number of DML statements in WALs decoded by each decoder thread in the local database.
dml_filtered_count	Total number of DML statements in WALs decoded and filtered by each decoder thread in the local database.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Metric	Description
toast_count	Number of modified TOAST table rows.
candidate_catalog_xmin	Indicates the **catalog_xmin** candidate point of the current logical replication slot.
candidate_xmin_lsn	Specifies the log confirmation receiving point required for the LSN-based logical replication slot to update **catalog_xmin**.
candidate_restart_valid	Specifies the log confirmation receiving point required for the LSN-based logical replication slot to update **restart_lsn**.
candidate_restart_lsn	Indicates the **restart_lsn** candidate point of the current logical replication slot.
candidate_xmin_csn	Specifies the log confirmation receiving point required for the CSN-based logical replication slot to update **catalog_xmin**.
candidate_restart_csn	Specifies the log confirmation receiving point required for the CSN-based logical replication slot to update **restart_lsn**.
candidate_csn_min	Candidate point of the current logical replication slot dictionary_csn_min. For details, see the **pg_get_replication_slot...** function.

Parameters:

- slot_name

  Indicates the name of the streaming replication slot.

  Value range: character strings, which can only consist of lowercase letters, digits, underscores (_), question marks (?), hyphens (-), and periods (.). One or two periods alone cannot be used as the replication slot name.

Return types: int, text, and text.

Example:

```
gaussdb=# SELECT * FROM gs_logical_parallel_decode_status('replication_slot');
 stat_id |          stat_name           |        value
---------+------------------------------+---------------------
       1 | slot_name                    | replication_slot_lsn
       2 | reader_lsn                   | 0/1E249228
       3 | wal_read_total_time          | 4769541
       4 | wal_wait_total_time          | 4754879
       5 | parser_total_time            | 12727
       6 | decoder_total_time           | 215633
       7 | sender_total_time            | 41707
       8 | net_send_total_time          | 28435
       9 | net_wait_total_time          | 11918
      10 | net_send_total_bytes         | 931076
      11 | transaction_count            | 19
      12 | big_transaction_count        | 1
      13 | max_transaction_tuples       | 10000
      14 | sent_transaction_count       | 19
      15 | spill_disk_transaction_count | 0
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
    16 | spill_disk_bytes             | 0
    17 | spill_disk_count             | 0
    18 | input_queue_full_count       | 226
    19 | output_queue_full_count      | 13
    20 | dml_count                    | 10000
    21 | dml_filtered_count           | 0
    22 | toast_count                  | 0
    23 | candidate_catalog_xmin       | 83576
    24 | candidate_xmin_lsn           | 0/1E0992A0
    25 | candidate_restart_valid      | 0/1E0992A0
    26 | candidate_restart_lsn        | 0/1E0992A0
    27 | candidate_xmin_csn           | 0
    28 | candidate_restart_csn        | 0
    29 | candidate_csn_min            | 17157
(29 rows)
```

Note: According to the definitions of statistical items, they must meet the following requirements:

wal_read_total_time >= wal_wait_total_time;

transaction_count >= big_transaction_count;

transaction_count >= sent_transaction_count;

transaction_count >= spill_disk_transaction_count;

dml_count >= dml_filtered_count;

dml_count >= toast_count;

If spill_transaction_count == 0, then spill_disk_bytes == 0;

However, frequent locking and unlocking are required, which greatly affects the performance. As a result, the preceding constraints may not be met in multi-thread cases.

transaction_count indicates the number of transactions in all databases.

sent_transaction_count indicates the number of transactions sent by the local database because transactions that are not in the local database will not be sent.

If the value of **slot_name** does not exist, the function does not report an error and the return value is empty.

- gs_logical_parallel_decode_reset_status('slot_name')

  Description: Resets indicators in **gs_logical_parallel_decode_status('slot_name')**.

  Parameters:

  – slot_name

    Indicates the name of the streaming replication slot.

    Value range: character strings, which can only consist of lowercase letters, digits, underscores (_), question marks (?), hyphens (-), and periods (.). One or two periods alone cannot be used as the replication slot name.

  Return type: text.

  Example:

```
gaussdb=# SELECT * FROM gs_logical_parallel_decode_reset_status('replication_slot');
 gs_logical_parallel_decode_reset_status
-----------------------------------------
 OK
(1 row)

gaussdb=# SELECT * FROM gs_logical_parallel_decode_status('replication_slot');
 stat_id |          stat_name           |       value
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
---------+-------------------------------+----------------------
      1 | slot_name                     | replication_slot_lsn
      2 | reader_lsn                    | 0/1E2497F0
      3 | wal_read_total_time           | 0
      4 | wal_wait_total_time           | 0
      5 | parser_total_time             | 0
      6 | decoder_total_time            | 0
      7 | sender_total_time             | 0
      8 | net_send_total_time           | 0
      9 | net_wait_total_time           | 0
     10 | net_send_total_bytes          | 0
     11 | transaction_count             | 0
     12 | big_transaction_count         | 0
     13 | max_transaction_tuples        | 0
     14 | sent_transaction_count        | 0
     15 | spill_disk_transaction_count | 0
     16 | spill_disk_bytes              | 0
     17 | spill_disk_count              | 0
     18 | input_queue_full_count        | 0
     19 | output_queue_full_count       | 0
     20 | dml_count                     | 0
     21 | dml_filtered_count            | 0
     22 | toast_count                   | 0
     23 | candidate_catalog_xmin        | 83594
     24 | candidate_xmin_lsn            | 0/1E249528
     25 | candidate_restart_valid       | 0/1E249528
     26 | candidate_restart_lsn         | 0/1E249528
     27 | candidate_xmin_csn            | 0
     28 | candidate_restart_csn         | 0
     29 | candidate_csn_min             | 17176
(29 rows)
```

Note: The return value is the execution result. If the value of **slot_name** does not exist, the function does not report an error and the return value is **invalid slot name**.

Do not reset a replication slot that is being observed. The error information is as follows:

a. If **slot_name** is empty, the following error is reported: "ERROR: inputString should not be NULL".

b. If **slot_name** is not empty but does not exist, no error is reported but "invalid slot name" is displayed.

c. If **slot_name** is not empty but the replication slot corresponding to **slot_name** is being observed, no error is reported but "can't reset during observing! use gs_logical_decode_stop_observe to stop" is displayed.

- gs_logical_decode_start_observe('slot_name', window, interval)

  Description: Enables logical replication performance sampling. In a distributed environment, this function must be executed on DNs.

  Parameters:

  – slot_name

    Indicates the name of the streaming replication slot.

    Value range: character strings, which can only consist of lowercase letters, digits, underscores (_), question marks (?), hyphens (-), and periods (.). One or two periods alone cannot be used as the replication slot name.

  – window

    Specifies the sampling window.

    Value range: integers from 2 to 1024. Sampled data in the latest *interval* × *window* is collected.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

  - interval

    Specifies the performance monitoring interval, in seconds.

    Value range: 1s to 60s (time interval type). Sampled data in the latest *interval* × *window* is collected.

    Return type: text.

  Note: The return value is the execution result. If the value of **slot_name** does not exist, the function does not report an error and the return value is **invalid slot name**.

  Do not enable the observe function for a replication slot that is being observed. The error information is as follows:

  a. If **slot_name** is empty, the following error is reported: "ERROR: inputString should not be NULL".
  b. If **slot_name** is not empty but does not exist, no error is reported but "invalid slot name" is displayed.
  c. If the value of **window** is less than **2**, "window has to be >= 2" is displayed.
  d. If the value of **window** is greater than **1024**, "window has to be <= 1024" is displayed.
  e. If the value of **interval** is less than 1s, "sample interval has to be >= 1s" is displayed.
  f. If the value of **interval** is greater than 60s, "sample interval has to be <= 60s" is displayed.
  g. If **slot_name** is not empty but the observe function has been enabled for the replication slot corresponding to **slot_name**, no error is reported and the message "observe has started!" is displayed.

- gs_logical_decode_stop_observe('slot_name')

  Description: Stops logical replication performance sampling. In a distributed environment, this function must be executed on DNs.

  Parameters:

  - slot_name

    Indicates the name of the streaming replication slot.

    Value range: character strings, which can only consist of lowercase letters, digits, underscores (_), question marks (?), hyphens (-), and periods (.). One or two periods alone cannot be used as the replication slot name.

  - Return type: text.

  Note: The return value is the execution result. If the value of **slot_name** does not exist, the function does not report an error and the return value is **invalid slot name**.

  Do not disable the observe function for a replication slot that is not observed. The error information is as follows:

  a. If **slot_name** is empty, the following error is reported: "ERROR: inputString should not be NULL".
  b. If **slot_name** is not empty but does not exist, no error is reported but "invalid slot name" is displayed.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

c. If **slot_name** is not empty but the observe function has been disabled for the replication slot corresponding to **slot_name**, no error is reported and the message "observe not started!" is displayed.

- gs_logical_decode_observe_data('slot_name')

  Description: Displays the original logical replication performance sampling data. In a distributed environment, this function must be executed on DNs.

  Table 1-138 Metrics

Metric	Description
slot_name	Name of the logical replication slot.
sample_time	Performance indicator sampling time, in microseconds.
reader_lsn	Location of the logical logs to be decoded.
wal_read_total_time	Time required for loading the log module, in microseconds.
wal_wait_total_time	Time required for waiting for the log module, in microseconds.
parser_total_time	Time required for the reader thread to process data, in microseconds.
decoder_total_time	Total processing duration of all decoder threads, in microseconds.
sender_total_time	Time required for the sender thread to process data, in microseconds.
net_send_total_time	Time required for the network to send logical logs, in microseconds.
net_send_total_bytes	Number of bytes of logical logs sent by the network.
transaction_count	Number of transactions.
big_transaction_count	Number of large transactions.
sent_transaction_count	Number of transactions sent by the local database.
spill_transaction_count	Number of flushed transactions.
spill_disk_bytes	Total number of bytes flushed to disk.

  Parameters:

  – slot_name

    Indicates the name of the streaming replication slot.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Value range: character strings, which can only consist of lowercase letters, digits, underscores (_), question marks (?), hyphens (-), and periods (.). One or two periods alone cannot be used as the replication slot name.

– Return type: SETOF record

Example:

```
gaussdb=# SELECT * FROM gs_logical_decode_observe_data('replication_slot');
 slot_name |          sample_time          | reader_lsn | wal_read_total_time | wal_wait_total_time |
parser_total_time | decoder_total_time | sender_total_time | net_send_total_time |
net_send_total_bytes | transaction_count | big_
transaction_count | sent_transaction_count | spill_transaction_count | spill_disk_bytes

Table 1-139 Metrics

Metric	Description
slot_name	Name of the logical replication slot.
sample_time	Performance metric sampling time.
logical_decode_rate	Overall processing rate of logical decoding, in byte/s.
wal_read_rate	Processing rate in the WAL reading phase, in byte/s.
parser_rate	Processing rate in the WAL parsing phase, in byte/s.
decoder_rate	Processing rate in the decoding phase, in byte/s.
sender_rate	Processing rate in the sending phase, in byte/s.
net_send_rate	Network sending rate, in byte/s.

Parameters:

- slot_name

  Indicates the name of the streaming replication slot.

  Value range: character strings, which can only consist of lowercase letters, digits, underscores (_), question marks (?), hyphens (-), and periods (.). One or two periods alone cannot be used as the replication slot name.
- Return type: SETOF record

Example:

```
gaussdb=# SELECT * FROM gs_logical_decode_observe('replication_slot');
    slot_name     |          sample_time          | logical_decode_rate | wal_read_rate | parser_rate  |
decoder_rate  |  sender_rate  | net_send_rate

```

Note: If the value of **slot_name** does not exist, the function does not report an error and the return value is an empty record. If the denominator is 0, the

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

latest collected valid data is returned. If the denominator is not 0 and the numerator is 0, **0** is returned.

Formulas:

- logical_decode_rate = (reader_lsn1 - reader_lsn2) / (sample_time1 - sample_time2)
- wal_read_rate = (reader_lsn1 - reader_lsn2) / (wal_read_total_time1 - wal_read_total_time2) - (wal_wait_total_time1 - wal_wait_total_time2)
- parser_rate = (reader_lsn1 - reader_lsn2) / (parser_total_time1 - parser_total_time2)
- decoder_rate = (reader_lsn1 - reader_lsn2) / avg(decoder_total_time1[i]-decoder_total_time2[i])
- sender_rate = (reader_lsn1 - reader_lsn2) / (sender_total_time1 - sender_total_time2) - (net_send_total_time1 - net_send_total_time2)
- net_send_rate = (net_sent_bytes1 - net_sent_bytes2) / (net_send_total_time1 - net_send_total_time2) - (net_wait_total_time1 - net_wait_total_time2)

- gs_logical_decode_observe_status('slot_name')

  Description: Queries the monitoring status of a specified logical decoding task. In a distributed environment, this function must be executed on DNs.

  Parameters:

  - slot_name

    Indicates the name of the streaming replication slot.

    Value range: character strings, which can only consist of lowercase letters, digits, underscores (_), question marks (?), hyphens (-), and periods (.). One or two periods alone cannot be used as the replication slot name.

  - Return type: text.

  Example:

```
gaussdb=# SELECT * FROM gs_logical_decode_observe_status('replication_slot');
 gs_logical_decode_observe_status
----------------------------------
 START
(1 row)

gaussdb=# SELECT * FROM gs_logical_decode_observe_status('replication_slot');
 gs_logical_decode_observe_status
----------------------------------
 invalid slot name
(1 row)

gaussdb=# SELECT * FROM gs_logical_decode_stop_observe('replication_slot');
 gs_logical_decode_stop_observe
--------------------------------
 OK
(1 row)

gaussdb=# SELECT * FROM gs_logical_decode_observe_status('replication_slot');
 gs_logical_decode_observe_status
----------------------------------
 STOP
(1 row)
```

  Note: The return value is the monitoring status of the logical decoding task. If the value of **slot_name** does not exist, the function does not report an error and returns "invalid slot name".

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- gs_get_parallel_decode_thread_info()

  Description: Executes on the DN where parallel decoding is performed and returns the thread information of parallel decoding.

  Return types: int64, text, text, and int.

  Example:

```
gaussdb=# SELECT * FROM gs_get_parallel_decode_thread_info();
    thread_id    | slot_name | thread_type | seq_number
-----------------+-----------+-------------+------------
 140335364699904 | slot1     | sender      |          1
 140335214098176 | slot1     | reader      |          1
 140335325312768 | slot1     | decoder     |          1
 140335291750144 | slot1     | decoder     |          2
 140335274968832 | slot1     | decoder     |          3

 140335129818880 | slot2     | decoder     |          1
 140335113037568 | slot2     | decoder     |          2
(10 rows)
```

  Note: In the return values, **thread_id** indicates the thread ID, **slot_name** indicates the replication slot name, **thread_type** indicates the thread type (including the sender, reader and decoder), and **seq_number** indicates the sequence number of each thread with same type in the current replication slot. Each parallel decoding connection only has one sender and reader. Therefore, the sequence numbers of the sender and reader are both 1. The sequence numbers of the decoder are arranged from 1 to the decoding degree of parallelism (DOP) of the current replication slot.

- gs_get_logical_decode_parameter()

  Description: Queries the parameter options of active parallel logical decoding tasks.

  Table 1-140 Description

Column	Return Type	Description
slot_name	text	Replication slot name.
include_xids	bool	Specifies whether the decoding information contains xid.
include_timestamp	bool	Specifies whether decoded information contains the timestamp.
skip_empty_xacts	bool	Specifies whether to ignore empty transactions in the decoding result.
only_local	bool	Specifies whether to decode only the data generated in the current database.
include_username	bool	Specifies whether the BEGIN log of a transaction contains the username.
enable_ddl_decoding	bool	Specifies whether to enable the decoding of DDL statements.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Column	Return Type	Description
enable_ddl_json_format	bool	Specifies whether to enable the JSON output format of DDL reverse parsing.
max_txn_in_memory	int64	Maximum memory occupied by transactions. (This parameter is deprecated and does not take effect.)
max_reorderbuffer_in_memory	int64	Maximum memory for the current decoding task.
decode_style	char	Decoding format.
parallel_decode_num	int64	Number of decoder threads for parallel decoding.
sending_batch	int64	Specifies whether to send messages in batches.
parallel_queue_size	int64	Specifies the length of the queue for interaction between parallel logical decoding threads.
enable_heartbeat	bool	Specifies whether to generate heartbeat logs
slice_id	int64	Specifies the shard ID of the replication table.
output_start_csn	int64	CSN position where the output starts.
output_start_lsn	int64	LSN position where the output starts.
logical_reader_bind_cpu	int64	ID of the CPU bound to the reader thread.
logical_decoder_bind_cpu_index	int64	Index of the CPU bound to the decoder thread.
auto_advance	bool	Specifies whether to automatically update.
skip_generated_columns	bool	Specifies whether to skip the result output of the generated column.
big_transaction_limit	int64	Memory usage limit for determining whether a transaction is a large transaction, in bytes.
exclUser	text	Lists the names of blacklisted users.
table_white_list	text	Whitelist table parameter.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Column	Return Type	Description
desc_memory_limit	int64	Total memory (in MB) for maintaining table metadata information by a logical decoding task.
max_logical_decode_memory	int64	Total memory (in GB) for parallel decoding tasks.
max_control_memory_size	int64	Upper limit (in GB) of the **max-logical-decode-memory** parameter.
max_queue_cache_num	int64	Upper limit of the **max-decode-to-sender-cache-num** parameter.
max_toast_memory_size	int64	Upper limit (in MB) of the memory used for reading the **toast** column in Xlogs.
restart_lsn	int64	A logical decoding control parameter for specifying the decoding start point.
timezone_is_utc	bool	Logical decoding control parameter, which is used to control the output of time type data with time zones.
enable_decode_position	bool	(Logical decoding control parameter) Specifies whether to send decoding position logs when the logs are read during logical decoding.
standby_connection	bool	(Configurable only for streaming decoding) Specifies whether to restrict decoding to standby nodes only.
sender_timeout	int64	Specifies the heartbeat timeout threshold (in milliseconds) between GaussDB and client. This option is valid only for streaming decoding.
change_log_max_len	int64	Specifies the maximum length of the logical log buffer, in bytes.
max_decode_to_sender_cache_num	int64	Specifies the threshold of the number of cached parallel decoding logs.
output_order	bool	Specifies whether to output decoding results based on CSNs. This option is valid only for streaming decoding.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Example:

```
gaussdb=# SELECT * FROM gs_get_logical_decode_parameter();
 slot_name |
configs
                  -----------
+-----------------------
```

NOTE

The constraints are as follows:

- The current network and hardware environment are normal.
- When making function calls, set **wal_level** to **logical**. The system can only parse the log files generated when **wal_level** is **logical**. If the Xlog file being used is not at the logical level, the parsed content will not have the expected values or types. There is no other impact. If **wal_level** is not set to **logical**, an error will be reported and the file will not be parsed.
- In this parsing mode, the system reads data from Xlog text records. So, it cannot parse data not found in Xlogs. If related Xlogs are missing, the missing logs cannot be parsed.
- If **enable_decode_parent_xid** is disabled, only the Xlogs related to the transaction are parsed from the start LSN. The parent transaction and child transactions are not parsed.
- If **enable_decode_parent_xid** is enabled, the parsing begins at the start LSN. The output contains only the child transaction details and subsequent transactions. The parent-child relationship can be established only after the child transaction is parsed. Therefore, information about the parent transaction before the child transaction and other child transactions at the same level is not output. If complete top-level transaction information is required, specify the transaction ID as the top-level transaction ID and set **start_lsn** properly.
- The name of a table cannot be obtained if its **relfilenode** has changed, for example, when the table is truncated or dropped.
- If a schema or table name has changed, you cannot get the name of its historical version.
- When a function is executed, if the output file size exceeds 100 MB, the file will be truncated and an error will be reported.
- If an XID is smaller than the minimum XID in the Xlog, no error is reported and the returned file is empty.
- If the retrieval range of **start_lsn** is too large or **start_lsn** is set to **NULL** (indicating that the traversal starts from the beginning), Xlog parsing may be interrupted because the underlying Xlogs have been recycled. In this case, you are advised to adjust the **start_lsn** range and try again.

Parameters:

– start_lsn

Specifies the start LSN for parsing.

Value range: character strings in the format of *xlogid*|*xrecoff*, for example, '1/2AAFC60'. If the value is **NULL**, the start position of the log to be parsed is not limited.

– upto_lsn

Specifies the end LSN for parsing.

Value range: character strings in the format of *xlogid*|*xrecoff*, for example, '1/2AAFC60'. If the value is **NULL**, the end position of the log to be parsed is not limited.

– xid

Transaction ID.

Value range:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

> NOTE
>
> If the XID set by the user exceeds the maximum XID used by the current database system, the system displays a message indicating that the entered XID is invalid.

- **options**: specifies optional parameters, consisting of multiple pairs of **options_name** and **options_value**. You can retain the default values.
  - enable_decode_parent_xid

    Specifies whether to parse the parent and child transactions of a specified XID.

    Value type: Boolean.

    Value range:

    - **false**: The table information of a specified transaction is parsed.
    - **true**: The parent and related child transactions of a specified transaction are parsed.

    Default value: **false**.

    > NOTE
    >
    > Only Xlogs generated in versions later than 505.2.0 support the construction of parent-child transaction relationships.

Return type: text.

Example:

```
gaussdb=# SELECT * FROM gs_logical_get_transaction_table_info('0/202FC320', '0/20306EE8',
'221557', 'enable_decode_parent_xid', '1');
                                    output_filepath

Table 1-141 Metrics

Metric	Description
XID	XID.
TOP_XID	Top-level XID.
PARENT_XID	Parent XID.
RELFILE_NODE	Table file object identifier.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Metric	Description
START_LSN	Start LSN of a transaction.
END_LSN	End LSN of a transaction.
CSN	Commit sequence number.
TABLE_OID	Table object identifier.
SCHEMA_NAME	Schema to which the table belongs.
TABLE_NAME	Table name.
OPERATION	Operation type.
ADDITIONAL_INFO	DDL information.
IS_COMMITTED	Specifies whether a transaction is committed.
INSERT_COUNT	Number of inserted records.
UPDATE_COUNT	Number of updated records.
DELETE_COUNT	Number of deleted records.
DDL_COUNT	Number of DDL statements.

- gs_get_distribute_decode_status()

  Description: Obtains the distributed decoding status details (by replication slot) on the current node. This command must be executed on CNs. If it is executed on DNs, null is returned.

  Return types: text, int, int, int64, xid, xid, text, text, and text.

```
gaussdb=# SELECT * FROM gs_get_distribute_decode_status();
 slot_name | logical_receiver_num | slice_num | walsender_thread_id | last_sent_csn |
last_confirmed_csn |       receiver_queue_length       |          connect_times          |
csn_receive_array
-----------+----------------------+-----------+---------------------+---------------+--------------------

(1 row)
```

Table 1-142 Metrics

Metric	Type	Description
slot_name	text	Replication slot name.
logical_receiver_num	int	Number of receiver threads started for distributed decoding.
slice_num	int	Number of shards in a cluster.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Metric	Type	Description
walsender_thread_id	int64	WAL sender thread ID.
last_sent_csn	xid	CSN that is sent recently.
last_confirmed_csn	xid	The last CSN returned from the client that has been confirmed for reception.
receiver_queue_length	text	Length of the log queue received on each DN (displayed in the character string format after concatenation).
connect_times	text	Number of times that each DN is connected (displayed in the character string format after concatenation).
csn_receive_array	text	Latest CSN obtained by each DN (displayed in the character string format after concatenation).

- gs_logical_decode_meta_cache_summary('slot_name')

  Description: Obtains statistics about the decoding metadata cache of active replication slots in parallel logical decoding, including global metrics such as the number of cached objects, number of versions, total memory usage, cache hit ratio, and system catalog scan hit ratio.

  Parameters:

  – slot_name

    Indicates the name of the streaming replication slot.

    Value type: character string.

    Value range: a string consisting of lowercase letters, digits, underscores (_), question marks (?), hyphens (-), or periods (.). One or two periods alone cannot be used as the replication slot name.

Table 1-143 Metrics

Metric	Description
type	Type of the logical decoding metadata. The value can be **table**, **partition**, **type**, **enum**, **auth**, or **database**.
entry_num	Number of metadata entries.
version_num	Total number of metadata entry versions (each entry may have multiple versions).
total_mem_size	Total memory of the metadata cache, in bytes.
hit_count	Number of cache hits.
miss_count	Number of cache misses.
hit_ratio	Cache hit ratio.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Metric	Description
scan_count	Number of times system catalogs are scanned.
scan_hit_count	Number of times system catalogs are hit.
scan_hit_ratio	Hit ratio of system catalog scans.
extra_info	Other information.

Example:

```
gaussdb=# SELECT * FROM gs_logical_decode_meta_cache_summary('slot1');
   type    | entry_num | version_num | total_mem_size | hit_count | miss_count | hit_ratio | scan_count |
scan_hit_count | scan_hit_ratio | extra_info
-----------+-----------+-------------+----------------+-----------+------------+-----------+------------
+----------------+----------------+------------
 table     |        53 |          53 |         173056 |         0 |          0 |         0 |          0 |
0 |
 partition |         0 |           0 |              0 |         0 |          0 |         0 |          0 |
 type      |        14 |          14 |           1791 |         0 |          0 |         0 |          0 |
|
 enum      |         0 |           0 |              0 |         0 |          0 |         0 |          0 |
 auth      |         1 |           1 |            136 |         0 |          0 |         0 |          0 |

(6 rows)
```

- gs_logical_decode_meta_cache_stats('slot_name', 'type', 'mode', 'limit_num')

  Description: Obtains statistics about top *N* objects in the decoding metadata cache of active replication slots in parallel logical decoding. The statistics can be queried by memory usage (**memory**), version chain length (**version_cnt**), number of misses (**miss_count**), or hit ratio (**hit_ratio**).

  Parameters:

  – slot_name

    Indicates the name of the streaming replication slot.

    Value type: character string.

    Value range: a string consisting of lowercase letters, digits, underscores (_), question marks (?), hyphens (-), or periods (.). One or two periods alone cannot be used as the replication slot name.

  – type

    Type name of the metadata.

    Value range: **table_oid**, **table_rfn**, **partition**, **type**, **enum**, **auth** and **database**.

  – mode

    Query dimension.

    Value range: **memory**, **version_cnt**, **miss_count**, and **hit_ratio**.

  – limit_num

    Maximum number of output rows.

    Value type: integer.

    Value range: 1 to 1000.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 1-144 Metrics

Metric	Description
oid	OID of a metadata entry.
name	Name of a metadata entry.
relfilenode	**relfilenode** of a metadata entry.
version_cnt	Number of versions of a metadata entry.
invalid_version_cnt	Number of invalid versions of a metadata entry.
total_mem_size	Total memory occupied by a metadata entry, in bytes.
avg_version_size	Average memory occupied by each version of a metadata entry, in bytes.
hit_count	Number of times a metadata entry is hit.
miss_count	Number of times a metadata entry is not hit.
hit_ratio	Hit ratio of a metadata entry.
create_time	Time when a metadata entry is loaded to the memory.
evict_fail_count	Number of times a metadata entry fails to be evicted.
evict_count	Number of times a metadata entry is evicted.
latest_evict_time	Time when a metadata entry was last evicted.
warning_flags	Exception flag information of a metadata entry.
extra_info	Other information.

Example:

```
gaussdb=# SELECT * FROM gs_logical_decode_meta_cache_stats('slot1', 'table_oid', 'memory', 20);
  oid  |                 name                 | relfilenode | version_cnt | invalid_version_cnt | total_mem_size |
avg_version_size | hit_count | miss_count | hit_ratio |          create_time          | evict_fail_count |
evict_count | latest_evict_time | warning_flags | extra_info

NOTICE

During function execution, you need to access the hash table that caches the decoding metadata and obtain a lock to ensure consistent statistics. During the execution, lock contention with the logical decoding thread may occur, affecting the decoding performance. You are advised not to frequently call this function. It is recommended that this function be used in scenarios such as fault locating and performance analysis.

- gs_logical_decode_meta_cache_obj_detail('slot_name', 'type', oid, 'mode', 'limit_num')

  Description: Obtains detailed statistics and version chain details about a specified object in the decoding metadata cache of active replication slots in parallel logical decoding, including the number of versions, valid range (**csnmin**/**csnmax**), memory usage, and hit ratio.

  Parameters:

  – slot_name

    Indicates the name of the streaming replication slot.

    Value type: character string.

    Value range: a string consisting of lowercase letters, digits, underscores (_), question marks (?), hyphens (-), or periods (.). One or two periods alone cannot be used as the replication slot name.

  – type

    Type name of the metadata.

    Value range: **table**, **partition**, **type**, **enum**, **auth** and **database**.

  – oid

    OID of the metadata to be queried.

  – mode

    Output mode of the query result.

    Value range: **memory** and **file**.

  – limit_num

    Maximum number of output rows.

    Value type: integer.

    Value range: When **mode** is set to **memory**, the value ranges from 1 to 1000. When **mode** is set to **file**, the value ranges from 1 to 2147483647.

Table 1-145 Metrics

Metric	Description
oid	OID of a metadata version.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Metric	Description
relfilenode	**relfilenode** of a metadata version.
name	Name of a metadata version.
csnmin	**csnmin** information of a metadata version.
csnmax	**csnmax** information of a metadata version.
is_invalid	Specifies whether a metadata version is valid.
mem_size	Memory usage of a metadata version, in bytes.
hit_count	Number of times a metadata version is hit.
refcnt	Reference count of a metadata version.
createtime	Time when a metadata version is loaded to the memory.
extra_info	Other information. When **mode** is set to **file**, it indicates the output file path.

Example:

```
gaussdb=# SELECT * FROM gs_logical_decode_meta_cache_obj_detail('slot1', 'table', 54921, 'memory',
100);
  oid   | relfilenode | name | csnmin | csnmax | is_invalid | mem_size | hit_count | refcnt |
createtime           | extra_info

NOTICE

During function execution, you need to access the hash table that caches the decoding metadata and obtain a lock to ensure consistent statistics. During the execution, lock contention with the logical decoding thread may occur, affecting the decoding performance. You are advised not to frequently call this function. It is recommended that this function be used in scenarios such as fault locating and performance analysis.

- gs_get_distribute_decode_status_detail()

  Description: Obtains the distributed decoding status details (by DN) on the current node. This command must be executed on CNs. If it is executed on DNs, null is returned.

  Return types: text, int, int64, int, int, and xid.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gaussdb=# SELECT * FROM gs_get_distribute_decode_status_detail();
 slot_name | slice_id |     thread_id     | queue_len | connect_times | received_csn
-----------+----------+-------------------+-----------+---------------+--------------
 slot1     |        0 | 139959895848704 |         1 |             2 |      2012244
 slot1     |        1 | 139959895848704 |         1 |             2 |      2012244

Table 1-146 Metrics

Metric	Type	Description
slot_name	text	Replication slot name.
slice_id	int	Shard ID (starting from 0).
thread_id	int64	ID of the receiver thread started for distributed decoding.
queue_len	int	Length of the log queue received on the current DN.
connect_times	int	Number of times that each DN is connected.
received_csn	xid	Latest CSN obtained from the current DN.

- gs_logical_dictionary_baseline()

  Description: Baselines the data dictionary data for logical decoding. If the operation is successful, the time required is returned. If the operation fails, the failure cause is returned.

  Return type: text.

- gs_logical_dictionary_disabled()

  Description: Disables the logical decoding data dictionary function and stops decoding incremental DDL statements. If the operation is successful, "OK" is returned. If the operation fails, the failure cause is returned.

  Return type: text.

⚠ CAUTION

If the data dictionary functionality is disabled, the replication slot cannot utilize the existing data dictionary for decoding. To enable this functionality, execute the gs_logical_dictionary_baseline() function to re-establish the logical data dictionary baseline and rebuild the replication slot.

- gs_logical_decode_lock()

  Description: Specifies the lock placing API for upgrading and managing the logical decoding component. If the lock is placed, **t** is returned. If the lock fails to be placed, **f** is returned. This function is for internal use only. You are advised not to use it.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter: **wait_time** specifies the lock waiting time. Value range: a non-negative number, in seconds. If no parameter is input, the lock waiting time is 0 seconds.

Return type: Boolean.

- gs_logical_decode_unlock()

  Description: Specifies the lock releasing API for upgrading and managing the logical decoding component. There is no input parameter. If the lock is released, **t** is returned. If the lock fails to be released, **f** is returned. This function is for internal use only. You are advised not to use it.

  Return type: Boolean.

- gs_add_logical_decoding_position_xlog()

  Description: After this function is executed, Xlogs of the XLOG_STANDBY_DECODE_POSITION type are generated. The logs will be read by a decoding task in the current database to feed back the decoding position. Only users with the SYSADMIN, replication, or OPRADMIN permission can call this function; otherwise, the call fails. The execution frequency of this function is calculated based on the database statistics. The frequency of calling this function by each database is controlled by node. The minimum calling interval is 1 second. This principle also applies to distributed scenarios. Each CN controls the calling frequency separately.

  Return type: text

- gs_change_replication_slot_plugin('slot_name', 'plugin_name')

  Description: Modifies the plug-in type of a logical replication slot.

  Parameters:

  – slot_name

    Indicates the name of the streaming replication slot.

    Value range: character strings, which can only consist of lowercase letters, digits, underscores (_), question marks (?), hyphens (-), and periods (.). One or two periods alone cannot be used as the replication slot name.

  – plugin_name

    Indicates the name of the plug-in.

    Value range: a string. Currently, **mppdb_decoding**, **sql_decoding**, **parallel_binary_decoding**, **parallel_json_decoding**, and **parallel_text_decoding** are supported.

    Return type: Boolean. The default value is **true**.

  Example:

  Query information about the current replication slot.

```
gaussdb=# SELECT * FROM pg_get_replication_slots();
 slot_name |          plugin          | slot_type | datoid | active | xmin | catalog_xmin | restart_lsn |
dummy_standby | confirmed_flush | confirmed_csn | dictionary_csn_min | slot_dictionary_type
-----------+--------------------------+-----------+--------+--------+------+--------------+-------------
+---------------+-----------------+---------------+--------------------+----------------------
 slot1     | parallel_json_decoding   | logical   |  12834 | f      |      |              | 0/125A15E0  | f             |
0/125E84D0      |               |              7787 | dictionary table
 slot2     | parallel_binary_decoding | logical   |  12834 | f      |      |              | 0/E9C71B0   | f             |
0/E9CA638       |               |              3860 | dictionary table
 slot3     | parallel_text_decoding   | logical   |  12834 | f      |      |              | 0/E9D96D0   | f             | 0/

 slot4     | mppdb_decoding           | logical   |  12834 | f      |      |              | 0/E9AFC38   | f             | 0/
EEE6508       |               |              3853 | dictionary table
(4 rows)
```

- gs_get_inter_cluster_version_info()

  Description: Queries the version number of primary and standby databases, the version of the logical decoding component, and the replication type (logical replication or physical replication). It is not supported in the current version.

  Return type: int, text, int, text, text

1.6.27.11 Segment-Page Storage Functions

NOTE

To create a segment-page table on a storage engine, you need to set **segment** to **on** when creating the table. Example:

```
CREATE TABLE t1(id int) WITH (segment=on, storage_type=astore);
CREATE TABLE t1(id int) WITH (segment=on, storage_type=ustore);
```

- The values of the fields related to the segment-page storage function are described as follows:

  a. **forknum**: data file fork.

     Value range: **0** (mainfork), **1** (fsmfork), and **2** (vm fork).

  b. **file id**: data file ID.

     Value range: **1** (metadata file) and **2** to **5** (data file).

  c. **blocks**: extent size.

     Value range: **1** (No.1 file), **8** (No.2 file), **128** (No.3 file), **1024** (No.4 file), and **4096** (No.5 file).

  d. **file_block_id**/**head_block_id**/**block_id**: offset page number of the physical page in the data file and other fields that indicate the page number.

     Value range: [0,4294967294].

  e. **page_ type**: page type.

     Value range:

     Meta pages: **file head**/**file_header**: file header; **spc head**/**spc_header**: space header; **map head**/**map_header**: mapping header; **map page**/

map_pages: mapping page; **reverse pointer page**/**inverse pointer page**/**ip pages**: inverse pointer page; **segment head page**/**segment head**: segment header page; **level1 page**: level-1 page; **data_pages**/**data extent**: data page; **fork head**: fork header.

Data pages: **heap**, **uheap**, **btree**, and **ubtree**.

Unknown pages: **unknown(data extent)**: all-zero segment page whose type cannot be determined; **unknown(fsm indexurq)**: fsm or indexurq page.

f. **contents**: storage content of a data file.

Value range: **permanent** (permanent), **unlogged** (no log), **temporary** (global temporary), and **temporary2** (local temporary)

- local_space_shrink(tablespacename TEXT, databasename TEXT)

  Description: Shrinks specified physical segment-page space on the current node. Only the currently connected database can be shrank.

  Return value: empty.

- gs_space_shrink(tablespace int4, database int4, extent_type int4, forknum int4)

  Description: Shrinks the physical size of the designated segment-page space, similar to **local_space_shrink**. However, it has different parameters, requiring the tablespace and database OIDs as inputs and specifying that **extent_type** must be an integer between 2 and 5. The value **1** of **extent_type** indicates segment-page metadata. Currently, the physical file that contains the metadata cannot be shrunk. This function is used only by tools. You are advised not to use it directly.

  Return value: empty.

- global_space_shrink(tablespacename TEXT, databasename TEXT)

  Description: Compresses segment-page storage space on all DNs in a cluster. This is performed on a CN.

  Note: If **global_space_shrink** locks the cluster, DDL operations cannot be performed. **local_space_shrink** does not lock the cluster.

- gs_seg_dump_page(tablespace_name name, file_id int4, bucketnode int4, file_block_id bigint, forknum int4 default 0)

  Description: Parses a specified page in segment-page mode and returns the parsed content. Only users with the SYSADMIN attribute and users with the OPRADMIN attribute in O&M mode can execute this function. This function is used to parse physical pages. The parsing result of one page is returned each time. The returned result does not contain the actual user data. This function does not require users to enter the page type. During implementation, the system attempts to determine the page type. If the page type cannot be determined, the system outputs possible parsing results.

  The following describes the parameters.

Name	Type	Description
table_space_name	NAME	Tablespace to which a segment object belongs. Value range: existing valid tablespace names.
file_id	INTEGER	Data file ID. Value range: [1,5] of the int4 type.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Name	Type	Description
bucketnode	INTEGER	• **0** to **1023** indicate the bucket nodes of a hash bucket table. • **1024** indicates the bucket node of a segment-page ordinary table. • **1025** indicates the bucket node of a segment-page global temporary table. • **1026** indicates the bucket node of a segment-page unlogged table. • **1027** indicates the bucket node of a segment-page local temporary table.
file_block_id	BIGINT	Offset page number of the physical page in the data file. The value range is [0,4294967294].
forknum	INTEGER DEFAULT 0	Fork number of a data file. The default value is **0**. Value range: • **0**: main fork. • **1**: FSM fork. • **2**: VM fork.

The following describes the return types.

Name	Type	Description
page_type	TEXT	Page type. Value range: • Service pages: **heap**, **uheap**, **btree**, **ubtree**, **gsivfflat_index**, and **gsdiskann_index** • Segment-page metapages: **bucket main head**, **file head**, **spc head**, **map head**, **map page**, **reverse pointer page**, **segment head page**, and **level1 page**. • Unknown pages: – **unknown(data extent)**: all-zero segment page whose type cannot be determined. – **unknown(fsm indexurq)**: fsm or indexurq page.
result	TEXT	Parsing result.

For example, perform the following operations after creating a segment-page ordinary table:

```
gaussdb=# SELECT * FROM gs_seg_dump_page('pg_default', 1, 1024, 4157);
     page_type     |                                result
-------------------+-----------------------------------------------------------------------------
 segment head page | Page information of block 4157/4157                                         +
                   |         pd_lsn: 0/2C90608 ,len 8 ,offset 0                                  +
                   |                                                                             +

(1 row)
```

- gs_seg_dump_page(relid oid, bucketnode int, block_id bigint, partition bool default false, forknum int4 default 0)

  Description: Parses a specified page in segment-page mode and returns the parsed content. This function is executed on DNs. Only users with the SYSADMIN attribute and users with the OPRADMIN attribute in O&M mode can execute this function. This function is used to parse logical pages. The parsing result of one page is returned each time. The returned result does not contain the actual user data. This function does not require users to enter the page type. During implementation, the system attempts to determine the page type. If the page type cannot be determined, the system outputs possible parsing results.

  The following describes the parameters.

Name	Type	Description
relid	OID	Segment object ID. Value range: existing valid segment-page OIDs. Not meeting this requirement will result in an error.
bucketnode	INTEGER	• **0** to **1023** indicate the bucket nodes of a hash bucket table. • **1024** indicates the bucket node of a segment-page ordinary table. • **1025** indicates the bucket node of a segment-page global temporary table. • **1026** indicates the bucket node of a segment-page unlogged table. • **1027** indicates the bucket node of a segment-page local temporary table.
block_id	BIGINT	Logical page number. The value range is [0,4294967294].

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Name	Type	Description
partition	BOOLEAN DEFAULT FALSE	Specifies whether the segment object is a partition. The default value is **false**. Value range: Boolean values, indicating whether the object corresponding to the input OID is a partition.
forknum	INTEGER DEFAULT 0	Fork number of a data file. The default value is **0**. Value range: ● **0**: main fork. ● **1**: FSM fork. ● **2**: VM fork.

The following describes the return values.

Name	Type	Description
page_type	TEXT	Page type. Value range: ● Service pages: **heap**, **uheap**, **btree**, and **ubtree**. ● Segment-page metapages: **bucket_main_head**, **file head**, **spc head**, **map head**, **map page**, **reverse pointer page**, **segment head page**, and **level1 page**. ● Unknown pages: – **unknown(data extent)**: all-zero segment page whose type cannot be determined. – **unknown(fsm indexurq)**: fsm or indexurq page.
result	TEXT	Parsing result.

For example, perform the following operations on a DN, and ensure that **relid** must be a valid OID of the segment-page object on the DN, and the object must have data so that the page information can be queried:

```
gaussdb=# SELECT * FROM gs_seg_dump_page(16788, 1024, 0);
 page_type |                                                 result

- gs_seg_get_spc_location(tablespace_name NAME, bucketnode INTEGER, head_block_id BIGINT, block_id BIGINT)

  Description: Calculates the physical location given a segment and logical page number. Only an administrator can query the information.

  The following describes the parameters.

Name	Type	Description
tablespace_name	NAME	Tablespace to which a segment object belongs.
bucketnode	INTEGER	• **0** to **1023** indicate the bucket nodes of a hash bucket table. • **1024** indicates the bucket node of a segment-page ordinary table. • **1025** indicates the bucket node of a segment-page global temporary table. • **1026** indicates the bucket node of a segment-page unlogged table. • **1027** indicates the bucket node of a segment-page local temporary table.
head_block_id	BIGINT	Page number of a segment header.
block_id	BIGINT	Logical page number.

  The following describes the return values.

Name	Type	Description
extent_id	INTEGER	Logical extent number of the logical page.
extent_size	INTEGER	Size of the logical extent where the logical page is located.
file_id	INTEGER	ID of the data file where the physical page is located. Value range: [1,5] of the int4 type.
file_block_id	BIGINT	Offset page number of the physical page in the data file.

For example, perform the following operations on the DN after creating a segment-page ordinary table in the tablespace and inserting data:

```
gaussdb=# SELECT * FROM gs_seg_get_spc_location('pg_default', 1024, 4157, 0);
 extent_id | extent_size | file_id | file_block_id
-----------+-------------+---------+---------------
         0 |           8 |       2 |          4157
(1 row)
```

- gs_seg_get_spc_location(relid OID, bucketnode INTEGER, block_id BIGINT, partition BOOLEAN DEFAULT FALSE, forknum INTEGER DEFAULT 0)

  Description: Calculates the physical location given a segment and logical page number. Only an administrator can query the information.

  The following describes the parameters.

Name	Type	Description
relid	OID	Segment object ID.
bucketnode	INTEGER	• **0** to **1023** indicate the bucket nodes of a hash bucket table. • **1024** indicates the bucket node of a segment-page ordinary table. • **1025** indicates the bucket node of a segment-page global temporary table. • **1026** indicates the bucket node of a segment-page unlogged table. • **1027** indicates the bucket node of a segment-page local temporary table.
block_id	BIGINT	Logical page number.
partition	BOOLEAN DEFAULT FALSE	Specifies whether the segment object is a partition. The default value is **FALSE**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Name	Type	Description
forknum	INTEGER DEFAULT 0	Fork of a segment object. The default value is **0**. Value range: • **0**: main fork. • **1**: FSM fork. • **2**: VM fork.

The following describes the return values.

Name	Type	Description
extent_id	INTEGER	Logical extent number of the logical page.
extent_size	INTEGER	Size of the logical extent where the logical page is located.
file_id	INTEGER	ID of the data file where the physical page is located. Value range: [1,5] of the int4 type.
file_block_id	BIGINT	Offset page number of the physical page in the data file.

For example, perform the following operations on a DN, and ensure that **relid** must be a valid OID of the segment-page object on the DN, and the object must have data:

```
gaussdb=# SELECT * FROM gs_seg_get_spc_location(24578,1024, 0);
 extent_id | extent_size | file_id | file_block_id
-----------+-------------+---------+---------------
         0 |           8 |       2 |          4157
(1 row)
```

- gs_seg_get_location(block_id BIGINT, as_extent BOOLEAN DEFAULT FALSE)

  Description: Calculates the physical location given a segment and logical page number. Only an administrator can query the information.

  The following describes the parameters.

Name	Type	Description
block_id	BIGINT	Logical page number.
as_extent	BOOLEAN DEFAULT FALSE	Specifies whether the **block_id** parameter is an extent number. The default value is **FALSE**.

The following describes the return values.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Name	Type	Description
extent_id	BIGINT	Extent number.
extent_size	INTEGER	Extent size.
extent_offset	INTEGER	Extent offset block number.
level0_slots_idx	INTEGER	Index of the extent in the level-0 slot array in the segment header.
level1_slots_idx	INTEGER	Index of the extent in the level-1 slot array in the segment header.
level1_page_offset	INTEGER	Offset of the extent on the level-1 slot page in the segment header.
segment_blocks	BIGINT	Number of pages containing this page or extended segments.
relative_fno	INTEGER	Number of the relative file that contains this page or extent.

Example:

```
gaussdb=# SELECT * FROM gs_seg_get_location(4157);
 extent_id | extent_size | extent_offset | level0_slots_idx | level1_slots_idx | level1_page_offset |
segment_blocks | relative_fno
-----------+-------------+---------------+------------------+------------------+--------------------
+----------------+--------------
        47 |         128 |            61 |               47 |                  |                  |          4158 |              3
(1 row)
```

- gs_seg_get_segment_layout()

  Description: Outputs the static segment layout. Only an administrator can query the information.

  The following describes the return values.

Name	Type	Description
version	TEXT	Segment-page version. The default value is **1.0**.
section_id	INTEGER	ID of the data section divided by a segment.
section_type	TEXT	Extent type of the segment data section. Value range: • **meta**: segment header. • **data**: data.
extent_size	INTEGER	Extent size. The unit is byte.
extent_page_count	INTEGER	Number of extent pages.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Name	Type	Description
extent_count_start	BIGINT	Start extent number.
extent_count_end	BIGINT	End extent number.
total_size	BIGINT	Size of the segment data section. The unit is byte.

Example:

```
gaussdb=# SELECT * FROM gs_seg_get_segment_layout();
 version | section_id | section_type | extent_size | extent_page_count | extent_count_start |
extent_count_end |   total_size
---------+------------+--------------+-------------+-------------------+--------------------+------------------
+----------------
 1.0     |          1 | meta         |        8192 |                 1 |                  0 |                0 |          8192
 1.0     |          2 | data         |       65536 |                 8 |                  1 |               16 |       1048576
 1.0     |          3 | data         |     1048576 |               128 |                 17 |              143 |     134217728
 1.0     |          4 | data         |     8388608 |              1024 |                144 |              255 |
1073741824
 1.0     |          5 | data         |    33554432 |              4096 |                256 |          1025255 |
34394366541824
(5 rows)
```

- gs_seg_get_datafile_layout()

  Description: Queries the static layout of data files 1 to 5. Only an administrator can query the information.

  The following describes the return values.

Name	Type	Description
version	TEXT	Segment-page version. The default value is **1.0**.
seg_storage_type	TEXT	• **segment** indicates common segment-page data. • **hashbucket** indicates hash bucket data.
file_id	INTEGER	Data file ID. Value range: [1,5] of the int4 type.
section_id	INTEGER	Data section ID of a data file.
section_type	TEXT	Type of the data file section. Value range: • **file_header** indicates the file header. • **spc_header** indicates the space header. • **map_header** indicates the mapping header. • **map_pages** indicates the mapping page. • **ip_pages(inverse pointer pages)** indicates the inverse pointer page. • **data_pages** indicates the data page.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Name	Type	Description
page_start	BIGINT	Start page number of the data section.
page_end	BIGINT	End page number of the data section.
page_count	BIGINT	Number of pages in the data section.
total_size	BIGINT	Size of the data section. The unit is byte.

Example:

```
gaussdb=# SELECT * FROM gs_seg_get_datafile_layout();
 version | seg_storage_type | file_id | section_id | section_type |  page_start  |   page_end   |
page_count  |   total_size
---------+------------------+---------+------------+--------------+--------------+--------------+-------------
+-----------------
 1.0     | segment          |       1 |          0 | file_header  |            0 |            0 |            1 |            8192
 1.0     | segment          |       1 |          1 | spc_header   |            1 |            1 |            1 |            8192
 1.0     | segment          |       1 |          2 | map_header   |            2 |            2 |            1 |            8192
 1.0     | segment          |       1 |          3 | map_pages    |            3 |           66 |           64 |          524288
 1.0     | segment          |       1 |          4 | ip_pages     |           67 |         4156 |         4090 |
33505280
 1.0     | segment          |       1 |          5 | data_pages   |         4157 |      4147260 |      4143104 |
33940307968

... (There is a large amount of data. Only part of the data is displayed.)
```

- gs_seg_get_slice_layout(file_id INTEGER, bucketnode INTEGER,slice_id INTEGER)

  Description: Outputs the static layout of a given data file fragment. Only an administrator can query the information.

  The following describes the parameters.

Name	Type	Description
file_id	INTEGER	Data file ID. Value range: [1,5] of the int4 type.
bucketnode	INTEGER	• **0** to **1023** indicate the bucket nodes of a hash bucket table. • **1024** indicates the bucket node of a segment-page ordinary table. • **1025** indicates the bucket node of a segment-page global temporary table. • **1026** indicates the bucket node of a segment-page unlogged table. • **1027** indicates the bucket node of a segment-page local temporary table.
slice_id	INTEGER	Slice file ID.

  The following describes the return values.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Name	Type	Description
version	TEXT	Segment-page version. The default value is **1.0**.
section_id	INTEGER	Data section ID of a data file.
section_type	INTEGER	Type of the data file section. Value range: • **file_header** indicates the file header. • **spc_header** indicates the space header. • **map_header** indicates the mapping header. • **map_pages** indicates the mapping page. • **ip_pages(inverse pointer pages)** indicates the inverse pointer page. • **data_pages** indicates the data page.
page_start	BIGINT	Start page number of the data section.
page_end	BIGINT	End page number of the data section.
page_count	BIGINT	Number of pages in the data section.
total_size	BIGINT	Size of the data section. The unit is byte.

Example:

```
gaussdb=# SELECT * FROM gs_seg_get_slice_layout(1,1024,0);
 version | section_id | section_type | page_start | page_end | page_count | total_size
---------+------------+--------------+------------+----------+------------+------------
 1.0     |          0 | file_header  |          0 |        0 |          1 |       8192
 1.0     |          1 | spc_header   |          1 |        1 |          1 |       8192
 1.0     |          2 | map_header   |          2 |        2 |          1 |       8192
 1.0     |          3 | map_pages    |          3 |       66 |         64 |     524288
 1.0     |          4 | ip_pages     |         67 |     4156 |       4090 |   33505280
 1.0     |          5 | data_pages   |       4157 |   131071 |     126915 | 1039687680
(6 rows)
```

- gs_seg_get_segment(tablespace_name NAME, bucketnode INTEGER, head_block_id BIGINT)

  Description: Outputs the segment header information of the segment header page in the segment header file of the tablespace. Only an administrator can query the information.

  The following describes the parameters.

Name	Type	Description
tablespace_name	NAME	Tablespace to which a segment object belongs.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Name	Type	Description
bucketnode	INTEGER	• **0** to **1023** indicate the bucket nodes of a hash bucket table. • **1024** indicates the bucket node of a segment-page ordinary table. • **1025** indicates the bucket node of a segment-page global temporary table. • **1026** indicates the bucket node of a segment-page unlogged table. • **1027** indicates the bucket node of a segment-page local temporary table.
head_block_id	BIGINT	Page number of a segment header.

The following describes the return values.

Name	Type	Description
blocks	BIGINT	Number of logical pages of a segment.
total_blocks	BIGINT	Number of physical pages of a segment.
extents	INTEGER	Number of logical extents of a segment.
total_extents	INTEGER	Number of physical extents of a segment.
head_lsn	TEXT	Segment header LSN.
level0_slots	BIGINT[]	Level-0 slot array of segment extent mapping.
level1_slots	BIGINT[]	Level-1 slot array of segment extent mapping.
fork_head	BIGINT[]	Fork head array of a segment.

For example, perform the following operations after creating a segment-page ordinary table:

```
gaussdb=# SELECT * FROM gs_seg_get_segment('pg_default', 1024, 4157);
 blocks | total_blocks | extents | total_extents | head_lsn | level0_slots | level1_slots |   fork_head
--------+--------------+---------+---------------+----------+--------------+--------------+---------------
      9 |           16 |       2 |             2 | 62211744 | {4157,4165}  | {}           | {4157,4158,-1}
(1 row)
```

- gs_seg_get_segment(relid OID, bucketnode INTEGER, partition BOOLEAN DEFAULT FALSE, forknum INTEGER DEFAULT 0)

  Description: Outputs the corresponding segment header information based on **relid** and **bucketnode**. Only an administrator can query the information.

  The following describes the parameters.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Name	Type	Description
relid	OID	Table OID.
bucketnode	INTEGER	• **0** to **1023** indicate the bucket nodes of a hash bucket table. • **1024** indicates the bucket node of a segment-page ordinary table. • **1025** indicates the bucket node of a segment-page global temporary table. • **1026** indicates the bucket node of a segment-page unlogged table. • **1027** indicates the bucket node of a segment-page local temporary table.
partition	BOOLEAN DEFAULT FALSE	Specifies whether the segment object is a partition. The default value is **false**. Value range: Boolean values, indicating whether the object corresponding to the input OID is a partition.
forknum	INTEGER DEFAULT 0	Fork number of a data file. The default value is **0**. Value range: • **0**: main fork. • **1**: FSM fork. • **2**: VM fork.

The following describes the return values.

Name	Type	Description
blocks	BIGINT	Number of logical pages of a segment.
total_blocks	BIGINT	Number of physical pages of a segment.
extents	INTEGER	Number of logical extents of a segment.
total_extents	INTEGER	Number of physical extents of a segment.
head_lsn	TEXT	Segment header LSN.
level0_slots	BIGINT[]	Level-0 slot array of segment extent mapping.
level1_slots	BIGINT[]	Level-1 slot array of segment extent mapping.
fork_head	BIGINT[]	Fork head array of a segment.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

For example, perform the following operations on a DN, and ensure that **relid** must be the OID of the queried segment page object on the DN:

```
gaussdb=# SELECT * FROM gs_seg_get_segment(16768, 1024);
 blocks | total_blocks | extents | total_extents | head_lsn | level0_slots | level1_slots |    fork_head
--------+--------------+---------+---------------+----------+--------------+--------------+-----------------
      9 |           16 |       2 |             2 | 62211744 | {4157,4165}  | {}           | {4157,4158,4294967295}
(1 row)
```

- gs_seg_get_extents(tablespace_name NAME, bucketnode INTEGER, head_block_id BIGINT)

  Description: Outputs all extents of the segment object on the segment header page in the segment header file of the tablespace, including **segment head**, **fork head**, **level1 page** in file 1, and data extents in files 2 to 5. Only an administrator can query the information.

  The following describes the parameters.

Name	Type	Description
tablespace_name	NAME	Tablespace to which a segment object belongs.
bucketnode	INTEGER	• **0** to **1023** indicate the bucket nodes of a hash bucket table. • **1024** indicates the bucket node of a segment-page ordinary table. • **1025** indicates the bucket node of a segment-page global temporary table. • **1026** indicates the bucket node of a segment-page unlogged table. • **1027** indicates the bucket node of a segment-page local temporary table.
head_block_id	BIGINT	Page number of a segment header.

The following describes the return values.

Name	Type	Description
extent_id	INTEGER	Logical extent number.
file_id	INTEGER	ID of the data file where the extent is located. Value range: [1,5] of the int4 type.
forknum	INTEGER	Fork of a segment object. Value range: • **0**: main fork. • **1**: FSM fork. • **2**: VM fork.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Name	Type	Description
block_id	BIGINT	Start page number in the data file where the extent is located.
blocks	INTEGER	Extent size. Value range: • **1** indicates file 1. • **8** indicates file 2. • **128** indicates file 3. • **1024** indicates file 4. • **4096** indicates file 5.
usage_type	TEXT	Usage type of an extent. Value range: • **segment head** indicates the segment header. • **fork head** indicates the fork header. • **level1 page** indicates the level-1 page. • **data extent** indicates data extents.

For example, perform the following operations after creating a segment-page ordinary table:

```
gaussdb=# SELECT * FROM gs_seg_get_extents('pg_default', 1024, 4157);
 extent_id | file_id | forknum | block_id | blocks |  usage_type
-----------+---------+---------+----------+--------+--------------
           |       1 |       0 |     4157 |      1 | segment head
         0 |       2 |       0 |     4157 |      8 | data extent
         1 |       2 |       0 |     4165 |      8 | data extent
(3 rows)
```

- gs_seg_get_extents(relid OID, bucketnode INTEGER, partition BOOLEAN DEFAULT FALSE, forknum INTEGER DEFAULT 0)

  Description: Outputs all extents of the segment object on the segment header page in the corresponding segment header file, including **segment head**, **fork head**, **level1 page** in file 1 and, data extents in files 2 to 5. Only an administrator can query the information.

  The following describes the parameters.

Name	Type	Description
relid	OID	Table OID.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Name	Type	Description
bucketnode	INTEGER	• **0** to **1023** indicate the bucket nodes of a hash bucket table. • **1024** indicates the bucket node of a segment-page ordinary table. • **1025** indicates the bucket node of a segment-page global temporary table. • **1026** indicates the bucket node of a segment-page unlogged table. • **1027** indicates the bucket node of a segment-page local temporary table.
partition	BOOLEAN DEFAULT FALSE	Specifies whether the segment object is a partition. The default value is **false**. Value range: Boolean values, indicating whether the object corresponding to the input OID is a partition.
forknum	INTEGER DEFAULT 0	Fork number of a data file. The default value is **0**. Value range: • **0**: main fork. • **1**: FSM fork. • **2**: VM fork.

The following describes the return values.

Name	Type	Description
extent_id	INTEGER	Logical extent number.
file_id	INTEGER	ID of the data file where the extent is located. Value range: [1,5] of the int4 type.
forknum	INTEGER	Fork of a segment object. Value range: • **0**: main fork. • **1**: FSM fork. • **2**: VM fork.
block_id	BIGINT	Start page number in the data file where the extent is located.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Name	Type	Description
blocks	INTEGER	Extent size. Value range: • **1** indicates file 1. • **8** indicates file 2. • **128** indicates file 3. • **1024** indicates file 4. • **4096** indicates file 5.
usage_type	TEXT	Usage type of an extent. Value range: • **segment head** indicates the segment header. • **fork head** indicates the fork header. • **level1 page** indicates the level-1 page. • **data extent** indicates data extents.

In the following example, **relid** must be a valid OID of a multipart page object:

```
gaussdb=# SELECT * FROM gs_seg_get_extents(16768, 1024);
 extent_id | file_id | forknum | block_id | blocks |  usage_type
-----------+---------+---------+----------+--------+--------------
           |       1 |       0 |     4157 |      1 | segment head
         0 |       2 |       0 |     4157 |      8 | data extent
         1 |       2 |       0 |     4165 |      8 | data extent
(3 rows)
```

- gs_seg_free_spc_remain_segment(tablespace_name NAME, head_file_id INTEGER, bucketnode INTEGER, head_block_id BIGINT)

  Description: Releases the page occupied by the segment page-based residual segment in file 1 in a specified tablespace. You can query residual segments in the **GS_SEG_SPC_REMAIN_SEGMENTS** view. Only an administrator can query the information. This query can be executed only on the primary node.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTICE

- This function is an offline segment-page clearing method. The current version provides the online clearing function: gs_seg_auto_free_remain_segment().
- To ensure the consistency between the queried residual segments and residual extents and the consistency of residual clearing, this function and the **GS_SEG_SPC_REMAIN_SEGMENTS** view must be executed in the DDL- or DML-restricted state. The current version does not provide the DML/DDL restriction capability. Therefore, when using this feature, ensure that the operating environment is in the DDL-\DML-restricted state.
- Multiple residual clearing operations cannot be performed on the same database of the same node at the same time, including manually executing this function, manually performing online clearing, and performing online clearing scheduled by AUTOVACUUM.

The following describes the parameters.

Name	Type	Description
tablespace_name	NAME	Tablespace name.
head_file_id	INTEGER	ID of a data file in which a segment header of a segment-page-type residual segment is located. The value is **1**.
bucketnode	INTEGER	• **0** to **1023** indicate the bucket nodes of a hash bucket table. • **1024** indicates the bucket node of a segment-page ordinary table. • **1025** indicates the bucket node of a segment-page global temporary table. • **1026** indicates the bucket node of a segment-page unlogged table. • **1027** indicates the bucket node of a segment-page local temporary table.
head_block_id	BIGINT	Page number of a segment header.

Return type: void.

Example:

```
gaussdb=# SELECT * FROM gs_seg_free_spc_remain_segment('pg_default', 1, 1024, 4159);
 gs_seg_free_spc_remain_segment
--------------------------------

(1 row)
```

- gs_seg_auto_free_remain_segment()

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description: Releases the page occupied by the segment page-based residual segment in file 1 in a specified tablespace on the local node. This query can be executed only by administrators on the primary node.

NOTICE

- This function is an online segment-page clearing method.
- This function can be used only when **enable_auto_segment_remain_cleanup** is set to **on**. For details about how to enable it, see **Developer Options**.
- Multiple residual clearing operations cannot be performed on the same database of the same node at the same time, including manually executing this function, manually performing offline clearing, and performing online clearing scheduled by AUTOVACUUM.

Parameter: void.

Return type: void.

Example:

```
gaussdb=# SELECT * FROM gs_seg_auto_free_remain_segment();
 gs_seg_auto_free_remain_segment
---------------------------------

(1 row)
```

- gs_seg_free_spc_remain_extent(tablespace_name NAME, file_id INTEGER, bucketnode INTEGER, forknum INTEGER, block_id BIGINT)

  Description: Releases residual segment-page-type isolated extents in a specified tablespace. Residual isolated extents can be queried in the **GS_SEG_SPC_REMAIN_EXTENTS** view. Only an administrator can query the information. This query can be executed only on the primary node.

  NOTICE

  - This function is an offline segment-page clearing method. The current version provides the online clearing function: gs_seg_auto_free_remain_segment().
  - Multiple residual clearing operations cannot be performed on the same database of the same node at the same time, including manually executing this function, manually performing online clearing, and performing online clearing scheduled by AUTOVACUUM.

  The following describes the parameters.

Name	Type	Description
tablespace_name	NAME	Tablespace name.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Name	Type	Description
file_id	INTEGER	ID of the data file where the segment-page-type residual extent is located. The value ranges from files 1 to 5.
bucketnode	INTEGER	• **0** to **1023** indicate the bucket nodes of a hash bucket table. • **1024** indicates the bucket node of a segment-page ordinary table. • **1025** indicates the bucket node of a segment-page global temporary table. • **1026** indicates the bucket node of a segment-page unlogged table. • **1027** indicates the bucket node of a segment-page local temporary table.
forknum	INTEGER	Fork number of a data file. Value range: • **0**: main fork. • **1**: FSM fork. • **2**: VM fork.
block_id	BIGINT	Page number of a segment header.

Return type: void.

Example:

```
gaussdb=# SELECT * FROM gs_seg_free_spc_remain_extent('pg_default', 1, 1024, 0, 4159);
 gs_seg_free_spc_remain_extent
-------------------------------

(1 row)
```

- gs_seg_get_datafiles(database_name NAME)

  Description: Displays information about all data files of an instance. Only an administrator can query the information.

  The following describes the parameters.

Name	Type	Description
database_name	NAME	Database name. The default value is **current_database()**, indicating the name of the current database.

The following describes the return values.

Name	Type	Description
file_name	TEXT	Data file name, for example, **base/17467/2_fsm**.
file_id	INTEGER	Data file ID. The value ranges from files 1 to 5.
bucketnode	INTEGER	• **0** to **1023** indicate the bucket nodes of a hash bucket table. • **1024** indicates the bucket node of a segment-page ordinary table. • **1025** indicates the bucket node of a segment-page global temporary table. • **1026** indicates the bucket node of a segment-page unlogged table. • **1027** indicates the bucket node of a segment-page local temporary table.
forknum	INTEGER	Fork type of a data file.
tablespace_name	NAME	Name of the tablespace to which a data file belongs.
contents	TEXT	Storage content of a data file. Value range: • **permanent**: permanent. • **unlogged**: no log. • **temporary**: global temporary. • **temporary2**: local temporary.
extent_size	INTEGER	Extent size of a data file.
meta_blocks	BIGINT	Number of allocated metadata pages of a data file.
data_blocks	BIGINT	Number of allocated data pages of a data file.
total_blocks	BIGINT	Total number of physical pages in a data file.
high_water_mark	BIGINT	High watermark of the number of pages used by a data file.
utilization	REAL	Percentage of used blocks to the total number of blocks, that is, (**data_blocks** + **meta_blocks**)/ **total_blocks**.

For example, perform the following operations after creating a segment-page table:

```
gaussdb=# SELECT * FROM gs_seg_get_datafiles();
  file_name   | file_id | bucketnode | forknum | tablespace_name | contents  | extent_size | meta_blocks
| data_blocks | total_blocks | high_water_mark | utilization
--------------+---------+------------+---------+-----------------+-----------+-------------+-------------
+-------------+--------------+-----------------+-------------
 base/15949/1 |       1 |       1024 |       0 | pg_default      | permanent |           1 |        4157 |           1
```

```
|       16384 |      1048702976 | 2.24208e-44
 base/15949/2 |       2 |       1024 |       0 | pg_default     | permanent |          8 |       4157 |          8
|       16384 |      1048717312 | 2.24208e-44
(2 rows)
```

- gs_seg_get_spc_extents(tablespace_name NAME, file_id INTEGER, bucketnode INTEGER, forknum INTEGER, skip_unused BOOLEAN DEFAULT TRUE)

  Description: Obtains all extent information of a specified tablespace. Only an administrator can query the information.

  The following describes the parameters.

Name	Type	Description
tablespace_name	NAME	Tablespace name.
file_id	INTEGER	Data file ID. Value range: [1,5] of the int4 type.
bucketnode	INTEGER	• **0** to **1023** indicate the bucket nodes of a hash bucket table. • **1024** indicates the bucket node of a segment-page ordinary table. • **1025** indicates the bucket node of a segment-page global temporary table. • **1026** indicates the bucket node of a segment-page unlogged table. • **1027** indicates the bucket node of a segment-page local temporary table.
forknum	INTEGER	Data file fork. Value range: • **0**: main fork. • **1**: FSM fork. • **2**: VM fork.
skip_unused	BOOLEAN DEFAULT TRUE	Specifies whether to output only allocated extents. The default value is **TRUE**, indicating that only allocated extents are output.

  The following describes the return values.

Name	Type	Description
block_id	BIGINT	Start page number of a data extent.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Name	Type	Description
blocks	INTEGER	Data extent size. Value range: ● **1** indicates file 1. ● **8** indicates file 2. ● **128** indicates file 3. ● **1024** indicates file 4. ● **4096** indicates file 5.
contents	TEXT	Stores content. Value range: ● **permanent**: permanent. ● **unlogged**: no log. ● **temporary**: global temporary. ● **temporary2**: local temporary.
in_used	TEXT	Specifies whether a resource has been allocated. Value range: ● **Y**: allocated. ● **N**: not allocated.
mapblock_location	TEXT	Position of the extent in the map block. Format: (page_id, offset).
head_file_id	INTEGER	ID of the data file where the segment header is located.
head_block_id	BIGINT	Page number of a segment header.
usage_type	TEXT	Usage type of an extent. Value range: ● **segment head** indicates the segment header. ● **fork head** indicates the fork header. ● **level1 page** indicates the level-1 page. ● **data extent** indicates data extents.
remain_flag	TEXT	Specifies whether it is a residual extent after the SHRINK operation. Value range: ● **Y**: residual extent upon SHRINK. ● **N**: not a residual extent upon SHRINK.
special_data	INTEGER	Special data section of the inverse pointer corresponding to an extent.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Name	Type	Description
ipblock_location	TEXT	Position of the inverse pointer corresponding to an extent. Format: (block_id, offset).

Example:

```
gaussdb=# SELECT * FROM gs_seg_get_spc_extents('pg_default', 1,1024, 0);
 block_id | blocks | contents  | in_used | mapblock_location | head_file_id | head_block_id |  usage_type
| remain_flag | special_data | ipblock_location
----------+--------+-----------+---------+-------------------+--------------+---------------+--------------
+-------------+--------------+------------------
    4157 |      1 | permanent | Y       | (4157,0)          |            1 |          4157 | segment head | N
|           0 | (67,0)
    4158 |      1 | permanent | Y       | (4157,1)          |            1 |          4158 | fork head    | N
|           1 | (67,1)
(2 rows)
```

1.6.27.12 Bucket System Functions

- gs_bucket_get_data_distribution(relation REGCLASS, forknum INTEGER, including_toast Boolean)

  Description: Obtains the data distribution of a specific hash bucket table.

  The following describes the parameters.

Name	Type	Description
relation	REGCLASS	Table name.
forknum	INTEGER	Data file branch. Possible values include: • **0**: main fork. • **1**: FSM fork. • **2**: VM fork. • **-1**: sum of all other **forknum** values.
including_toast	Boolean	Specifies whether to include the TOAST table in data distribution statistics.

  Returned values

Name	Type	Description
node_name	TEXT	Database node name.
bucketnode	INT2	Bucket ID.
used_blocks	INT8	Number of used data blocks under the bucket ID.
allocated_blocks	INT8	Number of requested data blocks under the bucket ID.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Example:

```
gaussdb=# select * from gs_bucket_get_data_distribution('bucket_table', 0, true);

 node_name | bucketnode | used_blocks | allocated_blocks
-----------+------------+-------------+------------------
 datanode1 |          0 | 1           | 8
 datanode1 |          1 | 1           | 8
 datanode1 |          2 | 1           | 8
 datanode1 |          3 | 1           | 8
 datanode1 |          4 | 1           | 8
 datanode1 |          5 | 1           | 8
 datanode1 |          6 | 1           | 8
 datanode1 |          7 | 1           | 8
 datanode1 |          8 | 1           | 8
 datanode1 |          9 | 1           | 8
 datanode1 |         10 | 1           | 8
 datanode1 |         11 | 1           | 8
 datanode1 |         12 | 1           | 8
 datanode1 |         13 | 1           | 8
 datanode1 |         14 | 1           | 8
 datanode1 |         15 | 1           | 8
 datanode1 |         16 | 1           | 8
 datanode1 |         17 | 1           | 8
 datanode1 |         18 | 1           | 8
 datanode1 |         19 | 1           | 8
 datanode1 |         20 | 1           | 8
 datanode1 |         21 | 1           | 8
 datanode1 |         22 | 1           | 8
 datanode1 |         23 | 1           | 8
 datanode1 |         24 | 1           | 8
(Only part of the data is displayed.)
```

- gs_redis_get_plan(origin_group_id OID, target_group_id OID)

  Description: Obtains a complete migration plan. It can be called internally only during scale-out and only on CNs.

  Parameters:

Name	Type	Description
origin_group_id	OID	Source node group.
target_group_id	OID	New node group.

  Returned values

Name	Type	Description
sender_id	OID	Source node OID.
sender_name	CSTRING	Name of the source node.
receiver_id	OID	New node OID.
receiver_name	CSTRING	Name of the new node.
bucket_number	INT4	Number of buckets in **bucket_list**.
bucket_list	OIDVECTOR_EXTEND	List of buckets involved in the migration plan.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- gs_redis_get_bucket_statistics()

  Description: Obtains the log flow transmission status. It can be called internally only during scale-out.

  Parameter: void

  Returned values

Name	Type	Description
bucket_id	OID	Bucket ID.
redis_state	INT1	Scale-out status of the bucket. The value **0** indicates that the scale-out has not started, and the value **1** indicates that the scale-out baseline data has been completed.
xlog_count	INT8	Number of Xlogs generated by the bucket on the original DN after the current database scale-out starts (that is, after gs_redis_set_distributed_db is called last time).
sndr_latest_lsn	INT8	Latest LSN generated by the bucket on the original DN after the current database scale-out starts (that is, after gs_redis_set_distributed_db is called last time).
parser_latest_lsn	INT8	Latest LSN where the bucket is parsed to by the scale-out thread of the original DN after the current database scale-out starts (that is, after gs_redis_set_distributed_db is called last time).
parser_latest_lsn_new	INT8	Latest LSN of bucketxlog where the bucket is parsed to by the scale-out thread of the original DN after the current database scale-out starts (that is, after gs_redis_set_distributed_db is called last time).
rcvr_redo_latest_lsn	INT8	Latest LSN where the bucket is replayed to by the scale-out thread of the new DN after the current database scale-out starts (that is, after gs_redis_set_distributed_db is called last time).
rcvr_redo_latest_lsn_new	INT8	Latest LSN of bucketxlog where the bucket is parsed to by the scale-out thread of the original DN after the current database scale-out starts (that is, after gs_redis_set_distributed_db is called last time).
rcvr_checkpoint	INT8	Checkpoint of the bucket after the current database scale-out starts (that is, after the last calling of gs_redis_set_distributed_db).
rcvr_redo_start_lsn	INT8	Original LSN for starting the replay of the bucket after the scale-out of the current database starts (that is, after the last calling of gs_redis_set_distributed_db).

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Name	Type	Description
rcvr_redo_end_lsn	INT8	Original LSN for ending the replay of the bucket after the scale-out of the current database starts (that is, after the last calling of gs_redis_set_distributed_db).

- gs_redis_set_distributed_db(db_name CSTRING, bucketgroup SMALLINT)

  Description: Sets the database that is being redistributed using hash bucket. It can be called internally only during scale-out and only on DNs.

  Parameters:

  - **db_name**: specifies the name of the database to be redistributed.
  - **bucketgroup**: bucket group to be re-distributed. This has no effect in the current version.

  Return type: void

- gs_redis_parse_slicebucket_tranfer_file(plan_json CSTRING, type CSTRING)

  Description: Obtains the slice bucket migration plan. It can be called internally only during scale-out and only on CNs. It is not supported in the current version.

  The following describes the parameters.

Name	Type	Description
plan_json	TEXT	Slice migration file specified by the user.
type	CSTRING	Plan type, which can be **'incremental'** or **'full'**. The default value is **'full'**.

  The following describes the return types.

Name	Type	Description
idx	INT	ID of the database to be migrated.
database_name	CSTRING	Name of the database to be migrated.

- gs_redis_get_slicebucket_plan()

  Description: Obtains the slice bucket migration plan of the current database. It can be called internally only during scale-out and only on CNs. It is not supported in the current version.

  Parameter: void

  Returned values

Name	Type	Description
sender_id	OID	OID of the source node.
sender_name	CSTRING	Name of the source node.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Name	Type	Description
receiver_id	OID	OID of the target node.
receiver_name	CSTRING	Name of the new node.
bucket_number	INT4	Number of buckets in **bucket_list**.
bucket_list	OIDVECTOR_EXTEND	List of buckets involved in the migration plan.
bucketgroup	OID	Group to which the bucket in the bucket list belongs. The value ranges from 0 to 4.

- gs_redis_hashbucket_update_segment_header(origin_group_id OID, target_group_id OID)

  Description: Updates the headers of all hash bucket tables in the current database. It can be called internally only during scale-out and only on CNs.

  Parameters:

Name	Type	Description
origin_group_id	OID	Source node group.
target_group_id	OID	New node group.

  Return type: Boolean

- gs_redis_local_get_segment_header(table_name REGCLASS, bucketlist OIDVECTOR_EXTEND)

  Description: Obtains the header of a segment-page table. It can be called only on DNs.

  Parameters:

Name	Type	Description
table_name	REGCLASS	Table name.
bucketlist	OIDVECTOR_EXTEND	Bucket list.

  Return type: header_info

  Example:

```
gaussdb=#  SELECT * FROM gs_redis_local_get_segment_header('mytable', '256');
 gs_redis_local_get_segment_header
-----------------------------------------------------------------------------------------------------------------------------
-----
4294967295,4294967295,4294967295,4294967295,4294967295,4294967295,4294967295,4294967295,
4294967295,4294967295,4294967295,4294967295,4294967295, ... (Only part of the data is displayed.)
(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- gs_redis_local_update_segment_header(table_name REGCLASS, header_info CSTRING)

  Description: Updates the header of a segment-page table. It can be called only on DNs.

  Parameters:

Name	Type	Description
table_name	REGCLASS	Table name.
header_info	CSTRING	Header of a segment-page table.

  Return type: void

  Example:

```
gaussdb=#  SELECT * FROM gs_redis_local_update_segment_header('mytable',
'4294967295,4294967295,4294967295,4294967295, ....'); (Only part of the data is displayed.)
 gs_redis_local_update_segment_header
---------------------------------------------
 0
(1 row)
```

- gs_redis_hashbucket_update_inverse_pointer(buckets TEXT, origin_dn_name TEXT, new_dn_name TEXT)

  Description: Updates the inverse pointers of buckets of this batch in all hash bucket tables in the current database. It can be called internally only during scale-out and only on CNs.

  Parameters:

Name	Type	Description
buckets	TEXT	List of buckets that are brought online this time.
origin_dn_name	TEXT	Source node name.
new_dn_name	TEXT	New node name.

  Return type: void

- gs_redis_local_get_inverse_pointer(buckets TEXT, origin_dn_name TEXT, new_dn_name TEXT)

  Description: Obtains the inverse pointer. It can be called internally only during scale-out and only on DNs.

  The following describes the parameters.

Name	Type	Description
buckets	TEXT	List of buckets that are brought online this time.
origin_dn_name	TEXT	Source node name.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Name	Type	Description
new_dn_name	TEXT	New node name.

Return type: void

- gs_redis_local_update_inverse_pointer(table_name TEXT, header_info TEXT, bucketlist TEXT)

  Description: Records Xlogs for updating inverse pointers. It can be called internally only during scale-out and only on DNs.

  The following describes the parameters.

Name	Type	Description
table_name	REGCLASS	Table name.
header_info	TEXT	Header of a segment-page table.
bucketlist	TEXT	Bucket list.

  Return type: void

- gs_redis_local_set_hashbucket_frozenxid

  Description: Changes the **relfrozenxid64** value of the hash bucket table in the system catalog. It can be called internally only during scale-out and only on DNs.

  Parameter description: void

  Return type: void

- gs_redis_set_hashbucket_frozenxid(origin_group_id OID, target_group_id OID)

  Description: Changes the **relfrozenxid64** value of the hash bucket table in the system catalog on the new DN. It can be called internally only during scale-out and only on CNs.

  Parameters:

Name	Type	Description
origin_group_id	OID	Source node group.
target_group_id	OID	New node group.

  Return type: void

- gs_redis_set_nextxid(xid BIGINT)

  Description: Modifies the **next_xid** value of a DN. It can be called internally only during scale-out and only on DNs.

  Parameter: **xid** indicates the expected value of **next_xid**.

  Return type: void

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- gs_redis_set_csn(csn BIGINT)

  Description: Changes the **next_csn** value of a DN. It can be called internally only during scale-out and only on DNs in GTM-free mode.

  Parameters:

  – **csn**: specifies the expected value of **next_csn**.

  Return type: void

- gs_redis_check_bucket_flush(dn_array NAME[])

  Description: Determines whether all private buffers for RTO replay are flushed. It can be called internally only during scale-out.

  Parameters:

  – **dn_array**: specifies the DN name list.

  Return type: Boolean

- gs_redis_get_flush_page_lsn(isclean bool)

  Description: Queries the page refreshing information of bucket scale-out replay.

  Permission: It can be called only in the debug version and can be called internally only during scale-out.

  Parameters:

  – **isclean**: specifies whether to clear page refreshing information. The value is of the Boolean type.

  Returned values

Name	Type	Description
node_name	TEXT	DN where the page is located.
space_id	OID	Tablespace ID.
db_id	OID	Database ID.
file_id	OID	Data file ID. The value ranges from 1 to 5.
bucket_id	OID	Bucket partition ID. The value ranges from 0 to 1023.
forknum	OID	Data file fork. The value ranges from 0 to 2.
blocknum	OID	Offset page number of the physical page in the data file.
latest_flush_lsn	UINT8	Latest LSN of the dirty page to be flushed.

- gs_redis_show_bucketxid(bucketid_list OIDVECTOR_EXTEND)

  Description: Queries the bucketxid corresponding to a specified bucket. It can be called internally only during scale-out and only on DNs.

  Parameters:

  – **bucketid_list**: specifies the bucket list.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Return type: CString

- gs_redis_drop_bucket_files(plan_json CSTRING)

  Description: Deletes the range bucket files that have been physically migrated from the source node. It can be called internally only during scale-out and only on CNs. It is not supported in the current version.

  The following describes the parameters.

Name	Type	Description
plan_json	CSTRING	Slice migration file specified by the user.

  Return type: Boolean

- gs_redis_drop_bucket_files(origin_group_id OID, target_group_id OID)

  Description: Deletes the files that have been physically migrated from the source node. It can be called internally only during scale-out and only on CNs.

  Parameters:

Name	Type	Description
origin_group_id	OID	Source node group.
target_group_id	OID	New node group.

  Return type: Boolean

- gs_redis_local_drop_bucket_files(bucketlist CSTRING, bucketnum SMALLINT)

  Description: Deletes the corresponding bucket list. It can be called internally only during scale-out and only on DNs.

  The following describes the parameters.

Name	Type	Description
bucketlist	CSTRING	Specified bucket list.
bucketnum	SMALLINT	Number of buckets.

  Return type: Boolean

- gs_redis_local_drop_bucket_files(database_name NAME, bucketlist CSTRING, bucketnum SMALLINT)

  Description: Deletes the bucket list of the corresponding database from the range bucket table. It can be called internally only during scale-out and only on DNs. It is not supported in the current version.

  The following describes the parameters.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Name	Type	Description
database_name	NAME	Specified database name.
bucketlist	CSTRING	Specified bucket list.
bucketnum	SMALLINT	Number of buckets.

Return type: Boolean

- gs_redis_slicebucket_update_segment_header()

  Description: Updates the headers of all slice bucket tables in the current database. It can be called internally only during scale-out and only on CNs. It is not supported in the current version.

  Input parameter: void

  Return type: Boolean

- gs_redis_get_undo_state(mode INTEGER)

  Description: Obtains the undo status during scale-out and redistribution. It can be called internally only during scale-out.

  The following describes the parameters.

Name	Type	Description
mode	INTEGER	Mode for determining the undo status during redistribution: Options include: ● **0**: specifies whether there are transactions to be undone before the undo monitoring point **next_xid**. ● **1**: specifies whether there are new undo transactions whose ID is smaller than the monitoring point **next_xid**. ● **2**: specifies whether there are transactions to be undone whose ID is greater than the monitoring point **next_xid**.

  The return value **state** is of the INT4 type, indicating the undo status during scale-out and redistribution. The meanings of the return values vary depending on the parameter values:

  – When **mode** is set to **0**:

    ▪ If **state** is set to **0**, there are no transactions to be undone (**xmin** > **next_xid**).

    ▪ If **state** is set to **1**, there are no transactions to be undone (**xmin** ≤ **next_xid**).

    ▪ If **state** is set to **2**, there are transactions to be undone.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

  - When **mode** is set to **1**:
    - If **state** is set to **0**, there are no new undo transactions before the monitoring point **next_xid**.
    - If **state** is set to **1**, there are new undo transactions before the monitoring point **next_xid**.
  - When **mode** is set to **2**:
    - If **state** is set to **0**, there are no transactions to be undone after the monitoring point **next_xid**.
    - If **state** is set to **1**, there are transactions to be undone after the monitoring point **next_xid**.

1.6.27.13 Undo System Functions

To check the storage mode used by the current rollback segment, query the **undostoragetype** field in the gs_global_config system catalog. **segpage** indicates the segment-page mode, which is a reserved parameter and is not supported currently. **page** indicates the page mode.

Example:

```
gaussdb=# SELECT * FROM gsd_global_config where name like '%undostoragetype%';
      name       |  value
-----------------+---------
 undostoragetype |  page
(1 row)
```

NOTE

Undo system functions can be executed on DNs but cannot be executed on CNs.

- gs_undo_meta(type, zoneId, location)

  Description: Specifies metadata of a module in the undo system.

  Parameters:
  - **type** (metadata type)
    - **0**: indicates metadata corresponding to an undo zone (record).
    - **1**: indicates metadata corresponding to an undo zone (transaction slot).
    - **2**: indicates metadata corresponding to an undo space (record).
    - **3**: indicates metadata corresponding to an undo space (transaction slot).
  - **zoneId** (undo zone ID)
    - **–1**: indicates metadata of all undo zones.
    - **0** to 1024 x 1024 – 1: indicates the meta information of the corresponding zone ID.
  - **location** (read location)
    - **0**: indicates that data is read from the current memory.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **1**: indicates that data is read from a physical file.

Return type: record

NOTE

This system function supports only the rollback segments in page storage mode.

Table 1-147 gs_undo_meta parameters

Category	Parameter	Type	Description
Output parameter	zoneId	oid	ID of an undo zone.
Output parameter	persistType	oid	Persistence level.
Output parameter	insert	text	Position of the next undo record to be inserted.
Output parameter	discard	text	Position of the undo record that is recycled in common mode.
Output parameter	end	text	Position of the undo record that is forcibly recycled. Values smaller than the value of this parameter indicate that the record has been recycled.
Output parameter	used	text	Undo space that has been used.
Output parameter	lsn	text	Modifies the LSN of an undo zone.
Output parameter	pid	oid	ID of a thread bound to an undo zone.

- gs_undo_translot(location, zoneId)

  Description: Specifies transaction slot information of the undo system.

  Parameters:

  - **location** (read location)
    - **0**: indicates that data is read from the current memory.
    - **1**: indicates that data is read from a physical file.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

– **zoneId** (undo zone ID)

  - **–1**: indicates metadata of all undo zones.
  - **0** to 1024 x 1024 – 1: indicates the meta information of the corresponding zone ID.

Return type: record

NOTE

This system function supports only the rollback segments in page storage mode.

Table 1-148 gs_undo_translot parameters

Category	Parameter	Type	Description
Output parameter	groupId	oid	Undo zone ID that is used.
Output parameter	xactId	text	Transaction ID.
Output parameter	startUndoPtr	text	Position where an undo record is inserted at the start of a transaction corresponding to a transaction slot.
Output parameter	endUndoPtr	text	Position where an undo record is inserted at the end of a transaction corresponding to a transaction slot.
Output parameter	lsn	text	Transaction slot pointer.
Output parameter	slot_states	oid	Transaction status. • **0** indicates that the transaction has been committed. • **1** indicates that the task is being executed. • **2** indicates that the rollback is in progress. • **3** indicates that the rollback is complete.

- gs_stat_undo([bool init])
  Description: Collects undo statistics.
  Return type: record

NOTE

When rollback segments are stored in files in page storage mode, the following format is used.

Table 1-149 gs_stat_undo parameters

Category	Parameter	Type	Description
Input parameter	init	bool	(Optional) Specifies whether to clear statistics and restart statistics collection.
Output parameter	curr_used_zone_count	int	Number of used undo zones.
Output parameter	top_used_zones	text	Information about the first three undo zones with the maximum usage. The output format is as follows: • **zoneId1**: used size of zone 1. • **zoneId2**: used size of zone 2. • **zoneId3**: used size of zone 3.
Output parameter	curr_used_undo_size	int	Total size of the undo tablespace that is being used. The unit is MB.
Output parameter	undo_threshold	int	Calculation result of the value of the GUC parameter **undo_space_limit_size** × 80%, in MB.
Output parameter	global_recycle_xid	xid	XID of the transaction recycled to the undo space. The undo records generated by the transaction whose XID is smaller than the value of XID are recycled.
Output parameter	oldest_xmin	xid	Oldest active transaction.
Output parameter	total_undo_chain_len	int8	Total length of all accessed undo chains.
Output parameter	max_undo_chain_len	int8	Maximum length of the accessed undo chain.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Category	Parameter	Type	Description
Output parameter	create_undo_file_count	uint32	Number of created undo files.
Output parameter	discard_undo_file_count	uint32	Number of deleted undo files.
Output parameter	info	text	If the input parameter is **false**, suggestions on the **undo_space_limit_size**, **undo_limit_size_per_transaction**, and **undo_retention_time** parameters are provided. If the input parameter is **true**, init (clearing statistics) is required, and only 'The statistics have been initialized.' is displayed.

Example 1: Clear undo statistics.

```
gaussdb=# SELECT * FROM gs_stat_undo(true);
curr_used_zone_count |   top_used_zones    | curr_used_undo_size | undo_threshold | global_recycle_xid
| oldest_xmin | total_undo_chain_len | max_undo_chain_len | create_undo_file_coun
t | discard_undo_file_count |                info
----------------------+---------------------+---------------------+----------------+--------------------
+-------------+----------------------+--------------------+----------------------
--+-------------------------+-------------------------------------
                   3 | 0 : 0, 0 : 0, 0 : 0 |                   1 |         209715 |             15741 |       15741
|                  0 |                   0 |
2 |                     0 | The statistics have been initialized.
(1 row)
```

Example 2: Output undo statistics.

```
gaussdb=# SELECT * FROM gs_stat_undo(false);
curr_used_zone_count |   top_used_zones    | curr_used_undo_size | undo_threshold | global_recycle_xid
| oldest_xmin | total_undo_chain_len | max_undo_chain_len | create_undo_file_coun
t | discard_undo_file_count |
            info

----------------------+---------------------+---------------------+----------------+--------------------
+-------------+----------------------+--------------------+----------------------
--+-------------------------
+-----------------------------------------------------------------------------------------------------------------------------------
-------------------------------------
-----------------------------------------------------------------------------------------------------------------------------------
-------------------------------------------------------------
-
                   3 | 0 : 0, 0 : 0, 0 : 0 |                   1 |         209715 |             16253 |       16253
|                  0 |                   0 |
2 |                     0 | Based on the statistic info from last initialization, undo_space_limit_size is
recommended to set >= 120953 blocks, undo_limit_size_per_transaction is
recommended to set <= 327150 blocks, undo_retention_time is recommended to set <= 259200
seconds. Since last initialization, max undo space used by a single transaction is 32715 blocks.
(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- gs_undo_record(undoptr)

  Description: Parses undo records.

  Parameter: **undoptr** (undo record pointer).

  Return type: record

  NOTE

  This system function supports only the rollback segments in page storage mode.

- gs_undo_dump_parsepage_mv(relpath text, blkno bigint, reltype text, rmem boolean)

  Description: Parses the page header information of the disk page in the Ustore table, header information of each tuple, flag bit information, and all historical undo version information that can be queried.

  Return type: text.

  Note: Only SYSADMIN or OPRADMIN can execute this function.

  NOTE

  Currently, this API supports only Ustore tables.

  Table 1-150 gs_undo_dump_parsepage_mv parameters

Category	Parameter	Type	Description
Input parameter	relpath	text	Relative path of the Ustore table data file, in the format of *Tablespace name*|*Database OID*|*relfilenode*. For example, **base/16603/16384**. You can run the **pg_relation_filepath('tablename')** command to query the relative path.
Input parameter	blkno	int8	• **–1**: All block pages are parsed. • **0**–*MaxBlocNumber*: A specified block page is parsed.
Input parameter	reltype	text	Table type. Currently, only the Ustore table is supported. The value is **uheap**.
Input parameter	rmem	Boolean	• **false** • **true** Currently, the value can only be **false**, indicating that the corresponding page is parsed from the disk file.
Output parameter	output	text	Absolute path of the parsing result file.

- gs_undo_meta_dump_zone(zone_id int, read_memory boolean)

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description: Parses undo zone metadata in an undo module.

Return type: record

NOTE

When rollback segments are stored in files in page storage mode, the following format is used.

Table 1-151 gs_undo_meta_dump_zone parameters

Category	Parameter	Type	Description
Input parameter	zone_id	int	Undo zone ID. ● **–1**: All undo zones are queried. ● **0–1048575**: The undo zone metadata is queried based on the zone ID.
Input parameter	read_memory	Boolean	● **true**: Data is read from the current memory. ● **false**: Data is read from the physical file.
Output parameter	zone_id	oid	Undo zone ID.
Output parameter	persist_type	oid	Persistence levels: ● **0**: ordinary table ● **1**: unlogged table ● **2**: temporary table
Output parameter	insert	text	Position of the next undo record to be inserted.
Output parameter	discard	text	Position of the undo record that is recycled in common mode.
Output parameter	forcediscard	text	Position of the undo record that is forcibly recycled. Values smaller than the value of this parameter indicate that the record has been recycled.
Output parameter	lsn	text	Modifies the LSN of an undo zone.

Example:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gaussdb=# SELECT * FROM gs_undo_meta_dump_zone(-1,true);
 zone_id | persist_type | insert | discard | forcediscard |   lsn
---------+--------------+--------+---------+--------------+----------
       0 |            0 | 244577 | 244577  | 244577       | 43967224
       1 |            0 | 108    | 66      | 66           | 43967568
  349525 |            1 | 24     | 24      | 24           | 0
  349526 |            1 | 24     | 24      | 24           | 0
  699050 |            2 | 24     | 24      | 24           | 0
  699051 |            2 | 24     | 24      | 24           | 0
(6 rows)
```

- gs_undo_meta_dump_spaces(zone_id int, read_memory boolean)

  Description: Parses metadata of an undo record space and a transaction slot space in an undo module.

  Return type: record

  NOTE

  This system function supports only the rollback segments in page storage mode.

  Table 1-152 gs_undo_meta_dump_spaces parameters

Category	Parameter	Type	Description
Input parameter	zone_id	int	Undo zone ID. • **–1**: All undo zones are queried. • **0**–**1048575**: The undo zone metadata is queried based on the zone ID.
Input parameter	read_memory	Boolean	• **true**: Data is read from the current memory. • **false**: Data is read from the physical file.
Output parameter	zone_id	int	Undo zone ID.
Output parameter	undorecord_space_tail	text	End position of an undo record space.
Output parameter	undorecord_space_head	text	Start position of an undo record space.
Output parameter	undorecord_space_lsn	text	Modifies the LSN of an undo record space.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Category	Parameter	Type	Description
Output parameter	undoslot_space_tail	text	End position of a transaction slot space.
Output parameter	undoslot_space_head	text	Start position of a transaction slot space.
Output parameter	undoreslot_space_lsn	text	Modifies the LSN of a transaction slot space.

- gs_undo_meta_dump_slot(zone_id int, read_memory boolean)
  Description: Parses transaction slot metadata in an undo module.
  Return type: record

  NOTE

  This system function supports only the rollback segments in page storage mode.

  Table 1-153 gs_undo_meta_dump_slot parameters

Category	Parameter	Type	Description
Input parameter	zone_id	int	Undo zone ID. • **–1**: All undo zones are queried. • **0**–**1048575**: The undo zone metadata is queried based on the zone ID.
Input parameter	read_memory	Boolean	• **true**: Data is read from the current memory. • **false**: Data is read from the physical file.
Output parameter	zone_id	int	Undo zone ID.
Output parameter	allocate	text	Allocation position of the undo transaction slot.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Category	Parameter	Type	Description
Output parameter	recycle	text	Recycling position of the undo transaction slot.
Output parameter	frozen_xid	text	Frozen XID, which is used to determine the visibility.
Output parameter	global_frozen_xid	text	Minimum frozen XID in the system. Transactions whose XID is smaller than the value of this parameter are visible.
Output parameter	recycle_xid	text	Recycled XID. Transactions whose XID is smaller than the value of this parameter are recycled.
Output parameter	global_recycle_xid	text	Minimum recycled XID in the system. Transactions whose XID is smaller than the value of this parameter are recycled.

- gs_undo_translot_dump_slot(zone_id int, read_memory boolean)

  Description: Parses a transaction slot in an undo zone.

  Return type: record

  NOTE

  When rollback segments are stored in files in page storage mode, the following format is used.

Table 1-154 gs_undo_translot_dump_slot parameters

Category	Parameter	Type	Description
Input parameter	zone_id	int	Undo zone ID. • **–1**: All undo zones are queried. • **0**–**1048575**: The undo zone metadata is queried based on the zone ID.
Input parameter	read_memory	Boolean	• **true**: Data is read from the current memory. • **false**: Data is read from the physical file.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Category	Parameter	Type	Description
Output parameter	zone_id	oid	Undo zone ID.
Output parameter	slot_xid	text	Transaction ID.
Output parameter	start_undoptr	text	Position where the undo record is inserted at the start of the transaction corresponding to a slot.
Output parameter	end_undoptr	text	Position where the undo record is inserted at the end of the transaction corresponding to a slot.
Output parameter	slot_ptr	text	Position of a transaction slot.
Output parameter	slot_states	oid	Transaction state. • **0**: committed • **1**: being executed • **2**: being rolled back • **3**: rolled back

Example:

```
gaussdb=# SELECT * FROM gs_undo_translot_dump_slot(-1,true);
 zone_id |     slot_xid     |  start_undoptr   |   end_undoptr    |     slot_ptr     | slot_states
---------+------------------+------------------+------------------+------------------+-------------
       1 | 0000000000015758 | 0000000000000042 | 000000000000006C | 0000000000000038 |           0
(1 row)
```

- gs_undo_translot_dump_xid(slot_xid xid, read_memory boolean)

  Description: Parses a transaction slot in an undo zone based on the XID.

  Return type: record

  NOTE

  When rollback segments are stored in files in page storage mode, the following format is used.

Table 1-155 gs_undo_translot_dump_xid parameters

Category	Parameter	Type	Description
Input parameter	slot_xid	xid	Transaction ID to be queried.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Category	Parameter	Type	Description
Input parameter	read_memory	Boolean	• **true**: Data is read from the current memory. • **false**: Data is read from the physical file.
Output parameter	zone_id	oid	Undo zone ID.
Output parameter	slot_xid	text	Transaction ID.
Output parameter	start_undoptr	text	Position where the undo record is inserted at the start of the transaction corresponding to a slot.
Output parameter	end_undoptr	text	Position where the undo record is inserted at the end of the transaction corresponding to a slot.
Output parameter	slot_ptr	text	Position of a transaction slot.
Output parameter	slot_states	oid	Transaction state. • **0**: committed • **1**: being executed • **2**: being rolled back • **3**: rolled back

Example:

```
gaussdb=# SELECT * FROM gs_undo_translot_dump_xid('15758',false);
 zone_id |     slot_xid     |  start_undoptr   |   end_undoptr    |     slot_ptr     | slot_states
---------+------------------+------------------+------------------+------------------+-------------
       1 | 0000000000015758 | 0000000000000042 | 000000000000006C | 0000000000000038 |           0
(1 row)
```

- gs_undo_dump_record(undoptr bigint)

  Description: Parses the undo record information of a specified URP.

  Return type: record

  NOTE

  When rollback segments are stored in files in page storage mode, the following format is used.

Table 1-156 gs_undo_dump_record parameters

Category	Parameter	Type	Description
Input parameter	undoptr	xid	Start position of the undo record to be parsed. The value is in decimal format.
Output parameter	undoptr	xid	Start position of the undo record to be parsed in the current undo zone.
Output parameter	xactid	xid	Transaction ID.
Output parameter	cid	text	Command ID.
Output parameter	reloid	text	Relation OID.
Output parameter	relfilenode	text	Relfinode of the file.
Output parameter	utype	text	Undo record type.
Output parameter	blkprev	text	Position of the previous undo record in the same block.
Output parameter	blockno	text	Block number.
Output parameter	uoffset	text	Undo record offset.
Output parameter	prevurp	text	Position of the previous undo record.
Output parameter	payloadlen	text	Length of the undo record data.
Output parameter	oldxactid	text	Previous transaction ID.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Category	Parameter	Type	Description
Output parameter	partitionoid	text	Partition OID.
Output parameter	tablespace	text	Tablespace.
Output parameter	alreadyread_bytes	text	Length of the read undo record.
Output parameter	prev_undorec_len	text	Length of the previous undo record.
Output parameter	td_id	text	ID of the transaction directory.
Output parameter	reserved	text	Reserved flag of the source version tuple stored in an undo record.
Output parameter	flag	text	Status flag of the source version tuple stored in an undo record.
Output parameter	flag2	text	Number of source version tuple columns stored in an undo record.
Output parameter	t_hoff	text	Length of the undo record data header.

Example (If the undo record is not recycled, the input parameter undoptr can be queried after being converted to a decimal value using the output parameter **end_undoptr** of the gs_undo_translot_dump_slot function.):

```
gaussdb=# SELECT * FROM gs_undo_dump_record('0000000000000042');
 undoptr |   xactid   | cid | reloid | relfilenode | utype |  blkprev   | blockno | uoffset | prevurp |
payloadlen | oldxactid | partitionoid | tablespace | alreadyread_byt
es | prev_undorec_len | td_id | reserved | flag | flag2 | t_hoff
---------+------------+-----+--------+-------------+-------+------------+---------+---------+---------
+------------+-----------+--------------+------------+----------------
---+------------------+-------+----------+------+-------+--------
      42 | 1073807360 | 0   | 0      | 108986369   | 0     | 1024786474 | 0       | 0       | 0       |
0          | 0            | 0          | 36
   | 16390            | -1    | -1       | -1   | -1    | -1
(1 row)
```

- gs_undo_dump_xid(undo_xid xid)

  Description: Parses undo records based on the XID.

  Return type: record

NOTE

When rollback segments are stored in files in page storage mode, the following format is used.

Table 1-157 gs_undo_dump_xid parameters

Category	Parameter	Type	Description
Input parameter	undo_xid	xid	Transaction ID.
Output parameter	undoptr	xid	Start position of the undo record to be parsed in the current undo zone.
Output parameter	xactid	xid	Transaction ID.
Output parameter	cid	text	Command ID.
Output parameter	reloid	text	Relation OID.
Output parameter	relfilenode	text	Relfinode of the file.
Output parameter	utype	text	Undo record type.
Output parameter	blkprev	text	Position of the previous undo record in the same block.
Output parameter	blockno	text	Block number.
Output parameter	uoffset	text	Undo record offset.
Output parameter	prevurp	text	Position of the previous undo record.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Category	Parameter	Type	Description
Output parameter	payloadlen	text	Length of the undo record data.
Output parameter	oldxactid	text	Previous transaction ID.
Output parameter	partitionoid	text	Partition OID.
Output parameter	tablespace	text	Tablespace.
Output parameter	alreadyread_bytes	text	Length of the read undo record.
Output parameter	prev_undorec_len	text	Length of the previous undo record.
Output parameter	td_id	text	ID of the transaction directory.
Output parameter	reserved	text	Reserved flag of the source version tuple stored in an undo record.
Output parameter	flag	text	Status flag of the source version tuple stored in an undo record.
Output parameter	flag2	text	Number of source version tuple columns stored in an undo record.
Output parameter	t_hoff	text	Length of the undo record data header.

Example:

```
gaussdb=# SELECT * FROM gs_undo_dump_xid('15779');
 undoptr | xactid | cid | reloid | relfilenode | utype | blkprev | blockno | uoffset | prevurp | payloadlen |
oldxactid | partitionoid | tablespace | alreadyread_bytes | pr
ev_undorec_len | td_id | reserved | flag | flag2 | t_hoff
---------+--------+-----+--------+-------------+-------+---------+---------+---------+---------+------------
+-----------+--------------+------------+-------------------+---
---------------+-------+----------+------+-------+--------
   108 |  15779 | 0   | 16767  | 16767       | 64    | 0       | 0       | 3       | 0       | 0         | 0         |
```

(1 row)
```

- gs_verify_undo_record(type, start_idx, end_idx, location)

  Description: Verifies undo records. Currently, only the disk verification mode is supported. Offline verification can be performed only when services are not running. Before the verification, you need to manually perform checkpoint flushing.

  Return type: record

  NOTE

  When rollback segments are stored in files in page storage mode, the following format is used.

Table 1-158 gs_verify_undo_record parameters

Category	Parameter	Type	Description
Input parameter	type	text	Verification type. ● **'urp'**: verifies all undo records in a specified URP range. ● **'zone'**: verifies all undo records of all zones in a specified zone range.
Input parameter	start_idx	int8	Start position. ● When **type** is set to **'urp'**, this parameter indicates the start position of undo records. ● When **type** is set to **'zone'**, this parameter indicates the start undo zone ID.
Input parameter	end_idx	int8	End position. ● When **type** is set to **'urp'**, this parameter indicates the end position of undo records. ● When **type** is set to **'zone'**, this parameter indicates the end undo zone ID.
Input parameter	location	bool	● **0**: memory verification ● **1**: disk verification Currently, this parameter can only be set to **1**.
Output parameter	zone_id	int8	Undo zone ID.

Category	Parameter	Type	Description
Output parameter	detail	text	Verification error information.

Example 1: Verify the undo record whose URP is 24.

```
gaussdb=# SELECT * FROM gs_verify_undo_record('urp', 24, 24, 1);
zone_id | detail
--------+--------
(0 rows)
```

Example 2: Verify all undo records from zone 0 to zone 2 on the disk.

```
gaussdb=# SELECT * FROM gs_verify_undo_record('zone', 0, 2, 1);
zone_id | detail
--------+--------
(0 rows)
```

NOTE

If an error is reported when this function is called, contact Huawei technical support.

- gs_verify_undo_slot(type, start_idx, end_idx, location)

  Description: Verifies undo transaction slots. Currently, only the disk verification mode is supported. Offline verification can be performed only when services are not running. Before the verification, you need to manually perform checkpoint flushing.

  Return type: record

  NOTE

  When rollback segments are stored in files in page storage mode, the following format is used.

  Table 1-159 gs_verify_undo_slot parameters

Category	Parameter	Type	Description
Input parameter	type	text	Verification type. • **'zone'**: verifies all transaction slots of all zones in a specified zone range.
Input parameter	start_idx	int8	Start undo zone ID.
Input parameter	end_idx	int8	End undo zone ID.

Category	Parameter	Type	Description
Input parameter	location	bool	• **0**: memory verification • **1**: disk verification Currently, this parameter can only be set to **1**.
Output parameter	zone_id	int8	Undo zone ID.
Output parameter	detail	text	Verification error information.

Example: Verify all transaction slot records from zone 0 to zone 2 on the disk.

```
gaussdb=# SELECT * FROM gs_verify_undo_slot('zone', 0, 2, 1);
zone_id | detail
--------+--------
(0 rows)
```

NOTE

If an error is reported when this function is called, contact Huawei technical support.

- gs_verify_undo_meta(type, start_idx, end_idx, location)

  Description: Verifies undo metadata. Currently, only the disk verification mode is supported. Offline verification can be performed only when services are not running. Before the verification, you need to manually perform checkpoint flushing.

  Return type: record

  NOTE

  This system function supports only the rollback segments in page storage mode.

Table 1-160 gs_verify_undo_meta parameters

Category	Parameter	Type	Description
Input parameter	type	text	Verification type. The value of **type** can only be **'all'**, indicating that all meta information of all zones in the specified zone range is verified.
Input parameter	start_idx	int64	Start undo zone ID.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Category	Parameter	Type	Description
Input parameter	end_idx	int64	End undo zone ID.
Input parameter	location	bool	• **0**: memory verification • **1**: disk verification Currently, this parameter can only be set to **1**.
Output parameter	zone_id	int64	Undo zone ID.
Output parameter	detail	text	Verification error information.

Example: Verify all meta information records from zone 0 to zone 2 on the disk.

```
gaussdb=# SELECT * FROM gs_verify_undo_meta('all', 0, 2, 1);
zone_id | detail
---------+---------
(0 rows)
```

NOTE

If an error is reported when this function is called, contact Huawei technical support.

- gs_async_rollback_worker_status()

  Description: Monitors the status of active asynchronous rollback threads.

  Return type: record

Table 1-161 gs_async_rollback_worker_status parameters

Category	Parameter	Type	Description
Output parameter	datid	oid	Database ID.
Output parameter	pid	int8	Thread ID.
Output parameter	sessionid	int8	Session ID.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Category	Parameter	Type	Description
Output parameter	usesysid	oid	ID of the user who initiates the thread.
Output parameter	state	int	Thread status. • **0**: undefined • **1**: idle • **2**: running
Output parameter	rollback_start_time	timestamptz	Timestamp when a thread is started.
Output parameter	idx	oid	Index of an asynchronous rollback thread in the array.
Output parameter	xid	xid	XID of the transaction that is being rolled back.
Output parameter	progress	text	Rollback progress of the transaction (number of undo records that have been rolled back/total number of undo records, in percentage).

- gs_async_rollback_xact_status()

  Description: Monitors the hash table of asynchronous rollback tasks.

  Return type: record

  Table 1-162 gs_async_rollback_xact_status parameters

Category	Parameter	Type	Description
Output parameter	xid	xid	XID of the transaction that requires asynchronous rollback.
Output parameter	start_undoptr	xid	Pointer to the start undo record of the transaction.
Output parameter	end_undoptr	xid	Pointer to the end undo record of the transaction.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Category	Parameter	Type	Description
Output parameter	dbid	uint32	ID of the database where the transaction is located.
Output parameter	slot_ptr	xid	Pointer to the transaction slot corresponding to the transaction.
Output parameter	launched	bool	Checks whether there is an active asynchronous rollback thread.

- gs_undo_recycler_status()

  Description: Monitors the status of asynchronous recycling threads.

  Return type: record

  Table 1-163 gs_undo_recycler_status parameters

Category	Parameter	Type	Description
Output parameter	datid	oid	Database ID.
Output parameter	pid	int8	Thread ID.
Output parameter	sessionid	int8	Session ID.
Output parameter	usesysid	oid	ID of the user who initiates the thread.
Output parameter	state	int	Thread status. • **0**: undefined • **1**: idle • **2**: running
Output parameter	backend_start	timestamptz	Timestamp when a thread is started.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Category	Parameter	Type	Description
Output parameter	total_recycle_time	xid	Total recycling time.
Output parameter	max_recycle_time	xid	Maximum recycling time.
Output parameter	total_recycle_size	xid	Total recycled space.
Output parameter	total_recycle_count	xid	Total number of recycling times.
Output parameter	recycle_sleep_count	xid	Number of sleep times.
Output parameter	recycle_sleep_time	xid	Total sleep time.
Output parameter	max_recycle_sleep_time	xid	Maximum sleep time.
Output parameter	last_recycle_timestamp	timestamptz	Timestamp of the last successful recycling.
Output parameter	last_update_global_recycle_xid_timestamp	timestamptz	Timestamp of the last global recycling transaction.

- gs_undo_launcher_status()

  Description: Monitors the status of asynchronous rollback launcher threads.

  Return type: record

  Table 1-164 gs_undo_launcher_status parameters

Category	Parameter	Type	Description
Output parameter	datid	oid	Database ID.
Output parameter	pid	int64	Thread ID.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Category	Parameter	Type	Description
Output parameter	sessionid	int64	Session ID.
Output parameter	usesysid	oid	ID of the user who initiates the thread.
Output parameter	state	int32	Thread status. • **0**: undefined • **1**: idle • **2**: running
Output parameter	backend_start	timestamptz	Timestamp when a thread is started.
Output parameter	total_async_rollback_task_count	uint64	Total number of asynchronous rollback tasks initiated after the database on the local node is started.
Output parameter	average_async_rollback_time	uint64	Average duration of an asynchronous rollback task.
Output parameter	max_async_rollback_time	uint64	Maximum duration of an asynchronous rollback task.
Output parameter	min_async_rollback_time	uint64	Minimum duration of an asynchronous rollback task.

1.6.27.14 HTAP System Functions

- gs_global_imcv_info()

  Description: Displays basic information about the IMCV table in the current database, such as the loading status of column-store data and memory or disk space usage. In a distributed system, this function can be executed only on CNs. The basic information about the IMCV tables on all DNs is returned.

  Return type: record

  NOTICE

  - This function is available only when **enable_htap** is set to **on**.
  - Only a system administrator has the permission to execute this function.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 1-165 gs_global_imcv_info parameters

Parameter	Parameter	Type	Description
Output parameter	node_name	text	Node name.
Output parameter	rel_name	name	Table name.
Output parameter	partition_name	name	Partition name.
Output parameter	subpartition_name	name	Subpartition name.
Output parameter	schema_name	name	Schema name.
Output parameter	user_name	name	Username.
Output parameter	imcvnattr	smallint	Number of loaded columns.
Output parameter	imcvkey	int2vector	Array of loaded columns.
Output parameter	priority	smallint	Loading priority. (Currently, the priority does not take effect.) ● **'1'**: PRIORITY_NONE (no priority). ● **'2'**: PRIORITY_LOW (low priority). ● **'3'**: PRIORITY_HIGH (high priority).

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Parameter	Type	Description
Output parameter	rowgroup_num	integer	Expected number of row groups (that is, the number of row groups after full loading).
Output parameter	populated_rowgroup_num	integer	Number of row groups that are actually loaded. (The value should be equal to that of **rowgroup_num** after full loading.)
Output parameter	cu_num_in_mem	integer	Number of IMCUs in the memory.
Output parameter	cu_mem_size	bigint	Memory occupied by IMCU, in bytes.
Output parameter	cu_num_in_disk	integer	Number of IMCUs in the disk.
Output parameter	cu_disk_size	bigint	Disk size occupied by IMCU, in bytes.

Examples

```
htapdb=# SELECT * FROM gs_global_imcv_info();
  node_name   |         rel_name         |       partition_name        | subpartition_name | schema_name |

- gs_imcv_flush(reloid oid, partoid oid, parallelism integer, rebuild_mode integer)

  Description: Immediately rebuilds a specified IMCV table or the partition in the database and displays the rebuild result. During the rebuild, the IMCV table is refreshed, old data is removed, and inactive data in the current table is synchronized. When this function is executed on a CN, the IMCV of the table on all nodes is rebuilt. When this function is executed on a DN, the IMCV of the table on the DN is rebuilt.

  Return type: record

  NOTICE

  - This function is available only when **enable_htap** is set to **on**.
  - Only SYSADMIN or OPRADMIN can execute this function.
  - This function cannot be executed in a transaction block.
  - During parallel loading or rebuilding, each worker occupies extra resources, such as memory, CPU, and I/O (flushing is enabled). Therefore, exercise caution when controlling the degree of parallelism for loading or rebuilding based on the actual hardware resources and system load.

  Table 1-167 gs_imcv_flush parameters

Category	Parameter	Type	Description
Input parameter	reloid	oid	Table OID.
Input parameter	partoid	oid	Partition OID. When all partitions of a partitioned table or a non-partitioned table are queried, the value can be **0**.
Input parameter	parallelism	integer	Degree of parallelism, that is, the number of bgworkers used by a loading or rebuilding task. The value ranges from 1 to 256. If the actual number of bgworkers in the background is insufficient, the bgworkers that can be started are used to execute the rebuilding task.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Category	Parameter	Type	Description
Input parameter	rebuild_mode	integer	Rebuilding mode. Value range: ● **0**: non-forcible rebuilding. Rebuilding is triggered only when column-store data is not synchronized to row-store data. ● **1**: forcible rebuilding. Rebuilding is triggered regardless of whether the column-store data is the latest.
Output parameter	total	integer	Number of row groups that are actually processed.
Output parameter	success	integer	Number of row groups that are successfully processed.
Output parameter	error	integer	Number of row groups that fail to be processed. For example, the loading or rebuilding operation is not performed due to insufficient memory.
Output parameter	skip	integer	Number of row groups that are skipped. For example, the data is the latest, and the rebuilding operation is not performed.

Example:

```
htapdb=# SELECT * FROM gs_imcv_flush(20834, 20838,1,1);
 total | success | error | skip
-------+---------+-------+------
 1     | 1       | 0     | 0
(1 row)
```

- gs_imcv_flush(relname text, partname text, parallelism integer, rebuild_mode integer)

  Description: Immediately rebuilds a specified IMCV table or the partition in the database and displays the rebuild result. During the rebuild, the IMCV table is refreshed, old data is removed, and inactive data in the current table is synchronized. When this function is executed on a CN, the IMCV of the table on all nodes is rebuilt. When this function is executed on a DN, the IMCV of the table on the DN is rebuilt.

  Return type: record

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTICE

- This function is available only when **enable_htap** is set to **on**.
- Only SYSADMIN or OPRADMIN can execute this function.
- This function cannot be executed in a transaction block.
- During parallel loading or rebuilding, each worker occupies extra resources, such as memory, CPU, and I/O (flushing is enabled). Therefore, exercise caution when controlling the degree of parallelism for loading or rebuilding based on the actual hardware resources and system load.

Table 1-168 gs_imcv_flush parameters

Category	Parameter	Type	Description
Input parameter	relname	text	Table name.
Input parameter	partname	text	Partition name. When all partitions of a partitioned table or a non-partitioned table are queried, the value can be **NULL** or ''. The default value can be used. In this case, if the table contains partitions, all partitions are processed.
Input parameter	parallelism	integer	Degree of parallelism, that is, the number of bgworkers used by a loading or rebuilding task. The value ranges from 1 to 256. If the actual number of bgworkers in the background is insufficient, the bgworkers that can be started are used to execute the rebuilding task. The default value can be used. In this case, the degree of parallelism is **1**, that is, no parallelism is performed.
Input parameter	rebuild_mode	integer	Rebuilding mode. Value range: • **0**: non-forcible rebuilding. Rebuilding is triggered only when column-store data is not synchronized to row-store data. • **1**: forcible rebuilding. Rebuilding is triggered regardless of whether column-store data is fresh. The default value can be used, indicating non-forcible rebuilding.
Output parameter	total	integer	Number of row groups that are actually processed.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Category	Parameter	Type	Description
Output parameter	success	integer	Number of row groups that are successfully processed.
Output parameter	error	integer	Number of row groups that fail to be processed. For example, the loading or rebuilding operation is not performed due to insufficient memory.
Output parameter	skip	integer	Number of row groups that are skipped. For example, the data is the latest, and the rebuilding operation is not performed.

Example:

```
-- Set partname, parallelism, and rebuild_mode to their default values.
htapdb=# SELECT * FROM gs_imcv_flush('htap_flush_by_name_part1');
 total | success | error | skip
-------+---------+-------+------
 2     | 2       | 0     | 0
(1 row)
-- Set parallelism and rebuild_mode to their default values.
htapdb=# SELECT * FROM gs_imcv_flush('htap_flush_by_name_part1',
'htap_flush_by_name_part1_p1');
 total | success | error | skip
-------+---------+-------+------
 1     | 0       | 0     | 1
(1 row)
-- Set rebuild_mode to the default value.
htapdb=# SELECT * FROM gs_imcv_flush('htap_flush_by_name_part1',
'htap_flush_by_name_part1_p1',1);
 total | success | error | skip
-------+---------+-------+------
 1     | 0       | 0     | 1
(1 row)
htapdb=# SELECT * FROM gs_imcv_flush('htap_flush_by_name_part1',

- gs_global_htap_tmu_data(relname text, partname text, rowgroup_id integer)

  Description: Views active transaction statistics in the real-time transaction unit TMU. This function can be executed only on a distributed CN and returns information about all DNs. If **rowgroup_id** is set to **0**, all active transaction statistics in the table are returned. If **rowgroup_id** is set to a value greater than 0, the active transaction statistics in the specified row group in the table are returned.

  Return type: record

- Only a system administrator has the permission to execute this function.

Table 1-169 gs_global_htap_tmu_data parameters

Category	Parameter	Type	Description
Input parameter	relname	text	Table name. If you want to query cross-schema table information, you can set the value in the '*schema.relname*' format.
Input parameter	partname	text	Partition name. When all partitions of a partitioned table or a non-partitioned table are queried, the value can be **NULL** or **''**.
Input parameter	rowgroup_id	integer	Identifies a row group.
Output parameter	node_name	text	Node name.
Output parameter	rel_name	name	Table name.
Output parameter	partition_name	name	Name of a partition. If it is not a partition, this column is left empty.
Output parameter	subpartition_name	name	Name of a subpartition. If it is not a subpartition, this column is left empty.
Output parameter	schema_name	name	Schema name.
Output parameter	rel_oid	oid	Table OID.
Output parameter	rowgroup_id	integer	Identifies a row group.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Category	Parameter	Type	Description
Output parameter	page_id	integer	Page ID in the row group being searched.
Output parameter	flag	smallint	The value **0** indicates a non-dirty page, and the value **1** indicates a dirty page.
Output parameter	xid	xid	ID of the transaction that operates the data.

Example:

```
htapdb=# SELECT * FROM gs_global_htap_tmu_data('htap_flush_by_name_part1',
'htap_flush_by_name_part1_p1', 0);
 node_name |          rel_name          |       partition_name        | subpartition_name | schema_name |
rel_oid | rowgroup_id | page_id | flag |  xid
-----------+----------------------------+-----------------------------+-------------------+-------------
+-------------+---------+------+--------
 datanode2 | htap_flush_by_name_part1 | htap_flush_by_name_part1_p1 |                   | public      |
16389 |           1 |       0 |    0 | 203236
(1 row)
```

- gs_htap_tmu_data(relname text, partname text, rowgroup_id integer)

  Description: Views active transaction statistics in the real-time transaction unit TMU and returns active transaction statistics in the table on the current node. If **rowgroup_id** is set to **0**, all active transaction statistics in the table are returned. If **rowgroup_id** is set to a value greater than 0, the active transaction statistics in the specified row group in the table are returned.

  Return type: record

NOTICE

- This function is available only when **enable_htap** is set to **on**.
- Only SYSADMIN or OPRADMIN can execute this function.

Table 1-170 gs_htap_tmu_data parameters

Category	Parameter	Type	Description
Input parameter	relname	text	Table name. If you want to query cross-schema table information, you can set the value in the '*schema.relname*' format.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Category	Parameter	Type	Description
Input parameter	partname	text	Partition name. When all partitions of a partitioned table or a non-partitioned table are queried, the value can be **NULL** or ''.
Input parameter	rowgroup_id	integer	Identifies a row group.
Output parameter	rel_name	name	Table name.
Output parameter	partition_name	name	Name of a partition. If it is not a partition, this column is left empty.
Output parameter	subpartition_name	name	Name of a subpartition. If it is not a subpartition, this column is left empty.
Output parameter	schema_name	name	Schema name.
Output parameter	rel_oid	oid	Table OID.
Output parameter	rowgroup_id	integer	Identifies a row group.
Output parameter	page_id	integer	Page ID in the row group being searched.
Output parameter	flag	smallint	The value **0** indicates a non-dirty page, and the value **1** indicates a dirty page.
Output parameter	xid	xid	ID of the transaction that operates the data.

Example:

```
htapdb=# SELECT * FROM gs_htap_tmu_data('htap_flush_by_name_part1',
'htap_flush_by_name_part1_p2',0);

Table 1-173 gs_global_imcv_bgworker_status parameters

Category	Parameter	Type	Description
Output parameter	node_name	text	Database node name.
Output parameter	worker_pid	bigint	Thread ID.
Output parameter	database_id	oid	Database ID.
Output parameter	relation_id	oid	OID of the IMCV table that is being processed.
Output parameter	rowgroup_id	integer	Identifies a row group.
Output parameter	worker_status	text	Specifies the working state of a thread, which can be **init** (initialized), **running** (in progress), or **ready** (idle).
Output parameter	worker_type	text	Task type. The options are as follows: • **background_invalid_worker**: No task is being executed. • **background_unknown_worker**: An unknown task is executed. • **background_rowgroup_rebuild_worker**: A row group is rebuilt. • **background_async_populate_worker**: Asynchronous loading is performed. • **background_cache_worker**: A task in the cache is executed.
Output parameter	start_time	timestamp with time zone	Timestamp when a thread is started.

Example:

Table 1-174 gs_imcv_bgworker_status parameters

Category	Parameter	Type	Description
Output parameter	worker_pid	bigint	Thread ID.
Output parameter	database_id	oid	Database ID.
Output parameter	relation_id	oid	OID of the IMCV table that is being processed.
Output parameter	rowgroup_id	integer	Identifies a row group.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Category	Parameter	Type	Description
Output parameter	worker_status	cstring	Specifies the working state of a thread, which can be **init** (initialized), **running** (in progress), or **ready** (idle).
Output parameter	worker_type	cstring	Task type. The value can be **background_invalid_worker** (no task is being executed), **background_unknown_worker** (unknown task), **background_rowgroup_rebuild_worker** (rebuilding a row group), **background_async_populate_worker** (asynchronous loading), or **background_cache_worker** (cache task).
Output parameter	start_time	timestamp with time zone	Timestamp when a thread is started.

Example:

```
htapdb=# SELECT * FROM gs_imcv_bgworker_status();
   worker_pid    | database_id | relation_id | rowgroup_id | worker_status |        worker_type
|          start_time
-----------------+-------------+-------------+-------------+---------------+---------------------------
+-------------------------------
 140067573069568 |       16384 |           0 |           0 | ready         | background_invalid_worker |

```

- gs_global_imcu_meta(rel_name text, partname text)

  Description: Displays the IMCU metadata in the IMCV table with the specified **rel_name** in the current database. In a distributed system, this function can be executed only on CNs. The information about all DNs is returned.

  Return type: record

  NOTICE

  - This function is available only when **enable_htap** is set to **on**.
  - Only a system administrator has the permission to execute this function.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 1-175 gs_global_imcu_meta parameters

Category	Parameter	Type	Description
Input parameter	relname	text	IMCV table name. If you want to query cross-schema table information, you can set the value in the '*schema.relname*' format.
Input parameter	partname	text	IMCV partition name. When all partitions of a partitioned table or a non-partitioned table are queried, the value can be **NULL** or ''.
Output parameter	node_name	text	Database node name.
Output parameter	rel_name	name	IMCV table name.
Output parameter	partition_name	name	IMCV partition name.
Output parameter	subpartition_name	name	IMCV subpartition name.
Output parameter	schema_name	name	Schema name.
Output parameter	rowgroup_id	integer	ID of the row group where the IMCU is located.
Output parameter	row_count	integer	Number of rows of the IMCU.
Output parameter	imcu_size	integer	IMCU size, in bytes.
Output parameter	imcu_data_size	integer	IMCU data size (excluding IMCU metadata), in bytes.
Output parameter	compressed_data_size	integer	IMCU data size after compression.
Output parameter	compressed_ratio	real	Compression ratio of the IMCU data.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Category	Parameter	Type	Description
Output parameter	compressed_type	text	Compression algorithm of the IMCU. • **none**: There is no IMCU data and the data cannot be compressed. • **uncompressed**: Data is not compressed. • **delta_plus_rle**: The IMCU data is compressed using the delta_plus_rle compression algorithm. • **lz4_compressed**: The IMCU data is compressed using the lz4 compression algorithm. • **dict_compressed**: The IMCU data is compressed using the dict compression algorithm.
Output parameter	imcu_mode	integer	Characteristics of column data loaded by the IMCU: • **1**: common. • **2**: all empty. • **3**: same value. • **4**: no maximum or minimum value. • **8**: contains a blank line. • **16**: no sum value.
Output parameter	magic	integer	XID value of the transaction when IMCU data is generated. This value is used to check whether the IMCU data is valid.
Output parameter	attnum	smallint	attnum corresponding to the column loaded by IMCU.
Output parameter	scan_cnt	bigint	Total number of times that the IMCU is scanned.
Output parameter	hit_cnt	bigint	Number of times that the memory-state IMCU is hit.
Output parameter	data_location	smallint	Specifies that the IMCU is in the memory, in the disk, or in escape state. • **0**: memory. • **1**: disk. • **2**: escape state. Only metadata is created due to insufficient memory. When this part of data is queried, it is read from the row store.

(14 rows)
```

Note: In this example, each row represents a IMCU (the column whose **attnum** is **0** is the **CTID** column).

- gs_imcu_meta(rel_name text, partname text)

  Description: Displays the IMCU metadata in the IMCV table with the specified **rel_name** in the current database. In a distributed system, the information about the current node is returned.

  Return type: record

Table 1-176 gs_imcu_meta parameters

Category	Parameter	Type	Description
Input parameter	relname	text	IMCV table name. If you want to query cross-schema table information, you can set the value in the '*schema.relname*' format.
Input parameter	partname	text	IMCV partition name. When all partitions of a partitioned table or a non-partitioned table are queried, the value can be **NULL** or ''.
Output parameter	rel_name	name	IMCV table name.
Output parameter	partition_name	name	IMCV partition name.
Output parameter	subpartition_name	name	IMCV subpartition name.
Output parameter	schema_name	name	Schema name.
Output parameter	rowgroup_id	integer	ID of the row group where the IMCU is located.
Output parameter	row_count	integer	Number of rows of the IMCU.
Output parameter	imcu_size	integer	IMCU size, in bytes.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Category	Parameter	Type	Description
Output parameter	imcu_data_size	integer	IMCU data size (excluding IMCU metadata), in bytes.
Output parameter	compressed_data_size	integer	IMCU data size after compression.
Output parameter	compressed_ratio	real	Compression ratio of the IMCU data.
Output parameter	compressed_type	text	Compression algorithm of the IMCU. • **none**: There is no IMCU data and the data cannot be compressed. • **uncompressed**: Data is not compressed. • **delta_plus_rle**: The IMCU data is compressed using the delta_plus_rle compression algorithm. • **lz4_compressed**: The IMCU data is compressed using the lz4 compression algorithm. • **dict_compressed**: The IMCU data is compressed using the dict compression algorithm.
Output parameter	imcu_mode	integer	Characteristics of column data loaded by the IMCU: • **1**: common. • **2**: all empty. • **3**: same value. • **4**: no maximum or minimum value. • **8**: contains a blank line. • **16**: no sum value.
Output parameter	magic	integer	XID value of the transaction when IMCU data is generated. This value is used to check whether the IMCU data is valid.
Output parameter	attnum	smallint	attnum corresponding to the column loaded by IMCU.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Category	Parameter	Type	Description
Output parameter	scan_cnt	bigint unsigned	Total number of times that the IMCU is scanned.
Output parameter	hit_cnt	bigint unsigned	Number of times that the memory-state IMCU is hit.
Output parameter	data_location	smallint	Specifies that the IMCU is in the memory, in the disk, or in escape state. • **0**: memory. • **1**: disk. • **2**: escape state. Only metadata is created due to insufficient memory. When this part of data is queried, it is read from the row store.

Example:

```
htapdb=# SELECT * FROM gs_imcu_meta('htap_flush_by_name_part1',
'htap_flush_by_name_part1_p2');
        rel_name         |       partition_name        | subpartition_name | schema_name | rowgroup_id |

(7 rows)
```

Note: In this example, each row represents a IMCU (the column whose **attnum** is **0** is the **CTID** column).

- gs_global_htap_file_status(db_name text)

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description: Displays the usage information about the IMCU flush files of HTAP column-store tables. In a distributed system, this function can be executed only on CNs. The information about all DNs is returned.

Return type: record

NOTICE

- This function is available only when **enable_htap** is set to **on**.
- Only a system administrator has the permission to execute this function.

Table 1-177 gs_global_htap_file_status parameters

Category	Parameter	Type	Description
Input parameter	db_name	text	Database name. If the value is '' or **NULL**, all databases are queried.
Output parameter	node_name	text	Database node name.
Output parameter	db_oid	integer	Database ID.
Output parameter	file_name	text	Data file name.
Output parameter	file_id	integer	Data file ID. In the current version, only **2** is returned.
Output parameter	extent_size	integer	Extent size of a data file.
Output parameter	allocated_blocks	bigint	Number of pages that have been allocated to the IMCU in the data file.
Output parameter	total_blocks	bigint	Total number of physical pages in a data file on the disk.
Output parameter	high_water_mark	bigint	High watermark of the number of pages used by a data file.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Category	Parameter	Type	Description
Output parameter	utilization	real	Percentage of used blocks to the total number of blocks.
Output parameter	ext	text	Extended column. The value is **NULL** in the current version.

Example:

```
htapdb=# SELECT * FROM gs_global_htap_file_status('htapdb');
 node_name | db_oid |        file_name         | file_id | extent_size | allocated_blocks | total_blocks |
high_water_mark | utilization | ext
-----------+--------+--------------------------+---------+-------------+------------------+--------------
+-----------------+-------------+-----
 datanode1 |  16384 | global/imcu/16384/2_imcu |       2 |           4 |                0 |            0 |
0 |           1 |
 datanode2 |  16384 | global/imcu/16384/2_imcu |       2 |           4 |                0 |            0 |
0 |           1 |
(2 rows)
```

- gs_htap_file_status(db_name text)

  Description: Displays the usage information about the IMCU flush files of HTAP column-store tables. In a distributed system, the information about the current node is returned.

  Return type: record

Table 1-178 gs_htap_file_status parameters

Category	Parameter	Type	Description
Input parameter	db_name	text	Database name. If the value is **''** or **NULL**, all databases on the current node are queried.
Output parameter	db_oid	oid	Database ID.
Output parameter	file_name	text	Data file name.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Category	Parameter	Type	Description
Output parameter	file_id	integer	Data file ID. In the current version, only **2** is returned.
Output parameter	extent_size	integer	Extent size of a data file.
Output parameter	allocated_blocks	bigint	Number of pages that have been allocated to the IMCU in the data file.
Output parameter	total_blocks	bigint	Total number of physical pages in a data file on the disk.
Output parameter	high_water_mark	bigint	High watermark of the number of pages used by a data file.
Output parameter	utilization	real	Percentage of used blocks to the total number of blocks.
Output parameter	ext	text	Extended column. The value is **NULL** in the current version.

Example:

```
htapdb=# SELECT * FROM gs_htap_file_status('htapdb');
 db_oid |        file_name          | file_id | extent_size | allocated_blocks | total_blocks | high_water_mark | utilization | ext
--------+---------------------------+---------+-------------+------------------+--------------+-----------------+-------------+-----
  16384 | global/imcu/16384/2_imcu |       2 |           4 |                0 |            0 |               0 |           1 |
(1 row)
```

- gs_global_htap_scan_hit_status(relname text, partname text)

  Description: Queries the IMCU hit ratio information at the table level. In a distributed system, this function can be executed only on CNs. The information about all DNs is returned. If the value of **reloid** is **0**, the hit rates of all IMCV tables in the current database are returned. If the value of **reloid** is not 0, the hit rate of the specified table is returned.

  Return type: record

Table 1-179 gs_global_htap_scan_hit_status parameters

Category	Parameter	Type	Description
Input parameter	relname	text	Table name. If you want to query cross-schema table information, you can set the value in the '*schema.relname*' format.
Input parameter	partname	text	Partition name. When all partitions of a partitioned table or a non-partitioned table are queried, the value can be **NULL** or ''.
Output parameter	node_name	text	Database node name.
Output parameter	rel_name	name	Table name.
Output parameter	partition_name	name	Partition name.
Output parameter	subpartition_name	name	Subpartition name.
Output parameter	schema_name	name	Schema name.
Output parameter	column_number	integer	Column No.
Output parameter	column_name	name	Column name.
Output parameter	imcu_in_cache_cnt	bigint unsigned	Number of IMCUs stored in the cache.
Output parameter	imcu_ave_scan_cnt	bigint unsigned	Average number of times that each IMCU is used in the column.
Output parameter	imcu_total_scan_cnt	bigint unsigned	Total number of times that IMCUs are used in the column.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Category	Parameter	Type	Description
Output parameter	imcu_ave_hit_cnt	bigint unsigned	Average number of cache hits per IMCU in the column.
Output parameter	imcu_total_hit_cnt	bigint unsigned	Total number of cache hits of IMCUs in the column.
Output parameter	total_hit_percentage	real	Total cache hit ratio of IMCUs in this column.

Example:

```
htapdb=# SELECT * FROM gs_global_htap_scan_hit_status('htap_flush_by_name_part1',
'htap_flush_by_name_part1_p2');

- gs_htap_scan_hit_status(relname text, partname text)

  Description: Queries the IMCU hit rate information at the table level. In a distributed system, the information about the current node is returned. If both **relname** and **partname** are **null** or empty, the hit rates of all IMCV tables in the current node are returned. In other cases, the hit rates of the specified table or partition are returned.

  Return type: record

NOTICE

- This function is available only when **enable_htap** is set to **on**.
- Only SYSADMIN or OPRADMIN can execute this function.

Table 1-180 gs_htap_scan_hit_status parameters

Category	Parameter	Type	Description
Input parameter	relname	text	Table name. If you want to query cross-schema table information, you can set the value in the '*schema.relname*' format.
Input parameter	partname	text	Partition name. When all partitions of a partitioned table or a non-partitioned table are queried, the value can be **NULL** or **''**.
Output parameter	rel_name	name	Table name.
Output parameter	partition_name	name	Partition name.
Output parameter	subpartition_name	name	Subpartition name.
Output parameter	schema_name	name	Schema name.
Output parameter	column_number	integer	Column sequence number.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Category	Parameter	Type	Description
Output parameter	column_name	name	Column name.
Output parameter	imcu_in_cache_cnt	bigint unsigned	Number of IMCUs stored in the cache.
Output parameter	imcu_total_cnt	bigint unsigned	Total number of IMCUs in a column.
Output parameter	imcu_ave_scan_cnt	bigint unsigned	Average number of times that each IMCU is used in the column.
Output parameter	imcu_total_scan_cnt	bigint unsigned	Total number of times that IMCUs are used in the column.
Output parameter	imcu_ave_hit_cnt	bigint unsigned	Average number of cache hits per IMCU in the column.
Output parameter	imcu_total_hit_cnt	bigint unsigned	Total number of cache hits of IMCUs in the column.
Output parameter	total_hit_percentage	real	Total cache hit rate of IMCUs in the column.

Example:

```
gaussdb=# SELECT * FROM gs_htap_scan_hit_status('htap_flush_by_name_part1',
'htap_flush_by_name_part1_p1');
        rel_name         |       partition_name        | subpartition_name | schema_name | column_number
| column_name | imcu_in_cache_cnt | imcu_total_cnt | imcu_ave_scan_cnt | imcu_total_scan_cnt |
imcu_ave_hit_cnt | imcu_total_hit_cnt | tot
al_hit_percentage

```

- gs_imcu_size_estimation(relname text, partname text, colnum_name_array text[])

  Description: Returns the estimated memory usage for creating IMCV column-store data for a specified column in a specified partition of a table. When this function is executed on a DN, the estimated value of the current node is returned. When this function is executed on a CN, the estimated value of each node is returned.

  Return type: record

  NOTICE

  - This function is available only when **enable_htap** is set to **on**.
  - Only SYSADMIN or OPRADMIN can execute this function.
  - This function cannot be executed on the standby node. The restrictions of this function are the same as those of HTAP DDL. The error information is the same as that of DDL execution.

  Table 1-181 gs_imcu_size_estimation parameters

Category	Parameter	Type	Description
Input parameter	relname	text	Table name. If you want to query cross-schema table information, you can set the value in the '*schema.relname*' format.
Input parameter	partname	text	Partition name. When all partitions of a partitioned table or a non-partitioned table are queried, the value can be **NULL** or **''**.
Input parameter	colnum_name_array	text[]	Column name array.
Output parameter	node_name	name	Node name.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Category	Parameter	Type	Description
Output parameter	estimated_size	bigint unsigned	Estimated memory usage, in bytes.

Example:

```
htapdb=# SELECT * FROM gs_imcu_size_estimation('estimate_htap', '', ARRAY['id']);
 node_name | estimated_size
-----------+----------------
 datanode1 | 28411
 datanode2 | 28089
(2 rows)
```

- gs_htap_data_maintenance(rel_oid oid, type integer)

  Description: Maintains column-store data and provides two capabilities: (1) unloads column-store data (clears the memory and disk space); (2) flushes all column-store data to disks.

  Return type: text.

NOTICE

This API directly unloads IMCV to protect the row-store TP service. As a result, an error is reported for the service that has used IMCV Scan. Therefore, you need to fully confirm the impact before using this API. This function is used only for emergency escape when the cluster cannot be shut down due to excessive usage of resources (such as IMCV memory) caused by configuration or other reasons.

NOTE

- This function is available only when **enable_htap** is set to **on**.
- Only SYSADMIN or OPRADMIN can execute this function.
- This function cannot be executed in a transaction.
- In distributed mode, this function can be executed only on DNs.

Table 1-182 gs_htap_data_maintenance parameters

Category	Parameter	Type	Description
Input parameter	rel_oid	oid	OID of a row-store table. The value **0** indicates that all tables in the database on the current DN are processed.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Category	Parameter	Type	Description
Input parameter	type	integer	Processing type. The options are as follows: • **0**: All IMCV data of the corresponding table is unloaded, including the memory and flushed data files. Only metadata is retained. The gs_imcv system catalog still contains information. The status is **'E'** in the gs_imcv_status view. When the input parameter **rel_oid** is set to **0**, IMCV data of all tables is unloaded, flushed files are deleted, and disk space is released. After the IMCV is unloaded using this API, the IMCV status is **'E'**. In this case, HTAP functions cannot be used. You need to create an IMCV again or run the VACUUM FULL command to change the IMCV status of the base table and corresponding partition to **'F'**. • **1**: This parameter has been deprecated. • **2**: IMCV data of the corresponding table is flushed to disk.

Example:

```
htapdb=# SELECT * FROM gs_htap_data_maintenance(16824,0);
 gs_htap_data_maintenance
--------------------------
 Maintenance finish.
(1 row)
htapdb=# SELECT * FROM gs_htap_data_maintenance(16824,2);
 gs_htap_data_maintenance
--------------------------
 Maintenance finish.
(1 row)
```

1.6.27.15 Other Functions

- pgxc_pool_check()

  Description: Checks whether the connection data buffered in the pool is consistent with pgxc_node.

  Return type: Boolean.

- pgxc_pool_reload()

  Description: Updates the connection information buffered in the pool.

  Return type: Boolean.

- reload_active_coordinator()

  Description: Updates the connection information buffered in the pool for all active CNs.

  Return type: void.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- pgxc_lock_for_backup()

  Description: Locks a cluster for taking backup that would be restored on the new node to be added.

  Return type: Boolean.

  Note: Only users with the SYSADMIN permission can call this function.

  NOTE

  pgxc_lock_for_backup locks a cluster before gs_dump or gs_dumpall is used to back up the cluster. After a cluster is locked, operations changing the system structure are not allowed. This function does not affect DML statements.

- pg_pool_validate(clear bool, node_name text)

  Description: Displays invalid connections in the pooler between the CN and node_name. When the value of **clear** is **true**, invalid connections are cleared.

  Return type: record.

- gs_validate_node_conn(validate_type cstring, validate_node_name cstring)

  Description: Displays or clears the connections received by the current node from a specified node.

  Return type: record.

Table 1-183 gs_validate_node_conn parameters

Category	Parameter	Type	Description
Input parameter	validate_type	cstring	Specifies an input parameter type. • **'check'**: displays the connections received by the current node from a specified node. • **'clear'**: clears the connections received by the current node from a specified node.
Input parameter	validate_node_name	cstring	Specifies a node name.
Output parameter	pid	bigint	Displays the ID of a thread where the current node receives connections from the specified node. If the thread is from a thread pool, the value is **0**.
Output parameter	sessionid	bigint	Displays the ID of a session where the current node receives connections from the specified node. If the thread is not from a thread pool, the value is **0**.
Output parameter	node_name	text	Displays the name of a node from which the current node receives connections.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- pgxc_pool_connection_status()

  Description: Checks whether the pooler connection status is **normal**.

  Return type: Boolean.

- pg_nodes_memory()

  Description: Queries the memory usage of all nodes.

  Return type: record.

- table_skewness(text)

  Description: Queries the percentage of table data among all nodes. This function is not applicable to hash bucket tables.

  Parameter: name of the table to be queried (text type).

  Return type: record.

- table_skewness(text, text, text)

  Description: Queries the percentage of a specified column in the table data among all nodes.

  Parameters: name of the table to be queried, specified column name, and number of records in the specified table. The default value is **0**, indicating that all records are queried. All parameters are of the text type.

  Return type: record.

  Return value description: Node ID, number of data rows in a specified column, and percentage of the data volume of the current node to the total data volume

  Example:

  ```
  -- Return the distribution of the first five rows of data in the column a of the table t on a node.
  gaussdb=# SELECT table_skewness('t', 'a',5);
   table_skewness
  ----------------
   (1,3,60.000%)
   (2,2,40.000%)
  (2 rows)

  -- Return the distribution of all data in the column a of the table t on a node.
  gaussdb=# SELECT table_skewness('t', 'a');
   table_skewness
  ----------------
   (1,7,70.000%)
   (2,2,20.000%)
   (0,1,10.000%)
  (3 rows)
  ```

- table_skewness_with_schema(text, text)

  Description: Checks the proportion of table data on all nodes. The function is the same as that of **table_skewness(text)**.

  text indicates that the types of the schema name and table name for the table to be queried are both text.

  Return type: record.

- table_data_skewness(colrecord, type)

  Description: Queries the node where the table data is located.

  Parameters:

  – **colrecord**: column name record of the table to be queried. The value is of the record type.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

  - **type**: hash distribution type. For details about its value, see the description of the **pclocatortype** column in the **PGXC_CLASS** system catalog.

  Return type: smallint.

  Example:

```
-- Return the node where the index column data of the 'test1' table is located.
gaussdb=# SELECT table_data_skewness(row(index), 'R') FROM test1;
 table_data_skewness
---------------------
                   4
                   3
                   1
                   2
(4 rows)
```

- table_distribution(schemaname text, tablename text)

  Description: Queries the storage space occupied by a specified table on each node.

  text indicates that the types of the schema name and table name for the table to be queried are both text.

  Return type: record.

  NOTE

  - To query the storage distribution of a specified table by using this function, you must have the SELECT permission on the table.
  - The performance of **table_distribution** is better than that of **table_skewness**. Especially, in scenarios with a large amount of data, **table_distribution** is recommended.
  - When you use **table_distribution** and want to view the space usage, you can use **dnsize** or **(sum(dnsize) over ())** to view the percentage.

- table_distribution()

  Description: Queries the storage distribution of all tables in the current database.

  Return type: record.

  NOTE

  - This function involves the query for information about all tables in the database. To execute this function, you must have the administrator rights.
  - Based on the table_distribution() function, GaussDB provides the PGXC_GET_TABLE_SKEWNESS view (see **PGXC_GET_TABLE_SKEWNESS**) as an alternative way to query data skew. You are advised to use this view when the number of tables in the database is less than 10000.

- plan_seed()

  Description: Obtains the seed value of the previous query statement (internal use).

  Return type: int.

- pg_stat_get_env()

  Description: Obtains the environment variable information of the current node. Only users with the SYSADMIN or MONADMIN permission can access the environment variable information.

  Return type: record.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Example:

```
gaussdb=# SELECT pg_stat_get_env();
                                                
```

- pgxc_get_node_env()

  Description: Provides the environment variable information about all nodes in a cluster.

  Return type: record.

- pgxc_disaster_read_set(text)

  Description: Configures node information about the standby cluster for DR on ETCD. Only the standby cluster for DR is available and can be called only by the initial user.

  Return type: Boolean

- pgxc_disaster_read_init()

  Description: Initializes readable DR resources and status information. Only the standby cluster for DR is available and can be called only by the initial user.

  Return type: Boolean

- pgxc_disaster_read_clear()

  Description: Clears readable DR resources and status information. Only the standby cluster for DR is available and can be called only by the initial user.

  Return type: Boolean.

- pgxc_disaster_read_status()

  Description: Provides node information about the standby cluster for DR. This function is available only for the standby cluster for DR.

  Return type: record.

- disaster_read_set_cn_status()

  Description: Updates the CN active status information during DR read. Only the standby cluster for DR is available.

  Return type: Boolean

  Example:

  ```
  gaussdb=# SELECT
  g_catalog.disaster_read_set_cn_status('44000000000
  ```

```
----------------------------
 t
(1 row)
```

- gs_switch_relfilenode()

  Description: Exchanges meta information of two tables or partitions. (This is only used for the redistribution tool. An error message is displayed when the function is directly used by users).

  Return type: int.

  NOTE

  This function may cause clearing of statistics. You are advised to collect statistics again after this function is called.

- pg_catalog.plancache_clean()

  Description: Clears the global plan cache that is not used on the current node. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

  Return type: Boolean.

- DBE_PERF.global_plancache_clean()

  Description: Clears the global plan cache that is not used on all nodes. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

  Return type: Boolean

- pg_catalog.global_plancache_set_invalid(hashkey, unique_sql_id)

  Description: Manually invalidates the GPC cache plan of the current node using the input parameters **hashkey** and **unique_sql_id** of the bigint type. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

  Return type: text.

  Example:

  ```
  -- Obtain hash_value from the dbe_perf.global_plancache_status view as the first input parameter and unique_sql_id as the second input parameter.
  gaussdb=# SELECT * FROM pg_catalog.global_plancache_set_invalid(3928396421,3641111755);
   global_plancache_set_invalid
  ------------------------------
   Execution succeeded.
  (1 row)
  ```

  NOTE

  - You are advised not to use this function because it increases the number of hard parsing times and affects performance.
  - The function does not support the invalidation of the plan whose **unique_sql_id** is **0**.

- pg_catalog.global_plancache_show_plan(hashkey, unique_sql_id)

  Description: Uses the input parameters **hashkey** and **unique_sql_id** of the bigint type to view the corresponding GPC cache plan. After a cluster is created, by default, you must have the MONADMIN permission to query this function. This function does not support the explain_perf_mode pretty mode.

  Return type: text.

  Example:

```
-- Obtain hash_value from the dbe_perf.global_plancache_status view as the first input parameter
and unique_sql_id as the second input parameter.
gaussdb=# SELECT * FROM pg_catalog.global_plancache_show_plan(3928396421,3641111755);
      global_plancache_show_plan
----------------------------------------
 Result  (cost=0.00..0.01 rows=1 width=0)+

(1 row)
```

NOTE

The function does not display the plan whose **unique_sql_id** is **0**.

- copy_error_log_create()

  Description: The error table required by the COPY FROM error tolerance mechanism has been changed to the system catalog created during initialization. Therefore, the current function always returns **true** for compatibility.

  Return type: Boolean.

  Table 1-184 pg_catalog.pgxc_copy_error_log information

Column	Type	Description
relname	character varying	Table name in the form of *Schema name*.*Table name*
begintime	timestamp with time zone	Time when a data format error was reported.
filename	character varying	Name of the source data file where a data format error occurs.
lineno	bigint	Number of the row where a data format error occurs in a source data file.
rawrecord	text	Raw record of a data format error in the source data file.
detail	text	Error details.
custom_id	text	Value of **copy_custom_id**, which indicates the customized ID information to be imported.

- pgxc_copy_error_func(boolean need_union, boolean only_dn)

  Description: Queries the content in the pg_catalog.gs_copy_error_log catalog on each node and returns the content. The names and data types of the columns in the return value **record** correspond to those in the pg_catalog.gs_copy_error_log catalog.

  Return type: setof record.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 1-185 pgxc_copy_error_func parameters

Parameter	Type	Description
need_union	Boolean	• **true**: queries data in both the pg_catalog.gs_copy_error_log and pg_catalog.gs_copy_error_old catalogs and performs the union_all operation. • **false**: queries only data in the pg_catalog.gs_copy_error_log catalog.
only_dn	Boolean	• **true**: queries only data on all DNs. • **false**: queries data on all nodes.

- gs_copy_error_insert(cstring relname, cstring begintime, cstring filename, bigint lineno, cstring rawrecord, cstring detail, cstring custom_id)

  Description: Inserts data into the pg_catalog.gs_copy_error_log catalog on a DN. This function is intended for internal use during COPY operations; users should not call it directly.

  Return type: Boolean.

  Table 1-186 gs_copy_error_insert parameters

Parameter	Type	Description
relname	cstring	Table name in the form of *Schema name*.*Table name*
begintime	cstring	Time when a data format error was reported.
filename	cstring	Name of the source data file where a data format error occurs.
lineno	bigint	Number of the row where a data format error occurs in a source data file.
rawrecord	cstring	Raw record of a data format error in the source data file.
detail	cstring	Error details.
custom_id	cstring	Value of **copy_custom_id**, which indicates the customized ID information to be imported.

- gs_copy_summary_func(boolean need_union)

  Description: Queries the content in the pg_catalog.gs_copy_summary_log catalog on the current node and returns the content. Currently, this function is not supported.

  Return type: setof record.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 1-187 gs_copy_summary_func parameters

Parameter	Type	Description
need_union	Boolean	• **true**: queries data in both the pg_catalog.gs_copy_summary_log and pg_catalog.gs_copy_summary_old catalogs and performs the union_all operation. • **false**: queries only data in the pg_catalog.gs_copy_summary_log catalog.

- pg_stat_get_data_senders()

  Description: Provides detailed information about the data-copy sender thread active at the moment.

  Return type: record.

- textlen()

  Description: Provides the method of querying the logical length of text.

  Return type: int.

- threadpool_status()

  Description: Displays the status of worker threads and sessions in the thread pool.

  Return type: record.

- get_local_active_session()

  Description: Provides sampling records of historical active sessions stored in the memory by current node. Users with the SYSADMIN or MONADMIN permission can view all historical active session records of the current node. Common users can view the historical active session records of the current session.

  Return type: record.

- dbe_perf.get_global_gs_asp(timestamp,timestamp)

  Description: Provides sampling records of the historical active sessions stored in the gs_asp system catalog of all nodes. The **event_start_time**, **current_xid**, and **top_xid** columns are added to GaussDB Kernel 505.0. After GaussDB Kernel is upgraded to GaussDB Kernel 505.0 or later, the columns cannot be queried during the upgrade observation period.

  Return type: record.

- get_wait_event_info()

  Description: Provides detailed information about the wait event.

  Return type: record.

- dbe_perf.get_datanode_active_session(text)

  Description: Provides sampling records of historical active sessions stored in the memory of primary DN, which is queried from CN. The **event_start_time**, **current_xid**, and **top_xid** columns are added to GaussDB Kernel 505.0. After GaussDB Kernel is upgraded to GaussDB Kernel 505.0 or later, the columns cannot be queried during the upgrade observation period.

  Return type: record.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Note: This function queries the records in the DBE_PERF.LOCAL_ACTIVE_SESSION view (see **DBE_PERF.LOCAL_ACTIVE_SESSION**) on the target DN and matches the records with those in the DBE_PERF.LOCAL_ACTIVE_SESSION view on all CNs to obtain the query string. Therefore, a large amount of memory is occupied.

- dbe_perf.get_datanode_active_session_hist(text,timestamp,timestamp)

  Description: Provides sampling records of historical active sessions stored in the gs_asp system catalog of primary DN, which is queried from CN. The **event_start_time**, **current_xid**, and **top_xid** columns are added to GaussDB Kernel 505.0. After GaussDB Kernel is upgraded to GaussDB Kernel 505.0 or later, the columns cannot be queried during the upgrade observation period.

  Return type: record.

  Note: This function queries the gs_asp records of a specified period on the target DN. If the period is specified too long, too many records will be queried, which takes a long time.

- generate_wdr_report(begin_snap_id bigint, end_snap_id bigint, report_type cstring, report_scope cstring, node_name cstring)

  Description: Generates a system diagnosis report based on two snapshots. By default, the initial user or MONADMIN can access the report. The result can be queried only in the system database but cannot be queried in the user database.

  Return type: text.

  Table 1-188 generate_wdr_report parameters

Parameter	Description	Value Range
begin_snap_id	Snapshot ID that starts the diagnosis report period.	1~9,223,372,036,854,775,807
end_snap_id	Snapshot ID that ends the diagnosis report period. By default, the value of **end_snap_id** is greater than that of **begin_snap_id**.	1~9,223,372,036,854,775,807
report_type	Specifies the type of the generated report.	• **summary** • **detail** • **all**: Both **summary** and **detail** are included.
report_scope	Specifies the scope for a report to be generated.	• **cluster**: database-level information • **node**: node-level information

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Description	Value Range
node_name	• If **report_scope** is set to **node**, this parameter is set to the name of the corresponding node. You can run the **SELECT * FROM pg_node_env;** command to query the node name. • If **report_scope** is set to **cluster**, the value can be omitted, left blank, or **NULL**.	• **cluster**: omitted, empty, or NULL. • **node**: node name in GaussDB.

- generate_wdr_db_report(db_name cstring, begin_snap_id bigint, end_snap_id bigint, report_type cstring, report_scope cstring, node_name cstring)

  Description: Generates database-level system diagnosis reports based on two snapshots. You need to run the command in the system database. By default, the initial user or users with the MONADMIN permission can access the database. The result can be queried only in the system database but cannot be queried in the user database.

  Return type: record.

  Table 1-189 generate_wdr_db_report parameters

Parameter	Description	Value Range
db_name	Specifies the name of a database.	N/A
begin_snap_id	Snapshot ID that starts the diagnosis report period.	1~9,223,372,036,854,775,807
end_snap_id	Snapshot ID that ends the diagnosis report period. By default, the value of **end_snap_id** is greater than that of **begin_snap_id**.	1~9,223,372,036,854,775,807
report_type	Specifies the type of the generated report.	• **summary** • **detail** • **all**: Both **summary** and **detail** are included.
report_scope	Specifies the scope for a report to be generated.	• **cluster**: database-level information • **node**: node-level information

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Description	Value Range
node_name	• If **report_scope** is set to **node**, this parameter is set to the name of the corresponding node. You can run the **SELECT * FROM pg_node_env;** command to query the node name. • If **report_scope** is set to **cluster**, the value can be omitted, left blank, or **NULL**.	• **cluster**: omitted, empty, or NULL. • **node**: node name in GaussDB.

- create_wdr_snapshot()

  Description: Manually generates system diagnosis snapshots. This function requires the SYSADMIN permission and can be executed only on the CCN.

  Return type: text.

- kill_snapshot()

  Description: Kills the WDR snapshot backend thread. Users who call this function must have the SYSADMIN permission or the REPLICATION permission, or inherit permissions of the built-in role gs_role_replication.

  Return type: void.

- dbe_perf.generate_asp_report(start_time timestamp with time zone, end_time timestamp with time zone, datanode text, slot_count bigint)

  Description: Generates ASP diagnosis reports based on timestamps and node information, which can be accessed by MONADMIN. **slot_count** indicates the number of time segments for displaying metrics. **datanode** can specify a partition DN (for example, dn_6001_6002_6003) or a DN (dn_6001, dn_6002, or dn_6003). This function can be used only on the CN.

  Return type: text.

- generate_asp_report(start_time timestamp with time zone, end_time timestamp with time zone, slot_count bigint, node_name text)

  Description: Generates ASP based on timestamps, which can be accessed by MONADMIN. **slot_count** indicates the number of time segments for displaying metrics. **node_name** is used to generate the ASP of a specified node. The value can only be the name of the current CN or can be left empty. When the value is left empty, this function is used to generate the report of the current node. This function can be used only on the CN.

  Return type: text.

- dbe_perf.get_active_session_profile(start_ts timestamp with time zone, end_ts timestamp with time zone, need_final boolean,node_name text)

  Description: Queries data in the ASP memory and disk based on timestamps. **need_final** specifies whether to query blocking information. The default value is **false**. **node_name** is used to distinguish the CN, active and standby DNs, for example, cn_5001, dn_6001 or dn_6002. This parameter cannot be left empty. The **event_start_time**, **current_xid**, and **top_xid** columns are added to GaussDB Kernel 505.0. After GaussDB Kernel is upgraded to GaussDB Kernel

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

505.0 or later, the columns cannot be queried during the upgrade observation period.

Return type: record.

- capture_view_to_json(text,integer)

  Description: Saves the view result to the directory specified by GUC: **perf_directory**. If **is_crossdb** is set to **1**, the view is accessed once for all databases. If the value of **is_crossdb** is **0**, the current database is accessed only once. Only users with the SYSADMIN or MONADMIN permission can execute this function.

  Return type: int.

- reset_unique_sql(text,text,bigint)

  Description: Clears the unique SQL statements in the memory of CN/DN. (The SYSADMIN or MONADMIN permission is required.)

  Return type: Boolean

  Table 1-190 reset_unique_sql parameters

Parameter	Type	Description
scope	text	Clearance scope type. The options are as follows: • **'GLOBAL'**: All CNs/DNs are cleared. If the value is **'GLOBAL'**, this function can be executed only on CNs. • **'LOCAL'**: The current node is cleared.
clean_type	text	• **'BY_USERID'**: Unique SQL statements are cleared based on user IDs. • **'BY_CNID'**: Unique SQL statements are cleared based on CN IDs. • **'ALL'**: All data is cleared.
clean_value	int8	Specifies the value to be cleared corresponding to **clean_type**. • If **clean_type** is set to **'BY_USERID'**, the records of the user whose ID is **clean_value** are cleared. • If **clean_type** is set to **'BY_CNID'**, the records of the CN whose ID is **clean_value** are cleared. • If the second parameter is set to **ALL**, the third parameter does not take effect and can be set to any value.

- wdr_xdb_query(db_name_str text, query text)

  Description: Provides the capability of executing local cross-database queries. For example, when logging to the **testdb** database, access tables in the **test** database. Only the initial user has the permission to run this command.

  ```
  SELECT col1 from wdr_xdb_query('dbname=test','select col1 from t1') as dd(col1 int);
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Return type: record.

- pg_wlm_jump_queue(pid int)

  Description: Moves a task to the top of the queue for CN.

  Return type: Boolean.

  - **true**: success
  - **false**: failure

- gs_wlm_switch_cgroup(pid int, cgroup text)

  Description: Moves a job to another Cgroup to change the job priority.

  Return type: Boolean.

  - **true**: success
  - **false**: failure

- pv_session_memctx_detail(threadid tid, MemoryContextName text)

  Description: Records information about the memory context **MemoryContextName** of the thread **tid** into the *threadid*_**timestamp.log** file in the *$GAUSSLOG*/**gs_log/***${node_name}*/**dumpmem** directory. You can obtain the thread ID by querying the **sessid** column in the PV_SESSION_MEMORY_DETAIL view (see **PV_SESSION_MEMORY_DETAIL**). In the officially released version, only the **MemoryContextName** that is an empty string (two single quotation marks indicate that the input is an empty string) is accepted. In this case, all memory context information is recorded. Otherwise, no operation is performed. This function can be executed only by the administrator.

  Return type: Boolean.

  - **true**: success
  - **false**: failure

- pg_shared_memctx_detail(MemoryContextName text)

  Description: Records information about the memory context **MemoryContextName** into the *threadid*_**timestamp.log** file in the *$GAUSSLOG*/**gs_log/***${node_name}*/**dumpmem** directory. Calling this function in the officially released version does not involve any operation. Only the administrator can execute this function.

  Return type: Boolean.

  - **true**: success
  - **false**: failure

- local_aio_completer_stat()

  Description: Displays statistics about the AIO Completer thread in the instance.

  Return type: record.

  Table 1-191 Return values of local_aio_completer_stat

Parameter	Type	Description
node_name	text	Name of the current instance.
tid	int8	ID of the AIO Completer thread.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Type	Description
thread_type	text	AIO Completer thread type (read or write).
aio_submitted_num	int8	Number of committed asynchronous I/O requests of the AIO Completer thread.
aio_completed_num	int8	Number of completed asynchronous I/O requests of the AIO Completer thread.
aio_incompleted_num	int8	Number of asynchronous I/O requests that are not completed of the AIO Completer thread.
slot_count_left	int8	Indicates the number of idle slots.

- local_aio_slot_usage_status()

  Description: Displays statistics about asynchronous I/O commit slots in the instance.

  Return type: record.

  Table 1-192 Return values of local_aio_slot_usage_status

Parameter	Type	Description
node_name	text	Name of the current instance.
slot_id	int4	Slot ID.
slot_type	char	Slot type. The value can be **r** (read) or **w** (write).
status	bool	Slot usage status.
buffer_id	int8	Buffer ID corresponding to the slot.
relfilenode_blocknum	text	Position of the physical page where the buffer corresponding to the slot is located.
lsn	int8	LSN corresponding to the page.
submitted_time	int8	Time when a page is committed asynchronously.
elapsed_time	int8	Waiting time of the page.

- remote_aio_completer_stat()

  Description: Displays statistics about the AIO Completer thread in other instances (used only on CNs).

  Return type: record.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 1-193 Return values of remote_aio_completer_stat

Parameter	Type	Description
node_name	text	Name of another instance.
tid	int8	ID of the AIO Completer thread.
thread_type	text	AIO Completer thread type (read or write).
aio_submitted_num	int8	Number of committed asynchronous I/O requests of the AIO Completer thread.
aio_completed_num	int8	Number of completed asynchronous I/O requests of the AIO Completer thread.
aio_incompleted_num	int8	Number of asynchronous I/O requests that are not completed of the AIO Completer thread.
slot_count_left	int8	Indicates the number of idle slots.

- remote_aio_slot_usage_status()

  Description: Displays statistics about asynchronous I/O commit slots in other instances.

  Return type: record.

  Table 1-194 Return values of remote_aio_slot_usage_status

Parameter	Type	Description
node_name	text	Name of another instance.
slot_id	int4	Slot ID.
slot_type	char	Slot type. The value can be **r** (read) or **w** (write).
status	bool	Slot usage status.
buffer_id	int8	Buffer ID corresponding to the slot.
relfilenode_blocknum	text	Position of the physical page where the buffer corresponding to the slot is located.
lsn	int8	LSN corresponding to the page.
submitted_time	int8	Time when a page is committed asynchronously.
elapsed_time	int8	Waiting time of the page.

- gs_get_io_type()

  Description: Displays the I/O mode of the instance.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Return type: text.

- **BIO**: The instance is running in BIO mode (ADIO is disabled).
- **DIO**: The instance is running in DIO mode (ADIO is enabled).
- **BIO->DIO (In progress)**: The current instance is switching from the BIO mode to the DIO mode.

- local_bgwriter_stat()

  Description: Displays the page flushing information of the bgwriter thread of the current instance.

  Return type: record.

  Table 1-195 Return values of local_bgwriter_stat

Parameter	Type	Description
node_name	text	Name of the current instance.
bgwr_actual_flush_total_num	int8	Total number of dirty pages flushed by the bgwriter thread since the last restart (unit: pages).
bgwr_last_flush_num	int4	Number of dirty pages flushed by the bgwriter thread since the last dirty page flushing (unit: pages).
candidate_slots	int4	Number of pages that can be used for cache page requests in the candidate queue.
get_buffer_from_list	int8	Number of cache pages obtained from the candidate queue since the last restart (unit: pages).
get_buf_clock_sweep	int8	Number of cache pages obtained from the clock sweep mechanism since the last restart (unit: pages).

- local_candidate_stat()

  Description: Displays the number of pages in the candidate buffer chain of this instance and buffer elimination information, including the normal buffer pool and segment buffer pool.

  Return type: record.

- gs_buffer_manager_info()

  Description: Prints the number of buffer page accesses and misses in the current database since the last time this function was called (or since startup if it has never been executed), as well as the read rate (that is, 1 – Hit rate), and the sleep time for each round of the elimination queue provided by the intelligent elimination algorithm.

  Total access: %lu, Total read: %lu, Read rate: %0.3f, Sleep time :%u

  Return type: text.

- local_ckpt_stat()

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description: Displays the information about checkpoints and flushing pages of the current instance.

Return type: record.

- local_double_write_stat()

  Description: Displays the doublewrite file status of the current instance.

  Return type: record.

  Table 1-196 local_double_write_stat parameters

Parameter	Type	Description
node_name	text	Instance name
curr_dwn	int8	Sequence number of the doublewrite file
curr_start_page	int8	Start page for restoring the doublewrite file
file_trunc_num	int8	Number of times that the doublewrite file is reused
file_reset_num	int8	Number of reset times after the doublewrite file is full
total_writes	int8	Total number of I/Os of the doublewrite file
low_threshold_writes	int8	Number of I/Os for writing doublewrite files with low efficiency (the number of I/O flushing pages at a time is less than 16)
high_threshold_writes	int8	Number of I/Os for writing doublewrite files with high efficiency (the number of I/O flushing pages at a time is more than 421)
total_pages	int8	Total number of pages that are flushed to the doublewrite file area
low_threshold_pages	int8	Number of pages that are flushed with low efficiency
high_threshold_pages	int8	Number of pages that are flushed with high efficiency
file_id	int8	ID of the current doublewrite file.

- local_pagewriter_running_stat()

  Description: Displays the running status of the threads responsible for batch dirty page flushing in the instance.

  Return type: record.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 1-197 local_pagewriter_running_stat() parameters

Category	Parameter	Type	Description
Output parameter	nodename	text	Instance name
Output parameter	tid	int8	Thread ID of the pagewriter.
Output parameter	type	text	Thread type.
Output parameter	extre_start_loc	int8	Position of the ultimate dirty page flushing.
Output parameter	extre_left_size	int4	Number of dirty pages skipped in the previous round of ultimate dirty page flushing.
Output parameter	full_ckpt	bool	Specifies whether the full dirty page flushing mode is enabled.
Output parameter	shutdown_progress	bool	Exit status.
Output parameter	buf_id_start	int4	Start buffer ID of the scanning thread range.
Output parameter	buf_id_end	int4	End buffer ID of the scanning thread.
Output parameter	standby_buf_start_id	int4	Start buffer ID of the scanning thread with read on standby.
Output parameter	standby_buf_end_id	int4	End buffer ID of the scanning thread with read on standby.
Output parameter	exception_count	int4	Number of historical thread exceptions.
Output parameter	recent_exception_time	timestamptz	Timestamp of the latest exception.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- local_pagewriter_accumulate_stat()

  Description: Displays bandwidth and lock conflict statistics for the batch dirty page flushing threads of the instance within the specified time range.

  Return type: record.

  Table 1-198 local_pagewriter_accumulate_stat() parameters

Category	Parameter	Type	Description
Input parameter	last_time	int8	Statistical period (seconds).
Output parameter	nodename	text	Instance name
Output parameter	tid	int8	Thread ID of the pagewriter.
Output parameter	type	text	Thread type.
Output parameter	bandwidth	float8	Average bandwidth (MB/s).
Output parameter	lock_conflict_count	int8	Number of pages skipped due to content lock conflicts.
Output parameter	avg_pagewriter_sleep	float8	Actual average dirty page flushing period.

- local_dirty_queue_advance_stat()

  Description: Displays the update progress of the dirty page queue of the current instance.

  Return type: record.

  Table 1-199 local_dirty_queue_advance_stat() parameters

Category	Parameter	Type	Description
Output parameter	nodename	text	Instance name

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Category	Parameter	Type	Description
Output parameter	dirty_queue_head	int8	Position of the dirty page queue header.
Output parameter	dirty_queue_tail	int8	Position of the dirty page queue tail.
Output parameter	dirty_queue_size	int8	Size of the dirty page queue.
Output parameter	dirty_queue_full	bool	Specifies whether the dirty page queue is full.
Output parameter	head_buffer	int4	Buffer value of the dirty page queue header.
Output parameter	head_buffer_lsn	text	Page LSN of the dirty page queue header.
Output parameter	head_buffer_content_lock_id	int8	lock_unique_id of the content lock for the dirty page queue head buffer.
Output parameter	head_buffer_io_lock_id	int8	lock_unique_id of the I/O lock for the dirty page queue head buffer.
Output parameter	extre_scan_current	int8	End position of the dirty page queue that has been allocated to the thread for ultimate dirty page flushing.

- local_single_flush_dw_stat()

  Description: Displays the elimination of doublewrite files on a single page in the instance.

  Return type: record.

- local_pagewriter_stat()

  Description: Displays the page flushing information and checkpoint information of the current instance.

  Return type: record.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 1-200 local_pagewriter_stat() parameters

Category	Parameter	Type	Description
Output parameter	node_name	text	Instance name.
Output parameter	pgwr_actual_flush_total_num	int8	Total number of dirty pages flushed from the startup to the current time.
Output parameter	pgwr_last_flush_num	int4	Number of dirty pages flushed in the previous batch.
Output parameter	remain_dirty_page_num	int8	Estimated number of remaining dirty pages.
Output parameter	queue_head_page_rec_lsn	text	**recovery_lsn** of the first dirty page in the dirty page queue of the current instance.
Output parameter	queue_rec_lsn	text	**recovery_lsn** of the dirty page queue of the current instance.
Output parameter	current_xlog_insert_lsn	text	Position where Xlogs of the current instance are written. This parameter is invalid for a standby node.
Output parameter	ckpt_redo_point	text	Checkpoint of the current instance.

- local_redo_stat()

  Description: Displays the replay status of the current standby instance.

  Return type: record.

  Note: The returned replay status includes the current replay position and the replay position of the minimum restoration point.
- local_recovery_status()

  Description: Displays log flow control information about the primary and standby nodes.

  Return type: record.
- local_rto_status()

  Description: Displays log flow control information about the primary and standby nodes.

  Return type: record.
- gs_wlm_switch_cgroup(sess_id int8, cgroup name)

  Description: Switches the Cgroup of a specified session.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Return type: record.

- comm_client_info()

  Description: Queries active client connections of a single node. For details about the returned result, see **COMM_CLIENT_INFO**.

  Return type: SETOF record

- pg_get_flush_lsn()

  Description: Returns the position of the Xlog flushed from the current node.

  Return type: text.

- pg_get_sync_flush_lsn()

  Description: Returns the position of the Xlog flushed by the majority on the current node.

  Return type: text.

- pgxc_wlm_rebuild_user_resource_pool()

  Description: Rebuilds user and resource pool cache information. Only system administrators can execute this function.

  Return type: Boolean.

- locktag_decode(locktag text)

  Description: Parses lock details from **locktag**.

  Example:

```
gaussdb=# SELECT locktag_decode('271b:0:0:0:0:6');
                locktag_decode
-----------------------------------------------
 locktype:transactionid, transactionid:10011
(1 row)
```

  Return type: text.

- disable_conn(disconn_mode text, host text, port integer)

  Description: Specifies that the CM Agent processes commands delivered by the CM Server. When a DN is selected as the primary DN, it is configured to reject connections to all DNs, forcibly connect to a DN, or connect to all DNs in polling mode. Only the initial user and system administrator can call this function.

  Return type: void.

  Table 1-201 disable_conn parameters

Parameter	Type	Description
disconn_mode	text	DN connection mode: • **'prohibit_connection'**: rejects to connect to all DNs. • **'specify_connection'**: forcibly connects to a DN. • **'polling_connection'**: connects to all DNs in polling mode.
host	text	IP address of the DN

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Type	Description
port	integer	Port number of the DN

- dbe_perf.get_global_full_sql_by_timestamp(start_timestamp timestamp with time zone, end_timestamp timestamp with time zone)

  Description: Obtains full SQL information about a cluster. The result can be queried only in the system database but cannot be queried in the user database.

  Return type: record.

  Table 1-202 dbe_perf.get_global_full_sql_by_timestamp parameters

Parameter	Type	Description
start_timestamp	timestamp with time zone	Start point of the SQL start time range.
end_timestamp	timestamp with time zone	End point of the SQL start time range. An error is reported during function execution if **start_timestamp** is greater than or equal to **end_timestamp**.

- dbe_perf.get_global_slow_sql_by_timestamp(start_timestamp timestamp with time zone, end_timestamp timestamp with time zone)

  Description: Obtains cluster-level slow SQL information. The result can be queried only in the system database but cannot be queried in the user database.

  Return type: record.

  Table 1-203 dbe_perf.get_global_slow_sql_by_timestamp parameters

Parameter	Type	Description
start_timestamp	timestamp with time zone	Start point of the SQL start time range.
end_timestamp	timestamp with time zone	End point of the SQL start time range. An error is reported during function execution if **start_timestamp** is greater than or equal to **end_timestamp**.

- statement_detail_decode(detail text, format text, pretty boolean)

  Description: Parses the **details** column in a full or slow SQL statement. The result can be queried only in the system database but cannot be queried in the user database.

  Return type: text.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 1-204 statement_detail_decode parameters

Parameter	Type	Description
detail	text	Set of events generated by the SQL statement (unreadable).
format	text	Parsing output format. The value is **plaintext**.
pretty	Boolean	Specifies whether to display the text in pretty format when **format** is set to **plaintext**. The options are as follows: • **true**: Events are separated by "\n". • **false**: Events are separated by commas (,).

- pgxc_get_csn(tid)

  Description: Returns the transaction commit sequence number (CSN) corresponding to a given transaction ID.

  Return type: int8.

- pgxc_get_csn(tid, bucketid)

  Description: Returns the transaction commit sequence number (CSN) corresponding to the transaction ID of the specified bucket ID. The input parameter **bucketid** indicates the physical bucket ID of the hash bucket table. For an ordinary table, the value is **–1**.

  Return type: int8.

- get_global_user_transaction()

  Description: Returns transaction information about each user on all nodes.

  Return types: node_name name, usename name, commit_counter bigint, rollback_counter bigint, resp_min bigint, resp_max bigint, resp_avg bigint, resp_total bigint, bg_commit_counter bigint, bg_rollback_counter bigint, bg_resp_min bigint, bg_resp_max bigint, bg_resp_avg bigint, bg_resp_total bigint, and dbid oid.

- pg_collation_for()

  Description: Returns the sorting rule corresponding to the input parameter string.

  Parameter: any. (Explicit type conversion is required for constants.)

  Return type: text.

- pgxc_unlock_for_sp_database(databasename text)

  Description: Releases a specified database lock.

  Parameter: **databasename** (database name).

  Return type: Boolean.

  Note: Only users with the SYSADMIN permission can call this function.

- pgxc_lock_for_sp_database(databasename text)

  Description: Locks a specified database.

  Parameter: **databasename** (database name).

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Return type: Boolean.

Note: Only users with the SYSADMIN permission can call this function.

- pgxc_unlock_for_transfer(schemaname text)

  Description: Releases the lock used for data transmission (data redistribution).

  Parameter: **schemaname** (schema name).

  Return type: Boolean.

  Note: Only users with the SYSADMIN permission can call this function.

- pgxc_lock_for_transfer(schemaname text)

  Description: Locks a database for data transmission (data redistribution).

  Parameter: **schemaname** (schema name).

  Return type: Boolean.

  Note: Only users with the SYSADMIN permission can call this function.

- gs_comm_proxy_thread_status()

  Description: Collects statistics on data packets sent and received by the proxy communications library **comm_proxy** when a user-mode network is configured for the cluster. This function is not supported in the current version.

  Parameter: nan.

  Return type: record.

- gs_catalog_attribute_records()

  Description: Returns the definition of each column in a system catalog specified by OID. Only ordinary system catalogs whose OIDs are less than 10000 are supported. Indexes and TOAST tables are not supported.

  Parameter: OID of a system catalog.

  Return type: record.

- dynamic_func_control(scope text, function_name text, action text, "{params}" text[])

  Description: Dynamically enables built-in functions. Currently, only full SQL statements can be dynamically enabled.

  Return type: record.

Table 1-205 dynamic_func_control parameters

Parameter	Type	Description
scope	text	Scope where the function is to be dynamically enabled. Currently, only **'GLOBAL'** and **'LOCAL'** are supported.
function_name	text	Function name. Currently, only **'STMT'** and **'GSTRACE'** are supported.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Type	Description
action	text	When **function_name** is set to **'STMT'**, **action** can only be set to **TRACK**, **UNTRACK**, **LIST**, or **CLEAN**. All users can use the **LIST** option. Other options can be used only when the SYSADMIN or MONADMIN permission is granted. • **TRACK**: records the full SQL information of normalized SQL statements. • **UNTRACK**: cancels the recording of full SQL information of normalized SQL statements. • **LIST**: lists normalized SQL information that is recorded in the current track. • **CLEAN**: cleans normalized SQL information that is recorded in the current track. When **function_name** is set to **'GSTRACE'**, **action** can only be set to **TRACE_SQL**, **TRACE_FUNC**, **UNTRACE_SQL**, **UNTRACE_FUNC**, **UNTRACE_ALL_SQL**, **UNTRACE_ALL_FUNC**, **LIST_TRACE_SQL**, **LIST_TRACE_FUNC**, **SHOW_TRACED_FUNC**, **SHOW_MANGLED_FUNC**, or **SHOW_SUBFUNC**. • **TRACE_SQL**: GSTrace registers the specified SQL statement to be traced. • **TRACE_FUNC**: GSTrace registers the specified function to be traced. • **UNTRACE_SQL**: GSTrace unregisters the specified SQL statement to be traced. • **UNTRACE_FUNC**: GSTrace unregisters the specified function to be traced. • **UNTRACE_ALL_SQL**: GSTrace cancels all SQL statements. • **UNTRACE_ALL_FUNC**: GSTrace cancels all functions. • **LIST_TRACE_SQL**: GSTrace views the configured SQL statements to be traced. • **LIST_TRACE_FUNC**: GSTrace views the configured functions to be traced. • **SHOW_TRACED_FUNC**: GSTrace views the status of the functions being traced. • **SHOW_MANGLED_FUNC**: GSTrace views the mangled name of a specified function. • **SHOW_SUBFUNC**: GSTrace specifies all subfunctions of a function.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Type	Description
params	text[]	When **function_name** is set to **'STMT'**, the **params** values corresponding to different actions are set as follows: • **TRACK**: **'{"Normalized SQLID", "L0/L1/L2"}'** • **UNTRACK**: **'{"Normalized SQLID"}'** • **LIST**: **'{}'** • **CLEAN**: **'{}'** When **function_name** is set to **'GSTRACE'**, the **params** values corresponding to different actions are set as follows: • **TRACE_SQL**: For details, see the input parameter description of the gstrace_reg_sql() function. • **TRACE_FUNC**: For details, see the input parameter description of the gstrace_reg_func() function. • **UNTRACE_SQL**: For details, see the input parameter description of the gstrace_unreg_sql() function. • **UNTRACE_FUNC**: For details, see the input parameter description of the gstrace_unreg_func() function. • **UNTRACE_ALL_SQL**: For details, see the input parameter description of the gstrace_unreg_all_sql() function. • **UNTRACE_ALL_FUNC**: For details, see the input parameter description of the gstrace_unreg_all_func() function. • **LIST_TRACE_SQL**: For details, see the input parameter description of the gstrace_list_configured_sql() function. • **LIST_TRACE_FUNC**: For details, see the input parameter description of the gstrace_list_configured_func() function. • **SHOW_TRACED_FUNC**: For details, see the description of the input parameters of the gstrace_show_traced_func() function. • **SHOW_MANGLED_FUNC**: For details, see the description of the input parameters of the gstrace_show_mangled_func() function. • **SHOW_SUBFUNC**: For details, see the input parameter description of the gstrace_show_subfunc() function.

- gs_parse_page_bypath(path text, blocknum bigint, relation_type text, read_memory boolean)

  Description: Parses a specified table page and returns the path for storing the parsed content.

  Return type: text.

  Note: Only SYSADMIN or OPRADMIN can execute this function. For pages that are not flushed to disks, the actual pages on the disks are empty. Therefore, the parsing result is empty, and the **relation_type** parameter does not take effect.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 1-206 gs_parse_page_bypath parameters

Parameter	Type	Description
path	text	• For an ordinary table or a segment-page ordinary table, the relative path is *Tablespace name*/*Database OID*/*Relfilenode of the table (physical file name)*, for example, **base/16603/16394**. • For the visibility map of an ordinary table, the relative path is *Tablespace name*/*Database OID*/*Visibility map of the ordinary table*. For example, **base/16603/16394_vm**. • For clog files, the parsed content is stored in the **pg_clog** directory. For example: 000000000000. • For csnlog files, the parsed content is stored in the **pg_csnlog** directory. For example: 000000000000. • For undo record files, the relative path is **undo/UNDOPERSISTENCE/zoneid.segno** in the **undo** directory. Example: undo/permanent/00000.0000009. • For undo meta files, the relative path is **undo/UNDOPERSISTENCE/zoneid.meta.segno** in the **undo** directory. Example: undo/permanent/00000.meta.0000004. • You can run the **pg_relation_filepath(table_name text)** command to query the relative path of the table file. To obtain the path of the partitioned table, view the pg_partition system catalog and call **pg_partition_filepath(partition_oid)**. • Valid path formats are as follows: – global/relNode – base/dbNode/relNode – pg_tblspc/spcNode/version_dir/dbNode/relNode

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Type	Description
blocknum	bigint	• **–1**: information about all blocks (forcibly parsed from disks) • **0**–*MaxBlockNumber*: information about the corresponding block • For B-tree/UB-tree indexes, **0** indicates the index meta-page. • For undo record files, the logical block number is used. The block number of the corresponding file is greater than or equal to **segno** x 128 and less than (**segno** + 1) x 128. • For undo meta files, the logical block number is used. The block number of the corresponding file is greater than or equal to **segno** x 4 and less than (**segno** + 1) x 4.
relation_type	text	• **heap**: Astore table • **uheap**: Ustore table • **btree**: B-tree index • **ubtree**: UB-tree index • **vm**: visibility map of the Astore ordinary table • **fsm**: freespace map file of a row-store table • **clog** (commit log): transaction status log • **csnlog** (commit sequence number log): snapshot timestamp log • **undo_slot**: transaction slot information • **undo_record**: undo record information • **indexurq**: indexurq page • **ugin_index**: UGIN • **gin_index**: GIN • **gist_index**: GiST index • **cmap**: cross-page transparent compression metadata • **pg_dw_turbo_compress**: doublewrite buffer for cross-page transparent compression
read_memory	Boolean	• **false**: The system parses the page from the disk file. • **true**: The system attempts to parse the page from the shared buffer. If the page does not exist in the shared buffer, the system parses the page from the disk file.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Example:

```
# Parse the information of all pages in the B-tree index file.
# Before calling the function, ensure that the file path exists based on the parameter description.
gaussdb=# SELECT gs_parse_page_bypath('base/16603/16394', -1, 'btree', false);
                      gs_parse_page_bypath
-----------------------------------------------------------------------
 gs_log_dir/dump/1663_16603_16394_-1.page
(1 row)

# Parse the visibility result of all blocks in the visibility map file.
gaussdb=# SELECT gs_parse_page_bypath('base/12828/16771_vm', -1, 'vm', false);
                       gs_parse_page_bypath
--------------------------------------------------------------------------
 gs_log_dir/dump/1663_12828_16771_-1_vm.page
(1 row)

# Parse the commit log of block 0 in the Clog file.
gaussdb=# SELECT gs_parse_page_bypath('000000000000', 0, 'clog', false);
                      gs_parse_page_bypath
-----------------------------------------------------------------------
 gs_log_dir/dump/000000000000.clog
(1 row)
```

The following is an example of an exception error:

```
# An error is reported when the value of the block number exceeds the value range.
gaussdb=# SELECT gs_parse_page_bypath('base/12828/16777', -10, 'heap', false);
ERROR:  Blocknum should be between -1 and 4294967294.
CONTEXT:  referenced column: gs_parse_page_bypath
```

- gs_xlogdump_lsn(start_lsn text, end_lsn text)

  Description: Parses Xlogs within the specified LSN range and returns the path for storing the parsed content. You can use pg_current_xlog_location() to obtain the current Xlog position.

  Parameters: **start_lsn** (LSN start position) and **end_lsn** (LSN end position).

  Return type: text.

  Note: Only SYSADMIN or OPRADMIN can execute this function.

- gs_xlogdump_xid(c_xid xid)

  Description: Parses Xlogs of a specified XID and returns the path for storing the parsed content. You can use txid_current() to obtain the current XID.

  Parameter: **c_xid** (transaction ID).

  Return type: text.

  Note: Only SYSADMIN or OPRADMIN can execute this function.

- gs_xlogdump_tablepath(path text, blocknum bigint, relation_type text)

  Description: Parses logs corresponding to a specified table page and returns the path for storing the parsed content.

  Return type: text.

  Note: Only SYSADMIN or OPRADMIN can execute this function.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 1-207 gs_xlogdump_tablepath parameters

Parameter	Type	Description
path	text	• For an ordinary table or a segment-page ordinary table, the relative path is *Tablespace name*/*Database OID*/*Relfilenode of the table (physical file name)*. For example, **base/16603/16394**. • For a segment-page hash bucket table, the relative path is *Tablespace name*/*Database OID*/*Logical page number of the segment head*_**b(bucketid)**, for example, **base/16603/16394_b1437**. • You can run the **pg_relation_filepath(table_name text)** command to query the relative path of the table file. To obtain the path of the partitioned table, view the pg_partition system catalog and call **pg_partition_filepath(partition_oid)**. • Valid path formats are as follows: – global/relNode – base/dbNode/relNode – pg_tblspc/spcNode/version_dir/dbNode/relNode For hash bucket tables, add _**b(bucketid)** to the end of the path.
blocknum	bigint	• **–1**: information about all blocks (forcibly parsed from disks) • **0**–*MaxBlockNumber*: information about the corresponding block
relation_type	text	• **heap**: Astore table • **btree**: B-tree index • **segment**: segment-page table

- gs_xlogdump_parsepage_tablepath(path text, blocknum bigint, relation_type text, read_memory boolean)

  Description: Parses the specified table page and logs corresponding to the table page and returns the path for storing the parsed content. It can be regarded as one execution of **gs_parse_page_bypath** and **gs_xlogdump_tablepath**. The prerequisite for executing this function is that the table file exists. To view logs of deleted tables, call **gs_xlogdump_tablepath**.

  Return type: text.

  Note: Only SYSADMIN or OPRADMIN can execute this function.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 1-208 gs_xlogdump_parsepage_tablepath parameters

Parameter	Type	Description
path	text	• For an ordinary table or a segment-page ordinary table, the relative path is *Tablespace name*/*Database OID*/*Relfilenode of the table (physical file name)*, for example, **base/16603/16394**. • You can run the **pg_relation_filepath(table_name text)** command to query the relative path of the table file. To obtain the path of the partitioned table, view the pg_partition system catalog and call **pg_partition_filepath(partition_oid)**. • Valid path formats are as follows: – global/relNode – base/dbNode/relNode – pg_tblspc/spcNode/version_dir/dbNode/relNode For hash bucket tables, add **_b(bucketid)** to the end of the path.
blocknum	bigint	• **–1**: information about all blocks (forcibly parsed from disks) • **0**–*MaxBlockNumber*: information about the corresponding block
relation_type	text	• **heap**: Astore table • **btree**: B-tree index • **indexurq**: indexurq page
read_memory	Boolean	• **false**: The system parses the page from the disk file. • **true**: The system attempts to parse the page from the shared buffer. If the page does not exist in the shared buffer, the system parses the page from the disk file.

- gs_shared_storage_xlogdump_lsn(start_lsn text, end_lsn text, xlog_file_path text)

  Description: Parses Xlogs within the specified LSN range of a Xlog shared disk and returns the path for storing the parsed content. You can use pg_current_xlog_location() to obtain the current Xlog position.

  Return type: text.

  Note: Only SYSADMIN or OPRADMIN can execute this function.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 1-209 gs_shared_storage_xlogdump_lsn input parameters

Parameter	Type	Description
start_lsn	text	Start LSN of the Xlog to be parsed.
end_lsn	text	End LSN of the Xlog to be parsed.
xlog_file_path	text	(Optional) Path of the shared Xlog disk where the Xlog to be parsed is located. If not specified, Xlogs of all shared disks on the current CN/DN are parsed.

Examples:

```
# Two input parameters are supported: start_lsn and end_lsn.
gaussdb=# SELECT * FROM
gs_shared_storage_xlogdump_lsn('00000000/01000000','00000000/19B08128');
                        output_filepath
-------------------------------------------------------------------
 /var/lib/engine/data1/data/dn_6001/01000000_19b08128_6001.xlog
(1 row)

# Three input parameters are supported: start_lsn, end_lsn, and xlog_file_path.
gaussdb=# SELECT * FROM
gs_shared_storage_xlogdump_lsn('00000000/01000000','00000000/19B08128','/data/nfs/6001');
                        output_filepath
-------------------------------------------------------------------
 /var/lib/engine/data1/data/dn_6001/01000000_19b08128_6001.xlog
(1 row)
```

- gs_shared_storage_ctlinfo()

  Description: Obtains information about the metadata of the shared disk on the current CN/DN.

  Return type: record.

Table 1-210 gs_shared_storage_ctlinfo output parameters

Parameter	Type	Description
xlog_file_path	text	Path of the Xlog shared disk.
system_id	text	The **system_id** value stored on the current shared disk.
term	text	The **term** value stored on the current shared disk.
xlog_file_size	text	Size of the Xlog space on the Xlog shared disk.
insert_tail	text	Minimum valid LSN on the Xlog shared disk.
insert_head	text	Maximum valid LSN on the Xlog shared disk.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Type	Description
shared_storage_flush_lsn	text	Actual flushed LSN on the Xlog shared disk.

Examples:

```
gaussdb=# SELECT * FROM gs_shared_storage_ctlinfo();
 xlog_file_path |      system_id       | term | xlog_file_size |    insert_tail    |    insert_head    |
shared_storage_flush_lsn
----------------+----------------------+------+----------------+-------------------+-------------------
+--------------------------
 /data/nfs/6001 | 18020659526041888084 | 1    | 1073741824     | 00000000/01000000 |
00000000/19B08128 | 00000000/19B08128
(1 row)
```

- gs_index_verify(oid oid, uint32 blkno)

  Description: Checks whether the sequence of keys on the UB-tree index page or index tree is correct.

  Return type: record.

  Table 1-211 gs_index_verify parameters

Parameter	Type	Description
oid	oid	• Index file's relfilenode. It can be queried using **SELECT relfilenode FROM pg_class where relname=***'name'*, where *'name'* indicates the name of the index file.
blkno	uint32	• **0**: indicates that all pages in the index tree are checked. • If the value is greater than 0, the index page whose page code is equal to the value of **blkno** is checked.

- gs_index_recycle_queue(Oid oid, int type, uint32 blkno)

  Description: Parses the UB-tree index recycling queue information.

  Return type: record.

  Table 1-212 gs_index_recycle_queue parameters

Parameter	Type	Description
oid	oid	• Index file relfilenode, which can be queried using **select relfilenode from pg_class where relname='***Index file name***'**.
type	int	• **0**: The entire queue to be recycled is parsed. • **1**: The entire empty page queue is parsed. • **2**: A single page is parsed.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Type	Description
blkno	uint32	ID of the recycling queue page. This parameter is valid only when **type** is set to **2**. The value of **blkno** ranges from 1 to 4294967294.

- gs_stat_wal_entrytable(int64 idx)

  Description: Exports the content of the write-ahead log insertion status table in the Xlog.

  Return type: record.

  Table 1-213 gs_stat_wal_entrytable parameters

Category	Parameter	Type	Description
Input parameter	idx	int64	• **–1**: queries all elements in an array. • **0**–*Maximum value*: content of a specific array element.
Output parameter	idx	uint64	Records the indexes in the corresponding array.
Output parameter	endlsn	uint64	Records the LSN label. Determines whether the Xlog corresponding to the current entry has been completely copied to the WAL buffer. • **0**: Not copied. • Other values: Copied.
Output parameter	lrc	int32	Records the corresponding LRC.
Output parameter	status	uint32	This parameter is reserved in the current version. The query result is **0**.

- gs_walwriter_flush_position()

  Description: Outputs the refresh position of write-ahead logs.

  Return type: record.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 1-214 gs_walwriter_flush_position parameters

Category	Parameter	Type	Description
Output parameter	last_flush_status_entry	int32	Index obtained after the Xlog flushes the tblEntry of the last flushed disk.
Output parameter	last_scanned_lrc	int32	LRC obtained after the Xlog flushes the last tblEntry scanned last time.
Output parameter	curr_lrc	int32	Latest LRC usage in the WALInsertStatusEntry status table. The LRC indicates the LRC value corresponding to the WALInsertStatusEntry when the next Xlog record is written.
Output parameter	curr_byte_pos	uint64	The latest Xlog position after the Xlog is written to the WAL file, which is also the next Xlog insertion point.
Output parameter	prev_byte_size	uint32	Length of the previous Xlog record.
Output parameter	flush_result	uint64	Position of the current global Xlog flush.
Output parameter	send_result	uint64	Xlog sending position on the current host.
Output parameter	shm_rqst_write_pos	uint64	The write position of the LogwrtRqst request in the XLogCtl recorded in the shared memory.
Output parameter	shm_rqst_flush_pos	uint64	The flush position of the LogwrtRqst request in the XLogCtl recorded in the shared memory.
Output parameter	shm_result_write_pos	uint64	The write position of the LogwrtResult request in the XLogCtl recorded in the shared memory.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Category	Parameter	Type	Description
Output parameter	shm_result_flush_pos	uint64	The flush position of the LogwrtResult request in the XLogCtl recorded in the shared memory.
Output parameter	curr_time	text	Current time.

- gs_walwriter_flush_stat(int operation)

  Description: Collects statistics on the frequency of writing and synchronizing WALs, data volume, and Xlog file information.

  Return type: record.

  Table 1-215 gs_walwriter_flush_stat parameters

Category	Parameter	Type	Description
Input parameter	operation	int	• **–1** (default): disables the statistics function. • **0**: enables the statistics function. • **1**: queries statistics. • **2**: resets statistics.
Output parameter	write_times	uint64	Number of times that the Xlog calls the write API.
Output parameter	sync_times	uint64	Number of times that the Xlog calls the sync API.
Output parameter	total_xlog_sync_bytes	uint64	Total number of backend thread requests for writing data to Xlogs.
Output parameter	total_actual_xlog_sync_bytes	uint64	Total amount of Xlogs flushed when the sync API is called.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Category	Parameter	Type	Description
Output parameter	avg_write_bytes	uint32	Amount of Xlogs written each time the XLogWrite API is called.
Output parameter	avg_actual_write_bytes	uint32	Amount of Xlogs written each time the write API is called.
Output parameter	avg_sync_bytes	uint32	Average amount of Xlogs for each sync request.
Output parameter	avg_actual_sync_bytes	uint32	Actual amount of Xlogs flushed each time sync is called.
Output parameter	total_write_time	uint64	Total time of calling the write operation (unit: μs).
Output parameter	total_sync_time	uint64	Total time for calling the sync API (unit: μs).
Output parameter	avg_write_time	uint32	Average time for calling the write API each time (unit: μs).
Output parameter	avg_sync_time	uint32	Average time for calling the sync API each time (unit: μs).
Output parameter	curr_init_xlog_segno	uint64	ID of the latest Xlog segment file.
Output parameter	curr_open_xlog_segno	uint64	ID of the Xlog segment file that is being written.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Category	Parameter	Type	Description
Output parameter	last_reset_time	text	Time when statistics were last collected.
Output parameter	curr_time	text	Current time.

- pg_ls_tmpdir()

  Description: Returns the name, size, and last modification time of each file in the temporary directory (**pgsql_tmp**) of the default tablespace.

  Parameter: nan.

  Return type: record.

  Note: Only SYSADMIN or MONADMIN can execute this function.

Category	Parameter	Type	Description
Output parameter	name	text	File name.
Output parameter	size	int8	File size (unit: byte).
Output parameter	modification	timestamptz	Last file modification time.

- pg_ls_tmpdir(oid)

  Description: Returns the name, size, and last modification time of each file in the temporary directory (**pgsql_tmp**) of the specified tablespace.

  Parameter: oid.

  Return type: record.

  Note: Only SYSADMIN or MONADMIN can execute this function.

Category	Parameter	Type	Description
Input parameter	oid	oid	Tablespace ID.
Output parameter	name	text	File name.
Output parameter	size	int8	File size (unit: byte).

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Category	Parameter	Type	Description
Output parameter	modification	timestamptz	Last file modification time.

- pg_ls_waldir()

  Description: Returns the name, size, and last modification time of each file in the WAL directory.

  Parameter: nan.

  Return type: record.

  Note: Only SYSADMIN or MONADMIN can execute this function.

Category	Parameter	Type	Description
Output parameter	name	text	File name.
Output parameter	size	int8	File size (unit: byte).
Output parameter	modification	timestamptz	Last file modification time.

- gs_stat_anti_cache()

  Description: Returns AntiCache statistics.

  Parameter: nan.

  Return type: record.

Category	Parameter	Type	Description
Output parameter	table_nums	int8	Number of partitions.
Output parameter	table_init_size	int8	Initial size of a partition.
Output parameter	table_max_size	int8	Upper limit of the partition size.
Output parameter	anti_cache_upper_limit_size	int8	Upper limit of the AntiCache size.
Output parameter	anti_cache_size	int8	Real-time AntiCache size.
Output parameter	anti_cache_max_table_size	int8	Real-time maximum partition size.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Category	Parameter	Type	Description
Output parameter	anti_cache_min_table_size	int8	Real-time minimum partition size.

- gs_stat_vlog_buffer()

  Description: Returns verifyLog buffer statistics.

  Parameter: nan.

  Return type: record.

Category	Parameter	Type	Description
Output parameter	vbuffer_write_offset	int8	Vlog write location.
Output parameter	vbuffer_flushed_offset	int8	Vlog disk flushing location.
Output parameter	max_vbuffer_flushed_value	int8	Maximum number of bytes for vlog flushing.
Output parameter	min_vbuffer_flushed_vlaue	int8	Minimum number of bytes for vlog flushing.
Output parameter	ave_vbuffer_flushed_vlaue	int8	Average number of bytes for vlog flushing.
Output parameter	vbuffer_flush_latency	int8	Vlog refresh delay.

- gs_stat_vlog_related_io()

  Description: Returns I/O statistics about read and write operations on the verifylog file.

  Parameter: nan.

  Return type: record.

Category	Parameter	Type	Description
Output parameter	read_data_iops	float8	Number of pages read from files per second.
Output parameter	vlog_read_iops	float8	Number of pages read from vlogs per second.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Category	Parameter	Type	Description
Output parameter	vlog_write_iops	float8	Number of pages written to vlogs per second.

- gs_stat_vlog_file()

  Description: Queries the Verifylog (Vlog) files that have not been recycled.

  Parameter: nan.

  Return type: record.

Category	Parameter	Type	Description
Output parameter	last_recycled_segno	int8	Number of the last Vlog file segment that has been recycled.
Output parameter	target_recycle_segno	int8	Number of the target Vlog file segment to be recycled.
Output parameter	max_segno	int8	Maximum number of Vlog file segments.

- pause_anti_cache_recycle(boolean pause)

  Description: Specifies whether to suspend AntiCache recycling. This function is for internal use only.

  Parameter: **pause** specifies whether to suspend AntiCache recycling. The value is of the Boolean type. If **pause** is set to **true**, AntiCache recycling is suspended. If **pause** is set to **false**, AntiCache recycling is normal.

  Return type: text.

  Examples:

```
# In the internal version, set the AntiCache to be recycled normally.
gaussdb=# select * from pause_anti_cache_recycle(false);
           result
----------------------------
 Anticache recycle resumed.
(1 row)

# In the internal version, set the AntiCache recycling to be suspended.
gaussdb=# select * from pause_anti_cache_recycle(true);
          result
--------------------------
 Anticache recycle paused.
(1 row)

# This parameter cannot be set in the official version.
gaussdb=# select * from pause_anti_cache_recycle(false);
                        result
-------------------------------------------------------
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
This function is not allowed to use in release version.
(1 row)
```

- gs_write_term_log(void)

  Description: Writes a log to record the current **term** value of a DN. The standby DN returns **false**. After the data is successfully written to the primary DN, **true** is returned.

  Return type: Boolean.

- gs_stat_space(bool init)

  Description: Queries the status of extended pages when the INSERT operation is performed on a Ustore table.

  Return type: record.

Category	Parameter	Type	Description
Input parameter	init	bool	Specifies whether to reset the statistics.
Output parameter	access_func	int8	Total number of access times of the relation_get_buffer_for_utuple API.
Output parameter	cache_blk	int8	Number of times that the relation_get_buffer_for_utuple API obtains buffers.
Output parameter	cache_succ	int8	Number of times that the relation_get_buffer_for_utuple API successfully obtains buffers.
Output parameter	nblk_first	int8	Number of times that relation_get_buffer_for_utuple obtains **nblocks-1** for the first time.
Output parameter	nblk_first_succ	int8	Number of times that relation_get_buffer_for_utuple obtains **nblocks-1** successfully for the first time.
Output parameter	nblk_second	int8	Number of times that relation_get_buffer_for_utuple obtains **nblocks-1** for the second time.
Output parameter	nblk_second_succ	int8	Number of times that relation_get_buffer_for_utuple obtains **nblocks-1** successfully for the second time.
Output parameter	fsm_first	int8	Number of times that FSM is accessed for the first time.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Category	Parameter	Type	Description
Output parameter	fsm_first_success	int8	Number of times that FSM is accessed successfully for the first time.
Output parameter	fsm_rewrite	int8	Number of FSM writeback times.
Output parameter	fsm_second	int8	Number of times that FSM is accessed for the second time.
Output parameter	fsm_second_success	int8	Number of times that FSM is accessed successfully for the second time.
Output parameter	prune_count	int8	Number of prune times in relation_get_buffer_for_utuple.
Output parameter	prune_space	int8	Total prune space in relation_get_buffer_for_utuple.
Output parameter	coprune_count	int8	Number of times that joint prune is performed.
Output parameter	coprune_scan_blocks	int8	Total number of pages scanned for joint prune.
Output parameter	coprune_prune_count	int8	Number of joint prune times.
Output parameter	coprune_prune_space	int8	Total space for joint prune.
Output parameter	con_extend_count	int8	Number of concurrent extended pages.
Output parameter	con_extend_time	int8	Total time for concurrent page extension.
Output parameter	single_extend_time	int8	Number of single-page extension times.

Example:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gaussdb=# SELECT * FROM gs_stat_space(false);
 access_func | cache_blk | cache_succ | nblk_first | nblk_first_succ | nblk_second | nblk_second_succ |
fsm_first | fsm_first_success | fsm_rewrite | fsm_
second | fsm_second_success | prune_count | prune_space | coprune_count | coprune_scan_blocks |
coprune_prune_count | coprune_prune_space | con_extend_count
 | con_extend_time | single_extend_count
-------------+-----------+------------+------------+-----------------+--------------+-------------------+-----------
+-------------------+-------------+-----
-------+-------------------+-------------+-------------+---------------+--------------------+--------------------
+---------------------+-----------------
-+-----------------+--------------------
    10082397 |  10082397 |   10082235 |        88 |            78 |       47021 |           47021 |       162
|              74 |      360996 |
360996 |           270948 |       6711 |          0 |        45497 |           222619 |                0
|                0 |            3675
 |       25542884 |             26791
(1 row)
```

Note: Pay special attention to the value of **cache_succ**. If it is small, the system cache is invalid. If the value of **prune_space** is small, the Ustore data page cleaning mechanism may be faulty. If the value of **con_extend_time** is too large, the Ustore concurrent page extension takes a long time.

- gs_redo_upage(directory_path text, backup_path text, blocknum bigint, relation_type text, xlog_path text, lsn text)

  Description: Redoes a specific Ustore data page that is backed up to a specified LSN and verifies the page in this process. If a damaged page is detected, the page is flushed to the disk and the disk flushing path, page LSN, and damage information is returned; otherwise, the page is redone to the specified LSN and flushed to the disk, and the result is returned. Only SYSADMIN or OPRADMIN can execute this function.

  Return type: record.

Category	Parameter	Type	Description
Input parameter	directory_path	text	Specifies the directory for storing the backup file.
Input parameter	backup_path	text	Relative path of the backup table file, which is combined with the directory where the backup file is located to form the complete path of the table file, for example, **base/15635/12488**. If the backup file does not exist, set this parameter to null.
Input parameter	blocknum	bigint	**0** to *MaxBlockNumber*: block number of the corresponding page.
Input parameter	relation_type	text	• **uheap**: Ustore data page • **ubtree**: Ustore index page • **indexurq**: URQ page • **undo_record**: undo record page • **undo_slot**: transaction slot page
Input parameter	xlog_path	text	Absolute path of the archive log directory.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Category	Parameter	Type	Description
Input parameter	lsn	text	The LSN consists of two hexadecimal numbers (32 bits each), which are separated by a slash (/), for example, 2/962D1DF8. If the value is **0**, the latest version is used.
Output parameter	output_filename	text	Path and name of the file to be flushed to the disk.
Output parameter	output_lsn	text	LSN of the last page redo.
Output parameter	corruption_desc	text	Page damage description.

- gs_xlogdump_bylastlsn(last_lsn text, blocknum bigint, relation_type text)

  Description: Inputs a page LSN and block number, parses the WAL corresponding to the LSN, obtains the last LSN of the corresponding block number, continues parsing until the last LSN is 0 or the WAL of an earlier version has been reused and recycled, and flushes the parsed log to a specified path. Only SYSADMIN or OPRADMIN can execute this function. This system function cannot be called by the standby node.

  Return type: text.

Category	Parameter	Type	Description
Input parameter	last_lsn	text	Parses the LSN of a specified page in hexadecimal notation, for example, 12BA/32CDEDDD. The LSN can be obtained using a page parsing tool (such as gs_parse_page_bypath).
Input parameter	blocknum	bigint	Specifies the logical block number of a page. Value range: **–1** to *MaxBlockNumber*. If the block number is set to **–1**, the default block number is obtained from the WAL.
Input parameter	relation_type	text	Specifies the type of the page to be parsed. Valid value: **uheap**, **ubtree**, **heap**, **btree**, **undo_record**, and **undo_slot**.
Output parameter	output_filepath	text	Specifies the path for flushing WAL parsing results to disks.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Example:

```
# Obtain the page LSN.
# Before calling the function, ensure that the file path exists based on the parameter description.
gaussdb=# SELECT * FROM gs_parse_page_bypath('base/15833/16768', 0, 'uheap', false);
                    output_filepath
-----------------------------------------------------------------
 data1/database/cluster/primary/data/1663_15833_16768_0.page
(1 row)
gaussdb=# SELECT * FROM gs_xlogdump_bylastlsn('0/4593570', -1, 'uheap');
                    output_filepath
-----------------------------------------------------------------------
 /data1/database/cluster/primary/data/gs_log/dump/4593570_-1.xlog
(1 row)
gaussdb=# SELECT * FROM gs_xlogdump_bylastlsn('0/4593570', 0, 'ubtree');
ERROR:  The input lsn 0/4593570 related xlog is not ubtree.
```

- dbe_perf.get_full_sql_by_parent_id_and_timestamp(parent_id bigint, start_timestamp timestamp with time zone, end_timestamp timestamp with time zone)

  Description: Obtains the records of database-level full SQL statements and their substatements that execute a stored procedure in a specified period based on **parent_id**. The result can be queried only in the system database but cannot be queried in the user database.

  Return type: record.

Parameter	Type	Description
parent_id	bigint	Specifies the unique_sql_id of the statement calling a stored procedure.
start_timestamp	timestamp with time zone	Start point of the SQL start time range.
end_timestamp	timestamp with time zone	End point of the SQL start time range.

  Example:

```
gaussdb=# CREATE TABLE test(a int,b int);
NOTICE:  The 'DISTRIBUTE BY' clause is not specified. Using 'a' as the distribution column by default.
HINT:  Please use 'DISTRIBUTE BY' clause to specify suitable data distribution column.
CREATE TABLE
gaussdb=# INSERT INTO test values(1,1);
INSERT 0 1
gaussdb=# CREATE PROCEDURE mypro1() as num int;
gaussdb$# begin
gaussdb$# INSERT INTO test values(2,2);
gaussdb$# DELETE FROM test where a = 2;
gaussdb$# end;
gaussdb$# /
CREATE PROCEDURE

- gs_index_dump_read(int8 reset, text out_type)

  Description: Queries the buffer read information generated in the cyclic queue when an index is used to obtain a new page. The buffer read information traverses leaf pages from left to right using the same key as the index page.

  Return type: record.

Category	Parameter	Type	Description
Input parameter	reset	int8	• **0**: The statistics are reset to the initial value 0 and the statistics are collected again. • **1**: The current statistics are displayed.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Category	Parameter	Type	Description
Input parameter	out_type	text	• **urq**: outputs statistics about cyclic queues. • **ubtree**: outputs statistics on index pages. • **all**: outputs all statistics about cyclic queues and index pages.
Output parameter	relfilenode	oid	Index relfilenode corresponding to the maximum buffer read value.
Output parameter	max_count	int8	Maximum buffer read value.
Output parameter	ave_count	int8	Average buffer read value.

NOTE

- Currently, this API supports only Ustore index tables.
- When this API is executed, the reset operation is performed to clear all records and set all records to **0**. If you query the information again, the query result is always 0 until the information is collected next time. The following are query examples:

```
gaussdb=# SELECT * FROM gs_index_dump_read(0, 'all');
relfilenode | max_count | ave_count
--------------+-------------+-------------
|                 |
(1 row)
gaussdb=# SELECT * FROM gs_index_dump_read(1, 'all');
relfilenode | max_count | ave_count
--------------+-------------+-------------
0 |                 0 |                 0
0 |                 0 |                 0
(2 rows)
```

- pg_get_ilmdef(pidx integer)

  Description: Specifies a row-store compression system function, which returns the corresponding policy information based on the input ILM policy index.

  Return type: text.

Category	Parameter	Type	Description
Input parameter	pidx	integer	Sequence number of an ILM policy.
Output parameter	ilm_policy_info	text	Specifies the policy information of an ILM policy.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- gs_shared_storage_flush_stat(int operation)

  Description: Collects statistics on the amount of written data, write speed, write time, amount of read data, read speed, and read time of shared disks.

  Return type: record.

Category	Parameter	Type	Description
Input parameter	operation	int	• **–1**: disables the statistics function. • **0** (default): enables the statistics function. • **1**: queries statistics. • **2**: resets statistics. After the statistics function is disabled and then enabled again, the previous statistics are cleared.
Output parameter	stat_switch	bool	Specifies whether the statistics function is enabled.
Output parameter	write_times	uint64	Number of times that the shared_storage_xlog_copy thread calls the dorado_write_xlog API.
Output parameter	avg_write_bytes	uint32	Amount of Xlogs to be written each time the dorado_write_xlog API is called, in byte.
Output parameter	avg_actual_write_bytes	uint32	Actual amount of Xlogs to be written each time the dorado_write_xlog API is called, in byte.
Output parameter	total_write_time	uint64	Total time for calling the dorado_write_xlog API, in μs.
Output parameter	avg_write_time	uint32	Average time for calling the dorado_write_xlog API each time, in μs.
Output parameter	avg_write_speed	uint32	Average speed of calling the dorado_write_xlog API to write Xlogs, in KB/s.
Output parameter	avg_actual_write_speed	uint32	Actual average speed of calling the dorado_write_xlog API to write Xlogs, in KB/s.
Output parameter	total_write_sleep_time	uint64	Total sleep time of the shared_storage_xlog_copy thread.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Category	Parameter	Type	Description
Output parameter	read_times	uint64	Number of times that the walreceiver thread calls the dorado_read_xlog API.
Output parameter	avg_read_bytes	uint32	Amount of Xlogs to be written each time the dorado_read_xlog API is called, in byte.
Output parameter	avg_actual_read_bytes	uint32	Actual amount of Xlogs to be written each time the dorado_read_xlog API is called, in byte.
Output parameter	total_read_time	uint64	Total time for calling the dorado_read_xlog API, in μs.
Output parameter	avg_read_time	uint32	Average time for calling the dorado_read_xlog API each time, in μs.
Output parameter	avg_read_speed	uint32	Average speed of calling the dorado_read_xlog API to write Xlogs, in KB/s.
Output parameter	avg_actual_read_speed	uint32	Actual average speed of calling the dorado_read_xlog API to write Xlogs, in KB/s.
Output parameter	total_read_sleep_time	uint64	Total sleep time of the walreceiver thread.
Output parameter	stat_start_time	timestamptz	Start time of the statistics. If the statistics are not reset, the value is the start time of GaussDB. If the statistics are reset, the value is the last reset time.
Output parameter	stat_end_time	timestamptz	End time of the current statistics collection. If the statistics collection function is enabled, the value is the current time. If the statistics collection function is disabled, the value is the last time when the statistics collection function is disabled.

Example:

```
gaussdb=# SELECT * FROM gs_shared_storage_flush_stat(1);
 stat_switch | write_times | avg_write_bytes | avg_actual_write_bytes | total_write_time |
avg_write_time | avg_write_speed | avg_actual_write_speed | total_write_sleep_time | read_times | avg
_read_bytes | avg_actual_read_bytes | total_read_time | avg_read_time | avg_read_speed |
avg_actual_read_speed | total_read_sleep_time |        stat_start_time        |        stat_end_time
```

- gs_stat_freespace(Oid relid, Oid partid, char type, int sample_ratio)

  Description: Estimates the bloat rate of a table, partitioned table, or index based on statistics or sampling, and outputs space usage statistics and bloat rate information.

  Return type: record.

Category	Parameter	Type	Description
Input parameter	relation_oid	OID	OID of a data table, main table of the partitioned table, or index to be queried.
Input parameter	partition_oid	OID	OID of a partitioned table, subpartitioned table, or local partitioned index. ● If **relation_oid** refers to a non-partitioned table, non-local partitioned index, or GPI, this parameter is meaningless. ● If **relation_oid** refers to a partitioned table, subpartitioned table, or local partitioned index, and **partition_oid** is set to **0**, information about all partitions will be output.
Input parameter	relation_type	CHAR	Table type: ● **'r'**: The target table is a row-store data table. ● **'i'**: The target table is a row-store index table.
Input parameter	sample_ratio	INT8	Sampling ratio. The value ranges from 0 to 100. ● When **sample_ratio** is set to **0**, **INFO** indicates the bloat rate estimated based on statistics. ● When the value of **sample_ratio** ranges from 1 to 100, **INFO** indicates the bloat rate estimated through sampling.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Category	Parameter	Type	Description
Input parameter	read_memory	BOOL	Specifies whether to read pages from the memory. • **true**: indicates that the page is read from the memory. • **false**: indicates that pages are read from disks. Currently, the value can only be **false**.
Output parameter	OID	OID	OID of the queried data table, partitioned table, subpartitioned table, or index.
Output parameter	INFO	TEXT	• When **sample_ratio** is set to **0**, **INFO** indicates the estimated page bloat rate. • When the value of **sample_ratio** is greater than 0, **INFO** indicates the page usage statistics based on sampling, including the page header length, average tuple length, average number of normal tuples, average number of dead tuples, average number of unused tuples, average number of redirected tuples, and average number of TDs per page (for Ustore data tables), average potential_freespace per page, actual freespace (page upper – page lower), total number of pages in the relation, estimated space occupied by data tables/indexes based on sampling information, and estimated bloat rate of the data table/index based on sampling information.

NOTE

- Currently, this API supports only row-store tables and does not support time series tables, segment-page tables, hash bucket tables, local temporary tables, or global temporary tables. Indexes that do not support table types also do not support space statistics estimation.
- This API is used to query data on a CN. The query result only indicates the statistics and bloat rate estimation of the node, excluding the information about the corresponding DN. To query the DN statistics and bloat rate estimation result, you need to connect to the DN.
- When this API is used on the standby node and the value of **sample_ratio** is **0**, the estimation is based on statistics and the real-time accuracy cannot be ensured.

Example:

```
-- Query ordinary table information.
-- Create tables.
gaussdb=# DROP TABLE IF EXISTS t;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
NOTICE:  table "t" does not exist, skipping

```

execute this function for multiple times until the returned result is 0. If the fastupdate option is not enabled for the index, the pending list will not be cleared, and the result is **0**.

Return type: bigint.

- gs_walrcv_writer_stat(int operation)

  Description: Collects statistics on the frequency of writing and synchronizing WALs received by the standby node, data volume, and Xlog file information.

  Return type: record.

Category	Parameter	Type	Description
Input parameter	operation	int	• **–1** (default): disables the statistics function. • **0**: enables the statistics function. • **1**: queries statistics. • **2**: resets statistics. After the statistics function is disabled and then enabled again, the previous statistics are cleared.
Output parameter	enable_stat	bool	Specifies whether the statistics function is enabled.
Output parameter	total_write_bytes	uint64	Total number of WAL files written to the standby node (unit: byte).
Output parameter	write_count	uint64	Number of times that the standby node writes WAL files.
Output parameter	total_write_time	uint64	Total time for writing WAL files to the standby node (unit: μs).
Output parameter	avg_write_time	uint64	Average time for calling the write API when the standby node writes WAL files each time (unit: μs).
Output parameter	max_write_time	uint64	Maximum duration for calling the write API when the standby node writes WAL files (unit: μs).
Output parameter	avg_write_bytes	uint64	Average value of the WAL file written to the standby node each time (unit: byte).

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Category	Parameter	Type	Description
Output parameter	total_sync_time	uint64	Total time for flushing WAL files on the standby node to disk (unit: μs).
Output parameter	avg_sync_time	uint64	Average time for calling the sync API when WAL files on the standby node are flushed to disk each time (unit: μs).
Output parameter	max_sync_time	uint64	Maximum duration for calling the sync API when the standby node writes WAL files (unit: μs).
Output parameter	current_xlog_segno	uint64	ID of the Xlog segment file that is being written on the standby node.
Output parameter	newest_xlog_segno	uint64	ID of the latest Xlog segment file on the standby node.
Output parameter	stat_start_time	timestamptz	Start time for collecting statistics.
Output parameter	stat_end_time	timestamptz	End time of the statistics collection.

Example:

```
gaussdb=# SELECT * FROM gs_walrcv_writer_stat(1);
-[ RECORD 1 ]------+------------------------------
enable_stat        | t
total_write_bytes  | 100754464
write_count        | 88426
total_write_time   | 3811972
avg_write_time     | 43
max_write_time     | 381739
avg_write_bytes    | 1139
total_sync_time    | 22280240
avg_sync_time      | 251
max_sync_time      | 655533
current_xlog_segno | 8154
newest_xlog_segno  | 8274
stat_start_time    | 2024-12-05 09:29:15.324159+08
stat_end_time      | 2024-12-05 09:29:45.92897+08
```

- gstrace_reg_sql(scope text, unique_sql_id text)

  Description: Adds the SQL statements to be traced. A maximum of 1,000 SQL statements can be traced for a database instance. After successful execution, the result (success or failure) of adding the SQL statements to be traced is returned. To call this function, you must have the MONADMIN or SYSADMIN permission.

  The following lists related parameters.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Input Parameter	Description	Value Range
scope	Required. Scope of a function.	Text type. The value can be **'LOCAL'** or **'GLOBAL'**. **'LOCAL'** means that the configuration takes effect only on the current node, while **'GLOBAL'** means that it takes effect on all CNs and DNs.
unique_sql_id	Required. Unique SQL ID of the traced SQL statement to be added.	Text type. The **unique_query_id** value retrieved from the statement_history table.

Return type: text.

Example:

```
gaussdb=# SELECT pg_catalog.gstrace_reg_sql('LOCAL', '3545025713');
-[ RECORD 1 ]------+------------------------------
 (datanode,"ACTION:      [GSTRACE]->[TRACE_SQL]          +
 RESULT:                                              +
 SUCCESSFUL - etrace unique_sql_id (3545025713) tracked")
```

- gstrace_reg_func(scope text, function_name text, so_index text, so_offset text, level text)

  Description: Adds the functions to be traced. A maximum of 1,000 functions can be traced for a database instance. After successful execution, the result (success or failure) of adding the functions to be traced is returned. To call this function, you must have the MONADMIN or SYSADMIN permission.

  The following lists related parameters.

Input Parameter	Description	Value Range
scope	Required. Scope of a function.	Text type. The value can be **'LOCAL'** or **'GLOBAL'**. **'LOCAL'** means that the configuration takes effect only on the current node, while **'GLOBAL'** means that it takes effect on all CNs and DNs.
function_name	Required. Name of a traced function to be added.	Text type. Only the name of a system function is supported.
so_index	Optional. SO index of a function.	Text type. The **so_index** value of the system function retrieved using the pg_catalog.gstrace_show_mangled_func() function.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Input Parameter	Description	Value Range
so_offset	Required when **so_index** is set; otherwise, it is not required. SO offset of a function.	Text type. The **so_offset** value of the system function retrieved using the pg_catalog.gstrace_show_mangled_func() function.
level	Required. Drill-down level of a function.	Text type. The value can be **'0'** or **'1'**. **'0'** indicates that only the function itself is traced, while **'1'** indicates that the function and its subfunctions are traced.

Return type: text.

Example 1: The input parameters do not contain the SO index and SO offset.

```
gaussdb=# SELECT pg_catalog.gstrace_reg_func('LOCAL', 'pg_sleep', '0');
------------------------------------------------------------------------------
 (datanode,"ACTION:      [GSTRACE]->[TRACE_FUNC]                          +
 RESULT:                                                                  +
 SUCCESSFUL - etrace function (_Z8pg_sleepP20FunctionCallInfoData) tracked")
```

Example 2: The input parameters contain the SO index and SO offset.

```
gaussdb=# SELECT pg_catalog.gstrace_show_mangled_func('LOCAL', 'pg_sleep');
                    gstrace_show_mangled_func
------------------------------------------------------------------------------
 (datanode,"ACTION:      [GSTRACE]->[SHOW_MANGLED_FUNC]                   +
 RESULT:                                                                  +
 SUCCESSFUL - function (pg_sleep)'s gangled func are these:               +
 function_name                          so_index so_name        so_offset+
 _Z8pg_sleepP20FunctionCallInfoData       0        gaussdb        59877694 +
 ")

gaussdb=# SELECT pg_catalog.gstrace_reg_func('LOCAL', 'pg_sleep', '0', '59877694', '0');
                       gstrace_reg_func
------------------------------------------------------------------------------
 (datanode,"ACTION:      [GSTRACE]->[TRACE_FUNC]                          +
 RESULT:                                                                  +
 SUCCESSFUL - etrace function (_Z8pg_sleepP20FunctionCallInfoData) tracked")
```

- gstrace_unreg_sql(scope text, unique_sql_id text)

  Description: Deletes a traced SQL statement. After successful execution, the result (success or failure) of deleting the traced SQL statement is returned. To call this function, you must have the MONADMIN or SYSADMIN permission.

  The following lists related parameters.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Input Parameter	Description	Value Range
scope	Required. Scope of a function.	Text type. The value can be **'LOCAL'** or **'GLOBAL'**. **'LOCAL'** means that the configuration takes effect only on the current node, while **'GLOBAL'** means that it takes effect on all CNs and DNs.
unique_sql_id	Required. Unique SQL ID of the traced SQL statement to be deleted.	Text type. The **unique_query_id** value retrieved from the statement_history table.

Return type: text.

Example:

```
gaussdb=# SELECT pg_catalog.gstrace_unreg_sql('LOCAL', '3545025713');
                      gstrace_unreg_sql
-------------------------------------------------------------------
(datanode,"ACTION:      [GSTRACE]->[UNTRACE_SQL]              +
RESULT:                                                       +
SUCCESSFUL - etrace unique_sql_id (3545025713) delete tracked")
```

- gstrace_unreg_func(scope text, function_name text, so_index text, so_offset text)

  Description: Deletes a traced function. After successful execution, the result (success or failure) of deleting the traced function is returned. To call this function, you must have the MONADMIN or SYSADMIN permission.

  The following lists related parameters.

Input Parameter	Description	Value Range
scope	Required. Scope of a function.	Text type. The value can be **'LOCAL'** or **'GLOBAL'**. **'LOCAL'** means that the configuration takes effect only on the current node, while **'GLOBAL'** means that it takes effect on all CNs and DNs.
function_name	Required. Name of a traced function to be deleted.	Text type. Only the name of a system function is supported.
so_index	Optional. SO index of a function.	Text type. The **so_index** value of the system function retrieved using the pg_catalog.gstrace_show_mangled_func() function.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Input Parameter	Description	Value Range
so_offset	Required when **so_index** is set; otherwise, it is not required. SO offset of a function.	Text type. The **so_offset** value of the system function retrieved using the pg_catalog.gstrace_show_mangled_func() function.

Return type: text.

Example 1: The input parameters do not contain the SO index and SO offset.

```
gaussdb=# SELECT pg_catalog.gstrace_unreg_func('LOCAL', 'pg_sleep');

- gstrace_unreg_all_sql(scope text)

  Description: Deletes all traced SQL statements. After successful execution, the result (success or failure) of deleting the traced SQL statements is returned. To call this function, you must have the MONADMIN or SYSADMIN permission.

  The following lists related parameters.

Input Parameter	Description	Value Range
scope	Required. Scope of a function.	Text type. The value can be **'LOCAL'** or **'GLOBAL'**. **'LOCAL'** means that the configuration takes effect only on the current node, while **'GLOBAL'** means that it takes effect on all CNs and DNs.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Return type: text.

Example:

```
gaussdb=# SELECT pg_catalog.gstrace_unreg_all_sql('LOCAL');
              gstrace_unreg_all_sql
-----------------------------------------------------------
 (datanode,"ACTION:      [GSTRACE]->[UNTRACE_ALL_SQL]+
 RESULT:                                 +
 SUCCESSFUL - all traced SQL have been deleted!")
```

- gstrace_unreg_all_func(scope text)

  Description: Deletes all traced functions. After successful execution, the result (success or failure) of deleting the traced functions is returned. To call this function, you must have the MONADMIN or SYSADMIN permission.

  The following lists related parameters.

Input Parameter	Description	Value Range
scope	Required. Scope of a function.	Text type. The value can be **'LOCAL'** or **'GLOBAL'**. **'LOCAL'** means that the configuration takes effect only on the current node, while **'GLOBAL'** means that it takes effect on all CNs and DNs.

  Return type: text.

  Example:

```
gaussdb=# SELECT pg_catalog.gstrace_unreg_all_func('LOCAL');
              gstrace_unreg_all_func
-----------------------------------------------------------
 (datanode,"ACTION:      [GSTRACE]->[UNTRACE_ALL_FUNC]+
 RESULT:                                 +
 SUCCESSFUL - all tracked functions have been deleted!+
 ")
```

- gstrace_list_configured_sql(scope text)

  Description: Views the SQL statements that are being traced. To call this function, you must have the MONADMIN or SYSADMIN permission.

  The following lists related parameters.

Input Parameter	Description	Value Range
scope	Required. Scope of a function.	Text type. The value can be **'LOCAL'** or **'GLOBAL'**. **'LOCAL'** means that the configuration takes effect only on the current node, while **'GLOBAL'** means that it takes effect on all CNs and DNs.

  Return type: SETOF record

  The following describes the return columns.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Column	Type	Description
unique_sql_id	bigint	Unique SQL ID of the SQL statement to be traced.

Example:

```
gaussdb=# SELECT pg_catalog.gstrace_list_configured_sql('LOCAL');
            gstrace_list_configured_sql
-----------------------------------------------------
 (datanode,"ACTION:      [GSTRACE]->[LIST_TRACE_SQL]+

 ")
```

- gstrace_list_configured_func(scope text)

  Description: Views the functions that are being traced. To call this function, you must have the MONADMIN or SYSADMIN permission.

  The following lists related parameters.

Input Parameter	Description	Value Range
scope	Required. Scope of a function.	Text type. The value can be **'LOCAL'** or **'GLOBAL'**. **'LOCAL'** means that the configuration takes effect only on the current node, while **'GLOBAL'** means that it takes effect on all CNs and DNs.

  Return type: SETOF record

  The following describes the return columns.

Column	Type	Description
function_name	text	Name of the function being traced.
so_index	int	SO index of a function. **0** corresponds to GaussDB bin, while **1** corresponds to **libgtmclient.so**.
so_name	text	SO name.
so_offset	int	SO offset of a function.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Column	Type	Description
level	int	Drill-down level of a function. **0** indicates that only the function itself is traced, while **1** indicates that the function and its subfunctions are traced.

Example:

```
gaussdb=# SELECT pg_catalog.gstrace_list_configured_func('LOCAL');
                          gstrace_list_configured_func
-------------------------------------------------------------------------------------
(datanode,"ACTION:      [GSTRACE]->[LIST_TRACE_FUNC]                                +
RESULT:                                                                             +
SUCCESSFUL - these function are tracking:                                           +
function_name                       so_index so_name       so_offset       level+
_Z8pg_sleepP20FunctionCallInfoData      0       gaussdb        59877694        0    +
")
```

- gstrace_show_traced_func(scope text)

  Description: Views the status of the functions being traced. To call this function, you must have the MONADMIN or SYSADMIN permission.

  The following lists related parameters.

Input Parameter	Description	Value Range
scope	Required. Scope of a function.	Text type. The value can be **'LOCAL'** or **'GLOBAL'**. **'LOCAL'** means that the configuration takes effect only on the current node, while **'GLOBAL'** means that it takes effect on all CNs and DNs.

  Return type: SETOF record

  The following describes the return columns.

Column	Type	Description
function_name	text	Name of the function being traced.
so_index	int	SO index of a function. **0** corresponds to GaussDB bin, while **1** corresponds to **libgtmclient.so**.
so_name	text	SO name.
so_offset	int	SO offset of a function.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Column	Type	Description
level	int	Drill-down level of a function. **0** indicates that only the function itself is traced, while **1** indicates that the function and its subfunctions are traced.
module	text	Module requesting to trace this function.
if_traced	bool	Specifies whether the function assembly has a jump tracing instruction.
if_hp_conflict	bool	Specifies whether the tracing is automatically canceled due to a conflict with the hot patch.
if_blacklist	bool	Specifies whether a function is in the traced function blacklist.
ref_count	int	Number of times that a function is traced.

Example:

```
gaussdb=# SELECT pg_catalog.gstrace_show_traced_func('LOCAL');
                                                
```

Input Parameter	Description	Value Range
function_name	Required. Name of a traced function to be added.	Text type. Only the name of a system function is supported.

Return type: SETOF record

The following describes the return columns.

Column	Type	Description
function_name	text	Name of the function being traced.
so_index	int	SO index of a function. **0** corresponds to GaussDB bin, while **1** corresponds to **libgtmclient.so**.
so_name	text	SO name.
so_offset	int	SO offset of a function.

Example:

```
gaussdb=# SELECT pg_catalog.gstrace_show_mangled_func('LOCAL',
'_Z8pg_sleepP20FunctionCallInfoData');
                            gstrace_show_mangled_func
-------------------------------------------------------------------------------------
 (datanode,"ACTION:       [GSTRACE]->[SHOW_MANGLED_FUNC]                          +
 RESULT:                                                                          +
 SUCCESSFUL - function (_Z8pg_sleepP20FunctionCallInfoData)'s gangled func are these:+
 function_name                          so_index so_name        so_offset         +
 _Z8pg_sleepP20FunctionCallInfoData       0        gaussdb        59877694          +
 '')
```

- gstrace_show_subfunc(scope text, function_name text, so_index text, so_offset text)

  Description: Views all subfunctions of a specified function. To call this function, you must have the MONADMIN or SYSADMIN permission.

  The following lists related parameters.

Input Parameter	Description	Value Range
scope	Required. Scope of a function.	Text type. **'LOCAL'** and **'GLOBAL'** are supported in distributed mode. **'LOCAL'** means that the configuration takes effect only on the current node, while **'GLOBAL'** means that it takes effect on all CNs and DNs.
function_name	Required. Name of a traced function to be added.	Text type. Only the name of a system function is supported.
so_index	Optional. SO index of a function.	Text type. The **so_index** value of the system function retrieved using the pg_catalog.gstrace_show_mangled_func() function.
so_offset	Required when **so_index** is set; otherwise, it is not required. SO offset of a function.	Text type. The **so_offset** value of the system function retrieved using the pg_catalog.gstrace_show_mangled_func() function.

Return type: SETOF record

The following describes the return columns.

Column	Type	Description
function_name	text	Name of the function being traced.
so_index	int	SO index of a function. **0** corresponds to GaussDB bin, while **1** corresponds to **libgtmclient.so**.
so_name	text	SO name.
so_offset	int	SO offset of a function.

Example:

```
gaussdb=# SELECT pg_catalog.gstrace_show_subfunc('LOCAL', '_Z8pg_sleepP20FunctionCallInfoData');
                                    gstrace_show_subfunc
-------------------------------------------------------------------------------------------------
 (datanode,"ACTION:      [GSTRACE]->[SHOW_SUBFUNC]                                              +
 RESULT:                                                                                        +

")
```

- gs_last_demote_spent_time()

  Description: Obtains the time consumed in key steps of primary-to-standby switchover, such as thread exit and initialization, checkpoint, shared memory exit and initialization, doublewrite initialization, and buffer pool initialization. You need to query the primary-to-standby switchover information on the primary node of the cluster where the switchover is performed. After a successful switchover between clusters or within a cluster, you can query the related information. This information is stored in memory and will be reset after a restart.

  Return type: SETOF record

  The following describes the return columns.

Column	Type	Description
key_step_name	text	Key steps of primary-to-standby switchover: • **thread_exit**: The thread exits during primary-to-standby switchover. • **checkpoint**: flushes dirty page during primary-to-standby switchover. • **shmem_exit**: The shared memory exits during primary-to-standby switchover. • **shmem_init**: initializes the shared memory during primary-to-standby switchover. • **bufferpool_init**: initializes the buffer pool during primary-to-standby switchover. • **dw_init**: initializes the doublewrite during primary-to-standby switchover. • **thread_init**: initializes the thread during primary-to-standby switchover.
spent_time	int	Time consumed in key steps of primary-to-standby switchover.

  Example:

```
gaussdb=# SELECT * FROM gs_last_demote_spent_time();
  key_step_name  | spent_time
-----------------+------------
 thread_exit     |    1.00299
 checkpoint      |    3.19896
 shmem_exit      |    .397594
 shmem_init      |    1.74218
 bufferpool_init |    1.24905
 dw_init         |    .038082
 thread_init     |    .400442
(7 rows)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- gs_tcache_memory_flush()

  Description: Manually wakes up idle worker threads and stream worker threads, and executes **mallctl("thread.tcache.flush", NULL, NULL, NULL, 0);** on the corresponding threads to clear the jemalloc tcache cache.

  Return type: Boolean. If the operation is successful, **t** (true) is returned. If the operation fails, **f** (false) is returned.

  NOTE

  - This function takes effect only when the thread pool is enabled.
  - Only users with the SYSADMIN permission can use this function.
  - This function can reduce the other memory, but only reduces the jemalloc tcache. This function is invalid in scenarios where the other memory increases due to other causes (for example, the other memory increases due to memory fragments caused by a large number of hard parsing operations).

1.6.28 SPM Functions

CAUTION

Currently, the SPM feature is not supported in the distributed system. Therefore, when the following functions are called in the distributed system, an error message is displayed, indicating that the SPM feature is not supported in the distributed system.

- GS_SPM_EVOLUTE_PLAN(sql_hash, plan_hash)

  Description: GS_SPM_EVOLUTE_PLAN belongs to the DBE_SQL_UTIL schema and is a function used by the SPM feature to plan evolution.

  Parameters: For details, see **Table 1-216**.

  Table 1-216 GS_SPM_EVOLUTE_PLAN input parameters and return values

Parameter	Type	Description	Value Range
sql_hash	IN bigint	Specifies a hash value of SQL text.	-
plan_hash	IN bigint	Specifies a hash value of the outline text of the SQL plan.	-
evolute_status	OUT boolean	Determines whether the evolution is complete. **t** indicates normal. If an exception occurs, an error is reported.	t/f

  Return type: Boolean

- GS_SPM_SET_PLAN_STATUS(sql_hash, plan_hash, plan_status)

  Description: GS_SPM_SET_PLAN_STATUS belongs to the DBE_SQL_UTIL schema. It is an API used by the SPM feature to modify the baseline status.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

When the API takes effect, the **invalid** column in the gs_spm_baseline table is updated to **false**.

Parameters: For details, see **Table 1-217**.

Table 1-217 GS_SPM_SET_PLAN_STATUS input parameters and return values

Parameter	Type	Description	Value Range
sql_hash	IN bigint	Specifies a hash value of SQL text.	-
plan_hash	IN bigint	Specifies a hash value of the outline text of the SQL plan.	-
plan_status	IN text	Specifies the status of a plan.	• **ACC**: indicates that the plan has been accepted. • **UNACC**: indicates that the plan is not accepted. • **FIXED**: indicates a special ACC plan. The matching priority of this plan is higher than that of other ACC plans.
execute_status	OUT boolean	Determines whether the plan status change is complete. **t** indicates normal. If an exception occurs, an error is reported.	t/f

Return type: Boolean

- GS_SPM_DISPLAY_PLANS(sql_hash)

  Description: GS_SPM_DISPLAY_PLANS belongs to the DBE_SQL_UTIL schema and is a function used by the SPM feature to view all baselines of a single SQL statement.

  Parameters: For details, see **Table 1-218**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 1-218 GS_SPM_DISPLAY_PLANS input parameters and return values

Parameter	Type	Description	Value Range
sql_hash	IN bigint	Unique ID of an SQL statement.	-
sql_hash	OUT bigint	Specifies a hash value of SQL text.	-
plan_hash	OUT bigint	Specifies a hash value of the outline text of the SQL plan.	-
outline	OUT text	Specifies the combination character string of all hints of the outline corresponding to the current plan.	-
cost	OUT double	Specifies the cost of the current plan.	-
status	OUT text	Specifies the status of the current plan.	• **ACC**: indicates that the plan has been accepted. • **UNACC**: indicates that the plan is not accepted. • **FIXED**: indicates a special ACC plan. The matching priority of this plan is higher than that of other ACC plans.
gplan	OUT boolean	Determines whether the current plan is a gplan. **t** indicates gplan. If an exception occurs, an error is reported.	t/f

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Type	Description	Value Range
namespace_oids	OUT text	OID list in the current **search_path**. The OID must meet the following requirements: • OID of the schema on which the user has the permission. • OID of an existing schema. • OID of the schema where the non-local temporary table belongs.	-

Return type: bigint, text, double, text, boolean

- GS_SPM_RELOAD_PLAN(sql_hash, plan_hash)

  Description: GS_SPM_RELOAD_PLAN belongs to the DBE_SQL_UTIL schema and is a function used by the SPM feature to load a baseline in the baseline system catalog to the SPM global cache.

  Parameters: For details, see **Table 1-219**.

  Table 1-219 GS_SPM_RELOAD_PLAN input parameters and return values

Parameter	Type	Description	Value Range
sql_hash	IN bigint	Specifies a hash value of SQL text.	-
plan_hash	IN bigint	Specifies a hash value of the outline text of the SQL plan.	-
execute_status	OUT boolean	Determines whether the baseline loading is complete. **t** indicates normal. If an exception occurs, an error is reported.	t/f

  Return type: Boolean

- GS_SPM_VALIDATE_PLAN(sql_hash, plan_hash)

  Description: GS_SPM_VALIDATE_PLAN belongs to the DBE_SQL_UTIL schema and is a function used by the SPM feature to verify plan availability.

  Parameters: For details, see **Table 1-220**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 1-220 GS_SPM_VALIDATE_PLAN input parameters and return values

Parameter	Type	Description	Value Range
sql_hash	IN bigint	Specifies a hash value of SQL text.	-
plan_hash	IN bigint	Specifies a hash value of the outline text of the SQL plan.	-
execute_status	OUT boolean	Determines whether the verified plan is available: **t**: The verified plan is available. **f**: The verified plan is unavailable.	t/f

Return type: Boolean

- GS_SPM_DELETE_PLAN(sql_hash, plan_hash)

  Description: GS_SPM_DELETE_PLAN belongs to DBE_SQL_UTIL schema and is a function used by the SPM feature to delete the plan baseline.

  Parameters: For details, see **Table 1-221**.

Table 1-221 GS_SPM_DELETE_PLAN input parameters and return values

Parameter	Type	Description	Value Range
sql_hash	IN bigint	Specifies a hash value of SQL text.	-
plan_hash	IN bigint	Specifies a hash value of the outline text of the SQL plan.	-
execute_status	OUT boolean	Determines whether the plan deletion is complete. **t** indicates normal. If an exception occurs, an error is reported.	t/f

Return type: Boolean

1.6.29 Statistics Information Functions

Statistics information functions are divided into the following two categories: functions that access databases, using the OID of each table or index in a database to mark the database for which statistics are generated; functions that access servers, identified by the server thread ID, whose value ranges from 1 to the number of currently active servers.

- pg_stat_get_db_conflict_tablespace(oid)

  Description: Specifies the number of queries canceled due to a conflict between the restored tablespace and the deleted tablespace in the database.

  Return type: bigint.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- pg_stat_get_db_conflict_truncate(oid)

  Description: Number of queries canceled due to conflicts with TRUNCATE operations that are being replayed in the database.

  Return type: bigint.

- pg_stat_get_db_conflict_force_recycle(oid)

  Description: Number of queries canceled due to forcible recycling triggered by read on standby (ROS) with ultimate RTO.

  Return type: bigint.

- pg_stat_get_db_conflict_standby_query_timeout(oid)

  Description: Number of queries canceled because the query time exceeds the upper limit set by ROS with ultimate RTO.

  Return type: bigint.

- pg_stat_get_db_conflict_bufferpin(oid)

  Description: Number of conflicting buffers.

  Return type: bigint.

- pg_stat_get_db_conflict_snapshot(oid)

  Description: Number of conflicting snapshots.

  Return type: bigint.

- pg_stat_get_db_conflict_startup_deadlock(oid)

  Description: Number of conflicting deadlocks.

  Return type: bigint.

- pg_stat_get_db_conflict_all(oid)

  Description: Number of queries canceled due to database recovery conflicts (conflicts occurring only on the standby node).

  Return type: bigint.

- pg_control_group_config()

  Description: Prints Cgroup configurations on the current node. Only users with the SYSADMIN permission can execute this function.

  Return type: record.

- pg_stat_get_db_stat_reset_time(oid)

  Description: Specifies the most recent time when database statistics were reset. If the database is queried for the first time, the system time when the database is connected is returned. The reset time is updated when you call pg_stat_reset on the database and execute pg_stat_reset_single_table_counters against any table or index in it.

  Return type: timestamptz.

- pg_stat_get_function_total_time(oid)

  Description: Specifies the total wall clock time spent in the function, in microseconds. The time spent on this function calling other functions is included.

  Return type: bigint.

- pg_stat_get_xact_tuples_returned(oid)

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description: Specifies the number of rows read through sequential scans when the parameter is a table in the current transaction or the number of index entries returned when the parameter is an index.

Return type: bigint.

- pg_stat_get_xact_numscans(oid)

  Description: Specifies the number of sequential scans performed when the parameter is a table in the current transaction or the number of index scans performed when the parameter is an index.

  Return type: bigint.

- pg_stat_get_xact_blocks_fetched(oid)

  Description: Specifies the number of disk block fetch requests for a table or an index in the current transaction.

  Return type: bigint.

- pg_stat_get_xact_blocks_hit(oid)

  Description: Specifies the number of disk block fetch requests for tables or indexes found in cache in the current transaction.

  Return type: bigint.

- pg_stat_get_xact_function_calls(oid)

  Description: Specifies the number of times the function is called in the current transaction.

  Return type: bigint.

- pg_stat_get_xact_function_self_time(oid)

  Description: Specifies the time spent only on this function in the current transaction. The time spent on other function call inside this function is not included.

  Return type: bigint.

- pg_stat_get_xact_function_total_time(oid)

  Description: Specifies the total wall clock time spent on this function in the current transaction, in microseconds. The time spent on other function call inside this function is included.

  Return type: bigint.

- pg_lock_status()

  Description: Queries information about locks held by open transactions. All users can execute this function.

  Return type: For details, see the return result in **PG_LOCKS**, which is obtained by querying this function.

- bucket_lock_status()

  Description: Queries information about bucket locks held by open transactions. All users can execute this function.

  Return type: For details about the returned columns, see the columns except **node_name** in the view in **GS_BUCKET_LOCKS**.

- gs_bucket_lock_status()

  Description: Queries information about bucket locks held by open transactions on all nodes. All users can execute this function.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Return type: For details, see the return result in **GS_BUCKET_LOCKS**, which is obtained by querying this function.

- gs_lwlock_status()

  Description: Queries information about all lightweight locks in the database system, including lock waiting and lock holding information. All users can execute this function.

  Return type: SETOF record

- pg_stat_get_wal_senders()

  Description: Queries walsender information on the primary node.

  Return type: SETOF record

  The following table describes return columns.

Table 1-222 Return columns

Column	Type	Description
pid	bigint	Thread ID of the WAL sender.
sender_pid	integer	Lightweight thread ID of the WAL sender.
local_role	text	Type of the primary node.
peer_role	text	Type of the standby node.
peer_state	text	Status of the standby node.
state	text	Status of the WAL sender.
catchup_start	timestamp with time zone	Startup time of a catchup task.
catchup_end	timestamp with time zone	End time of a catchup task.
sender_sent_location	text	Sending position of the primary node.
sender_write_location	text	Writing position of the primary node.
sender_flush_location	text	Flushing position of the primary node.
sender_replay_location	text	Redo position of the primary node.
receiver_received_location	text	Receiving position of the standby node.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Column	Type	Description
receiver_write_location	text	Writing position of the standby node.
receiver_flush_location	text	Flushing position of the standby node.
receiver_replay_location	text	Redo position of the standby node.
sync_percent	text	Synchronization percentage.
sync_state	text	Synchronization status.
sync_group	text	Group to which the synchronous replication belongs.
sync_priority	text	Priority of synchronous replication.
sync_most_available	text	Maximum availability mode.
channel	text	Channel information of the WAL sender.

- get_paxos_replication_info()

  Description: Queries the primary/standby node replication status in Paxos mode.

  Return type: SETOF record

  The following table describes return columns.

  Table 1-223 Return columns

Column	Type	Description
paxos_write_location	text	Location of the Xlog that has been written to the Distribute Consensus Framework (DCF).
paxos_commit_location	text	Location of the Xlog agreed in the DCF.
local_write_location	text	Writing position of a node.
local_flush_location	text	Flushing position of a node.
local_replay_location	text	Redo position of a node.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Column	Type	Description
dcf_replication_info	text	DCF module information of a node. The character string is in JSON format. The fields in the character string are described as follows: **role**: role of the current node. The value can be **LEADER**, **FOLLOWER**, **LOGGER**, **PASSIVE**, or **UNKNOW**. **term**: election term. **run_mode**: DCF running mode. The value **0** indicates that the automatic election mode is enabled, the value **1** indicates the manual election mode, and the value **2** indicates that the automatic election mode is disabled. **work_mode**: DCF working mode. **hb_interval**: heartbeat interval between DCF nodes, in milliseconds. **elc_timeout**: DCF election timeout period, in milliseconds. **applied_index**: position of the log that is applied to the state machine. **commit_index**: position of the log that has been saved by most DCF nodes. Logs before **commit_index** have been made persistent. **first_index**: position of the first log saved on the DCF node. This position is moved backward when the DN calls **dcf_truncate**. The previous logs will be cleared. **last_index**: position of the last log saved by the DCF node. This position refers to the logs that are stored in the memory of the DCF node but are not made persistent. **cluster_min_apply_idx**: minimum location of the applied log in the cluster. **leader_id**: ID of the leader node. **leader_ip**: IP address of the leader node.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Column	Type	Description
		leader_port: port of the leader node, for DCF internal use. **nodes**: information of other nodes in the cluster, including the node ID, IP address, port number, and role.

Example:

```
gaussdb=# select * from get_paxos_replication_info();
 paxos_write_location | paxos_commit_location | local_write_location | local_flush_location |
local_replay_location |

                                                                dcf_replication_info

                                                                
```

Table 1-224 Return values

Parameter	Return Type	Description
local_role	text	Local role.
static_connections	integer	Connection statistics.
db_state	text	Database status.
detail_information	text	Detailed information.

- pg_stat_get_db_numbackends(oid)
  Description: Specifies the number of active server threads for a database.
  Return type: integer
- pg_stat_get_db_xact_commit(oid)
  Description: Specifies the number of transactions committed in a database.
  Return type: bigint.
- pg_stat_get_db_xact_rollback(oid)
  Description: Specifies the number of transactions rolled back in a database.
  Return type: bigint.
- pg_stat_get_db_blocks_fetched(oid)
  Description: Specifies the number of disk blocks fetch requests for a database.
  Return type: bigint.
- pg_stat_get_db_blocks_hit(oid)
  Description: Specifies the number of disk block fetch requests found in cache for a database.
  Return type: bigint.
- pg_stat_get_db_tuples_returned(oid)
  Description: Specifies the number of tuples returned by a database.
  Return type: bigint.
- pg_stat_get_db_tuples_fetched(oid)
  Description: Specifies the number of tuples fetched from a database.
  Return type: bigint.
- pg_stat_get_db_tuples_inserted(oid)
  Description: Specifies the number of tuples inserted in a database.
  Return type: bigint.
- pg_stat_get_db_tuples_updated(oid)
  Description: Specifies the number of tuples updated in a database.
  Return type: bigint.
- pg_stat_get_db_blk_read_time(oid)
  Description: Time spent in reading data file blocks by backends in this database (unit: ms).
  Return type: double.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- pg_stat_get_db_blk_write_time(oid)

  Description: Time spent in writing data file blocks by backends in this database (unit: ms).

  Return type: double.

- pg_stat_get_db_tuples_deleted(oid)

  Description: Specifies the number of tuples deleted in a database.

  Return type: bigint.

- pg_stat_get_db_conflict_lock(oid)

  Description: Specifies the number of lock conflicts in a database.

  Return type: bigint.

- pg_stat_get_db_deadlocks(oid)

  Description: Specifies the number of deadlocks in a database.

  Return type: bigint.

- pg_stat_get_numscans(oid)

  Description: Specifies the number of sequential scans done if parameters are in a table, or the number of index scans done if parameters are in an index.

  Return type: bigint.

- pg_stat_get_role_name(oid)

  Description: Obtains the username based on the user OID. Only users with the SYSADMIN o MONADMIN permission can access the information.

  Return type: text.

  Example:

  ```
  gaussdb=# SELECT pg_stat_get_role_name(10);
   pg_stat_get_role_name
  -----------------------
   aabbcc
  (1 row)
  ```

- pg_stat_get_tuples_returned(oid)

  Description: Specifies the number of active rows read by sequential scans when the argument is a table, or the number of index entries returned when the argument is an index.

  Return type: bigint.

- pg_stat_get_tuples_fetched(oid)

  Description: Specifies the number of rows fetched by bitmap scans if parameters are in a table, or the number of rows fetched by simple index scans in the original table if parameters are in an index.

  Return type: bigint.

- pg_stat_get_tuples_inserted(oid)

  Description: Specifies the number of rows inserted into a table.

  Return type: bigint.

- pg_stat_get_tuples_updated(oid)

  Description: Specifies the number of rows updated in a table.

  Return type: bigint.

- pg_stat_get_tuples_deleted(oid)

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description: Specifies the number of rows deleted from a table.

Return type: bigint.

- pg_stat_get_tuples_changed(oid)

  Description: Specifies the total number of inserted, updated, and deleted rows after a table was last analyzed or autoanalyzed.

  Return type: bigint.

- pg_stat_get_tuples_hot_updated(oid)

  Description: Specifies the number of rows hot updated in a table.

  Return type: bigint.

- pg_stat_get_live_tuples(oid)

  Description: Specifies the number of live rows in a table.

  Return type: bigint.

- pg_stat_get_dead_tuples(oid)

  Description: Specifies the number of dead rows in a table. It indicates the number of inactive row pointers in Ustore tables.

  Return type: bigint.

- pg_stat_get_blocks_fetched(oid)

  Description: Specifies the number of disk block fetch requests for a table or an index.

  Return type: bigint.

- pg_stat_get_blocks_hit(oid)

  Description: Specifies the number of disk block requests found in cache for a table or an index.

  Return type: bigint.

- pg_stat_get_xact_tuples_fetched(oid)

  Description: Specifies the number of tuple rows scanned in a transaction.

  Return type: bigint.

- pg_stat_get_xact_tuples_inserted(oid)

  Description: Specifies the number of tuple inserted into the active subtransactions related to a table.

  Return type: bigint.

- pg_stat_get_xact_tuples_deleted(oid)

  Description: Specifies the number of deleted tuples in the active subtransactions related to a table.

  Return type: bigint.

- pg_stat_get_xact_tuples_hot_updated(oid)

  Description: Specifies the number of hot updated tuples in the active subtransactions related to a table.

  Return type: bigint.

- pg_stat_get_xact_tuples_updated(oid)

  Description: Specifies the number of updated tuples in the active subtransactions related to a table.

  Return type: bigint.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- pg_stat_get_last_vacuum_time(oid)

  Description: Specifies the most recent time when the autovacuum thread is manually started to clear a table.

  Return type: timestamptz.

- pg_stat_get_last_autovacuum_time(oid)

  Description: Specifies the time of the last vacuum initiated by the autovacuum daemon thread on a table.

  Return type: timestamptz.

- pg_stat_get_vacuum_count(oid)

  Description: Specifies the number of times a table is manually cleared.

  Return type: bigint.

- pg_stat_get_autovacuum_count(oid)

  Description: Specifies the number of times the autovacuum daemon thread is started to clear a table.

  Return type: bigint.

- pg_stat_get_last_analyze_time(oid)

  Description: Specifies the last time when a table starts to be analyzed manually or by the autovacuum thread.

  Return type: timestamptz.

- pg_stat_get_last_autoanalyze_time(oid)

  Description: Specifies the time when the last analysis initiated by the autovacuum daemon thread on a table.

  Return type: timestamptz.

- pg_stat_get_analyze_count(oid)

  Description: Specifies the number of times a table is manually analyzed.

  Return type: bigint.

- pg_stat_get_autoanalyze_count(oid)

  Description: Specifies the number of times the autovacuum daemon thread analyzes a table.

  Return type: bigint.

- gs_stat_get_all_tabentries()

  Description: Obtains PgStat statistics of other nodes when the GUC parameter **enable_gsstat_cache** is set to **on**. This is an internal function. You are advised not to use it directly.

  Return type: SETOF record

  For return parameters, see **Table 1-225**.

Table 1-225 Description

Parameter	Return Type	Description
node_name	name	Node name (**node_name** in **pgxc_node**).

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Return Type	Description
nspname	name	Schema name.
relname	name	Name of a table or index.
tuples_returned	bigint	If it is a table, the number of rows read by a sequential scan is returned. If it is an index, the number of index rows is returned.
tuples_fetched	bigint	If it is a table, the number of rows fetched with a bitmap scan is returned. If it is an index, the number of rows fetched with a simple index scan is returned.
tuples_inserted	bigint	Number of rows inserted into a table.
tuples_updated	bigint	Number of rows updated in a table.
tuples_deleted	bigint	Number of rows deleted from a table.
tuples_hot_updated	bigint	Number of rows HOT-updated in a table.
n_live_tuples	bigint	Number of live rows in a table.
n_dead_tuples	bigint	Number of dead rows in a table. It indicates the number of inactive row pointers in Ustore tables.
blocks_fetched	bigint	Number of disk block fetch requests for a table or index.
blocks_hit	bigint	Number of disk block requests found in cache for a table or index.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Return Type	Description
numscans	bigint	If it is a table, the number of rows read by a sequential scan is returned. If it is an index, the number of index rows is returned.
autovac_vacuum_timestamp	timestamp with time zone	Time of the last vacuum initiated by the autovacuum daemon on this table.
autovac_vacuum_count	bigint	Number of times that the autovacuum daemon starts cleanup on the table.
autovac_analyze_timestamp	timestamp with time zone	Time of the last analyze initiated by the autovacuum daemon on this table.
autovac_analyze_count	bigint	Number of times the autovacuum daemon analyzes a table.
state_change_timestamp	timestamp with time zone	The update time of monitoring indicator fields in each table in the DBE_PERF.stat_all_tables view is returned.
index_stat_change_timestamp	timestamp with time zone	The update time of monitoring indicator fields in each table in the DBE_PERF.stat_all_indexes view is returned.
state_io_change_timestamp	timestamp with time zone	The update time of monitoring indicator fields in each table in the DBE_PERF.statio_all_indexes and DBE_PERF.statio_all_tables views is returned.

- pg_total_autovac_tuples(bool)

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description: Returns tuple records related to the total autovac, such as **nodename**, **nspname**, **relname**, and tuple IUDs. The input parameter specifies whether to query the **relation** information.

Return type: SETOF record

The following table describes return parameters.

Table 1-226 Description

Parameter	Return Type	Description
nodename	name	Node name.
nspname	name	Name of a namespace.
relname	name	Name of an object, such as a table, an index, or a view.
partname	name	Partition name.
n_dead_tuples	bigint	Number of dead rows in a table partition. It indicates the number of inactive row pointers in Ustore tables.
n_live_tuples	bigint	Number of live rows in a table partition.
changes_since_analyze	bigint	Number of changes generated by ANALYZE.

- pg_total_gsi_autovac_tuples(bool)

  Description: Returns tuple records related to **total autovac**, such as **nodename**, **nspname**, **relname**, and number of GSI records that have changed since the last ANALYZE. The input parameter specifies whether to query relation information. This function assists AUTOVACUUM on GSIs. Avoid direct use by users.

  Return type: SETOF record

- pg_autovac_status(oid)

  Description: Returns autovac information, such as **nodename**, **nspname**, **relname**, **analyze**, **vacuum**, thresholds for the ANALYZE and VACUUM operations, and the number of analyzed or vacuumed tuples. Only users with the SYSADMIN permission can use this function.

  Return type: SETOF record

  The following table describes return parameters.

  Table 1-227 Return parameters

Parameter	Return Type	Description
nspname	text	Name of a namespace.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Return Type	Description
relname	text	Name of an object, such as a table, an index, or a view.
nodename	text	Node name.
doanalyze	Boolean	Specifies whether to execute **ANALYZE**.
anltuples	bigint	Number of ANALYZE tuples.
anlthresh	bigint	ANALYZE threshold.
dovacuum	Boolean	Specifies whether to execute **VACUUM**.
vactuples	bigint	Number of VACUUM tuples.
vacthresh	bigint	VACUUM threshold.

- pg_autovac_timeout(oid)

  Description: Returns the number of consecutive timeouts during the autovac operation on a table. If the table information is invalid or the node information is abnormal, **NULL** will be returned.

  Return type: bigint.
- pg_autovac_coordinator(oid)

  Description: Returns the name of the CN performing the autovac operation on a table. If the table information is invalid or the node information is abnormal, **NULL** is returned.

  Return type: text.
- pg_stat_get_last_data_changed_time(oid)

  Description: Returns the time when INSERT, UPDATE, DELETE, or TRUNCATE was last performed on a table, or the time when EXCHANGE, TRUNCATE, or DROP was last performed on a partition or subpartition. The data in the **last_data_changed** column of the **PG_STAT_ALL_TABLES** view is calculated by using this function. The performance of obtaining the last modification time by using the view is poor when the table has a large amount of data. In this case, you are advised to use functions. The input parameter is a table OID.

  Return type: timestamptz.
- pg_stat_set_last_data_changed_time(oid)

  Description: Manually changes the time when **INSERT**, **UPDATE**, **DELETE**, or **EXCHANGE**/**TRUNCATE**/**DROP PARTITION** was last performed.

  Return type: void.
- pg_stat_get_last_updated(oid, text)

  Description: Returns the update time of table monitoring metrics in the DBE_PERF.stat_all_tables, DBE_PERF.stat_all_indexes,

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

DBE_PERF.statio_all_indexes, and DBE_PERF.statio_all_tables views. The input parameter 1 is the table OID, and the input parameter 2 is of the text type. The value can be **"stat_table"**, **"stat_index"**, or **"stat_io"**.

Return type: timestamptz.

- pg_backend_pid()

  Description: Specifies the thread ID of the server thread attached to the current session.

  Return type: integer

- pg_stat_get_activity(integer)

  Description: Returns a record about the backend thread with the specified PID. A record for each active backend in the system is returned if **NULL** is specified. The returned result does not contain the **connection_info** column. The initial user and users with the SYSADMIN or MONADMIN permission can view all data. Common users can only query their own results.

  Example:

```
gaussdb=# SELECT pg_backend_pid();
 pg_backend_pid
-----------------
 139881386280704
(1 row)

-- The query result depends on the preceding return value.
gaussdb=# SELECT * FROM pg_stat_get_activity(139881386280704);
 datid |       pid       | sessionid | usesysid | application_name | state  |
query                       | waiting |          xact_start           |          query_start          |
    backend_start         |         state_change          | client_addr | client_hostname | client_port | enqueue
|     query_id      |   srespool   | global_sessionid | unique_sql_id | trace_id
-------+-----------------+-----------+----------+------------------+--------
+-----------------------------------------------------+---------+-------------------------------
+--------------------------------+-----
-------------------------+------------------------------+-------------+-----------------+-------------+---------
+-------------------+--------------+------------------+---------------+----------
 16545 | 139881386280704 |        69 |       10 | gsql             | active | select * from
pg_stat_get_activity(139881386280704); | f       | 2022-01-18 19:43:05.167718+08 | 2022-01-18
19:43:05.167718+08 | 2022
-01-18 19:42:33.513507+08 | 2022-01-18 19:43:05.16773+08 |                  |                  |          -1 |         |
72620543991624410 | default_pool | 1938253334#69#0  |    3751941862 |
(1 row)
```

  Return type: SETOF record

  The following table describes return parameters.

Table 1-228 Description

Parameter	Return Type	Description
datid	oid	OID of the database that the user session connects to in the backend.
pid	bigint	Backend thread ID.
sessionid	bigint	Session ID.
usesysid	oid	OID of the user logged in to the backend.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Return Type	Description
application_name	text	Name of the application connected to the backend.
state	text	Overall status of the backend.
query	text	Latest query at the backend. If the value of **state** is **active**, this column shows the ongoing query. In all other states, it shows the last query that was executed.
waiting	Boolean	Specifies whether the backend is currently waiting for a lock. If the backend is currently waiting for a lock, the value is **true**.
xact_start	timestamp with time zone	Time when current transaction was started (null if no transaction is active). If the current query is the first of its transaction, the value of this column is the same as that of the **query_start** column.
query_start	timestamp with time zone	Time when the currently active query was started, or time when the last query was started if **state** is not **active** For a stored procedure, function, or package, the first query time is queried and does not change with the running of statements in the stored procedure.
backend_start	timestamp with time zone	Time when this process was started, that is, when the client connected to the server.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Return Type	Description
state_change	timestamp with time zone	Time when **state** was last modified.
client_addr	inet	IP address of the client connected to the backend. If this column is **NULL**, it indicates either the client is connected via a Unix socket on the server or this is an internal thread, such as **AUTOVACUUM**.
client_hostname	text	Host name of the connected client, as reported by a reverse DNS lookup of **client_addr**. This column will be non-null only for IP connections and only when **log_hostname** is enabled.
client_port	integer	TCP port number that the client uses for communication with this backend (**–1** if a Unix socket is used).
enqueue	text	Unsupported currently.
query_id	bigint	ID of a query.
srespool	name	Name of the resource pool.
global_sessionid	text	Global session ID.
unique_sql_id	bigint	Unique SQL statement ID.
trace_id	text	Driver-specific trace ID, which is associated with an application request.

- pg_stat_get_activity_with_conninfo(integer)

  Description: Returns a record about the backend thread with the specified PID. A record for each active backend in the system is returned if **NULL** is specified. The initial user, system administrators and users with the

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

MONADMIN permission can view all data. Common users can only query their own results.

Return type: SETOF record

The following table describes return values.

Return Value	Return Type	Return values
datid	oid	OID of the database that the user session connects to in the backend.
pid	bigint	Backend thread ID.
sessionid	bigint	Session ID.
usesysid	oid	OID of the user logged in to the backend.
application_name	text	Name of the application connected to the backend.
state	text	Overall status of the backend.
query	text	Latest query at the backend. If the value of **state** is **active**, this column shows the ongoing query. In all other states, it shows the last query that was executed.
waiting	Boolean	Specifies whether the backend is currently waiting for a lock. If the backend is currently waiting for a lock, the value is **true**.
xact_start	timestamp with time zone	Time when current transaction was started (null if no transaction is active). If the current query is the first of its transaction, the value of this column is the same as that of the **query_start** column.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Return Value	Return Type	Return values
query_start	timestamp with time zone	Time when the currently active query was started, or time when the last query was started if **state** is not **active** For a stored procedure, function, or package, the first query time is queried and does not change with the running of statements in the stored procedure.
backend_start	timestamp with time zone	Time when this process was started, that is, when the client connected to the server.
state_change	timestamp with time zone	Time when **state** was last modified.
client_addr	inet	IP address of the client connected to the backend. If this column is **NULL**, it indicates either the client is connected via a Unix socket on the server or this is an internal thread, such as **AUTOVACUUM**.
client_hostname	text	Host name of the connected client, as reported by a reverse DNS lookup of **client_addr**. This column will be non-null only for IP connections and only when **log_hostname** is enabled.
client_port	integer	TCP port number that the client uses for communication with this backend (**–1** if a Unix socket is used).
enqueue	text	Unsupported currently.
query_id	bigint	ID of a query.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Return Value	Return Type	Return values
connection_info	text	A string in JSON format recording the driver type, driver version, driver deployment path, and thread owner of the connected database.
srespool	name	Name of the resource pool.
global_sessionid	text	Global session ID.
unique_sql_id	bigint	Unique SQL statement ID.
trace_id	text	Driver-specific trace ID, which is associated with an application request.
top_xid	xid	Top-level transaction ID of a transaction.
current_xid	xid	Current transaction ID of a transaction.
xlog_quantity	bigint	Size of Xlogs currently used by a transaction, in bytes.
control_status	text	If CPU resources are controlled due to abnormal SQL statements, the value will be **under_cpu_throttle**. Otherwise, it will be **normal**.

- gs_get_explain(integer)

  Description: Returns a running plan for the backend thread with the specified PID. The PID cannot be empty. This function takes effect only when the GUC parameter **track_activities** is set to **on**. Only explainable SQL statements whose plans do not contain stream operators are supported. Details are as follows:

  – If the GUC parameter **plan_collect_thresh** is set to **-1**, the return result of the function is always empty.

  – If the GUC parameter **plan_collect_thresh** is set to **0**, the current SQL execution time is greater than or equal to the value of **log_min_duration_statement**, and the total number of tuples processed by all operators in the plan is greater than or equal to 10000, the system

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

starts to collect plans in running state. Each time the total number of tuples processed by all operators exceeds 10000, a collection is performed.

- If the GUC parameter **plan_collect_thresh** is set to a value greater than 0, running plans are collected incrementally based on the threshold specified by this parameter.
- In addition, this function can view only the plans generated on CNs. To view the plans generated on DNs, see the gs_get_dn_explain function.

The return value type is text. The following table describes the types and meanings of the fields.

Return Value	Return Type	Return values
Character string of the plans in the running state	text	**A-rows** in the plan string indicates the number of rows returned by the operator in real time.

- gs_get_dn_explain(text, bigint)

  Description: Returns a running plan for the backend thread of the DN with the specified node name (from the **node_name** field in the **pgxc_node** system catalog) and global session ID. The global session ID cannot be empty. This function takes effect only when the GUC parameter **track_activities** is set to **on**. Only explainable SQL statements whose plans do not contain stream operators are supported. Details are as follows:

  - Same as the gs_get_explain function. The global session ID is calculated based on the **global_sessionid** field in **pg_stat_activity**. The format of **global_sessionid** is *${number1}.${number2}#{number3}*. Note that *number1* is a signed number. When *number1* is a positive number, for example, **1938253334:1#0**, the parameter value of the gs_get_dn_explain function should be *${number2}* x 10000000000 + *${number1}*. When *number1* is a negative number, convert it to a 32-bit unsigned number. For example, if the value of **global_sessionid** is **-1736975100:1#0**, the parameter value of the gs_get_dn_explain function should be *${number2}* x 10000000000 + (*${number1}* + 4294967296).
  - In addition, this function can be executed only with the ADMIN or MONADMIN permission.

  The return value type is text. The following table describes the types and meanings of the fields.

Return Value	Return Type	Return values
Character string of the plans in the running state	text	**A-rows** in the plan string indicates the number of rows returned by the operator in real time.

- pg_stat_get_activity_ng(integer)

  Description: Returns a record about the active backend thread with the specified PID. A record for each active backend thread is returned if **NULL** is

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

specified. System administrators and users with the MONADMIN permission can view all data. Common users can query only their own data.

Return type: SETOF record

The following table describes return fields.

Name	Type	Description
datid	oid	Database OID.
pid	bigint	Backend thread ID.
sessionid	bigint	Session ID.
node_group	text	Node group of the user to which the data belongs.

- pg_stat_get_function_calls(oid)

  Description: Specifies the number of times the function has been called.

  Return type: bigint.

- pg_stat_get_function_self_time(oid)

  Description: Specifies the time spent on only this function. The time spent on nested functions to call other functions is excluded.

  Return type: bigint.

- pg_stat_get_backend_idset()

  Description: Sets the number of currently active server threads (from 1 to the number of active server threads).

  Return type: setofinteger

- pg_stat_get_backend_pid(integer)

  Description: Specifies the ID of the given server thread.

  Return type: bigint.

- pg_stat_get_backend_dbid(integer)

  Description: Specifies the ID of the database connected to the given server thread.

  Return type: oid.

- pg_stat_get_backend_userid(integer)

  Description: Specifies the user ID of the given server process. This function can be called only by system administrators.

  Return type: oid.

- pg_stat_get_backend_activity(integer)

  Description: Active command of the given server thread, but only if the current user is a system administrator or the same user as that of the session being queried and **track_activities** is enabled.

  Return type: text.

- pg_stat_get_backend_waiting(integer)

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description: Returns true if the given server thread is waiting for a lock, but only if the current user is a system administrator or the same user as that of the session being queried and **track_activities** is enabled.

Return type: Boolean

- pg_stat_get_backend_activity_start(integer)

  Description: Specifies the time when the given server thread's currently executing query is started only if the current user is a system administrator or the user of the session being queried and **track_activities** is enabled.

  Return type: timestamp with time zone

- pg_stat_get_backend_xact_start(integer)

  Description: Specifies the time when the given server thread's currently executing transaction is started only if the current user is a system administrator or the user of the session being queried and **track_activities** is enabled.

  Return type: timestamp with time zone

- pg_stat_get_backend_start(integer)

  Description: Specifies the time when the given server thread is started. If the current user is neither a system administrator nor the same user as that of the session being queried, **NULL** is returned.

  Return type: timestamp with time zone

- pg_stat_get_backend_client_addr(integer)

  Description: Specifies the IP address of a backend connected to a specified client. If the connection is over a UDS, or if the current user is neither a system administrator nor the same user as that of the session being queried, **NULL** will be returned.

  Return type: inet.

- pg_stat_get_backend_client_port(integer)

  Description: Specifies the TCP port of a backend connected to a specified client. If the connection is over a UDS, **–1** will be returned. If the current user is neither a system administrator nor the same user as that of the session being queried, **NULL** will be returned.

  Return type: integer

- pg_stat_get_bgwriter_timed_checkpoints()

  Description: Specifies the time when the background writer thread starts scheduled checkpoints (because **checkpoint_timeout** has expired).

  Return type: bigint.

- pg_stat_get_bgwriter_requested_checkpoints()

  Description: Specifies the time when the background writer thread starts checkpoints based on requests from the backend because **checkpoint_segments** has been exceeded or the **CHECKPOINT** command has been executed.

  Return type: bigint.

- pg_stat_get_bgwriter_buf_written_checkpoints()

  Description: Specifies the number of buffers written by the background writer thread during checkpoints.

  Return type: bigint.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- pg_stat_get_bgwriter_buf_written_clean()

  Description: Specifies the number of buffers written by the background writer thread for routine cleaning of dirty pages.

  Return type: bigint.

- pg_stat_get_bgwriter_maxwritten_clean()

  Description: Specifies the time when the background writer thread stops its cleaning scan because it has written more buffers than specified in the **bgwriter_lru_maxpages** parameter.

  Return type: bigint.

- pg_stat_get_buf_written_backend()

  Description: Specifies the number of buffers written by the backend thread because they need to allocate a new buffer.

  Return type: bigint.

- pg_stat_get_buf_alloc()

  Description: Specifies the total number of the allocated buffers.

  Return type: bigint.

- pg_stat_clear_snapshot()

  Description: Discards the current statistics snapshot. Only users with the SYSADMIN or MONADMIN permission can execute this function.

  Return type: void.

- pg_stat_reset()

  Description: Resets all statistics counters for the current database to zero (the SYSADMIN permission is required).

  Return type: void.

- gs_stat_reset()

  Description: Resets all statistics counters for the current database on each node to zero (the SYSADMIN permission is required).

  Return type: void.

- pg_stat_reset_shared(text)

  Description: Resets all statistics counters for the current database in each node in a shared cluster to zero (the SYSADMIN permission is required).

  Return type: void.

- pg_stat_reset_single_table_counters(oid)

  Description: Resets statistics for a single table or index in the current database to zero (the SYSADMIN permission is required).

  Return type: void.

- pg_stat_reset_single_function_counters(oid)

  Description: Resets statistics for a single function in the current database to zero (the SYSADMIN permission is required).

  Return type: void.

- pgxc_fenced_udf_process(integer)

  Description: Displays the number of UDF master and worker threads. Only users with the SYSADMIN or MONADMIN permission can execute this

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

function. If the input parameter is set to **1**, the number of Master threads is queried. If the input parameter is set to **2**, the number of Worker threads is queried. If the input parameter is set to **3**, all Worker threads are terminated.

Return type: text.

- fenced_udf_process(integer)

  Description: Shows the number of local UDF Master and Work processes. Only users with the SYSADMIN or MONADMIN permission can terminate all worker processes. If the input parameter is set to **1**, the number of master processes is queried. If the input parameter is set to **2**, the number of worker processes is queried. If the input parameter is set to **3**, all worker processes are terminated.

  Return type: text.

- total_cpu()

  Description: Obtains the CPU time used by the current node, in jiffies.

  Return type: bigint.

- total_memory()

  Description: Obtains the size of the virtual memory used by the current node, in KB.

  Return type: bigint.

- pgxc_terminate_all_fenced_udf_process()

  Description: Kills all UDF worker threads. Only users with the SYSADMIN or MONADMIN permission can execute this function.

  Return type: Boolean.

- gs_get_nodegroup_tablecount(name)

  Description: Obtains the total number of user tables in all databases in a node group.

  Return type: integer

- pgxc_max_datanode_size(name)

  Description: Obtains the maximum disk space occupied by database files on all DNs in a node_group. The unit is byte.

  Return type: bigint.

- gs_check_tables_distribution()

  Description: Checks whether the user table distribution in the system is consistent. If no record is returned, table distribution is consistent. This function cannot be called during redistribution in scale-in or scale-out.

  Return type: record.

- pg_stat_bad_block()

  Description: Obtains damage information about pages after the current node is started.

  Return type: record.

- pgxc_stat_bad_block()

  Description: Obtains damage information about pages after all nodes in the cluster are started.

  Return type: record.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- pg_stat_bad_block_clear()

  Description: Deletes the page damage information that is read and recorded on the node (the SYSADMIN permission is required).

  Return type: void.

- pgxc_stat_bad_block_clear

  Description: Deletes the page damage information that is read and recorded on all nodes in the cluster (the SYSADMIN permission is required).

  Return type: void.

- pgxc_log_comm_status(void)

  Description: When the SCTP communication mode is used, the PGXC system view exports the communication layer status of DNs to each log file. (Due to specification changes, the current version no longer supports this feature. Do not use it.)

  Return type: void.

- gs_respool_exception_info(pool text)

  Description: Queries the query rule of a specified resource pool.

  Return type: record.

- gs_control_group_info(pool text)

  Description: Queries information about Cgroups associated with a resource pool. Only users with the SYSADMIN permission can execute this function.

  Return type: record.

  The command output is as follows:

Attribute	Value	Description
name	class_a:workload_a1	Class name and workload name.
class	class_a	Class Cgroup name.
workload	workload_a1	Workload Cgroup name.
type	DEFWD	Cgroup type (**Top**, **CLASS**, **BAKWD**, **DEFWD**, or **TSWD**).
gid	87	Cgroup ID.
shares	30	Percentage of CPU resources to those on the parent node.
limits	0	Percentage of CPU cores to those on the parent node.
rate	0	Allocation ratio in Timeshare.
cpucores	0-3	Number of CPU cores.

- gs_all_control_group_info()

  Description: Collects information about all Cgroups in the database. For details about the columns returned by the function, see **GS_ALL_CONTROL_GROUP_INFO**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Return type: record.

- gs_get_control_group_info()

  Description: Collects information about all Cgroups. For details about the columns returned by the function, see **GS_GET_CONTROL_GROUP_INFO**. Only users with the SYSADMIN permission can execute this function.

  Return type: record.

- gs_get_session_sql_memory()

  Description: Views the memory usage of currently running statements. For details about the columns returned by the function, see **DBE_PERF.SESSION_SQL_MEMORY**.

  Return type: record.

- gs_get_global_session_sql_memory()

  Description: Views the memory usage of currently running statements on all nodes. For details about the columns returned by the function, see **DBE_PERF.GLOBAL_SESSION_SQL_MEMORY**.

  Return type: record.

- gs_blackbox_dump()

  Description: Exports black box files from the system to the *$GAUSSLOG*/**gs_blackbox/***{nodename}* directory. If the command is successfully executed, the black box file names generated in the *$GAUSSLOG*/**gs_blackbox/***{nodename}* directory is returned.

  Return type: text.

- gs_blackbox_show(blackBoxFile cstring)

  Description: Parses black box files and displays them in a table.

  Parameters:

Parameter	Description	Value Range
blackBoxFile	The black box files to be parsed. If no parameter is specified, the black box files collected by the current process are displayed.	The value is a string or is not specified. If a valid black box file name is specified, the file with the specified name in the *$GAUSSLOG*/**gs_blackbox/***nodename* directory is read. Only the file name is supported. An error is reported if the file with the specified name does not exist in the *$GAUSSLOG*/**gs_blackbox/***nodename* directory.

  Return type: SETOF record

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

The following table describes return values.

Return Value	Return Type	Return values
type	text	Black box field type.
tid	bigint	Thread ID.
sample_time	timestamp	Collection time.
value	text	Content recorded in the black box.

The following table describes query results.

type	tid	sample_time	value
ERRNUMBER	123456	2024-03-19 09:33:17.386	19460
BLACK_BOX_PLSQL_EXCEPTION	45678	2024-03-19 09:33:18.396	message: "Dropped rowtype entry for non-dropped column when make tuple." funcname: basic_make_tuple_from_row filename:pl_exec.cpp context:xxxx

- gs_blackbox_list()

  Description: Lists black box files in the black box directory of the current instance. The default directory is *$GAUSSLOG*/**gs_blackbox/***{nodename}*.

  Return type: SETOF record

  The following table describes return values.

Return Value	Return Type	Return values
file	text	Name of the black box file.

- get_instr_workload_info(integer)

  Description: Obtains the transaction volume and time information on the current CN.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Return type: record.

Attribute	Type	Description
user_oid	oid	User ID.
commit_counter	bigint	Number of frontend transactions that were committed.
rollback_counter	bigint	Number of frontend transactions that were rolled back.
resp_min	bigint	Minimum response time of frontend transactions (unit: μs).
resp_max	bigint	Maximum response time of frontend transactions (unit: μs).
resp_avg	bigint	Average response time of frontend transactions (unit: μs).
resp_total	bigint	Total response time of frontend transactions (unit: μs).
bg_commit_counter	bigint	Number of backend transactions that were committed.
bg_rollback_counter	bigint	Number of backend transactions that were rolled back.
bg_resp_min	bigint	Minimum response time of backend transactions (unit: μs).
bg_resp_max	bigint	Maximum response time of backend transactions (unit: μs).
bg_resp_avg	bigint	Average response time of backend transactions (unit: μs).
bg_resp_total	bigint	Total response time of backend transactions (unit: μs).
dist_commit_counter	bigint	Number of distributed transactions that are committed.
dist_rollback_counter	bigint	Number of distributed transactions that are rolled back.
dist_resp_min	bigint	Minimum response time of distributed transactions (unit: μs).
dist_resp_max	bigint	Maximum response time of distributed transactions (unit: μs).

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Attribute	Type	Description
dist_resp_avg	bigint	Average response time of distributed transactions (unit: μs).
dist_resp_total	bigint	Total response time of distributed transactions (unit: μs).
dbid	oid	Database ID.

NOTE

Only the information about the main transaction is collected. The information about the sub-transaction is not collected.

- pv_instance_time()

  Description: Obtains the time consumed in each execution phase on the current node.

  Return type: record.

Stat_name Attribute	Value	Description
DB_TIME	1062385	Total end-to-end time consumed by all threads (unit: μs).
CPU_TIME	311777	Total CPU time consumed by all threads (unit: μs).
EXECUTION_TIME	380037	Total time spent on the executor (unit: μs).
PARSE_TIME	6033	Total time spent in parsing SQL statements (unit: μs).
PLAN_TIME	173356	Total time spent in generating an execution plan (unit: μs).
REWRITE_TIME	2274	Total time spent on query rewriting (unit: μs).
PL_EXECUTION_TIME	0	Total time spent in executing PL/pgSQL statements (unit: μs).
PL_COMPILATION_TIME	557	Total time spent in compiling SQL statements (unit: μs).
NET_SEND_TIME	1673	Total time spent in sending data over the network (unit: μs).
DATA_IO_TIME	426622	Total time spent on data reads/writes (unit: μs).

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- DBE_PERF.get_global_instance_time()

  Description: Provides the time consumed in each key phase in the entire cluster. The time consumed can be queried only on the CN. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

  Return type: record.

- get_instr_unique_sql()

  Description: Obtains information about normalized SQL statements executed on the current node. Users with the SYSADMIN or MONADMIN permission can query all information. Other users can query only information about the statements executed by themselves. For details about the columns returned by the function, see **DBE_PERF.STATEMENT**.

  Return type: record.

- get_instr_wait_event(integer)

  Description: Obtains the statistics on wait events of the current node.

  Return type: record.

- get_instr_user_login()

  Description: Obtains the number of user login and logout times on the current node. Only users with the SYSADMIN or MONADMIN permission can execute this function.

  Return type: record.

- get_instr_rt_percentile(integer)

  Description: Obtains the distribution information about the response time of 80% and 95% SQL statements in the CCN. The unified cluster information is stored on the CCN. The query result from other nodes is **0**.

  Return type: record.

- get_node_stat_reset_time()

  Description: Obtains statistics about reset (restart, primary/standby switchover, and database deletion) time of the current node.

  Return type: record.

- gs_paxos_stat_replication()

  Description: Queries the standby node information on the primary node.

  Return type: SETOF record

  The following table describes return columns.

Column	Type	Description
local_role	text	Role of the sender node.
peer_role	text	Role of the receiver node.
local_dcf_role	text	DCF role of the sender node.
peer_dcf_role	text	DCF role of the receiver node.
peer_state	text	Status of the receiver node.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Column	Type	Description
sender_write_location	text	Location in the Xlog buffer where the node that sends logs is written.
sender_commit_location	text	Barrier reached for the DCF logs of the sender node.
sender_flush_location	text	Location in the Xlog disk where the node that sends logs is written.
sender_replay_location	text	Location where the sender node replays logs.
receiver_write_location	text	Location in the Xlog buffer where the node that receives logs is written.
receiver_commit_location	text	Barrier reached for the DCF logs of the receiver node.
receiver_flush_location	text	Location in the Xlog disk where the node that receives logs is written.
receiver_replay_location	text	Location where the receiver node replays Xlogs.
sync_percent	text	Synchronization percentage.
dcf_run_mode	int4	DCF synchronization mode.
channel	text	Channel information.

- get_paxos_replication_info()

  Description: Queries the primary/standby node replication status in Paxos mode.

  Return type: SETOF record

  The following table describes return columns.

Column	Type	Description
paxos_write_location	text	Location of the Xlog that has been written to the Distribute Consensus Framework (DCF).
paxos_commit_location	text	Location of the Xlog agreed in the DCF.
local_write_location	text	Writing position of a node.
local_flush_location	text	Flushing position of a node.
local_replay_location	text	Redo position of a node.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Column	Type	Description
dcf_replication_info	text	DCF module information of a node.

- gs_wlm_get_user_info(int)

  Description: Obtains information about all users. The input parameter is of the int type and can be any int value or **NULL**. Only users with the SYSADMIN permission can execute this function.

  Return type: record.

- gs_wlm_readjust_user_space(oid)

  Description: Corrects the storage space usage of a specified user. Common users can modify only their own usage. Administrators can modify the usage of all users. If **oid** is set to **0**, the usage of all users needs to be modified.

  Return type: record.

- gs_wlm_readjust_user_space_through_username(text name)

  Description: Corrects the storage space usage of a specified user. Common users can use this function to modify only their own usage. Only the administrator can modify the usage of all users. If the value of **name** is **0000**, the usage of all users needs to be modified.

  Return type: record.

- gs_wlm_readjust_user_space_with_reset_flag(text name, boolean isfirst)

  Description: Corrects the storage space usage of a specified user. If the input parameter **isfirst** is set to **true**, statistics are collected from 0. Otherwise, statistics are collected from the previous result. Common users can use this function to modify only their own usage. Only the administrator can modify the usage of all users. If the value of **name** is **0000**, the usage of all users needs to be modified.

  Return type: record.

- gs_io_wait_status()

  Description: Returns the real-time statistics on I/O control on the current node.

  Return type: SETOF record

Name	Type	Description
node_name	text	Node name.
device_name	text	Name of the data disk mounted to the node.
read_per_second	float	Number of read completions per second.
write_per_second	float	Number of write completions per second.
write_ratio	float	Ratio of the disk write I/Os to the total I/Os.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Name	Type	Description
io_util	float	Percentage of the I/O time to the total CPU time per second.
total_io_util	integer	Level of the CPU time occupied by the last three I/Os. The value ranges from 0 to 6.
tick_count	integer	Interval for updating disk I/O information. The value is fixed to 1 second. The value is cleared each time before data is read.
io_wait_list_len	integer	Size of the I/O request thread wait queue. If the value is **0**, no I/O is under control.

- gs_get_shared_memctx_detail(text)

  Description: Returns the memory allocation details of the specified memory context, including the file, line number, and size of each memory allocation (the size of the same line in the same file is accumulated). The memory context is limited to the one queried through the PG_SHARED_MEMORY_DETAIL view (see **PG_SHARED_MEMORY_DETAIL**). The input parameter is the memory context name (that is, the **contextname** column in the result returned by the PG_SHARED_MEMORY_DETAIL view). To execute this function, you must have the SYSADMIN or MONADMIN permission.

  Return type: SETOF record

Name	Type	Description
file	text	Name of the file where the memory is applied for.
line	int8	Line number of the code in the file where the requested memory is located.
size	int8	Size of the allocated memory. The value is accumulated when memory is allocated multiple times to the same line in the same file.

- gs_get_session_memctx_detail(text)

  Description: Returns the memory allocation details of the specified memory context, including the file, line number, and size of each memory allocation (the size of the same line in the same file is accumulated). This parameter is valid only in thread pool mode. Only the memory context queried through the PV_SESSION_MEMORY_CONTEXT view (see **PV_SESSION_MEMORY_CONTEXT**) can be queried. The input parameter is the memory context name (that is, the **contextname** column in the result returned by the PV_SESSION_MEMORY_CONTEXT view). To execute this function, you must have the SYSADMIN or MONADMIN permission.

  Return type: SETOF record

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Name	Type	Description
file	text	Name of the file where the memory is applied for.
line	int8	Line number of the code in the file where the requested memory is located.
size	int8	Size of the allocated memory, in bytes. The value is accumulated if the memory is allocated for multiple times to the same line of the same file.

NOTE

This function takes effect only in thread pool mode.

- gs_get_thread_memctx_detail(tid,text)

  Description: Returns the memory allocation details of the specified memory context, including the file, line number, and size of each memory allocation (the size of the same line in the same file is accumulated). Only the memory context queried through the PV_THREAD_MEMORY_CONTEXT view (see **PV_THREAD_MEMORY_CONTEXT**) can be queried. The first input parameter is the thread ID (the **tid** column of the data returned by the PV_THREAD_MEMORY_CONTEXT view), and the second parameter is the memory context name (the **contextname** column of the data returned by the PV_THREAD_MEMORY_CONTEXT view). To execute this function, you must have the SYSADMIN or MONADMIN permission.

  Return type: SETOF record

Name	Type	Description
file	text	Name of the file where the memory is applied for.
line	int8	Line number of the code in the file where the requested memory is located.
size	int8	Size of the allocated memory, in bytes. The value is accumulated if the memory is allocated for multiple times to the same line of the same file.

- gs_get_history_memory_detail(cstring)

  Description: Queries historical memory snapshot information. The input parameter type is cstring. The value can be **NULL** or the name of the memory snapshot log file.

  a. If the value of the input parameter is **NULL**, the list of all memory snapshot log files on the current node is displayed.

  b. If the value of the input parameter is the name of the memory snapshot log file in the list queried in **a**, the detailed information about the memory snapshot recorded in the log file is displayed.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

c. If you enter any other input parameter, the system displays a message indicating that the input parameter is incorrect or the file fails to be opened.

To execute this function, you must have the SYSADMIN or MONADMIN permission.

Return type: text.

Name	Type	Description
memory_info	text	Memory information. If the input parameter of the function is set to **NULL**, the memory snapshot file list is displayed. If the input parameter is set to the name of the memory snapshot file, the content of the file is displayed.

- gs_stat_get_hotkeys_info()

  NOTE

  If the GUC parameter **enable_hotkeys_collection** is set to **off**, the gs_stat_get_hotkeys_info and global_stat_get_hotkeys_info functions as well as the global_stat_hotkeys_info view cannot be queried. The use of the gs_stat_clean_hotkeys and global_stat_clean_hotkeys APIs is not affected.

  Description: Obtains the hotspot key statistics on the current node.

  Return type: record.

```
gaussdb=# SELECT * FROM gs_stat_get_hotkeys_info() order by count, hash_value;
 database_name | schema_name |    table_name     | key_value | hash_value | count
---------------+-------------+-------------------+-----------+------------+-------
 regression    | public      | hotkey_single_col | {22}      | 1858004829 |     2
 regression    | public      | hotkey_single_col | {11}      | 2011968649 |     2
(2 rows)
```

Name	Type	Description
database_name	text	Name of the database where the hotspot key is located.
schema_name	text	Name of the schema where the hotspot key is located.
table_name	text	Name of the table where the hotspot key is located.
key_value	text	Value of the hotspot key.
hash_value	bigint	Hash value of the hotspot key in the database. If the table is a list or range distributed table, the value of this column is **0**.
count	bigint	Frequency of accessing the hotspot key.

- gs_stat_clean_hotkeys()

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- Hot key detection is designed for high-concurrency and heavy-traffic scenarios. In the scenario where the access is performed for several times, the query result may be inaccurate.
- The clearing API is designed to clear only the statistics in the LRU queue but not the historical data in the FIFO. Therefore, if the historical key value in the FIFO is accessed again after the clearing, the historical key value is still processed as a hotspot key. This rule also applies to **global_stat_clean_hotkeys**.

Description: Clears statistics on hotspot keys on the current node.

Return type: Boolean.

```
gaussdb=# SELECT * FROM gs_stat_clean_hotkeys();
 gs_stat_clean_hotkeys
-----------------------
 t
(1 row)
```

- gs_stat_progress_vacuum(pid)

  Description: Displays the current VACUUM progress. Only the VACUUM progress of Astore and Ustore page tables is collected. Hash bucket and segment-page tables are not supported.

  Return type: record.

Table 1-229 Return parameters

Name	Type	Description
pid	bigint	PID of the VACUUM thread.
dataname	text	Name of the database that is being vacuumed.
relid	oid	OID of the table that is being vacuumed.
relname	text	Name of the table that is being vacuumed.
phase	text	Current VACUUM phase.
detail	text	Vacuum progress details, including the total number of pages, number of scanned pages, number of vacuumed pages, and number of vacuumed indexes.

Table 1-230 Description of phase values

phase	Type	Description
invalid	text	VACUUM is starting and a table lock will be obtained.
initialize	text	VACUUM is preparing to scan the heap table. This phase is expected to be very short.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

phase	Type	Description
vacuuming main part	text	VACUUM is vacuuming the primary partitioned table (usually the GPI of the primary partitioned table). You can view the vacuum progress in the **detail** column.
scanning heap	text	VACUUM is scanning the heap table and defragmenting or freezing each page if necessary. You can view the vacuum progress in the **detail** column.
vacuuming indexes	text	VACUUM is vacuuming indexes. If the table has indexes, this phase occurs at least once and may continue scanning the heap table only after the indexes are vacuumed multiple times as required. You can view the vacuum progress in the **detail** column.
vacuuming heap	text	VACUUM is vacuuming the heap table (different from scanning the heap table) and is executed after each index vacuum. If the heap table is not completely scanned, the scanning will continue after this phase. You can view the vacuum progress in the **detail** column.
vacuuming part cache	text	VACUUM is vacuuming dead tuples in cached partitions. You can view the vacuum progress in the **detail** column.
cleaning up indexes	text	VACUUM is vacuuming indexes. This phase is executed after the heap table is completely scanned and all indexes and heap tables are vacuumed.
truncating heap	text	VACUUM is truncating the tail empty pages of the heap table and returning the empty pages to the OS.
vacuuming urq	text	VACUUM is recycling the index pages of the Ustore table.
unknown phase	text	The current state is unknown and is not defined in the preceding phases. Generally, this state does not occur.

```
-- Set GUC parameters.
gaussdb=# SET vacuum_cost_delay=100;
SET
gaussdb=# CREATE TABLE t1 (a int, b int, c text) with (storage_type=astore)

```

- global_comm_get_recv_stream()

  Description: Obtains the status of the stream received by all communications libraries on all DNs. For details about the columns returned by the function, see **PG_COMM_RECV_STREAM**.

  Return type: record.

- global_comm_get_send_stream()

  Description: Obtains the status of the stream sent by all communications libraries on all DNs. For details about the columns returned by the function, see **PG_COMM_SEND_STREAM**.

  Return type: record.

- global_comm_get_status()

  Description: Obtains the communications library status on all DNs. For details about the columns returned by the function, see **PG_COMM_STATUS**.

  Return type: record.

- global_comm_client_info()

  Description: Obtains information about active client connections of global nodes. For details about the columns returned by the function, see **COMM_CLIENT_INFO**.

  Return type: record.

- global_comm_get_client_info()

  Description: Obtains information about client connections of global nodes. For details about the columns returned by the function, see **COMM_CLIENT_INFO**.

  Return type: record.

- pgxc_stat_activity()

  Description: Displays information about all CNs in the current cluster queried by the current user. Only users with the SYSADMIN or MONADMIN permission can execute this function, and common users can view only their own information. Three columns are added to version 505.0.0. During the gray upgrade observation period, an error is reported. You need to use the PG_STAT_ACTIVITY view (see **PG_STAT_ACTIVITY**) to directly connect to the target node for query.

  Return type: record.

Name	Type	Description
coorname	text	Name of a CN in the current cluster.
datid	oid	OID of the database that the user session connects to in the backend.
datname	text	Name of the database that the user session connects to in the backend.
pid	bigint	Backend thread ID.
sessionid	bigint	Session ID.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Name	Type	Description
usesysid	oid	OID of the user logged in to the backend.
usename	text	Name of the user logged in to the backend.
application_name	text	Name of the application connected to the backend.
client_addr	inet	IP address of the client connected to the backend. If this column is **NULL**, it indicates either the client is connected via a Unix socket on the server or this is an internal thread, such as **AUTOVACUUM**.
client_hostname	text	Host name of the connected client, as reported by a reverse DNS lookup of **client_addr**. This column will be non-null only for IP connections and only when **log_hostname** is enabled.
client_port	integer	TCP port number that the client uses for communication with this backend (**–1** if a Unix socket is used).
backend_start	timestamp with time zone	Time when this process was started, that is, when the client connected to the server.
xact_start	timestamp with time zone	Time when current transaction was started (null if no transaction is active). If the current query is the first of its transaction, the value of this column is the same as that of the **query_start** column.
query_start	timestamp with time zone	Time when the currently active query was started, or time when the last query was started if **state** is not **active** For a stored procedure, function, or package, the first query time is queried and does not change with the running of statements in the stored procedure.
state_change	timestamp with time zone	Time when **state** was last modified.
waiting	Boolean	Specifies whether the backend is currently waiting for a lock. If the backend is currently waiting for a lock, the value is **true**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Name	Type	Description
enqueue	text	Queuing status of a statement. The value can be: • **waiting in queue**: The statement is in the queue. • **Empty**: The statement is running.
state	text	Overall status of the backend. The value can be: • **active**: The backend is executing a query. • **idle**: The backend is waiting for a new client command. • **idle in transaction**: The backend is in a transaction, but there is no statement being executed in the transaction. • **idle in transaction** (aborted): The backend is in a transaction, but there are statements failed in the transaction. • **fastpath function call**: The backend is executing a fast-path function. • **disabled**: This state is reported if **track_activities** is disabled in this backend. **NOTE** Only system administrators can view the session status of their accounts. The state information of other accounts is empty. For example, after user **judy** is connected to the database, the **state** information of user **joe** and the initial user **omm** in the PGXC_STAT_ACTIVITY view is empty. SELECT datname, usename, usesysid, state,pid FROM pgxc_stat_activity; datname | usename | usesysid | state | pid ----------+---------+----------+--------+----------------- testdb | omm | 10 | | 139968752121616 testdb | omm | 10 | | 139968903116560 db_tpcds | judy | 16398 | active | 139968391403280 testdb | omm | 10 | | 139968643069712 testdb | omm | 10 | | 139968680818448 testdb | joe | 16390 | | 139968563377936 (6 rows)

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Name	Type	Description
resource_pool	name	Resource pool used by the user.
query_id	bigint	ID of a query.
query	text	Latest query at the backend. If the value of **state** is **active**, this column shows the ongoing query. In all other states, it shows the last query that was executed.
global_sessionid	text	Global session ID.
unique_sql_id	bigint	Unique SQL statement ID.
trace_id	text	Driver-specific trace ID, which is associated with an application request.
top_xid	xid	Top-level transaction ID of a transaction.
current_xid	xid	Current transaction ID of a transaction.
xlog_quantity	bigint	Size of Xlogs currently used by a transaction, in bytes.

- pgxc_stat_activity_with_conninfo()

  Description: Displays query information about the current user on all CNs in the current cluster. For details, see the **PGXC_STAT_ACTIVITY** view. Only users with the SYSADMIN or MONADMIN permission can execute this function, and common users can view only their own information.

  Return type: record.

- pgxc_stat_all_tables()

  Description: Displays statistics on a row in each table (including TOAST tables) on each node. Only users with the SYSADMIN or MONADMIN permission can execute this function.

  Return type: record.

- pgxc_get_thread_wait_status()

  Description: Queries the call hierarchy between threads generated by all SQL statements on each node in a cluster and the blocking status of each thread.

  Return type: record.

- pv_session_memory

  Description: Collects statistics on memory usage at the session level, including all the memory allocated to GaussDB and stream threads on DNs for jobs currently executed by users.

  NOTE

  If the GUC parameter **enable_memory_limit** is set to **off**, this function cannot be used.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Return type: record.

Table 1-231 Return values

Name	Type	Description
sessid	text	Thread start time and ID.
init_mem	integer	Memory allocated to the currently executed jobs before they enter the executor, in MB.
used_mem	integer	Memory allocated to the currently executed jobs, in MB.
peak_mem	integer	Peak memory allocated to the currently executed jobs, in MB.

- DBE_PERF.gs_stat_activity_timeout(int)

  Description: Obtains information about query jobs whose execution time exceeds the timeout threshold on the current node. The correct result can be returned only when the GUC parameter **track_activities** is set to **on**. The timeout threshold ranges from 0 to 2147483. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

  Return type: SETOF record

Name	Type	Description
database	name	Name of the database to which a user session is connected.
pid	bigint	Backend thread ID.
sessionid	bigint	Session ID.
usesysid	oid	OID of the user logged in to the backend.
application_name	text	Name of the application connected to the backend.
query	text	Query that is being executed on the backend.
xact_start	timestamptz	Time when the current transaction is started.
query_start	timestamptz	Time when the current query starts For a stored procedure, function, or package, the first query time is queried and does not change with the running of statements in the stored procedure.
query_id	bigint	ID of a query.

- DBE_PERF.global_stat_activity_timeout(int)

  Description: Obtains information about query jobs whose execution time exceeds the timeout threshold in the current system (all CNs). The correct

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

result can be returned only when the GUC parameter **track_activities** is set to **on**. The timeout threshold ranges from 0 to 2147483. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

Return type: SETOF record

Name	Type	Description
nodename	text	Name of the CN connected to the user session.
database	name	Name of the database to which a user session is connected.
pid	bigint	Backend thread ID.
sessionid	bigint	Session ID.
usesysid	oid	OID of the user logged in to the backend.
application_name	text	Name of the application connected to the backend.
query	text	Query that is being executed on the backend.
xact_start	timestamptz	Time when the current transaction is started.
query_start	timestamptz	Time when the current query starts For a stored procedure, function, or package, the first query time is queried and does not change with the running of statements in the stored procedure.
query_id	bigint	ID of a query.

- DBE_PERF.get_global_active_session()

  Description: Displays a summary of samples in the ACTIVE SESSION PROFILE memory on all CNs and primary DNs. After a cluster is created, by default, you must have the MONADMIN permission to query this function. The **event_start_time**, **current_xid**, and **top_xid** columns are added to GaussDB Kernel 505.0. After GaussDB Kernel is upgraded to GaussDB Kernel 505.0 or later, the columns cannot be queried during the upgrade observation period.

  Return type: record.

- DBE_PERF.get_global_os_runtime()

  Description: Displays the running status of the current OS. This function can be queried only on CNs. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

  Return type: record.

- DBE_PERF.get_global_os_threads()

  Description: Provides thread status information on all normal nodes in the entire cluster. The information can be queried only on CNs. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Return type: record.

- DBE_PERF.get_global_os_threads()

  Description: Provides thread status information on all normal nodes in the entire cluster. The information can be queried only on CNs. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

  Return type: record.

- DBE_PERF.get_summary_workload_sql_count()

  Description: Provides the count information of SELECT, UPDATE, INSERT, DELETE, DDL, DML, and DCL in different loads in the entire cluster. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

  Return type: record.

- DBE_PERF.get_summary_workload_sql_elapse_time()

  Description: Provides SELECT, UPDATE, INSERT, DELETE, and response time information (TOTAL, AVG, MIN, and MAX) in different loads in the entire cluster. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

  Return type: record.

- DBE_PERF.get_global_workload_transaction()

  Description: Obtains the transaction volume and time information on all nodes in the cluster. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

  Return type: record.

- DBE_PERF.get_global_session_stat()

  Description: Obtains the session status information on all nodes in the cluster. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

  Return type: record.

  NOTE

  The status information contains the following 14 items: commit, rollback, sql, table_scan, blocks_fetched, physical_read_operation, shared_blocks_dirtied, local_blocks_dirtied, shared_blocks_read, local_blocks_read, blocks_read_time, blocks_write_time, sort_imemory, and sort_idisk.

- DBE_PERF.get_global_session_time()

  Description: Provides the time consumed in each key phase on each node in the entire cluster. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

  Return type: record.

- DBE_PERF.get_global_session_memory()

  Description: Aggregates statistics on memory usage at the session level on each node in the unit of MB, including all the memory allocated to GaussDB and stream threads on DNs for jobs currently executed by users. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

  Return type: record.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- DBE_PERF.get_global_session_memory_detail()

  Description: Aggregates statistics on thread memory usage on each node by the MemoryContext node. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

  Return type: record.

- DBE_PERF.get_global_session_stat_activity()

  Description: Aggregates information about running threads on each node in the cluster. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

  Return type: record.

- DBE_PERF.get_global_thread_wait_status()

  Description: Aggregates the blocking waiting status of the backend thread and auxiliary thread on all nodes. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

  Return type: record.

- DBE_PERF.get_global_operator_history_table()

  Description: Aggregates the operator records (persistent) after jobs are executed by the current user on all CNs. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

  Return type: record.

- DBE_PERF.get_global_operator_history()

  Description: Aggregates the operator records after jobs are executed by the current user on all CNs. After a cluster is created, by default, you must have the MONADMIN or SYSADMIN permission to query this function.

  Return type: record.

- DBE_PERF.get_global_operator_runtime()

  Description: Aggregates real-time operator records of jobs executed by the current user on all CNs. After a cluster is created, by default, you must have the MONADMIN or SYSADMIN permission to query this function.

  Return type: record.

- DBE_PERF.get_global_statement_complex_history()

  Description: Aggregates the historical records of complex queries executed by the current user on all CNs. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

  Return type: record.

- DBE_PERF.get_global_statement_complex_history_table()

  Description: Aggregates the historical records of complex queries (persistent) executed by the current user on all CNs. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

  Return type: record.

- DBE_PERF.get_global_statement_complex_runtime()

  Description: Aggregates real-time information about complex queries executed by the current user on all CNs. After a cluster is created, by default, you must have the MONADMIN or SYSADMIN permission to query this function.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Return type: record.

- DBE_PERF.get_global_memory_node_detail()

  Description: Aggregates the memory usage of a database on all nodes. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

  Return type: record.

- DBE_PERF.get_global_shared_memory_detail()

  Description: Aggregates the usage information about the shared memory contexts on all nodes. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

  Return type: record.

- DBE_PERF.get_global_comm_delay()

  Description: Aggregates the communications library delay status on all DNs. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

  Return type: record.

- DBE_PERF.get_global_comm_recv_stream()

  Description: Aggregates the status of the stream received by the communications library on all DNs. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

  Return type: record.

- DBE_PERF.get_global_comm_send_stream()

  Description: Aggregates the status of the stream sent by the communications library on all DNs. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

  Return type: record.

- DBE_PERF.get_global_comm_status()

  Description: Aggregates the status of the communications library on all DNs. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

  Return type: record.

- DBE_PERF.get_global_statio_all_indexes()

  Description: Aggregates index information and I/O statistics in the current database on all nodes. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

  Return type: record.

- DBE_PERF.get_local_toastname_and_toastindexname()

  Description: Provides the mapping between the name and index of the local TOAST table and its associated tables. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

  Return type: record.

- DBE_PERF.get_summary_statio_all_indexes()

  Description: Collects I/O statistics on specific indexes, covering all index lines in the current database on all nodes. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Return type: record.

- DBE_PERF.get_global_statio_all_sequences()

  Description: Provides I/O status information about all sequences in the namespace. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

  Return type: record.

- DBE_PERF.get_global_statio_all_tables()

  Description: Aggregates I/O statistics on each table in the database on each node. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

  Return type: record.

- DBE_PERF.get_summary_statio_all_tables()

  Description: Collects statistics on I/Os of each table in the cluster. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

  Return type: record.

- DBE_PERF.get_local_toast_relation()

  Description: Provides the mapping between the name of the local TOAST table and its associated tables. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

  Return type: record.

- DBE_PERF.get_global_statio_sys_indexes()

  Description: Aggregates I/O status information about all system catalog indexes in namespaces on each node. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

  Return type: record.

- DBE_PERF.get_summary_statio_sys_indexes()

  Description: Collects statistics on I/O status information about all system catalog indexes in the namespaces on each node. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

  Return type: record.

- DBE_PERF.get_global_statio_sys_sequences()

  Description: Provides I/O status information about all system catalog sequences in namespaces. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

  Return type: record.

- DBE_PERF.get_global_statio_sys_tables()

  Description: Provides I/O status information about all system catalogs in the namespaces on each node. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

  Return type: record.

- DBE_PERF.get_summary_statio_sys_tables()

  Description: Collects I/O status information about all system catalogs in the namespaces of the cluster. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Return type: record.

- DBE_PERF.get_global_statio_user_indexes()

  Description: Provides I/O status information about all user relationship table indexes in the namespaces on each node. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

  Return type: record.

- DBE_PERF.get_summary_statio_user_indexes()

  Description: Aggregates I/O status information about all user relationship table indexes in the namespaces of the cluster. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

  Return type: record.

- DBE_PERF.get_global_statio_user_sequences()

  Description: Displays I/O status information about all user sequences in the namespaces on each node. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

  Return type: record.

- DBE_PERF.get_global_statio_user_tables()

  Description: Displays I/O status information about all user relationship tables in the namespaces on each node. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

  Return type: record.

- DBE_PERF.get_summary_statio_user_tables()

  Description: Aggregates I/O status information about all user relationship tables in the namespaces of the cluster. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

  Return type: record.

- DBE_PERF.get_global_dn_stat_all_tables()

  Description: Aggregates statistics on all tables in the database on each DN. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

  Return type: record.

- DBE_PERF.get_global_cn_stat_all_tables()

  Description: Aggregates statistics on all tables in the database on each CN. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

  Return type: record.

- DBE_PERF.get_summary_dn_stat_all_tables()

  Description: Collects statistics on all tables in the database on each DN. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

  Return type: record.

- DBE_PERF.get_summary_cn_stat_all_tables()

  Description: Collects statistics on all tables in the database on each CN. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Return type: record.

- DBE_PERF.get_global_stat_all_indexes()

  Description: Aggregates statistics on all indexes in the database on all nodes. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

  Return type: record.

- DBE_PERF.get_summary_stat_all_indexes()

  Description: Collects statistics on all indexes in the database on all nodes. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

  Return type: record.

- DBE_PERF.get_global_stat_sys_tables()

  Description: Aggregates statistics on the system catalogs of all the namespaces in the pg_catalog or information_schema schema on each node. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

  Return type: record.

- DBE_PERF.get_summary_stat_sys_tables()

  Description: Collects statistics on the system catalogs of all the namespaces in the pg_catalog or information_schema schema on each node. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

  Return type: record.

- DBE_PERF.get_global_stat_sys_indexes()

  Description: Aggregates index status information about all system catalogs in the pg_catalog or information_schema schema on each node. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

  Return type: record.

- DBE_PERF.get_summary_stat_sys_indexes()

  Description: Collects index status information about all system catalogs in the pg_catalog or information_schema schema on each node. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

  Return type: record.

- DBE_PERF.get_global_stat_user_tables()

  Description: Aggregates status information about user-defined ordinary tables in all namespaces. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

  Return type: record.

- DBE_PERF.get_summary_stat_user_tables()

  Description: Collects status information about user-defined ordinary tables in all namespaces. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

  Return type: record.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- DBE_PERF.get_global_stat_user_indexes()

  Description: Aggregates status information about the indexes of user-defined ordinary tables in all databases. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

  Return type: record.

- DBE_PERF.get_summary_stat_user_indexes()

  Description: Collects status information about the indexes of user-defined ordinary tables in all databases. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

  Return type: record.

- DBE_PERF.get_global_stat_database()

  Description: Aggregates statistics on databases on all nodes. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

  Return type: record.

- DBE_PERF.get_global_stat_database_conflicts()

  Description: Collects statistics on databases on all nodes. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

  Return type: record.

- DBE_PERF.get_global_stat_xact_all_tables()

  Description: Aggregates transaction status information about all ordinary tables and TOAST tables in namespaces. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

  Return type: record.

- DBE_PERF.get_summary_stat_xact_all_tables()

  Description: Collects transaction status information about all ordinary tables and TOAST tables in the namespace. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

  Return type: record.

- DBE_PERF.get_global_stat_xact_sys_tables()

  Description: Aggregates transaction status information about system catalogs in namespaces on all nodes. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

  Return type: record.

- DBE_PERF.get_summary_stat_xact_sys_tables()

  Description: Collects transaction status information about system catalogs in namespaces on all nodes. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

  Return type: record.

- DBE_PERF.get_global_stat_xact_user_tables()

  Description: Aggregates transaction status information about user tables in namespaces on all nodes. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

  Return type: record.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- DBE_PERF.get_summary_stat_xact_user_tables()

  Description: Collects transaction status information about user tables in namespaces on all nodes. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

  Return type: record.

- DBE_PERF.get_global_stat_user_functions()

  Description: Aggregates transaction status information about user-defined functions in namespaces on all nodes. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

  Return type: record.

- DBE_PERF.get_global_stat_xact_user_functions()

  Description: Collects transaction status information about user-defined functions in namespaces on all nodes. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

  Return type: record.

- DBE_PERF.get_global_stat_bad_block()

  Description: Aggregates information about the failure to read files such as tables and indexes on all nodes. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

  Return type: record.

- DBE_PERF.get_global_file_redo_iostat()

  Description: Collects information about the failure to read files such as tables and indexes on all nodes. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

  Return type: record.

- DBE_PERF.get_global_file_iostat()

  Description: Collects I/O statistics of data files on all nodes. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

  Return type: record.

- DBE_PERF.get_global_locks()

  Description: Aggregates lock information on all nodes. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

  Return type: record.

- DBE_PERF.get_global_replication_slots()

  Description: Aggregates logical replication information on all nodes. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

  Return type: record.

- DBE_PERF.GET_GLOBAL_PARALLEL_DECODE_STATUS()

  Description: Displays the parallel decoding information of replication slots on all primary DNs in a cluster. After a cluster is created, by default, you must have the MONADMIN permission to query this function. This function can be executed only on CNs. An error is reported when it is executed on DNs. The

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

returned value is the same as that of the view in **DBE_PERF.GLOBAL_PARALLEL_DECODE_STATUS**.

Return type: record.

- DBE_PERF.GET_GLOBAL_PARALLEL_DECODE_THREAD_INFO()

  Description: Displays the parallel decoding thread information of replication slots on all primary DNs in a cluster. After a cluster is created, by default, you must have the MONADMIN permission to query this function. This function can be executed only on CNs. An error is reported when it is executed on DNs. The returned value is the same as that of the view in **DBE_PERF.GLOBAL_PARALLEL_DECODE_THREAD_INFO**.

  Return type: record.

- DBE_PERF.get_global_bgwriter_stat()

  Description: Aggregates statistics on the background write thread activities on all nodes. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

  Return type: record.

- DBE_PERF.get_global_replication_stat()

  Description: Aggregates status information about log synchronization on all nodes, such as the location where the sender sends logs and the location where the receiver receives logs. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

  Return type: record.

- DBE_PERF.get_global_pooler_status()

  Description: Aggregates cache connection status in the pooler on all CNs. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

  Return type: record.

- DBE_PERF.get_global_transactions_running_xacts()

  Description: Aggregates information about running transactions on each node. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

  Return type: record.

- DBE_PERF.get_summary_transactions_running_xacts()

  Description: Collects information about running transactions on each node. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

  Return type: record.

- DBE_PERF.get_global_transactions_prepared_xacts()

  Description: Aggregates information about transactions that are currently prepared for two-phase commit on each node. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

  Return type: record.

- DBE_PERF.get_summary_transactions_prepared_xacts()

  Description: Collects information about transactions that are currently prepared for two-phase commit on each node. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Return type: record.

- DBE_PERF.get_summary_statement()

  Description: Aggregates the status of historical statements executed on each node. After a cluster is created, by default, you must have the MONADMIN permission to query this function. For details about the columns returned by the function, see **DBE_PERF.SUMMARY_STATEMENT**.

  Return type: record.

- DBE_PERF.get_global_statement_count()

  Description: Aggregates SELECT, UPDATE, INSERT, DELETE, and response time information (TOTAL, AVG, MIN, and MAX) on each node. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

  Return type: record.

- DBE_PERF.get_global_config_settings()

  Description: Aggregates GUC parameter settings on each node. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

  Return type: record.

- DBE_PERF.get_global_wait_events()

  Description: Aggregates status information about the wait events on each node. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

  Return type: record.

- DBE_PERF.get_statement_responsetime_percentile()

  Description: Obtains the distribution information about the response time of 80% and 95% SQL statements in the cluster. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

  Return type: record.

- DBE_PERF.get_summary_user_login()

  Description: Collects statistics on the number of user login and logout times on each node in the cluster. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

  Return type: record.

- DBE_PERF.get_global_record_reset_time()

  Description: Aggregates statistics on reset (restart, primary-standby switchover, and database deletion) time in the cluster. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

  Return type: record.

- DBE_PERF.standby_statement_history(only_slow[, time1, time2])

  Description: Queries full SQL statements on the standby node. The primary node queries full SQL statements using the statement_history table, while the standby node queries using this function. To execute this function, you must have the MONADMIN permission. For details about the columns returned by the function, see **STATEMENT_HISTORY**.

  Parameters: See **Table 1-232**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Return type: record.

Table 1-232 standby_statement_history parameters

Parameter	Type	Description
only_slow	Boolean	Specifies whether to query only slow SQL statements. • **true** indicates yes, which is equivalent to **select .. where is_slow_sql = true**. • **false** or **NULL** indicates that all SQL statements are queried, that is, **is_slow_sql** is not used as a filter condition.
time1	timestamptz	Minimum time specified by **finish_time** for querying SQL statements. This parameter is optional.
time2	timestamptz	Maximum time specified by **finish_time** for querying SQL statements. This parameter is optional. An error is reported during function execution if **time1** is greater than or equal to **time2**.

NOTE

- The two time parameters **time1** and **time2** indicate the time segment to which **finish_time** of the queried SQL statement belongs. They indicate the start time and end time respectively. If **NULL** or no value is entered, there is no limit. The function of **time1** and **time2** is the same as that of **select .. where finish_time between time1 and time2**.
- The data generated from this function on the standby node is not stored in a table, and there is no index on the **start_time** column. You are advised to use the parameter to search for **finish_time**.
- Full/Slow SQL statements on the standby node are written to disks asynchronously. Therefore, the storage of user SQL information may be delayed. You are advised to query this API to expand the query time range.

- DBE_PERF.global_io_wait_info()

  Description: Queries real-time I/O control statistics on all CNs and DNs. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

  Return type: record.

- pg_stat_get_mem_mbytes_reserved(tid)

  Description: Collects statistics on variables related to resource management, which is used only for fault locating.

  Parameter: thread ID.

  Return type: text.

- pg_stat_get_file_stat()

  Description: Collects statistics on data file I/Os to indicate I/O performance and detect performance problems such as abnormal I/O operations.

  Return type: record.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- pg_stat_get_redo_stat()

  Description: Displays statistics on the replay of session thread logs.

  Return type: record.

- pg_stat_get_status(int8)

  Description: Tests the blocking status about the backend thread and auxiliary thread of the current instance.

  Return type: record.

- get_local_rel_iostat()

  Description: Queries the accumulated I/O status of data files on the current node.

  Return type: record.

- DBE_PERF.get_global_rel_iostat()

  Description: Aggregates I/O statistics on data files on all nodes. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

  Return type: record.

- pg_catalog.plancache_status(is_with_plan)

  Description: Specifies whether to display the GPC status information on the current node, that is, the **plan_info** column. The input parameter **is_with_plan** is of the Boolean type. The default value is **false**. If the input parameter is **true**, the **plan_info** information is displayed. The information returned by the function is the same as that in **DBE_PERF.GLOBAL_PLANCACHE_STATUS**. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

  Return type: record.

  NOTE

  - When the input parameter of **pg_catalog.plancache_status** is set to **true** and there are a large number of plans, the performance may deteriorate. You are advised to use the pg_catalog.global_plancache_show_plan function to query the detailed plan information of a single SQL statement.
  - If you do not have the permission on the table on which the plan depends, an error message indicating insufficient permission is displayed in the **plan_info** column.

- DBE_PERF.global_plancache_status(is_with_plan)

  Description: Specifies whether to display the GPC status information on all nodes, that is, the **plan_info** column. The input parameter **is_with_plan** is of the Boolean type. The default value is **false**. If the input parameter is **true**, the **plan_info** information is displayed. For details about the information returned by the function, see **DBE_PERF.GLOBAL_PLANCACHE_STATUS**. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

  Return type: record.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- When the input parameter of **DBE_PERF.global_plancache_status** is set to **true** and there are a large number of plans, the performance may deteriorate. You are advised to use the pg_catalog.global_plancache_show_plan function to query the detailed plan information of a single SQL statement.
- If you do not have the permission on the table on which the plan depends, an error message indicating insufficient permission is displayed in the **plan_info** column.

- pg_catalog.gs_plancache_stat()

  Description: Displays information about parameterized statements of all sessions in the current process. The information returned by the function is consistent with **DBE_PERF.GS_PLANCACHE_STAT**. To query this function, you must have the MONADMIN permission.

  Return type: record.

- pg_catalog.gs_dist_plancache_stat()

  Description: Displays information about parameterized statements of all processes on the standby node. The information returned by the function is consistent with **DBE_PERF.GS_DIST_PLANCACHE_STAT**. To query this function, you must have the MONADMIN permission.

  Return type: record.

- DBE_PERF.global_threadpool_status()

  Description: Displays the status of worker threads and sessions in thread pools on all nodes. For details about the information returned by the function, see **DBE_PERF.GLOBAL_THREADPOOL_STATUS**. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

  Return type: record.

- comm_check_connection_status()

  Description: Returns the connection status between the CN and all active nodes (CNs and primary DNs). This function can be queried only on CNs and can be used by common users.

  Parameter: nan.

  Return types: node_name text, remote_name text, remote_host text, remote_port integer, is_connected boolean, and no_error_occur boolean.

- DBE_PERF.global_comm_check_connection_status()

  Description: Returns the connection status between all CNs and all active nodes (CNs and primary DNs). This function can be queried only on CNs. Permission control is inherited from the **DBE_PERF** schema. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

  Parameter: nan.

  Return types: node_name text, remote_name text, remote_host text, remote_port integer, is_connected boolean, and no_error_occur boolean.

- remote_candidate_stat()

  Description: Displays the number of pages in the candidate buffer chain of this instance and buffer elimination information, including the normal buffer pool and segment buffer pool.

  Return type: record.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 1-233 remote_candidate_stat parameters

Name	Type	Description
node_name	text	Node name.
candidate_slots	integer	Number of pages in the candidate buffer chain of the current normal buffer pool.
get_buf_from_list	bigint	Number of times that pages are obtained from the candidate buffer chain during buffer eviction in the current normal buffer pool.
get_buf_clock_sweep	bigint	Number of times that pages are obtained from the original eviction solution during buffer eviction in the current normal buffer pool.
seg_candidate_slots	integer	Number of pages in the candidate buffer chain of the current segment buffer pool.
seg_get_buf_from_list	bigint	Number of times that pages are obtained from the candidate buffer chain during buffer eviction in the current segment buffer pool.
seg_get_buf_clock_sweep	bigint	Number of times that pages are obtained from the original eviction solution during buffer eviction in the current segment buffer pool.

- remote_ckpt_stat()

  Description: Displays the checkpoint information and log flushing information about all instances in the cluster (unavailable on DNs, except for the current node).

  Return type: record.

  Table 1-234 remote_ckpt_stat parameters

Parameter	Type	Description
node_name	text	Instance name.
ckpt_redo_point	text	Checkpoint of the current instance.
ckpt_clog_flush_num	int8	Number of Clog flushing pages from the startup time to the current time.
ckpt_csnlog_flush_num	int8	Number of CSN log flushing pages from the startup time to the current time.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Type	Description
ckpt_multixact_flush_num	int8	Number of MultiXact flushing pages from the startup time to the current time.
ckpt_predicate_flush_num	int8	Number of predicate flushing pages from the startup time to the current time.
ckpt_twophase_flush_num	int8	Number of two-phase flushing pages from the startup time to the current time.

- remote_double_write_stat()

  Description: Displays doublewrite file status of all instances in the cluster (unavailable on DNs, except for the current node).

  Return type: record.

  Table 1-235 remote_double_write_stat parameters

Parameter	Type	Description
node_name	text	Instance name.
curr_dwn	int8	Sequence number of the doublewrite file.
curr_start_page	int8	Start page for restoring the doublewrite file.
file_trunc_num	int8	Number of times that the doublewrite file is reused.
file_reset_num	int8	Number of reset times after the doublewrite file is full.
total_writes	int8	Total number of I/Os of the doublewrite file.
low_threshold_writes	int8	Number of I/Os for writing doublewrite files with low efficiency (the number of I/O flushing pages at a time is less than 16).
high_threshold_writes	int8	Number of I/Os for writing doublewrite files with high efficiency (the number of I/O flushing pages at a time is more than 421).
total_pages	int8	Total number of pages that are flushed to the doublewrite file area.
low_threshold_pages	int8	Number of pages that are flushed with low efficiency.
high_threshold_pages	int8	Number of pages that are flushed with high efficiency.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Type	Description
file_id	int8	ID of the current doublewrite file.

- remote_single_flush_dw_stat()

  Description: Displays the single-page doublewrite file eviction status of all instances in the cluster (unavailable on DNs, except for the current node).

  Return type: record.

  Table 1-236 remote_single_flush_dw_stat parameters

Parameter	Type	Description
node_name	text	Instance name.
curr_dwn	integer	Sequence number of the doublewrite file.
curr_start_page	integer	Start position of the current doublewrite file.
total_writes	bigint	Total number of data write pages in the current doublewrite file.
file_trunc_num	bigint	Number of times that the doublewrite file is reused.
file_reset_num	bigint	Number of reset times after the doublewrite file is full.

- remote_pagewriter_stat()

  Description: Displays the page flushing information and checkpoint information about all instances in the cluster (unavailable on DNs, except for the current node).

  Return type: record.

  Table 1-237 remote_pagewriter_stat parameters

Parameter	Type	Description
node_name	text	Instance name.
pgwr_actual_flush_total_num	int8	Total number of dirty pages flushed from the startup time to the current time.
pgwr_last_flush_num	int4	Number of dirty pages flushed in the previous batch.
remain_dirty_page_num	int8	Estimated number of dirty pages that are not flushed.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Type	Description
queue_head_page_rec_lsn	text	**recovery_lsn** of the first dirty page in the dirty page queue of the current instance.
queue_rec_lsn	text	**recovery_lsn** of the dirty page queue of the current instance.
current_xlog_insert_lsn	text	Position of writing Xlogs in the current instance.
ckpt_redo_point	text	Checkpoint of the current instance.

- remote_recovery_status()

  Description: Displays log flow control information about the primary and standby nodes (except the current node and DNs).

  Return type: record.

  Table 1-238 remote_recovery_status parameters

Parameter	Type	Description
node_name	text	Node name (including the primary and standby nodes).
standby_node_name	text	Name of the standby node.
source_ip	text	IP address of the primary node.
source_port	int4	Port number of the primary node.
dest_ip	text	IP address of the standby node.
dest_port	int4	Port number of the standby node.
current_rto	int8	Current log flow control time of the standby node (unit: s).
target_rto	int8	Expected flow control time of the standby node specified by the corresponding GUC parameter (unit: s).
current_sleep_time	int8	Sleep time required to achieve the expected flow control time (unit: μs).

- remote_rto_stat()

  Description: Displays log flow control information about the primary and standby nodes (except the current node and DNs).

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Return type: record.

Table 1-239 remote_rto_stat parameters

Parameter	Type	Description
node_name	text	Node name (including the primary and standby nodes).
rto_info	text	Flow control information, including the current log flow control time (unit: second) of the standby node, the expected flow control time (unit: second) specified by the GUC parameter, and the primary node sleep time (unit: μs) required to reach the expectation.

- remote_redo_stat()

  Description: Displays the log replay status of all instances in the cluster (unavailable on DNs, except for the current node).

  Return type: record.

  Table 1-240 remote_redo_stat parameters

Parameter	Type	Description
node_name	text	Instance name.
redo_start_ptr	int8	Start point for replaying the instance logs.
redo_start_time	int8	Start time (UTC) when the instance logs are replayed.
redo_done_time	int8	End time (UTC) when the instance logs are replayed.
curr_time	int8	Current time (UTC) of the instance.
min_recovery_point	int8	Position of the minimum barrier for the instance logs.
read_ptr	int8	Position for reading the instance logs.
last_replayed_read_ptr	int8	Position for replaying the instance logs.
recovery_done_ptr	int8	Replay position after the instance is started.
read_xlog_io_counter	int8	Number of I/Os when the current instance reads and replays logs.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Type	Description
read_xlog_io_total_dur	int8	Total I/O latency when the current instance reads and replays logs.
read_data_io_counter	int8	Number of data page I/O reads during replay in the current instance.
read_data_io_total_dur	int8	Total I/O latency of data page reads during replay in the current instance.
write_data_io_counter	int8	Number of data page I/O writes during replay in the current instance.
write_data_io_total_dur	int8	Total I/O latency of data page writes during replay in the current instance.
process_pending_counter	int8	Number of synchronization times of log distribution threads during replay in the instance.
process_pending_total_dur	int8	Total synchronization latency of log distribution threads during replay in the instance.
apply_counter	int8	Number of synchronization times of redo threads during redo in the current instance
apply_total_dur	int8	Total synchronization latency of redo threads during redo in the current instance
speed	int8	Log replay rate of the current instance.
local_max_ptr	int8	Maximum number of replay logs received by the localhost after the instance is started.
primary_flush_ptr	int8	Log point where the host flushes logs to a disk.
worker_info	text	Replay thread information of the instance. If parallel replay is not enabled, the value is null.

- pgxc_gtm_snapshot_status()

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description: Queries for transaction information on the current GTM. This function is supported only in GTM mode, and is not supported in GTM-LITE or GTM-FREE mode.

Return type: record.

The following table describes return parameters.

Table 1-241 PGXC_GTM_SNAPSHOT_STATUS return parameters

Name	Type	Description
xmin	xid	Minimum XID of the running transactions.
xmax	xid	XID of the transaction next to the executed transaction with the maximum XID.
csn	integer	Specifies the sequence number of the transaction to be committed.
oldestxmin	xid	Minimum XID of the executed transactions.
xcnt	integer	Number of the running transactions.
running_xids	text	XID of the running transaction.

- pv_os_run_info()

  Description: Displays the running status of the current OS. For details about the columns, see **PV_OS_RUN_INFO**.

  Parameter: nan.

  Return type: SETOF record
- pv_session_stat()

  Description: Collects session status information by session thread or autovacuum thread. For details about the columns, see **PV_SESSION_STAT**.

  Parameter: nan.

  Return type: SETOF record
- pv_session_time()

  Description: Collects statistics on the running time of session threads and the time consumed in each execution phase. For details about the columns, see **PV_SESSION_TIME**.

  Parameter: nan.

  Return type: SETOF record
- pg_stat_get_db_temp_bytes()

  Description: Collects statistics on the total amount of data written to temporary files through database query. All temporary files are calculated, regardless of why they were created or how **log_temp_files** is configured.

  Parameter: oid.

  Return type: bigint.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- pg_stat_get_db_temp_files()

  Description: Queries the number of temporary files created in the database. All temporary files are calculated, regardless of why they were created (such as sorting or hashing) or how **log_temp_files** is configured.

  Parameter: oid.

  Return type: bigint.

- gs_prepared_statements()

  Description: Displays prepared statements that are available in all sessions. Only users with the SYSADMIN permission can execute this function. The columns in the information returned by the function are the same as those in **GS_ALL_PREPARED_STATEMENTS**.

  Return type: record.

- local_redo_time_count([int])

  Description: Returns the time consumption statistics of the replay process on the current node (valid data exists only on the standby node). In parallel replay mode, it returns the process duration statistics of each replayer thread. In ultimate RTO mode, it returns the process duration statistics of each replayer thread and the process duration statistics of different log types.

  Parameters:

Parameter	Type	Description
operation	int	Optional. If no value is entered, statistics are queried. ● **–1** (default): disables the statistics function. ● **0**: enables the statistics function. ● **1**: queries statistics. ● **2**: resets statistics. After the statistics function is disabled and then enabled again, the previous statistics are cleared.

  The return values are as follows.

  Table 1-242 local_redo_time_count return parameters

Column	Description
thread_name	Thread name.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Column	Description
step1_total	Total duration of step 1. The process of each thread is as follows: ● Ultimate RTO: **redo batch**: obtains a log from a queue. **redo manager**: obtains a log from a queue. **redo worker**: obtains a log from a queue. **trxn manager**: reads a log from a queue. **trxn worker**: reads a log from a queue. **read worker**: reads an Xlog page (overall) from a file. **read page worker**: obtains a log from a queue. **startup**: obtains a log from a queue. ● Parallel replay: **page redo**: obtains a log from a queue. **startup**: reads a log.
step1_count	Number of accumulated execution times of step 1.
step2_total	Total duration of step 2. The process of each thread is as follows: ● Ultimate RTO: **redo batch**: processes logs (overall). **redo manager**: processes logs (overall). **redo worker**: processes logs (overall). **trxn manager**: processes logs (overall). **trxn worker**: processes logs (overall). **read worker**: specifies the time required for reading the Xlog page. **read page worker**: generates and sends LSN forwarders. **startup**: checks whether to replay to the specified position. ● Parallel replay: **startup**: checks whether to replay to the specified position.
step2_count	Number of accumulated execution times of step 2.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Column	Description
step3_total	Total duration of step 3. The process of each thread is as follows: ● Ultimate RTO: **redo batch**: updates the standby state. **redo manager**: processes data logs. **redo worker**: replays page logs (overall). **trxn manager**: updates the flushing LSN. **trxn worker**: replays logs. **read worker**: updates the Xlog segment. **read page worker**: obtains a new item. **startup**: collects statistics on the wait time of delayed replay feature. ● Parallel replay: **page redo**: updates the standby state. **startup**: collects statistics on the wait time of delayed replay feature.
step3_count	Number of accumulated execution times of step 3.
step4_total	Total duration of step 4. The process of each thread is as follows: ● Ultimate RTO: **redo batch**: parses Xlogs. **redo manager**: processes DDL operations. **redo worker**: reads data pages. **trxn manager**: synchronizes the wait time. **trxn worker**: updates the LSN of the current thread. **read page worker**: stores logs in the distribution thread. **startup**: distributes logs (overall). ● Parallel replay: **page redo**: replays undo logs. **startup**: distributes logs (overall).
step4_count	Number of accumulated execution times of step 4.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Column	Description
step5_total	Total duration of step 5. The process of each thread is as follows: ● Ultimate RTO: **redo manager**: processes database logs. **redo worker**: replays data page logs. **trxn manager**: distributes data to the trxn worker. **trxn worker**: completes waiting for the notification of strong synchronization logs. **read page worker**: updates the LSN of the current thread. **startup**: decodes logs. ● Parallel replay: **page redo**: replays share trxn logs. **startup**: replays logs.
step5_count	Number of accumulated execution times of step 5.
step6_total	Total duration of step 6. The process of each thread is as follows: ● Ultimate RTO: **redo worker**: replays non-data page logs. **trxn manager**: updates global LSNs. ● Parallel replay: **page redo**: replays synctrxn logs. **startup**: forcibly synchronizes the wait time.
step6_count	Number of accumulated execution times of step 6.
step7_total	Total duration of step 7. The process of each thread is as follows: ● Ultimate RTO: **redo manager**: creates tablespaces. **redo worker**: updates FSM. ● Parallel replay: **page redo**: replays a single log.
step7_count	Number of accumulated execution times of step 7.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Column	Description
step8_total	Total duration of step 8. The process of each thread is as follows: ● Ultimate RTO: **redo worker**: forcibly synchronizes the wait time. **redo manager**: processes segment-page logs. ● Parallel replay: **page redo**: replays all workers do logs.
step8_count	Number of accumulated execution times of step 8.
step9_total	Total duration of step 9. The process of each thread is as follows: ● Ultimate RTO: **redo manager**: processes segment-page undo logs. ● Parallel replay: **page redo**: replays multi-worker do logs.
step9_count	Number of accumulated execution times of step 9.

Process duration statistics of the log type (If this function is disabled, replayed logs are sampled for statistics.)

Column	Process Description
thread_name	Name of the sample.
step1_total	Ultimate RTO: ● For data logs, it specifies the total time required for processing logs, including step 2. ● For transaction logs, it replays transaction logs.
step1_count	Number of accumulated execution times of step 1.
step2_total	Ultimate RTO: ● For data logs, it specifies the total time required for replaying page logs, including step 3 and step 4. The main difference between step 2 and (step 3+step 4) is the construction of multi-version pages that perform read on standby. ● For transaction logs, it specifies the synchronization waiting time before transaction thread replay.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Column	Process Description
step2_count	Number of accumulated execution times of step 2.
step3_total	Ultimate RTO: • For data logs, it reads data pages.
step3_count	Number of accumulated execution times of step 3.
step4_total	Ultimate RTO: • For data logs, it replays data page logs.
step4_count	Number of accumulated execution times of step 4.
step5_total	Ultimate RTO: • For transaction logs, it records the replay time of the redo_worker thread.
step5_count	Number of accumulated execution times of step 5.
step6_total	Ultimate RTO: • For data logs, it updates FSM.
step6_count	Number of accumulated execution times of step 6.
Step7_total	Ultimate RTO: • For transaction logs, it records the synchronization wait time of the redo_worker thread.
Step7_count	Number of accumulated execution times of step 7.

- local_xlog_redo_statics()

  Description: Returns the statistics on each type of logs that have been replayed on the current node (valid data exists only on the standby node).

  The return values are as follows.

  Table 1-243 local_xlog_redo_statics parameters

Column	Description
xlog_type	Log types.
rmid	Resource manager ID.
info	Xlog operation.
num	Number of logs.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Column	Description
extra	Valid values are available for page replay logs and xact logs. • Number of pages read from the disk if the log is of the page type. • Number of deleted files if the log is of the xact type.

- remote_bgwriter_stat()

  Description: Displays information about pages flushed by the bgwriter threads of all instances in the cluster, number of pages in the candidate buffer chain, and buffer eviction information (not available on the DN, except for the current node).

  Return type: record.

  Table 1-244 remote_bgwriter_stat parameters

Parameter	Type	Description
node_name	text	Instance name.
bgwr_actual_flush_total_num	bigint	Total number of dirty pages flushed by the bgwriter thread from the startup time to the current time.
bgwr_last_flush_num	integer	Number of dirty pages flushed by the bgwriter thread in the previous batch.
candidate_slots	integer	Number of pages in the current candidate buffer chain.
get_buffer_from_list	bigint	Number of times that pages are obtained from the candidate buffer chain during buffer eviction.
get_buf_clock_sweep	bigint	Number of times that pages are obtained from the original eviction solution during buffer eviction.

  Example:

  The remote_bgwriter_stat function is used to query the page refreshing information of the bgwriter thread.

```
gaussdb=# SELECT * FROM remote_bgwriter_stat();
 node_name | bgwr_actual_flush_total_num | bgwr_last_flush_num | candidate_slots |
get_buffer_from_list | get_buf_clock_sweep
```

(3 rows)
```

- gs_stack()

  Description: Displays the call stack of a thread. To query this function, you must have the SYSADMIN or MONADMIN permission.

  Parameter: **tid** (thread ID). **tid** is an optional parameter. If it is specified, the function returns the call stack of the thread corresponding to **tid**. If it is not specified, the function returns the call stacks of all threads.

  Return value: If **tid** is specified, the return value is of the TEXT type. If **tid** is not specified, the return value is a SETOF record.

  Example:

  Obtain the call stack of a specified thread.

```
gaussdb=# SELECT * FROM gs_stack(139663481165568);
                        gs_stack
------------------------------------------------------------------------
 __poll + 0x2d                                                         +
 WaitLatchOrSocket(Latch volatile*, int, int, long) + 0x29f        +

  NOTE

  Concurrent execution of multiple gs_stack() functions is not supported.

- gs_perf_start(duration integer[, freq integer])

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description: Collects the stack call data of the on-CPU flame graph of each thread on the current node. The function returns the flame graph flushing address. To query this function, you must have the SYSADMIN or MONADMIN permission. This function is available in **ROOT** or **DBUSER** mode and unavailable in **DISABLE** mode.

The parameters are described as follows.

Parameter	Description	Type	Range
duration	Stack collection duration, in seconds. If a floating-point number is entered, the first digit after the decimal point is rounded off.	integer	1–60
freq	(Optional) Stack collection frequency, in Hz. The default value is **100**. If a floating-point number is entered, the first digit after the decimal point is rounded off.	integer	10–1000

Return type: text.

Example:

Set the frequency to 100 Hz and collect on-CPU stack information for 10s.

```
gaussdb=# SELECT gs_perf_start(10,100);
                                gs_perf_start
-------------------------------------------------------------------------------
 Successfully collected perf flamegraph data, the result filepaths are :          +
 $GAUSSLOG/gs_flamegraph/cn_5001/flamegraph-manual-oncpu-2025-03-03_104812.html.gz;+
 Record 886 cpu clock samples.                                                    +

(1 row)
```

NOTICE

Before executing this function and the following gs_perf_start_offcpu(), gs_perf_start_all(), and gs_perf_start_detail() functions, ensure that gs_perf_service is running properly. During data collection, gs_perf_service needs to apply for a ring buffer. The buffer size is controlled by **/proc/sys/kernel/perf_event_mlock_kb** in the OS. If the error message "perf mmap failed" is displayed during the collection, adjust the size of **/proc/sys/kernel/perf_event_mlock_kb** and perform the collection again.

- gs_perf_start_offcpu(duration integer)

  Description: Collects the stack call data of the off-CPU flame graph of each thread on the current node. The function returns the flame graph flushing address. To query this function, you must have the SYSADMIN or MONADMIN permission. This function is available in **ROOT** mode and unavailable in **DBUSER** or **DISABLE** mode.

  The parameters are described as follows.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Description	Type	Range
duration	Stack collection duration, in milliseconds. If a floating-point number is entered, the first digit after the decimal point is rounded off.	integer	50~3000

Return type: text.

Example:

Collect off-CPU stack information for 2000 ms.

```
gaussdb=# SELECT gs_perf_start_offcpu(2000);
                                gs_perf_start_offcpu
-------------------------------------------------------------------------------------
 Successfully collected perf flamegraph data, the result filepaths are :          +
 $GAUSSLOG/gs_flamegraph/cn_5001/flamegraph-manual-offcpu-2025-03-03_104918.html.gz;+
 Record 48 sched switch samples.                                                  +

(1 row)
```

- gs_perf_start_detail(duration integer[, freq integer])

  Description: Collects the on-CPU and off-CPU call stack details of all threads on all CPU cores on the host where the current node is located. The function returns the address of the compressed file of multi-core and multi-thread raw data. Each time this command is executed, the historical multi-core and multi-thread data is deleted. To query this function, you must have the SYSADMIN or MONADMIN permission. This function is available in **ROOT** mode and unavailable in **DBUSER** or **DISABLE** mode.

  The parameters are described as follows.

Parameter	Description	Type	Range
duration	Stack collection duration, in milliseconds. If a floating-point number is entered, the first digit after the decimal point is rounded off.	integer	50~3000
freq	(Optional) Stack collection frequency, in Hz. The default value is **100**. If a floating-point number is entered, the first digit after the decimal point is rounded off.	integer	10–1000

Return type: text.

Example:

Collect multi-core and multi-thread flame graph data for 2000 ms.

```
gaussdb=# SELECT gs_perf_start_detail(2000);
                               gs_perf_start_detail
```

```
-----------------------------------------------------------------------------------------------------
 Successfully collected perf detail data, the result filepath is :                                  +
 $GAUSSLOG/gs_flamegraph/cn_5001/detail-2025-03-03_105043.lz4                                       +
 Please save the file locally, otherwise the file will be deleted during the next data collection.+
 Record 1735211 samples.                                                                            +

(1 row)
```

- gs_perf_start_all(duration integer[, freq integer])

  Description: Collects the stack call data of the on-CPU and off-CPU flame graphs on all nodes of the host where the current node is located. The function returns the flame graph flushing addresses on all nodes. To query this function, you must have the SYSADMIN or MONADMIN permission. This function is available in **ROOT** mode. In **DBUSER** mode, only on-CPU flame graph data can be collected. In **DISABLE** mode, this function is unavailable.

  The parameters are described as follows.

Parameter	Description	Type	Range
duration	Stack collection duration, in milliseconds. If a floating-point number is entered, the first digit after the decimal point is rounded off.	integer	50~3000
freq	(Optional) Stack collection frequency, in Hz. The default value is **100**. If a floating-point number is entered, the first digit after the decimal point is rounded off.	integer	10–1000

  Return type: text.

  Example:

  Set the frequency to 100 Hz and collect the on-CPU and off-CPU flame graph data on all nodes of the host where the current node is located for 1000 ms.

```
gaussdb=# SELECT gs_perf_start_all(1000,100);
                                        gs_perf_start_all
-------------------------------------------------------------------------------------------------------------

 Please visit gs_flamegraph directory(all nodes of current machine) to get results for individual nodes.+
 Record 664 cpu clock samples.                                                                           +
 Record 370 sched switch samples.                                                                         +

(1 row)
```

- gs_perf_list()

  Description: Views the collected on-CPU and off-CPU flame graph data saved on the current node. The multi-core and multi-thread flame graph records are not displayed. This function is available in **ROOT** or **DBUSER** mode and unavailable in **DISABLE** mode.

  Parameter: nan.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Return type: SETOF record

The following table describes the fields returned by the function.

Name	Type	Description
nodename	text	Name of a collection node.
filename	text	Name of a file to be collected and flushed to disk.
collect_type	text	Collection type.

Example:

Query the flame graph generation records saved on the current node.

```
gaussdb=# SELECT * FROM gs_perf_list() limit 10;
 nodename |                          filename                          | collect_type

- gs_perf_query([filename text])

  Description: Queries the historical on-CPU and off-CPU flame graph stack call data. The function collects the function call stacks of each thread, sums up the function running time, and returns the collection result. To query this function, you must have the SYSADMIN or MONADMIN permission. This function is available in **ROOT** or **DBUSER** mode and unavailable in **DISABLE** mode.

  The parameters are described as follows.

Parameter	Description	Type
filename	Name of a historically collected file. This parameter is optional. The default value is the latest manually collected flame graph.	text

  Return type: SETOF record

  The following table describes the fields returned by the function.

Name	Type	Description
backtrace	text	Stack name (in a tree structure).
period	bigint	Execution time of a stack.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Name	Type	Description
level	integer	Level of the stack call tree where a stack is located.
sequence	integer	Sequence in the stack call tree after sorting.
thread_name	text	Name of the thread where a stack is located.
overhead	float	Percentage of the stack execution time.

Example:

Query the collected stack information.

```
gaussdb=# SELECT * FROM gs_perf_query() WHERE overhead > 2 AND level < 10;
                                backtrace                                |   period    | level | sequence |
thread_name  | overhead

- gs_perf_query_general([filename text])

  Description: Queries the percentage of functions called by stacks in the historical on-CPU and off-CPU flame graphs. The sum of the percentages may not be 1 due to calculation precision. To query this function, you must have the SYSADMIN or MONADMIN permission. This function is available in **ROOT** or **DBUSER** mode and unavailable in **DISABLE** mode.

  The parameters are described as follows.

Parameter	Description	Type
filename	Name of a historically collected file. This parameter is optional. The default value is the latest manually collected flame graph.	text

  Return type: SETOF record

  The following table describes the fields returned by the function.

Name	Type	Description
function_name	text	Stack function name.
percentage	float	Percentage of stack function calls.

  Example:

  Query the percentage of flame graph function calls generated in the latest manual collection.

```

- gs_perf_report()

  In the current version, the collection logic defaults to flushing to disk. Manual flushing is no longer required. It displays the address of the on-CPU file that is manually queried last time. To query this function, you must have the SYSADMIN or MONADMIN permission. This function is available in **ROOT** or **DBUSER** mode and unavailable in **DISABLE** mode.

  Parameter: nan.

  Return type: text.

  Example:

  Generate a flame graph file.

```
testdb3=# SELECT * FROM gs_perf_report();
                gs_perf_report
-------------------------------------------------
 flamegraph-manual-oncpu-2025-01-24_140232.html.gz
(1 row)
```

- gs_perf_clean()

  Description: The collection logic defaults to flushing to disk in the current version. After collection, the memory context is no longer occupied. Therefore, you do not need to manually clear the memory data. In the current version, a message is displayed, indicating that the function is deprecated. In later versions, the function is directly removed. To query this function, you must have the SYSADMIN or MONADMIN permission. This function is available in **ROOT** or **DBUSER** mode and unavailable in **DISABLE** mode.

  Parameter: nan.

  Return type: text.

  Example:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Clear data generated by perf.

```
gaussdb=# SELECT * FROM gs_perf_clean();
                                                gs_perf_clean
-------------------------------------------------------------------------------------------------------------------------------
----------
 gs_perf_clean is a duplicated function. now you don't need clean perf memory. this function will be removed in the next version
(1 row)
```

- gs_perf_start_shaking_collect(scope text, unique_querys textarray, duration int, max_collect_times int, ringbuffer_size int)

  Description: Enables performance jitter monitoring and returns whether the operation is successful. After performance jitter monitoring is enabled, the existing performance jitter flame graph files are cleared. If the gs_perf_start_shaking_collect function is repeatedly executed and the previous performance jitter monitoring is not complete, only the **unique_querys** parameter is reset and the existing performance jitter flame graph file is cleared at the next time, which does not affect the behavior of gs_perf_service. When a slow SQL statement is executed and belongs to the input parameter **unique_querys**, the performance jitter flame graph is generated. If the slow SQL statement is executed on the CN, the performance jitter flame graphs of all nodes are collected. Otherwise, the performance jitter flame graph of the local node is collected. If the performance jitter monitoring fails to be enabled on a node, the system attempts to disable the performance jitter monitoring on the node. To query this function, you must have the SYSADMIN or MONADMIN permission. This function is available in **ROOT** mode and unavailable in **DBUSER** or **DISABLE** mode.

  Table 1-245 gs_perf_start_shaking_collect parameters

Parameter	Type	Description	Range
scope	text	**local** indicates that the monitoring of the local node is started. **all** indicates that the performance jitter monitoring of all nodes is enabled. **all** can be used only on distributed CNs. This parameter is required. If it is set to NULL, the value is **local**.	**local** or **all**.
unique_querys	textarray	List of monitored unique SQL IDs. If a slow SQL statement is in the list, the performance jitter exists. This parameter is required. If it is set to NULL, the value is an empty list.	The list length ranges from 0 to 32.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Type	Description	Range
duration	int	Maximum continuous monitoring duration of performance jitter, in minutes. This parameter is required. If it is set to NULL, the value is **60**.	5-6000
max_collect_times	int	Maximum number of performance jitter snapshots that can be saved from a performance jitter flame graph. If the number of snapshots exceeds the value, the perf data collection stops. This parameter is required. If it is set to NULL, the value is **3**.	1-10
ringbuffer_size	int	Size of the ring buffer for storing performance perf, in MB. This parameter is required. If it is set to NULL, the value is **8**.	1-32

The following table describes return values.

Table 1-246 Return values of gs_perf_start_shaking_collect

Name	Type	Description
nodename	text	Node name.
message	text	If the return value is "Successfully entered CPU_SHAKE mode.", the performance jitter monitoring is enabled successfully. If the return value is "Current is in CPU_SHAKE mode.", the monitoring is enabled repeatedly. If the return value is "Unexpected Result: start_shaking_collect error, try to close shaking collect success. Details: *Detailed error information*", the monitoring fails to be enabled on the node and is successfully stopped. If the return value is "Unexpected Result: start_shaking_collect error, try to close shaking collect failed. Details: *Detailed error information*", the monitoring fails to be enabled on the node and fails to be stopped. This problem usually occurs when the node is disconnected.

NOTE

- gs_perf_start_shaking_collect(), gs_perf_do_shaking_collect(), gs_perf_close_shaking_collect(), and gs_perf_get_shaking_collect_status() can be executed only when gs_perf_service is running properly. In addition, gs_perf_service needs to apply for a ring buffer during collection. The size of the buffer is controlled by the number of CPU cores and the input parameter **ringbuffer_size** of gs_perf_start_shaking_collect().
- If you manually stop the execution of gs_perf_start_shaking_collect(), gs_perf_do_shaking_collect(), gs_perf_close_shaking_collect(), or gs_perf_get_shaking_collect_status() or the message return times out, only the frontend SQL statement is interrupted, and the perf_service process does not stop the corresponding task. During the execution of gs_perf_do_shaking_collect(), you can run **sudo kill -9 perf_service** *PID* to stop the perf_service process and forcibly interrupt the background task.
- Enabling and disabling performance jitter monitoring and saving performance jitter flame graphs are performed by physical machine. Therefore, when you perform these operations on a node, the monitoring status of other nodes on the same physical machine is affected. For example, after performance jitter monitoring is enabled on a node, other nodes on the same host also enter the monitoring status and the monitoring cannot be enabled again.
- When **scope** is set to **all**, the implementation of enabling and disabling performance jitter monitoring and saving performance jitter flame graphs is to traverse all nodes in sequence and perform the corresponding enabling, disabling, and saving operations on each node. Therefore, only one node on the same host returns a success message, and other nodes return failure messages indicating repeated execution.
- After a node in the cluster is faulty, if the system function is called and **scope** is set to **all**, corresponding operations are performed only on normal nodes, which are not affected by the faulty node. In the returned result, the **node_name** column of the faulty node is *node_host*:***node_port***.
- When a monitored SQL statement triggers a slow SQL statement and performance jitter data of all nodes are collected, the system traverses all nodes in sequence and collects the performance jitter data of the host where the nodes are located. The traversal sequence is not fixed. This ensures that the performance jitter data of one node on each physical machine is collected.
- After some shards are upgraded, you can run the new performance jitter flame graph function on them. The returned results of the upgraded shards are returned normally.
- After the collection process gs_perf_service is restarted, the performance jitter monitoring is disabled. You need to run the command again if you want to enable the performance jitter monitoring.
- After the gs_perf_start_shaking_collect() function is used to start performance jitter monitoring, the database takes about 1 second to initialize flame graph resources and then collects the performance jitter flame graph file.

- gs_perf_do_shaking_collect(scope text)

  Description: Flushes the multi-core and multi-thread flame graphs for performance jitter to disks, that is, saves the performance jitter snapshot and returns the result of whether the snapshot is saved successfully. This function depends on the gs_perf_start_shaking_collect() API. The performance jitter snapshot can be flushed to disks only after performance jitter monitoring is enabled. The minimum interval between two flushes is 1 minute. To prevent the background collection process from being hung, when the performance jitter flame graph is generated on a single node, if the background collection process gs_perf_service is not complete within 10 minutes or gs_perf_service exits abnormally during performance jitter collection, a timeout message is

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

returned. To execute this function, you must have the SYSADMIN or MONADMIN permission. This function is available in **ROOT** mode and unavailable in **DBUSER** or **DISABLE** mode.

Table 1-247 gs_perf_do_shaking_collect parameters

Parameter	Type	Description	Range
scope	text	**local** indicates that the perf data of the local node is flushed to disks. **all** indicates that the perf data of all nodes is flushed to disks. **all** can be used only on distributed CNs. This parameter is required. If it is set to NULL, the value is **local**.	**all** or **local**.

The following table describes return values.

Table 1-248 Return values of gs_perf_do_shaking_collect

Name	Type	Description
nodename	text	Node name.
message	text	The return value "Successfully collect perf detail data ....." indicates that the performance jitter snapshot is saved successfully. The return value "Current is not in CPU_SHAKE mode." indicates that the monitoring status is not enabled, and the performance jitter snapshot fails to be saved. The return value "Skipping collection this time....." indicates that the performance jitter snapshot is repeatedly saved within 1 minute. The return value "Unexpected Result: do_shaking_collect error. Details: *Detailed error information*" indicates that the execution fails.

Example:

Flush the performance jitter snapshots to disks on all nodes. The saving success, snapshot path, and flushing time are returned.

```
gaussdb=# SELECT * FROM gs_perf_do_shaking_collect('all');
 nodename |

- gs_perf_close_shaking_collect(scope text)

  Description: Disables performance jitter monitoring and returns whether the operation is successful. This function depends on the gs_perf_start_shaking_collect() API. The monitoring must be started before being disabled. Otherwise, a message is returned, indicating that the monitoring is not in progress. To query this function, you must have the SYSADMIN or MONADMIN permission. This function is available in **ROOT** mode and unavailable in **DBUSER** or **DISABLE** mode.

  Table 1-249 gs_perf_close_shaking_collect parameters

Parameter	Type	Description	Range
scope	text	**local** indicates that the monitoring of the current node is stopped. **all** indicates that the monitoring of all nodes is stopped. **all** can be used only on distributed CNs. This parameter is required. If it is set to NULL, the value is **local**.	**local** or **all**.

  The following table describes return values.

  Table 1-250 Return values of gs_perf_close_shaking_collect

Name	Type	Description
nodename	text	Node name.

Name	Type	Description
message	text	The return value "Successfully exit CPU_SHAKE mode." indicates that the performance jitter monitoring is disabled successfully. The return value "Current is not in CPU_SHAKE mode." indicates that the monitoring status is not enabled and fails to be disabled. The return value "Unexpected Result: close_shaking_collect error. Detail: *Detailed error information*" indicates that the disabling fails.

Example:

```
gaussdb=# SELECT * FROM gs_perf_close_shaking_collect('all');
 nodename |              message
----------+-----------------------------------
 cn_5001  | Current is not in CPU_SHAKE mode.

 dn_6008  | IN SHAKE MODE
(12 rows)
```

- gs_tpworker_execstmt_stat()

  Description: Displays the runtime information of a statement. If the SYSADMIN or MONADMIN user runs the statement, the information about all the statements that are being executed is displayed. Common users can query only the information about the SQL statements executed by themselves.

  Return type: SETOF record

Name	Type	Description
db_oid	oid	OID of the database that the user session connects to in the backend.
db_name	name	Name of the database that the user session connects to in the backend.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Name	Type	Description
threadpool_worker	varchar	NUMA group to which a thread belongs and thread ID. The format is *numagroup_threadid*.
thread_id	bigint	Thread ID.
session_id	bigint	Session ID.
query_id	bigint	ID of the SQL statement that is being executed.
query_text	text	Content of the SQL statement that is being executed.
unique_sql_id	bigint	Unique ID generated by the SQL statement.
client_hostname	text	Host name of the connected client, as reported by a reverse DNS lookup of **client_addr**. This column will be non-null only for IP connections and only when **log_hostname** is enabled.
client_app_name	text	Name of the client app.
stmt_slow_time_threshold	int	Preset timeout interval for marking an SQL statement as a slow SQL statement, in milliseconds.
stmt_start_time	timestamp with time zone	Time when the statement starts to be executed for a stored procedure, function, or package, the first query time is queried and does not change with the running of statements in the stored procedure.
stmt_elapse_time	bigint	Time elapsed since the query starts.
stmt_control_status	varchar	Current statement status. • **Waiting**: The session access is successful but it is not executed by the thread. • **Running**: The current statement is executed properly. • **Control**: The current statement enters the resource control phase.
stmt_control_rule	text	Slow SQL control rule corresponding to the current language.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Name	Type	Description
stmt_control_iostat	text	IOPS value and maximum IOPS of the current statement. The format is *curVal*|*maxVal*.
stmt_control_memstat	text	This field is reserved and is not supported currently.
stmt_control_cpustat	text	This field is reserved and is not supported currently.
stmt_control_netstat	text	This field is reserved and is not supported currently.

- gs_tpworker_execslot_stat()

  Description: Displays the thread running information. If the SYSADMIN or MONADMIN user runs the command, information about all threads is displayed. Common users can query only information about the threads where the SQL statements executed by themselves are located.

  Return type: SETOF record

Name	Type	Description
numagroup	int	NUMA group to which the current thread belongs.
worker_id	int	Thread ID of the current thread.
worker_bind_type	text	Thread binding mode. The value can be **numabind**, **cpubind**, **allbind**, or **nobind**.
worker_cpu_affinity	text	Affinity between threads and CPU cores, that is, the range of CPU cores that can be scheduled by threads.
worker_status	varchar	Current thread status. • **Waiting**: The session access is successful but it is not executed by the thread. • **Running**: The current statement is executed properly. • **Control**: The current statement enters the resource control phase.
served_query_id	bigint	ID of the SQL statement that is being executed.
served_query_text	text	Content of the SQL statement that is being executed.

- gs_session_all_settings(sessionid bigint)

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description: Queries the full GUC parameter settings of the session corresponding to the session ID on the local node. To execute this function, you must have the SYSADMIN or MONADMIN permission.

Input parameter description: **sessionid** indicates the session ID.

Return type: SETOF record

The following table describes return fields.

Name	Type	Description
name	text	Parameter name.
setting	text	Current parameter value.
unit	text	Implicit unit of a parameter.

Example:

```
gaussdb=# CREATE USER testuser WITH PASSWORD '********' sysadmin;
gaussdb=# SET SESSION AUTHORIZATION testuser PASSWORD '********';
gaussdb=> SELECT sessionid FROM pg_stat_activity WHERE usename = 'testuser';
 sessionid
-----------
    788861
(1 row)

gaussdb=> SELECT * FROM gs_session_all_settings(788861) WHERE name = 'work_mem';
   name   | setting | unit
----------+---------+------
 work_mem | 131072  | kB
(1 row)

gaussdb=> RESET SESSION AUTHORIZATION;
gaussdb=# DROP USER testuser;
```

- gs_session_all_settings()

  Description: Queries full GUC parameter settings of all sessions on the local node. To execute this function, you must have the SYSADMIN or MONADMIN permission.

  Return type: SETOF record

Name	Type	Description
sessionid	bigint	Session ID.
pid	bigint	Backend thread ID.
name	text	Parameter name.
setting	text	Current parameter value.
unit	text	Implicit unit of a parameter.

  Example:

```
gaussdb=# SELECT * FROM gs_session_all_settings() WHERE name = 'work_mem';
   sessionid    |       pid       |   name   | setting | unit
----------------+-----------------+----------+---------+------
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

 140549764413184 | 140549764413184 | work_mem | 65536   | kB
(4 rows)
```

- gs_local_wal_preparse_statistics()

  Description: Queries the latest startup of the log pre-parsing thread on the local node as well as the pre-parsing logs. Only the user with the SYSADMIN permission can execute this function. The log pre-parsing thread is typically started by the CM component when the HA replication link of the standby DN is disconnected. If the log pre-parsing thread has been started, you can call this function to query the latest pre-parsing status. If the thread has not been started, this function returns the default value. In the DR scenario, the DN and CN of the standby cluster automatically start the log pre-parsing thread. Note that the CN only starts the log pre-parsing thread in the standby cluster.

  Return type: SETOF record

Name	Type	Description
preparser_term	text	Maximum term value obtained from the latest pre-parsing log.
preparser_start_time	timestamptz	Time when the latest pre-parsing is started.
preparser_end_time	timestamptz	End time of the latest pre-parsing.
preparser_start_location	text	Start position of the latest pre-parsing log.
preparser_end_location	text	End position of the latest pre-parsing log.
preparser_total_bytes	int8	Number of latest pre-parsed logs, in bytes.
preparser_speed	int8	Latest pre-parsing speed, in bytes/ms.
is_valid	bool	Specifies whether the latest pre-parsing result can be used for leader selection.

The following is an example of the query result after the log pre-parsing thread is started:

```
gaussdb=# SELECT * FROM gs_local_wal_preparse_statistics();

(1 row)
```

- gs_hot_standby_space_info()

  Description: Queries the total number and total size of files in the **standby_read/base_page**, **standby_read/block_info_meta** and **standby_read/lsn_info_meta** folders.

  Return type: SETOF record

Name	Type	Description
base_page_file_num	xid	Total number of base_page_files.
base_page_total_size	xid	Total size of the base_page_files.
lsn_info_meta_file_num	xid	Total number of lsn_info_meta_files.
lsn_info_meta_total_size	xid	Total size of the lsn_info_meta_files.
block_info_meta_file_num	xid	Total number of block_info_meta_files.
block_info_meta_total_size	xid	Total size of the block_info_meta_files.

  Example:

```
gaussdb=# SELECT * FROM gs_hot_standby_space_info();
 base_page_file_num | base_page_total_size | lsn_info_meta_file_num | lsn_info_meta_total_size |
block_info_meta_file_num | block_info_meta_total_size
--------------------+----------------------+------------------------+--------------------------
+--------------------------+---------------------------
                 6 |               163840 |                      6 |                     3136 |                       16
|                   147456
(1 row)
```

- exrto_file_read_stat()

  Description: Queries the number of disk access times and total access latency of new **base page files**, **lsn info meta files**, and **block info meta files** read on a standby node. Only a CN of a standby cluster for DR or a standby DN can be connected for query. In other cases, the query result is **0**.

  Return type: SETOF record

Name	Type	Description
lsn_info_page_disk_read_counter	int8	Number of disk access times of **lsn info meta files**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Name	Type	Description
lsn_info_page_disk_read_dur	int8	Total latency of **lsn info meta file** access to disks.
blk_info_meta_disk_read_counter	int8	Number of disk access times of **block info meta files**.
blk_info_meta_disk_read_dur	int8	Total latency of **block info meta file** access to disks.
base_page_read_disk_counter	int8	Number of disk access times of **base page files**.
base_page_read_disk_dur	int8	Total latency of **base page file** access to disks.

Example:

```
gaussdb=# SELECT * FROM exrto_file_read_stat();
 lsn_info_page_disk_read_counter | lsn_info_page_disk_read_dur | blk_info_meta_disk_read_counter |
blk_info_meta_disk_read_dur | base_page_read_disk_counter | base_page_read_disk_dur
---------------------------------+-----------------------------+---------------------------------
+-----------------------------+-----------------------------+-------------------------
                          14987 |                       92313 |                           23879 |                      129811
|                           0 |                           0
(1 row)
```

- gs_exrto_recycle_info()

  Description: Queries the resource recycling location, including the recycling LSN of each thread, global recycling LSN, and the earliest snapshot LSN of a query thread. Only a CN of a standby cluster for DR or a standby DN can be connected for query. In other cases, the query result is **0**.

  Return type: SETOF record

Name	Type	Description
page_redo_worker_thread_id	text	Reclamation LSN location of redo thread. **thread_id** indicates the redo thread ID.
global_recycle_lsn	text	LSN of global reclamation location.
exrto_snapshot_oldest_lsn	text	Earliest snapshot LSN of a query thread.

  Example:

```
gaussdb=# SELECT * FROM gs_exrto_recycle_info();
            thread_id             | recycle_lsn
----------------------------------+-------------
 page_redo_worker_140148895381248 | 0/7B4552E0
 page_redo_worker_140148872312576 | 0/7B4535B8
 global_recycle_lsn               | 0/7B4535B8
 exrto_snapshot_oldest_lsn        | 0/8488E6D0
(4 rows)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- gs_stat_get_db_conflict_all(oid)

  Description: Queries the number of sent replay conflict signals of different types.

  Parameter: The input parameter is the OID of the database.

  Return type: SETOF record

Name	Type	Description
conflict_all	int8	Number of sent replay conflict signals.
conflict_tablespace	int8	Number of sent replay conflict signals of the tablespace type.
conflict_lock	int8	Number of sent replay conflict signals of the **lock** type.
conflict_snapshot	int8	Number of sent replay conflict signals of the snapshot type.
conflict_bufferpin	int8	Number of sent replay conflict signals of the bufferpin type.
conflict_startup_deadlock	int8	Number of sent replay conflict signals of the **startup_deadlock** type.
conflict_truncate	int8	Number of sent replay conflict signals of the truncate type.
conflict_standby_query_timeout	int8	Number of sent replay conflict signals of the standby_query_timeout type.
conflict_force_recycle	int8	Number of sent replay conflict signals of the force_recycle type.

  Example:

```
gaussdb=# SELECT * FROM gs_stat_get_db_conflict_all(12738);
 conflict_all | conflict_tablespace | conflict_lock | conflict_snapshot | conflict_bufferpin |
conflict_startup_deadlock | conflict_truncate | conflict_standby_query_timeout | conflict_force_recycle
--------------+---------------------+---------------+-------------------+--------------------
+---------------------------+-------------------+-------------------------------+------------------------
            0 |                 0 |             0 |                 0 |                 0 |                         0 |                 0
|                         0 |                   0
(1 row)
```

- gs_redo_stat_info([int])

  Description: Queries statistics about WAL replay, including the cache hit ratio of the replayer thread, the number of files deleted by replaying DDL logs, the physical reads generated when the replayer thread reads data pages, and the wait event information when the replayer thread reads WALs. The query must be executed by connecting to the standby DN.

  Return type: SETOF record

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Category	Name	Type	Description
Input parameter	operation	int	Optional. If no value is entered, statistics are queried. • **1**: queries statistics. • **2**: resets cache hit ratio statistics.
Output parameter	buffer_hit_rate	float8	Cache hit ratio of the replayer thread.
Output parameter	ddl_unlink_nrels_count	int8	Number of files deleted by replaying DDL logs.
Output parameter	read_buffer_io_counter	int8	Number of times that wait events for physical reads are triggered when the replayer thread reads data pages.
Output parameter	read_buffer_io_total_dur	int8	Total duration of wait events for physical reads when the replayer thread reads data pages.
Output parameter	read_buffer_io_avg_dur	int8	Average duration of wait events for physical reads when the replayer thread reads data pages.
Output parameter	read_buffer_io_min_dur	int8	Minimum duration of wait events for physical reads when the replayer thread reads data pages.
Output parameter	read_buffer_io_max_dur	int8	Maximum duration of wait events for physical reads when the replayer thread reads data pages.
Output parameter	read_wal_buf_counter	int8	Number of times that wait events are triggered when the replayer thread reads WALs.
Output parameter	read_wal_buf_total_dur	int8	Total duration of wait events when the replayer thread reads WALs.
Output parameter	read_wal_buf_avg_dur	int8	Average duration of wait events when the replayer thread reads WALs.
Output parameter	read_wal_buf_min_dur	int8	Minimum duration of wait events when the replayer thread reads WALs.
Output parameter	read_wal_buf_max_dur	int8	Maximum duration of wait events when the replayer thread reads WALs.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Example:

```
gaussdb=# SELECT * FROM gs_redo_stat_info();
-[ RECORD 1 ]------------+----------
buffer_hit_rate          | 70.5707
ddl_unlink_nrels_count   | 3
read_buffer_io_counter   | 1732
read_buffer_io_total_dur | 2850806
read_buffer_io_avg_dur   | 1645
read_buffer_io_min_dur   | 3
read_buffer_io_max_dur   | 981639
read_wal_buf_counter     | 9779
read_wal_buf_total_dur   | 193612470
read_wal_buf_avg_dur     | 19798
read_wal_buf_min_dur     | 3
read_wal_buf_max_dur     | 1914777
```

- gs_recovery_conflict_waitevent_info()

  Description: Queries wait event information about the function that processes redo conflicts. You need to connect to a CN of a standby cluster for DR or a standby DN for query.

  Return type: SETOF record

Name	Type	Description
conflict_lock_counter	int8	Number of times that lock redo conflicts are triggered.
conflict_lock_total_dur	int8	Total duration for processing lock redo conflicts.
conflict_lock_avg_dur	int8	Average duration for processing lock redo conflicts.
conflict_lock_min_dur	int8	Minimum duration for processing lock redo conflicts.
conflict_lock_max_dur	int8	Maximum duration for processing lock redo conflicts.
conflict_snapshot_counter	int8	Number of times that snapshot redo conflicts are triggered.
conflict_snapshot_total_dur	int8	Total duration for processing snapshot redo conflicts.
conflict_snapshot_avg_dur	int8	Average duration for processing snapshot redo conflicts.
conflict_snapshot_min_dur	int8	Minimum duration for processing snapshot redo conflicts.
conflict_snapshot_max_dur	int8	Maximum duration for processing snapshot redo conflicts.
conflict_tablespace_counter	int8	Number of times that tablespace redo conflicts are triggered.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Name	Type	Description
conflict_tablespace_total_dur	int8	Total duration for processing tablespace redo conflicts.
conflict_tablespace_avg_dur	int8	Average duration for processing tablespace redo conflicts.
conflict_tablespace_min_dur	int8	Minimum duration for processing tablespace redo conflicts.
conflict_tablespace_max_dur	int8	Maximum duration for processing tablespace redo conflicts.
conflict_database_counter	int8	Number of times that database redo conflicts are triggered.
conflict_database_total_dur	int8	Total duration for processing database redo conflicts.
conflict_database_avg_dur	int8	Average duration for processing database redo conflicts.
conflict_database_min_dur	int8	Minimum duration for processing database redo conflicts.
conflict_database_max_dur	int8	Maximum duration for processing database redo conflicts.
conflict_truncate_counter	int8	Number of times that TRUNCATE redo conflicts are triggered.
conflict_truncate_total_dur	int8	Total duration for processing TRUNCATE redo conflicts.
conflict_truncate_avg_dur	int8	Average duration for processing TRUNCATE redo conflicts.
conflict_truncate_min_dur	int8	Minimum duration for processing TRUNCATE redo conflicts.
conflict_truncate_max_dur	int8	Maximum duration for processing TRUNCATE redo conflicts.
conflict_standby_query_timeout_counter	int8	Number of times that standby_query_timeout redo conflicts are triggered.
conflict_standby_query_timeout_total_dur	int8	Total duration for processing standby_query_timeout redo conflicts.
conflict_standby_query_timeout_avg_dur	int8	Average duration for processing standby_query_timeout redo conflicts.
conflict_standby_query_timeout_min_dur	int8	Minimum duration for processing standby_query_timeout redo conflicts.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Name	Type	Description
conflict_standby_query_timeout_max_dur	int8	Maximum duration for processing standby_query_timeout redo conflicts.
conflict_force_recycle_counter	int8	Number of times that force_recycle redo conflicts are triggered.
conflict_force_recycle_total_dur	int8	Total duration for processing force_recycle redo conflicts.
conflict_force_recycle_avg_dur	int8	Average duration for processing force_recycle redo conflicts.
conflict_force_recycle_min_dur	int8	Minimum duration for processing force_recycle redo conflicts.
conflict_force_recycle_max_dur	int8	Maximum duration for processing force_recycle redo conflicts.
conflict_bufferpin_counter	int8	Number of times that buffer pin redo conflicts are triggered.
conflict_bufferpin_total_dur	int8	Total duration for processing buffer pin redo conflicts.
conflict_bufferpin_avg_dur	int8	Average duration for processing buffer pin redo conflicts.
conflict_bufferpin_min_dur	int8	Minimum duration for processing buffer pin redo conflicts.
conflict_bufferpin_max_dur	int8	Maximum duration for processing buffer pin redo conflicts.

Example:

```
gaussdb=# SELECT * FROM gs_recovery_conflict_waitevent_info();
-[ RECORD 1 ]----------------------------+------
conflict_lock_counter                   | 0
conflict_lock_total_dur                 | 0

conflict_bufferpin_max_dur              | 0
```

- gs_display_delay_ddl_info()

  Description: Views information about files that are delayed for deletion on the standby node.

  Return type: SETOF record

Name	Type	Description
type	INT4	Indicates that the deleted object is a table or database.
lsn	TEXT	Marks the location of a particular log file.
tablespace	INT4	Indicates the physical space for storing tables and indexes in a database.
database	INT4	Indicates the physical storage location of a database.
relation	INT4	Indicates the object in a database, which can be the physical location of a table, view, or index.
bucketid	INT4	Specifies the bucket to which the relationship object belongs.
opt	INT4	Indicates the attribute of a compressed table.
forknum	INT4	Specifies a suffix name for a subject name. You can find a unique physical file based on the subject name and suffix name.

  Example:

```
gaussdb=# SELECT * FROM gs_display_delay_ddl_info();
 type | lsn | tablespace | database | relation | bucketid | opt | forknum
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- gs_plsql_statements(sessionid bigint, pkg id oid, function id oid)

  Description: Returns the memory information about a stored procedure.

  Return type: SETOF record

  The following table describes the fields returned by the function.

Name	Type	Description
pid	bigint	Background thread ID.
sessionid	bigint	Session ID.
global_sessionid	text	Global session ID.
databaseid	oid	Database ID.
pkg_id	oid	ID of the package to which the stored procedure belongs. If the stored procedure does not belong to a package, the value is **0**.
func_id	oid	Stored procedure ID.
func_signature	text	Stored procedure name (name+fn_collation +search_path).
plsql_compiled_totalsize	bigint	Total memory size of the stored procedure compilation product.
plsql_plan_totalsize	bigint	Total memory size of the plan within the stored procedure.

Example:

```
gaussdb=#
CREATE OR REPLACE PROCEDURE proc_assign AS
    a int := 0;
BEGIN
    a = a + 1;
    RAISE INFO '%', a;
END;
/
gaussdb=# CALL proc_assign();

- gs_global_plsql_statements(sessionid bigint, pkg id oid, function id oid)

  Description: Returns the memory information about a stored procedure.

  Return type: SETOF record

  The following table describes the fields returned by the function.

Name	Type	Description
node_name	text	Name of the current node.
pid	bigint	Background thread ID.
sessionid	bigint	Session ID.
global_sessionid	text	Global session ID.
databaseid	oid	Database ID.
pkg_id	oid	ID of the package to which the stored procedure belongs. If the stored procedure does not belong to a package, the value is **0**.
func_id	oid	Stored procedure ID.
func_signature	text	Stored procedure name (name +fn_collation+search_path).
plsql_compiled_totalsize	bigint	Total memory size of the stored procedure compilation product.
plsql_plan_totalsize	bigint	Total memory size of the plan within the stored procedure.

Example:

gaussdb=# DROP PROCEDURE proc_assign;
```

- gs_plsql_statements_details(sessionid bigint, pkg id oid, function id oid)

  Description: Returns the memory information about the plan cache statements of a stored procedure.

  NOTE

  When the function is queried, GaussDB determines whether to allow access based on the permissions of **current_user**. If **current_user** is an initial user or a system administrator, they can query information about all sessions. If **current_user** is a common user, they can only view their own session information (**session_user** refers to the information about the current user).

  Return type: SETOF record

  The following table describes the fields returned by the function.

Name	Type	Description
pid	bigint	Background thread ID.
sessionid	bigint	Session ID.
global_sessionid	text	Global session ID.
databaseid	oid	Database ID.
pkg_id	oid	ID of the package to which the stored procedure belongs. If the stored procedure does not belong to a package, the value is **0**.
func_id	oid	Stored procedure ID.
func_signature	text	Stored procedure name (name+fn_collation +search_path).
lineno	bigint	Line number of the statement in the stored procedure.
query	text	Plan cache statement.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Name	Type	Description
usedsize	bigint	Memory size used by plan cache statements.
totalsize	bigint	Total memory size of plan cache statements.

Example:

```
gaussdb=#
CREATE OR REPLACE PROCEDURE proc_assign AS
    a int := 0;
BEGIN
    a = a + 1;
    RAISE INFO '%', a;
END;
/
gaussdb=# CALL proc_assign();
INFO:  1
 proc_assign
-------------

gaussdb=# DROP PROCEDURE proc_assign;
```

- gs_global_plsql_statements_details(sessionid bigint, pkg id oid, function id oid)

  Description: Returns the memory information about the plan cache statements of a stored procedure.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

When the function is queried, GaussDB determines whether to allow access based on the permissions of **current_user**. If **current_user** is an initial user or a system administrator, they can query information about all sessions. If **current_user** is a common user, they can only view their own session information (**session_user** refers to the information about the current user).

Return type: SETOF record

The following table describes the fields returned by the function.

Name	Type	Description
node_name	text	Name of the current node.
pid	bigint	Background thread ID.
sessionid	bigint	Session ID.
global_sessionid	text	Global session ID.
databaseid	oid	Database ID.
pkg_id	oid	ID of the package to which the stored procedure belongs. If the stored procedure does not belong to a package, the value is **0**.
func_id	oid	Stored procedure ID.
func_signature	text	Stored procedure name (name +fn_collation+search_path).
lineno	bigint	Line number of the statement in the stored procedure.
query	text	Plan cache statement.
usedsize	bigint	Memory size used by plan cache statements.
totalsize	bigint	Total memory size of plan cache statements.

Example:

```
gaussdb=#
CREATE OR REPLACE PROCEDURE proc_assign AS
    a int := 0;
BEGIN
    a = a + 1;
    RAISE INFO '%', a;
END;
/
gaussdb=# CALL proc_assign();
INFO:  1
 proc_assign
-------------
```

```
(1 row)

gaussdb=# SELECT * FROM pg_catalog.gs_global_plsql_statements_details(pg_current_sessid());
  node_name   |    pid     |    sessionid    | global_sessionid | databaseid | pkg_id | func_id
|
    func_signature                                          | lineno
|
                                query                                                
```

```
gaussdb=# DROP PROCEDURE proc_assign;
```

Functions for Collecting Statistics in Partitioned Tables

- gs_stat_get_partition_stats(oid)
  Description: Obtains the statistics of a specific partition.
  Return type: record.
- gs_stat_get_xact_partition_stats(oid)
  Description: Obtains transaction statistics of a specific partition.
  Return type: record.
- gs_stat_get_all_partitions_stats()
  Description: Obtains the statistics of all partitions.
  Return type: SETOF record
- gs_stat_get_xact_all_partitions_stats()
  Description: Obtains transaction statistics of all partitions.
  Return type: SETOF record
- gs_statio_get_all_partitions_stats()
  Description: Obtains the I/O statistics of all partitions.
  Return type: SETOF record
  Examples of the preceding five functions

CAUTION

Statistics are reported asynchronously during execution. Based on UDP, delay and packet loss may occur during background thread processing. The following example is for reference only.

Querying out-of-transaction statistics:

```
gaussdb=# CREATE TABLE part_tab1

- gs_stat_get_partition_analyze_count(oid)

  Description: Specifies the number of times that a user starts analysis on a partition.

  Return type: bigint.

- gs_stat_get_partition_autoanalyze_count(oid)

  Description: Specifies the number of times that the autovacuum daemon thread starts analysis in a partition.

  Return type: bigint.

- gs_stat_get_partition_autovacuum_count(oid)

  Description: Specifies the number of times that the autovacuum daemon thread starts vacuum in a partition.

  Return type: bigint.

- gs_stat_get_partition_last_analyze_time(oid)

  Description: Specifies the last time when a partition starts to be analyzed manually or by the autovacuum thread.

  Return type: timestamptz.

- gs_stat_get_partition_last_autoanalyze_time(oid)

  Description: Specifies the time when the last analysis initiated by the autovacuum daemon thread in a partition.

  Return type: timestamptz.

- gs_stat_get_partition_last_autovacuum_time(oid)

  Description: Specifies the time of the last vacuum initiated by the autovacuum daemon thread in a partition.

  Return type: timestamptz.

- gs_stat_get_partition_last_data_changed_time(oid)

  Description: Specifies the last time of a modification in a partition, such as insert, update, delete, and truncate. Currently, this parameter is not supported.

  Return type: timestamptz.

- gs_stat_get_partition_last_vacuum_time(oid)

  Description: Specifies the most recent time when the user manually vacuumed a table or when the autovacuum thread was started to vacuum a partition.

  Return type: timestamptz.

- gs_stat_get_partition_numscans(oid)

  Description: Specifies the number of rows read by sequential scan in a partition.

  Return type: bigint.

- gs_stat_get_partition_tuples_returned(oid)

  Description: Specifies the number of rows read by sequential scan in a partition.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Return type: bigint.

- gs_stat_get_partition_tuples_fetched(oid)

  Description: Specifies the number of rows fetched by bitmap scans in a partition.

  Return type: bigint.

- gs_stat_get_partition_vacuum_count(oid)

  Description: Specifies the number of times that a user starts vacuum in a partition.

  Return type: bigint.

- gs_stat_get_xact_partition_tuples_fetched(oid)

  Description: Specifies the number of tuple rows scanned in a transaction.

  Return type: bigint.

- gs_stat_get_xact_partition_numscans(oid)

  Description: Specifies the number of sequential scans performed on a partition in the current transaction.

  Return type: bigint.

- gs_stat_get_xact_partition_tuples_returned(oid)

  Description: Specifies the number of rows read through sequential scans in a partition in the current transaction.

  Return type: bigint.

- gs_stat_get_partition_blocks_fetched(oid)

  Description: Specifies the number of disk block fetch requests for a partition.

  Return type: bigint.

- gs_stat_get_partition_blocks_hit(oid)

  Description: Specifies the number of disk block requests found in cache for a partition.

  Return type: bigint.

- pg_stat_get_partition_tuples_inserted(oid)

  Description: Specifies the number of rows inserted into the corresponding table partition.

  Return type: bigint.

- pg_stat_get_partition_tuples_updated(oid)

  Description: Specifies the number of rows that have been updated in the corresponding table partition.

  Return type: bigint.

- pg_stat_get_partition_tuples_deleted(oid)

  Description: Specifies the number of rows deleted from the corresponding table partition.

  Return type: bigint.

- pg_stat_get_partition_tuples_changed(oid)

  Description: Specifies the total number of inserted, updated, and deleted rows after a table partition was last analyzed or autoanalyzed.

  Return type: bigint.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- pg_stat_get_partition_live_tuples(oid)

  Description: Specifies the number of live rows in a partitioned table.

  Return type: bigint.

- pg_stat_get_partition_dead_tuples(oid)

  Description: Specifies the number of dead rows in a partitioned table. It indicates the number of inactive row pointers in Ustore tables.

  Return type: bigint.

- pg_stat_get_xact_partition_tuples_inserted(oid)

  Description: Specifies the number of inserted tuples in the active sub-transactions related to a table partition.

  Return type: bigint.

- pg_stat_get_xact_partition_tuples_deleted(oid)

  Description: Specifies the number of deleted tuples in the active sub-transactions related to a table partition.

  Return type: bigint.

- pg_stat_get_xact_partition_tuples_hot_updated(oid)

  Description: Specifies the number of hot updated tuples in the active sub-transactions related to a table partition.

  Return type: bigint.

- pg_stat_get_xact_partition_tuples_updated(oid)

  Description: Specifies the number of updated tuples in the active sub-transactions related to a table partition.

  Return type: bigint.

- pg_stat_get_partition_tuples_hot_updated(oid)

  Description: Returns statistics on the number of hot updated tuples in a partition with a specified partition ID.

  Parameter: oid.

  Return type: bigint.

- gs_stat_partition_analyze_vacuum(oid)

  Description: Obtains vacuum/analyze statistics about a specific partition for cache acceleration.

  Parameter: partoid.

  Return type: record.

- gs_stat_get_parttabentries()

  Description: Obtains the vacuum/analyze statistics about partitioned tables on other nodes. This is an internal function. You are advised not to use it directly.

  Return type: record.

- gs_wlm_respool_cpu_info()

  Description: Displays the limit and usage of CPU resources in a resource pool.

  Return type: SETOF record

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Name	Type	Description
respool_name	name	Name of the resource pool.
control_group	name	Cgroup name.
cpu_affinity	name	Value of cores bound to the CPU.
cpu_usage	integer	CPU usage of a resource pool. If CPU control is not performed for the resource pool, the value of this parameter is **0**.

NOTE

If the CN and DN are deployed together, the CN and DN share the same CPU resources. Therefore, the **cpu_usage** values of the CN and DN are the same. If the CN and DN are independently deployed, the **cpu_usage** values of the CN and DN are displayed separately.

Example:

```
gaussdb=# SELECT * FROM GS_WLM_RESPOOL_CPU_INFO();
 respool_name |     control_group      | cpu_affinity | cpu_usage
--------------+------------------------+--------------+-----------
 respool_cpu_2 | respool_cpu_2:Medium | 0-95          |         78
 default_pool  | DefaultClass:Medium  | 0-32          |         65
(2 rows)
```

- gs_wlm_respool_connection_info()

  Description: Displays the limit and usage of the number of connections in ta resource pool.

  Return type: SETOF record

Name	Type	Description
respool_name	name	Name of the resource pool.
max_connections	name	Maximum number of connections to a resource pool.
curr_connections	integer	Number of existing connections in the current resource pool.

Example:

```
gaussdb=# SELECT * FROM GS_WLM_RESPOOL_CONNECTION_INFO();
 respool_name  | max_connections | curr_connections
---------------+-----------------+------------------
 respool1      |              -1 |                0
 default_pool  |              -1 |                1
(2 rows)
```

- gs_wlm_respool_memory_info()

  Description: Displays the limit and usage of memory resources in a resource pool.

  Return type: SETOF record

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Name	Type	Description
respool_name	name	Name of the resource pool.
max_dynamic_memory	integer	Maximum dynamic memory that can be used.
current_dynamic_memory	integer	Used dynamic memory.
max_shared_memory	integer	Maximum shared memory that can be used.
current_shared_memory	integer	Shared memory that has been used.
shared_memory_hits_percent	integer	This function is unavailable and is reserved for future evolution. This column is reserved and the value is **0**.

NOTE

When the dynamic memory usage of the resource pool exceeds the maximum value, the returned value of the GUC parameter **current_dynamic_memory** may be greater than the value of **max_dynamic_memory**. This is normal because no memory is allocated.

Example:

```
gaussdb=# SELECT * FROM GS_WLM_RESPOOL_MEMORY_INFO();
 respool_name   | max_dynamic_memory | current_dynamic_memory | max_shared_memory |
current_shared_memory | shared_memory_hits_percent
----------------+--------------------+------------------------+-------------------+------------------------
+----------------------------
 default_pool   | -1                 | 3383kB                 | -1                | 3848kB                 |
0
 resource_pool_a | 30720kB           | 0kB                    | -1                | 0kB
|                        0
(2 rows)
```

- gs_wlm_respool_concurrency_info()

  Description: Displays the limit and usage of concurrent resources in a resource pool.

  Return type: SETOF record

Name	Type	Description
respool_name	name	Name of the resource pool.
max_concurrency	integer	Maximum number of concurrent queries allowed by the resource pool.
running_concurrency	integer	Number of concurrent tasks that are being executed in the current resource pool.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Name	Type	Description
waiting_concurrency	integer	Number of concurrent tasks that are waiting in the current resource pool. If the number of concurrent requests is not limited in the resource pool, the value of this parameter is **0**.

Example:

```
gaussdb=# SELECT * FROM GS_WLM_RESPOOL_CONCURRENCY_INFO();
 respool_name   | max_concurrency | running_concurrency | waiting_concurrency
----------------+-----------------+---------------------+---------------------
 default_pool   |              -1 |                   1 |                   0
 resource_pool_a |             -1 |                   0 |                   0
(2 rows)
```

- gs_wlm_respool_io_info()

  Description: Displays the limit and usage of I/O resources in a resource pool.

  Return type: SETOF record

Name	Type	Description
respool_name	name	Name of the resource pool.
io_limits	integer	Maximum number of I/Os triggered per second (unit: IOPS). The value **0** indicates there is no limit.
io_priority	text	Priority of I/O resource control. It takes effect when the I/O usage reaches 90%. **None** indicates there is no control.
current_iops	integer	Number of times that the current I/O has been triggered (unit: IOPS). ● The value is related to the I/O statistics algorithm and occasionally exceeds the upper limit, which is normal. ● If I/O control is not performed for the resource pool, the value of this parameter is **0**.

NOTE

During I/O control, the unit of I/O operations is defined by the GUC parameter **io_control_unit**. The value of **io_control_unit** is one IOPS.

Example:

```
gaussdb=# SELECT * FROM GS_WLM_RESPOOL_IO_INFO();
 respool_name   | io_limits | io_priority | current_iops
----------------+-----------+-------------+--------------
 default_pool   |         0 | None        |            0
 resource_pool_a |        0 | Low         |            0
(2 rows)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- gs_wlm_user_space_info()

  Description: Displays the storage space usage of a user.

  Return type: SETOF record

Name	Type	Description
user_name	name	Username.
max_permanent_space	bigint	Maximum permanent storage space that can be used by a user, in bytes.
current_permanent_space	bigint	Permanent storage space used by the current user, in bytes.
max_temp_space	bigint	Maximum temporary storage space that can be used by a user, in bytes.
current_temp_space	bigint	Temporary storage space used by the current user, in bytes.
max_spill_space	bigint	Maximum operator-level data flushing storage space that can be used by a user, in bytes.
current_spill_space	bigint	Operator flushing storage space used by the current user, in bytes.

  Example:

```
gaussdb=# SELECT * FROM GS_WLM_USER_SPACE_INFO();
          user_name          | max_permanent_space | current_permanent_space | max_temp_space |
current_temp_space | max_spill_space | current_spill_space
-----------------------------+---------------------+-------------------------+----------------+--------------------
+-----------------+--------------------
 xy                          |                  -1 |                    2464 |             -1 |                  0 |              -1
|                  0
(1 rows)
```

- gs_wlm_session_io_info()

  Description: Displays the I/O usage of a session.

  Return type: SETOF record

Name	Type	Description
session_id	integer	Session ID.
io_limits	integer	Maximum number of I/Os triggered per second (unit: IOPS). The value **0** indicates there is no limit.
io_priority	text	Priority of I/O resource control. It takes effect when the I/O usage reaches 90%. **None** indicates there is no control.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Name	Type	Description
current_iops	integer	Number of times that the current I/O has been triggered (unit: IOPS). The current I/O statistics occasionally exceed the upper limit, which is related to the I/O statistics algorithm and is normal.
wait_time	integer	Total waiting time after the current I/O exceeds the upper limit.

NOTE

During I/O control, the unit of I/O operations is defined by the GUC parameter **io_control_unit**. The value of **io_control_unit** is one IOPS.

Example:

```
gaussdb=# SELECT * FROM GS_WLM_SESSION_IO_INFO();
   session_id    | io_limits | io_priority | current_iops | wait_time
-----------------+-----------+-------------+--------------+-----------
 139976325986048 |        10 | None        |            0 |      2709
(1 row)
```

- gs_wlm_session_memory_info()

  Description: Displays the memory usage of a session.

  Return type: SETOF record

Name	Type	Description
session_id	integer	Session ID.
sess_used_dynamic_memory	bigint	Used dynamic memory, in bytes.
sess_max_dynamic_memory	bigint	Maximum dynamic memory that can be used, in bytes.

  Example:

```
gaussdb=# SELECT * FROM GS_WLM_SESSION_MEMORY_INFO();
    sessid      | sess_used_dynamic_memory | sess_max_dynamic_memory
----------------+--------------------------+-------------------------
 139976325986048 |                  4326056 |                      -1
 139976402532096 |                  4452664 |                      -1
(2 rows)
```

- gs_emergency_operation_records()

  Description: Displays the usage of the UDS O&M channel on the current node.

  Return type: SETOF record

Name	Type	Description
record_time	timestamptz	Time when the O&M channel is used.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Name	Type	Description
action	text	Operations performed through the O&M channel.
source	text	Source of the O&M channel. The value can be **gsql** or **cm**.
detail	text	Operation result.

- gs_memory_profiling(option integer)

  Description: Generates the jeprof report of the current process of GaussDB. **option** specifies whether to enable the memory collection function. The return result is a string based on the actual input.

  Parameters: **option**: specifies the operation option, which is of the integer type.

  - **0**:Memory collection is disabled. The function returns the "memory profiling closed" message.
  - **1**: Memory collection is enabled. The function returns the "memory profiling opened" message.
  - **2**: Memory collection is enabled. In this case, memory calls are collected and a jeprof report is generated. The report is stored in the **mem_log** directory and named in the format of **jeprof-***YY-mm-dd_HHMMSS*. The function returns the "dump succeeded" message.
  - Others: The message "Invalid input, please input 0(disable), 1(enable) or 2(dump)." is displayed.

  Return type: text.

  NOTE

  - Only users with the SYSADMIN permission can use this function.
  - Enabling memory collection affects performance. Therefore, you are advised to enable this function only in non-performance-sensitive scenarios where memory problems (for example, memory leakage) need to be analyzed. You can run the following command to generate a jeprof report in the PDF format:
    jeprof --show_bytes *gaussdbbin path* -pdf *Path of the generated jeprof report* > *Expected output file*.pdf

- gs_jemalloc_info_details()

  Description: Collects statistics on key fields of jemalloc and generates a jemalloc statistics report. The statistics report is stored in the **mem_log** directory and named in the format of **memory_stat_report-***YY-mm-dd_HHMMSS***.log**.

  Return type: SETOF record

  Table 1-255 gs_jemalloc_info_details columns

Name	Type	Description
nodename	text	Node name
memorytype	text	Column

Name	Type	Description
memorymbytes	integer	Virtual memory size of the corresponding field (unit: MB)

NOTE

Only users with the SYSADMIN permission can use this function.

1.6.30 Trigger Functions

- pg_get_triggerdef(oid)

  Description: Obtains the definition information of a trigger.

  Parameter: OID of the trigger to be queried

  Return type: text

  Example:

```
-- Create the tri_insert table.
gaussdb=# CREATE TABLE tri_insert (a int, b int);
CREATE TABLE
-- Create the trigger_func function.
gaussdb=# CREATE FUNCTION trigger_func() RETURNS trigger LANGUAGE plpgsql AS '
 BEGIN
 RAISE NOTICE ''trigger_func(%) called: action = %, when = %, level = %'', TG_ARGV[0], TG_OP,
TG_WHEN, TG_LEVEL;
 RETURN NULL;
 END;';
CREATE FUNCTION
-- Create the before_ins_stmt_trig trigger.
gaussdb=# CREATE TRIGGER before_ins_stmt_trig BEFORE INSERT ON tri_insert FOR EACH row
EXECUTE PROCEDURE trigger_func('before_ins_stmt');
CREATE TRIGGER
-- Create the after_ins_when_trig trigger.
gaussdb=# CREATE TRIGGER after_ins_when_trig AFTER INSERT ON tri_insert FOR EACH ROW WHEN
(new.a IS NOT NULL) EXECUTE PROCEDURE trigger_func('after_ins_when');
CREATE TRIGGER
-- View the trigger definition information of the tri_insert table.
gaussdb=# SELECT pg_get_triggerdef(oid) FROM pg_trigger WHERE tgrelid = 'tri_insert'::regclass;

pg_get_triggerdef
----------------------------------------------------------------------------------------------------------------------------
---------------------------------
 CREATE TRIGGER after_ins_when_trig AFTER INSERT ON tri_insert FOR EACH ROW WHEN ((new.a IS
NOT NULL)) EXECUTE PROCEDURE trigger_func('after_ins_when')
 CREATE TRIGGER before_ins_stmt_trig BEFORE INSERT ON tri_insert FOR EACH ROW EXECUTE
PROCEDURE trigger_func('before_ins_stmt')
(2 rows)
```

- pg_get_triggerdef(oid, boolean)

  Description: Obtains the definition information of a trigger.

  Parameter: OID of the trigger to be queried and whether it is displayed in pretty mode

  NOTE

  Boolean parameters take effect only when the WHEN condition is specified during trigger creation.

  Return type: text

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Example:

```
-- View the trigger definition information of the tri_insert table in non-pretty mode.
gaussdb=# SELECT pg_get_triggerdef(oid, false) FROM pg_trigger WHERE tgrelid = 'tri_insert'::regclass;

pg_get_triggerdef
-------------------------------------------------------------------------------------------------------------------------------------------------------------
 CREATE TRIGGER after_ins_when_trig AFTER INSERT ON tri_insert FOR EACH ROW WHEN ((new.a IS NOT NULL)) EXECUTE PROCEDURE trigger_func('after_ins_when')
 CREATE TRIGGER before_ins_stmt_trig BEFORE INSERT ON tri_insert FOR EACH ROW EXECUTE PROCEDURE trigger_func('before_ins_stmt')
(2 rows)

-- View the trigger definition information of the tri_insert table in pretty mode.
gaussdb=# SELECT pg_get_triggerdef(oid, true) FROM pg_trigger WHERE tgrelid = 'tri_insert'::regclass;

pg_get_triggerdef
-------------------------------------------------------------------------------------------------------------------------------------------------------------
 CREATE TRIGGER after_ins_when_trig AFTER INSERT ON tri_insert FOR EACH ROW WHEN (new.a IS NOT NULL) EXECUTE PROCEDURE trigger_func('after_ins_when')
 CREATE TRIGGER before_ins_stmt_trig BEFORE INSERT ON tri_insert FOR EACH ROW EXECUTE PROCEDURE trigger_func('before_ins_stmt')
(2 rows)

-- Clear the tri_insert table.
gaussdb=# DROP TABLE tri_insert CASCADE;
DROP TABLE
-- Clear the trigger_func function.
gaussdb=# DROP FUNCTION trigger_func;
DROP FUNCTION
```

- suppress_redundant_updates_trigger()

  Description: Suppresses update operations that do not change data. This function is called before data update. If the updated data does not change, the update operation does not take effect.

  Return type: trigger.

  > NOTE
  >
  > This function is a built-in trigger execution function. It can be called only when a trigger is defined and takes effect only in a BEFORE UPDATE trigger.

  Example:

```
-- Create the tri_update table.
gaussdb=# CREATE TABLE tri_update (a int, b int);
CREATE TABLE
-- Insert data (1,1).
gaussdb=# INSERT INTO tri_update VALUES(1,1);
INSERT 0 1
-- Create a BEFORE UPDATE trigger. The trigger function is suppress_redundant_updates_trigger.
gaussdb=# CREATE TRIGGER before_update_trig BEFORE UPDATE ON tri_update FOR EACH ROW EXECUTE PROCEDURE suppress_redundant_updates_trigger();
WARNING:  Trigger function with non-plpgsql type is not recommended.
DETAIL:  Non-plpgsql trigger function are not shippable by default.
HINT:  Unshippable trigger may lead to bad performance.
CREATE TRIGGER
-- The data in the table remains unchanged, that is, (1,1). The update operation is not performed.
gaussdb=# UPDATE tri_update SET b=1;
UPDATE 0
-- Drop the tri_update table.
gaussdb=# DROP TABLE tri_update CASCADE;
DROP TABLE
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

1.6.31 Hash Functions

- bucketabstime (value, flag)

  Description: Hashes the value in the abstime format and finds the corresponding hash bucket.

  Parameter: **value** indicates the value to be converted, which is of the abstime type. **flag** is of the int type, indicating the data distribution mode. The value **0** indicates hash distribution.

  Return type: int32

  Example:

```
gaussdb=# SELECT bucketabstime('2011-10-01 10:10:10.112',1);
 bucketabstime
---------------
         13954
(1 row)
```

- bucketbool (value, flag)

  Description: Hashes the value in the boolean format and finds the corresponding hash bucket.

  Parameter: **value** indicates the value to be converted, which is of the Boolean type. **flag** is of the int type, indicating the data distribution mode. The value **0** indicates hash distribution.

  Return type: int32

  Example:

```
gaussdb=# SELECT bucketbool(true,1);
 bucketbool
------------
          1
(1 row)
gaussdb=# SELECT bucketbool(false,1);
 bucketbool
------------
          0
(1 row)
```

- bucketbpchar(value, flag)

  Description: Hashes the value in the bpchar format and finds the corresponding hash bucket.

  Parameter: **value** indicates the value to be converted, which is of the bpchar type. **flag** is of the int type, indicating the data distribution mode. The value **0** indicates hash distribution.

  Return type: int32

  Example:

```
gaussdb=# SELECT bucketbpchar('test',1);
 bucketbpchar
--------------
         9761
(1 row)
```

- bucketbytea (value, flag)

  Description: Hashes the value in the bytea format and finds the corresponding hash bucket.

  Parameter: **value** indicates the value to be converted, which is of the bytea type. **flag** is of the int type, indicating the data distribution mode. The value **0** indicates hash distribution.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Return type: int32

Example:

```
gaussdb=# SELECT bucketbytea('test',1);
 bucketbytea
-------------
        9761
(1 row)
```

- bucketcash (value, flag)

  Description: Hashes the value in the money format and finds the corresponding hash bucket.

  Parameter: **value** indicates the value to be converted, which is of the money type. **flag** is of the int type, indicating the data distribution mode. The value **0** indicates hash distribution.

  Return type: int32

  Example:

  ```
  gaussdb=# SELECT bucketcash(10::money,1);
   bucketcash
  ------------
        8468
  (1 row)
  ```

- getbucket (value, flag)

  Description: Obtains the hash bucket from the distribution key.

  value indicates the value to be entered, which can be of the following types:

  "char", abstime, bigint, Boolean, bytea, character varying, character, date, double precision, int2vector, integer, interval, money, name, numeric, nvarchar2, oid, oidvector, raw, real, record, reltime, smalldatetime, smallint,text, time with time zone, time without time zone, timestamp with time zone, timestamp without time zone, tinyint, uuid

  flag is of the integer type, indicating the data distribution mode.

  Return type: integer

  Example:

  ```
  gaussdb=# SELECT getbucket(10,'H');
   getbucket
  -----------
      14535
  (1 row)

  gaussdb=# SELECT getbucket(11,'H');
   getbucket
  -----------
      13449
  (1 row)

  gaussdb=# SELECT getbucket(11,'R');
   getbucket
  -----------
      13449
  (1 row)

  gaussdb=# SELECT getbucket(12,'R');
   getbucket
  -----------
       9412
  (1 row)
  ```

- ora_hash(expression,[seed])

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description: Calculates the hash value of a given expression. **expression**: The value can be a character string, time, row ID, or number. The hash value is calculated based on the expression. **seed**: an int8 value that can return different results for the same input value. This parameter is optional and is used to calculate the hash value with a random number.

Return type: hash value of the int8 type.

Example:

```
gaussdb=# SELECT ora_hash(123);
 ora_hash
------------
 4089882933
(1 row)
gaussdb=# SELECT ora_hash('123');
 ora_hash
------------
 2034089965
(1 row)
gaussdb=# SELECT ora_hash('sample');
 ora_hash
------------
 1573005290
(1 row)
gaussdb=# SELECT ora_hash(to_date('2012-1-2','yyyy-mm-dd'));
 ora_hash
------------
 1171473495
(1 row)
gaussdb=# SELECT ora_hash(123,234);
 ora_hash
------------
 -9089505052966355682
(1 row)
gaussdb=# SELECT ora_hash('123',234);
 ora_hash
------------
 5742589019960764616
(1 row)
gaussdb=# SELECT ora_hash('sample',234);
 ora_hash
------------
 -1747984408055821656
(1 row)
gaussdb=# SELECT ora_hash(to_date('2012-1-2','yyyy-mm-dd'),234);
 ora_hash
------------
 -3306025179710572679
(1 row)
gaussdb=# SELECT ora_hash('AAAAAAAAAP//AAAAAAAAAAAAAAAA'::rowid);
  ora_hash
------------
 2241979125
(1 row)
```

NOTE

This function is valid only when **a_format_version** is set to **10c** and **a_format_dev_version** is set to **s2**.

- hash_array(anyarray)

  Description: Hashes an array, obtains the result of an array element using the hash function, and returns the combination result.

  Parameter: data of the anyarray type.

  Return type: integer

  Example:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gaussdb=# SELECT hash_array(ARRAY[[1,2,3],[1,2,3]]);
 hash_array
------------
 -382888479
(1 row)
```

- hash_numeric(numeric)

  Description: Calculates the hash value of numeric data.

  Parameter: data of the numeric type.

  Return type: integer

  Example:

  ```
  gaussdb=# SELECT hash_numeric(30);
   hash_numeric
  --------------
    -282860963
  (1 row)
  ```

- hash_range(anyrange)

  Description: Calculates the hash value of a range.

  Parameter: data of the anyrange type.

  Return type: integer

  Example:

  ```
  gaussdb=# SELECT hash_range(numrange(1.1,2.2));
   hash_range
  ------------
    683508754
  (1 row)
  ```

- hashbpchar(character)

  Description: Calculates the hash value of bpchar.

  Parameter: data of the character type.

  Return type: integer

  Example:

  ```
  gaussdb=# SELECT hashbpchar('hello');
   hashbpchar
  -------------
   -1870292951
  (1 row)
  ```

- hashchar(char)

  Description: Converts char and Boolean data into hash values.

  Parameter: data of the char or bool type.

  Return type: integer

  Example:

  ```
  gaussdb=# SELECT hashbpchar('hello');
   hashbpchar
  -------------
   -1870292951
  (1 row)

  gaussdb=# SELECT hashchar('true');
    hashchar
  ------------
   1686226652
  (1 row)
  ```

- hashenum(anyenum)

  Description: Converts enumerated values to hash values.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter: data of the anyenum type.

Return type: integer

Example:

```
gaussdb=# CREATE TYPE b1 AS ENUM('good', 'bad', 'ugly');
CREATE TYPE
gaussdb=# call hashenum('good'::b1);
  hashenum
------------
 1821213359
(1 row)
gaussdb=# DROP TYPE b1;
```

- hashfloat4(real)

  Description: Converts float4 values to hash values.

  Parameter: data of the real type.

  Return type: integer

  Example:

  ```
  gaussdb=# SELECT hashfloat4(12.1234);
   hashfloat4
  ------------
   1398514061
  (1 row)
  ```

- hashfloat8(double precision)

  Description: Converts float8 values to hash values.

  Parameter: data of the double precision type.

  Return type: integer

  Example:

  ```
  gaussdb=# SELECT hashfloat8(123456.1234);
   hashfloat8
  ------------
   1673665593
  (1 row)
  ```

- hashinet(inet)

  Description: Converts inet or cidr values to hash values.

  Parameter: data of the inet type.

  Return type: integer

  Example:

  ```
  gaussdb=# SELECT hashinet('127.0.0.1'::inet);
    hashinet
  -------------
   -1435793109
  (1 row)
  ```

- hashint1(tinyint)

  Description: Converts INT1 values to hash values.

  Parameter: data of the tinyint type.

  Return type: uint32

  Example:

  ```
  gaussdb=# SELECT hashint1(20);
    hashint1
  -------------
   -2014641093
  (1 row)
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- hashint2(smallint)
  Description: Converts INT2 values to hash values.
  Parameter: data of the smallint type.
  Return type: uint32
  Example:

```
gaussdb=# SELECT hashint2(20000);
  hashint2
------------
 -863179081
(1 row)
```

- bucketchar()
  Description: Calculates the hash value of the input parameter.
  Parameter: char, integer
  Return type: integer
- bucketdate()
  Description: Calculates the hash value of the input parameter.
  Parameter: date, integer
  Return type: integer
- bucketfloat4()
  Description: Calculates the hash value of the input parameter.
  Parameter: real, integer
  Return type: integer
- bucketfloat8()
  Description: Calculates the hash value of the input parameter.
  Parameters: double precision, integer
  Return type: integer
- bucketint1()
  Description: Calculates the hash value of the input parameter.
  Parameter: tinyint, integer
  Return type: integer
- bucketint2()
  Description: Calculates the hash value of the input parameter.
  Parameter: smallint, integer
  Return type: integer
- bucketint2vector()
  Description: Calculates the hash value of the input parameter.
  Parameter: int2vector, integer
  Return type: integer
- bucketint4()
  Description: Calculates the hash value of the input parameter.
  Parameter: integer, integer
  Return type: integer

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- bucketint8()
  Description: Calculates the hash value of the input parameter.
  Parameter: bigint, integer
  Return type: integer
- bucketinterval()
  Description: Calculates the hash value of the input parameter.
  Parameter: interval, integer
  Return type: integer
- bucketname()
  Description: Calculates the hash value of the input parameter.
  Parameter: name, integer
  Return type: integer
- bucketnumeric()
  Description: Calculates the hash value of the input parameter.
  Parameter: numeric, integer
  Return type: integer
- bucketnvarchar2()
  Description: Calculates the hash value of the input parameter.
  Parameter: nvarchar2, integer
  Return type: integer
- bucketoid()
  Description: Calculates the hash value of the input parameter.
  Parameters: oid, integer
  Return type: integer
- bucketoidvector()
  Description: Calculates the hash value of the input parameter.
  Parameter: oidvector, integer
  Return type: integer
- bucketraw()
  Description: Calculates the hash value of the input parameter.
  Parameter: raw, integer
  Return type: integer
- bucketreltime()
  Description: Calculates the hash value of the input parameter.
  Parameter: reltime, integer
  Return type: integer
- bucketsmalldatetime()
  Description: Calculates the hash value of the input parameter.
  Parameter: smalldatetime, integer
  Return type: integer

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- buckettext()
  Description: Calculates the hash value of the input parameter.
  Parameter: text, integer
  Return type: integer
- buckettime()
  Description: Calculates the hash value of the input parameter.
  Parameter: time without time zone, integer
  Return type: integer
- buckettimestamp()
  Description: Calculates the hash value of the input parameter.
  Parameter: timestamp without time zone, integer
  Return type: integer
- buckettimestamptz()
  Description: Calculates the hash value of the input parameter.
  Parameter: timestamp with time zone, integer
  Return type: integer
- buckettimetz()
  Description: Calculates the hash value of the input parameter.
  Parameter: time with time zone, integer
  Return type: integer
- bucketuuid()
  Description: Calculates the hash value of the input parameter.
  Parameter: uuid, integer
  Return type: integer
- bucketvarchar()
  Description: Calculates the hash value of the input parameter.
  Parameter: character varying, integer
  Return type: integer

1.6.32 Prompt Message Function

- report_application_error()
  Description: This function can be used to throw errors during PL execution.
  Return type: void

  Table 1-256 report_application_error parameters

Parameter	Type	Description	Required
log	text	Content of an error message.	Yes

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Type	Description	Required
code	int4	Error code corresponding to an error message. The value ranges from –20999 to –20000.	No

Example:

```
gaussdb=# CREATE OR REPLACE FUNCTION GET_RESULT_UNKNOWN(
gaussdb(#     IN context_id int, /*context_id*/
gaussdb(#     IN col_type text /*col_type*/
gaussdb(# )RETURNS INTEGER
gaussdb-# AS $$
gaussdb$# BEGIN
gaussdb$#     if col_type is NULL then
gaussdb$#         PG_CATALOG.REPORT_APPLICATION_ERROR('invalid input for the third parameter
col_type should not be null');
gaussdb$#     end if;
gaussdb$#     PG_CATALOG.REPORT_APPLICATION_ERROR('UnSupport data type for
column_value(context: '||context_id||', '||PG_CATALOG.QUOTE_LITERAL(col_type)||')');
gaussdb$#     return -1;
gaussdb$# END;
gaussdb$# $$ LANGUAGE plpgsql;
CREATE FUNCTION
gaussdb=# CALL GET_RESULT_UNKNOWN(NULL, NULL);
ERROR:  invalid input for the third parameter col_type should not be null
CONTEXT:  SQL statement "CALL pg_catalog.report_application_error('invalid input for the third
parameter col_type should not be null')"
PL/pgSQL function get_result_unknown(integer,text) line 4 at PERFORM
```

1.6.33 Fault Injection System Function

gs_fault_inject(int64, text, text, text, text, text)

Description: Specifies a function that cannot be called. The WARNING message **unsupported fault injection** is reported when this function is called, which does not affect or change the database.

Parameter: fault injection of the int64 type (**0**: CLOG extended page; **1**: CLOG page reading; **2**: forcible deadlock)

- If the first input parameter of text is set to **2** and the second input parameter of text is set to **1**, the second input parameter deadlock occurs. Other input parameters are not deadlocked. When the first input parameter is **0** or **1**, the second input parameter indicates the number of the start page from which the CLOG starts to be extended or read.
- The third input parameter of text indicates the number of extended or read pages when the first input parameter is **0** or **1**.
- The fourth to sixth input parameters of text are reserved.

Return type: int64

1.6.34 Redistribution Functions

The following functions are system functions used by gs_redis during redistribution (Do not call them unless absolutely necessary.):

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- pg_get_redis_rel_end_ctid(text, name, int, int)
- pg_get_redis_rel_start_ctid(text, name, int, int)
- pg_enable_redis_proc_cancelable()
- pg_disable_redis_proc_cancelable()
- pg_tupleid_get_blocknum(tid)
- pg_tupleid_get_offset(tid)
- pg_tupleid_get_ctid_to_bigint(ctid)

1.6.35 Distribution Key Recommendation Functions

Distribution key recommendation is used to recommend distribution keys and distribution modes in a distributed database. The purpose is to reduce the labor cost of selecting distribution keys during service migration or rollout.

- sqladvisor.init(char, boolean, boolean, boolean, int, int)

Description: Initializes parameters.

Return type: Boolean

Table 1-257 Parameter description of init

Parameter	Type	Description	Required
kind	char	Recommendation type. Currently, this parameter can only be set to **D**.	Yes
isUseCost	boolean	Specifies whether optimizers are used. If data is available, optimizers are used.	Yes
isUseCollect	boolean	Specifies whether the analysis is started from the collected load. The default value is **false**.	No
isConstraintPrimaryKey	boolean	Specifies whether primary key constraints are retained. The default value is **true**.	No
sqlCount	int	Number of collected SQL statements. The default value is **10000**. The value ranges from 1 to 100000.	No
maxMemory	int	Maximum memory occupied by distribution key recommendation. The default value is **1024**. The value ranges from 1 to 10240, in MB.	No

- sqladvisor.set_weight_params(real, real, real)

Description: Sets the weight of different components in heuristic rules. A default parameter is set when the init function is called. This function does not need to be called during analysis.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Return type: Boolean

Table 1-258 Parameter description of set_weight_params

Parameter	Type	Description	Required
joinWeight	real	Weight of JOIN. The value ranges from 0 to 1000.	Yes
groupbyWeight	real	Weight of GROUP BY. The value ranges from 0 to 1000.	Yes
qualWeight	real	Weight of predicate. The value ranges from 0 to 1000.	Yes

NOTE

This function is optional. When the init function is executed, the default weights of JOIN, GROUP BY, and predicate are preset to 1.0, 0.1, and 0.05, respectively.

- sqladvisor.set_cost_params(bigint, boolean, text)

Description: Parameter that can be set in the Whtif cost model.

Return type: Boolean

Table 1-259 Parameter description of set_cost_params

Parameter	Type	Description	Required
maxTime	bigint	Maximum recommendation duration, in minutes. If the value is less than or equal to **0**, the duration is not limited by default.	Yes
isTotalSQL	boolean	Specifies whether all SQL statements are used for calculation. The value **true** indicates that all SQL statements are used for calculation. The value **false** indicates that SQL statements whose cost is too high or too low are filtered out based on the percentile.	Yes
compressLevel	text	Search space size of the recommendation algorithm. The options are **low**, **med**, and **high**.	Yes

NOTE

- This function is optional. When the init function is executed, **maxTime** is preset to **–1**, **isTotalSQL** is preset to **true**, and **compressLevel** is preset to **high**.
- A lower compression level indicates longer time, and it is more likely that a better result can be achieved.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- sqladvisor.assign_table_type(text)

Description: Specifies a table as a replication table.

Parameter: table name.

Return type: Boolean

NOTE

The specified replication table must be used before **analyze_query** and **analyze_workload** are called.

- sqladvisor.analyze_query(text, int)

Description: Imports SQL statements to be recommended and analyzes the components of the statements.

Return type: Boolean

Table 1-260 Parameter description of analyze_query

Parameter	Type	Description	Required
query	text	SQL statement.	Yes
frequency	int	Frequency of a statement in the load. The default value is **1**. The value ranges from 1 to 2147483647.	No

NOTE

- If the value of the **query** parameter contains special characters, such as single quotation marks ('), you can use single quotation marks (') to escape the special characters.
- This function is not supported in semi-online mode.

- sqladvisor.analyze_workload()

Description: Analyzes the load information collected online.

Return type: Boolean

- sqladvisor.get_analyzed_result(text)

Description: Obtains beneficial components extracted from the current table.

Parameter: text

Return type: record

The following table describes return columns.

Name	Type	Description
schema_name	text	Schema name.

Name	Type	Description
table_name	text	Table name.
col_name	text	Column name.
operator	text	Operator type.
count	int	Number of times that an operator is used.

- sqladvisor.run()

Description: Performs calculation and analysis based on the specified schema and input SQL statements.

Return type: Boolean

- sqladvisor.get_distribution_key()

Description: Obtains the recommendation result.

NOTE

The analysis result is saved in a session. If the session disconnects, the result will be lost.

Return type: record

The following table describes return columns.

Name	Type	Description
db_name	text	Database name.
schema_name	text	Schema name.
table_name	text	Table name.
distribution_type	text	Recommended distribution type.
distribution_key	text	Recommended distribution key.
start_time	timestamp	Recommended start time.
end_time	timestamp	Recommended end time.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Name	Type	Description
cost_improve	text	Cost increase brought by the recommendation result.
comment	text	Comment.

- sqladvisor.clean()

Description: Clears all the memory in the recommendation process of a session.

Return type: Boolean

- sqladvisor.start_collect_workload(int, int)

Description: Starts online load collection.

Return type: Boolean

Table 1-261 Parameter description of start_collect_workload

Parameter	Type	Description	Required
sqlCount	int	Maximum number of SQL statements for online load collection. The value ranges from 1 to 100000 and the default value is **10000**.	Yes
maxMemory	int	Maximum memory occupied by online load collection. The default value is **1024**. The value ranges from 1 to 10240, in MB.	Yes

NOTICE

- The online collection function can be called only by the system administrator.
- The load of only one database can be collected at a time.
- Currently, only common SQL statements as well as DML and DQL statements in stored procedures are supported.

- sqladvisor.end_collect_workload()

Description: Disables online load collection.

Return type: Boolean

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTICE

- The online collection function can be disabled only by the system administrator.

- sqladvisor.clean_workload()

Description: Clears the memory in the load.

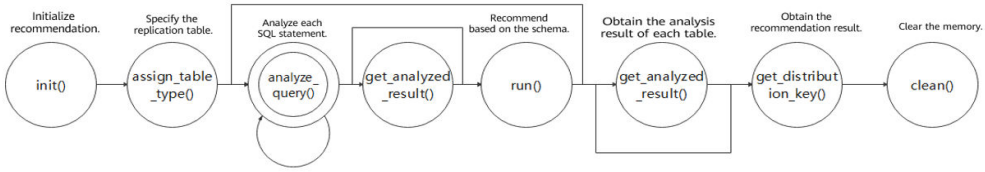
Return type: Boolean

NOTICE

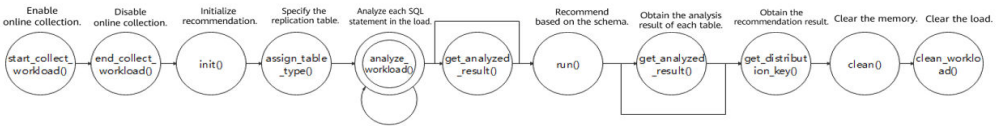
- The function of clearing memory in the load can be called only by the system administrator.
- You must manually execute the cleanup function.

Suggestions

- The following figure shows the call state machine in heuristic or what-if cost recommendation mode.



- The following figure shows the call state machine in semi-online recommendation mode.



1.6.36 Internal Functions

The following functions in GaussDB are used only for internal logic function implementation. You are advised not to use them because unexpected results may occur.

- Selectivity calculation functions

areajoinsel	areasel	arraycontjoinsel	arraycontsel	contjoinsel	contsel	eqjoinsel
eqsel	iclikejoinsel	iclikesel	icnlikejoinsel	icnlikesel	icregexeqjoinsel	icregexeqsel
icregexnejoinsel	icregexnesel	likejoinsel	likesel	neqjoinsel	neqsel	nlikejoinsel

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

nlikesel	positionjoinsel	positionsel	regexeqjoinsel	regexeqsel	regexnejoinsel	regexnesel
scalargtjoinsel	scalargtsel	scalarltjoinsel	scalarltsel	tsmatchjoinsel	tsmatchsel	-

- Statistics collection functions

array_typanalyze	range_typanalyze	ts_typanalyze	local_rto_stat	remote_rto_stat	gs_plan_trace_delete	gs_plan_trace_watch_sqlid
gs_plan_trace_show_sqlids	standby_statement_history_internal	-	-	-	-	-

- Internal functions for sorting

bpchar_sortsupport	bytea_sortsupport	date_sortsupport	numeric_sortsupport	timestamp_sortsupport	-	-

- Functions for reading data remotely
  - gs_read_block_from_remote is used to read the pages of a non-segment-page table file. By default, only the initial user can view the data. Other users can use the data only after being granted permissions.
  - gs_read_segment_block_from_remote is used to read the pages of a segment-page table file. By default, only the initial user can view the data. Other users can use the data only after being granted permissions.
- Functions for reading files remotely
  - gs_read_file_size_from_remote is used to read the size of a specified file. Before using the gs_repair_file function to repair a file, you need to obtain the size of the file from the remote end to verify the missing file information and repair the missing files one by one. By default, only the initial user can view the data. Other users can use the data only after being granted permissions.
  - gs_read_file_from_remote is used to read a specified file. After obtaining the file size by using the gs_read_file_size_from_remote function, gs_repair_file reads the remote file segment by segment using this function. By default, only the initial user can view the data. Other users can use the data only after being granted permissions.
- Auxiliary functions for incrementally rebuilding other standby or cascaded standby DNs using the standby DN.
  - gs_standby_incremental_filemap_create is used to create a temporary filemap file for incremental rebuilding on the standby DN. The filemap file is used to store the path and size of the data to be transmitted during the incremental rebuilding. This API can be called only when the initial user is used and **application** is **gs_rewind**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

  - gs_standby_incremental_filemap_insert is used to insert file information into a specified temporary filemap file. The file information includes the file path, transfer start point, length of data to be transmitted at a time, and rebuild flag bit. This API can be called only when the initial user is used and **application** is **gs_rewind**.
  - gs_standby_incremental_filemap_execute is used to obtain file information stored in a specified temporary filemap file and delete the specified filemap file for data transmission during incremental standby DN rebuilding. This API can be called only when the initial user is used and **application** is **gs_rewind**.

1.6.37 Sensitive Data Discovery Function

- gs_sensitive_data_discovery(scan_target text, scan_classifier text)

  Description: Scans target data and returns statistical scanning results.

  Parameters:

  scan_target: specifies the object to be scanned. The value must be the name of a schema, table, or column, and you must include its parent names. For example, to scan a column, specify *schema_name*.*table_name*.*column_name*.

  scan_classifier: specifies the classifier to be used. Five classifiers can be specified: **email**, **creditcard**, **phonenumber**, **chinesename**, and **encryptedcontent**. Multiple classifiers are separated by commas (,). The value **all** indicates all classifiers are selected.

  Return type: record

  For details, see "Feature Usage Guidelines > Sensitive Data Discovery" in *Developer Guide*.

- gs_sensitive_data_discovery_detail(scan_target text, scan_classifier text)

  Description: Scans the target data and returns the detailed scanning result.

  scan_target: specifies the object to be scanned. The value must be the name of a schema, table, or column, and you must include its parent names. For example, to scan a column, specify *schema_name*.*table_name*.*column_name*.

  scan_classifier: specifies the classifier to be used. Five classifiers can be specified: **email**, **creditcard**, **phonenumber**, **chinesename**, and **encryptedcontent**. Multiple classifiers are separated by commas (,). The value **all** indicates all classifiers are selected.

  Return type: record

  For details, see "Feature Usage Guidelines > Sensitive Data Discovery" in *Developer Guide*.

1.6.38 Dynamic Data Masking Functions

- creditcardmasking(col text, letter char default 'x')

  Description: Replaces the digits before the last four bits following the col string with letters.

  Parameter: Character string to be replaced or character string used for replacement

  Return type: text.

- basicemailmasking(col text, letter char default 'x')

  Description: Replaces the characters before the first at sign (@) in the col string with letters.

  Parameter: Character string to be replaced or character string used for replacement

  Return type: text.

- fullemailmasking(col text, letter char default 'x')

  Description: Replaces the characters (except first **@**) before the last period (.) in the col string with letters.

  Parameter: Character string to be replaced or character string used for replacement

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Return type: text.

- alldigitsmasking(col text, letter char default '0')

  Description: Replaces the digits in the col string with letters.

  Parameter: Character string to be replaced or character string used for replacement

  Return type: text.

- shufflemasking(col text)

  Description: Sorts the characters in the col string out of order.

  Parameter: Character string to be replaced or character string used for replacement

  Return type: text.

- randommasking(col text)

  Description: Randomizes the characters in the col string.

  Parameter: Character string to be replaced or character string used for replacement

  Return type: text.

- **Optional:** regexpmasking(col text, reg text, replace_text text, pos INTEGER default 0, reg_len INTEGER default -1)

  Description: Replaces the col string with a regular expression.

  Parameters: Character string to be replaced, regular expression, replacement start position, and replacement length.

  Return type: text.

1.6.39 Hierarchical Recursion Query Functions

The following functions can be used in a hierarchical recursion query statement to return information about the connection path.

- sys_connect_by_path(col, separator)

  Description: Returns the connection path from the root node to the current row. This function applies only to hierarchical recursion queries.

  The **col** parameter indicates the name of the column displayed in the path. Only columns of the CHAR, VARCHAR, NVARCHAR2, TEXT, ROWID, INT1, INT2, INT4, INT8, FLOAT4, FLOAT8, and NUMERIC type are supported. The **separator** parameter indicates the separator between path nodes. Currently, the col input of the function does not support expression input. If the column content is the same as the separator, the function can run properly and no error is reported.

  Return type: TEXT

  Example:

```
-- Create a table and insert data.
gaussdb=# CREATE TABLE connect_by_table(id int,pid int,name text);
CREATE TABLE
gaussdb=# INSERT INTO connect_by_table VALUES(1,0,'a'),(2,1,'b'),(3,2,'c'),(4,1,'d');
INSERT 0 4
-- Query.
gaussdb=# SELECT *, sys_connect_by_path(name, '-') FROM connect_by_table START WITH id = 1
CONNECT BY prior id = pid ORDER BY pid, id;
 id | pid | name | sys_connect_by_path
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
----+-----+------+---------------------
 1 |   0 | a    | -a
 2 |   1 | b    | -a-b
 4 |   1 | d    | -a-d
 3 |   2 | c    | -a-b-c
(4 rows)
-- Restore the environment.
gaussdb=# DROP TABLE connect_by_table;
DROP TABLE
```

- connect_by_root(col)

  Description: Returns the value of a column in the top-most parent row of the current row. This function applies only to hierarchical recursion queries.

  The **col** parameter indicates the name of an output column. Only columns of the following types are supported: INT8, INT1, INT2, OID, INT4, BOOL, CHAR, NAME, FLOAT4, FLOAT8, ABSTIME, RELTIME, DATE, CASH, TIME, TIMESTAMP, TIMESTAMPTZ, SMALLDATETIME, UUID, INTERVAL, TIMETZ, INT2VECTOR, CLOB, NVARCHAR2, VARCHAR, TEXT, ROWID, VECTOR, BPCHAR, RAW, BYTEA, NUMERIC, XID, CID, and TID. The whitelist restriction cannot be bypassed by forcibly converting the type to the preceding types, for example, connect_by_root(col::text) (where **col** is not of the type in the whitelist) is not supported.

  Return type: data type of the specified column **col**.

  Example:

```
-- Create a table and insert data.
gaussdb=# CREATE TABLE connect_by_table(id int,pid int,name text);
CREATE TABLE
gaussdb=# INSERT INTO connect_by_table VALUES(1,0,'a'),(2,1,'b'),(3,2,'c'),(4,1,'d');
INSERT 0 4
-- Query.
gaussdb=# SELECT *, connect_by_root(name) FROM connect_by_table START WITH id = 1 CONNECT
BY prior id = pid ORDER BY pid, id;
 id | pid | name | connect_by_root
----+-----+------+-----------------
 1 |   0 | a    | a
 2 |   1 | b    | a
 4 |   1 | d    | a
 3 |   2 | c    | a
(4 rows)
-- Restore the environment.
gaussdb=# DROP TABLE connect_by_table;
DROP TABLE
```

1.6.40 Hotkey Feature Functions

- gs_stat_get_hotkeys_info()

  Description: Obtains hotkey information queried on the local node.

  Return type: Tuple

  Example:

```
gaussdb=# SELECT * FROM  gs_stat_get_hotkeys_info() order by count, hash_value;
 database_name | schema_name |     table_name     | key_value | hash_value | count
---------------+-------------+--------------------+-----------+------------+-------
 regression    | public      | hotkey_single_col | {22}      | 1858004829 |     2
 regression    | public      | hotkey_single_col | {11}      | 2011968649 |     2
(2 rows)
```

- gs_stat_clean_hotkeys()

  Description: Clears hotkey cache and resets hotkey status information.

  Return type: bool, and the return value is always **true**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Example:

```
gaussdb=# SELECT * FROM  gs_stat_clean_hotkeys();
 gs_stat_clean_hotkeys
-----------------------
 t
(1 row)
```

1.6.41 Global SysCache Functions

- gs_gsc_table_detail(database_id default NULL, rel_id default NULL)

  Description: Queries the table metadata in the global system cache in a database. The user who calls this function must have the **SYSADMIN** permission.

  Parameter: Specifies the database and table to be queried in the global system cache. The default value **NULL** or value **–1** of **database_id** indicates all databases. The value **0** indicates a shared table. Other values indicate a specified database and a shared table. **rel_id** indicates the OID of a specified table. The default value **NULL** or value **–1** indicates all tables. Other values indicate a specified table. If **database_id** does not exist, an error is reported. If **rel_id** does not exist, the query result is empty.

  Return type: tuple

  ```
  gaussdb=# SELECT * FROM  gs_gsc_table_detail(-1) limit 1;
  database_oid | database_name | reloid |          relname          | relnamespace | reltype | reloftype |
  relowner | relam | relfilenode | reltablespace | relhasindex | relisshared | relkind | relnatts | relhasoids |
  relhaspkey | parttype | tdhasuids | attnames  | extinfo
  --------------+---------------+--------+--------------------------+--------------+---------+-----------+----------
  +-------+-------------+---------------+-------------+-------------+---------+----------+------------+------------
  +----------+-----------+-----------+---------
  0 |               |   2676 | pg_authid_rolname_index |           11 |       0 |         0 |       10 |   403 |           0
  |          1664 | f           | t           | i       |         1 | f          | f          | n       | f         | 'rolname' |
  (1 row)
  ```

- gs_gsc_catalog_detail(database_id default NULL, rel_id default NULL)

  Description: Queries the system catalog row information in the global system cache in a database. The user who calls this function must have the **SYSADMIN** permission.

  Parameter: Specifies the database and table to be queried in the global system cache. The default value **NULL** or value **–1** of **database_id** indicates all databases. The value **0** indicates a shared table. Other values indicate a specified database and a shared table. **rel_id** indicates the ID of a specified table, including all system catalogs in the system cache. The default value **NULL** or value **–1** indicates all tables. Other values indicate a specified table. If **database_id** does not exist, an error is reported. If **rel_id** does not exist, the result is empty.

  Return type: tuple

  Example:

  ```
  -- Obtain the OID of a specific database through pg_database, for example, running SELECT oid, * FROM pg_database;.
  -- In the returned tuple, find the value of the OID column based on the datname column, and then run the following query command. In the example, the obtained OID is 16574.
  gaussdb=# SELECT * FROM  gs_gsc_catalog_detail(16574, 1260);
   database_id | database_name | rel_id | rel_name  | cache_id |  self  |  ctid  | infomask | infomask2 |
  hash_value | refcount
  -------------+---------------+--------+-----------+----------+--------+--------+----------+-----------+------------
  +----------
            0 |               |   1260 | pg_authid |       10 | (0, 9) | (0, 9) |    10507 |        26 |  531311568 |

(10 rows)
```

- gs_gsc_clean(database_id default NULL)

  Description: Clears the global system cache. Note that data in use will not be cleared. The user who calls this function must have the **SYSADMIN** permission.

  Parameter: Specifies the database whose global system cache needs to be cleared. The default value **NULL** or value **–1** indicates that the global system cache of all databases is forcibly cleared. The value **0** indicates that the global system cache of only the shared table is cleared. Other values indicate that the global system cache of a specified database and a specified shared table is cleared. If **database_id** does not exist, an error is reported.

  Return type: Boolean

  Example:

  ```
  gaussdb=# SELECT * FROM  gs_gsc_clean();
  gs_gsc_clean
  --------------
  t
  (1 row)
  ```

- gs_gsc_dbstat_info(database_id default NULL)

  Description: Obtains GSC memory statistics on the local node, including cache query, hit, loading, expiration, and occupied space information of tuples, relations, and partitions, database-level eviction information, thread reference information, and memory usage information. This function can be used to locate performance problems. For example, if the value of the hits or searches array is far less than 1, the value of **global_syscache_threshold** may be too small. As a result, the query hit ratio decreases. The user who calls this function must have the **SYSADMIN** permission.

  Parameter: Specifies the global system cache statistics of the database to be queried. Value **NULL** or **–1** indicates that all databases are queried. Value **0** indicates that only the shared table is queried. Other values indicate that a specified database and a specified shared table are queried. If an invalid value is entered, an error is reported, indicating that **database_id** does not exist.

  Return type: tuple

  Example:

  ```
  gaussdb=# SELECT * FROM  gs_gsc_dbstat_info();
  database_id | database_name | tup_searches | tup_hits | tup_miss | tup_count | tup_dead | tup_memory
  | rel_searches | rel_hits | rel_mis
  s | rel_count | rel_dead | rel_memory | part_searches | part_hits | part_miss | part_count | part_dead |
  part_memory | total_memory | swa
  pout_count | refcount
  ```

1.6.42 Data Damage Detection and Repair Functions

- The restrictions for repairing files or pages of the primary and standby nodes are as follows.

File Type	File/ Page	Primary/ Standby	Detection and Repair
Ordinary row-store tables (including Astore and Ustore), segment-page tables, and cross-page transparent compression tables, excluding indexes and compressed tables	File and page	Primary	Manual detection and repair.
Undo files (excluding undo meta)	Page	Primary	Manual detection and repair (excluding analyse verify).
init fork file for unlogged tables	File	Primary	Manual detection and repair.
Ordinary row-store tables (Astore and Ustore), ILM compressed tables, cross-page transparent compression tables, segment-page tables, hash bucket tables, indexes (B-tree and UB-tree), and undo files (excluding undo meta. Undo files support only when the CRC verification fails.)	Page	Standby	Automatic detection and repair during replay.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

CAUTION

The main standby node and cascaded standby node of the standby cluster can be repaired.

A critical section is used in the database to ensure the consistency of access to key resources. Errors cannot be thrown in the critical section. If a damaged page is accessed in the critical area, PANIC is triggered. Repair detection and automatic repair are not supported. Typical operations that access the critical area during execution include database write operations such as INSERT, DELETE, UPDATE, and DROP.

During the execution of AUTOVACUUM and ANALYZE, the remote access function is temporarily disabled to ensure the accuracy of page reading. As a result, the standby node may fail to restore the primary node.

- gs_verify_data_file(verify_segment bool)

  Description: Checks whether files in the current database of the current instance are lost. The verification only checks whether intermediate segments are lost in the main file of the data table. The default value is **false**, indicating that the segment-page table data file is not verified. When this parameter is set to **true**, only segment-page table files are verified; hash bucket files are not supported for verification. By default, only the initial user, users with the SYSADMIN attribute, and users with the OPRADMIN attribute in the O&M mode can view the information. Other users can view the information only after being granted permissions.

  The returned result is as follows:

  – Non-segment-page table: **rel_oid** and **rel_name** indicate the table OID and table name of the corresponding file, and **miss_file_path** indicates the relative path of the lost file.

  – Segment-page table: All tables are stored in the same file. Therefore, **rel_oid** and **rel_name** cannot display information about a specific table. For a segment-page table, if the first file is damaged, the subsequent files such as .1 and .2 are not checked. For example, if 3, 3.1, and 3.2 are damaged, only 3 damage can be detected. When the number of segment-page files is less than 5, the files that are not generated are also detected during function detection. For example, if there are only files 1 and 2, files 3, 4, and 5 are detected during segment-page file detection. In the following examples, the first is an example of checking a non-segment-page table, and the second is an example of checking a segment-page table.

  Parameters:

  – verify_segment

    Specifies the range of files to be checked. **false** indicates that non-segment-page tables are verified. **true** indicates that segment-page tables are verified.

    The value can be **true** or **false** (default value).

  Return type: record

  Example (The abnormal line is displayed only when an exception is detected. Otherwise, no line is displayed.):

  Verify a non-segment-page table:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gaussdb=# SELECT * FROM  gs_verify_data_file();
node_name         | rel_oid |  rel_name    |  miss_file_path
------------------+---------+--------------+------------------
dn_6001_6002_6003 |   16554 |     test     | base/16552/24745
```

Verify a segment-page table:

```
gaussdb=# SELECT * FROM  gs_verify_data_file(true);
     node_name     | rel_oid | rel_name | miss_file_path
-------------------+---------+----------+----------------
 dn_6001_6002_6003 |       0 | none     | base/16552/2
```

- gs_repair_file(tableoid Oid, path text, timeout int)

  Description: Repairs the file based on the input parameters. Only the primary DN with normal primary/standby connection is supported. Only the main file of the data table can be repaired. The parameters are set based on the OID and path returned by the gs_verify_data_file function. The value of table OID for a segment-page table ranges from 0 to 4294967295. (The internal verification determines whether a file is a segment-page table file based on the file path. The table OID is not used for a segment-page table file.) If the repair is successful, **true** is returned. If the repair fails, the failure cause is displayed. By default, only the initial user, users with the SYSADMIN permission, and users with the OPRADMIN permission in the O&M mode on the primary DN can view the information. Other users can view the information only after being granted permissions.

  CAUTION

  1. If a file on a DN is damaged, a verification error at the PANIC level is reported when the DN is promoted to primary. The DN cannot be promoted to primary, which is normal.
  2. If a file exists but its size is 0, the file will not be repaired. To repair the file, you need to delete the file whose size is 0 and then repair it.
  3. You can delete a file only after the file descriptor is automatically closed. You can manually restart the process or perform a primary/standby switchover.
  4. The restoration function requires that the paths of the files to be restored on the primary and standby nodes be the same. If the paths are different, the restoration fails. That is, if the RELATIVE LOCATION tablespace is used, the path is different because tblspcversiondir is different. As a result, the restoration fails.

  Parameters:

  – tableoid

    OID of the table corresponding to the file to be repaired. Set this parameter based on the **rel_oid** column in the list returned by the gs_verify_data_file function.

    Value range: OID ranging from 0 to 4294967295. Note: A negative value will be forcibly converted to a non-negative integer.

  – path

    Path of the file to be repaired. Set this parameter based on the **miss_file_path** column in the list returned by the gs_verify_data_file function.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Value range: a string

– timeout

Specifies the duration for waiting for the standby DN to replay. The repair file needs to wait for the standby DN to be put back to the corresponding location on the current primary DN. Set this parameter based on the replay duration of the standby DN.

Value range: 60s to 3600s.

Return type: Boolean

Example (Set **tableoid** and **path** based on the output of gs_verify_data_file):

Page-based storage:

```
gaussdb=# SELECT * FROM gs_repair_file(16554,'base/16552/24745',360);
gs_repair_file
----------------
t
```

Segment-page storage:

```
gaussdb=# SELECT * FROM gs_repair_file(16554,'base/16552/2',360);
gs_repair_file
----------------
t
```

- local_bad_block_info()

  Description: Displays the page damage of the instance. You can read the page from the disk and record the page CRC failure. By default, only the initial user, users with the SYSADMIN attribute, users with the MONADMIN attribute, users with the OPRADMIN attribute in the O&M mode, and monitor users can view the information. Other users can view the information only after being granted permissions. **file_path** indicates the relative path of a damaged file. The segment-page format is supported. **block_num** indicates the number of the page where the file is damaged. The page number starts from 0. **check_time** indicates the time when the page damage is detected. **repair_time** indicates the time when the page is repaired.

  Return type: record

  Example (Related entries are displayed only when there are damaged records. Otherwise, no log is displayed.):

```
gaussdb=# SELECT * FROM  local_bad_block_info();
node_name    | spc_node | db_node | rel_node| bucket_node | fork_num | block_num |    file_path     |
check_time            |   repair_time
-----------------+-------+--------+--------+--------------+----------+-----------+-----------------
+--------------------------+-------------------------------
dn_6001_6002_6003|  1663 |  16552 |  24745 |        -1    |    0    | 0        | base/16552/24745 |
2022-01-13 20:19:08.385004+08 | 2022-01-13 20:19:08.407314+08
```

- remote_bad_block_info()

  Description: Queries the page damage of other instances except the current instance when a query is performed on the CN. The recorded data is the same as that of the local_bad_block_info function executed on other instances. The execution result on the DN is empty. By default, only the initial user, users with the SYSADMIN attribute, users with the MONADMIN attribute, users with the OPRADMIN attribute in the O&M mode, and monitor users can view the information. Other users can view the information only after being granted permissions.

  Return type: record

- local_clear_bad_block_info()

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description: Deletes data of repaired pages from local_bad_block_info, that is, information whose **repair_time** is not empty. By default, only the initial user, users with the SYSADMIN permission, users with the OPRADMIN attribute in the O&M mode, and monitor users can view the information. Other users can view the information only after being granted permissions.

Return type: Boolean

Example:

```
gaussdb=# SELECT * FROM  local_clear_bad_block_info();
result
--------
t
```

- remote_clear_bad_block_info()

  Description: Clears the data of the repaired pages of other instances except the current instance when this function is executed on the CN, that is, information whose **repair_time** is not empty. The execution result on the DN is empty. By default, only the initial user, users with the SYSADMIN permission, users with the OPRADMIN attribute in the O&M mode, and monitor users can view the information. Other users can view the information only after being granted permissions.

  Return type: record

- gs_inconsistency_info(reset bool)

  Description: Displays or resets data inconsistency information in the database. If the input parameter **reset** is set to **true**, data inconsistency information is reset. If the input parameter **reset** is set to **false**, data inconsistency information is displayed. By default, only the initial user, users with the SYSADMIN attribute, users with the MONADMIN attribute, users with the OPRADMIN attribute in the O&M mode, and monitor users can view the information. Other users can view the information only after being granted permissions. **inconsistency_type** indicates the inconsistency type, **node_name** indicates the node name, **spc_node** indicates the tablespace ID, **db_node** indicates the database node ID, **rel_node** indicates the table ID, **bucket_node** indicates the hash bucket ID, **backend** indicates the temporary table ID, **index_oid** indicates the index OID, **tuple_blkno** indicates the page number of the heap table where the tuple is located, **tuple_offset** indicates the offset of the heap table page where the tuple is located, **count** indicates the number of times the inconsistency information occurs, and **last_update_time** indicates the last time when the inconsistent information is updated.

  Return type: record

  When the input parameter **reset** is set to **false** and inconsistency information is detected, related items are displayed. In other cases, no line is displayed. Example:

```
gaussdb=# SELECT * FROM gs_inconsistency_info(false);
 inconsistency_type  | node_name | spc_node | db_node | rel_node | bucket_node | backend | index_oid
| tuple_blkno | tuple_offset | count |        last_update_time
---------------------+-----------+----------+---------+----------+-------------+---------+-----------+-------------
+--------------+-------+-------------------------------
 INCONSISTENCY_INDEX | sgnode    |     1663 |   12902 |    16722 |          -1 |      -1 |     16728 |
0 |            1 |     1 | 2024-11-20 16:18:56.85289-05
```

- gs_verify_and_tryrepair_page (path text, blocknum Oid, verify_mem bool, is_segment bool)

  Description: Verifies the page specified by the instance. By default, only the initial user, users with the SYSADMIN permission, and users with the

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

OPRADMIN permission in the O&M mode on the primary DN can view the information. Other users can view the information only after being granted permissions. In the command output, **disk_page_res** indicates the verification result of the page on the disk, **mem_page_res** indicates the verification result of the page in the memory, and **is_repair** specifies whether the repair function is triggered during the verification. **t** indicates that the page is repaired, and **f** indicates that the page is not repaired.

NOTE

- If a page on a DN is damaged, a verification error at the PANIC level is reported when the DN is promoted to primary. The DN cannot be promoted to primary, which is normal.
- The repair triggered by this function can only repair pages in the memory. The repair takes effect only after the memory pages are flushed to disks and the physical pages are repaired.

Parameters:

- path

  Path of the damaged file. Set this parameter based on the **file_path** column in local_bad_block_info. To verify the undo pages of the Ustore table, enter the path of the undo pages to be verified.

  Value range: a string

- blocknum
