-- Drop the human_staff database.
gaussdb=# DROP DATABASE human_staff;
DROP DATABASE
```

For details about gsql meta-commands, see **Meta-Command Reference**.

----End

Example 2

Obtain the help information.

```
gsql --help
gsql is the GaussDB Kernel interactive terminal.

Usage:
  gsql [OPTION]... [DBNAME [USERNAME]]

General options:
  -c, --command=COMMAND    run only single command (SQL or internal) and exit
  -d, --dbname=DBNAME      database name to connect to (default: "omm")
  -f, --file=FILENAME      execute commands from file, then exit
  -l, --list               list available databases, then exit
  -v, --set=, --variable=NAME=VALUE
                           set gsql variable NAME to VALUE
  -V, --version            output version information, then exit
  -X, --no-gsqlrc          do not read startup file (~/.gsqlrc)
  -1 ("one"), --single-transaction
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
                      execute command file as a single transaction
  -?, --help              show this help, then exit

Input and output options:
  -a, --echo-all          echo all input from script
  -e, --echo-queries      echo commands sent to server
  -E, --echo-hidden       display queries that internal commands generate
  -k, --with-key=KEY      the key for decrypting the encrypted file
  -L, --log-file=FILENAME  send session log to file
  -m, --maintenance       can connect to cluster during 2-pc transaction recovery
  -n, --no-libedit        disable enhanced command line editing (libedit)
  -o, --output=FILENAME   send query results to file (or |pipe)
  -q, --quiet             run quietly (no messages, only query output)
  -C, -C1, --enable-client-encryption=1
                      enable client encryption feature
  -C2, --enable-client-encryption=2
                      enable client sorting based client encryption feature
  -C3, --enable-client-encryption=3
                      enable Trusted Domain operation based on client encryption feature

  -s, --single-step       single-step mode (confirm each query)
  -S, --single-line       single-line mode (end of line terminates SQL command)
  -y, --slash-command     enable slash command to re-execute query in buffer

Output format options:
  -A, --no-align          unaligned table output mode
  -F, --field-separator=STRING
                      set field separator (default: "|")
  -H, --html              HTML table output mode
  -P, --pset=VAR[=ARG]    set printing option VAR to ARG (see \pset command)
  -R, --record-separator=STRING
                      set record separator (default: newline)
  -r                      if this parameter is set,use libedit
  -t, --tuples-only       print rows only
  -T, --table-attr=TEXT   set HTML table tag attributes (e.g., width, border)
  -x, --expanded          turn on expanded table output
  -z, --field-separator-zero
                      set field separator to zero byte
  -0, --record-separator-zero
                      set record separator to zero byte
  -2, --pipeline          use pipeline to pass the password, forbidden to use in terminal
                      must use with -c or -f

Connection options:
  -h, --host=HOSTNAME     database server host or socket directory (default: "/data/huawei/wisequery/
perfadm_mppdb")
                      allow multi host IP address with comma separator, Use the
                      PGTARGETSESSIONATTRS(default: "primary") variable to select the
                      IP address to be connected.
                      (PGTARGETSESSIONATTRS can be {read-write|read-only|primary|
                       standby|prefer-standby|any})
  -p, --port=PORT         database server port (default: "5432")
  -U, --username=USERNAME  database user name (default: "omm")
  -W, --password=PASSWORD  the password of specified database user

Emergency O&M command:
  -O, --emergency-command=EMERGENCYCOMMAND
                      emergency O&M command

For more information, type "\?" (for internal commands) or "\help" (for SQL
commands) from within gsql, or consult the gsql section in the GaussDB Kernel
documentation.
```

Example 3

Run an O&M command through the UDS O&M channel. The following is a simple example of how to check the memory usage through the UDS O&M channel:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Step 1 Log in to the server where the GaussDB node is located and run the following gsql command to check whether the memory usage records, such as memory overview and memory context, are generated:

```
gsql -O "{port} mem_log"
```

{port} specifies the database node name. If **true** is displayed, the detailed information is generated. If the execution fails, the failure cause is displayed.

```
-- In the example, 19995 is the database listening port.
gsql -O "19995 mem_log"
true
```

Step 2 Check the content of the **mem_log** file generated in the *$GAUSSLOG*/**mem_log/***{nodename}* directory. *{nodename}* specifies the database node name.

```
-- In the example, datanode specifies the database node name.
ls -l $GAUSSLOG/mem_log/datanode
total 8
-rw-------. 1 omm omm 7543 May 28 15:15 mem_log-2025-05-28_151518.log
```

Step 3 Run the following command to view the file:

```
cat $GAUSSLOG/mem_log/datanode/mem_log-time.log
```

mem_log-time.log is the file generated in the *$GAUSSLOG*/**mem_log/***datanode* directory in **Step 2**. (The file name extension is .log.)

----End

4.2.1.2 Meta-Command Reference

This section describes meta-commands provided by gsql after GaussDB CLI tool is used to connect to a database. After connecting to the database, you can run the **\?** command to display the help information about all available meta-commands.

Precautions

- The format of the gsql meta-command is a backslash (\) followed by a command verb, and then a parameter. The parameters are separated from the command verb and from each other by any number of whitespace characters.
- To include whitespace characters into an argument, you must quote them with single quotation marks. To include a single quotation mark into such an argument, precede it by a backslash. Anything contained in single quotation marks is furthermore subject to C-like substitutions for \n (new line), \t (tab), \b (backspace), \r (carriage return), \f (form feed), \digits (octal), and \xdigits (hexadecimal).
- Text enclosed in backquotes (`) is taken as a command line input to the shell. The command output (without new line characters at the end) replaces the text enclosed in backquotes (`) in the original argument, which is used as the argument value.
- If an unquoted argument begins with a colon (:), the argument is taken as a gsql variable and the value of the variable is used as the argument value instead.
- Some commands take an SQL identifier (such as a table name) as a parameter. These parameters follow the SQL syntax rules: Unquoted letters are forced to lowercase, while double quotation marks ("") protect letters from case conversion and allow incorporation of whitespace into the identifier. Within double quotation marks, paired double quotation marks

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

reduce to a single double quotation mark in the result name. For example, **FOO"BAR"BAZ** is interpreted as **fooBARbaz**, and **"Aweird""name"** becomes **Aweird"name**.

- The analysis of parameters stops at another unquoted backslash (\), which is considered the beginning of a new meta-command. Parameters end with two backslashes (\\) and then SQL statements can be analyzed, if any. In this way, SQL and gsql commands can be used together in a line. But in any case, the arguments of a meta-command cannot continue beyond the end of the line.
- M-compatible databases do not support the **\h** meta-command.

Commands and Parameters

For details about meta-commands, see **Table 4-12**, **Table 4-13**, **Table 4-14**, **Table 4-15**, **Table 4-17**, **Table 4-19**, **Table 4-20**, **Table 4-21**, and **Table 4-23**.

NOTE

FILE mentioned in the following commands indicates a file path. This path can be an absolute path such as **/home/gauss/file.txt**, or a relative path such as **file.txt**. By default, a **file.txt** is created in the path where the user runs gsql commands.

Table 4-12 Common meta-commands

Parameter	Description	Value Range
\copyright	Displays GaussDB version and copyright information.	-
\g [FILE] or ;	Performs a query operation and sends the result to a file or pipe.	-
\h(\help) [NAME]	Provides syntax help on the specified SQL statement.	If the name is not specified, then gsql will list all the commands for which syntax help is available. If the name is an asterisk (*), syntax help on all SQL statements is displayed.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Description	Value Range
\parallel [on [num]|off]	Controls the parallel execution function. • **on**: The switch is enabled and the maximum number of concurrently executed tasks is **num**. The default value of **num** is **1024**. • **off**: This switch is disabled. **NOTE** • Parallel execution is not allowed in a running transaction and a transaction is not allowed to be started during parallel execution. • Parallel execution of **\d** meta-commands is not allowed. • If SELECT statements are run concurrently, the return results may be displayed randomly but acceptable; however, if a core dump or process response failure occurs, it is not acceptable. • It is not recommended that you run **SET** statements in concurrent tasks because they may cause unexpected results. • Creation of a temporary table is not supported. If temporary tables are required, create them before parallel execution is enabled, and use them only in the parallel execution. Temporary tables cannot be created in parallel execution. • When **\parallel** is executed, *num* independent gsql processes can be connected to the database server. • The total duration of all **\parallel** tasks cannot exceed **session_timeout**. Otherwise, the connection may fail during concurrent execution. • One or more commands following **\parallel on** will be executed only after **\parallel off** is executed. Therefore, **\parallel on** must be followed by **\parallel off**. Otherwise, the commands following **\parallel on** cannot be executed. • The maximum number of connections allowed by the server is determined based on **max_connection** and the number of current connections. Set **num** based on the allowed number of connections.	-
\q	Exits the gsql program. This command is executed in a script file only when the script terminates.	-

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 4-13 Query buffer meta-commands

Parameter	Description
\e [FILE] [LINE]	Uses an external editor to edit the query buffer or file.
\ef [FUNCNAME [LINE]]	Edits the function definition using an external editor. If **LINE** is specified, the cursor will point to the specified line of the function body.
\p	Prints the current query buffer to the standard output.
\r	Resets or clears the query buffer.
\w FILE \w |COMMAND	Outputs the current query buffer to a file specified by **FILE**. Sends the current query buffer to the shell command specified by **COMMAND**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 4-14 Input/Output commands

Parameter	Description
\copy { table [(column_list)] | (query) } { from | to } { filename | stdin | stdout | pstdin | pstdout } [copy_parameter] [parallel integer] [NO_SPLIT_FILE] [FIELD_NO_EOL]	After logging in to the database on any gsql client, you can import and export data. This is an operation of running the **SQL COPY** command, but not the server that reads or writes data to a specified file. Instead, data is transferred between the server and the local file system. In this way, local user permissions instead of server permissions are required for file access, and the user does not need to be the initial user.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Description
	NOTE ● \COPY only applies to small-batch data import with uniform formats. GDS or COPY is preferred for data import. ● \COPY specifies the number of clients to import data to implement parallel import of data files. Currently, the value range is [1, *Twice the number of CPU cores of the client*]. ● When **\COPY** specifies the **parallel** parameter for parallel import, multiple threads are started to import data. Each thread is an independent transaction. Therefore, data may be partially imported. Exercise caution when importing data in parallel after fully understanding the possible results of parallel import. ● \COPY can specify **pstdin** and **pstdout**. **pstdin** declares that the input is the standard input from gsql, and **pstdout** declares that the output is the standard output from gsql. ● The parallel import using \COPY has the following limitations: Parallel import of temporary tables is not supported. Parallel import within a transaction is not supported. Parallel import of binary files is not supported. Parallel import of data encrypted using AES-128 is not supported. Parallel import is not supported when the **COPY** option contains **EOL**. In these cases, even if the **parallel** parameter is specified, the non-parallel process is still executed. If the data file contains fewer than 100 lines, the non-parallel process is also executed. Parallel import is not supported when a sequence is specified. Otherwise, an error is reported. If a table (for example, **t1**) with a trigger inserting data to the table is imported in parallel and the table has constraints, a deadlock may occur due to parallel import. Specifically, multiple parallel import processes operate the **t1** table. Due to constraints (such as the UNIQUE and FOREIGN KEY), lock wait occurs between different transactions. If a loop is formed during the wait, the database deadlock detection mechanism is triggered. As a result, the import fails and a deadlock error is reported. Therefore, if the target table with constraints contains a trigger inserting data into the table, parallel import is not recommended. When parallel import is performed on a table with constraints (such as the UNIQUE constraint), if the LOAD syntax is not used and the data file contains data that violates the constraints, a deadlock may occur due to parallel import. Specifically, multiple parallel import threads operate the **t1** table. Due to constraints (such as UNIQUE and FOREIGN KEY), lock wait occurs between different transactions. If a loop is formed during the wait, the database deadlock detection mechanism is triggered. As a result, the data import fails and an error is reported. Therefore, if the target table contains constraints (such as UNIQUE KEY), you are advised to use the LOAD syntax for parallel import. The **FIELD_NO_EOL** option takes effect when the value of **parallel** is greater than 1. With the **FIELD_NO_EOL** option, the data import speeds up. However, you need to ensure that the data rows in the imported data file do not contain newline characters. If the data rows contain newline characters, the following problems may occur: ● A complete data row is split into two parts by the newline character in the data field. The two parts are allocated to different threads for sending data to the client. As a result, the inserted field does not comply with the original table definition. ● Once **SKIP** is used, the specified number of data rows will be skipped. A newline character in the field may cause a row of data to be incorrectly considered as two rows of data. As a result, the number of data rows skipped is incorrect. ● The **NO_SPLIT_FILE** option added to the \COPY statement takes effect when the value of **parallel** is greater than 1. When this option is added, the original parallelism logic is kept and maximum value of DOP is **8**. By default, the DOP upper limit 8 is removed and data files are automatically split to implement parallelism.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Description
\echo [STRING]	Writes character strings to the standard output.
prompt [STRING]	Writes character strings to the standard output, which is equivalent to **\echo**.
\i FILE	Reads content from *FILE* and uses them as the input for a query.
\i+ FILE KEY	Runs commands in an encrypted file.
\ir FILE	Similar to **\i**, but resolves relative path names differently.
\ir+ FILE KEY	Similar to **\i+**, but resolves relative path names differently.
\o [FILE]	Sends all subsequent query results to the file specified by **FILE**.
\o [| COMMAND]	Sends all subsequent query results to the shell command specified by **COMMAND**.
\qecho [STRING]	Writes character strings to the query output flow.
\print_copy_lines [on | off]	Specifies whether to print "COPY XXX" in the output of the **COPY FROM STDIN** command. This function is enabled by default. • **on**: Running the **COPY FROM STDIN** command will print the number of data rows that have been imported. • **off**: Running the **COPY FROM STDIN** command does not print how many rows of data have been imported.

Table 4-15 Information display meta-commands

Parameter	Description	Value Range	Example
\d[S+]	Lists all tables, views, and sequences of all schemas in **search_path**. When objects with the same name exist in different schemas in **search_path**, only the object in the schema that ranks first in **search_path** is displayed.	-	Lists all tables, views, and sequences of all schemas in **search_path**. `gaussdb=# \d`

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Description	Value Range	Example
\d[S+] NAME	Lists the structure of specified tables, views, and indexes. When objects with the same name exist in different schemas in **search_path**, only the object in the schema that ranks first in **search_path** is displayed.	-	Lists the structure of table **a**. `gaussdb=# \dtable+ a`
\d+ [PATTERN]	Lists all tables, views, and indexes. When objects with the same name exist in different schemas in **search_path**, only the object in the schema that ranks first in **search_path** is displayed. If **PATTERN** is specified, only tables, views, and indexes whose names match **PATTERN** are displayed.	-	Lists all tables, views, and indexes whose names start with **f**. `gaussdb=# \d+ f*`
\da[S] [PATTERN]	Lists all available aggregate functions, together with the data type they perform operations on and the return value types. When objects with the same name exist in different schemas in **search_path**, only the object in the schema that ranks first in **search_path** is displayed. If **PATTERN** is specified, only aggregate functions whose names match **PATTERN** are displayed.	-	Lists all available aggregate functions whose names start with **f**, together with their return value types and the data types. `gaussdb=# \da f*`
\db[+] [PATTERN]	Lists all available tablespaces. If **PATTERN** is specified, only tablespaces whose names match **PATTERN** are displayed.	-	Lists all available tablespaces whose names start with **p**. `gaussdb=# \db p*`

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Description	Value Range	Example
\dc[S+] [PATTERN]	Lists all available conversions between character-set encodings. When objects with the same name exist in different schemas in **search_path**, only the object in the schema that ranks first in **search_path** is displayed. If **PATTERN** is specified, only conversions whose names match **PATTERN** are displayed.	-	Lists all available conversions between character-set encodings. `gaussdb=# \dc *`
\dC[+] [PATTERN]	Lists all available type conversions. When objects with the same name exist in different schemas in **search_path**, only the object in the schema that ranks first in **search_path** is displayed. If **PATTERN** is specified, only conversions whose names match **PATTERN** are displayed.	PATTERN must be the actual type name and cannot be an alias.	Lists all type conversions whose patten names start with **c**. `gaussdb=# \dC c*`
\dd[S] [PATTERN]	Displays all visible objects. When objects with the same name exist in different schemas in **search_path**, only the object in the schema that ranks first in **search_path** is displayed. If **PATTERN** is specified, only matched objects are displayed. The objects include aggregations, functions, operators, types, relations (tables, views, indexes, and sequences), and rules.	-	Lists all visible objects. `gaussdb=# \dd`
\ddp [PATTERN]	Lists all default permissions. If **PATTERN** is specified, only permissions whose names match **PATTERN** are displayed.	-	Lists all default permissions. `gaussdb=# \ddp`

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Description	Value Range	Example
\dD[S+] [PATTERN]	Lists all available domains. When objects with the same name exist in different schemas in **search_path**, only the object in the schema that ranks first in **search_path** is displayed. If **PATTERN** is specified, only domains whose names match **PATTERN** are displayed.	-	Lists all available domains. `gaussdb=# \dD`
\det[+] [PATTERN]	Lists all foreign tables. When objects with the same name exist in different schemas in **search_path**, only the object in the schema that ranks first in **search_path** is displayed. If **PATTERN** is specified, only tables whose names match **PATTERN** are displayed.	-	Lists all foreign tables. `gaussdb=# \det`
\des[+] [PATTERN]	Lists all foreign servers. If **PATTERN** is specified, only servers whose names match **PATTERN** are displayed.	-	Lists all foreign servers. `gaussdb=# \des`
\deu[+] [PATTERN]	Lists all user mappings. If **PATTERN** is specified, only information whose name matches **PATTERN** is displayed.	-	Lists all user mappings. `gaussdb=# \deu`
\dew[+] [PATTERN]	Lists all encapsulated external data. If **PATTERN** is specified, only data whose name matches **PATTERN** is displayed.	-	Lists all encapsulated external data. `gaussdb=# \dew`

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Description	Value Range	Example
\df[antw] [S+] [PATTERN]	Lists all available functions, together with their parameters and return types. **a** indicates an aggregate function, **n** indicates a common function, **t** indicates a trigger, and **w** indicates a window function. When objects with the same name exist in different schemas in **search_path**, only the object in the schema that ranks first in **search_path** is displayed. If **PATTERN** is specified, only functions whose names match **PATTERN** are displayed.	-	Lists all available functions, together with their parameters and return types. `gaussdb=# \df`
\dF[+] [PATTERN]	Lists all text search configuration information. When objects with the same name exist in different schemas in **search_path**, only the object in the schema that ranks first in **search_path** is displayed. If **PATTERN** is specified, only configurations whose names match **PATTERN** are displayed.	-	Lists all text search configuration information. `gaussdb=# \dF+`
\dFd[+] [PATTERN]	Lists all text search dictionaries. When objects with the same name exist in different schemas in **search_path**, only the object in the schema that ranks first in **search_path** is displayed. If **PATTERN** is specified, only dictionaries whose names match **PATTERN** are displayed.	-	Lists all text search dictionaries. `gaussdb=# \dFd`

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Description	Value Range	Example
\dFp[+] [PATTERN]	Lists all text search analyzers. When objects with the same name exist in different schemas in **search_path**, only the object in the schema that ranks first in **search_path** is displayed. If **PATTERN** is specified, only analyzers whose names match **PATTERN** are displayed.	-	Lists all text search analyzers. `gaussdb=# \dFp`
\dFt[+] [PATTERN]	Lists all text search templates. When objects with the same name exist in different schemas in **search_path**, only the object in the schema that ranks first in **search_path** is displayed. If **PATTERN** is specified, only templates whose names match **PATTERN** are displayed.	-	Lists all text search templates. `gaussdb=# \dFt`
\dg[+] [PATTERN]	Lists all database roles. If **PATTERN** is specified, only roles whose names match **PATTERN** are displayed. **NOTE** Since the concepts of "users" and "groups" have been unified into "roles", this command is now equivalent to **\du**. Both commands are retained to ensure compatibility with earlier versions.	-	Lists all database roles named **j?e** (the question mark (?) indicates any character). `gaussdb=# \dg j?e`
\dL[S+] [PATTERN]	Lists all available program languages. If **PATTERN** is specified, only languages whose names match **PATTERN** are displayed.	-	Lists all available program languages. `gaussdb=# \dL`

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Description	Value Range	Example
\dm[S+] [PATTERN]	Lists materialized views. When objects with the same name exist in different schemas in **search_path**, only the object in the schema that ranks first in **search_path** is displayed. If **PATTERN** is specified, only materialized views whose names match **PATTERN** are displayed.	-	Lists materialized views. `gaussdb=# \dm`
\dn[S+] [PATTERN]	Lists all schemas (namespace). If **+** is added to the command, the permission and description of each schema are listed. If **PATTERN** is specified, only schemas whose names match the pattern are shown. By default, only schemas you created are displayed.	-	Lists information about all schemas whose names start with **d**. `gaussdb=# \dn+ d*`
\do[S] [PATTERN]	Lists available operators with their operand and return types. When objects with the same name exist in different schemas in **search_path**, only the object in the schema that ranks first in **search_path** is displayed. If **PATTERN** is specified, only operators whose names match **PATTERN** are displayed. By default, only the operators created by the user are listed.	-	Lists available operators with their operand and return types. `gaussdb=# \do`

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Description	Value Range	Example
\dO[S+] [PATTERN]	Lists collation rules. When objects with the same name exist in different schemas in **search_path**, only the object in the schema that ranks first in **search_path** is displayed. If **PATTERN** is specified, only rules whose names match **PATTERN** are displayed. By default, only user-created rules are shown.	-	Lists collation rules. gaussdb=# \dO
\dp [PATTERN]	Lists tables, views, and related permissions. When objects with the same name exist in different schemas in **search_path**, only the object in the schema that ranks first in **search_path** is displayed. If **PATTERN** is specified, only tables and views whose names match the pattern are shown.	-	Lists tables, views, and related permissions. gaussdb=# \dp The following result about **\dp** is displayed: rolename=xxxx/yyyy -- Assigns permissions to a role. =xxxx/yyyy -- Assigns permissions to public. *xxxx* indicates the assigned permissions, and *yyyy* indicates the roles with the assigned permissions. For details about permission descriptions, see **Table 4-16**.
\drds [PATTERN1 [PATTERN2]]	Lists all parameters that have been modified. These settings can be for roles, for databases, or for both. **PATTERN1** and **PATTERN2** indicate a role pattern and a database pattern, respectively. If **PATTERN** is specified, only rules whose names match **PATTERN** are displayed. If the default value is used or * is specified, all settings are listed.	-	List all the modified configuration parameters of the database. gaussdb=# \drds * *dbname*

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Description	Value Range	Example
\dT[S+] [PATTERN]	Lists all data types. When objects with the same name exist in different schemas in **search_path**, only the object in the schema that ranks first in **search_path** is displayed. If **PATTERN** is specified, only types whose names match **PATTERN** are displayed.	-	Lists all data types. `gaussdb=# \dT`
\du[+] [PATTERN]	Lists all database roles. If **PATTERN** is specified, only roles whose names match **PATTERN** are displayed. **NOTE** Since the concepts of "users" and "groups" have been unified into "roles", this command is now equivalent to **\dg**. Both commands are retained to ensure compatibility with earlier versions.	-	Lists all database roles. `gaussdb=# \du`

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Description	Value Range	Example
\dE[S+] [PATTERN] \di[S+] [PATTERN] \ds[S+] [PATTERN] \dt[S+] [PATTERN] \dv[S+] [PATTERN]	In this group of commands, the letters E, i, s, t, and v stand for foreign table, index, sequence, table, and view, respectively. You can specify any or a combination of these letters sequenced in any order to obtain an object list. When objects with the same name exist in different schemas in **search_path**, only the object in the schema that ranks first in **search_path** is displayed. For example, **\dit** lists all indexes and tables. If **PATTERN** is specified, only objects whose names match **PATTERN** are displayed. By default, only objects you created are displayed. You can specify **PATTERN** or **S** to view other system objects.	-	Lists all indexes and views. `gaussdb=# \div`
\dx[+] [PATTERN]	Lists installed extensions. If **PATTERN** is specified, only extensions whose names match **PATTERN** are displayed.	-	Lists installed extensions. `gaussdb=# \dx`
\l[+]	Lists the names, owners, character set encodings, and permissions of all the databases in the server.	-	List the names, owners, character set encodings, and permissions of all the databases in the server. `gaussdb=# \l`

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Description	Value Range	Example

\sf[+] FUNCNAME	Displays the definition of a function.
	NOTE
	• If the function name contains parentheses, enclose the function name with double quotation marks and add the parameter type list following the double quotation marks. Also enclose the list with parentheses.
	• If a function with the same name exists, the definitions of multiple functions are returned.
		-	Assume a function **function_a** and a function **func()name**. This parameter will be as follows:
			`gaussdb=# \sf function_a`
			`gaussdb=# \sf "func()name"(argtype1, argtype2)`

\z [PATTERN]	Lists all tables, views, and sequences in the database and their access permissions. If a pattern is given, it is a regular expression, and only matched tables, views, and sequences are shown.	-	Lists all tables, views, and sequences in the database and their access permissions. `gaussdb=# \z`

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- In Table 4-15, **S** indicates that the system object is displayed and **+** indicates that additional object information is displayed.
- **PATTERN** specifies the name of the object to be displayed. Pay attention to the following points about **PATTERN**:
  - In the simplest case, PATTERN is the exact name of the object. Characters in **PATTERN** are usually converted to lowercase (as in SQL names), for example, **\dt FOO** will display a table named **foo**. As in SQL names, placing double quotation marks (") around a pattern prevents them being folded to lower case. If you need to include a double quotation mark (") in a pattern, write it as a pair of double quotation marks ("") within a double-quote sequence, which is in accordance with the rules for SQL quoted identifiers. For example, **\dt "FOO""BAR"** will be displayed as a table named **FOO"BAR** instead of **foo"bar**. You cannot put double quotation marks around just part of a pattern, which is different from the normal rules for SQL names. For example, **\dt FOO"FOO"BAR** will be displayed as a table named **fooFOObar** if just part of a pattern is quoted.
  - Whenever the **PATTERN** parameter is omitted completely, the **\d** commands display all objects that are visible in the current schema search path, which is equivalent to using an asterisk (*) as the pattern. An object is regarded to be visible if it can be referenced by name without explicit schema qualification. To see all objects in the database regardless of their visibility, use a dot within double quotation marks (*.*) as the pattern.
  - Within a pattern, the asterisk (*) matches any sequence of characters (including no characters) and a question mark (?) matches any single character. This notation is comparable to Unix shell file name patterns. For example, **\dt int*** displays tables whose names start with **int**. But within double quotation marks, the asterisk (*) and the question mark (?) lose these special meanings and are just matched literally.
  - A pattern that contains a dot (.) is interpreted as a schema name pattern followed by an object name pattern. For example, **\dt foo*.*bar*** displays all tables (whose names include **bar**) in schemas starting with **foo**. If no dot appears, then the pattern matches only visible objects in the current schema search path. Likewise, the dot within double quotation marks loses its special meaning and becomes an ordinary character.
  - Senior users can use regular-expression notations, such as character classes. For example [0-9] can be used to match any digit. All regular-expression special characters work as specified in POSIX. The following characters are excluded:
    - A dot (.) is used as a delimiter.
    - An asterisk (*) is translated into an asterisk prefixed with a dot (.*), which is a regular-expression marking.
    - A question mark (?) is translated into a dot (.).
    - A dollar sign ($) is matched literally.
  - You can write ?, (*R*+|), (*R*|), and *R* to the following pattern characters: ., *R*.*, and *R*.?. The dollar sign ($) does not need to be used as a regular expression character because **PATTERN** must match the entire name instead of being interpreted as a regular expression (in other words, $ is automatically appended to **PATTERN**). If you do not expect a pattern to be anchored, write an asterisk (*) at its beginning or end. All regular-expression special characters within double quotation marks lose their special meanings and are matched literally. Regular-expression special characters in operator name patterns (such as the **\do** parameter) are also matched literally.

Table 4-16 Description of permissions

Parameter	Description
r	**SELECT**: allows users to read data from specified tables and views.
w	**UPDATE**: allows users to update columns for specified tables.
a	**INSERT**: allows users to insert data to specified tables.
d	**DELETE**: allows users to delete data from specified tables.
D	**TRUNCATE**: allows users to delete all data from specified tables.
x	**REFERENCES**: allows users to create a FOREIGN KEY constraint (not supported in distributed mode).
t	**TRIGGER**: allows users to create a trigger on specified tables.
X	**EXECUTE**: allows users to use specified functions and the operators that are realized by the functions.
U	**USAGE**: ● For procedural languages, allows users to specify a procedural language when creating a function. ● For schemas, allows users to access objects included in specified schemas. ● For sequences, allows users to use the nextval function.
C	**CREATE**: ● For databases, allows new schemas to be created within the database. ● For schemas, allows users to create objects in a schema. ● For tablespaces, allows users to create tables in a tablespace and set the tablespace to default one when creating databases and schemas.
c	**CONNECT**: allows users to connect to specified databases.
T	**TEMPORARY**: allows users to create temporary tables.
A	**ALTER**: allows users to modify the attributes of a specified object.
P	**DROP**: allows users to delete specified objects.
m	**COMMENT**: allows users to define or modify comments of a specified object.
i	**INDEX**: allows users to create indexes on specified tables.
v	**VACUUM**: allows users to perform ANALYZE and VACUUM operations on specified tables.
*	Grants the preceding permissions.

Table 4-17 Formatting meta-commands

Parameter	Description	Value Range
\a	Switches between aligned and unaligned table output formats.	-
\C [STRING]	Sets the title for the table output, or cancels the title (if there is no parameter).	Any character string or null.
\f [STRING]	Specifies the character or string used to separate fields in unaligned output mode.	Any character string.
\H	Switches between standard output and HTML table output.	-
\pset NAME [VALUE]	Sets options affecting the output of query result tables.	For details about the value of **NAME**, see **Table 4-18**.
\t [on | off]	Switches the table output format.	• **on**: Only data rows are displayed. Column titles and row counts are not displayed. • **off**: The entire table, including the column titles and row counts, is displayed.
\T [STRING]	Specifies attributes to be placed within the table tag in HTML output format. If this parameter is left empty, no setting is performed.	-
\x [on | off | auto]	Switches the display mode of the extended rows.	• **on**: The extended display mode is enabled. Each field is displayed in a separate row. • **off**: The extended display mode is disabled and the standard table display mode is used. • **auto**: The extended display mode is used depending on the width of the query result.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 4-18 Adjustable printing options

Option	Description	Value Range
border	Controls the border style of the table output.	• The value is an integer greater than 0 in HTML format. • The value range in other formats is as follows: – **0**: no border. No border is displayed when the table is output. – **1**: inner borders dividing columns, without outside borders. – **2**: all borders, including the outside and inner borders.
expanded (or x)	Switches between regular and expanded formats.	• **on**: The extended display mode is enabled. Each field is displayed in a separate row. • **off**: The extended display mode is disabled and the standard table display mode is used. The standard format is effective only in the aligned and wrapped modes. • **auto**: The extended display mode is used depending on the width of the query result.
fieldsep	Specifies the delimiter between columns in unaligned output mode.	Any character string. Common values include **","**, **"\t"**, and **"|"**. If this option is not set, spaces are used as delimiters by default.
fieldsep_zero	Sets the delimiter between columns in unaligned output mode to ASCII NUL.	-
footer	Sets the footer of the query result.	• **on**: The footer information is displayed. • **off**: The footer information is not displayed.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Option	Description	Value Range
format	Specifies the output format of the query result.	• **unaligned (u)**: Columns are displayed in unaligned mode and are separated by the current delimiter. • **aligned (a)**: The table is displayed in aligned mode. • **wrapped (w)**: The table is displayed similar to the aligned mode but automatically wraps any excessively long value. • **html (h)**: The table is displayed in HTML table format. • **latex (l)**: The table is displayed in LaTeX format. • **troff-ms (t)**: The table is displayed in the troff ms macro format.
null	Specifies the display mode of NULL values.	Any character string. If this option is not set, whitespace characters are used to replace NULL values by default.
numericlocale	Determines whether to use the locale of the current system when numbers are output.	• **on**: The locale settings of the current system are used for formatting when numbers are output. For example, the number 1,000.00 is displayed as 1,000.00 in English and 1.000,00 in German. • **off**: The standard numeric format, such as 1000.00, is used for number output.
pager	Determines the use of a pager for query and gsql help outputs. If the *PAGER* environment variable is set, the output is redirected to the specified program. Otherwise, the platform-dependent default value is used.	• **on**: The pager is used for terminal output that does not fit the screen. • **off**: The pager is not used. • **always**: The pager is used for all terminal output regardless of whether it fits the screen.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Option	Description	Value Range
recordsep	Sets the record delimiter in unaligned output mode.	Any character string. Common values include the newline characters (\n), carriage return character (\r), and carriage return line feed character (\r\n). If this option is not set, the newline character (\n) is used as the record delimiter by default.
recordsep_zero	Sets the record delimiter between columns in unaligned output mode to ASCII NUL.	-
tableattr (or T)	Specifies attributes to be placed inside the HTML table tag in HTML output format (such as cellpadding or bgcolor). Note: If the **\pset** border command has been executed, you do not need to set the border.	For example, bgcolor=#FFFFFF. If no value is given, the table attributes are not set.
title	Specifies the title of the query result.	Any character string. If this option is not set, no title is displayed in the query result.
tuples_only (or t)	Enables or disables the tuples-only mode. Full display may show extra information, such as column headers, titles, and various footers. In tuples-only mode, only the table data is shown.	-
feedback	Specifies whether to output the number of result lines.	-

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 4-19 Connection meta-commands

Parameter	Description	Value Range
\c[onnect] [DBNAME|- USER|- HOST|- PORT|-]	Connects to a new database. If a database name contains more than 63 bytes, only the first 63 bytes are valid and are used for connection. However, the database name displayed in the command line of gsql is still the name before the truncation. **NOTE** If the database login user is changed during reconnection, you need to enter the password of the new user. The maximum length of the password is 999 bytes, which is restricted by the maximum value of the GUC parameter **password_max_length**.	-
\encoding [ENCODING]	Sets the client character set encoding.	Without an argument, this command shows the current encoding.
\conninfo	Prints information about the current connected database.	-

Table 4-20 OS meta-commands

Parameter	Description	Value Range
\cd [DIR]	Changes the current working directory.	An absolute path or relative path that meets the OS path naming convention.
\setenv NAME [VALUE]	Sets the *NAME* environment variable to **VALUE**. If **VALUE** is not provided, do not set the environment variable.	-
\timing [on | off]	Toggles a display of how long each SQL statement takes, in milliseconds (exclude the time of screen displaying).	• **on**: The display is enabled. • **off**: The display is disabled.
\! [COMMAND]	Runs OS commands. If no command follows **\!**, running it will open an independent shell UI for user interaction.	-

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 4-21 Variable meta-commands

Parameter	Description
\prompt [TEXT] NAME	Prompts the user to enter a value and stores it in a gsql variable. *TEXT* indicates the text that prompts the user to enter, and *NAME* indicates the gsql variable that stores the input value. Example: gaussdb=# \prompt 'Enter area name: ' area Enter area name: Asia gaussdb=# SELECT * FROM HR.areaS WHERE area_name = :'area'; area_id | area_name ---------+----------- 3 | Asia (1 row)
\set [NAME [VALUE]]	Sets the internal variable *NAME* to **VALUE**. If more than one value is given, the variable value is the concatenation result of all values. If no second argument is given, the variable is just set with no value. Some common variables are processed differently in gsql and they are combinations of uppercase letters, numbers and underscores. **Table 4-22** is a list of all variables that are processed differently.
\unset NAME	Deletes the variable name of gsql.

Table 4-22 Common **\set** commands

Command	Command Description	Value Range
\set VERBOSITY value	Controls the redundant lines in error reports.	• **default**: Critical and major error texts and text locations, error details, and error messages (possibly involving multiple lines) are all returned. • **verbose**: All error information is returned. • **terse**: Only critical and major error texts and text locations are returned (which is generally suitable for single-line error information).

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Command	Command Description	Value Range
\set ON_ERROR_STOP value	If this variable is set, the script execution stops immediately. If this script is called from another script, that script will be stopped immediately as well. If the primary script is called using the **-f** option rather than from one gsql session, gsql will return error code **3**, indicating the difference between the current error and critical errors. (The error code for critical errors is **1**.)	• **on**: The execution stops if an error occurs. In interactive mode, gsql returns the output of executed commands immediately. • **off**: An error, if occurring during the execution, is ignored, and the execution continues.
\set AUTOCOMMIT [on | off]	Controls the auto commit behavior of the current gsql connection. By default, the gsql connection is automatically committed, and each individual statement is implicitly committed. If auto commit is disabled for performance or other purposes, you need to explicitly run the **COMMIT** command to ensure that transactions are committed. For example, execute the COMMIT statement to explicitly commit transactions after a specified service SQL statement is executed. Particularly, ensure that all transactions are committed before the gsql client exits. **NOTE** Auto commit is enabled in gsql by default. If you disable it, all the statements executed later will be packaged in implicit transactions, and you cannot execute statements that cannot be executed within a transaction.	• **on**: Auto commit is enabled. • **off**: Auto commit is disabled.

Table 4-23 Fully-encrypted meta-commands

Parameter	Description
\send_token	A full encryption function used to send keys to the server for caching. This function is used when the memory decryption emergency channel is enabled.
\st	A full encryption function used to send keys to the server for caching. This function is used when the memory decryption emergency channel is enabled.
\clear_token	A full encryption function used to destroy the keys cached on the server. This function is used when the memory decryption emergency channel is enabled.
\ct	A full encryption function used to destroy the keys cached on the server. This function is used when the memory decryption emergency channel is enabled.
\key_info KEY_INFO	A full encryption function used to set the parameters for accessing an external key manager.

NOTE

- The fully-encrypted memory decryption emergency channel is not supported in a distributed system.
- The M-compatible mode does not support fully-encrypted databases.

Table 4-24 Common simple O&M meta-commands

Simple O&M Command	Description	SQL Statement
\view stmt_track {unique_sql_id}	**stmt_track**: records the level-2 full SQL information of a specified SQL statement. **unique_sql_id**: specifies the unique SQL ID of the SQL statement to be recorded.	SELECT * FROM pg_catalog.dynamic_func_control('LOCAL', 'STMT', 'TRACK', '{"{unique_sql_id}", "L2"}');
\view stmt_untrack {unique_sql_id}	**stmt_untrack**: cancels the recording of the level-2 full SQL information of a specified SQL statement. **unique_sql_id**: specifies the unique SQL ID of the SQL statement whose recording needs to be canceled.	SELECT * FROM pg_catalog.dynamic_func_control('LOCAL', 'STMT', 'UNTRACK', '{"{unique_sql_id}"}');

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Simple O&M Command	Description	SQL Statement
\view stmt_list	**stmt_list**: queries the record list.	SELECT * FROM pg_catalog.dynamic_func_control('LOCAL', 'STMT', 'LIST', '{}');
\view stmt_clean	**stmt_clean**: clears the record list.	SELECT * FROM pg_catalog.dynamic_func_control('LOCAL', 'STMT', 'CLEAN', '{}');
\view explain_and_stack {pid}	**explain_and_stack**: queries the runtime plan and stack of a specified session. **pid**: specifies the PID of a session.	SELECT pg_catalog.gs_get_explain(pid), pg_catalog.gs_stack(pid) FROM pg_catalog.pgxc_stat_activity WHERE pid = {pid};
\view slow_sql {top_n}	**slow_sql**: queries real-time slow SQL statements. **top_n**: specifies the number of rows to be queried.	SELECT pid, sessionid, pg_catalog.SUBSTRING(query, 0, 100), state, usename, pg_catalog.NOW() - query_start AS elp FROM pg_catalog.pgxc_stat_activity WHERE state != 'idle' AND usename NOT IN ('rdsAdmin', 'rdsMetric', 'rdsBackup', 'rdsRepl', 'dbmind_monitor_agent', 'dbmind_monitor') ORDER BY elp DESC LIMIT {top_n};
\view slow_trans {top_n}	**slow_trans**: queries real-time long transactions. **top_n**: specifies the number of rows to be queried.	SELECT pid, sessionid, pg_catalog.SUBSTRING(query, 0, 100), state, usename, pg_catalog.NOW() - xact_start AS elp FROM pg_catalog.pgxc_stat_activity WHERE state != 'idle' AND usename NOT IN ('rdsAdmin', 'rdsMetric', 'rdsBackup', 'rdsRepl', 'dbmind_monitor_agent', 'dbmind_monitor') ORDER BY elp DESC LIMIT {top_n};

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Simple O&M Command	Description	SQL Statement
\view wait_event	**wait_event** (without parameters): queries the current statement and wait event.	SELECT a.pid, a.sessionid, a.datname, a.usename, a.client_addr, a.xact_start, a.query_start, (pg_catalog.NOW() - a.query_start)::text "query_runtime", w.wait_status, w.wait_event, w.locktag, w.lockmode, w.block_sessionid, a.query FROM pg_catalog.pgxc_stat_activity a JOIN pg_catalog.pgxc_thread_wait_status w ON a.sessionid = w.sessionid WHERE a.pid <> pg_catalog.pg_backend_pid() AND a.state = 'active' AND a.client_addr IS NOT NULL ORDER BY query_runtime DESC;
\view wait_event {unique_sql_id} {start_time} {end_time}	**wait_event** (with three parameters): queries the historical wait events of a specified slow SQL statement. **unique_sql_id**: specifies the unique SQL ID of the slow SQL statement to be queried. **start_time**: specifies the start time. For example, '2025-01-01 00:00'. **end_time**: specifies the end time. For example, '2025-01-01 00:00'.	SELECT *, pg_catalog.statement_detail_decode(details, 'plaintext', true) FROM dbe_perf.statement_history WHERE unique_query_id = {unique_sql_id} AND start_time > {start_time} AND start_time < {end_time} ORDER BY db_time DESC;
\view thr_wait_event	**thr_wait_event** (without parameters): queries real-time overall wait events.	SELECT wait_status, wait_event, pg_catalog.COUNT(*) FROM pg_catalog.pgxc_thread_wait_status GROUP BY 1, 2 ORDER BY 3 DESC;
\view thr_wait_event {sessionid}	**thr_wait_event** (with one parameter): queries wait events of a specified statement. **sessionid**: specifies the session ID.	SELECT * FROM pg_catalog.pgxc_thread_wait_status WHERE sessionid = {sessionid};

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Simple O&M Command	Description	SQL Statement
\view gs_asp {start_time} {end_time}	**gs_asp**: queries the overall wait events in a specified period. **start_time**: specifies the start time. For example, '2025-01-01 00:00'. **end_time**: specifies the end time. For example, '2025-12-31 23:59'.	SELECT wait_status, event, pg_catalog.COUNT(*) FROM pg_catalog.gs_asp WHERE sample_time BETWEEN {start_time} AND {end_time} GROUP BY 1, 2 ORDER BY 3 DESC;
\view pg_stats {table_name} {att_name}	**pg_stats**: queries the distribution of statistics information in a specified table. **table_name**: specifies the table name. **att_name**: specifies the column name.	SELECT * FROM pg_catalog.pg_stats WHERE tablename = '{table_name}' AND attname = '{att_name}';
\view autovac {table_name}	**autovac**: queries the threshold of updating statistics information. **table_name**: specifies the table name.	SELECT * FROM pg_catalog.pg_autovac_status('{table_name}'::regclass);
\view thr_pool	**thr_pool**: queries the thread pool usage.	SELECT node_name, worker_info FROM dbe_perf.global_threadpool_status;
\view failed_proc {proc_name}	**failed_proc**: queries invalid views or stored procedures. **proc_name**: specifies the invalid function.	SELECT re.ev_class, cl.relname FROM pg_catalog.pg_rewrite re, pg_catalog.pg_class cl WHERE re.ev_action LIKE '%{proc_name}%' AND cl.oid = re.ev_class;

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Simple O&M Command	Description	SQL Statement
\view failed_proc_pkg	**failed_proc_pkg**: queries the package of the invalid stored procedure.	SELECT DISTINCT object_type, pg_catalog.pg_get_userbyid(creator) AS owner, CASE object_type WHEN 'P' THEN (SELECT DISTINCT pg_catalog.UPPER(pkgname) FROM pg_catalog.gs_package WHERE oid = (SELECT propackageid FROM pg_catalog.pg_proc WHERE oid = object_oid)) WHEN 'B' THEN (SELECT DISTINCT pg_catalog.UPPER(pkgname) FROM pg_catalog.gs_package WHERE oid = object_oid) WHEN 'S' THEN (SELECT DISTINCT pg_catalog.UPPER(pkgname) FROM pg_catalog.gs_package WHERE oid = object_oid) END package_name FROM pg_catalog.pg_object WHERE valid = 'f' AND object_type IN ('P', 'B', 'S');
\view failed_index	**failed_index**: queries unavailable indexes.	SELECT a.schemaname, a.relname, a.indexrelname, b.indisusable FROM pg_catalog.pg_stat_user_indexes a, pg_catalog.pg_index b WHERE a.indexrelid = b.indexrelid AND b.indisusable = 'f';
\view table_size	**table_size**: queries the sizes of all tables in the current database and outputs the sizes in descending order.	SELECT schemaname, relname, pg_catalog.pg_total_relation_size(pg_catalog.CONCAT(schemaname, '.', relname)) / 1024 / 1024 / 1024 "GB" FROM pg_catalog.pg_stat_user_tables ORDER BY 3 DESC;

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Simple O&M Command	Description	SQL Statement
\view dead_tup {top_n}	**dead_tup**: queries the number of dead tuples. **top_n**: specifies the number of rows to be queried.	SELECT relname, n_live_tup, n_dead_tup, (n_dead_tup / (n_live_tup + 1)) AS rating, last_vacuum, last_autovacuum, last_analyze, last_autoanalyze FROM pg_catalog.pg_stat_user_tables ORDER BY rating DESC, n_dead_tup DESC LIMIT {top_n};
\view table_size {table_name}	**table_size**: queries the size of a specified table. **table_name**: specifies the table name.	SELECT * FROM pg_catalog.pg_size_pretty(pg_catalog.pg_total_relation_size('{table_name}'::regclass));
\view login {start_time} {end_time} {ip} {port}	**login**: queries the login and logout information of the specified IP address and port. **start_time**: specifies the start time. For example, '2024-01-01 00:00:00'. **end_time**: specifies the end time. For example, '2025-12-31 23:59:59'. **ip**: specifies the IP address. **port**: specifies the port number.	SELECT *, pg_catalog.SUBSTRING(client_conninfo::varchar, pg_catalog.POSITION(client_conninfo::varchar, '@'::varchar) + 1, 15) AS ip FROM pg_catalog.pg_query_audit({start_time}, {end_time}) WHERE ip = '{ip}' AND remote_port = '{port}';
\view mem	**mem**: queries the current memory usage.	SELECT * FROM pg_catalog.pg_total_memory_detail;
\view thr_mem {top_n}	**thr_mem** (with one parameter): queries the memory context usage of all database threads. **top_n**: specifies the number of rows to be queried.	SELECT contextname, pg_catalog.SUM(totalsize) / 1024 / 1024 "totalsize", pg_catalog.SUM(freesize) / 1024 / 1024 "freesize", pg_catalog.COUNT(*) "sum" FROM pg_catalog.pv_thread_memory_context GROUP BY contextname ORDER BY sum DESC LIMIT {top_n};

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Simple O&M Command	Description	SQL Statement
\view thr_mem {context_name} {top_n}	**thr_mem** (with two parameters): queries the thread ID of the thread that uses the most memory. **context_name**: specifies the name of the memory context. **top_n**: specifies the number of rows to be queried.	SELECT * FROM pg_catalog.pv_thread_memory_detail() WHERE contextname = '{context_name}' ORDER BY totalsize DESC LIMIT {top_n};
\view sess_mem {top_n}	**sess_mem**: queries the memory context usage of all sessions in the database. **top_n**: specifies the number of rows to be queried.	SELECT contextname, pg_catalog.SUM(totalsize) / 1024 / 1024 "totalsize", pg_catalog.SUM(freesize) / 1024 / 1024 "freesize", pg_catalog.COUNT(*) "sum" FROM pg_catalog.pv_session_memory_context GROUP BY contextname ORDER BY sum DESC LIMIT {top_n};
\view thr_mem_detail {tid} {context_name}	**thr_mem_detail**: queries the memory usage of a specified thread. **tid**: specifies the thread ID. **context_name**: specifies the name of the memory context.	SELECT * FROM pg_catalog.gs_get_thread_memctx_detail({tid}, '{context_name}');
\view sess_mem_tp {context_name}	**sess_mem_tp**: queries the memory usage of a specified memory context. **context_name**: specifies the name of the memory context.	SELECT * FROM pg_catalog.gs_get_session_memctx_detail('{context_name}');
\view shared_mem {top_n}	**shared_mem**: queries the usage of the global shared memory context in the database. **top_n**: specifies the number of rows to be queried.	SELECT contextname, pg_catalog.SUM(totalsize) / 1024 / 1024 "totalsize MB", pg_catalog.SUM(freesize) / 1024 / 1024 "freesize MB", pg_catalog.COUNT(*) "sum" FROM pg_catalog.pg_shared_memory_detail GROUP BY contextname ORDER BY sum DESC LIMIT {top_n};

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Simple O&M Command	Description	SQL Statement
\view sess_mem_detail {top_n}	**sess_mem_detail**: queries the usage of a session-level memory context. **top_n**: specifies the number of rows to be queried.	SELECT contextname, pg_catalog.SUM(totalsize) / 1024 / 1024 "totalsize MB", pg_catalog.COUNT(1) "count" FROM pg_catalog.pv_session_memory_detail() GROUP BY contextname ORDER BY 2 DESC LIMIT {top_n};
\view sess_mem_detail_tp {top_n}	**sess_mem_detail_tp**: queries the usage of a session-level memory context (valid only when the thread pool mode is enabled). **top_n**: specifies the number of rows to be queried.	SELECT sessid, pg_catalog.SUM(totalsize) / 1024 / 1024 "totalsize MB", pg_catalog.COUNT(1) "count" FROM pg_catalog.pv_session_memory_context GROUP BY sessid ORDER BY 2 DESC LIMIT {top_n};
\view thr_mem_pv {top_n}	**thr_mem_pv**: queries the usage of a thread-level memory context. **top_n**: specifies the number of rows to be queried.	SELECT contextname, pg_catalog.SUM(totalsize) / 1024 / 1024 "totalsize", pg_catalog.SUM(freesize) / 1024 / 1024 "freesize", pg_catalog.COUNT(1) "count" FROM pg_catalog.pv_thread_memory_detail() GROUP BY 1 ORDER BY 2 DESC LIMIT {top_n};
\view total_mem {top_n}	**total_mem**: queries the memory usage of the current database node. **top_n**: specifies the number of rows to be queried.	SELECT * FROM pg_catalog.pg_total_memory_detail LIMIT {top_n};
\view avg_cpu {top_n}	**avg_cpu**: queries the average CPU time of SQL statements and outputs the query result in descending order. **top_n**: specifies the number of rows to be queried.	SELECT unique_sql_id, cpu_time / (n_calls) "average_cpu_time" FROM dbe_perf.statement WHERE n_calls != 0 ORDER BY 2 DESC LIMIT {top_n};

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Simple O&M Command	Description	SQL Statement
\om create_abort_sql_patch {patch_name} {unique_sql_id}	**create_abort_sql_patch**: creates an abort SQL patch. **patch_name**: specifies the SQL patch name. **unique_sql_id**: specifies the unique SQL ID.	SELECT * FROM dbe_sql_util.create_abort_sql_patch('{patch_name}', {unique_sql_id});
\om kill_sess_thr {username} {database} {context_name}	**kill_sess_thr**: kills SQL statements that occupy a large amount of memory based on the thread memory usage. **username**: specifies the username. **database**: specifies the database name. **context_name**: specifies the name of the memory context.	EXECUTE DIRECT ON COORDINATORS 'SELECT pg_catalog.pg_terminate_session(pid, sessionid), pid, sessionid FROM pg_catalog.pgxc_stat_activity WHERE usename = ''{username}'' AND datname != ''postgres'' AND datname = ''{database}'' AND pid IN (SELECT tid FROM pg_catalog.pv_thread_memory_context WHERE contextname = ''{context_name}'') AND state = ''idle'';';
\om kill_sess_sess {username} {database} {context_name}	**kill_sess_sess**: kills SQL statements that occupy a large amount of memory based on session memory usage. **username**: specifies the username. **database**: specifies the database name. **context_name**: specifies the name of the memory context.	EXECUTE DIRECT ON COORDINATORS 'SELECT pg_catalog.pg_terminate_session(pid, sessionid), pid, sessionid FROM pg_catalog.pgxc_stat_activity WHERE usename = ''{usename}'' AND datname != ''postgres'' AND datname = ''{database}'' AND pid IN (SELECT threadid FROM pg_catalog.pv_session_memory_context WHERE contextname = ''{context_name}'');';

Examples

Example 1

Obtain the help information.

```
-- Connect to a database. (Replace the database name and port number as required.)
gsql -d postgres -p 8000
gsql ((GaussDB Kernel XXX.X.XXX build f521c606) compiled at 2021-09-16 14:55:22 last mr 6385 release)
Non-SSL connection (SSL connection is recommended when requiring high-security)
Type "help" for help.

-- View all SQL statements supported by GaussDB.
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gaussdb=#  \h
Available help:
  ABORT
  ALTER AGGREGATE
 ... ...

-- View the parameters of the DROP TABLE syntax.
gaussdb=#  \h DROP TABLE
Command:     DROP TABLE
Description: remove a table
Syntax:
DROP TABLE [ IF EXISTS ]
    { [schema.]table_name } [, ...] [ CASCADE | RESTRICT ] [ PURGE ];

-- View meta-commands supported by gsql.
gaussdb=#  \?
General
  \copyright             show GaussDB Kernel usage and distribution terms
  \g [FILE] or ;         execute query (and send results to file or |pipe)
... ...
```

Example 2

Use a meta-command.

```
-- Connect to a database. (Replace the database name and port number as required.)
gsql -d postgres -p 8000
gsql ((GaussDB Kernel XXX.X.XXX build f521c606) compiled at 2021-09-16 14:55:22 last mr 6385 release)
Non-SSL connection (SSL connection is recommended when requiring high-security)
Type "help" for help.

-- Create a table.
gaussdb=# CREATE SCHEMA HR;
CREATE SCHEMA
gaussdb=# CREATE TABLE HR.areaS(area_ID NUMBER,area_NAME VARCHAR2(25));
NOTICE:  The 'DISTRIBUTE BY' clause is not specified. Using 'area_id' as the distribution column by default.
HINT:  Please use 'DISTRIBUTE BY' clause to specify suitable data distribution column.
CREATE TABLE

-- View the definition of a table.
gaussdb=#  \d HR.areaS
              Table "hr.areas"
  Column   |         Type          | Modifiers
-----------+-----------------------+-----------
 area_id   | numeric               |
 area_name | character varying(25) |

-- Insert four rows of data into HR.areaS.
gaussdb=# INSERT INTO HR.areaS (area_ID, area_NAME) VALUES (1, 'Europe');
INSERT 0 1
gaussdb=# INSERT INTO HR.areaS (area_ID, area_NAME) VALUES (2, 'Americas');
INSERT 0 1
gaussdb=# INSERT INTO HR.areaS (area_ID, area_NAME) VALUES (3, 'Asia');
INSERT 0 1
gaussdb=# INSERT INTO HR.areaS (area_ID, area_NAME) VALUES (4, 'Middle East and Africa');
INSERT 0 1

-- View a table.
gaussdb=# SELECT * FROM HR.areaS;
area_id |       area_name
---------+------------------------
       4 | Middle East and Africa
       1 | Europe
       2 | Americas
       3 | Asia
(4 rows)

-- Use the \pset command to display a table in different ways.
gaussdb=# \pset border 2
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
Border style is 2.

gaussdb=# SELECT * FROM HR.areaS;
+---------+------------------------+
| area_id |       area_name        |
+---------+------------------------+
|       4 | Middle East and Africa |
|       1 | Europe                 |
|       2 | Americas               |

4.2.1.3 FAQ

Low Connection Performance

- Problem: **log_hostname** is enabled, but DNS is incorrect.

  Solution:

  Connect to the database, and run **show log_hostname** to check whether **log_hostname** is enabled in the database.

  If it is enabled, the database kernel will use DNS to check the name of the host where the client is deployed. If the host where the CN is located is configured with an incorrect or unreachable DNS, the database connection will take a long time to set up. For details, see GUC parameter **log_hostname**.

- Problem: The database kernel runs the initialization statement slowly.

  Solution:

  It is difficult to locate faults in this scenario. Try using the **strace** Linux command.

  ```
  strace gsql -U MyUserName -d gaussdb -h 127.0.0.1 -p 23508 -r -c '\q'
  Password for MyUserName:
  ```

  The database connection process will be printed on the screen. For example, if the following operations are suspended for a long time, the database executes the **SELECT VERSION()** statement slowly.

  ```
  sendto(3, "Q\0\0\0\25SELECT VERSION()\0", 22, MSG_NOSIGNAL, NULL, 0) = 22
  poll([{fd=3, events=POLLIN|POLLERR}], 1, -1) = 1 ([{fd=3, revents=POLLIN}])
  ```

  After the database is connected, you can run the **explain performance select version()** statement to find the reason why the initialization statement was run slowly. For more information, see "Introduction to the SQL Execution Plan" in *SQL Optimization Guide*.

  An uncommon scenario is that the disk of the machine where the database CN resides is full or faulty, affecting queries and leading to user authentication failures. As a result, the connection process is suspended. To solve this problem, clear the data disk space of the database CN.

- Problem: The TCP connection is set up slowly.

  Solution:

  Run **strace** to check whether the initialization statement is run slowly. If the following information is displayed for a long time:

  ```
  connect(3, {sa_family=AF_FILE, path="/home/test/tmp/gaussdb_llt1/.s.PGSQL.61052"}, 110) = 0
  ```

  Or,

  ```
  connect(3, {sa_family=AF_INET, sin_port=htons(61052), sin_addr=inet_addr("127.0.0.1")}, 16) = -1
  EINPROGRESS (Operation now in progress)
  ```

  It indicates that the physical connection between the client and the database is set up slowly. In this case, check whether the network is unstable or has high throughput.

- Problem: The connection is slow due to full resource load.

  Solution:

  When the CPU, memory, or I/O usage is close to 100%, the gsql connection is slow.

  – Run the **top** command to check the CPU usage. Run the **free** command to check the memory usage. Run the **iostat** command to check the I/O

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

load. You can also check the monitor logs in the CM Agent and the monitoring records on the database O&M platform.

- For peak load scenarios caused by a large number of slow queries in a short period of time, you can use the port specified by (*Port number of the database server* + 1) to query the pg_stat_activity view. For slow queries, you can use the system function pg_terminate_backend to kill sessions.
- If service overloading exists for a long time (that is, there is no obvious slow query, or new queries still become slow after slow queries are killed), reduce the service load and increase database resources.

Problems in Setting Up Connections

- Problem: The following error message is displayed: "gsql: could not connect to server: No route to host."

  Solution:

  This problem occurs because an unreachable address or port is specified. Check whether the values of **-h** and **-p** parameters are correct.

- Problem: The following error message is displayed: "gsql: FATAL: Invalid username/password,login denied."

  Solution:

  This problem occurs generally because an incorrect username or password was entered. Contact the database administrator to check whether the username and password are correct.

- Problem: The following error message is displayed: "gsql: FATAL: Forbid remote connection with trust method!"

  Solution:

  For security purposes, remote database login in trust mode is forbidden. In this case, you need to modify the connection authentication information in the **gs_hba.conf** file. Contact the administrator.

  NOTE

  Do not modify the configurations of database cluster hosts in the **gs_hba.conf** file. Otherwise, the database may become faulty. It is recommended that service applications be deployed outside the database cluster.

- Problem: The database can be connected from the host where the CN is located by adding **-h 127.0.0.1**, but the connection fails if **-h 127.0.0.1** is removed.

  Solution:

  Run the SQL statement **show unix_socket_directory** to check whether the **unix socket directory** used by the database CN is the same as that specified by the environment variable *$PGHOST* in the **shell** directory. If they are different, set *$PGHOST* to the directory specified by **unix_socket_directory**.

  For more details about **unix_socket_directory**.

- Problem: The following error message is displayed: "The "libpq.so" loaded mismatch the version of gsql, please check it."

  Solution:

  This problem occurs because the version of **libpq.so** used in the environment does not match that of **gsql**. Run the **ldd gsql** command to check the version

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

of the loaded **libpq.so**, and then load correct **libpq.so** by modifying the environment variable **LD_LIBRARY_PATH**.

- Problem: The following error message is displayed: "gsql: symbol lookup error: xxx/gsql: undefined symbol: libpqVersionString."

  Solution:

  This problem occurs because the version of **libpq.so** used in the environment does not match that of gsql (or the PostgreSQL **libpq.so** exists in the environment). Run the **ldd gsql** command to check the version of the loaded **libpq.so**, and then load correct **libpq.so** by modifying the environment variable *LD_LIBRARY_PATH*.

- Problem: The following error message is displayed: "gsql: connect to server failed: Connection timed out."

  Is the server running on host "xx.xxx.xxx.xxx" and accepting TCP/IP connections on port xxxx?

  Solution:

  This problem is caused by network connection faults. Check the network connection between the client and the database server. If you cannot ping from the client to the database server, the network connection is abnormal. Contact network management personnel for troubleshooting.

  ```
  ping -c 4 10.10.10.1
  PING 10.10.10.1 (10.10.10.1) 56(84) bytes of data.
  From 10.10.10.1: icmp_seq=2 Destination Host Unreachable
  From 10.10.10.1 icmp_seq=2 Destination Host Unreachable
  From 10.10.10.1 icmp_seq=3 Destination Host Unreachable
  From 10.10.10.1 icmp_seq=4 Destination Host Unreachable
  --- 10.10.10.1 ping statistics ---
  4 packets transmitted, 0 received, +4 errors, 100% packet loss, time 2999ms
  ```

- Problem: The following error message is displayed: "gsql: FATAL: permission denied for database "gaussdb"

  DETAIL: User does not have CONNECT privilege."

  Solution:

  This problem occurs because the user does not have the permission to access the database. To solve this problem, perform the following steps:

  a. Connect to the database as a database administrator.

     ```
     gsql -d gaussdb -U dbadmin -p 8000
     ```

  b. Grant the user with the permission to access the database.

     ```
     GRANT CONNECT ON DATABASE gaussdb TO user1;
     ```

  In addition, many common misoperations may cause users to fail to connect to the database, for example, entering an incorrect database name, username, or password. In this case, the client tool will display the corresponding error messages.

  ```
  gsql -d gaussdb -p 8000
  gsql: FATAL:  database "gaussdb" does not exist

  gsql -d gaussdb -U user1 -p 8000
  Password for user user1:
  gsql: FATAL:  Invalid username/password,login denied.
  ```

- Problem: The following error message is displayed: "gsql: FATAL: sorry, too many clients already, active/non-active: 197/3."

  Solution:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

This problem occurs because the number of system connections exceeds the allowed maximum. Contact the DBA database administrator to release unnecessary sessions.

You can check the number of connections of user sessions as described in **Table 4-25**.

You can view the session status in the **PG_STAT_ACTIVITY** view. To release unnecessary sessions, use the **pg_terminate_backend** function.

```
SELECT datid,pid,state FROM pg_stat_activity;
 datid |       pid       | state
-------+-----------------+--------
 13205 | 139834762094352 | active
 13205 | 139834759993104 | idle
(2 rows)
```

The value of **pid** is the thread ID of the session. Terminate the session using its thread ID.

```
SELECT PG_TERMINATE_BACKEND(139834759993104);
```

If a command output similar to the following is displayed, the session is successfully terminated:

```
PG_TERMINATE_BACKEND
----------------------
 t
(1 row)
```

Table 4-25 Viewing the number of session connections

Description	Command

View the maximum number of sessions connected to a specific user.	Run the following command to view the upper limit of **user1**'s connections. **-1** indicates that no upper limit is set for **USER1**'s session connections.
	`gaussdb=# SELECT ROLNAME,ROLCONNLIMIT FROM PG_ROLES WHERE ROLNAME='user1';`
	` rolname | rolconnlimit`
	`---------+--------------`
	` user1 |  -1`
	`(1 row)`

View the number of session connections that have been used by a specified user.	Run the following command to view the number of connections that have been used by **user1**. **1** indicates the number of connections that have been used by **user1**.
	`gaussdb=# SELECT COUNT(*) FROM dv_sessions WHERE USERNAME='user1';`
	` count`
	`-------`
	`  1`
	`(1 row)`

View the maximum number of session connections of a specific database.	Run the following command to view the upper limit of **gaussdb**'s session connections. **-1** indicates that no upper limit is set for **gaussdb**'s session connections.
	`gaussdb=# SELECT DATNAME,DATCONNLIMIT FROM PG_DATABASE WHERE DATNAME='gaussdb';`
	` datname | datconnlimit`
	`----------+--------------`
	` gaussdb |  -1`
	`(1 row)`

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description	Command
View the number of session connections that have been used by a specified database.	Run the following command to view the number of session connections that have been used by **gaussdb**. **1** indicates the number of session connections that have been used by **gaussdb**. gaussdb=# SELECT COUNT(*) FROM PG_STAT_ACTIVITY WHERE DATNAME='gaussdb'; count ------- 1 (1 row)
View the number of session connections that have been used by all users.	Run the following command to view the number of session connections that have been used by all users: gaussdb=# SELECT COUNT(*) FROM dv_sessions; count ------- 10 (1 row)

- Problem: The following error message is displayed: "gsql: wait xxx.xxx.xxx.xxx:xxxx timeout expired."

  Solution:

  When gsql initiates a connection request to the database, a 5-minute timeout period is used. If the database cannot correctly authenticate the client request and client identity within this period, gsql will exit the connection process for the current session, and will report the above error.

  Generally, this problem is caused by the incorrect host and port (that is, the *xxx* part in the error information) specified by the **-h** and **-p** parameters. As a result, the communication fails. Occasionally, this problem is caused by network faults. To resolve this problem, check whether the host name and port number of the database are correct.

- Problem: The following error message is displayed: "gsql: could not receive data from server: Connection reset by peer."

  Solution:

  Check whether CN logs contain information similar to "FATAL: cipher file "/data/coordinator/server.key.cipher" has group or world access." This error is usually caused by incorrect tampering with the permissions for data directories or some key files. For details about how to correct the permissions, see related permissions for files on other normal instances.

- Problem: The following error message is displayed: "gsql: FATAL: GSS authentication method is not allowed because XXXX user password is not disabled."

  Solution:

  In **gs_hba.conf** of the target CN, the authentication mode is set to **gss** for authenticating the IP address of the current client. However, this authentication algorithm cannot authenticate clients. Change the authentication algorithm to **sha256** and try again. For details, contact the administrator..

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- Do not modify the configurations of database cluster hosts in the **gs_hba.conf** file. Otherwise, the database may become faulty.
- It is recommended that service applications be deployed outside the database cluster.

Other Faults

- Problem: A core dump or abnormal exit occurs due to a bus error.

  Solution:

  Generally, this problem is caused by changes to the shared dynamic library (.so file in Linux) loaded during process running. Alternatively, if the process binary file changes, the execution code for the OS to load machines or the entry for loading a dependency library will change accordingly. In this case, the OS terminates the process for protection purposes, generating a core dump file. To resolve this problem, please try again. In addition, do not run service programs in a cluster during O&M operations, such as an upgrade, preventing such a problem caused by file replacement during the upgrade.

  NOTE

  Possibly, a stack of the core dump file contains dl_main and its function calling. The file is used by the OS to initialize a process and load the shared dynamic library. If the process has been initialized but the shared dynamic library has not been loaded, the process cannot be considered completely started.

4.3 Data Import and Export Tools

4.3.1 Overview

Table 4-26 Overview

Tool	Description
COPY	Syntax for importing and exporting database data in batches. COPY can be used to import and export table-level data and export query result sets. For more information, see **COPY**.
\COPY	A meta-command used on the gsql client for importing and exporting table-level data in batches. It is based on the COPY ... FROM STDIN/STDOUT usage and encapsulates packets through libpq so as to store data on the gsql client. For details, see **Table 4-14**.
gs_dump	A logical database backup tool. To export information about a single database, you can export the definitions and data of all or some objects (such as schemas, tables, and views) in a database. For details, see **gs_dump for Exporting Database Information**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Tool	Description
gs_dumpall	A logical database backup tool. You can export object definitions and data of all databases in an instance, including data of the default database, data of user-defined databases, and global objects of all databases. For details, see **gs_dumpall for Exporting All Database Information**.
gs_restore	A logical database restoration tool. It imports files exported using gs_dump. For details, see **gs_restore for Importing Data**.

Instance-Level Import and Export

gs_dumpall is recommended for users who want to logically back up an entire database instance. gs_dumpall can export data of all databases in an instance, including the data of the default database, user-defined database, and global objects shared with all databases.

NOTICE

- gs_dumpall does not back up or restore GUC parameters.
- gs_dumpall supports only plain-text format export. Therefore, only gsql can be used to restore a file exported using gs_dumpall.
- After restoration, you are advised to run **ANALYZE** on each database to provide useful statistics for the optimizer.

During backup, you are advised to run the following command as the initial user or a user with the SYSADMIN permission:

```
nohup gs_dumpall -U root -W ******** -f /data/backup/bkp2.sql -p 8000 > /data/backup/dumpall_backup.log &
```

During restoration, you are advised to run the following command as the initial user or a user with the SYSADMIN permission:

```
nohup gsql -d postgres -p 8000 -U root -W ******** -f /data/backup/bkp2.sql -a > /data/backup/dumpall_restore.log &
```

Database-Level Import and Export

gs_dump is recommended for users who want to back up a single database logically. gs_dump supports four archive formats. The following table lists the application scenarios of different archive formats. You can select an archive format as needed.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 4-27 Formats of exported files

Format	Value of -F	Description	Suggestion	Import Tool
Plain-text	p	A plain-text script file containing SQL statements and commands. The commands can be executed on gsql, a command line terminal, to rebuild database objects and load table data.	For a small-sized database or the exported SQL file needs to be modified, the plain-text format is recommended.	Before using **gsql** to restore database objects, you can use a text editor to edit the exported plain-text file as needed.
Custom	c	A binary file that allows the restoration of all or selected database objects from an exported file.	For medium- or large-sized databases, the backup result needs to be exported to a single file. In this case, the custom format is recommended.	You can use **gs_restore** to import database objects from a custom-, directory-, or tar-format archive.
Directory	d	A directory containing directory files of database objects and the data files of tables and BLOBs.	For medium- or large-sized databases, database objects and data files need to be stored and exported in different directories. In this case, the directory format is recommended.	

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Format	Value of -F	Description	Suggestion	Import Tool
.tar archive	t	A tar-format archive that allows the restoration of all or selected database objects from an exported file. The .tar file cannot be further compressed and has an 8-GB limitation on the size of each single file.	For a small-sized database, you need to export the archive result and pack it. In this case, the .tar format is recommended.	

NOTICE

- gs_dump does not back up or restore global objects (roles, tablespaces, and corresponding permissions) shared with all databases. Therefore, ensure that global objects have been created on the target database or new instance before the restoration.
- gs_dump and gs_restore do not support import and export across database compatibility modes. Ensure that the database compatibility mode and compatibility configuration parameters of the source database are the same as those of the target database.
- Do not modify the files and contents exported using the **-F c**, **-F d**, or **-F t** format. Otherwise, the restoration may fail. If you need to modify or replace the file exported using the **-F p** format, edit them with caution.
- After restoration, you are advised to run **ANALYZE** on the database to provide useful statistics for the optimizer.

You are advised to run the following command as the initial user or a user with the SYSADMIN permission to back up data. The source database is **my_database**, and the exported data contains object definitions and data.

```
-- Plain-text
nohup gs_dump my_database -U root -W ******** -p 8000 -F p -f /data/backup/my_database_backup.sql > /
data/backup/my_database_backup.log &
-- Custom
nohup gs_dump my_database -U root -W ******** -p 8000 -F c -f /data/backup/my_database_backup.dmp > /
data/backup/my_database_backup.log &
-- Directory
nohup gs_dump my_database -U root -W ******** -p 8000 -F d -f /data/backup/my_database_backup > /data/
backup/my_database_backup.log &
-- .tar archive
nohup gs_dump my_database -U root -W ******** -p 8000 -F t -f /data/backup/my_database_backup.tar > /
data/backup/my_database_backup.log &
```

Before restoration, you need to create a target database that has the same attributes as the source database and does not contain any data.

```
-- Run the following gsql meta-command to view the database attribute information:
\l+
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
-- Create a target database based on the queried attribute information.
create database my_database2 encoding='xxxxx' LC_COLLATE='xxxxx' LC_CTYPE ='xxxxx' TEMPLATE=xxx
DBCOMPATIBILITY 'xxx';
```

Run the following command as the initial user or a user with the SYSADMIN permission to restore the database:

```
-- Plain-text
nohup gsql -d my_database2 -p 8000 -U root -W ******** -f /data/backup/my_database_backup.sql -a > /
data/backup/my_database_restore.log &
-- Custom
nohup gs_restore /data/backup/my_database_backup.dmp -d my_database2 -p 8000 -U root -W ******** -F c
-v > /data/backup/my_database_restore.log &
-- Directory
nohup gs_restore /data/backup/my_database_backup -d my_database2 -p 8000 -U root -W ******** -F d -v
> /data/backup/my_database_restore.log &
-- .tar archive
nohup gs_restore /data/backup/my_database_backup.tar -d my_database2 -p 8000 -U root -W ******** -F t -
v > /data/backup/my_database_restore.log &
```

Schema-Level Import and Export

To back up user data by schema, you are advised to use the gs_dump tool with the **-n** parameter. The **-n** parameter can be used repeatedly to back up multiple schemas.

You are advised to run the following command as the initial user or a user with the SYSADMIN permission to back up data. The source database is **my_database**, and the exported data contains object definitions and data.

```
-- Plain-text
nohup gs_dump my_database -U root -W ******** -p 8000 -F p -f /data/backup/my_schema_backup.sql -n
my_schema > /data/backup/my_schema_backup.log &
-- Custom
nohup gs_dump my_database -U root -W ******** -p 8000 -F c -f /data/backup/my_schema_backup.dmp -n
my_schema > /data/backup/my_schema_backup.log &
-- Directory
nohup gs_dump my_database -U root -W ******** -p 8000 -F d -f /data/backup/my_schema_backup -n
my_schema > /data/backup/my_schema_backup.log &
-- .tar archive
nohup gs_dump my_database -U root -W ******** -p 8000 -F t -f /data/backup/my_schema_backup.tar -n
my_schema > /data/backup/my_schema_backup.log &
```

Before restoration, you need to create a target database that has the same attributes as the source database and does not contain the target schema.

```
-- Run the following gsql meta-command to view the database attribute information:
\l+
-- Create a target database based on the queried attribute information.
create database my_database2 encoding='xxxxx' LC_COLLATE='xxxxx' LC_CTYPE ='xxxxx' TEMPLATE=xxx
DBCOMPATIBILITY 'xxx';
```

Run the following command as the initial user or a user with the SYSADMIN permission to restore the database:

```
-- Plain-text
nohup gsql -d my_database2 -p 8000 -U root -W ******** -f /data/backup/my_schema_backup.sql -a > /data/
backup/my_schema_restore.log &
-- Custom
nohup gs_restore /data/backup/my_database_backup.dmp -d my_database2 -p 8000 -U root -W ******** -F c
-v -n my_schema > /data/backup/my_schema_restore.log &
-- Directory
nohup gs_restore /data/backup/my_database_backup -d my_database2 -p 8000 -U root -W ******** -F d -v -
n my_schema > /data/backup/my_schema_restore.log &
-- .tar archive
nohup gs_restore /data/backup/my_database_backup.tar -d my_database2 -p 8000 -U root -W ******** -F t -
v -n my_schema > /data/backup/my_schema_restore.log &
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table-Level Import and Export

Many tools are available for table-level import and export. You can select a proper tool based on the scenarios.

1. You need to export the definition and data of a single table to the same file. You are advised to use the plain-text archive exported by gs_dump together with the **-t** parameter. The **-t** parameter can be used repeatedly to back up multiple tables.

   You are advised to run the following command as the initial user or a user with the SYSADMIN permission to back up data. The source database is **my_database**, and the target table is **my_table** in **my_schema**.

   ```
   nohup gs_dump my_database -U root -W ******** -p 8000 -F p -f /data/backup/my_table_backup.sql -t my_schema.my_table > /data/backup/my_table_backup.log &
   ```

   Before restoration, create a target database with the same attributes as the source database, and ensure that the target schema exists in the database and no target table exists. Then, run the following command as the initial user or a user with the SYSADMIN permission to restore the database:

   ```
   nohup gsql -d my_database2 -p 8000 -U root -W ******** -f /data/backup/my_table_backup.sql -a > /data/backup/my_table_restore.log &
   ```

2. You only need to export the definition of a single table and do not need the data in the table.

   You are advised to use the plain-text archive exported by the gs_dump tool together with the **-s** parameter. The command is as follows:

   ```
   nohup gs_dump my_database -U root -W ******** -p 8000 -F p -f /data/backup/my_table_backup.sql -t my_schema.my_table -s > /data/backup/my_table_backup.log &
   ```

   Before restoration, create a target database with the same attributes as the source database, and ensure that the target schema exists in the database and no target table exists. Then, run the following command as the initial user or a user with the SYSADMIN permission to restore the database:

   ```
   nohup gsql -d my_database2 -p 8000 -U root -W ******** -f /data/backup/my_table_backup.sql -a > /data/backup/my_table_restore.log &
   ```

3. You need to export the data of a single table and do not need the table definition.

   a. To export data to a database node, you are advised to use the COPY command.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTICE

- In most scenarios, for database security purposes, when **enable_copy_server_files** is disabled, only the initial user can run the **COPY FROM FILENAME** or **COPY TO FILENAME** command. When **enable_copy_server_files** is enabled, users with the SYSADMIN permission or users who inherit the permissions of the built-in role gs_role_copy_files can run the commands. By default, **COPY FROM FILENAME** or **COPY TO FILENAME** cannot be executed on database configuration files, key files, certificate files, or audit logs to prevent unauthorized users from viewing or modifying sensitive files. When **enable_copy_server_files** is enabled, the system administrators can configure the GUC parameter **safe_data_path** to set the whitelist of paths that can be used by common users for import and export. If this GUC parameter is not enabled (default), the paths used by common users are not intercepted.
- If the database is deployed in a sandbox, the file specified by using COPY is in the sandbox.

You are advised to run the following command to export data to a standard CSV file on the corresponding database node:

```
COPY my_schema.my_table TO '/data/backup/my_table.csv' CSV;
```

Then run the following command to import data to the target table:

```
COPY my_schema.my_table2 FROM '/data/backup/my_table.csv' CSV;
```

b. To export data to the client, you are advised to use the \COPY meta-command.

Run the following command to export data to a standard CSV file on the client:

```
\COPY my_schema.my_table TO '/data/backup/my_table.csv' CSV;
```

Then run the following command to import data to the target table:

```
\COPY my_schema.my_table2 FROM '/data/backup/my_table.csv' CSV;
```

4. You need a custom data format for data import and export, for example, the delimiter and newline character.

   COPY or \COPY is recommended.

4.3.2 gs_dump for Exporting Database Information

Description

gs_dump, provided by GaussDB, is used to export database information. You can export a database or its objects (such as schemas, tables, and views). The database can be the default **postgres** database or a user-specified database.

- gs_dump supports SSL-encrypted communication.
- When gs_dump is used to export data, other users can still access (read or write) the database cluster.
- gs_dump can export complete, consistent data. For example, if gs_dump is started to export database A at T1, data of the database at that time point will be exported, and modifications on the database after that time point will not be exported.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- gs_dump can export database information to a plain-text SQL script file or archive file.
  - Plain-text SQL script: It contains the SQL statements required to restore the database. You can use **gsql for Connecting to a Database** to execute the SQL script. With only a little modification, the SQL script can rebuild a database on other hosts or database products.
  - Archive file: It contains data required to restore the database. It can be a tar-, directory-, or custom-format archive. For details, see **Table 4-28**. The export result must be used with **gs_restore for Importing Data** to restore the database. The system allows users to select or even to sort the content to be imported.
- gs_dump supports four export file formats, which are specified by **[-F, --format=]**. For details, see **Table 4-28**.

Table 4-28 Formats of exported files

Format	Value of -F	Description	Suggestion	Import Tool
Plain-text	p	A plain-text script file containing SQL statements and commands. The commands can be executed on gsql, a command line terminal, to rebuild database objects and load table data.	For a small-sized database or the exported SQL file needs to be modified, the plain-text format is recommended.	Before using **gsql for Connecting to a Database** to restore database objects, you can use a text editor to edit the exported plain-text file as required.
Custom	c	A binary file that allows the restoration of all or selected database objects from an exported file.	You are advised to use custom-format archive files for medium or large database.	Objects and data of the three archive formats can only be imported using the **4.7.5-gs_restore** tool. You can also use gs_restore to select the database objects to be imported.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Format	Value of -F	Description	Suggestion	Import Tool
Directory	d	A directory containing directory files of database objects and the data files of tables and BLOBs.	Database objects and data files need to be stored and exported in different directories. Therefore, the directory format is recommended.	
.tar archive	t	A tar-format archive that allows the restoration of all or selected database objects from an exported file. The tar file cannot be further compressed and has an 8-GB limitation on the size of each single file.	You need to export the archive result and pack it. The tar format is recommended.	

NOTE

To reduce the size of an exported file, you can use the gs_dump tool to compress it to a directory archive file or custom-format file. When a directory archive or custom-format archive is generated, medium compression is used by default. Archived exported files cannot be compressed using gs_dump.

Precautions

- Before using gs_dump, ensure that the gs_dump version is consistent with the database version. gs_dump of a later version may not be fully compatible with kernel data of an earlier version.
- gs_dump is not suitable for scenarios where there are too many objects (such as tables, views, and indexes) in the database. If the number of objects in the database exceeds 100,000 or the dependency between objects is too complex, the export using gs_dump takes a long time.
- Do not modify the files and contents exported using the **-F c**, **-F d**, or **-F t** format. Otherwise, the restoration may fail. For files exported using the **-F p** format, you can edit the exported files with caution if necessary.
- To ensure data consistency and integrity, gs_dump sets an access shared lock on the table to be dumped by default. If another conflicting lock has been set

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

for the table in other transactions, gs_dump locks the table after that lock is released. If the table cannot be locked within the specified time, the dump fails. You can customize the timeout interval to wait for lock release by specifying the **--lock-wait-timeout** parameter. For details about lock conflicts, see **LOCK**.

- Stored procedures and functions cannot be exported in encrypted mode.
- For materialized views, this tool supports only definition export. After importing materialized views, you need to manually run the REFRESH statement to restore data.
- gs_dump does not export materialized view-related tables whose names start with matviewmap_ or mlog_, tables with the **internal_mask** option, or tables in the recycle bin.
- For temporary objects, this tool can export only global temporary tables.
- This tool cannot be used on standby nodes.
- The distribution information in the system catalog on the DN is incomplete. Therefore, when gs_dump is used on the DN, the table distribution information is not dumped.
- When gs_dump is used to export partitioned indexes, the attributes of some index partitions cannot be exported, for example, the unusable status of index partitions. You can query the PG_PARTITION system catalog or ADM_IND_PARTITIONS view to obtain the attributes of an index partition. You can run the ALTER INDEX statement to manually set the attributes of an index partition.
- For scheduled tasks, this tool can export only non-periodic scheduled tasks created using advanced packages from a MySQL-compatible database.
- gs_dump does not export user-defined tokenweight dictionaries. You can manually create the corresponding tokenweight dictionary according to the dictionary information displayed in the error message "WARNING: dictionary xx cannot be automatically exported, please create it manually."
- Common users cannot export directories and synonyms. If a common user attempts to export related data, the message "WARNING: xx not dumped because current user is not a superuser" is displayed. To perform export, you must be the initial user or a user with the SYSADMIN permission. When importing the exported data, ensure that the syntax meets the user permission and operation restrictions. For details, see **CREATE DIRECTORY** and **CREATE SYNONYM**.
- If local data exists in **template1** of the source database instance, restore the output of gs_dump to an empty database (copy from **template0** instead of **template1**). Otherwise, an error may occur because the definition of the added object is copied. To create an empty database without any local additions, copy data from template0 rather than template1. For example:
  ```
  CREATE DATABASE foo WITH TEMPLATE template0;
  ```
- The size of a single tar file must be smaller than 8 GB. (This is the tar file format limitations.) The total size of a .tar archive and any of the other output formats are not limited, except possibly by the OS.
- The dump file generated by gs_dump does not contain the statistics used by the optimizer to make execution plans. Therefore, you are advised to run **ANALYZE** after restoring from a dump file to ensure optimal performance. The dump file does not contain the **ALTER DATABASE... SET** command,

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

database users, and other installation settings. These settings are dumped by gs_dumpall.

- gs_dump does not export invalid functions. Before exporting functions, ensure that the functions are valid. If a function is invalid, an alarm is generated, indicating that the function corresponding to the OID is invalid.
- If the parameter type of a non-PACKAGE function is the table column type (table.column%type) or view column type (view.column%type) and the column type is a basic type, the parameter type is converted to the corresponding basic type in the exported function definition. Changing the column type of a table by executing **ALTER TABLE MODIFY COLUMN** and then running **ALTER FUNCTION COMPILE**, or changing the column type of a view query table, rebuilding the view, and executing **ALTER FUNCTION COMPILE** does not change the parameter type in the **PROARGSRC** column of the function in the PG_PROC system catalog. In the exported function definition, the parameter type remains the basic type before the object column type is changed.
- The current design of gs_dump is incompatible with separation of duties. In separation of duties, gs_dump can be used only by the initial user. The file to be imported must also be executed by the initial user.
- If the object to be exported contains a trigger, add the **--use-set-session-authorization --all** parameter and export the object in text format. Otherwise, the owner information of the trigger cannot be correctly restored.
- Using gs_dump will not dump model objects.
- When a system administrator uses gs_dump to export data, objects created by the initial user are not exported. The objects created by the initial user can only be exported by the initial user. When a common user uses gs_dump to export data, only all objects whose owner is the common user are exported.
- If the exported objects contain views that depend on internal functions of packages, an error indicating that the view dependency object does not exist is generated when the objects are imported to the target end for the first time. In this case, you need to run the **gs_dump --schema-only** command to back up metadata and import the metadata to the target end again.
- When using gs_dump to export database-level advanced compression policies, ensure that the entire database is exported and you have the system administrator permission. If the preceding conditions are not met, the related policies are exported as independent policies at the table, partition, or subpartition level instead of being processed as database-level policies.
- gs_dump exports the actual status of a sequence. After the sequence is restored to the target end, the sequence continues in the previous state.
- For some backup files that are exported from an earlier version not supporting Ustore, when they are restored to a version supporting Ustore, tables will be created in Ustore format and subject to Ustore specification limitations. If you want to restore the tables to the Astore format, set **enable_default_ustore_table** to **off**.
- When gs_dump is used to export an interval partitioned table, only the range partitions of the partitioned table can be exported. The interval partitions of the partitioned table cannot be exported. For the sparsely partitioned index of the partitioned table, the same principle applies. That is, only the sparsely partitioned index created on range partitions can be exported. The sparsely partitioned index on the interval partitions cannot be exported.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- If **ddl_invalid_mode** is set to **invalid**, dependencies on the objects that are dropped will not be deleted, but the dependency relationships will be invalidated. In other words, the pg_depend system catalog still contains dependency records. In this case, when gs_dump is used for backup, an error message "cache lookup failed" will be displayed because a dependency relationship exists but the corresponding dependent object cannot be found. To continue export, you need to restore the dependency relationship (by rebuilding the dependent object or deleting the object that is depended on).
- By default, gs_dump exports invalid views and displays a message if any. An error may be reported when the views are imported in versions earlier than 507.0. You can specify the **--ignore-invalid-views** option to skip exporting invalid views.
- gs_dump does not export data in the **rowid** system column. It exports only data in the user column when **rowid** is used as the data type.
- If the target database to which the full-text search data is imported does not have the corresponding full-text search file, or the **-c** option is specified during the import or export, the import will fail. In this case, you need to create these data objects in the target database and then import the data again, or do not specify the **-c** option during the import or export.
- When gs_dump is used to export a view, if the view definition contains SELECT * and the columns in the base table have been changed after the view is created, the asterisks (*) in the exported file will be expanded based on the current column structure of the target table after the file is imported to the target database.
- During gs_redis redistribution, gs_redis locks the data in CANCELABLE mode and proactively sends a SIGTERM signal to the gs_dump thread that holds the conflicting lock. As a result, gs_dump export may be forcibly terminated and fail.
- If the objects exported by gs_dump contain user views, ensure that the **proc_outparam_override** configuration of the **behavior_compat_options** parameter in the export environment is the same as that in the restoration environment. Otherwise, the import may fail.
- The export result of gs_dump does not contain status information such as all session parameter settings (for example, **behavior_compat_options**). If the statement execution result depends on the status information, the session parameters of the source and target databases must be the same. Otherwise, an error may be reported or data may be inconsistent.

Syntax

```
gs_dump [OPTION]... [DBNAME]
```

Parameters

- DBNAME

  Specifies the database to be connected. No short or long option is required. For example:

  ```
  gs_dump -p port_number testdb -f dump1.sql
  ```

  Or,

  ```
  export PGDATABASE=testdb
  gs_dump -p port_number -f dump1.sql
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

For details about how to use **DBNAME**, see **Table 4-7** in "gsql Usage Guide."

- OPTION

  There are three types of parameters: general parameters, dump parameters, and connection parameters.

  Common parameters:

  – -f, --file=FILENAME

    Sends the output to the specified file or directory. If this parameter is omitted, the standard output is generated. If the output format is **-F c**, **-F d**, or **-F t**, the **-f** parameter must be specified. If the value of the **-f** parameter contains a directory, the current user must have the read and write permission on the directory.

  – -F, --format=c|d|t|p

    Selects an exported file format. The formats are as follows:

    - **c|custom**: outputs a custom-format archive as a directory to be used as the input of gs_restore. This is the most flexible output format in which users can manually select it and reorder the archived items during the restoration process. An archive in this format is compressed by default.
    - d|directory: creates a directory containing directory files and the data files of tables and BLOBs.
    - **t|tar**: outputs a tar-format archive as the input of gs_restore. The .tar format is compatible with the directory format. Extracting a .tar archive generates a valid directory-format archive. However, the .tar archive cannot be further compressed and has an 8-GB limitation on the size of a single table. The order of table data items cannot be changed during restoration.
    - p|plain: generates a text SQL script file. This is the default value.

  – -v, --verbose

    Specifies the verbose mode. If it is specified, gs_dump writes detailed object comments and number of startups/stops to the dump file, and progress messages to standard errors.

  – -V, --version

    Prints the gs_dump version and exits.

  – -Z, --compress=0-9

    Specifies the used compression level.

    Value range: 0 to 9

    - 0 indicates no compression.
    - 1 indicates the lowest compression ratio and the fastest processing speed.
    - 9 indicates the highest compression ratio and the slowest processing speed.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- For the custom-format archive, this option specifies the compression level of a single table data segment. By default, data is compressed at a medium level. The .tar archive format and plain-text format do not support compression currently.
- For the parameter value, the part before the first non-digit character will be used. If the string begins with a non-digit character, **0** is used.

– --lock-wait-timeout=TIMEOUT

Specifies the timeout period (in milliseconds) for waiting for a level-1 shared table lock when the dump starts. If no such lock is obtained in the specified period, the dump fails. The timeout interval can be specified in any of the formats accepted by SET statement_timeout.

The lock is held throughout the entire export process, without blocking DML statements.

– -?, --help

Displays help information about gs_dump parameters and exits.

– --ignore-invalid-views

If this parameter is specified, invalid views will not be exported. If invalid views are detected during the export, a message will be displayed.

Dump parameters:

– -a, --data-only

Generates only the data, not the schema (data definition). Dumps the table data and sequence values.

– -b, --blobs

Reserved for function extension. The option is not recommended.

– -c, --clean

Before writing the command of creating database objects into the backup files, writes the command of cleaning (deleting) database objects to the backup files. If no objects exist in the target database, gsql or gs_restore probably displays some error information.

This parameter is used only for the plain-text format. For the archive format, you can specify the option when using gs_restore.

NOTE

- None of the statements exported to the backup file for deleting database objects are cascading DROP statements.
- At t1, database 1 is connected to export table 1 to the **backup01.dmp** file using the **-c** parameter. At t2, view 1 is created in database 1 and depends on table 1. At t3, **backup01.dmp** is restored to database 1 using the **-c** parameter of gs_restore. Non-cascading DROP is used. When table 1 is deleted, the error message "ERROR: table table cannot be dropped because other objects depend on it." is displayed, and when table 1 is created, the error message "ERROR: Relation "table1" already exists." is displayed. In this case, delete related dependent objects or execute the cascading DROP command after evaluating the impact.

– -C, --create

The backup file content starts with the commands of creating the database and connecting to the created database. If the command script

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

is executed in this mode, the database that is connected before the script is executed is not affected.

This parameter is used only for the plain-text format. For the archive format, you can specify the option when using gs_restore.

NOTE

- This option is not supported in M-compatible databases. To import data, create a database in M-compatible mode on the target instance, export data from the source instance, and connect to the newly created M-compatible database on the target instance.
- If **-n**, **-t**, or **--include-table-file** is specified, the **-C** option becomes invalid.

– -E, --encoding=ENCODING

Creates the dump in the specified character set encoding. By default, the dump file is created in the database encoding. Setting the environment variable *PGCLIENTENCODING* to the required dump encoding can also achieve the same result.

NOTE

If transcoding is required for the specified dump encoding and data in the table contains invalid characters, the error message "invalid byte sequence" will be displayed during export. You are advised to specify the **-s** parameter when using gs_dump to export only definitions and execute **COPY** with the encoding fault tolerance option separately to export and import data.

– -g, --exclude-guc=GUC_PARAM

Specifies the **set** command that does not contain related GUC parameters in the exported text file. Currently, only **enable_cluster_resize** is supported. If other parameters are specified, no error is reported but the setting does not take effect.

– -j, --jobs=NUM

Exports data in parallel.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- If **-j** is not specified, serial export is used by default.
- The specified number of parallel tasks cannot exceed twice the number of CPU cores on the client. When the client runs in a container, the number of CPUs obtained is the number of CPUs on the host, which may be greater than the number of CPUs that can be used by the container. You are advised to set the degree of parallelism to a value less than twice the number of CPUs that can be used by the client. Parallel export of a table is implemented by concurrently executing multiple transactions through multiple processes. The actual degree of parallelism is limited by the thread pool model of the server and increases the pressure on the server. Set the degree of parallelism based on the actual needs. For example, the degree of parallelism cannot exceed the number of idle CPUs on the client or the maximum number of connections on the server. It is recommended that the number of parallel tasks be greater than or equal to 4.
- Parallel export supports only the directory archive format.
- By default, parallel export is specific to a single table. That is, when only one table is exported, the data of the table can be split into multiple export tasks and exported to multiple files in parallel. You can specify the **--disable-inter-table-parallel** parameter to disable single-table parallel export. When single-table parallel export is disabled, table-level parallel export is used. That is, parallel export takes effect only when data of multiple tables is exported.
- When data is exported and imported in parallel, data in the same table will be placed in the same transaction. That is, the parallel import efficiency is not improved.
- Parallel export conflicts with the **--inserts**, **--column-inserts**, and **--attribute-inserts** options.
- Parallel export conflicts with the **--query** option.
- Bucket tables do not support single-table parallel export.
- The parallel export performance is affected by the compression parameter **-Z**. You are advised to set the compression level properly. The default compression level is medium; alternatively, you can set it to **0** (indicating no compression). A higher compression level indicates higher CPU usage on the client. In addition, the export speed may decrease due to CPU preemption on the client.
- Parallel export cannot be used during the upgrade observation period.
- Single-table parallel export cannot be used on DNs. That is, **-j** and **--disable-inter-table-parallel** must be specified on DNs at the same time.
- Parallel export in distributed mode has certain overheads. When the number of parallel tasks is small, the parallel optimization effect is not obvious.

– -n, --schema=SCHEMA

Dumps only schemas matching the schema names. This option contains the schema and all its contained objects. If this option is not specified, all non-system schemas in the target database will be dumped. Multiple **-n** options can be specified to select multiple modes. The schema parameter is interpreted as a pattern according to the same rule used by the **\d** command of gsql. Therefore, multiple schemas can also be selected by writing wildcard characters in the pattern. When you use wildcard characters, quote patterns to prevent the shell from expanding the wildcard characters.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- If **-n** is specified, gs_dump does not dump any other database objects that the selected schemas might depend upon. Therefore, there is no guarantee that the results of a specific-schema dump can be automatically restored to an empty database.
- If **-n** is specified, the non-schema objects are not dumped.
- In M-compatible mode, if a database with **templatem** is created by running **CREATE DATABASE**, data is exported by specifying **db_name**; if a database is created by running **CREATE DATABASE** *db_name*, data is exported by specifying **-n** because such database is equivalent to a schema.
- GaussDB automatically converts uppercase letters in object names to lowercase letters. If a schema name contains uppercase letters, add extra quotation marks, for example, **-n '"Sch1"'** or **-n "\"Sch1\""**.
- When **-n** is specified, pattern "*" cannot be used to match system schemas in the database during export.

Multiple schemas can be dumped. For example, in the following example, both **sch1** and **sch2** are dumped.

```
gs_dump -h host_name -p port_number testdb -f backup/bkp_shl2.sql -n sch1 -n sch2
```

– -N, --exclude-schema=SCHEMA

Does not dump any tables matching the table pattern. The pattern is interpreted according to the same rule as for -n. **-N** can be specified multiple times to exclude schemas matching any of the specified patterns.

When both -n and -N are specified, the schemas that match at least one -n option but no -N is dumped. If -N is specified and -n is not, the schemas matching -N are excluded from what is normally dumped.

Dump allows you to exclude multiple schemas during dumping. For example, in the following example, **sch1** and **sch2** are excluded during the dump.

```
gs_dump -h host_name -p port_number testdb -f backup/bkp_shl2.sql -N sch1 -N sch2
```

NOTE

GaussDB automatically converts uppercase letters in object names to lowercase letters. If a schema name contains uppercase letters, add extra quotation marks, for example, **-N '"Sch1"'** or **-N "\"Sch1\""**.

– -o, --oids

Dumps OIDs as parts of the data in each table. Use this option if your application references the OID columns in some way (for example, in a FOREIGN KEY constraint). If the preceding situation does not occur, do not use this parameter. This option cannot be used together with the **--inserts/--column-inserts** option.

– -O, --no-owner

Do not output commands to set ownership of objects to match the original database. By default, gs_dump issues the ALTER OWNER or SET SESSION AUTHORIZATION command to set ownership of created database objects. These statements will fail when the script is running unless it is started by a system administrator (or the same user who owns all of the objects in the script). To make a script that can be used by any user for restoration and give the user ownership of all objects, specify **-O**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

This parameter is used only for the plain-text format. For the archive format, you can specify the option when using gs_restore.

- -s, --schema-only

  Dumps only the object definition (schema) but not data.

- -q, --target=VERSION

  Exports text files compatible with databases of other versions. Currently, parameters of V1 and V5 are supported. If other parameters are specified, no error is reported but the setting does not take effect. The **v1** value means to export GaussDB v5 data as a text file compatible with GaussDB v1. The **v5** value means to export GaussDB v5 data as a text file, reducing errors that may occur when data is imported to a GaussDB v5 database.

  When **v1** is specified, you are advised to use it along with parameters such as **--exclude-guc="enable_cluster_resize"**, **--exclude-function**, and **--exclude-with**. Otherwise, an error may be reported during data import to a GaussDB v1 database.

- -S, --sysadmin=NAME

  Reserved for function extension. The option is not recommended.

- -t, --table=TABLE

  Specifies a list of tables, views, sequences, or foreign tables not to be dumped. You can use multiple **-t** parameters or wildcard characters to specify tables. For example, in the following example, both **schema1.table1** and **schema2.table2** are dumped.

  ```
  gs_dump -h host_name -p port_number testdb -f backup/bkp_shl2.sql -t schema1.table1 -t schema2.table2
  ```

  When you use wildcard characters, quote patterns to prevent the shell from expanding the wildcard characters.

  The **-n** and **-N** options have no effect when **-t** is used because tables selected by using **-t** are not affected the **-n** and **-N** options.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- The number of **-t** parameters must be less than or equal to 100.
- If the number of **-t** parameters is greater than 100, you are advised to use the **--include-table-file** parameter to replace some **-t** parameters.
- If **-t** is specified, gs_dump does not dump any other database objects that the selected tables might depend upon. Therefore, there is no guarantee that the results of a specific-table dump can be automatically restored to an empty database.
- **-t** *tablename* only dumps visible tables in the default search path. **-t** **.tablename* dumps the tables specified by *tablename* in all schemas (except the system schemas) in the database. **-t** *schema.table* dumps tables in a specific schema.
- **-t** *tablename* does not export trigger information from a table.
- If the table name contains uppercase letters, you need to add **\"** to the table name when using the **-t** parameter to specify the export. To export the **"abC"** table, specify **-t \"abC\"**. To export the **schema."abC"** table, specify **-t schema.\"abC\"**.
- **-t ""** does not match any table.
- When the **-t** parameter contains multiple dot (.) separators, only the last two separators are effective. The name between the second-to-last and last separators is the schema name, and the name after the last separator is the table name. For example, running **-t schema_a.schema_b.schema_c.table1** actually exports **table1** from **schema_c** and running **-t schema_a.schema_b.schema_c.*.table1** actually exports **table1** from all schemas.

– --include-table-file=FILENAME

  Specifies the table file to be dumped.

– -T, --exclude-table=TABLE

  Specifies a list of table, view, sequence, or foreign table objects not to be dumped. You can use multiple **-T** parameters or wildcard characters to specify multiple lists.

  When both **-t** and **-T** are specified, it will dump the objects in the **-t** list, but not those in the **-T** list.

  For example, in the following example, **table1** and **table2** are excluded during the dump.

  ```
  gs_dump -h host_name -p port_number testdb -f backup/bkp_shl2.sql -T table1 -T table2
  ```

  NOTE

  For auto-increment columns, the **-T** parameter does not take effect.

– --exclude-table-file=FILENAME

  Specifies the table file not to be dumped.

  NOTE

  Same as **--include-table-file**, the content format of this parameter is as follows:

  schema1.table1

  schema2.table2

  .....

– -x, --no-acl

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Prevents the dumping of access permissions (**GRANT**/**REVOKE** commands). Only ACL objects are affected. Privilege objects are not affected.

- --exclude-function

  Specifies that functions and stored procedures are not exported.

- --exclude-with

  Specifies that the description such as **WITH(orientation=row, compression=on)** is not added to the end of the exported table definition.

- --binary-upgrade

  Reserved for function extension. The option is not recommended.

  NOTE

  M-compatible databases do not support this option.

- --binary-upgrade-usermap="USER1=USER2"

  Reserved for function extension. The option is not recommended.

- --column-inserts|--attribute-inserts

  Exports data by running the INSERT command with explicit column names {INSERT INTO table (column, ...) VALUES ...}. This will cause a slow restoration. However, since this option generates an independent command for each row, an error in reloading a row causes only the loss of the row rather than the entire table content.

  NOTE

  M-compatible databases do not support this option.

- --disable-dollar-quoting

  Disables the use of dollar sign ($) for function bodies, and forces them to be quoted using the SQL standard string syntax.

- --disable-inter-table-parallel

  This option takes effect only during parallel export. If this option is specified, table-level parallel export is used.

- --include-alter-table

  Exports columns that are deleted from a table.

- --disable-triggers

  Reserved for function extension. The option is not recommended.

- --exclude-table-data=TABLE

  Does not dump table data that matches any patterns. The pattern is interpreted according to the same rule as for **-t**.

  --exclude-table-data can be entered more than once to exclude tables matching any of several patterns. When the user needs the specified table definition rather than data in the table, this option is helpful.

  To exclude data of all tables in the database, see **-s, --schema-only**.

- --include-query-file=FILENAME

  When exporting table data, you can use this parameter to configure predicate filter conditions in batches in the file, so as to export specified table data.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Predicate conditions are separated by '\n'. **FILENAME** supports the following formats:

i. [schema_name.][table_name:] query_clause

ii. query=[schema_name.][table_name:] query_clause

NOTE

- The line starting with a number sign (#) in the file is regarded as a comment line.
- **--include-query-file** and **--query** can be used together, but only one predicate condition can be specified for the same table.
- For details about other rules of predicate conditions, see the description of the **--query** parameter.

– --inserts

Dumps data when the **INSERT** command (rather than the **COPY** command) is delivered, resulting in slow recovery.

However, since this option generates an independent command for each row, an error in reloading a row causes only the loss of the row rather than the entire table content. Note that the restoration may fail if you rearrange the column order. The **--column-inserts** option is unaffected against column order changes.

NOTE

M-compatible databases do not support this option.

– --log-level=LOG|DEBUG|DEBUG1|DEBUG2|DEBUG3

Specifies the log level of gs_dump. **LOG** records normal execution information, and **DEBUG** records some debugging information. A larger **DEBUG** value indicates a higher log level and more debugging details.

– --no-security-labels

Reserved for function extension. The option is not recommended.

– --no-tablespaces

Does not select any tablespaces. All the objects will be created during the restoration process, no matter which tablespace is selected when using this option.

This parameter is used only for the plain-text format. For the archive format, you can specify the option when using gs_restore.

– --no-unlogged-table-data

Reserved for function extension. The option is not recommended.

– --non-lock-table

Shields the table locking behavior during the export using gs_dump. This parameter is called only between APIs. You are advised not to call this parameter.

NOTE

When gs_dump is used to export a table, a shared lock is added to the table to be exported in the entire transaction by default. This lock blocks the execution of concurrent DDL statements on the table, ensuring that no error is reported due to the impact on concurrent DDL statements.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

– --query=[schema_name.][table_name:]query_clause

  Adds predicate conditions to export specified table data.

  query_clause is a standard query clause starting with WHERE.

  NOTE

  - If predicate conditions need to be added for multiple tables, multiple **--query** parameters are required.
  - You can specify multiple **query** parameters at the same time, but only one **query** parameter can be specified for the same table.
  - The **-t** parameter takes precedence over the **--query** parameter. When both the **-t** and **--query** parameters are used, tables to be exported are selected based on the **-t** parameter, and then filtered based on the predicates.
  - The **--query** parameter only concatenates predicates and does not escape them. You need to escape them by yourself if necessary.
  - The used predicates must comply with the SQL standard and can be properly executed. Otherwise, an error will be reported during data export.
  - Predicates cannot be specified for views and materialized views. Otherwise, an error will be reported during data export.
  - The export performance is affected by the query performance of predicates.
  - The WHERE clause in the **--query** parameter must be enclosed in single or double quotation marks. If the WHERE clause contains a filter condition of the character type, the WHERE clause must be enclosed in double quotation marks.

    For example, if the filter condition in the WHERE clause is not of the character type, you can use single or double quotation marks to enclose the filter condition.

    ```
    --query=test_schema.test_table:'where test_attr > 3'
    --query=test_schema.test_table:"where test_attr > 3"
    ```

    For example, if the filter condition in the WHERE clause is of the character type, the filter condition must be enclosed in double quotation marks.

    ```
    --query=test_schema.test_table:"where test_attr = 'a'"
    ```

  - GaussDB automatically converts uppercase letters in object names to lowercase letters. If **schema_name**, **table_name**, or **query_clause** contains uppercase letters or special characters, extra quotation marks are required.

    For example, if the schema name contains uppercase letters or special characters, do as follows:

    ```
    --query="\"TEST_SCHEMA\"".test_table:"where test_attr > 3"
    ```

    For example, if the predicate condition contains uppercase letters (the column name contains uppercase letters), do as follows:

    ```
    --query=test_schema.test_table:"where \"TEST_attr\" > 3"
    ```

– --quote-all-identifiers

  Forcibly quotes all identifiers. In the migration to a later version, additional keywords may be introduced. This option is helpful.

  NOTE

  M-compatible databases do not support this option.

– --section=SECTION

  Dumps specified sections (pre-data, data, and post-data).

– --serializable-deferrable

  Uses a serializable transaction during the dump process to ensure that the snapshot used is consistent with the subsequent database state. To

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

achieve this, it must wait for a specific point in an error-free transaction stream (where all concurrent read/write transactions that might conflict with the dump have either committed or rolled back). This guarantees a successful dump and avoids triggering serialization_failure errors that would force other transactions to retry.

This option provides no benefit for dumps intended solely for DR (as DR only requires a fully usable restored dataset, not a strictly consistent snapshot). It is ideal for the following scenario: generating a backup for reports or other read-only workloads while the primary database is continuously updated by business operations—where the copy requires a strictly consistent state. Without this option, the dump might reflect an anomalous state that "no serial execution could ever produce." For example, in batch processing, the dump might contain contradictory results such as "a batch is marked as closed, but its constituent items have not yet fully appeared."

This option will make no difference if there are no active read/write transactions when gs_dump is started. If the read/write transactions are active, the dump start time will be delayed for an uncertain period.

– --use-set-session-authorization

Specifies that the standard SQL **SET SESSION AUTHORIZATION** command rather than **ALTER OWNER** is generated to determine the object ownership. When the **SET SESSION AUTHORIZATION** command is used to dump data, if the object history in the dump file is incorrect, the data may not be restored correctly. A dump by running **SET SESSION AUTHORIZATION** requires the system administrator permission, whereas running **ALTER OWNER** requires a lower permission. However, the SET SESSION AUTHORIZATION statement supports ciphertext passwords. The script exported using this parameter may not be restored. Therefore, you are advised not to use this parameter to export the script.

NOTE

Application scope of SET SESSION AUTHORIZATION:

- A system administrator can switch to a common user using the SET SESSION AUTHORIZATION statement, but cannot switch to the initial user, SYSADMIN, OPRADMIN, MONADMIN, POLADMIN, or AUDITADMIN.
- Other users cannot switch to another user using the SET SESSION AUTHORIZATION statement.

– --all

Specifies that the gs_dump tool is called by the gs_dumpall tool. You are advised not to use this parameter unless you need to export triggers.

– --with-copy-format=FILE_FORMAT

Specifies the format of the data file exported by gs_dump.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- The value of **FILE_FORMAT** is a string. Only the TEXT and CSV formats are allowed. The default value is **TEXT**.
- The value of **FILE_FORMAT** can be **CSV** only in the directory archive format.
- When **FILE_FORMAT** is set to **CSV**, **--inserts**, **--column-inserts**, or **--attribute-inserts** cannot be used at the same time.
- After data is exported in the directory archive format, users must use the gs_restore tool to import and restore the data. In this case, users do not need to pay attention to the format of the exported data file. If users specify CSV as the format of the data file to be exported, **--with-copy-format** can be set to **CSV**.

– --with-encryption=AES128

Specifies that dumping data needs to be encrypted using AES-128.

– --with-key=KEY

The AES-128 key rules are as follows:

Consists of 8 to 16 characters.

Contains at least three of the following character types: uppercase characters, lowercase characters, digits, and special characters (limited to ~!@#$ %^&*()-_=+\|[{}];:,<.>/?).

NOTE

Stored procedures and functions cannot be exported in encrypted mode.

– --with-salt=RANDVALUES

gs_dumpall uses this parameter to transfer a random value.

– --include-nodes

Includes the TO NODE or TO GROUP statement in the dumped CREATE TABLE/CREATE FOREIGN TABLE statement.

– --include-extensions

Includes extensions in the dump.

NOTICE

Extensions are for internal use only. Only advanced packages or extensions in the database can be operated.

– --include-depend-objs

Includes information about the objects that depend on the specified object in the backup result. This parameter takes effect only if the **-t** or **--include-table-file** parameter is specified.

– --exclude-self

Excludes information about the specified object from the backup result. This parameter takes effect only if the **-t** or **--include-table-file** parameter is specified.

– --pipeline

Uses a pipe to transmit the password. This parameter cannot be used on devices.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

– --no-transaction

By default (when this option is disabled), when files in plain-text format are exported, statements such as CREATE, ALTER ... OWNER TO, SET SESSION AUTHORIZATION, and RESET SESSION AUTHORIZATION will be wrapped in a separate transaction block for execution. If this option is enabled, these statements are output directly without being wrapped in BEGIN/COMMIT.

– --dont-overwrite-file

The existing files in plain-text, .tar, and custom formats will be overwritten. This option is not applicable to the directory format.

For example:

Assume that the backup.sql file exists in the current directory. If you specify -f backup.sql in the input command, and the backup.sql file is generated in the current directory, the original file will be overwritten.

If the backup file exists and **--dont-overwrite-file** is specified, an error will be reported with the message that the dump file exists.

```
gs_dump -p port_number testdb -f backup.sql -F plain --dont-overwrite-file
```

NOTE

- **-s/--schema-only** and **-a/--data-only** do not coexist.
- **-c/--clean** and **-a/--data-only** do not coexist.
- **--inserts/--column-inserts** and **-o/--oids** do not coexist because OIDS cannot be set using the INSERT statement.
- **--role** must be used with **--rolepassword**.
- **--binary-upgrade-usermap** must be used with **--binary-upgrade**.
- **--include-depend-objs**/**--exclude-self** takes effect only when **-t**/**--include-table-file** is specified.
- **--exclude-self** must be used with **--include-depend-objs**.
- **--with-encryption=AES-128** supports only **-F p/plain**.
- **--with-key=KEY** supports only **-F p/plain**.
- **--with-salt=RANDVALUES** is called by gs_dumpall and does not require manual input.

Connection parameters:

– -h, --host=HOSTNAME

Specifies the host name. If the value begins with a slash, it is used as the directory for the UDS. By default, the value is obtained from the *PGHOST* environment variable (if set).

This parameter applies only to external connections of a cluster. For the localhost in the cluster, you can use IPv4 address **127.0.0.1** or IPv6 address **::1**.

– -p, --port=PORT

Specifies the host port number. If the thread pool is enabled, you are advised to use the pooler port, that is, the host port number plus 1. By default, the value is obtained from the *PGPORT* environment variable (if set).

– -U, --username=NAME

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Specifies the username for connecting to a host. The initial user cannot be used for cross-node execution. By default, the value is obtained from the *PGUSER* environment variable (if set).

NOTE

Before exporting and importing data as a common user, grant the permission to create schemas in the corresponding database to the common user, for example, **GRANT CREATE ON DATABASE db**_*xxx* **TO user**_*xxx*;.

- -w, --no-password

  Never issues a password prompt. The connection attempt fails if the host requires password for authentication and the password is not provided in other ways. This parameter is useful in batch jobs and scripts in which no user password is required.

- -W, --password=PASSWORD

  Specifies the user password for connection. If the host uses the trust authentication policy, administrators do not need to enter the **-W** option. If the **-W** option is not provided and you are not a system administrator, the system will ask you to enter a password. To ensure system security, you are advised to enter the password in interactive mode.

- --role=ROLENAME

  Specifies a role name to be used for creating the dump. If this option is selected, the SET ROLE command will be issued after the database is connected to gs_dump. It is useful when the authenticated user (specified by **-U**) lacks the permissions required by gs_dump. It allows the user to switch to a role with the required permissions. Some installations have a policy against logging in directly as a system administrator. This option allows dumping data without violating the policy.

- --rolepassword=ROLEPASSWORD

  Password of the role

Examples

In the following examples, **backup/MPPDB_backup.sql** indicates an exported file, where **backup** indicates the relative path of the current directory. **37300** indicates the port number of the database server. **testdb** indicates the name of the database to be accessed.

NOTE

Before exporting files, ensure that the directory exists and you have the read and write permissions on the directory.

Example 1

Use gs_dump to export the full information of the **testdb** database. The exported **MPPDB_backup.sql** file is in plain-text format.

```
gs_dump -U omm -f backup/MPPDB_backup.sql -p 37300 testdb -F p
gs_dump[user='omm'][localhost][port='37300'][testdb][2018-06-27 09:49:17]: The total objects number is 356.
gs_dump[user='omm'][localhost][port='37300'][testdb][2018-06-27 09:49:17]: [100.00%] 356 objects have been dumped.
gs_dump[user='omm'][localhost][port='37300'][testdb][2018-06-27 09:49:17]: dump database testdb successfully
gs_dump[user='omm'][localhost][port='37300'][testdb][2018-06-27 09:49:17]: total time: 1274  ms
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Example 2

Use gs_dump to export the full information of the **testdb** database. The exported **MPPDB_backup.tar** file is in .tar format.

```
gs_dump -U omm -f backup/MPPDB_backup.tar -p 37300 testdb -F t
gs_dump[user='omm'][localhost][port='37300'][testdb][2018-06-27 10:02:24]: The total objects number is 1369.
gs_dump[user='omm'][localhost][port='37300'][testdb][2018-06-27 10:02:53]: [100.00%] 1369 objects have been dumped.
gs_dump[user='omm'][localhost][port='37300'][testdb][2018-06-27 10:02:53]: dump database testdb successfully
gs_dump[user='omm'][localhost][port='37300'][testdb][2018-06-27 10:02:53]: total time: 50086  ms
```

Example 3

Use gs_dump to export the full information of the **testdb** database. The exported **MPPDB_backup.dmp** file is in custom format.

```
gs_dump -U omm -f backup/MPPDB_backup.dmp -p 37300 testdb -F c
gs_dump[user='omm'][localhost][port='37300'][testdb][2018-06-27 10:05:40]: The total objects number is 1369.
gs_dump[user='omm'][localhost][port='37300'][testdb][2018-06-27 10:06:03]: [100.00%] 1369 objects have been dumped.
gs_dump[user='omm'][localhost][port='37300'][testdb][2018-06-27 10:06:03]: dump database testdb successfully
gs_dump[user='omm'][localhost][port='37300'][testdb][2018-06-27 10:06:03]: total time: 36620  ms
```

Example 4

Use gs_dump to export the full information of the **testdb** database. The exported **MPPDB_backup** file is in directory format.

```
gs_dump -U omm -f backup/MPPDB_backup -p 37300  testdb -F d
gs_dump[user='omm'][localhost][port='37300'][testdb][2018-06-27 10:16:04]: The total objects number is 1369.
gs_dump[user='omm'][localhost][port='37300'][testdb][2018-06-27 10:16:23]: [100.00%] 1369 objects have been dumped.
gs_dump[user='omm'][localhost][port='37300'][testdb][2018-06-27 10:16:23]: dump database testdb successfully
gs_dump[user='omm'][localhost][port='37300'][testdb][2018-06-27 10:16:23]: total time: 33977  ms
```

Example 5

Use gs_dump to export the information of the **testdb** database, excluding the information of the table specified in the **/home/MPPDB_temp.sql** file. The exported MPPDB_backup.sql file is in plain-text format.

```
gs_dump -U omm -p 37300 testdb --exclude-table-file=/home/MPPDB_temp.sql -f backup/MPPDB_backup.sql
gs_dump[user='omm'][localhost][port='37300'][testdb][2018-06-27 10:37:01]: The total objects number is 1367.
gs_dump[user='omm'][localhost][port='37300'][testdb][2018-06-27 10:37:22]: [100.00%] 1367 objects have been dumped.
gs_dump[user='omm'][localhost][port='37300'][testdb][2018-06-27 10:37:22]: dump database testdb successfully
gs_dump[user='omm'][localhost][port='37300'][testdb][2018-06-27 10:37:22]: total time: 37017  ms
```

Example 6

Use gs_dump to export only the information about the views that depend on the **testtable** table.

```
gs_dump -U omm -s -p 37300 testdb -t PUBLIC.testtable --include-depend-objs --exclude-self -f backup/MPPDB_backup.sql -F p
gs_dump[user='omm'][localhost][port='37300'][testdb][2018-06-15 14:12:54]: The total objects number is 331.
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gs_dump[user='omm'][localhost][port='37300'][testdb][2018-06-15 14:12:54]: [100.00%] 331 objects have been dumped.
gs_dump[user='omm'][localhost][port='37300'][testdb][2018-06-15 14:12:54]: dump database testdb successfully
gs_dump[user='omm'][localhost][port='37300'][testdb][2018-06-15 14:12:54]: total time: 327  ms
```

Related Tools

gs_dumpall for Exporting All Database Information, **gs_restore for Importing Data**, and **gsql for Connecting to a Database**

4.3.3 gs_dumpall for Exporting All Database Information

Description

gs_dumpall, provided by GaussDB, is used to export all database information, including the data of the default **postgres** database, data of user-specified databases, and global objects of all databases in a cluster.

When gs_dumpall is used to export data, other users can still access (read or write) the database cluster.

gs_dumpall can export complete, consistent data. For example, if gs_dumpall is started to export database from the entire cluster at T1, data of the cluster databases at that time point will be exported, and modifications on the cluster databases after that time point will not be exported.

gs_dumpall exports all databases from the entire cluster in two parts:

- gs_dumpall exports all global objects, including information about database users and groups, tablespaces, and attributes (for example, global access permissions).
- gs_dumpall calls gs_dump to export SQL scripts from each cluster database, which contain all the SQL statements required to restore databases.

The exported files are both plain-text SQL scripts. Use **gsql for Connecting to a Database** to execute them to restore databases.

gs_dumpall supports SSL-encrypted communication. The method is the same as that of using gsql.

Before using gs_dumpall, ensure that the gs_dumpall version is consistent with the gs_dump version and database version. gs_dumpall of a later version may not be fully compatible with the kernel data of an earlier version.

Because running gs_dumpall will call gs_dump, some limitations on exporting objects within a database are the same as those of gs_dump.

Precautions

- Do not modify any exported file. Otherwise, restoration may fail.
- To ensure the data consistency and integrity, gs_dumpall acquires a shared lock on the table to be dumped. If a shared lock has been set for the table in other transactions, gs_dumpall locks the table after it is released. If the table cannot be locked within the specified time, the dump fails. You can customize the timeout interval to wait for lock release by specifying the **--lock-wait-timeout** parameter.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- During an export, gs_dumpall reads all tables in a database. Therefore, you need to connect to the database as a database cluster administrator to export a complete file. When you use gsql to execute scripts, administrator permissions are also required to add users and user groups, and create databases. Before importing a backup, you need to verify the security to prevent administrator permissions from being exploited.
- If you use gs_dumpall to export all database objects and want to import them to a new instance environment, ensure that the names and permissions of the users used for the export and import are the same. Otherwise, an error message will be displayed, indicating that the names are inconsistent or the permissions are insufficient.
- For scheduled tasks, this tool can export only scheduled tasks created using CREATE EVENT or non-periodic scheduled tasks created using advanced packages from a MySQL-compatible database.
- gs_dumpall does not export user-defined tokenweight dictionaries. You can manually create the corresponding tokenweight dictionary according to the dictionary information displayed in the error message "WARNING: dictionary xx cannot be automatically exported, please create it manually."
- Only one M-compatible database can be created globally. If an M-compatible database is exported, ensure that no other M-compatible database exists in the target instance environment.
- If transcoding is required for the specified dump encoding and data in the table contains invalid characters, the error message "invalid byte sequence" will be displayed during export. You are advised to specify the **-s** parameter when using gs_dump to export only definitions and execute **COPY** with the encoding fault tolerance option separately to export and import data.
- The current design of gs_dumpall is incompatible with separation of duties. In separation of duties, gs_dumpall can be used only by the initial user. The file to be imported must also be executed by the initial user.
- When a system administrator uses gs_dumpall to export data, objects created by the initial user are not exported. The objects created by the initial user can only be exported by the initial user.
- If the exported objects contain views that depend on internal functions of packages, an error indicating that the view dependency object does not exist is generated when the objects are imported to the target end for the first time. In this case, you need to run the **gs_dumpall --schema-only** command to back up metadata and import the metadata to the target end again.
- By default, gs_dumpall exports invalid views and displays a message if any. An error may be reported when the views are imported in versions earlier than 507.0. You can specify the **--ignore-invalid-views** option to skip exporting invalid views.

Syntax

```
gs_dumpall [OPTION]...
```

Parameters

Common parameters:

- -f, --filename=FILENAME

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Sends the output to the specified file. If this option is omitted, the standard output is used.

- -v, --verbose

  Specifies the verbose mode. This will cause gs_dumpall to output detailed object comments and start/stop times to the dump file, and progress messages to standard errors.

- -V, --version

  Prints the gs_dumpall version and exits.

- --lock-wait-timeout=TIMEOUT

  Specifies the timeout period (in milliseconds) for waiting for a shared table lock when the dump starts. If no such lock is obtained in the specified period, the dump fails. The timeout interval can be specified in any of the formats accepted by SET statement_timeout.

- -?, --help

  Displays help about the command line parameters for gs_dumpall and exits.

- --ignore-invalid-views

  If this parameter is specified, invalid views will not be exported. If invalid views are detected during the export, a message will be displayed.

Dump parameters:

- -a, --data-only

  Dumps only the data, not the schema (data definition).

- -c, --clean

  Runs SQL statements to delete databases before rebuilding them. Statements for dumping roles and tablespaces are added.

- -g, --globals-only

  Dumps only global objects (roles and tablespaces) but no databases.

- -o, --oids

  Dumps OIDs as parts of the data in each table. Use this parameter if your application references the OID columns in some way. If the preceding situation does not occur, do not use this parameter.

- -O, --no-owner

  Do not output commands to set ownership of objects to match the original database. By default, gs_dumpall issues the ALTER OWNER or SET SESSION AUTHORIZATION statement to set ownership of created schema elements. These statements will fail when the script is running unless it is started by a system administrator (or the same user who owns all of the objects in the script). By specifying **-O**, you can compile a script that can be stored by any user. The script grants the user the permission to own all objects because the ALTER OWNER or SET SESSION AUTHORIZATION statement is not used and the execute user permission is always used during the import. Therefore, before importing the dump file, check whether there are risks in the dump file. For example, check whether the dump file contains a privilege escalation statement and whether the statement is known to the administrator.

- -r, --roles-only

  Dumps only roles but not databases or tablespaces.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- -s, --schema-only

  Dumps only the object definition (schema) but not data.

- -S, --sysadmin=NAME

  Reserved for function extension. The option is not recommended.

- -t, --tablespaces-only

  Dumps only tablespaces but not databases or roles.

- -x, --no-privileges

  Prevents the dumping of access permissions (**GRANT**/**REVOKE** commands).

- --column-inserts|--attribute-inserts

  Exports data by running the **INSERT** command with column names specified. This will cause a slow restoration. However, since this option generates an independent command for each row, an error in reloading a row causes only the loss of the row rather than the entire table content.

  NOTE

  M-compatible databases do not support this option. This option is skipped when an M-compatible database is exported.

- --disable-dollar-quoting

  Disables the use of dollar sign ($) for function bodies, and forces them to be quoted using the SQL standard string syntax.

- --disable-triggers

  Reserved for function extension. The option is not recommended.

- --inserts

  Dumps data when the INSERT statement (rather than COPY) is issued. This will cause a slow restoration. The restoration may fail if you rearrange the column order. The --column-inserts parameter is safer against column order changes, though even slower.

  NOTE

  M-compatible databases do not support this option. This option is skipped when an M-compatible database is exported.

- --no-security-labels

  Reserved for function extension. The option is not recommended.

- --no-tablespaces

  Do not output statements to create tablespaces or select tablespaces for objects. All the objects will be created during the restoration process, no matter which tablespace is selected when using this option.

- --no-unlogged-table-data

  Reserved for function extension. The option is not recommended.

- --include-alter-table

  Exports information about deleted columns in the table.

- --quote-all-identifiers

  Forcibly quotes all identifiers. This parameter is useful when you dump a database for migration to a later version, in which additional keywords may be introduced.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

> **NOTE**
>
> M-compatible databases do not support this option. This option is skipped when an M-compatible database is exported.

- --dont-overwrite-file

  Do not overwrite the current file.

- --use-set-session-authorization

  Specifies that the standard SQL **SET SESSION AUTHORIZATION** command rather than **ALTER OWNER** is generated to determine the object ownership. This makes dumping more standard. However, if a dump file contains objects that have historical problems, restoration may fail. A dump by running **SET SESSION AUTHORIZATION** requires the system administrator permissions, whereas running **ALTER OWNER** requires lower permissions. However, the SET SESSION AUTHORIZATION statement supports user and permission switching using a ciphertext password. The script exported using this parameter may not be restored. Therefore, you are advised not to use this parameter to export the script.

  > **NOTE**
  >
  > Application scope of SET SESSION AUTHORIZATION:
  >
  > - A system administrator can switch to a common user using the SET SESSION AUTHORIZATION statement, but cannot switch to the initial user, SYSADMIN, OPRADMIN, MONADMIN, POLADMIN, or AUDITADMIN.
  > - Other users cannot switch to another user using the SET SESSION AUTHORIZATION statement.

- --with-encryption=AES128

  Specifies that dumping data needs to be encrypted using AES-128.

- --with-key=KEY

  The AES-128 key rules are as follows:

  Consists of 8 to 16 characters.

  Contains at least three of the following character types: uppercase characters, lowercase characters, digits, and special characters (limited to ~!@#$ %^&*()-_=+\|[{}];:,<.>/?).

- --include-extensions

  Backs up all CREATE EXTENSION statements if the include-extensions parameter is set.

  NOTICE

  Extensions are for internal use only. Only advanced packages or extensions in the database can be operated.

- --include-templatedb

  Includes template databases during the dump.

- --dump-nodes

  Includes nodes and Node Groups during the dump.

- --include-nodes

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Includes TO NODE statement in the dumped CREATE TABLE statement.

- --include-buckets

  Reserved for function extension. The option is not recommended.

- --dump-wrm

  Includes workload resource manager (resource pool, load group, and load group mapping) during the dump.

  NOTE

  This option is not supported when an M-compatible database is connected for export.

- --binary-upgrade

  Reserved for function extension. The option is not recommended.

  NOTE

  M-compatible databases do not support this option. This option is skipped when an M-compatible database is exported.

- --binary-upgrade-usermap="USER1=USER2"

  Reserved for function extension. The option is not recommended.

- --non-lock-table

  This parameter is used only for inter-software API calling.

- --tablespaces-postfix

  Reserved for function extension. The option is not recommended.

- --parallel-jobs

  Specifies the number of concurrent backup processes. The value range is 1–1000.

- --no-transaction

  By default, when files in plain-text format are exported, statements such as CREATE, ALTER ... OWNER TO, SET SESSION AUTHORIZATION, and RESET SESSION AUTHORIZATION will be wrapped in a separate transaction block for execution. If this option is enabled, these statements are output directly without being wrapped in BEGIN/COMMIT.

- --pipeline

  Uses a pipe to transmit the password. This parameter cannot be used on devices.

NOTE

- The **-g/--globals-only** and **-r/--roles-only** parameters do not coexist.
- The **-g/--globals-only** and **-t/--tablespaces-only** parameters do not coexist.
- The **-r/--roles-only** and **-t/--tablespaces-only** parameters do not coexist.
- The **-s/--schema-only** and **-a/--data-only** parameters do not coexist.
- The **-r/--roles-only** and **-a/--data-only** parameters do not coexist.
- The **-t/--tablespaces-only** and **-a/--data-only** parameters do not coexist.
- The **-g/--globals-only** and **-a/--data-only parameters** do not coexist.
- **--tablespaces-postfix** must be used with **--binary-upgrade**.
- **--binary-upgrade-usermap** must be used with **--binary-upgrade**.
- **--parallel-jobs** must be used with **-f/--file**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Connection parameters:

- -h, --host=HOSTNAME

  Specifies the host name. If the value begins with a slash (/), it is used as the UDS directory. The default value is taken from the *PGHOST* environment variable. If it is not set, a UDS connection is attempted.

  This parameter is used only for defining names of the hosts outside a cluster. For the localhost in the cluster, you can use IPv4 address **127.0.0.1** or IPv6 address **::1**.

  Environment variable: *PGHOST*

- -l, --database=DATABASENAME

  Specifies the name of the database connected to dump all objects and discover other databases to be dumped. If this parameter is not specified, the **postgres** database will be used. If the **postgres** database does not exist, **template1** will be used.

  NOTE

  No matter which database is specified as the database to be connected for export, you must connect to the default database when using gsql to import data to a new instance. Otherwise, syntax incompatibility may occur, resulting in import errors. In particular, if the M-compatible database is incorrectly connected for import, the creation fails because CREATE DATABASE on the M-compatible database is equivalent to CREATE SCHEMA.

- -p, --port=PORT

  Specifies the TCP port listened on by the server or the local UDS file name extension to ensure a correct connection. The default value is the *PGPORT* environment variable.

  If the thread pool is enabled, you are advised to use the pooler port, that is, the listening port number plus 1.

  Environment variable: *PGPORT*

- -U, --username=NAME

  Specifies the name of the connected user. The initial user cannot be used for cross-node execution.

  Environment variable: *PGUSER*

- -w, --no-password

  Never issues a password prompt. The connection attempt fails if the server requires password for authentication and the password is not provided in other ways. This parameter is useful in batch jobs and scripts in which no user password is required.

- -W, --password=PASSWORD

  Specifies the user password for connection. If the authentication policy of the host is **trust**, the password of the system administrator is not verified. That is, you do not need to enter the **-W** option. If this parameter is not specified and you are not a system administrator, the system prompts you to enter the password in interactive mode. To ensure system security, you are advised to enter the password in interactive mode.

- --role=ROLENAME

  Specifies a role name to be used for creating the dump. This option causes gs_dumpall to issue the SET ROLE statement after connecting to the

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

database. It is useful when the authenticated user (specified by **-U**) lacks the permissions required by gs_dumpall. It allows the user to switch to a role with the required permissions. Some installations have a policy against logging in directly as a system administrator. This option allows dumping data without violating the policy.

- --rolepassword=ROLEPASSWORD

  Specifies the password of the specific role.

Notes

- gs_dumpall internally calls gs_dump. For details about the diagnosis information, see **gs_dump for Exporting Database Information**.
- After restoration, it is advised to run **ANALYZE** on each database so that the optimizer can provide useful statistics.
- gs_dumpall requires all needed tablespace directories to be empty before the restoration. Otherwise, database creation will fail if the databases are in non-default locations.

Examples

Use gs_dumpall to export all databases from a cluster at a time.

NOTE

gs_dumpall supports only plain-text format export. Therefore, only gsql can be used to restore a file exported using gs_dumpall.

- Export all databases.

  backup/bkp2.sql indicates the exported file, **29900** indicates the port number of the database server, and **omm** indicates the username.

```
gs_dumpall -U omm -f ./backup/bkp2.sql -p 29900
gs_dump[user='omm'][localhost][port='29900'][dbname='postgres'][2024-11-11 11:00:01]: The total objects number is 458.
gs_dump[user='omm'][localhost][port='29900'][dbname='postgres'][2024-11-11 11:00:01]: [100.00%] 458 objects have been dumped.
gs_dump[user='omm'][localhost][port='29900'][dbname='postgres'][2024-11-11 11:00:01]: dump database dbname='postgres' successfully
gs_dump[user='omm'][localhost][port='29900'][dbname='postgres'][2024-11-11 11:00:01]: total time: 3239  ms
gs_dumpall[user='omm'][localhost][port='29900'][2024-11-11 11:00:01]: dumpall operation successful
gs_dumpall[user='omm'][localhost][port='29900'][2024-11-11 11:00:01]: total time: 3305  ms
```

- Specify four jobs to concurrently export all databases.

```
gs_dumpall -U omm -f ./backup/bkp2.sql -p 29900 --parallel-jobs 4
gs_dump[user='omm'][localhost][port='29900'][dbname='postgres'][2024-11-11 11:04:13]: The total objects number is 458.
gs_dump[user='omm'][localhost][port='29900'][dbname='postgres'][2024-11-11 11:04:13]: [100.00%] 458 objects have been dumped.
gs_dump[user='omm'][localhost][port='29900'][dbname='postgres'][2024-11-11 11:04:13]: dump database dbname='postgres' successfully
gs_dump[user='omm'][localhost][port='29900'][dbname='postgres'][2024-11-11 11:04:13]: total time: 3261  ms
gs_dumpall[user='omm'][localhost][port='29900'][2024-11-11 11:04:13]: dumpall operation successful
gs_dumpall[user='omm'][localhost][port='29900'][2024-11-11 11:04:13]: total time: 3320  ms
```

- Export only global objects (roles and tablespaces).

```
gs_dumpall -U omm -f ./backup/bkp2.sql -p 29900 -g
gs_dumpall[user='omm'][localhost][port='29900'][2024-11-11 11:06:00]: dumpall operation successful
gs_dumpall[user='omm'][localhost][port='29900'][2024-11-11 11:06:00]: total time: 45  ms
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- Encrypt the exported files using AES-128.

  Replace ******** with the actual password.

```
gs_dumpall -U omm -f ./backup/bkp2.sql -p 29900 --with-encryption=AES128 --with-key='********'
gs_dump[user='omm'][localhost][port='29900'][dbname='postgres'][2024-11-11 11:07:20]: The total objects number is 459.
gs_dump[user='omm'][localhost][port='29900'][dbname='postgres'][2024-11-11 11:07:20]: [100.00%] 459 objects have been dumped.
gs_dump[user='omm'][localhost][port='29900'][dbname='postgres'][2024-11-11 11:07:21]: dump database dbname='postgres' successfully
gs_dump[user='omm'][localhost][port='29900'][dbname='postgres'][2024-11-11 11:07:21]: total time: 3518  ms
gs_dumpall[user='omm'][localhost][port='29900'][2024-11-11 11:07:21]: dumpall operation successful
gs_dumpall[user='omm'][localhost][port='29900'][2024-11-11 11:07:21]: total time: 3764  ms
```

Related Commands

gs_dump for Exporting Database Information and **gs_restore for Importing Data**

4.3.4 gs_restore for Importing Data

Description

gs_restore, provided by GaussDB, is used to import data that was exported using gs_dump. It can also be used to import files exported by gs_dump.

It has the following functions:

- Imports data to the database.

  If a database is specified, data is imported to the database. For parallel import, the password for connecting to the database is required.

- Imports data to an archive file.

  If the **-l** parameter is specified, an archive file containing a brief summary of the data is generated.

gs_restore supports SSL-encrypted communication. The method is the same as that of using gsql.

Prerequisites

Before using gs_restore, ensure that the gs_restore version is consistent with the gs_dump version and database version.

Precautions

- When gs_restore is used to restore data to a new database, the value of **rowid** in the hidden system column can be changed, the value of the sequence associated with the hidden column can be changed, and the user column data of the rowid type remains unchanged.

Syntax

```
gs_restore [OPTION]... FILE
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- The **FILE** does not have a short or long option. It is used to specify the location for the archive files.
- The **dbname** or **-l** option is required as prerequisites. Users cannot enter **dbname** and **-l** parameters at the same time.
- gs_restore incrementally imports data by default. To prevent data exception caused by consecutive imports, use the **-e** and **-c** parameters for each import. **-c** indicates that the database objects that already exist in the database to be restored are cleared (deleted) before the database objects are rebuilt. **-e** indicates that if an error occurs when an SQL statement is sent to the database, the system exits. By default, the system continues to import data and displays a series of error information after the import is complete.
- If the owner of the schema object has the OPRADMIN system permission, the initial user is required for the import.
- During data import, if invalid characters are found and do not need to be transcoded, you can set the database compatibility parameter **copy_special_character_version** to **'no_error'** to import the data. Otherwise, an error is reported but the import is not interrupted.
- The current design of gs_restore is incompatible with separation of duties. In separation of duties, gs_restore can be used only by the initial user. The file to be imported must also be executed by the initial user.

Parameters

Common parameters:

- -d, --dbname=NAME

  Connects to the **dbname** database and imports data to the database.

- -f, --file=FILENAME

  Specifies the output file for the generated archive, or the output file in the list specified using **-l**.

  The default is the standard output.

  NOTE

  -f cannot be used with **-d**.

- -F, --format=c|d|t

  Specifies the format of the archive. The format does not need to be specified because the gs_restore determines the format automatically.

  Value range:

  – **c/custom**: The archive form is the customized format in gs_dump.
  – **d/directory**: The archive format is **directory**.
  – **t/tar**: The archive format is **tar**.

- -l, --list

  Lists the formats of the archive. The operation output can be used for the input of the **-L** option.

  NOTE

  If filtering parameters, such as **-n** or **-t**, are used together with **-l**, they will restrict the listed items.

- -v, --verbose

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Specifies the verbose mode.

- -V, --version

  Prints the gs_restore version and exits.

- -?, --help

  Displays help information about gs_restore parameters and exits.

Import parameters:

- -a, --data-only

  Imports only the data, not the schema (data definition). gs_restore incrementally imports data.

- -c, --clean

  Cleans (deletes) existing database objects in the database to be restored before recreating them. If the target database does not contain the objects involved in the deletion operation, some promptive error information may be displayed.

  NOTE

  - None of the commands in the backup file for deleting database objects are cascading DROP commands.
  - At t1, database 1 is connected to export table 1 to the **backup01.dmp** file using the **-c** parameter. At t2, view 1 is created in database 1 and depends on table 1. At t3, **backup01.dmp** is restored to database 1 using the **-c** parameter of gs_restore. Non-cascading DROP is used. When table 1 is deleted, the error message "ERROR: table table cannot be dropped because other objects depend on it." is displayed, and when table 1 is created, the error message "ERROR: Relation "table1" already exists." is displayed. In this case, delete related dependent objects or execute the cascading DROP command after evaluating the impact.

- -C, --create

  Before data is imported to a database, CREATE DATABASE is used to create the database. (After this option is specified, the database specified by **-d** is only used to execute the **CREATE DATABASE** command, and all data is still imported to the created database.)

  NOTE

  This option is not supported in M-compatible databases. You must create a database in M-compatible mode on the target instance, export data from the source instance, and connect to the newly created M-compatible database on the target instance to import data.

- -e, --exit-on-error

  Exits if an error occurs when you send the SQL statement to the database. If you do not exit, the commands will still be sent and error information will be displayed when the import ends.

- -I, --index=NAME

  Imports only the definition of the specified index. Multiple indexes can be imported. Enter *-I index* multiple times to import multiple indexes.

  For example:

  ```
  gs_restore -h host_name -p port_number -d testdb -I Index1 -I Index2 backup/MPPDB_backup.tar
  ```

  In this example, **Index1** and **Index2** will be imported.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- -j, --jobs=NUM

  Specifies the number of concurrent, the most time-consuming jobs of gs_restore (such as loading data, creating indexes, or creating constraints). This parameter can greatly reduce the time to import a large database to a server running on a multi-processor machine.

  Each task may be a process or a thread, which is determined by the OS. Each task is connected to the server separately.

  The optimal value for this option depends on the server hardware settings, the client, the network, the number of CPU cores, and disk settings. It is recommended that the parameter be set to the number of CPU cores on the server. In addition, a larger value can also lead to faster import in many cases. However, an overly large value will lead to performance deterioration because of thrashing.

  This option supports the customized archive format only. The input file must be a regular file (not the pipe file). This parameter can be ignored when you select the script method rather than connecting to a database server. In addition, multiple jobs cannot be used with the **--single-transaction** option.

  NOTE

  - This parameter applies to multi-table, multi-index, and multi-constraint scenarios. In practice, the number of created processes (or threads) is related to the number of tables, indexes, and constraints. The maximum number of concurrent jobs does not exceed the specified number of jobs.
  - The specified number of parallel tasks cannot exceed twice the number of CPU cores on the client. When the client runs in a container, the number of CPUs obtained is the number of CPUs on the host, which may be greater than the number of CPUs that can be used by the container. You are advised to set the degree of parallelism to a value less than twice the number of CPUs that can be used by the client. Parallel import is implemented by concurrently executing multiple transactions through multiple processes. The actual degree of parallelism is limited by the thread pool model of the server and increases the pressure on the server. Set the degree of parallelism based on the actual needs. For example, the degree of parallelism cannot exceed the number of idle CPU cores on the client or the maximum number of connections on the server.

- -L, --use-list=FILENAME

  Imports only archive elements that are listed in **list-file** and imports them in the order that they appear in the file. If filtering parameters, such as **-n** or **-t**, are used with **-L**, they will further limit the items to be imported.

  list-file is normally created by editing the output of a previous **-l** parameter. File lines can be modified or removed, and can also be commented out by placing a semicolon (;) at the beginning of the row. An example is provided in this document.

- -n, --schema=NAME

  Restores only objects that are listed in schemas.

  This parameter can be used with the **-t** parameter to import a specific table.

  Entering **-n** *schemaname* multiple times can import multiple schemas.

  For example:

  ```
  gs_restore -h host_name -p port_number -d testdb -n sch1 -n sch2 backup/MPPDB_backup.tar
  ```

  In this example, **sch1** and **sch2** will be imported.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

> **NOTE**
>
> GaussDB automatically converts uppercase letters in object names to lowercase letters. If a schema name contains uppercase letters, add extra quotation marks, for example, -n '"Sch1"' or -n "\"Sch1\"".

- -O, --no-owner

  Do not output commands to set ownership of objects to match the original database. By default, gs_restore issues the ALTER OWNER or SET SESSION AUTHORIZATION statement to set ownership of created schema elements. Unless a system administrator or the user who has all the objects in the script initially connects to the database. Otherwise, the statement will fail. Any username can be used for the initial connection using **-O**, and this user will own all the created objects.

- -P, --function=NAME(args)

  Imports only listed functions. You need to correctly spell the function name and the parameter based on the contents of the dump file in which the function exists.

  Entering **-P** alone means to import all function-name(args) functions in a file. Entering **-P** with **-n** means to import the function-name(args) functions in a specified schema. Entering **-P** multiple times and using **-n** once means that all imported functions are in the **-n** schema by default.

  You can enter **-n schema-name -P 'function-name(args)'** multiple times to import functions in specified schemas.

  For example:

  ```
  ./gs_restore -h host_name -p port_number -d testdb -n test1 -P 'Func1(integer)' -n test2 -P 'Func2(integer)' backup/MPPDB_backup.tar
  ```

  In this example, both **Func1 (i integer)** in the **test1** schema and **Func2 (j integer)** in the **test2** schema will be imported.

- -s, --schema-only

  Imports only schemas (data definitions), instead of data (table content). The current sequence value will not be imported.

- -S, --sysadmin=NAME

  Reserved for function extension. The option is not recommended.

- -t, --table=NAME

  Imports only listed table definitions or data, or both. This parameter can be used with the **-n** parameter to specify a table object in a schema. When **-n** is not entered, the default schema is **PUBLIC**. Entering **-n** *schemaname* **-t** *tablename* multiple times can import multiple tables in a specified schema.

  For example:

  Import **table1** in the **PUBLIC** schema.

  ```
  gs_restore -h host_name -p port_number -d testdb -t table1 backup/MPPDB_backup.tar
  ```

  Import **test1** in the **test1** schema and **test2** in the **test2** schema.

  ```
  gs_restore -h host_name -p port_number -d testdb -n test1 -t test1 -n test2 -t test2 backup/MPPDB_backup.tar
  ```

  Import **table1** in the **PUBLIC** schema and **test1** in the **test1** schema.

  ```
  gs_restore -h host_name -p port_number -d testdb -n PUBLIC -t table1 -n test1 -t table1 backup/MPPDB_backup.tar
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTICE

- **-t** does not support the *schema_name.table_name* input format. If this format is specified, no error is reported but the setting does not take effect.
- When **-t** is specified, gs_restore does not import any other database objects that are attached to the selected table. Therefore, there is no guarantee that the results of a specific-table dump can be automatically imported to an empty database.
- **-t tablename** does not import trigger information from a table.

- -T, --trigger=NAME

  This parameter is reserved for extension.

- -x, --no-privileges/--no-acl

  Prevents the import of access permissions (**GRANT**/**REVOKE** commands).

- -1, --single-transaction

  Executes the import as a separate transaction.

  This option ensures that either all the commands are completed successfully, or no application is changed. This option means **--exit-on-error**.

- --disable-triggers

  Reserved for function extension. The option is not recommended.

- --log-level=LOG|DEBUG|DEBUG1|DEBUG2|DEBUG3

  Sets the log level of gs_restore. **LOG** records normal execution information, and **DEBUG** records some debugging information. A larger **DEBUG** value indicates a higher log level and more debugging details.

- --no-data-for-failed-tables

  By default, table data will be imported even if the statement to create a table fails (for example, the table exists). Data in such table is skipped using this parameter. This operation is useful if the target database already contains the desired table contents.

  This parameter takes effect only when you import data directly to a database, not when you output SQL scripts.

- --no-security-labels

  Reserved for function extension. The option is not recommended.

- --no-tablespaces

  Does not select any tablespaces. All the objects will be created during the import process, no matter which tablespace is selected when using this option.

- --no-transaction

  By default, statements such as CREATE, ALTER... OWNER TO, SET SESSION AUTHORIZATION, and RESET SESSION AUTHORIZATION are executed in a separate transaction block. If this option is enabled, these statements are executed directly without being wrapped in BEGIN/COMMIT.

- --section=SECTION

  Imports the listed sections (such as pre-data, data, or post-data).

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- --use-set-session-authorization

  This option is used for backing up the plain-text format.

  Generates the **SET SESSION AUTHORIZATION** statement as the output instead of the **ALTER OWNER** statement to determine object ownership. This parameter makes dump more standards-compatible. If the records of objects in exported files are referenced, import may fail. Only administrators can use the **SET SESSION AUTHORIZATION** statement to dump data, and the administrators must manually change and verify the passwords of exported files by referencing the **SET SESSION AUTHORIZATION** statement before import. The **ALTER OWNER** statement requires lower permissions.

- --pipeline

  Uses a pipe to transmit the password. This parameter cannot be used on devices.

NOTICE

- If any local additions need to add to the template1 database during the installation, restore the output of gs_restore into an empty database with caution. Otherwise, you are likely to obtain errors due to duplicate definitions of the added objects. To create an empty database without any local additions, copy data from template0 rather than template1. For example:

```
gaussdb=# CREATE DATABASE foo WITH TEMPLATE template0;
```

NOTE

- The **-d/--dbname** and **-f/--file** options do not coexist.
- The **-s/--schema-only** and **-a/--data-only** options do not coexist.
- The **-c/--clean** and **-a/--data-only** options do not coexist.
- When the **--single-transaction** option is used, **-j/--jobs** must be a single job.
- **--role** must be used with **--rolepassword**.

Connection parameters:

- -h, --host=HOSTNAME

  Specifies the host name. If the value begins with a slash (/), it is used as the UDS directory. The default value is taken from the *PGHOST* environment variable. If it is not set, a UDS connection is attempted.

  This parameter is used only for defining names of the hosts outside a cluster. For the localhost in the cluster, you can use IPv4 address **127.0.0.1** or IPv6 address **::1**.

  Environment variable: *PGHOST*

- -p, --port=PORT

  Specifies the TCP port listened on by the server or the local UDS file name extension to ensure a correct connection. The default value is the *PGPORT* environment variable.

  If the thread pool is enabled, you are advised to use the pooler port, that is, the listening port number plus 1.

  Environment variable: *PGPORT*

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- -U, --username=NAME

  Specifies the name of the connected user. The initial user cannot be used for cross-node execution.

  Environment variable: *PGUSER*

  > NOTE
  >
  > Before exporting and importing data as a common user, grant the permission to create schemas in the corresponding database to the common user, for example, **grant create on database db**_*xxx* **to user**_*xxx*.

- -w, --no-password

  Never issues a password prompt. The connection attempt fails if the server requires password for authentication and the password is not provided in other ways. This parameter is useful in batch jobs and scripts in which no user password is required.

- -W, --password=PASSWORD

  Specifies the user password for connection. If the authentication policy of the host is **trust**, the password of the system administrator is not verified. That is, you do not need to enter the **-W** parameter. If this parameter is not specified and you are not a system administrator, the system prompts you to enter the password in interactive mode. To ensure system security, you are advised to enter the password in interactive mode.

- --role=ROLENAME

  Specifies a role name for the import operation. If this parameter is selected, the SET ROLE statement will be issued after gs_restore connects to the database. It is useful when the authenticated user (specified by **-U**) lacks the permissions required by gs_restore. This parameter allows the user to switch to a role with the required permissions. Some installations have a policy against logging in directly as the initial user. This parameter allows data to be imported without violating the policy.

- --rolepassword=ROLEPASSWORD

  Specifies a role password for the import operation.

Examples

gs_restore is used to import the files exported by gs_dump.

- Example 1: Execute the gs_restore tool to import the exported **MPPDB_backup.dmp** file (custom format) to the **testdb** database.

  ```
  gs_restore backup/MPPDB_backup.dmp -p 8000 -d testdb
  restore operation successful
  total time: 13053  ms
  ```

- Example 2: Execute the gs_restore tool to import the exported **MPPDB_backup.tar** file (.tar format) to the **testdb** database.

  ```
  gs_restore backup/MPPDB_backup.tar -p 8000 -d testdb
  restore operation successful
  total time: 21203  ms
  ```

- Example 3: Execute the gs_restore tool to import the exported **MPPDB_backup** file (directory format) to the **testdb** database.

  ```
  gs_restore backup/MPPDB_backup -p 8000 -d testdb
  restore operation successful
  total time: 21003  ms
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- Example 4: Execute the gs_restore tool and import the **MPPDB_backup.dmp** file (in custom format). Specifically, import all the object definitions and data in the **PUBLIC** schema. Existing objects are deleted from the target database before the import. If an existing object references to an object in another schema, you need to manually delete the referenced object first.

```
gs_restore backup/MPPDB_backup.dmp -p 8000 -d testdb -e -c -n PUBLIC
Error while PROCESSING TOC:
Error from TOC entry 313; 1259 337399 TABLE table1 gaussdba
could not execute query: ERROR:  cannot drop table table1 because other objects depend on it
DETAIL:  view t1.v1 depends on table table1
HINT:  Use DROP ... CASCADE to drop the dependent objects too.
   Command was: DROP TABLE IF EXISTS public.table1;
```

  Manually delete the referenced object and create it again after the import is complete.

```
gs_restore backup/MPPDB_backup.dmp -p 8000 -d testdb -e -c -n PUBLIC
restore operation successful
total time: 2203  ms
```

- Example 5: Execute the gs_restore tool and import the **MPPDB_backup.dmp** file (in custom format). Specifically, import only the definition of **table1** in the **PUBLIC** schema.

```
gs_restore backup/MPPDB_backup.dmp -p 8000 -d testdb -e -c -s -n PUBLIC -t table1
restore operation successful
total time: 21000  ms
```

- Example 6: Execute the gs_restore tool and import the **MPPDB_backup.dmp** file (in custom format). Specifically, import only the data of **table1** in the **PUBLIC** schema.

```
gs_restore backup/MPPDB_backup.dmp -p 8000 -d testdb -e -a -n PUBLIC -t table1
restore operation successful
total time: 20203  ms
```

- Special case: Execute the gsql tool. Import the **MPPDB_backup.sql** file in the plain-text format exported using gs_dump or gs_dumpall to the **testdb** database.

```
-- In the following example, -f specifies an absolute file path, 8000 specifies the port number of the database server, and testdb specifies the name of the database to be accessed.
gsql -d testdb -p 8000 -f /home/omm/test/MPPDB_backup.sql
SET
SET
SET
SET
SET
ALTER TABLE
ALTER TABLE
ALTER TABLE
ALTER TABLE
ALTER TABLE
CREATE INDEX
CREATE INDEX
CREATE INDEX
SET
CREATE INDEX

5 Log Reference

5.1 Log Overview

During database running, a large number of logs are generated, including write-ahead logs (WALs, also called Xlogs) for ensuring database security and reliability and run logs and operation logs for daily database maintenance. If the database is faulty, you can refer to these logs to locate the fault and restore the database.

Log Type

The following table describes details about log types.

Table 5-1 Log types

Type	Description
System log	Logs generated during database running. They are used to record abnormal process information.
Operation log	Logs generated when a client tool (such as gs_guc) is operating databases.
Audit log	Logs used to record some of the database user operations after the database audit function is enabled.
WAL	Logs used to restore a damaged database. They are also called redo logs. You are advised to routinely back up WALs.
Memory log	Logs used to save the memory context statistics when the dynamic memory usage of the database process exceeds 90%.

	gtm_ctl-*Creation time*-current.log	*$GAUSSLOG*/bin/gtm_ctl
	gs_redis-*Creation time*-current.log	*$GAUSSLOG*/bin/gs_redis
Audit log	–	The default path is *$GAUSSLOG*/**pg_audit**. (If the OM tool is used for cluster deployment, the audit log path is *$GAUSSLOG*/**pg_audit/***instance name*.) The GUC parameter **audit_directory** can be used to configure the path.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Log Category	Log Name	Log Path
WAL	pg_xlog	*Data directory*/**pg_xlog**, for example, **/gaussdb/data/data_dn/pg_xlog** in a DN instance. **/gaussdb/data/data_dn** indicates the data directory of the cluster node.
Memory log	mem_log-*Creation time*.log	*$GAUSSLOG*/mem_log

5.2 System Logs

System logs include those generated by CNs and DNs, GTMs, and CMs during cluster running, and those generated when the cluster is deployed. If an error occurs during cluster running, you can locate the cause and troubleshoot the error based on system logs.

Log Storage Directory

Run logs of CNs, DNs, and GTMs are stored in the corresponding folders in the *$GAUSSLOG*/**gs_log** directory.

Logs of CMs (including the CM Agent, CM Server, cm_ctl, OM Monitor, and ETCD) are stored in the corresponding folders in the *$GAUSSLOG*/**cm** directory.

Logs generated during OM cluster installation and uninstallation are stored in the *$GAUSSLOG*/**om** directory.

Log Naming Rules

- The name format of CNs and DNs run logs is:

  gaussdb-*Creation time***.log**

  By default, a new log file is generated at 0:00 every day, or when the latest log file exceeds 16 MB or a cluster (CNs and DNs) is restarted.

  system_alarm-*Creation time***-current.log**
- The name format of GTM run logs is:

  gtm-*Creation time***.log**

  By default, a new log file is generated when the latest log file exceeds 16 MB or a GTM is restarted.
- The name formats of CM logs are:
  - CM Agent logs: **cm_agent-***Creation time***.log**, **cm_agent-***Creation time***-current.log**, **system_alarm-***Creation time***-current.log**, **system_call-current.log**, **system_stat-current.log**, and **gaussdb-***Creation time*_**000000.log**.
  - CM Server logs: **cm_server-***Creation time***.log**, **cm_server-***Creation time***-current.log**, **key_event-***Creation time***-current.log**, and **system_alarm-***Creation time***-current.log**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- cm_ctl logs: **cm_ctl-***Creation time***-current.log**.
- OM Monitor logs: **om_monitor-***Creation time***.log**, **om_monitor-***Creation time***-current.log**, and **system_alarm-***Creation time***-current.log**.

Logs whose names do not contain **current** are historical log files. Logs whose names contain **current** are current log files. When a process is called for the first time, a log file whose name contains **current** is created. If the size of this file exceeds 16 MB, the file is renamed in the historical log file name format, and a new log file is generated at the current time point.

NOTE

- Logs with prefixes cm_agent, cm_server, cm_ctl, and om_monitor are run logs of CM Agent, CM Server, cm_ctl, and OM Monitor respectively.
- Logs with the prefix system_alarm record the alarm reporting and clearance of cluster running exceptions in the CM Agent, CM Server, and OM Monitor.
- Logs with the prefix key_event are key event logs of the CM Server that record information about CM Server arbitration.
- Logs with the prefix system_call record the calling of tool commands when the CM Agent is running.
- Logs with the prefix system_stat record the disk I/O performance of the current system when the CM Agent is running.
- Logs with the prefix gaussdb are run logs when the fenced mode is enabled.
- Log names depend on the system timestamp. The database compresses old logs based on the time. If the system time is reversed, the log files that are being written may be compressed in advance. As a result, the log files cannot be written. In this case, you need to clear the logs at future time points for restoration.

Log Content Description

- The default format of each line of log content for CNs and DNs is as follows:

  Date+Time+Node name+Username+Database name+IP address+Session ID +Transaction ID+Application name+Log level+Log content

Table 5-3 Log parameters on CNs and DNs

Column	Description
Date	Date when a log is generated. The format is yyyy-mm-dd.
Time	Time when a log is generated. The format is hh:mm:ss:ms.
Node name	Node to which an error is reported.
Username	Name of the user who triggers log generation.
Database name	Name of the database that triggers log generation.
IP address	IP address of the client that triggers log generation.
Thread ID	Thread ID.
Session ID	ID of the session that triggers log generation.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Column	Description
Transaction ID	Transaction ID (**0** indicates that no transaction ID is assigned).
Thread name	Thread name.
Query ID	**query_id** indicates the ID of a query initiated by a user which is recorded in the background.
Module name	Module name.
Log level	Different log levels, such as **FATAL**, **ERROR**, and **LOG**, indicate different severities.
Log content	Log content.

- Content of a line in a GTM log:

  Log line No.+Thread ID+Date+Time+Log level+Log content

  Table 5-4 GTM log parameters

Column	Description
Log line No.	Number of the line where the log content is located in the log, because the current log may contain multiple lines.
Thread ID	ID of the thread that generates the log.
Date	Date when a log is generated. The format is yyyy-mm-dd.
Time	Time when a log is generated. The format is hh:mm:ss:ms.
Log level	Different log levels, such as **FATAL**, **ERROR**, and **LOG**, indicate different severities.
Log content	Log content.

- The content of a line in a CN or DN system_alarm log: Alarm ID+Alarm name +Alarm severity+Host scope list+Alarm source tag+Alarm operation type +Alarm description+Clearance type+Start timestamp+End timestamp. For details about log parameters, see **Table 5-5**.

  Table 5-5 system_alarm log parameters of the CN, DN, CM Agent, CM Server, and OM Monitor

Field Name	Field Name	Description
id	Alarm ID	Alarm ID.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Field Name	Field Name	Description
name	Alarm name	Alarm name.
level	Alarm severity	Different alarm severities indicate different severities, including **critical**, **major**, **minor**, and **notice**.
scope	Host scope list	Host scope list. Alarm platform that uses NewSQL. The value is fixed to **newsql**.
source_tag	Alarm source tag	Alarm source tag.
op_type	Alarm operation type	Operation type of an alarm. • **firing** indicates that an alarm is reported. If the value is **firing**, the log contains the alarm description and clearance type. • **resolved** indicates that the alarm is cleared. If the value is **resolved**, the log does not contain the alarm description and clearance type.
details	Alarm description	Detailed information about an alarm.
clear_type	Alarm clearance type	Type of alarm clearance. The options are **ADAC** and **ADMC**. • **ADAC**: The system can automatically detect the occurrence and rectification of the fault. • **ADMC**: The system can automatically detect the occurrence of the fault, but cannot detect the rectification of the fault.
start_timestamp	Start timestamp	Time when an alarm starts. • When the alarm is reported, **start_timestamp** has a value, and the value of **end_timestamp** is **0**. • When the alarm is cleared, the value of **start_timestamp** is **0**, and **end_timestamp** has a value.
end_timestamp	End timestamp	Time when an alarm ends.

- The content of the CM Agent, CM Server, cm_ctl, and OM Monitor logs is as follows:
  - The content of a line in a run log of the CM Agent, CM Server, cm_ctl, or OM Monitor: Date+Time+Thread ID+Thread name+Log level+Log content.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- The content of a line in a system_alarm log of the CM Agent, CM Server, or OM Monitor: Alarm ID+Alarm name+Alarm severity+Host scope list +Alarm source tag+Alarm operation type+Alarm description+Clearance type+Start timestamp+End timestamp.
- The content of a line in a key_event log of the CM Server: Date+Time +Thread ID+Thread name+Key event type+Arbitration object instance ID +Arbitration details.
- Most contents in a system_call log of the CM Agent: Date+Time+Node name+Username+Database name+IP address+Session ID+Transaction ID +Application name+Log level+Log content. For details about log parameters, see **Table 5-3**.
- The content of a system_stat log of the CM Agent: Time+OS+CPU information+Disk read/write status.

Table 5-6 Run log parameters of the CM Agent, CM Server, cm_ctl, and OM Monitor

Column	Description
Date	Date when a log is generated. The format is yyyy-mm-dd.
Time	Time when a log is generated. The format is hh:mm:ss:ms.
Thread ID	ID of the thread that generates the current log.
Thread name	Name of the thread that generates the current log. (This parameter does not exist in cm_ctl and OM Monitor run logs.)
Log level	Different log levels, such as **LOG**, **WARNING**, **ERROR**, and **FATAL**, indicate different severities.
Log content	Log content.

Table 5-7 key_event log parameters of the CM Server

Column	Description
Date	Date when a log is generated. The format is yyyy-mm-dd.
Time	Time when a log is generated. The format is hh:mm:ss:ms.
Thread ID	ID of the thread that generates the current log.
Thread name	Name of the thread that generates the current log.
Key event type	Type of a key event. The format is [KeyEvent: xxxx].

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Column	Description
Key event object instance ID	Object of a key event. The format is [Instance: xxxx].
Key event details	Details of a key event. The format is [Details: xxxx].

Table 5-8 system_stat log parameters of the CM Agent

Column	Description
Time	Time when a log is generated, in CST format.
OS	OS of a host.
CPU information	CPU usage. It includes the following information: ● **%user**: percentage of the time when the CPU is in user mode. ● **%nice**: percentage of the time when the CPU is in user mode with the NICE value. ● **%system**: percentage of the time when the CPU is in system mode. ● **%iowait**: percentage of the time that the CPU waits for input and output completion. ● **%steal**: percentage of the time that the virtual CPU waits involuntarily for the management program maintaining another virtual processor. ● **%idle**: percentage of CPU idle time.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Column	Description
Disk read/write	Disk I/O information. It includes the following information: • **rrqm/s**: number of read requests merged per second, that is, the number of times that read requests are merged into larger blocks. • **wrqm/s**:number of write requests merged per second, that is, the number of times that write requests are merged into larger blocks. • **r/s**: number of read requests completed per second. • **w/s**: number of write requests completed per second. • **rMB/s**: amount of data read per second. The unit is MB/s. • **wMB/s**: amount of data written per second. The unit is MB/s. • **r_await**: average waiting time of each read request, in milliseconds. • **w_await**: average waiting time of each write request, in milliseconds. • **%util**: disk usage, that is, the percentage of the time that the disk is occupied by disk I/O operations. • **%rrqm**: percentage of read requests that are merged before being sent to the device. • **%wrqm**: percentage of write requests that are merged before they are sent to the device. • **rareq-sz**: average size of read requests sent to the device, in KB. • **wareq-sz**: average size of write requests sent to the device, in KB. • **d/s**: number of discard requests processed by the device per second. • **dMB/s**: number of sectors discarded by the device per second. • **drqm/s**: number of discard requests merged into the device queue per second. • **%drqm**: percentage of discard requests that are merged before being sent to the device. • **d_await**: average time for sending discard requests to the device to be served. • **dareq-sz**: average size of discard requests sent to the device, in KB.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Column	Description
	• **f/s**: number of refresh requests processed by the device per second (after merge). • **f_await**: average time for sending refresh requests to the device to be served. • **aqu-sz**: average queue length of requests sent to the device.

Log Examples

- CNs and DNs
  - A typical run log is as follows:
    ```
    2023-09-14 21:28:52.647 dn_6001 rdsAdmin postgres localhost 139983342597888 0[0:0#0] 0 dn_6001 0 [BACKEND] LOG:  will update control file (create checkpoint), shutdown:0
    ```
  - A typical system_alarm log is as follows:
    ```

    ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

  - A typical system_alarm log is as follows:
    ```
    {"id":"0000001078919258","name":"ServerSwitchOver","level":"minor","scope":["newsql"],"source_tag":"pekphis351066-server_1","op_type":"firing","details":"Server standby server_1 switch over","clear_type":"ADMC","start_timestamp":1693031871104,"end_timestamp":0}
    ```
  - A typical key_event log is as follows:
    ```
    2023-09-04 15:45:10.468 tid=95440 AGENT_WORKER: [KeyEvent: KEY_EVENT_SWITCHOVER] [Instance: 6001] [Details: send switchover message, node=1, instance=6001]
    ```
- cm_ctl
  - A typical run log is as follows:
    ```
    2023-08-28 16:39:54.113 tid=72942  LOG: set cm_server.conf success.
    ```
- om_monitor
  - A typical run log is as follows: (The CM Agent startup check is complete, the files **cluster_manual_start**, **agent_config_file_r**, and **agent_binary_file_x** exist, the **config_change_flag** file does not exist, the CM Agent process did not exist, and the number of times that the CM Agent is started is 0.)
    ```
    2023-09-05 10:50:41.044 tid=100802  LOG: The CM Agent startup check is complete: cluster_manual_start=1, agent_config_file_r=1, agent_binary_file_x=1, config_change_flag=0, previous_status=0, start_count=0.
    ```
  - A typical system_alarm log is as follows:
    ```
    {"id":"0000001078919226","name":"AbnormalCMAProcess","level":"critical","scope":["newsql"],"source_tag":"pekphis351066-cma","op_type":"resolved","start_timestamp":0,"end_timestamp":1692953836127}
    ```

Log Discarding Mechanism

When an exception occurs during system log writing (for example, the log disk is faulty or overloaded), the system retries to write the log (the default retry timeout interval is 60 seconds). If the retry still fails, the system discards the log to prevent services from being affected by log writing blocking. When a log is discarded, the following alarm information is recorded in the OS log: "WARNING: logger pipe write failed, dropped a log message."

5.3 Operation Logs

Operation logs are generated when database tools are used by a database administrator or called by a cluster. If the cluster is faulty, you can backtrack user operations on the database and reproduce the fault based on the operation logs.

Log Storage Directory

The default paths are *$GAUSSLOG*/**om** and *$GAUSSLOG*/**bin**. If the environment variable *$GAUSSLOG* does not exist or its value is empty, the logs generated for a tool will be displayed, but not recorded in the log file of the tool.

Log Naming Rules

The log file name format is as follows:

- *tool name-log creation time*.**log**
- *tool name-log creation time*-**current.log**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

tool name-log creation time.**log** is a historical log file, and *tool name-log creation time*-**current.log** is a current log file.

If the size of a log file exceeds 16 MB, the next time the tool is called, the log file is renamed in the historical log file name format, and a new log file is generated at the current time point. For example, **gs_guc-2015-01-16_183728-current.log** is renamed as **gs_guc-2015-01-16_183728.log**, and **gs_guc-2015-01-17_142216-current.log** is generated.

Log Content Description

- Logs of OM tools, including gs_install, gs_preinstall, gs_om, gs_expand, gs_replace, gs_local, checkRunStatus (API for checking O&M operating status), JsonToDbclusterInfo (a tool used to convert cluster topology files in JSON format to XML files), killall_log, uploader (PSCP tool), and cmd_sender (PSSH tool). The content of each log line is as follows:

  Call chain ID+Date and time+Thread ID+Location where the log is reported +Thread name+Log level+[Step*]+Log content

  Table 5-9 Log parameters of tools or components contained in the OM

Column	Description
Call chain ID	ID of the call chain.
Date and time	Date and time when a log is generated. The format is yyyy-mm-dd hh:mm:ss.ms.
Thread ID	ID of the thread that generates the log.
Location where the log is reported	Number of the line where the log content is located in the executed file. The current log may contain multiple lines.
Thread name	Name of the thread that generates the log.
Log level	Different log levels, such as **LOG**, **DEBUG**, **WARNING**, and **ERROR**, indicate different severities.
Step*	ID of the step executed at the current time.
Log content	Log content.

- Content of a line in a gs_initdb log:

  Date+Time+Log level+Log content

  Table 5-10 gs_initdb log parameters

Column	Description
Date	Date when a log is generated. The format is yyyy-mm-dd.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Column	Description
Time	Time when a log is generated. The format is hh:mm:ss.
Log level	Different log levels, such as **LOG**, **WARNING**, **ERROR**, and **FATAL**, indicate different severities.
Log content	Log content.

- Content of a line in a gs_guc log:
  Date+Time+Log content

  Table 5-11 gs_guc log parameters

Column	Description
Date	Date when a log is generated. The format is yyyy-mm-dd.
Time	Time when a log is generated. The format is hh:mm:ss.
Log content	Log content.

- Content of a line in a gs_cgroup log:
  Call chain ID+Date and time+Thread ID+Location where the log is reported +Thread name+Log level+Log content

  Table 5-12 gs_cgroup log parameters

Column	Description
Call chain ID	ID of the call chain.
Date and time	Date and time when a log is generated. The format is yyyy-mm-dd hh:mm:ss.ms.
Thread ID	ID of the thread that generates the log.
Location where the log is reported	Number of the line where the log content is located in the executed file. The current log may contain multiple lines.
Thread name	Name of the thread that generates the log.
Log level	Different log levels, such as **LOG**, **DEBUG**, **WARNING**, and **ERROR**, indicate different severities.
Log content	Log content.

- Content of a line in a gs_clean log:
  Date+Time+Log content

Log Examples

- A typical OM tool log is as follows:
  ```
  [220822164bc111ee9466fa163e8dd000][2023-09-05 08:02:11.098083][11214]
  [InstallImpl.py(doStart:864)][gs_install][DEBUG][Step7]:Successfully started the cluster.
  ```
- A typical gs_initdb log is as follows:
  ```
  [2023-09-05 07:57:01]

  WARNING: enabling "trust" authentication for local connections
  You can change this by editing gs_hba.conf or using the option -A, or
  --auth-local and --auth-host, the next time you run gs_initdb.
  ```
- A typical gs_guc log is as follows:
  ```
  [2023-09-05 09:05:06]
  Begin to perform the total nodes: 3.
  Popen count is 3, Popen success count is 3, Popen failure count is 0.
  Begin to perform gs_guc for datanodes.
  [2023-09-05 09:05:07]
  expected instance path: [/var/lib/engine/data1/data/dn_6001/gaussdb.conf]
  expected instance path: [/var/lib/engine/data1/data/dn_6005/gaussdb.conf]
  gs_guc reload: key=value: [/var/lib/engine/data1/data/dn_6001/gaussdb.conf]
  server signaled
  gs_guc reload: key=value: [/var/lib/engine/data1/data/dn_6005/gaussdb.conf]
  server signaled

  Total instances: 2. Failed instances: 0.
  Success to perform gs_guc!

  Command count is 3, Command success count is 3, Command failure count is 0.

  Total instances: 6. Failed instances: 0.
  ALL: Success to perform gs_guc!
  ```
- A typical gs_cgroup log is as follows:
  ```
  [de86987e4bc011eeb3befa163e8dd000][2023-09-05 15:51:49.372997][947]
  [PreInstallUtility.py(setCgroup:1793)][gs_cgroup][DEBUG]:The gs_cgroup run with the following
  arguments: [/var/chroot/usr/local/package/dependency/bin/gs_cgroup -U Ruby --upgrade -c -H /var/
  chroot/usr/local/tool/Ruby ].
  '/sys/fs/cgroup/cpu,cpuacct/CM:Ruby' exists, omit to create this cgroup.
  '/sys/fs/cgroup/cpu,cpuacct/CM:Ruby' exists, omit to create this cgroup.
  ```
- A typical gs_clean log is as follows:
  ```
  2023-09-05 09:06:57  gs_clean: connected successfully
  ```
- A typical gs_ctl log is as follows:
  ```
  [2023-09-05 08:00:59.538][4053][dn_6004_6005_6006][gs_ctl]: finish fsync all files.
  ```
- A typical gs_initgtm log is as follows:
  ```
  [2023-09-05 09:05:06] gs_initgtm: input file location must be an absolute path.
  ```
- A typical gs_obs log is as follows:
  ```
  2025-01-21 11:06:42.867| INFO|[140565224322816]|Enter complete_multi_part_upload successfully !
  ```
- A typical gtm_ctl log is as follows:
  ```
  [2023-09-05 08:00:40]
   Set GTM syncmode succeeded.
  ```
- A typical gs_redis log is as follows:
  ```
  2023-09-05 08:53:01  1693903981339 worker 140463824475904
  [snapshot.snap_summary_stat_all_indexes] step[2]: END successfully
  ```

Maintenance Suggestion

You are advised to dump expired logs periodically to save disk space and prevent important logs from being lost.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

5.4 Audit Logs

CREATEROLE can use the audit logs to reproduce a series of events that cause faults in the database and identify unauthorized users, unauthorized operations, and the time when these operations are performed. After the audit function is enabled, a large number of audit logs will be generated, which occupy large storage space. You can customize an audit log maintenance policy based on the size of available storage space.

Log Storage Directory

Audit logs are stored in *$GAUSSLOG*/**pg_audit/** by default. If **om** is used for cluster deployment, they are stored in *$GAUSSLOG*/**pg_audit/***Instance name*. The log storage path can be specified by the GUC parameter **audit_directory**.

Log Query Methods

Only users with the AUDITADMIN permission can view audit records. The query methods are as follows:

- Query traditional audit records.
  ```
  gaussdb=# SELECT * FROM gs_query_audit('2021-03-03 21:30:00', '2021-03-03 22:00:00') where type = 'login_success' and username = 'user1';
  ```
- Query traditional audit records of all CNs.
  ```
  gaussdb=# SELECT * FROM gs_query_audit_dist('2021-03-03 21:30:00', '2021-03-03 22:00:00') where type = 'login_success' and username = 'user1';
  ```
- Query unified audit records.

```
gaussdb=# SELECT * FROM gs_query_unified_audit('2025-04-26 08:00:00','2025-04-26 17:00:00')where type = 'login_success' and username = 'user1';
```

The difference between the values of the **starttime** and **endtime** parameters indicates the query period, which can be any value ranging from 00:00:00 of the **starttime** parameter to 23:59:59 of the **endtime** parameter. Therefore, the **startime** and **endtime** parameters must be properly set to ensure that the required audit information is displayed.

Log Content Description

For details about the columns in the log, see the definitions of the gs_query_audit function in **Table 5-19**.

Table 5-19 Traditional audit log parameters

Parameter	Description
time	Operation time.
type	Operation type.
result	Operation result.
userid	User ID

Parameter	Description
unified_audit_policy	Unified audit policy information.

5.5 WALs

In a system using Write-ahead logs (WALs or Xlogs), all data file modifications are written to a log before they are applied. That is, corresponding logs must be written into a permanent device before a data file is modified. You can use WALs to restore the cluster if the system crashes. WALs can be recorded at different levels, which are specified by the **wal_level** parameter.

Log Running Mechanism

When GaussDB is started, a memory segment is allocated to cache logs generated during database running. The buffer size is specified by the **wal_buffers** parameter. To ensure transaction persistence, logs in **wal_buffers** must be flushed to disks.

WALs are written to disks in the following scenarios:

- Commit a transaction using COMMIT. The system calls the fdatasync function to write WAL data in **wal_buffers** to WAL files. (**wal_sync_method** specifies the function called during commit. The default value is **fdatasync**.)
- WAL writer periodically writes data. The WAL writer process periodically writes WAL data in **wal_buffers** to WAL files. The **wal_writer_delay** parameter specifies the interval at which the WAL writer process works. The default value is **200**, in ms. A longer delay might lead to insufficient WAL buffer and a shorter delay leads to continuously writing of the WALs, thereby increasing the load of disk I/O.

Log Storage Directory

The path is *Data directory*/**pg_xlog**.

- The WAL storage path of CNs is **/***<CN data directory>*/**pg_xlog**. The default size of a WAL file is 16 MB, which is specified by the **wal_segment_size** parameter. Generally, you do not need to change the size.

```
gaussdb=# SHOW wal_segment_size;
wal_segment_size
-----------------
16MB
(1 row)
```

- The following uses one DN as an example. You can run the following command to query the data directory: **/opt/gaussdb/data/dn/db_6001** indicates the data directory of the cluster node. Xlogs on the current node are stored in the **/opt/gaussdb/data/dn/db_6001/pg_xlog** directory.

```
$ cm_ctl query -Cvd
[    CMServer State    ]
node                        instance              state
--------------------------------------------------------------------------
1    192.168.10.182    1    /opt/gaussdb/data/cm/cm_server    Primary
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
[   Cluster State   ]

cluster_state  : Normal
redistributing : No
balanced       : Yes
current_az : AZ_ALL

[    Datanode State    ]

node                        instance               state
--------------------------------------------------------------------------
1    192.168.10.182 6001    /opt/gaussdb/data/dn/dn_6001 P Primary Normal
```

Log Naming Rules

WALs are saved as segment files. Each segment is 16 MB and is divided into multiple 8 KB pages. The name of a segment file consists of 24 hexadecimal characters. The name of a WAL file consists of the timeline, log file identifier, and log file segment identifier. For details, see **Table 5-21**.

The upper limit of the segment identifier of a WAL file is **FF**. If there is another WAL file, add 1 to the file identifier and reset the segment identifier to **0**. For example, the next file of 000000010000000000000FF is 000000010000000100000000. The timeline starts from 1, and the log file identifier and the segment identifier of the file both start from 0.

Table 5-21 WAL file naming rules

Column	Description
Timeline	Time line The value is an 8-digit hexadecimal number.
wal_file_num	Identifier of a WAL file The value is an 8-digit hexadecimal number.
wal_segment_num	Identifier of a WAL file segment The value is an 8-digit hexadecimal number.

The size of each WAL file is 16 MB. Typical WAL file names are as follows:

```
-rW----- 1 gaussdb d gaussdb d 16777216 Jun 11   12:33 000000010000000001000000F2
-rW----- 1 gaussdb d gaussdb d 16777216 Jun 11   18:10 000000010000000001000000F3
-rW----- 1 gaussdb d gaussdb d 16777216 Jun 11   22:18 000000010000000001000000F4
-rW----- 1 gaussdb d gaussdb d 16777216 Jun 12  03:58 000000010000000001000000F5
-rW----- 1 gaussdb d gaussdb d 16777216 Jun 12  07:59 000000010000000001000000F6
-rW----- 1 gaussdb d gaussdb d 16777216 Jun 12  13:45 000000010000000001000000F7
-rW----- 1 gaussdb d gaussdb d 16777216 Jun 12  17:30 000000010000000001000000F8
-rW----- 1 gaussdb d gaussdb d 16777216 Jun 12  23:10 000000010000000001000000F9
-rW----- 1 gaussdb d gaussdb d 16777216 Jun 13  03:10 000000010000000001000000FA
-rW----- 1 gaussdb d gaussdb d 16777216 Jun 13  08:39 000000010000000001000000FB
-rW----- 1 gaussdb d gaussdb d 16777216 Jun 13  12:43 000000010000000001000000FC
-rW----- 1 gaussdb d gaussdb d 16777216 Jun 13  17:08 000000010000000001000000FD
-rW----- 1 gaussdb d gaussdb d 16777216 Jun 13  16:32 000000010000000001000000FE
```

NOTE

The numbers in the WAL file name are used in ascending order in succession. Exhausting all available numbers takes a long time, and the numbers will start from zero again after they reach the maximum.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Log Content Description

The content of WALs depends on the types of recorded transactions. WALs can be used to restore a system after the system breaks down.

By default, GaussDB reads WALs for system restoration during each startup.

Log Application Scenario

Database recovery: When a database crashes unexpectedly, database changes have been recorded in Xlogs. After the database is restarted, the Xlogs after the checkpoint can be replayed to flush the modified data pages (recorded in the Xlogs but not modified in the data files) to disks, ensuring data integrity. This process is automatically completed after the database is started.

Data synchronization between the primary and standby DNs: The standby DN of GaussDB receives Xlogs from the primary DN and applies Xlogs to ensure data consistency between the primary and standby DNs. Data synchronization between the primary and standby databases can also be implemented using Xlogs.

Database backup and restoration: When GaussRoach is used to back up GaussDB, you need to copy data files and Xlogs generated during the backup to form a complete backup. You can use a full backup or an incremental backup and Xlogs to restore data to a specified point in time, that is, perform point-in-time recovery (PITR).

Logical replication: Logical replication tools, such as DRS, parse Xlogs to obtain data streams for incremental data synchronization.

Xlog Recycling

During database running, Xlogs are continuously generated. GaussDB clears Xlogs using the checkpoint mechanism (also called Xlog recycling). For details about the parameters related to Xlog recycling, see **Table 5-22**. For details about how to set parameters, see **Setting Parameters**.

Table 5-22 Parameters related to Xlog recycling

Parameter	Description
checkpoint_timeout	Sets the maximum time between automatic checkpoints. Specifically, this is the interval for the next automatic checkpoint after the last automatic checkpoint. The default value is 15 minutes. If the number of Xlogs accumulated between two automatic checkpoints is greater than the value of **checkpoint_segments**, an automatic checkpoint is triggered.
checkpoint_segments	Maximum number of WAL files that can be retained within the interval specified by **checkpoint_timeout**. The size of each log file is 16 MB.
enable_incremental_checkpoint	Specifies whether to enable incremental checkpointing. The default value is **on**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Description
incremental_checkpoint_timeout	Specifies the maximum interval between automatic checkpoints when the incremental checkpoint (enable_incremental_checkpoint) is enabled. The default value is 1 minute. That is, an incremental checkpoint is started every minute, and whether Xlogs need to be cleared is checked.
wal_keep_segments	Specifies the minimum number of Xlog files that can be retained in the **pg_xlog** directory. The standby node obtains the Xlogs from the primary node to perform streaming replication. The default value is **128**. Generally, when executing a checkpoint, the database checks whether the number of Xlogs in the **pg_xlog** directory is greater than the value of **wal_keep_segments**. If the number is greater than the value of **wal_keep_segments**, the database deletes the earliest Xlogs until the number of Xlogs is equal to the value of **wal_keep_segments**.
enable_xlog_prune	Specifies whether the primary node recycles logs when any standby node is disconnected and the size of Xlogs exceeds the value of max_size_for_xlog_prune. The value **on** indicates that the functionality is enabled. When a standby node is disconnected, Xlogs between the primary and standby DNs are not cleared to ensure that Xlogs are continuous. However, if **enable_xlog_prune** is enabled and the accumulated Xlog size is greater than the value of **max_size_for_xlog_prune** (generally 256 GB), Xlogs are cleared.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Description
max_size_for_xlog_prune	Maximum number of Xlogs retained on the primary node when the standby node is faulty. This parameter takes effect when **enable_xlog_prune** is enabled. The mechanism is as follows: 1. If all standby nodes specified by the replconninfo series GUC parameters are connected to the primary node, this parameter does not take effect. 2. This parameter takes effect when one or more standby nodes specified by the replconninfo series GUC parameters are disconnected from the primary node. If the number of Xlogs on the primary node is greater than the value of this parameter, the Xlogs will be forcibly recycled. Exception: In synchronous commit mode (that is, the **synchronous_commit** parameter is not set to **local** or **off**), if there are standby nodes connecting to the primary node, the primary node retains the logs after the minimum log receiving location in the majority of standby nodes. In this case, the number of retained logs may be greater than the value of **max_size_for_xlog_prune**. 3. If a standby node is being built, this parameter does not take effect. All logs on the primary node are retained to prevent failures caused by log recycling during the build operation.

Maintenance Suggestion

WALs are important for database restoration. You are advised to routinely back up WALs.

5.6 Memory Logs

Memory logs record memory context statistics generated when the dynamic memory usage of a database process exceeds the specified threshold, the dynamic memory fluctuation exceeds the specified threshold, or the statistical period reaches the specified value. The GUC parameter **memory_trace_level** determines whether to record memory logs. By default, level-1 logs are recorded. The GUC parameter **memory_log_config** is used to set more functions, such as the dynamic memory usage percentage threshold, memory fluctuation percentage threshold, statistical period, number of top memory contexts, and number of top SQL statements.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- An anti-oscillation mechanism is provided for generating memory logs. When the dynamic memory usage exceeds the threshold (specified by the first part of the **memory_log_config** parameter), the dynamic memory used for generating memory logs is recorded as the trigger memory. If the dynamic memory usage is continuously greater than the trigger memory minus 5% of dynamic memory upper limit, no memory log is generated because the dynamic memory usage exceeds the threshold. This prevents repeated log generation when the dynamic memory usage fluctuates slightly around the threshold.
- The memory context snapshot generation based on the memory fluctuation percentage (set in part 2 of the **memory_log_config** parameter) is based on a 3-second detection period. If the snapshot generation conditions are met within the 3-second detection period, no memory context snapshot is generated.
- Memory threshold triggering, memory fluctuation triggering, and periodic triggering cannot be performed together.
- Only the memory contexts in the format of *{Module name}_{Number}* can be combined by module name. If the memory contexts do not meet the requirement, they are not combined. For example, **pooler_memory_context**, **pooler_core_context**, and **pooler_agent_context** are three different memory contexts and are not combined.

Log Storage Directory

The memory logs of the database node are stored in the *$GAUSSLOG*/**mem_log** directory.

Log Naming Rules

The name format of database node memory logs is: **mem_log-***creation time*.**log**

Log Content Description

Detailed usage statistics of the global memory context, session-level memory context, and thread-level memory context of the database process, including the top 20 session-level and thread-level memory usage, corresponding client types, and SQL statements. If parallel logical decoding tasks are running, the log also contains the memory usage information of parallel logical decoding.

Top *n* memory contexts of each type, top *n* memory contexts of each query (specified by the fourth part of the **memory_log_config** parameter), and top *n* queries (specified by the fifth part of the **memory_log_config** parameter) are displayed based on the memory usage.

Table 5-23 Log parameters

Column	Description
Max_dynamic_memory	Maximum dynamic memory that can be used by the database process.
Dynamic_used_memory	Size of the dynamic memory used by the current process.
Dynamic_peak_memory	Historical maximum dynamic memory usage of the current process.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Column	Description
Dynamic_thread_cxt_used_memory	Size of the memory used by the thread-level memory context of the current process.
Dynamic_session_cxt_used_memory	Size of the memory used by the session-level memory context of the current process. This parameter is displayed only when the thread pool is enabled.
Dynamic_used_shrctx	Size of the memory occupied by the global memory context of the current process.
Dynamic_peak_shrctx	Historical maximum size of the memory occupied by the global memory context of the current process.
Max_backend_memory	Maximum memory size requested by the session connected to the HA port.
Backend_used_memory	Size of the memory that is being occupied by the session connected to the HA port.
other_used_memory	Size of other memory that is not applied for in the memory context.
unit	Unit of the memory size at the same level.
Context type	Memory context type, including **Shared Memory Context**, **Thread Memory Context**, and **Session Memory Context**.
Context	Name of the memory context. Memory contexts with the same name and module name (in the format of *{Module name}_{Number}*) are displayed together. Only the module name is displayed.
freeSize	Size of the idle memory cached in the memory context.
totalSize	Total size of the memory requested by the memory context.
File	File name of the code where the memory allocation is located. It is recorded only when **memory_trace_level** is set to **level2**.
Line	File line number of the code where the memory allocation is located. It is recorded only when **memory_trace_level** is set to **level2**.
Size	Accumulated size of the memory allocated for in a line of a file. It is recorded only when **memory_trace_level** is set to **level2**.
count	Number of memory contexts with the same name and module name.
query	Executed statement.
unique query id	Unique ID of a statement.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Column	Description
debug query id	Debugging ID of a statement.
session id	Session ID.
thread id	Thread ID.
mem size	Size of the memory allocated by a statement.
application name	Application name.

Log Examples

- When **memory_trace_level** is set to **level1**, the following logs are recorded:

```
{
  "Global Memory Statistics": {
  "Max_dynamic_memory": 34012,
  "Dynamic_used_memory": 3645,
  "Dynamic_peak_memory": 3664,

}
```

Graphical Memory Information (HTML File)

When a .log file in JSON format is generated, a .gz package of the HTML file with the same name is generated in the same directory. Decompress the package, export the HTML file and the **echarts.min.js** file in the same directory, and use a browser to open the HTML file. You can view the graphical memory information.

The memory information corresponds to the memory log in JSON format and consists of the following parts:

- **Global Memory Statistics**: displays the ring chart of the proportion of dynamic memory of each category to the maximum dynamic memory.
- **Shared Memory Context**: displays the memory bar chart of the shared memory context. If the fourth part of the GUC parameter **memory_log_config** is set to **0**, it is not displayed.
- **Session Memory Context**: displays the memory bar chart of the session memory context. If the fourth part of the GUC parameter **memory_log_config** is set to **0**, or the GUC parameter **enable_thread_pool** is set to **off**, it is not displayed.
- **Thread Memory Context**: displays the memory bar chart of the thread memory context. If the fourth part of the GUC parameter **memory_log_config** is set to **0**, it is not displayed.
- **SQL Details**: displays the memory information of the executed statement or thread. If the fifth part of the GUC parameter **memory_log_config** is set to **0**,

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

it is not displayed. If there are memory contexts, you can click each statement to display the memory bar chart of the top *n* memory contexts.

NOTE

Compared with **level1**, when the GUC parameter **memory_trace_level** is set to **level2**, the memory location and size information about the memory context is displayed. You can click the bar chart of each memory context to display the memory location and size.

The following table describes the columns of the information displayed in each part.

Table 5-24 Display information

Column	Description
Dynamic used share ctx memory	Size of the dynamic memory used by the current process.
Dynamic thread cxt used memory	Size of the memory used by the thread-level memory context of the current process.
Dynamic session cxt used memory	Size of the memory used by the session-level memory context of the current process. This parameter is displayed only when the thread pool is enabled.
Dynamic unused memory	Size of the memory not used by the current process.
Context type	Memory context type, including **Shared Memory Context**, **Thread Memory Context**, and **Session Memory Context**.
Context	Name of the memory context. Memory contexts with the same name and module name (in the format of *{Module name}_{Number}*) are displayed together. Only the module name is displayed.
totalSize	Total size of the memory requested by the memory context.
File	File name of the code where the memory allocation is located. It is recorded only when **memory_trace_level** is set to **level2**.
Line	File line number of the code where the memory allocation is located. It is recorded only when **memory_trace_level** is set to **level2**.
Size	Accumulated size of the memory allocated for in a line of a file. It is recorded only when **memory_trace_level** is set to **level2**.
query	Executed statement.
unique query id	Unique ID of a statement.
debug query id	Debugging ID of a statement.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Column	Description
session id	Session ID.
thread id	Thread ID.
mem size	Size of the memory allocated by a statement.
application name	Application name.

6 Database GUC Parameters

6.1 Viewing Parameters

Viewing GUC Parameters

GaussDB uses a set of default GUC parameters after it is installed. You can modify the GUC parameters to enable GaussDB to better fit your service scenarios and data volume.

Procedure

Step 1 Connect to the database. For details, see "Database Quick Start > Connecting to a Database > Using gsql to Connect to a Database" in *Developer Guide*.

Step 2 Check the value of the GUC parameter.

- Method 1: Run the **SHOW** command.
  - View the value of a certain parameter.
    ```
    gaussdb=# SHOW client_encoding;
    ```
    The **client_encoding** parameter is used to check the character encoding type of the client.
  - View values of all parameters.
    ```
    gaussdb=# SHOW ALL;
    ```
- Method 2: Query the pg_settings view.
  - View the value of a certain parameter.
    ```
    gaussdb=# SELECT * FROM pg_settings WHERE NAME='client_encoding';
    ```
  - View values of all parameters.
    ```
    gaussdb=# SELECT * FROM pg_settings;
    ```

----End

Examples

Check the character encoding type of the client.

```
gaussdb=# SHOW client_encoding;
 client_encoding
-----------------
 UTF8
(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Viewing CM Parameters

You can view CM parameters in the configuration files or by running commands.

- Viewing parameters in the configuration files

  You can view CM Agent parameters in the **cm_agent.conf** file in the CM Agent data directory and CM Server parameters in the **cm_server.conf** file in the CM Server data directory.

- Viewing parameters by running commands

  ```
  cm_ctl list --param {--agent | --server} [-n NODEID]
  ```

  Parameters

  – **--agent**: lists CM Agent parameters.

  – **--server**: lists CM Server parameters.

  – **-n** *NODEID*: lists the CM parameters of a specified node. *NODEID* indicates the node name, which can be queried by running the **cm_ctl query -Cv** command.

  Examples

  – List CM Agent parameters.

  ```
  cm_ctl list --param --agent
  ```

  – List CM Server parameters.

  ```
  cm_ctl list --param --server
  ```

6.2 Setting Parameters

Setting GUC Parameters

GaussDB provides six types of GUC parameters and multiple methods for modifying GUC parameters. You can set GUC parameters for databases, users, and sessions. For details, see **Table 6-1**.

- Parameter names are case-insensitive.
- The parameter values can be integers, floating points, strings, Boolean values, or enumerated values.
  – The Boolean values can be (**on**, **off**), (**true**, **false**), (**yes**, **no**), or (**1**, **0**). The Boolean values (**on**, **off**) are recommended for GaussDB.
  – The enumerated value range is specified in the **enumvals** column of the system catalog pg_settings.
  – For parameters of the floating-point (real) type, the decimal point is required. For example, 1.0e-3 is valid, but 1e-3 is invalid.
  – According to the IEEE 754 standard, +0 and –0 are defined for floating-point numbers. In this case, the value **–0** can be verified for numeric parameters.
  – gs_guc has a precision threshold of 1.0e-9 for checking the range of floating-point numbers.
- For parameters using units, specify their units during the setting. Otherwise, default units are used.
  – The default units are specified in the **unit** column of pg_settings.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

  - The unit of memory can be KB, MB, or GB.
  - The unit of time can be ms, s, min, h, or d.
- You can set parameters related to CNs and DNs at a time, but cannot do the same to other parameters.

For details about parameters, see **GUC Parameters**.

Table 6-1 GUC parameter types

Parameter Type	Description	Setting Method
INTERNAL	Fixed parameters. They are set during database creation and cannot be modified. Users can only view the parameters by running the **SHOW** command or in the pg_settings view.	None
POSTMASTER	Database server parameters. They can be set when the database is started or in the configuration file.	Method 1 in **Table 6-2**.
SIGHUP	Global database parameters. They can be set during database startup or be modified later.	Method 1 or 2 in **Table 6-2**.
BACKEND	Session connection parameters. They are specified during session connection creation and cannot be modified after that. The parameter setting becomes invalid when the session is disconnected. The parameters of this type are internal parameters and not recommended for users to set it.	Method 1 or 2 in **Table 6-2**. **NOTE** The parameter setting takes effect when the next session is created.
SUSET	Database administrator parameters. They can be set by common users during database startup or after the database is started. They can also be set by database administrators using SQL statements.	Method 1 or 2 by a common user, or method 3 by a database administrator in **Table 6-2**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter Type	Description	Setting Method
USERSET	Common user parameters. They can be set by any user at any time.	Method 1, 2, or 3 in Table 6-2. **NOTE** When you set parameters of the USERSET type, the parameter value set using **ALTER DATABASE** takes precedence over that set using gs_guc. To make the parameter settings of gs_guc take effect, run the **alter database** *xxx* **reset** *xxx* command to reset the parameters.

You can set GUC parameters in GaussDB using the methods listed in Table 6-2.

Table 6-2 Methods for setting GUC parameters

No.	Setting Method
Method 1	1. Log in to the management console. 2. On the **Instances** page, click the name of the target instance to go to the **Basic Information** page. 3. In the navigation pane on the left, choose **Parameters**. On the displayed page, modify parameters. If the parameters cannot be modified on the console, evaluate the modification risks and contact customer service for modification. 4. Reboot the DB instance to make the modifications take effect. **NOTE** Rebooting instances will interrupt user operations. Plan a proper execution window before the reboot.
Method 2	1. Log in to the management console. 2. On the **Instances** page, click the name of the target instance to go to the **Basic Information** page. 3. In the navigation pane on the left, choose **Parameters**. On the displayed page, modify parameters. If the parameters cannot be modified on the console, evaluate the modification risks and contact customer service for modification.
Method 3	Modify a session-level parameter. • Set a session-level parameter. gaussdb=# SET *paraname* TO *value*; The parameter value in the current session is changed. After you exit the session, the setting becomes invalid.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- If you use method 1 or 2 to set a parameter that does not belong to the current node, the database displays a message indicating that the parameter is not supported.
- You cannot set a parameter in the unit of pages by using method 1 or method 2.
- When you use method 3 to set a parameter, if the parameter value is an integer, leading zeros will be filtered out. For example, **SET** *paraname* **TO** *008192* and **SET** *paraname* **TO** *8192* have the same effect.

Setting CM Parameters

GaussDB CM parameters fall into two categories: those that take effect only after a cluster restart, and those take effect immediately after a reload. For details, see **Table 6-3**.

Table 6-3 Methods for setting CM parameters

No.	Setting Method

Method 1	1. Run the following command to modify parameters:
	`cm_ctl set --param {--agent | --server} [-n NODEID] -k "PARAMETER=value"`
	NOTE
	Parameters
	• **--agent**: sets CM Agent parameters.
	• **--server**: sets CM Server parameters.
	• **-n** *NODEID*: sets the CM parameters of a specified node. *NODEID* indicates the node name, which can be queried by running the **cm_ctl query -Cv** command. If this parameter is not set, all nodes are set by default.
	• **-k "***PARAMETER***=***value***"**: specifies the parameters to be set and values of the parameters. Only existing parameters can be set. Parameters cannot be added or deleted.
	Examples
	• Set the CM Agent parameter **incremental_build** to **on**.
	`cm_ctl set --param --agent -k "incremental_build=on"`
	• Set the CM Server parameter **switch_rto** to **600**.
	`cm_ctl set --param --server -k "switch_rto=600"`
	2. Restart the cluster for the parameters to take effect.
	`cm_ctl stop && cm_ctl start`
	NOTE
	Restarting the cluster results in operation interruption. Properly plan the restart to avoid affecting users.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

No.	Setting Method

Method 2	1. Run the following command to modify parameters:
	`cm_ctl set --param {--agent | --server} [-n NODEID] -k "PARAMETER=value"`
	NOTE
	Parameters
	• **--agent**: sets CM Agent parameters.
	• **--server**: sets CM Server parameters.
	• **-n** *NODEID*: sets the CM parameters of a specified node. *NODEID* indicates the node name, which can be queried by running the **cm_ctl query -Cv** command. If this parameter is not set, all nodes are set by default.
	• **-k "***PARAMETER***=***value***"**: specifies the parameters to be set and values of the parameters. Only existing parameters can be set. Parameters cannot be added or deleted.
	Examples
	• Set the CM Agent parameter **incremental_build** to **on**.
	`cm_ctl set --param --agent -k "incremental_build=on"`
	• Set the CM Server parameter **switch_rto** to **600**.
	`cm_ctl set --param --server -k "switch_rto=600"`
	2. Dynamically load CM parameters.
	`cm_ctl reload --param {--agent | --server} [-n NODEID]`
	NOTE
	Parameters
	• **--agent**: dynamically loads CM Agent parameters.
	• **--server**: dynamically loads CM Server parameters.
	• **-n** *NODEID*: dynamically loads the CM parameters of a specified node. *NODEID* indicates the node name, which can be queried by running the **cm_ctl query -Cv** command.
	Examples
	• Dynamically load CM Agent parameters.
	`cm_ctl reload --param --agent`
	• Dynamically load CM Server parameters.
	`cm_ctl reload --param --server`

6.3 GUC Parameters

6.3.1 GUC Parameter Usage

A database provides many GUC parameters. Changing these parameters will affect the behavior of the database system. Before modifying these parameters, learn the specifications of these parameters and the impact of the modification on the database. Otherwise, unexpected results may occur.

- Some internal database parameters are related to the environment and have been specified during database installation. You are advised not to modify them. If the modification is required, ensure that the content and format are correct. Otherwise, the instance will be abnormal. For example, set the **listen_addresses**, **port**, and **local_bind_address** (IP address) parameters, and various parameters for setting the file output path.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- Due to the size of hardware resources, the following parameters need to be modified with caution: memory, number of connections, and parameters that affect disk space usage. Before modifying the parameters, check the hardware specifications to ensure that the modified parameters do not exceed the hardware size limit. Otherwise, the database instance may fail to apply for sufficient resources and the instance status may be abnormal.
- Due to the association between parameters, you need to read the specifications of the parameters before modifying the parameters. For example, the value of **max_wal_senders** must be smaller than that of **max_connections** so that the database can be started properly.
- If this parameter is set to a large value or a small value, services may be affected. Therefore, you need to learn the meaning of this parameter and modify it with caution. For example, if the **session_timeout** parameter is set to **1** (in seconds) and no operation is performed within 1 second after the service is connected to the server, the service is disconnected. As a result, the service execution is affected. **log_min_messages** specifies the log level. If the log level is too low, a large number of logs will be recorded, affecting the performance.

Precautions

- If the value range of a parameter is a string, the string should comply with the path and file naming conventions of the OS running the target database.
- If the maximum value of a parameter is *INT_MAX*, the maximum parameter value varies by OS. *INT_MAX* indicates the maximum value of the INT data type. The value is **2147483647**.
- If the maximum value of a parameter is *DBL_MAX*, the maximum parameter value varies by OS. The value is the maximum value of the FLOAT data type.
- Some GUC parameters affect the selection of functions and operators, compilation of stored procedures, and generation of execution plans. As a result, views, default values of function parameters, compilation products of stored procedures, and plan cache are affected. Due to these mechanisms, subsequent GUC parameter changes may not affect these behaviors.
  - View: When defining a view, the database generates rewriting rules based on the GUC parameter status. Subsequent operations on the view directly follow the corresponding rules without being affected by GUC parameters (which affect the generation of rewriting rules).
  - Default value of a function parameter: For a function parameter, a function is selected as the default parameter value based on the GUC parameter status when the function parameter is created and the OID of the function that is used as the default value is recorded in the corresponding system catalog (pg_proc). When this function parameter is executed later, the function OID recorded in the system catalog will be used as the default value, and the value is not affected by GUC parameters.
  - Compilation product of a stored procedure: When compiling a stored procedure, the database generates a compilation product based on the GUC parameter status. When executing the stored procedure, the database directly uses the compilation product without being affected by GUC parameters (which affect the generation of compilation products).

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

– Plan cache: When executing an SQL statement, the database generates an execution plan based on the GUC parameter status. If the plan is cached, the SQL statement will be executed according to the plan without being affected by GUC parameters (which affect the generation of execution plans).

The following table lists the GUC parameters that exert influence. You can view the function of each GUC parameter.

GUC Parameter	Enabled	Disabled	Impact	Example

convert_string_to_digit	Character strings are preferentially converted to numbers.	Character strings cannot be preferentially converted to numbers.	Views, default values of function parameters, stored procedure compilation products, and plan cache.	CREATE or REPLACE FUNCTION test(c numeric) RETURN text package AS
				BEGIN

GUC Parameter	Enabled	Disabled	Impact	Example

set behavior_compat_options = 'ignore_like_default_escape';	This option can be enabled when **standard_conforming_strings** is set to **on**. After this option is enabled, the backslash in the pattern string can be regarded as a common character and be used for fuzzy match.	In LIKE fuzzy match, the backslash in the pattern string is used as an escape character to remove the special meaning of the wildcard.	Plan cache.	gaussdb=# SET standard_conforming_strings = on;

6.3.2 File Location

After a database has been installed, three configuration files (**gaussdb.conf**, **gs_hba.conf**, and **gs_ident.conf**) are automatically generated and saved in the data directory. You can use the methods described in this section to change the names and save paths of these configuration files.

When changing the storage directory of a configuration file, set **data_directory** in **gaussdb.conf** to the actual data directory.

NOTE

If a configuration file is incorrectly modified, the database will be seriously affected. Do not modify the configuration files mentioned in this section after installation.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

data_directory

Parameter description: Specifies the GaussDB **data** directory. Only the SYSADMIN user can access this parameter.

Parameter type: string.

Unit: none

Value range: valid path of a directory.

Default value: Specify this parameter during installation. If this parameter is not specified during installation, the database is not initialized by default.

Setting method: This parameter can be set as follows:

- Set it when GaussDB is installed.
- This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

config_file

Parameter description: Specifies the configuration file (**gaussdb.conf**) of the primary node.

Parameter type: string.

Unit: none

Value range: a string of more than 0 characters.

Default value: **gaussdb.conf** (The absolute directory of this file may be displayed in the actual situation.)

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

hba_file

Parameter description: Specifies the configuration file (**gs_hba.conf**) for host-based authentication (HBA). This parameter can be specified only in the **gaussdb.conf** file and can be accessed only by the SYSADMIN user.

Parameter type: string.

Unit: none

Value range: a string of more than 0 characters.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Default value: **gs_hba.conf** (The absolute directory of this file may be displayed in the actual situation.)

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: You are advised not to modify the parameters in the configuration file.

Risks and impacts of improper settings: The cluster upgrade and backup functions may be affected.

ident_file

Parameter description: Specifies the name of the configuration file (**gs_ident.conf)** for client authentication. Only the SYSADMIN user can access this parameter.

Parameter type: string.

Unit: none

Value range: a string of more than 0 characters.

Default value: **gs_ident.conf** (The absolute directory of this file may be displayed in the actual situation.)

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: You are advised not to modify the parameters in the configuration file.

Risks and impacts of improper settings: The cluster upgrade and backup functions may be affected.

external_pid_file

Parameter description: Specifies the extra PID file that can be used by the server management program. Only the SYSADMIN user can access this parameter.

Parameter type: string.

Unit: none

Value range: valid file name.

Default value: **""**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

NOTE

This parameter takes effect only after the database restarts.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

6.3.3 Connection and Authentication

6.3.3.1 Connection Settings

This section describes parameters related to client-server connection modes.

light_comm

Parameter description: Specifies whether the server uses the lightweight communications mode.

This parameter specifies whether the server uses the communication mode based on lightweight locks and non-blocking sockets.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The lightweight communications mode is used.
- **off**: The lightweight communications mode is not used.

Default value: **off**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

listen_addresses

Parameter description: Specifies the TCP/IP address of the client for a server to listen on.

This parameter specifies the IP address used by the GaussDB server for listening, for example, an IPv4 address or IPv6 address. Multiple NICs may exist on the host and each NIC can be bound to multiple IP addresses. This parameter specifies the IP addresses to which GaussDB is bound. The client can use the IP addresses specified by this parameter to connect to GaussDB or send requests to GaussDB.

Parameter type: string.

Unit: none

Value range:

- Host name or IP address. Multiple values are separated with commas (,).
- Asterisk (*), **::**, or **0.0.0.0**, indicating that all IP addresses will be listened on, which is not recommended due to potential security risks.
- If the parameter is not specified, the server does not listen on any IP address. In this case, only UDSs can be used for database connections.

Default value:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

After the cluster is installed, configure different default values based on the IP addresses of different instances in the **public_cloud.conf** file. The default value of CN is **"localhost,***IP address of the mgr.net NIC,IP address of the data.net NIC,IP address of the virtual.net NIC***"**. The default value of DN is **"***IP address of the data.net NIC***"**.

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

NOTE

localhost indicates that only local loopback is allowed.

The **public_cloud.conf** file contains the following NIC information: **mgr.net** (management NIC), **data.net** (data NIC), and **virtual.net** (virtual NIC).

If an IPv6 address is used and the IP address is a fe80 address block, add '%zone index' during the configuration.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

listen_address_ext

Parameter description: Specifies the extended TCP/IP address of the client for a server to listen on. This parameter specifies the IP addresses used by the GaussDB server as the extended listening IP address.

Parameter type: string.

Unit: none

Value range: an IPv4 or IPv6 address. Multiple IP addresses are not supported.

Default value: **"localhost"**.

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: In BMS deployment mode, this parameter is automatically configured when the cluster is installed and started. You are advised not to manually configure this parameter.

NOTE

- The setting of the **listen_address_ext** parameter involves the network topology and configuration of the extended IP addresses of the entire cluster. Therefore, it must be set and reloaded by using the OM tool.
- **listen_address_ext** is a network channel used to extend specific IP addresses. If this parameter is set to **"*"**, **"0.0.0.0"**, **"localhost"**, **"::-1"**, or **"127.0.0.1"**, the setting does not take effect. If required, you are advised to set these addresses in **listen_addresses**.
- **listen_address_ext** is used to configure distributed DNs. It does not take effect if it is configured for CNs.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

local_bind_address

Parameter description: Specifies the host IP address bound to the current node for connecting to other nodes in the cluster.

Parameter type: string.

Unit: none

Value range: an IPv4 or IPv6 address. Multiple IP addresses are not supported.

Default value:

After the cluster is installed, configure different default values based on the IP addresses of different instances in the **public_cloud.conf** file. The default value of CN/DN is "*IP address of the data.net NIC*".

NOTE

The **public_cloud.conf** file contains the following NIC information: **mgr.net** (management NIC), **data.net** (data NIC), and **virtual.net** (virtual NIC).

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impact of improper settings: This parameter is specified in the configuration file during installation. Do not modify this parameter unless necessary. Otherwise, database communications will be affected after the modification.

port

Parameter description: Specifies the TCP port listened on by the GaussDB.

Parameter type: integer.

Unit: none

Value range: 1 to 65535

NOTE

- When setting the port number, ensure that the port number is not in use. When setting the port numbers of multiple instances, ensure that the port numbers do not conflict.
- Ports 1 to 1023 are reserved for the OS. Do not use them.
- When the cluster is installed using the configuration file, pay attention to the ports reserved in the communication matrix in the configuration file. For example, the DN needs to reserve **dataPortBase** + 1 as the port used by internal tools. Therefore, during cluster installation, the maximum value of **port** is **65532** for CNs, **65529** for DNs, and **65534** for GTMs. Ensure that the port number does not conflict with each other.

Default value: **5432** (The actual value is specified in the configuration file during installation.)

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Risks and impact of improper settings: This parameter is specified in the configuration file during installation. Do not modify this parameter unless necessary. Otherwise, database communications will be affected after the modification.

max_connections

Parameter description: Specifies the maximum number of concurrent connections to the database. This parameter influences the concurrent processing capability of the cluster.

Parameter type: integer.

Unit: none

Value range: The minimum value is **10** (greater than the value of **max_wal_senders**). The theoretical maximum value is **262143**. The actual maximum value is a dynamic value, which is calculated using the formula: 262143 – **job_queue_processes** – **autovacuum_max_workers** – **max_inner_tool_connections** – **max_concurrent_autonomous_transactions** – **AUXILIARY_BACKENDS** – **AV_LAUNCHER_PROCS** – *min(max(newValue/4,64),1024)*. The values of **job_queue_processes**, **autovacuum_max_workers**, **max_inner_tool_connections**, and **max_concurrent_autonomous_transactions** depend on the settings of the corresponding GUC parameters. **AUXILIARY_BACKENDS** indicates the number of reserved auxiliary threads, which is fixed to **20**. **AV_LAUNCHER_PROCS** indicates the number of reserved autovacuum launcher threads, which is fixed to **2**. In *min(max(newValue/4,64),1024)*, **newValue** indicates the new value.

For different memory specifications, value range of this parameter in different instances is as follows:

Table 6-4 Value ranges of memory specifications for different instances in independent deployment mode

Memory Specifications	Value Range for CNs	Value Range for DNs
< 32 GB	[10,100]	[10,100]
[32GB,64GB)	[10,200]	[10,200]
[64GB,128GB)	[10,1000]	[10,2500]
[128GB,256GB)	[10,2000]	[10,6000]
[256GB,480GB)	[10,4000]	[10,12000]
≥ 480 GB	[10,8000]	[10,24000]

Default value:

- Independent deployment:

  CN: **8000** (128-core CPU/1024 GB memory, 60-core CPU/480 GB memory); **4000** (32-core CPU/256 GB memory); **2000** (16-core CPU/128 GB memory);

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

1000 (8-core CPU/64 GB memory); **100** (4-core CPU/32 GB memory, 4-core CPU/16 GB memory)

DN: **24000** (128-core CPU/1024 GB memory, 60-core CPU/480 GB memory); **12000** (32-core CPU/256 GB memory); **6000** (16-core CPU/128 GB memory); **2500** (8-core CPU/64 GB memory); **100** (4-core CPU/32 GB memory, 4-core CPU/16 GB memory)

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value of this parameter in the primary database node file. If this parameter is set to a smaller value, the number of available connections decreases. Before changing the value of this parameter, understand the parameter description and exercise caution to avoid risks caused by misoperations.

Risks and impacts of improper settings:

- If the value of **max_connections** exceeds the maximum dynamic value, the CN and DN fail to be started and the error message "invalid value for parameter "max_connections"" is displayed. Alternatively, the memory fails to be allocated during the node startup and the error message "Cannot allocate memory" is displayed.
- If the value of **max_connections** is not increased based on the external export specifications, the memory parameter is not adjusted in the same proportion. When the service load is heavy, the memory may be insufficient and the error message "memory is temporarily unavailable" is displayed.
- In the hybrid deployment scenario, if the value of **max_connections** on the CN is greater than the value of **max_connections** divided by the number of CNs on the DN and the total pressure on the client exceeds the value of **max_connections** on the DN, the CN may fail to connect to the DN, and the error message "pooler... Too many clients already" is displayed.
- If the value of **thread_pool_attr** is greater than or equal to that of **max_connections**, all proc resources are occupied by the thread pool. As a result, proc resources are insufficient.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- If the number of connections of the administrator exceeds the value of **max_connections**, the administrator can still connect to the database after the connections are used up by common users. If the number of connections exceeds the value of **sysadmin_reserved_connections**, an error is reported. That is, the maximum number of connections of an administrator is equal to the value of **max_connections** plus the value of **sysadmin_reserved_connections** plus the value of **sysadmin_reserved_connections** (number of dedicated reserved connections logged in through the port whose port number is the master port number plus 1).
- For common users, internal jobs use some connections. Therefore, the value of this parameter is slightly less than that of **max_connections**. The value depends on the number of internal connections.
- After the thread pool is enabled, the maximum number of stream threads is determined by the value of **max_connections**. If the number of stream threads reaches the upper limit, the error message "Exceed stream thread pool limitation..." is reported. In this case, you can increase the value of **max_connections** to increase the upper limit. This is a POSTMASTER parameter. Therefore, you can estimate the number of stream threads based on service requirements. The formula is as follows: Total number of stream threads = Number of concurrent services x Number of stream threads consumed by each concurrently executed statement (which can be viewed in the execution plan).
- **max_connections** indicates the number of node connections, including external and internal connections.
  - External connection: connection of a user application.
  - Internal connection: connection generated by an internal job.
- When DDL operations are used in a transaction, the CN establishes connections with other nodes in the cluster for synchronization until the transaction ends. The connections established by the CN occupy the number of connections on the corresponding node. If *N* concurrent DDL operations are performed in this scenario, the number of internal connections on a node increases by *N*. As a result, the number of connections available to external clients on the node decreases by *N*. For example, if gsql is used to create three connections on CN1 and DDL operations are performed in a transaction, CN1 establishes three internal connections on other nodes, that is, CN2 has three new internal connections from CN1. As a result, the number of connections available to external clients on CN2 decreases by three.

max_inner_tool_connections

Parameter description: Specifies the maximum number of concurrent connections of a tool which is allowed to connect to the database. This parameter influences the concurrent connection capability of the GaussDB tool.

Parameter type: integer.

Unit: none

Value range: The minimum value is **1** and the calculation formula of the maximum value is 262143 – **job_queue_processes** – **autovacuum_max_workers** – **max_connections** – **max_concurrent_autonomous_transactions** – **AUXILIARY_BACKENDS** – **AV_LAUNCHER_PROCS** – **min(max(max_connections/4,64),1024)**. The values of **job_queue_processes**, **autovacuum_max_workers**, **max_connections**, **max_concurrent_autonomous_transactions** depend on the settings of the corresponding GUC parameters. **AUXILIARY_BACKENDS** indicates that the number of reserved auxiliary threads is fixed to **20**. **AV_LAUNCHER_PROCS** reserves two launcher threads for autovacuum.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Default value: **50**. If the default value is greater than the maximum value supported by the kernel (determined when the **gs_initdb** command is executed), an error message is displayed.

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value of this parameter in the primary database node file.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

sysadmin_reserved_connections

Parameter description: Specifies the minimum number of connections reserved for an administrator, which is also the minimum number of connections reserved for the administrator to log in through the port whose port number is the master port plus 1. You are advised not to set this parameter to a large value. This parameter is used together with **max_connections**. The maximum number of connections for an administrator is equal to the value of **max_connections** plus the value of **sysadmin_reserved_connections** plus the value of **sysadmin_reserved_connections** (number of dedicated reserved connections logged in through the port whose port number is the master port plus 1).

NOTE

- When the thread pool function is enabled, if the thread pool is fully occupied, a processing bottleneck occurs. As a result, connections reserved by the administrator cannot be established. In this case, you can use gsql to establish connections through the port specified by the master port number plus 1 and clear useless sessions.
- When the reserved connections are used up, new connections will fail. In this case, you can only restart the cluster to restore the connections. Therefore, exercise caution when using the reserved connections.

Parameter type: integer.

Unit: none

Value range: 0 to *MIN(262143, max_connections)* (the smaller value between **262143** and **max_connections**). For details about how to calculate the value of **max_connections**, see **max_connections**.

Default value: **3**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

service_reserved_connections

Parameter description: Specifies the minimum number of connections reserved for background O&M users (with the persistence attribute). A large value is not recommended. This parameter is used together with **max_connections**. The

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

maximum number of connections of an O&M user can be calculated as follows: **max_connections** + **service_reserved_connections**.

Parameter type: integer.

Unit: none

Value range: 0 to 262143

Default value: **10**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this parameter is set to a small value, the O&M user (with the persistence attribute) cannot connect to the database and jobs cannot be executed when the number of connections reaches the maximum (**max_connections**). If the value is too large, there are too many idle resources.

extip_reserved_connections

Parameter description: Specifies the minimum number of common gsql service connections reserved for a user on the extended IP address specified by **listen_address_ext**. This parameter is used together with **max_connections**. The maximum number of connections of a corresponding service can be calculated as follows: **max_connections** + **service_reserved_connections**.

NOTE

This parameter is valid only when a specific IP address of **listen_address_ext** is configured for a distributed DN.

Parameter type: integer.

Unit: none

Value range: 0 to *MIN(262143, max_connections)* (the smaller value between **262143** and **max_connections**). For details about how to calculate the value of **max_connections**, see **max_connections**.

Default value: **5**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

unix_socket_directory

Parameter description: Specifies the UDS directory for the GaussDB server to listen to connections from the client. Only the SYSADMIN user can access this parameter.

Parameter type: string.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Unit: none

Value range: valid path of a directory.

NOTE

The parameter length limit varies by the maximum length of a path of a directory in the OS. In the Linux OS, the length of a socket path name (combination of a socket directory and a socket file name) cannot exceed 107 bytes, and the length of a directory cannot exceed 92 bytes. If this limit is exceeded, the error "Unix-domain socket path "xxx" is too long" will be reported.

Default value: **""**. The actual value is specified by **tmpMppdbPath** in the configuration file during installation.

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impact of improper configuration: If the configuration is incorrect (for example, the length exceeds the limit or the directory is invalid), the process cannot be started properly. You can retrieve the system_call log in the CM Agent directory to locate configuration issues.

unix_socket_group

Parameter description: Specifies the group of the UDS (the user of a socket is the user who starts the server). This parameter can work with **unix_socket_permissions** to control socket access.

Parameter type: string.

Unit: none

Value range: existing user groups in the system.

Default value: **""**, indicating the default group of the current user.

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

unix_socket_permissions

Parameter description: Specifies access permissions on the UDS.

The UDS uses the usual permission set of the Unix file system. The value of this parameter should be a number (acceptable for the **chmod** and **umask** commands). If a user-defined octal format is used, the number must start with 0.

Parameter type: integer.

Unit: none

Value range: an octal integer ranging from 0000 to 0777 (that is, 0 to 511 in the decimal format)

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

> **NOTE**
>
> In the Linux OS, a document has one document attribute and nine permission attributes, which are the read (r), write (w), and execute (x) permissions of the **owner**, **group**, and **others** groups.
>
> The r, w, and x permissions are represented by the following numbers:
>
> r: 4
>
> w: 2
>
> x: 1
>
> -: 0
>
> The three attributes in a group are accumulative.
>
> For example, **-rwxrwx---** indicates the following permissions:
>
> owner = rwx = 4+2+1 = 7
>
> group = rwx = 4+2+1 = 7
>
> others = --- = 0+0+0 = 0
>
> The permission of the file is 0770.

Default value: **0700** in octal (which is **448** in decimal)

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: You are advised to set it to **0770** (only allowing access from users connecting to the database and users in the same group as them) or **0700** (only allowing access from users connecting to the database).

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

application_name

Parameter description: Specifies the client name used in the current connection request.

Parameter type: string.

Unit: none

Value range: valid client name. The actual query result depends on the client used for queries or user configurations.

> **NOTE**
>
> When a standby node requests to replicate logs on the primary node, if this parameter is not an empty string, it is used as the name of the streaming replication slot of the standby node on the primary node. In this case, if the length of this parameter exceeds 61 bytes, only the first 61 bytes are used as the streaming replication slot name.

Default value: **""** (The actual value is the name of the application connected to the backend.)

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**. Note that after the client is connected, this parameter is set to the client name and the client level. Therefore, only the session-level parameters take effect. Other methods do not take effect because they are lower than the client level.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: The database depends on **application_name** to identify some internal processes. If you set **application_name** to the same name as an internal process, unexpected behavior may occur.

connection_info

Parameter description: Specifies the database connection information, including the driver type, driver version, driver deployment path, and process owner.

Parameter type: string.

Unit: none

Value range: a string.

Default value: **""**, indicating that the driver connected to the database does not support automatic setting of the **connection_info** parameter or the parameter is not set by users in applications.

NOTE

The following is an example of the concatenated value of **connection_info**:
{"driver_name":"ODBC","driver_version": "(GaussDB XXX.XXX.XXX build 290d125f) compiled at 2020-05-08 02:59:43 last mr 131 release","driver_path":"/usr/local/lib/gsqlodbcw.so","os_user":"omm"}

By default, **driver_name** and **driver_version** are displayed. The display of **driver_path** and **os_user** is controlled by the connection parameter **connectionExtraInfo** in the connection string. For details, see "Application Development Guide > Development Based on JDBC > Development Procedure > Connecting to a Database > Connection Parameter Reference" in *Developer Guide* and "Application Development Guide > Appendix > ODBC > Configuration Parameters" in *Developer Guide*.

Setting method: This is a USERSET parameter used for O&M. You are advised not to set the parameter. This parameter can be set only in a session. To change the parameter value, see "Method 3" in **Table 6-2**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

backend_version

Parameter description: Specifies the version number of the synchronous connection between CNs or between a CN and a DN. This parameter involves the version number and cannot be set randomly.

Parameter type: integer.

Unit: none

Value range: 0 to 100000

Default value: **0**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If the settings are incorrect, the versions of different nodes are inconsistent.

check_disconnect_query

Parameter description: Specifies whether to terminate the execution of statements on the GaussDB server after the client is disconnected abnormally (for example, socketTimeout is triggered by JDBC, rwtimeout is triggered by libpq and the connection is closed, or the client process is terminated during service running).

Parameter type: Boolean.

Unit: none

Value range:

- **on**: indicates that the GaussDB server stops running the corresponding statements after the client is disconnected unexpectedly.
- **off**: indicates that the GaussDB server does not stop running the corresponding statements after the client is disconnected unexpectedly.

Default value: **on**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

connection_reject_nodes

Parameter description: Specifies the blacklist of CNs/DNs that reject connections from other CNs. The blacklists are separated by commas (,), for example, **'cn_5001,cn_5002'**. When a CN (for example, **cn_5001**) in the blacklist attempts to connect to the local node, the connection will be rejected and the error message "Reject cn_5001 connection" will be displayed.

Parameter type: string.

Unit: none

Value range: a character string consisting of several node names and commas (,).

Default value: **""**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this parameter is set to a node name, other nodes will reject the connection request. As a result, a connection error is reported.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

enable_server_listener_thread

Parameter description: Specifies whether to enable the independent listening thread. When this function is enabled, an independent thread listens to the TCP port (**port**) listened by the GaussDB Kernel service. To enable the independent listening thread, set the GUC parameters **enable_thread_pool** and **enable_connect_thread_pool** to **on**.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: An independent thread listens to the TCP port (**port**) listened by the GaussDB Kernel service.
- **off**: The postmaster thread of the service instance process listens to the TCP port (**port**) listened by the GaussDB Kernel service.

Default value:

- For a newly installed database: **on**.
- For a database upgraded from a version earlier than 507.0.0: **off**.
- For an upgrade from 507.0.0 or later: original parameter value.

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value. Enabling the independent listening thread will add running threads. If hardware resources are limited, you are advised to determine whether to enable this function based on the actual test result.

Risks and impacts of improper settings: If this function is not enabled, when the postmaster thread competes with other threads, the efficiency of the service listening port may decrease, affecting the time required for establishing a connection with the client. Before the modification, fully verify the change in a test environment.

6.3.3.2 Security and Authentication

This section describes parameters about client-to-server authentication.

authentication_timeout

Parameter description: Specifies the longest duration to wait before the client authentication times out. If a client is not authenticated by the server within the period, the server automatically disconnects from the client so that the client does not occupy connection resources.

Parameter type: integer.

Unit: seconds

Value range: 1–600

Default value: **60**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**. For example, if the value is **600** without a unit, **authentication_timeout** indicates 600s. If the value is **10min**, **authentication_timeout** indicates 10 minutes. If the unit is required, the value must be **s**, **min**, **h**, or **d**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If the value is too small, connection failures may occur frequently, affecting user experience. If the value is too large, security risks increase and resources are wasted.

auth_iteration_count

Parameter description: Specifies the number of iterations during the generation of encryption information for authentication.

Parameter type: integer.

Unit: none

Value range: 2048–134217728

Default value: **10000**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Set the number of iterations based on actual hardware conditions. You are advised to retain the default value.

Risks and impacts of improper settings: If the number of iterations is too small, the password storage security is reduced. If the number of iterations is too large, the performance deteriorates in scenarios involving password encryption, such as authentication and user creation.

session_authorization

Parameter description: Specifies the user ID of the current session. The value of this parameter can be queried only by running the **SHOW** statement.

Parameter type: string.

Unit: none

Value range: a valid user ID.

Default value: **""**

Setting method: This is a USERSET parameter. Set it based on the syntax provided in **SET SESSION AUTHORIZATION**. If you directly set the value, it can only be set to **DEFAULT**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

session_timeout

Parameter description: Specifies the longest duration allowed when no operations are performed on a client after it is connected to the server. If this parameter is not set to **0** and a user does not perform any operation for a period longer than the value of this parameter, the server is disconnected.

Parameter type: integer

Unit: seconds

Value range: 0–86400 (1 day)

- The value **0** indicates that the timeout setting is disabled.
- A positive number indicates the maximum duration in which no operation is performed after the connection to the server is set up. When the value of this parameter is exceeded, the client is disconnected from the server.

Default value: **1800**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**. For example, if the value is **600** without a unit, **session_timeout** indicates 600s. If the value is **10min**, **session_timeout** indicates 10 minutes. If the unit is required, the value must be **s**, **min**, **h**, or **d**.

Setting suggestion: Set this parameter based on service security requirements. A smaller value indicates higher security but more inconvenient use.

Risks and impacts of improper settings: If the value is too small, persistent connections in the service connection pool may become invalid, causing service failures.

NOTE

The gsql client of GaussDB has an automatic reconnection mechanism. For local connection of initialized users, the client reconnects to the server if the connection breaks after the timeout.

idle_in_transaction_timeout

Parameter description: Specifies the maximum idle duration of a transaction after the connection to the server is established and the transaction is started. If this parameter is not set to **0**, the transaction is idle, and no operation is performed for a period longer than the value of this parameter, the server is disconnected.

Parameter type: integer

Unit: seconds

Value range: 0–86400 (1 day)

- The value **0** indicates that the timeout setting is disabled.
- The positive number indicates the maximum idle duration of a transaction after the connection to the server is established and the transaction is started. When the value of this parameter is exceeded, the client is disconnected from the server.

Default value: **300** (5 minutes)

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**. For example, if the value is **600** without a unit, **idle_in_transaction_timeout** indicates 600s. If the value is **10min**, **idle_in_transaction_timeout** indicates 10 minutes. If the unit is required, the value must be **s**, **min**, **h**, or **d**.

Setting suggestion: Set this parameter based on service security requirements. A smaller value indicates higher security but more inconvenient use.

Risks and impacts of improper settings: If the value is too small, the client application may not send new requests in a timely manner after a transaction is started. As a result, the session times out and exits, affecting user experience.

NOTE

- The gsql client of GaussDB has an automatic reconnection mechanism. For local connection of initialized users, the client reconnects to the server if the connection breaks after the timeout.
- If both **idle_in_transaction_timeout** and **session_timeout** are enabled, the timeout interval takes effect regardless of whether the transaction is idle. The smaller timeout interval prevails.
- For a newly delivered instance, the value of this parameter is **300**. For an upgraded instance, the value of this parameter is **0** by default.
- After an idle transaction times out, the transaction start time, thread ID, application name, and query information is recorded in logs. This log file is used to locate the problem that an idle transaction exits due to timeout. The log file does not contain the prefix format **log_line_prefix**.

ssl

Parameter description: Specifies whether to enable the SSL connection on the server. Before using this option, read "Database Quick Start > Connecting to a Database > Using gsql to Connect to a Database" in *Developer Guide*.

Parameter type: Boolean

Unit: none

Value range:

- **on**: The SSL connection is enabled on the server. Whether SSL encrypted transmission is used during actual communication depends on the client configuration.
- **off**: The SSL connection is disabled on the server.

Default value: **on** (for CNs) or **off** (for DNs)

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: If high security is required, you are advised to enable this function. If high performance is required, you are advised to disable this function. GaussDB supports SSL when a client connects to a CN. You are advised to enable SSL connections only on CNs. The default value is **off** on DNs.

Risks and impacts of improper settings: Before enabling this parameter, ensure that the parameters **ssl_cert_file**, **ssl_key_file**, and **ssl_ca_file** are correctly set. If SM cryptographic algorithms are used, ensure that the parameters

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

ssl_enc_cert_file and **ssl_enc_key_file** are correctly set. Incorrect settings may cause cluster startup failures.

NOTE

The SSL communication between the primary and standby nodes is also affected by the GUC parameter **wal_replication_ssl**.

comm_ssl

Parameter description: Specifies whether to enable the SSL connection between primary DNs. Before using this option, read "Database Quick Start > Connecting to a Database > Using gsql to Connect to a Database" in *Developer Guide*.

Parameter type: Boolean

Unit: none

Value range:

- **on**: The SSL connection is enabled between primary DNs.
- **off**: The SSL connection is disabled between primary DNs.

Default value: **off**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: You are advised to enable this parameter only on DNs. The default value is **off** on CNs.

Risks and impacts of improper settings: To enable SSL connections, you also need to ensure that parameters such as **ssl_cert_file**, **ssl_key_file**, and **ssl_ca_file** are configured correctly. Incorrect configurations may cause startup failure of the cluster.

require_ssl

Parameter description: Specifies whether the server requires SSL connections. This parameter is valid only when **ssl** is set to **on**. Before using this option, read "Database Quick Start > Connecting to a Database > Using gsql to Connect to a Database" in *Developer Guide*.

Parameter type: Boolean

Unit: none

Value range:

- **on**: The server requires SSL connections.
- **off**: The server does not require SSL connections.

Default value: **off**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: GaussDB supports SSL when a client connects to a CN. It is recommended that the SSL connection be enabled only on CNs.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Risks and impacts of improper setting: If SSL-related parameters are incorrectly configured, enabling this parameter may cause communication connection setup failures or even cluster startup failures.

ssl_ciphers

Parameter description: Specifies the list of algorithms supported by SSL. Only the SYSADMIN user can access the list.

Parameter type: string.

Unit: none

Value range: a string. Separate multiple algorithms by semicolons (;).

Default value: **"ALL"**, indicating that all supported algorithms (excluding ADH, LOW, EXP, and MD5) can be used for the peer end.

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: You are advised not to specify the insecure algorithms DHE-RSA-AES128-GCM-SHA256 and DHE-RSA-AES256-GCM-SHA384.

Risks and impacts of improper setting: If **ssl_ciphers** is incorrectly set, the database cannot be started.

ssl_renegotiation_limit

Parameter description: Specifies the allowed traffic volume over an SSL-encrypted channel before the session key is renegotiated. The renegotiation mechanism reduces the probability that attackers use the password analysis method to crack the key based on a huge amount of data but causes big performance losses. The traffic indicates the sum of transmitted and received traffic.

Parameter type: integer.

Unit: KB

Value range: 0 to 2147483647. **0** indicates that the renegotiation mechanism is disabled.

Default value: **0**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**. For example, if the value is **1024** without a unit, **ssl_renegotiation_limit** indicates 1024 KB. If the value is **1MB**, **ssl_renegotiation_limit** indicates 1 MB. The unit must be KB, MB, or GB if required.

Setting suggestion: Retain the default value. The SSL renegotiation mechanism has been disabled because of potential risks. This parameter is reserved for version compatibility and does not take effect.

Risks and impacts of improper settings: Changing the value of this parameter may cause unexpected results in the cluster. Retain the default value.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

ssl_cert_file

Parameter description: Specifies the name of the file that contains the SSL server certificate. The path is relative to the data directory.

Parameter type: string.

Unit: none

Value range: valid file name, which must end with .crt.

Default value: **"server.crt"**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: When configuring the file path, ensure that the file path matches other SSL-related certificate and private key configuration files.

Risks and impacts of improper settings: If the file path is incorrect, the SSL connection cannot be established between the client and the database node, and the database cluster nodes cannot communicate with each other in SSL mode. As a result, data leakage may occur.

ssl_key_file

Parameter description: Specifies the name of the file that contains the SSL private key. The path is relative to the data directory.

Parameter type: string.

Unit: none

Value range: valid file name, which must end with .key.

Default value: **"server.key"**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: When configuring the file path, ensure that the file path matches other SSL-related certificate and private key configuration files.

Risks and impacts of improper settings: If the file path is incorrect, the SSL connection cannot be established between the client and the database node, and the database cluster nodes cannot communicate with each other in SSL mode. As a result, data leakage may occur.

ssl_enc_cert_file

Parameter description: Specifies the name of the SSL server certificate file that is encrypted using SM cryptographic algorithms. The path is relative to the data directory.

Parameter type: string.

Unit: none

Value range: valid file name, which must end with .crt.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Default value: ""

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: When configuring the file path, ensure that the file path matches other certificates and private key configuration files related to SSL that uses SM cryptographic algorithms.

Risks and impacts of improper settings: If the file path is incorrect, the SSL connection that uses SM cryptographic algorithms cannot be established between the client and the database node, and the cluster nodes of the database instance cannot communicate with each other in SSL that uses SM cryptographic algorithms. As a result, data leakage may occur.

ssl_enc_key_file

Parameter description: Specifies the name of the SSL server certificate file (with the private key) that is encrypted using SM cryptographic algorithms. The path is relative to the data directory.

Parameter type: string.

Unit: none

Value range: valid file name, which must end with .key.

Default value: ""

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: When configuring the file path, ensure that the file path matches other certificates and private key configuration files related to SSL that uses SM cryptographic algorithms.

Risks and impacts of improper settings: If the file path is incorrect, the SSL connection that uses SM cryptographic algorithms cannot be established between the client and the database node, and the cluster nodes of the database instance cannot communicate with each other in SSL that uses SM cryptographic algorithms. As a result, data leakage may occur.

ssl_ca_file

Parameter description: Specifies the name of the root certificate that contains CA information. Its path is relative to the data directory.

Parameter type: string.

Unit: none

Value range: valid file name, which must end with .pem. An empty character string indicates that no CA file is loaded and client certificate verification is not performed.

Default value: **"cacert.pem"**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Setting suggestion: If client certificate verification is required, configure the file path correctly.

Risks and impacts of improper settings: If the file path is incorrect, the database cannot verify the client certificate, reducing communication security.

ssl_crl_file

Parameter description: Specifies the name of the file that contains the certificate revocation list (CRL). If a client certificate is in the list, the certificate is invalid. The path is relative to the data directory.

Parameter type: string.

Unit: none

Value range: valid file name. An empty string indicates that there is no CRL.

Default value: **""**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If the file name in the CRL is incorrectly configured, invalid client certificates may be used to establish SSL connections, causing data leakage risks. Valid client certificates are considered revoked and SSL connections cannot be established.

enable_shared_sslctx

Parameter description: Specifies whether to enable global SSL certificate loading and SSL context sharing. This parameter is valid only when **SSL** is set to **on**.

Parameter type: Boolean

Unit: none

Value range:

- **on**: Global SSL certificate loading is enabled and the SSL context is initialized only once when the database is started.
- **off**: Global SSL certificate loading is disabled and the SSL context is initialized each time a session is established.

Default value: **off**. If the glibc version of an OS is earlier than 2.28, the value is **on**.

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: You are advised to disable this function. You are advised to enable this function only when high performance is required in SSL non-two-way authentication scenarios.

Risks and impacts of improper settings: After the global SSL certificate loading function takes effect, the new certificate cannot take effect in real time. You need to restart the database.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- If the glibc version of an OS is earlier than 2.28, the certificate loading efficiency is low. Therefore, the default value of this parameter is **on** in these OSs.
- If the SSL global context fails to be initialized during database startup, this parameter is automatically set to **off**, and the session-level SSL certificate is loaded.

ssl_cert_notify_time

Parameter description: Specifies the number of days prior to SSL server certificate expiration that a user will receive a reminder. When the SSL certificate is initialized during connection establishment, if the duration from the current time to the certificate expiration time is shorter than the specified value, an expiration notification is recorded in the log.

Parameter type: integer.

Unit: day

Value range: 7–180

Default value: **90**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**. The unit must be **d** if required.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If the value is too small, the server certificate expiration may not be detected in advance. As a result, the certificate cannot be replaced in a timely manner. If the value is too large, alarms may be frequently generated.

krb_server_keyfile

Parameter description: Specifies the location of the main configuration file of the Kerberos service. Only the SYSADMIN user can access the file.

Parameter type: string.

Unit: none

Value range: valid file path.

Default value: **""**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Contact technical support for assistance.

Risks and impacts of improper settings: If this parameter is incorrectly set, nodes in the cluster cannot use the Kerberos authentication function.

krb_srvname

Parameter description: Specifies the Kerberos service name.

Parameter type: string.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Unit: none

Value range: a string.

Default value: **"postgres"**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

krb_caseins_users

Parameter description: Specifies whether the Kerberos username is case-sensitive.

Parameter type: Boolean

Unit: none

Value range:

- **on**: It is case-insensitive.
- **off**: It is case-sensitive.

Default value: **off**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

modify_initial_password

Parameter description: After GaussDB is installed, there is only one initial user account (whose UID is 10) in the database. When a user logs in to the database using this initial account for the first time, this parameter specifies whether the password of the initial account needs to be modified.

NOTE

If the initial user password is not specified during the installation, the initial user password is empty by default after the installation. Before performing other operations, you need to set the initial user password using the gsql client. This parameter no longer takes effect and is reserved only for compatibility with upgrade scenarios.

Parameter type: Boolean

Unit: none

Value range:

- **on**: The password of the initial account needs to be modified upon the first login after the cluster is installed.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **off**: The password of the initial account does not need to be modified after the cluster is installed.

Default value: **off**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

password_policy

Parameter description: Specifies whether to check the password complexity when you run the **CREATE ROLE/USER** or **ALTER ROLE/USER** command to create or modify the GaussDB account.

Parameter type: integer.

Unit: none

Value range: **0** or **1**

- **0**: No password complexity policy is enabled.
- **1**: The password complexity policy is enabled.

Default value: **1**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: For security purposes, do not disable the password complexity policy.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

password_reuse_time

Parameter description: Specifies whether to check the reuse interval of the new password when you run the **ALTER USER** or **ALTER ROLE** command to change a user password.

NOTE

When you change the password, the system checks the values of **password_reuse_time** and **password_reuse_max**.

- If the values of **password_reuse_time** and **password_reuse_max** are both positive numbers, an old password can be reused when it meets either of the reuse conditions
- If the value of **password_reuse_time** is **0**, password reuse is restricted based on the number of reuse times, and not on the reuse interval.
- If the value of **password_reuse_max** is **0**, password reuse is restricted based on the reuse interval, and not on the number of reuse times.
- If the values of both **password_reuse_time** and **password_reuse_max** are **0**, password reuse is not restricted.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter type: floating-point number

Unit: day

Value range: 0 to 3650

- **0** indicates that the password reuse interval is not checked.
- A positive number indicates that a new password cannot be chosen from passwords in history that are newer than the specified number of days.

Default value: **0**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Set this parameter based on service security requirements. A larger value indicates higher security but more inconvenient use.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

password_reuse_max

Parameter description: Specifies whether to check the reuse times of the new password when you run the **ALTER USER** or **ALTER ROLE** command to change a user password. Only the SYSADMIN user can access this parameter.

NOTE

When you change the password, the system checks the values of **password_reuse_time** and **password_reuse_max**.

- If the values of **password_reuse_time** and **password_reuse_max** are both positive numbers, an old password can be reused when it meets either of the reuse conditions
- If the value of **password_reuse_time** is **0**, password reuse is restricted based on the number of reuse times, and not on the reuse interval.
- If the value of **password_reuse_max** is **0**, password reuse is restricted based on the reuse interval, and not on the number of reuse times.
- If the values of both **password_reuse_time** and **password_reuse_max** are **0**, password reuse is not restricted.

Parameter type: integer.

Unit: none

Value range: 0 to 1000

- **0** indicates that the password reuse times are not checked.
- A positive number indicates that the new password cannot be the one whose reuse times exceed the specified number.

Default value: **0**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Set this parameter based on service security requirements. A larger value indicates higher security but more inconvenient use.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

password_lock_time

Parameter description: Specifies the duration before a locked account is automatically unlocked.

NOTE

The account locking and unlocking functions take effect only when the values of **password_lock_time** and **failed_login_attempts** are positive numbers.

Parameter type: floating-point number

Unit: day

Value range: 0 to 365. The integer part of the value indicates the number of days, and the decimal part can be converted into hours, minutes, and seconds. For example, **password_lock_time=1.5** indicates one day and 12 hours.

- **0** indicates that an account is not automatically locked if the password verification fails.
- A positive number indicates the duration after which a locked account is automatically unlocked.

Default value: **1**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**. The unit must be **d** if required.

Setting suggestion: Retain the default value. The automatic unlock time should not be too long. This parameter and **failed_login_attempts** should be set within a proper range.

Risks and impacts of improper settings: If the value of **failed_login_attempts** is too small and the automatic unlock time is too long, the account cannot be used for a long time due to incorrect input, affecting user experience.

failed_login_attempts

Parameter description: If the number of incorrect password attempts reaches the value of **failed_login_attempts**, the current account is locked. The account is automatically unlocked after the time specified by **password_lock_time**. During this period, only the SYSADMIN user can access the account. If you fail to enter the password during login or fail to change the password when running the **ALTER USER** command, the system considers that the entered password is incorrect.

NOTE

The account locking and unlocking functions take effect only when the values of **failed_login_attempts** and **password_lock_time** are positive numbers.

Parameter type: integer.

Unit: none

Value range: 0 to 1000.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **0** indicates that the automatic locking function does not take effect.
- A positive number indicates that an account is locked when the number of incorrect password attempts reaches the specified number.

Default value: **10**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Set it to a value ranging from 5 to 10.

Risks and impacts of improper settings: If this parameter is set to a large value that allows too many incorrect password attempts (less than the maximum value of 1000), but no security measure is taken, security risk occurs. If this parameter is set to a small value (greater than 0 and less than 10), the account may be locked due to failed password attempts, affecting normal use.

enable_lock_account

Parameter description: If **failed_login_attempts** is set to **0**, the automatic lock function is disabled. In this setting, the system cannot record the number of login failures of an account. If **enable_lock_account** is set to disable the automatic lock function, the account will not be automatically locked after the number of consecutive login failures using incorrect passwords reaches the value of **failed_login_attempts**. In this case, the system reports an alarm to ensure account security. Manual locking by an administrator is not controlled by the parameter.

Parameter type: Boolean

Unit: none

Value range:

- **on**: An account is automatically locked when the number of consecutive login failures using incorrect passwords reaches the value of **failed_login_attempts**.
- **off**: An account is not automatically locked when the number of consecutive login failures using incorrect passwords reaches the value of **failed_login_attempts**.

Default value: **on**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: For security purposes, do not disable the automatic account locking function if the alarm function is not enabled.

Risks and impacts of improper settings: If it is set to **off**, account security deteriorates.

password_encryption_type

Parameter description: Specifies the encryption type of a user password. Changing the value of this parameter does not automatically trigger the change of the password encryption type of an existing user. Only the password of a new

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

user or the password changed by an existing user is encrypted using the new encryption type.

Parameter type: integer.

Unit: none

Value range: **0**, **1**, **2**, or **3**

- **0** indicates that passwords are encrypted with MD5.
- **1** indicates that passwords are encrypted with SHA-256 and MD5.
- **2** indicates that passwords are encrypted with SHA-256.
- **3** indicates that the passwords are encrypted with SM3.

Default value: 2

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impact of improper settings: The MD5 algorithm is not recommended and has low security. If this parameter is set to **0** or **1**, security risks exist.

NOTE

The FIPS mode does not support the MD5 and SM3 algorithms. If **password_encryption_type** is set to **0**, **1**, or **3**, the MD5 and SM3 algorithms do not take effect and the SHA-256 algorithm is forcibly used to encrypt user passwords.

password_min_length

Parameter description: Specifies the minimum length of an account password. Only the SYSADMIN user can access this parameter.

Parameter type: integer.

Unit: none

Value range: 6 to 999

Default value: **8**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Set this parameter according to the actual situations. You are advised to use the default value.

Risks and impact of improper settings: If this parameter is set to a value greater than **password_max_length**, accounts cannot be created.

password_max_length

Parameter description: Specifies the maximum length of an account password. Only the SYSADMIN user can access this parameter.

Parameter type: integer.

Unit: none

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Value range: 6 to 999

Default value: **32**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Set this parameter according to the actual situations. You are advised to use the default value.

Risks and impact of improper settings: If this parameter is set to a value smaller than **password_min_length**, accounts cannot be created.

password_min_uppercase

Parameter description: Specifies the minimum number of uppercase letters that an account password must contain. Only the SYSADMIN user can access this parameter.

Parameter type: integer.

Unit: none

Value range: 0 to 999.

- **0**: no limit.
- 1 to 999: minimum number of uppercase letters required in a password when you create an account.

Default value: **0**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Set this parameter according to the actual situations. You are advised to use the default value.

Risks and impact of improper settings: If this parameter is set to a value greater than **password_max_length**, accounts cannot be created.

password_min_lowercase

Parameter description: Specifies the minimum number of lowercase letters that an account password must contain. Only the SYSADMIN user can access this parameter.

Parameter type: integer.

Unit: none

Value range: 0 to 999.

- **0**: no limit.
- 1 to 999: minimum number of lowercase letters required in a password when you create an account.

Default value: **0**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Setting suggestion: Set this parameter according to the actual situations. You are advised to use the default value.

Risks and impact of improper settings: If this parameter is set to a value greater than **password_max_length**, accounts cannot be created.

password_min_digital

Parameter description: Specifies the minimum number of digits that an account password must contain. Only the SYSADMIN user can access this parameter.

Parameter type: integer.

Unit: none

Value range: 0 to 999.

- **0**: no limit.
- 1 to 999: minimum number of digits required in a password when you create an account.

Default value: **0**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Set this parameter according to the actual situations. You are advised to use the default value.

Risks and impact of improper settings: If this parameter is set to a value greater than **password_max_length**, accounts cannot be created.

password_min_special

Parameter description: Specifies the minimum number of special characters that must be contained in an account password. Only the SYSADMIN user can access this parameter.

Parameter type: integer.

Unit: none

Value range: 0 to 999.

- **0**: no limit.
- 1 to 999: minimum number of special characters required in a password when you create an account.

Default value: **0**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Set this parameter according to the actual situations. You are advised to use the default value.

Risks and impact of improper settings: If this parameter is set to a value greater than **password_max_length**, accounts cannot be created.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

password_effect_time

Parameter description: Specifies the validity period of an account password.

Parameter type: floating-point number

Unit: day

Value range: 0 to 999. The integer part indicates the number of days, and the decimal part can be converted into hours, minutes, and seconds. For example, **password_effect_time=0.5** indicates 0 days and 12 hours.

- **0**: The validity period restriction of an account password is disabled.
- 1 to 999: number of days for which an account password is valid. When the password is about to expire or has expired, the system prompts the user to change the password.

Default value: **0**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: You are advised to set the password validity period based on service security requirements. A smaller value indicates higher security.

Risks and impact of improper settings: If this parameter is set to **0**, security risks exist if the password is not changed for a long time.

password_notify_time

Parameter description: Specifies how many days in advance a user is notified before a password expires.

Parameter type: integer.

Unit: day

Value range: 0 to 999.

- **0**: The reminder is disabled.
- 1 to 999: number of days prior to password expiration that a user will receive a reminder.

Default value: **7**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impact of improper settings: If this parameter is set to **0**, password expiration is not reminded in advance.

enable_innertool_cert

Parameter description: Specifies whether internal tools use certificate authentication.

Parameter type: Boolean

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Unit: none

Value range:

- **on**: Internal tools use certificate-based authentication.
- **off**: Internal tools do not use certificate-based authentication.

Default value: **off**

NOTE

- This parameter takes effect only when both this parameter and **ssl** are enabled.
- By default, the certificate in the *$GAUSSHOME*/**share/sslcert/gsql** directory is used. **Common Name** of the certificate must be the same as the initial user. Otherwise, the authentication fails.
- After this parameter is enabled, the initial user uses certificate-based authentication, and other users use password-based authentication.
- After this parameter is enabled, the initial user can remotely connect to the database using certificate-based authentication.

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: The default value is recommended. If you have high security requirements, you are advised to enable this parameter and correctly configure related certificates.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

ldap_ca_file

Parameter description: Specifies the LDAP client certificate path.

Parameter type: string.

Unit: none

Value range: a string.

Default value: **"/etc/openldap/certs/cacert.pem"**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Set this parameter based on the actual certificate location.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

6.3.3.3 Communications Library Parameters

This section describes parameter settings and value ranges for communications libraries.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

tcp_keepalives_idle

Parameter description: Specifies the interval for transmitting keepalive signals on an OS that supports the **TCP_KEEPIDLE** socket option. If no keepalive signal is transmitted, the connection is in idle mode.

NOTE

- If the OS does not support **TCP_KEEPIDLE**, set this parameter to **0**.
- The parameter is ignored on an OS where connections are established using the UDS.
- If this parameter is set to **0**, the system value is used.
- This parameter is not shared among different sessions. That is, different session connections may have different values.
- The parameter value in the current session connection, not the value of the GUC copy, is displayed.

Parameter type: integer

Unit: seconds

Value range: 0 to 3600

Default value: **60**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**. For example, if the value is **60** without a unit, **tcp_keepalives_idle** indicates 60s. If the value is **1min**, **tcp_keepalives_idle** indicates 1 minute. If the unit is required, the value must be **s**, **min**, **h**, or **d**.

Setting suggestion: Before setting this parameter, ensure that the OS supports the **TCP_KEEPIDLE** socket option.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

tcp_keepalives_interval

Parameter description: Specifies the response time before retransmission on an OS that supports the **TCP_KEEPINTVL** socket option.

NOTE

- If the OS does not support **TCP_KEEPINTVL**, set this parameter to **0**.
- The parameter is ignored on an OS where connections are established using the UDS.
- If this parameter is set to **0**, the system value is used.
- This parameter is not shared among different sessions. That is, different session connections may have different values.
- The parameter value in the current session connection, not the value of the GUC copy, is displayed.

Parameter type: integer

Unit: seconds

Value range: 0 to 180

Default value: **30**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**. For example, if the value is **60** without a unit, **tcp_keepalives_interval** indicates 60s. If the value is **1min**, **tcp_keepalives_interval** indicates 1 minute. If the unit is required, the value must be **s**, **min**, **h**, or **d**.

Setting suggestion: Before setting this parameter, ensure that the OS supports the **TCP_KEEPINTVL** socket option.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

tcp_keepalives_count

Parameter description: Specifies the number of keepalive signals that can be waited before the GaussDB server is disconnected from the client on an OS that supports the **TCP_KEEPCNT** socket option.

NOTE

- If the OS does not support **TCP_KEEPCNT**, set this parameter to **0**.
- The parameter is ignored on an OS where connections are established using the UDS.
- If this parameter is set to **0**, the system value is used.
- This parameter is not shared among different sessions. That is, different session connections may have different values.
- The parameter value in the current session connection, not the value of the GUC copy, is displayed.

Parameter type: integer

Unit: none

Value range: 0 to 100. **0** indicates that the connection is immediately broken if GaussDB does not receive a keepalive signal from the client.

Default value: **20**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Before setting this parameter, ensure that the OS supports the **TCP_KEEPCNT** socket option.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

tcp_user_timeout

Parameter description: Specifies the maximum duration for which the transmitted data can remain in the unacknowledged state before the TCP connection is forcibly closed when the GaussDB sends data on the OS that supports the **TCP_USER_TIMEOUT** socket option.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- If the OS does not support the **TCP_USER_TIMEOUT** option, the value of this parameter does not take effect. The default value is **0**.
- The parameter is ignored on an OS where connections are established using the UDS.

Parameter type: integer

Unit: milliseconds

Value range: 0 to 3600000

Default value: **0**, indicating that the value is set based on the OS.

Note that the effective result of this parameter varies according to the OS kernel.

- For AArch64 EulerOS (Linux kernel version: 4.19), the timeout interval is the value of this parameter.
- For x86 Euler 2.5 (Linux kernel version: 3.10), the timeout interval is not the value of this parameter but the maximum value in different ranges. That is, the timeout interval is the maximum upper limit of the total Linux TCP retransmission duration to which the value of **tcp_user_timeout** belongs. For example, if **tcp_user_timeout** is set to **40000**, the total retransmission duration is 51 seconds.

  Table 6-5 Value of tcp_user_timeout for x86 Euler 2.5 (Linux kernel version: 3.10)

Number of Linux TCP Retransmission Times	Total Linux TCP Retransmission Duration Range (s)	Example of tcp_user_timeout (ms)	Actual Linux TCP Retransmission Duration (s)
1	(0.2,0.6]	400	0.6
2	(0.6,1.4]	1000	1.4
3	(1.4,3]	2000	3
4	(3,6.2]	4000	6.2
5	(6.2,12.6]	10000	12.6
6	(12.6,25.4]	20000	25.4
7	(25.4,51]	40000	51
8	(51,102.2]	80000	102.2
9	(102.2,204.6]	150000	204.6
10	(204.6,324.6]	260000	324.6
11	(324.6,444.6]	400000	444.6

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Note: The duration of each TCP retransmission increases exponentially with the number of retransmission times. When the duration of a TCP retransmission reaches 120 seconds, the duration of each subsequent retransmission does not change.

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Before setting this parameter, ensure that the OS supports the **TCP_USER_TIMEOUT** socket option.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

tcp_syn_retries

Parameter description: Specifies the number of SYN packet retransmissions due to SYN packet transmission failures in the three-way handshake for connecting to other internal nodes on the GaussDB that supports the **TCP_SYNCNT** socket option.

Parameter type: integer

Unit: none

Value range: 0–127. The value **0** indicates OS-based.

Default value: **0**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this parameter is set to a small value (greater than **0**) and the network fluctuates, the number of SYN retransmissions is small. If the retransmission duration is shorter than the network recovery duration, the connection setup fails. If this parameter is set to a large value and the network is disconnected, the number of SYN retransmissions is large and the retransmission takes a long time. As a result, the overall error reporting time is prolonged.

NOTICE

- If the OS does not support the **TCP_SYNCNT** option, setting this parameter to any value does not take effect but the value is **0** by default.
- The parameter is ignored on an OS where connections are established using the UDS.

comm_tcp_mode

Parameter description: Specifies whether the communications library uses the TCP protocol to set up a data channel. The parameter setting takes effect after you restart the cluster.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

> **NOTE**
>
> SCTP is no longer supported. This parameter is provided for compatibility, but its value is fixed at **on**.

Parameter type: Boolean

Unit: none

Value range: If this parameter is set to **on** for a CN, it connects to a DN using TCP. If this parameter is set to **on** for a DN, the DN communicates with each other using TCP.

Default value: **on**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

comm_sctp_port

Parameter description: Specifies the TCP port used to listen on data packet channels by the TCP proxy communications library.

Parameter type: integer

Unit: none

Value range: 0–65535

Default value: **25110** (The actual value is the value of the GUC parameter **port** plus 2.)

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: You are advised not to set this parameter. Related configurations are automatically delivered during cluster installation.

Risks and impacts of improper settings: This port number is automatically allocated during cluster deployment. Do not change the parameter. If the port number is incorrectly configured, the database communication fails.

comm_control_port

Parameter description: Specifies the TCP listening port used by the TCP proxy communications library.

Parameter type: integer

Unit: none

Value range: 0–65535

Default value: **25111** (The actual value is the value of the GUC parameter **port** plus 3.)

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: You are advised not to set this parameter. Related configurations are automatically delivered during cluster installation.

Risks and impacts of improper settings: This port number is automatically allocated during cluster deployment. Do not change the parameter. If the port number is incorrectly configured, the database communication fails.

comm_max_datanode

Parameter description: Specifies the maximum number of DNs supported by the TCP proxy communications library.

Parameter type: integer

Unit: none

Value range: 1 to 8192

Default value: maximum number of primary DNs supported by each node.

Setting method: This parameter is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**. During scale-in, this parameter takes effect only after the cluster is restarted.

Setting suggestion: The recommended value is **256**.

Risks and impacts of improper settings: If the parameter value is less than the number of DNs in the current cluster, the connection fails to be established. If the value is too large, too much memory is occupied.

comm_max_stream

Parameter description: Specifies the maximum number of concurrent data streams supported by the TCP proxy communications library. The value of this parameter must be greater than: Number of concurrent data streams x Number of operators in each stream x Square of **query_dop**.

Parameter type: integer

Unit: none

Value range: 2 to 60000

Default value: **1024**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion:

- You are advised not to set this parameter to a large value because this will cause high memory usage, which equals to 380 bytes x **comm_max_stream** x (**comm_max_datanode** + **max_coordinators**). If the number of concurrent data streams is large, the query is complex and the SMP is large, resulting in insufficient memory.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- If the process memory is sufficient, you can properly increase the value of **comm_max_stream**.

Risks and impacts of improper settings: If the value is too small, large-concurrency distributed stream queries will be restricted, and the error message "Cannot get stream index, maybe comm_max_stream is not enough" will be displayed. If the value is too large, too much memory will be occupied, and more system resources will be consumed when services are running in parallel. Before changing the values, check the specifications of the parameters and ensure that the hardware resources (such as CPU and memory) are sufficient. Otherwise, the cluster may be abnormal. Before service rollout, you need to complete distributed service reconstruction and perform pressure tests based on the actual service scenario to avoid errors caused by improper configuration.

comm_max_receiver

Parameter description: Specifies the maximum number of receiver threads for the TCP proxy communications library.

Parameter type: integer

Unit: none

Value range: 1 to 50

Default value: **4**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value to avoid thread switchover scheduling caused by excessive thread resources.

Risks and impacts of improper settings: If the value is too large, too many data receiving threads are started, wasting thread resources.

comm_quota_size

Parameter description: Specifies the maximum size of packets that can be consecutively sent by the TCP proxy communications library.

Parameter type: integer

Unit: KB

Value range: 0 to 2048000

Default value: **1024**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**. For example, if the value is **1024** without a unit, **comm_quota_size** indicates 1024 KB. If the value is **1MB**, **comm_quota_size** indicates 1 MB. The unit must be KB, MB, or GB if required.

Setting suggestion: Retain the default value. When you use a 1GE NIC, a small value ranging from 20 KB to 40 KB is recommended.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Risks and impacts of improper settings: If this parameter is set to a small value, the TCP communications library may wait for the quota during the sending and receiving phases.

comm_usable_memory

Parameter description: Specifies the maximum memory available for buffering on the TCP proxy communications library on a DN.

Parameter type: integer

Unit: KB

Value range: 102400 to 1073741823

Default value: **4096000** (that is, 4000 MB)

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**. For example, if the value is **102400** without a unit, **comm_usable_memory** indicates 102400 KB. If the value is **100MB**, **comm_usable_memory** indicates 100 MB. The unit must be KB, MB, or GB if required.

Setting suggestion: Retain the default value. Set this parameter based on the environment memory and deployment mode.

Risks and impacts of improper settings: If the value is too large, OOM occurs. If the value is too small, the performance of the TCP proxy communications library deteriorates.

comm_memory_pool

Parameter description: Specifies the size of the memory pool resources that can be used by the TCP proxy communications library on a DN.

Parameter type: integer

Unit: KB

Value range: 102400 to 1073741823

Default value: **2048000** (that is, 2000 MB)

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**. For example, if the value is **102400** without a unit, **comm_memory_pool** indicates 102400 KB. If the value is **100MB**, **comm_memory_pool** indicates 100 MB. The unit must be KB, MB, or GB if required.

Setting suggestion: Retain the default value. If the memory used by the communications library is small, set this parameter to a small value. Otherwise, set it to a large value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing. Before changing the values, check the specifications of the parameters and ensure that the hardware resources are sufficient. Otherwise, the cluster may be abnormal.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

comm_memory_pool_percent

Parameter description: Specifies the percentage of the memory pool resources that can be used by the TCP proxy communications library on a DN. This parameter is used to adaptively reserve memory used by the communications libraries.

Parameter type: integer

Unit: none

Value range: 0 to 100

Default value: **0**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value. If the memory used by the communications library is small, set this parameter to a small value. Otherwise, set it to a large value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

comm_client_bind

Parameter description: Specifies whether to bind the client of the communications library to a specified IP address when the client initiates a connection.

Parameter type: Boolean

Unit: none

Value range:

- **on**: The client is bound to a specified IP address.
- **off**: The client is not bound to a specified IP address.

Default value: **off**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: If multiple IP addresses of a node in the cluster are on the same network segment, set this parameter to **on**. In this case, the client is bound to the IP address specified by **listen_addresses**. The concurrency performance of the cluster depends on the number of random ports because a port can be used by only one client at a time.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

comm_no_delay

Parameter description: Specifies whether to use the **NO_DELAY** attribute of a communications library connection. The modification of this parameter takes effect only after the cluster is restarted.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter type: Boolean

Unit: none

Value range:

- **on**: The NO_DELAY attribute is used.
- **off**: The NO_DELAY attribute is not used.

Default value: **off**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Enable this parameter for delay-sensitive services and disable it for high throughput requirements. In addition, if packet loss occurs in the cluster because a large number of packets are received per second, set this parameter to **off** so that small packets are combined into large packets for transmission to reduce the total number of packets.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

comm_debug_mode

Parameter description: Specifies whether to enable the debug mode of the TCP proxy communications library, that is, whether to print logs about the communication layer.

Parameter type: Boolean

Unit: none

Value range:

- **on**: The debug logs of the communications library are printed.
- **off**: The debug logs of the communications library are not printed.

Default value: **off**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: If this parameter is set to **on**, a large number of logs will be printed, adding extra overhead and reducing database performance. Therefore, set it to **on** only in debugging scenarios.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

comm_ackchk_time

Parameter description: Specifies the duration after which the communications library server automatically triggers ACK when no data packet is received.

Parameter type: integer

Unit: milliseconds

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Value range: 0 to 20000. **0**: disabled.

Default value: **2000**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**. For example, if the value is **60** without a unit, **comm_ackchk_time** indicates 60 ms. If the value is **1min**, **comm_ackchk_time** indicates 1 minute. The unit must be **ms**, **s**, **min**, **h**, or **d** if required.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

comm_timer_mode

Parameter description: Specifies whether to enable the timer mode of the TCP proxy communications library, that is, whether to print timer logs in each phase of the communication layer.

Parameter type: Boolean

Unit: none

Value range:

- **on**: The timer logs of the communications library are printed.
- **off**: The timer logs of the communications library are not printed.

Default value: **off**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: If this parameter is set to **on**, a large number of logs will be printed, adding extra overhead and reducing database performance. Therefore, set it to **on** only in debugging scenarios.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

comm_stat_mode

Parameter description: Specifies whether to enable the statistics mode of the TCP proxy communications library, that is, whether to print statistics about the communication layer.

Parameter type: Boolean

Unit: none

Value range:

- **on**: The statistics logs of the communications library are printed.
- **off**: The statistics logs of the communications library are not printed.

Default value: **off**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Setting suggestion: If this parameter is set to **on**, a large number of logs will be printed, adding extra overhead and reducing database performance. Therefore, set it to **on** only in debugging scenarios.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

enable_stateless_pooler_reuse

Parameter description: Specifies whether to enable the reuse of the pooler connection pool. After the parameter is enabled, existing idle TCP connections can be reused. The setting takes effect after the cluster is restarted.

Parameter type: Boolean

Unit: none

Value range:

- **on**: The pooler reuse mode is enabled.
- **off**: The pooler reuse mode is disabled.

Default value: **on**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Synchronize the settings for CNs and DNs. If this parameter is set to **off** for CNs and **on** for DNs, the cluster communication fails. Set this parameter to the same value for CNs and DNs. Restart the cluster for the setting to take effect.

Risks and impacts of improper settings: If this parameter is disabled, the reuse granularity of the pooler connection pool decreases and the memory usage of DNs may increase.

comm_cn_dn_logic_conn

Parameter description: Specifies whether logical connections are used between CNs and DNs. The setting takes effect after the cluster is restarted.

NOTE

Logical connections between CNs and DNs are no longer supported. This parameter is provided for compatibility, but its value is fixed at **off**.

Parameter type: Boolean

Unit: none

Value range:

- **on**: The connections between CNs and DNs are logical, with the libcomm component in use.
- **off**: The connections between CNs and DNs are physical, with the libpq component in use.

Default value: **off**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this parameter is enabled, logical connections are used between CNs and DNs to eliminate the upper limit of sockets. Logical connections cause performance overhead of the communications library.

6.3.4 Resource Consumption

6.3.4.1 Memory

This section describes memory parameters.

NOTE

These parameters, except **local_syscache_threshold**, take effect only after the database restarts.

memorypool_enable

Parameter description: Specifies whether to enable a memory pool.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The memory pool is enabled.
- **off**: The memory pool is disabled.

Default value: **off**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

memorypool_size

Parameter description: Specifies the memory pool size.

Parameter type: integer.

Unit: KB

Value range: 131072–1073741823

Default value: **524288** (512 MB)

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**. For example, if the value is **131072** without a unit,

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

memorypool_size indicates 131072 KB. If the value is **128MB**, **memorypool_size** indicates 128 MB. The unit must be KB, MB, or GB if required.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

enable_memory_limit

Parameter description: Specifies whether to enable the logical memory management module.

NOTE

Fixed cost exists, that is, **shared_buffers** and metadata (about 200 MB). If **max_process_memory** minus the fixed cost is less than 2 GB, GaussDB forcibly sets **enable_memory_limit** to **off**. Metadata is the memory used in GaussDB and is related to some concurrent parameters, such as **max_connections**, **thread_pool_attr**, and **max_prepared_transactions**.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The logical memory management module is enabled.
- **off**: The logical memory management module is disabled.

Default value: **on**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this parameter is set to **off**, the memory used by the database is not limited. When a large number of concurrent or complex queries are performed, too much memory is used, which may cause OS OOM problems.

enable_threads_memory_reserve

Parameter description: Specifies whether to enable the background thread memory isolation module. After it is enabled, memory resources are reserved for background threads based on the background thread priority. When the logical memory management module is enabled (**enable_memory_limit** is set to **on**), it takes effect only when this parameter is set to **on**.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: enables the background thread memory isolation module.
- **off**: disables the background thread memory isolation module.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Default value: **on**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value. After this function is enabled, the reserved memory and memory usage upper limit of background threads with different priorities are as follows.

Memory	High Priority	Medium Priority	Low Priority
Reserved memory 1 (maximum available dynamic memory < 10 GB)	Maximum available dynamic memory/10	Maximum available dynamic memory/10	Maximum available dynamic memory/20
Reserved memory 1 (maximum available dynamic memory < 20 GB)	0.75GB	1.5GB	0.75GB
Reserved memory 1 (maximum available dynamic memory < 40 GB)	0.9GB	3.0GB	1.5GB
Reserved memory 1 (maximum available dynamic memory ≥ 40 GB)	1.0GB	4.0GB	2.0GB
Memory usage upper limit	None	Maximum available dynamic memory x 30%	Equal to the reserved memory

Risks and impacts of improper settings: If this parameter is set to **off**, the memory usage of background threads is continuously collected, but the memory used by background threads is not isolated. In the case of high concurrency or complex queries, too much memory is used. As a result, background threads may fail to apply for memory.

max_process_memory

Parameter description: Specifies the maximum physical memory of a database node.

Parameter type: integer.

Unit: KB

Value range: 2097152 to 2147483647

Default value: For details, see "Typical scenario settings."

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**. For example, if the value is **2097152** without a unit,

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

max_process_memory indicates 2097152 KB. If the value is **2GB**, **max_process_memory** indicates 2 GB. The unit must be KB, MB, or GB if required.

Setting suggestion: This parameter is used to prevent node OOM caused by memory bloat, ensuring system reliability. On DNs, the value of this parameter depends on the physical memory of the system and the number of primary DNs deployed on a single server. The recommended formula is as follows: (Physical memory – **vm.min_free_kbytes**) x 0.7/(n + Number of primary DNs). **vm.min_free_kbytes** in this formula indicates that the OS memory reserved for the kernel to receive and send data. Its value is at least 5% of the total memory. That is, **max_process_memory** = Physical memory size x 0.665/(n + Number of primary DNs). When the number of nodes in the cluster is less than or equal to 256, n = 1. When the number of nodes in the cluster is greater than 256 and less than 512, n = 2. When the number of nodes in the cluster is greater than 512, n = 3. In independent deployment, n = 0. You can set this parameter on CNs to the same value as that on DNs.

Risks and impacts of improper settings: If this parameter is set to an improper value, for example, greater than the physical memory of the server, OS OOM problems may occur.

Typical scenario settings:

The following typical scenario settings are the optimal output values provided after the recommended specifications are tested and optimized. For details, see **Table 6-6**, **Table 6-7**, **Table 6-8**, and **Table 6-9**.

- Distributed independent deployment (single node, 1 CN or 1 DN)

  Table 6-6 Distributed independent deployment settings

Resource Setting	Recommended Value on CN	Recommended Value on DN
128C/1024G	900GB	900GB
60C/480G	360GB	360GB
32C/256G	192GB	192GB
16C/128G	96GB	96GB
8C/64G	40GB	40GB
4C/32G	20GB	20GB
4C/16G	10GB	10GB

- Finance edition (standard) (single node, 1 CN + 2 DNs)

  Table 6-9 Finance edition (data computing) settings

Resource Setting	Recommended Value on CN	Recommended Value on DN
192C/1536G	160GB	300GB
128C/1024G	120GB	200GB
96C/768G	100GB	150GB
72C/576G	60GB	110GB
64C/512G	60GB	100GB
32C/256G	20GB	40GB

local_syscache_threshold

Parameter description: Specifies the maximum memory occupied by the system cache of a single session. When the actual system cache size exceeds the threshold, memory eviction is triggered. If **enable_global_syscache** and **enable_thread_pool** are enabled, this parameter indicates the total cache size of the current thread and sessions bound to the current thread.

Parameter type: integer.

Unit: KB

Value range: 1024 to 524288

Default value:

- Independent deployment: **16MB**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**. For example, if the value is **1024** without a unit, **local_syscache_threshold** indicates 1024 KB. If the value is **1MB**, **local_syscache_threshold** indicates 1 MB. The unit must be KB, MB, or GB if required.

Setting suggestion: You are advised to set this parameter to an integer multiple of 1024. The background noise memory is 2 MB. Each time a table or index is added, the memory increases by 11 KB.

Risks and impacts of improper settings: If the value is too small, memory is frequently evicted, affecting performance.

enable_memory_context_control

Parameter description: Enables the function of checking whether the number of memory contexts exceeds the specified limit. This parameter applies only to the DEBUG version.

Parameter type: Boolean.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Unit: none

Value range:

- **on**: The function of checking the number of memory contexts is enabled.
- **off**: The function of checking the number of memory contexts is disabled.

Default value: **off**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

uncontrolled_memory_context

Parameter description: Specifies which memory context will not be checked when the function of checking whether the number of memory contexts exceeds the specified limit is enabled. This parameter applies only to the DEBUG version.

NOTE

When the parameter is queried, the title meaning string "MmgrMemoryController white list:" is added to the beginning of the parameter value.

Parameter type: string.

Unit: none

Value range: a string.

Default value: **""**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

huge_pages

Parameter description: Specifies whether to enable huge pages of static memory for the shared memory of the database.

NOTE

To enable the static huge page memory function, you need to set sufficient static huge page memory resources in the OS kernel in advance. The related parameters are **vm.nr_hugepages** and **vm.nr_overcommit_hugepages**, which are set in the **/etc/sysctl.conf** file.

Parameter type: string.

Unit: none

Value range:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **on**: enables the function of applying for static huge page memory. If huge page memory resources cannot be applied for, the database fails to be started.
- **off**: disables the function of applying for static huge page memory and common shared memory is applied for.
- **try**: attempts to apply for static huge page resources. If the application fails, the system applies for common shared memory.

Default value: **try**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

shared_buffers

Parameter description: Specifies the size of shared memory used by GaussDB. Increasing the value of this parameter causes GaussDB to request more System V shared memory than the default configuration allows.

Parameter type: integer.

Unit: page (8 KB)

Value range: 16–1073741823

Default value: For details, see "Typical scenario settings."

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**. For example, if the value is **1024** without a unit, **shared_buffers** indicates 8192 KB (1024 x 8 KB). If the value is **8MB**, **shared_buffers** indicates 8 MB. If the value contains a unit, the value must be KB, MB, or GB and must be an integer multiple of 8 KB.

Setting suggestion:

- Set this parameter on DNs to a value greater than that on CNs because most queries in GaussDB are pushed down.
- Set **shared_buffers** to a value less than 40% of **max_process_memory**.
- If **shared_buffers** is set to a larger value, increase the value of **checkpoint_segments** because a longer interval is required to write a large amount of new or changed data.
- If the process fails to be restarted after the value of **shared_buffers** is changed, perform either of the following operations based on the error information:
  - Adjust the **kernel.shmall**, **kernel.shmmax**, and **kernel.shmmin** OS parameters.
  - Run the **free -g** command to check whether the available memory and swap space of the OS are sufficient. If the memory is insufficient, manually stop other user programs that occupy much memory.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

  - For different specifications, use the default values in the corresponding suggestions. You are advised not to change the value. Otherwise, the value of **shared_buffers** may be too large or too small. Note that the following condition must be met: **data_replicate_buffer_size** + **segment_buffers** + **shared_buffers** + **wal_buffers** + **temp_buffers** + **maintenance_work_mem** + **work_mem** + **query_mem** + (Standby node) **wal_receiver_buffer_size** < **max_process_memory** < Memory size of the physical machine.

Risks and impacts of improper settings: If this parameter value is set higher than the physical memory limit, the database will fail to start as it cannot request sufficient memory.

Typical scenario settings:

The following typical scenario settings are the optimal output values provided after the recommended specifications are tested and optimized. For details, see **Table 6-10**, **Table 6-11**, **Table 6-12**, and **Table 6-13**.

- Distributed independent deployment (single node, 1 CN or 1 DN)

  Table 6-10 Distributed independent deployment settings

Resource Setting	Recommended Value on CN	Recommended Value on DN	CN Value Range	DN Value Range
128C/1024G	8GB	304GB	256MB ~ 409.6GB	2GB ~ 409.6GB
60C/480G	4GB	140GB	256MB ~ 192GB	2GB ~ 192GB
32C/256G	2GB	76GB	256MB ~ 102.4GB	2GB ~ 102.4GB
16C/128G	2GB	40GB	256MB ~ 51.2GB	2GB ~ 51.2GB
8C/64G	1GB	16GB	256MB ~ 25.6GB	2GB ~ 25.6GB

enable_scale_cache

Parameter description: ScaleCache optimizes buffer management by improving the locality of buffer page pin and unpin, SIMD-accelerated hash retrieval, and lock-free index scan technology of copy on write, thereby improving the overall buffer performance. This parameter can be set only in the Arm 8 or later environment.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The ScaleCache buffer management mode is enabled.
- **off**: The ScaleCache buffer management mode is disabled.

Default value: **off**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

pin_buffer_group_cores

Parameter description: Specifies the number of CPU cores in each group when the ScaleCache function is used to group CPU cores during pin and unpin

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

optimization. This parameter can be set and modified only when **enable_scale_cache** is set to **on**. This parameter can be set only in the Arm 8 or later environment.

Parameter type: integer.

Unit: none

Value range: 1 to 1073741823

Default value: **4**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Set this parameter to a power of 2. If the number of CPU cores or the value of this parameter is not a power of 2, this parameter is set to **1**.

Risks and impacts of improper settings: Before modifying this parameter, ensure that the **enable_scale_cache** parameter is enabled. Before modifying this parameter, make sure you understand its meaning and fully verify the change in a test environment.

enable_shared_storage_aio

Parameter description: Specifies whether to enable the function of optimizing asynchronous parallel write logs in OceanStor Dorado shared storage mode.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The asynchronous write function of the OceanStor Dorado shared storage is enabled.
- **off**: The asynchronous write function of the OceanStor Dorado shared memory is disabled.

Default value: **off**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

page_version_check

Parameter description: Specifies whether to perform verification for underlying storage faults and pages not marked as dirty based on page version information. **page_version_check** is a level-3 switch. The verification for underlying storage faults is to check whether a page read from the underlying storage is of a correct version, which prevents loss of page version information caused by a fault such as a disk power failure. The verification for pages not marked as dirty is to check whether modified pages are not marked as dirty, and is controlled by an independent switch **page_missing_dirty_check**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter type: enumerated type

Unit: none

Value range:

- **off**: The verification for underlying storage faults and pages not marked as dirty is disabled.
- **memory**: The page version verification function (that is, verification for underlying storage faults and pages not marked as dirty) in pure memory mode is enabled. The page version information is cached only in the memory and will be lost after a restart.
- **persistence**: The persistent page version verification function (that is, verification for underlying storage faults and pages not marked as dirty) is enabled. The page version information is persisted to files and will not be lost after a restart.

Default value: **persistence** (192-core CPU/1536 GB memory, 128-core CPU/1024 GB memory, 104-core CPU/1024 GB memory, 96-core CPU/1024 GB memory, 96-core CPU/768 GB memory, 80-core CPU/640 GB memory, 80-core CPU/512 GB memory, 72-core CPU/576 GB memory, 64-core CPU/512 GB memory, 60-core CPU/480 GB memory, 32-core CPU/256 GB memory, 16-core CPU/128 GB memory); **off** (8-core CPU/64 GB memory, 4-core CPU/16 GB memory, 4-core CPU/32 GB memory)

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Set this parameter based on the server specifications. Recommended settings: **persistence** (192-core CPU/1536 GB memory, 128-core CPU/1024 GB memory, 104-core CPU/1024 GB memory, 96-core CPU/1024 GB memory, 96-core CPU/768 GB memory, 80-core CPU/640 GB memory, 80-core CPU/512 GB memory, 72-core CPU/576 GB memory, 64-core CPU/512 GB memory, 60-core CPU/480 GB memory, 32-core CPU/256 GB memory, 16-core CPU/128 GB memory); **off** (8-core CPU/64 GB memory, 4-core CPU/16 GB memory, 4-core CPU/32 GB memory).

Risks and impacts of improper settings: Setting this parameter to **memory** and **persistence** affects the performance of a device, and the one with smaller specifications suffers more. (For example, the performance of a 16-core CPU/128 GB storage device using TPC-C model is degraded by about 7%.) If the system needs to restart frequently, you are advised to set this parameter to **persistence** to ensure that the version information on the page is not lost. However, the performance will be affected.

page_version_full_validation

Parameter description: Inserts the page version into AntiCache during dirty page flushing for the buffer in AntiCache persistent state. This is more frequent than the memory mode in which the page version is inserted only when the buffer is eliminated. As a result, the AntiCache memory may be fully occupied, causing missing verification. To reduce the probability of missing verification and achieve 100% verification coverage, the insertion mode in persistent state and the Vlog file recycling mechanism need to be optimized. The **page_version_full_validation** parameter specifies whether to enable the full verification mode of AntiCache.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

After this parameter is enabled, if the memory is full when the page is inserted into AntiCache, the system first performs in-place verification on an existing page to release space and then inserts a new page version.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The AntiCache full verification mode is enabled.
- **off**: The AntiCache full verification mode is disabled.

Default value: **on**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

page_missing_dirty_check

Parameter description: Checks whether the modified pages are not marked as dirty. **page_missing_dirty_check** is controlled by **page_version_check**. If **page_version_check** is set to **off**, setting **page_missing_dirty_check** to **on** does not take effect.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The verification for pages not marked as dirty is performed.
- **off**: The verification for pages not marked as dirty is not performed.

Default value: **off**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: You are advised to enable this function in test scenarios to detect as many pages not marked as dirty that lead to code bugs in non-production environments as possible. On the live network, this function is disabled by default to avoid extra cost and performance deterioration.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

page_version_max_num

Parameter description: Specifies the maximum number of page versions that can be cached in the memory. This parameter is valid only when **page_version_check** is not set to **OFF**. Each **page_version** occupies 36 bytes of memory. Pay attention to the memory usage.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter type: integer.

Unit: none

Value range: 0 to 2147483647

- **0**: The value is automatically calculated based on the value of **shared_buffers** using the following formula: **page_version_max_num** = **shared_buffers** x 2. For example, 32 MB of **shared_buffers** corresponds to 4096 buffers. Therefore, the value of this parameter is set to **8192**.
- Non-zero values: The manually configured value is forcibly used. The parameter cannot be set a value less than 16 times of **page_version_partitions**. Otherwise, it is forcibly set to a value equal to the value of **page_version_partitions** multiplied by 16.

Default value: **0**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: If the memory is limited, the valid value must be twice to four times the value of **shared_buffers**. **Setting suggestion**: If high performance is required and the memory is sufficient, you are advised to manually set this parameter to a value larger than four times the value of **shared_buffers** and the ratio range of this parameter to **page_version_partitions** is [256,1024].

Risks and impacts of improper settings: If this parameter value is set higher than the physical memory limit, the database will fail to start as it cannot request sufficient memory.

page_version_partitions

Parameter description: Specifies the number of hash table partitions in cached page version information in the memory. This parameter directly affects the hash query efficiency and hash conflict probability. This parameter is valid only when **page_version_check** is not set to **OFF**.

Parameter type: integer.

Unit: none

Value range: 0–2097152

- **0**: The value is automatically calculated based on the value of **page_version_max_num** using the following formula: **page_version_partitions** = **page_version_max_num**/512. If the automatically calculated value is smaller than 4, the parameter is forcibly set to **4**.
- Non-zero values: The manually configured value is forcibly used. The minimum value is **4**. If the value is less than 4, the parameter is forcibly set to **4**.

Default value: **0**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Setting suggestion: If you have high performance requirements, you are advised to manually set this parameter to a value 1/256 to 1/1024 of the value of **page_version_max_num**.

Risks and impacts of improper settings: If the number of partitions is too large, the hash query efficiency decreases. If the number of partitions is too small, the probability of hash conflicts increases.

page_version_recycler_thread_num

Parameter description: Specifies the number of threads for recycling and verifying page version information. This parameter is valid only when **page_version_check** is not set to **off**.

Parameter type: integer.

Unit: none

Value range: 0–16

- If **page_version_check** is set to **memory**:
  - **0**: The value is automatically calculated based on **page_version_partitions**. The formula is as follows: page_version_recycler_thread_num = page_version_partitions/16384. If the automatically calculated value is greater than 4, the parameter is forcibly set to **4**.
  - Non-zero values: The manually configured value is forcibly used.
  - The value cannot be greater than that of **page_version_partitions**. Otherwise, it is forcibly set to a value equal to that of **page_version_partitions**.
- If **page_version_check** is set to **persistence**:

  If the value is less than 2, set this parameter to **2**. If the value is greater than or equal to 2, the manually configured parameter value is forcibly used.

Default value: **0**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

enable_cached_context

Parameter description: Specifies the number of cached memory contexts. If this parameter is set to **0**, the memory context optimization framework does not take effect.

Parameter type: integer.

Unit: none

Value range: 0 to 1024

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- If this parameter is set to **0**, the memory context optimization framework does not take effect.
- If this parameter is set to a non-zero value, the memory context optimization framework takes effect, and the value of this parameter is the number of cached memory contexts.

Default value: **128**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

verify_log_buffers

Parameter description: Specifies the size of the verifyLog buffer. This parameter is valid only when **page_version_check** is set to **persistence**. The verifyLog buffer memory is managed by page, and each page is 8 KB.

Parameter type: integer.

Unit: page (8 KB)

Value range: 4-262144

Default value: **1GB** (192-core CPU/1536 GB memory, 128-core CPU/1024 GB memory, 104-core CPU/1024 GB memory, 96-core CPU/1024 GB memory, 96-core CPU/768 GB memory, 80-core CPU/640 GB memory, 80-core CPU/512 GB memory, 72-core CPU/576 GB memory, 64-core CPU/512 GB memory, 60-core CPU/480 GB memory, 32-core CPU/256 GB memory); **512MB** (16-core CPU/128 GB memory); **256MB** (8-core CPU/64 GB memory); **128MB** (4-core CPU/32 GB memory); **16MB** (4-core CPU/16 GB memory)

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**. For example, the value **131072** of **verify_log_buffers** indicates that the size is 131072 x 8 KB = 1GB, and the value **131072kB** indicates that **verify_log_buffers** is 131072 KB. If the value contains a unit, the value must be KB, MB, or GB and must be an integer multiple of 8 KB.

Setting suggestion: Set this parameter based on the system hardware specifications.

1GB (192-core CPU/1536 GB memory, 128-core CPU/1024 GB memory, 104-core CPU/1024 GB memory, 96-core CPU/1024 GB memory, 96-core CPU/768 GB memory, 80-core CPU/640 GB memory, 80-core CPU/512 GB memory, 72-core CPU/576 GB memory, 64-core CPU/512 GB memory, 60-core CPU/480 GB memory, 32-core CPU/256 GB memory); **512MB** (16-core CPU/128 GB memory); **256MB** (8-core CPU/64 GB memory); **128MB** (4-core CPU/32 GB memory); **16MB** (4-core CPU/16 GB memory)

Risks and impacts of improper settings: If this parameter value is set higher than the physical memory limit, the database will fail to start as it cannot request sufficient memory.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

segment_buffers

Parameter description: Specifies the memory size of a GaussDB segment-page metadata page.

Parameter type: integer.

Unit: page (8 KB)

Value range: 16–1073741823

Default value: **1024** (that is, 8 MB)

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**. For example, if the value is **1024** without a unit, **segment_buffers** indicates 8192 KB (1024 x 8 KB). If the value is **8MB**, **segment_buffers** indicates 8 MB. If the value contains a unit, the value must be KB, MB, or GB and must be an integer multiple of 8 KB.

Setting suggestions: **segment_buffers** is used to cache the content of segment-page headers, which is key metadata information. To improve performance, it is recommended that the segment headers of ordinary tables be cached in the buffer and not be replaced. You are advised to set this parameter based on the following formula: Number of tables (including indexes and TOAST tables) x Number of partitions x 3 + 128. Multiplying by 3 is because each table (partition) has some extra metadata segments. Generally, a table has three segments. Adding 128 at last is because segment-page tablespace management requires a certain number of buffers. If this parameter is set to a small value, it takes a long time to create a segment-page table for the first time. Therefore, you are advised to retain the default value to avoid setting **segment_buffers** to an excessively large or small value. Note that the following condition must be met: **data_replicate_buffer_size** + **segment_buffers** + **shared_buffers** + **wal_buffers** + **temp_buffers** + **maintenance_work_mem** + **work_mem** + **query_mem** + (Standby node) **wal_receiver_buffer_size** < **max_process_memory** < Memory size of the physical machine.

Risks and impacts of improper settings: If this parameter value is set higher than the physical memory limit, the database will fail to start as it cannot request sufficient memory.

bulk_read_ring_size

Parameter description: Specifies the size of a ring buffer used for parallel data export.

Parameter type: integer.

Unit: KB

Value range: 256 to 2147483647

Default value: **16384** (that is, 16 MB)

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**. For example, if the value is **1024** without a unit, **bulk_read_ring_size** indicates 1024 KB. If the value is **1MB**, **bulk_read_ring_size** indicates 1 MB. The unit must be KB, MB, or GB if required.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

bulk_write_ring_size

Parameter description: Specifies the size of a ring buffer used for parallel data import.

Parameter type: integer.

Unit: KB

Value range: 16384 to 2147483647

Default value: **2097152** (that is, 2 GB)

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**. For example, if the value is **16384** without a unit, **bulk_write_ring_size** indicates 16384 KB. If the value is **16MB**, **bulk_write_ring_size** indicates 16 MB. The unit must be KB, MB, or GB if required.

Setting suggestion: Increase the value of this parameter on DNs if a huge amount of data will be imported.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

standby_shared_buffers_fraction

Parameter description: Specifies the **shared_buffers** proportion used on the server where a standby instance is deployed.

Parameter type: floating-point number

Unit: none

Value range: 0.1 to 1.0

Default value: **1**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

temp_buffers

Parameter description: Specifies the maximum size of local temporary buffers used by a database session.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- **temp_buffers** can be modified only before the first use of temporary tables within each session. Subsequent attempts to change the value of this parameter will not take effect on that session.
- A session allocates temporary buffers based on the value of **temp_buffers**. If a large value is set in a session that does not require many temporary buffers, only the cost of one buffer descriptor is added. If a buffer is used, additional 8192 bytes will be consumed for it.

Parameter type: integer.

Unit: page (8 KB)

Value range: 100 to 1073741823

Default value: **128** (that is, 1 MB)

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**. For example, if the value is **100** without a unit, **temp_buffers** indicates 800 KB (100 x 8 KB). If the value is **16MB**, **temp_buffers** indicates 16 MB. If the value contains a unit, the value must be KB, MB, or GB and must be an integer multiple of 8 KB.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

max_prepared_transactions

Parameter description: Sets the maximum number of transactions that can be in the "prepared" state simultaneously. Increasing the value of this parameter causes GaussDB to request more System V shared memory than the default configuration allows.

Parameter type: integer.

Unit: none

Value range: 0 to 262143

Default value:

- Independent deployment:

  2400 (128-core CPU/1024 GB memory); **1200** (60-core CPU/480 GB memory and 32-core CPU/256 GB memory); **800** (16-core CPU/128 GB memory); **400** (8-core CPU/64 GB memory); **300** (4-core CPU/32 GB memory); **200** (4-core CPU/16 GB memory)

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestions: The default value is recommended. You need to adjust the value only when a two-phase transaction reports an error indicating insufficient slots. To avoid failures in the preparation step, the value of this parameter must be greater than the number of worker threads in **thread_pool_attr** in thread pool mode. In non-thread pool mode, the value of this parameter must be greater than or equal to the value of **max_connections**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Risks and impacts of improper settings: When GaussDB is deployed as an HA system, set this parameter on standby nodes to a value greater than or equal to that on primary nodes. Otherwise, queries will fail on the standby nodes.

work_mem

Parameter description: Specifies the amount of memory to be used by internal sort operations and hash tables before they write data into temporary disk files. Sort operations are required for **ORDER BY**, **DISTINCT**, and **MERGE JOINS**. Hash tables are used in hash joins, hash-based aggregation, and hash-based processing of IN subqueries.

In a complex query, several sort or hash operations may run concurrently; each operation will be allowed to use as much memory as this parameter specifies. If the memory is insufficient, data will be written into temporary files. In addition, several running sessions could be performing such operations concurrently. Therefore, the total memory used may be many times the value of **work_mem**.

Parameter type: integer.

Unit: KB

Value range: 64 to 2147483647

Default value:

- Independent deployment:

  256MB (128-core CPU/1024 GB memory); **128MB** (60-core CPU/480 GB memory, 32-core CPU/256 GB memory, and 16-core CPU/128 GB memory); **64MB** (8-core CPU/64 GB memory); 32MB (4-core CPU/32 GB memory); **16MB** (4-core CPU/16 GB memory)

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**. For example, if the value is **1024** without a unit, **work_mem** indicates 1024 KB. If the value is **1MB**, **work_mem** indicates 1 MB. The unit must be KB, MB, or GB if required.

Setting suggestion:

If the physical memory specified by **work_mem** is insufficient, additional operator calculation data will be written into temporary tables based on query characteristics and the concurrency. This reduces performance by five to ten times, and prolongs the query response time from seconds to minutes.

- For complex serial queries, each query requires five to ten associated operations. Set **work_mem** using the following formula: **work_mem** = 50% of the memory/10.
- For simple serial queries, each query requires two to five associated operations. Set **work_mem** using the following formula: **work_mem** = 50% of the memory/5.
- For concurrent queries, set **work_mem** using the following formula: **work_mem** = **work_mem** for serial queries/Number of concurrent SQL statements.
- BitmapScan hash tables are also restricted by **work_mem**, but will not be forcibly flushed to disks. In the case of complete lossify, each 1 MB of memory used by the hash table corresponds to a 16-GB page of BitmapHeapScan.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

After the upper limit of **work_mem** is reached, the memory increases linearly with the data access traffic based on this ratio.

Risks and impacts of improper settings: The default value is the recommended value. You are advised not to change it. Before changing the values, check the specifications of the parameters and ensure that the hardware resources are sufficient. Otherwise, the cluster may be abnormal.

query_mem

Parameter description: Specifies the memory used by a query.

Parameter type: integer.

Unit: KB

Value range: 0 to 2147483647

- If the value of **query_mem** is greater than 32768 (that is, 32 MB), the optimizer adjusts the memory cost estimate to this value when generating an execution plan.
- If the value is less than 32768 (that is, 32 MB), the default value **0** is forcibly used. In this case, the optimizer does not adjust the estimated query memory.

Default value: **0**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**. For example, if the value is **32768** without a unit, **query_mem** indicates 32768 KB. If the value is **32MB**, **query_mem** indicates 32 MB. The unit must be KB, MB, or GB if required.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

query_max_mem

Parameter description: Specifies the maximum memory that can be used by a query.

Parameter type: integer.

Unit: KB

Value range: 0 to 2147483647

- If the value of **query_max_mem** is greater than 32768 (that is, 32 MB), an error is reported when the query memory usage exceeds the value.
- If the value is less than 32768 (that is, 32 MB), the default value **0** is used. In this case, the optimizer does not limit the query memory.

Default value: **0**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**. For example, if the value is **32768** without a unit, **query_max_mem** indicates 32768 KB. If the value is **32MB**, **query_max_mem** indicates 32 MB. The unit must be KB, MB, or GB if required.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

maintenance_work_mem

Parameter description: Specifies the maximum amount of memory to be used by maintenance operations, such as **VACUUM** and **CREATE INDEX**. This parameter may affect the execution efficiency of **VACUUM**, **VACUUM FULL**, **CLUSTER**, and **CREATE INDEX**.

Parameter type: integer.

Unit: KB

Value range: 1024 to 2147483647

Default value:

- Independent deployment:

  CN: **2GB** (128-core CPU/1024 GB memory); **1GB** (60-core CPU/480 GB memory); **512MB** (32-core CPU/256 GB memory); **256MB** (16-core CPU/128 GB memory); **128MB** (8-core CPU/64 GB memory); **64MB** (4-core CPU/32 GB memory); **32MB** (4-core CPU/16 GB memory)

  DN: **4GB** (128-core CPU/1024 GB memory); **2GB** (60-core CPU/480 GB memory); **1GB** (32-core CPU/256 GB memory); **512MB** (16-core CPU/128 GB memory); **256MB** (8-core CPU/64 GB memory); **128MB** (4-core CPU/32 GB memory); **64MB** (4-core CPU/16 GB memory)

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**. For example, if the value is **1024** without a unit, **maintenance_work_mem** indicates 1024 KB. If the value is **1MB**, **maintenance_work_mem** indicates 1 MB. The unit must be KB, MB, or GB if required.

Setting suggestion:

- The value of this parameter must be greater than that of **work_mem** so that database dumps can be more quickly cleared or restored. In a database session, only one maintenance operation can be performed at a time. Maintenance is usually performed when there are not many running sessions.
- When the thread described in **Autovacuum** is running, up to ***autovacuum_max_workers*** times this memory may be allocated. In this case, set **maintenance_work_mem** to a value greater than or equal to that of **work_mem**.
- If a large amount of data is to be clustered, increase the value of this parameter in the session.
- Use the default value. You are advised not to change the value. Otherwise, set **maintenance_work_mem** to an excessively large or small value. Note that the following condition must be met: **data_replicate_buffer_size** + **segment_buffers** + **shared_buffers** + **wal_buffers** + **temp_buffers** + **maintenance_work_mem** + **work_mem** + **query_mem** + (Standby node) **wal_receiver_buffer_size** < **max_process_memory** < Memory size of the physical machine.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Risks and impacts of improper settings: The default value is the recommended value. You are advised not to change it. Before changing the values, check the specifications of the parameters and ensure that the hardware resources are sufficient. Otherwise, the cluster may be abnormal.

max_stack_depth

Parameter description: Specifies the maximum safe depth of the GaussDB execution stack. The safety margin is required because the stack depth is not checked in every routine in the server, but only in key potentially-recursive routines, such as expression evaluation.

Parameter type: integer.

Unit: KB

Value range: 100–2147483647

Default value:

- If the value of the system thread stack size minus 640 KB is greater than or equal to 2 MB, the default value of this parameter is **2MB**.
- If the value of the system thread stack size minus 640 KB is less than 2 MB, the default value of this parameter is the system thread stack size minus 640 KB.

NOTICE

- You can run the **ulimit -s** command to view the size of the system thread stack.
- After the size of the system thread stack is modified, you need to restart the cluster for the database process to use the new size of the system thread stack. The database process inherits this limit from its parent process at start time and does not re-read the setting when running.

Setting method: This is a SUSET parameter. Set it based on instructions provided in Table 6-1. For example, if the value is **1024** without a unit, **max_stack_depth** indicates 1024 KB. If the value is **1MB**, **max_stack_depth** indicates 1 MB. The unit must be KB, MB, or GB if required.

Setting suggestion:

- The database needs to reserve 640 KB stack depth. Therefore, the optimal value of this parameter is equal to the system thread stack size minus 640 KB.
- The value of this parameter cannot be greater than the system thread stack size minus 640 KB. If you use the gs_guc tool to set this parameter to a value greater than the system thread stack size minus 640 KB, the setting fails.
- Since not all operations can be detected, you are advised to set a specific value for this parameter.
- The default value is **2 MB**, which is relatively small and does not easily cause system breakdown.

Risks and impacts of improper settings:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- If the system thread stack size minus 640 KB is less than the minimum value of this parameter, the database will fail to start.
- Setting this parameter to a value greater than the actual kernel limit means that a running recursive function may crash an individual backend process.

enable_early_free

Parameter description: Specifies whether the operator memory can be released in advance.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The operator memory can be released in advance.
- **off**: The operator memory cannot be released in advance.

Default value: **on**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

memory_trace_level

Parameter description: Specifies the control level for recording memory allocation information when the dynamic memory usage exceeds the specified percentage threshold (90% by default, which can be changed by setting the **memory_log_config** parameter) of the maximum dynamic memory. This parameter takes effect only when the GUC parameters **use_workload_manager** and **enable_memory_limit** are enabled.

Parameter type: enumerated type

Unit: none

Value range:

- **none**: indicates that memory allocation information is not recorded.
- **level1**: After the dynamic memory usage exceeds the specified percentage threshold of the maximum dynamic memory, the following memory information is recorded and saved in the *$GAUSSLOG*/**mem_log** directory:
  - Global memory overview.
  - Memory usage of the top 20 memory contexts of the instance, session, and thread types.
  - The **totalsize** and **freesize** columns for each memory context.
- **level2**: After the dynamic memory usage exceeds the specified percentage threshold of the maximum dynamic memory, the following memory information is recorded and saved in the *$GAUSSLOG*/**mem_log** directory:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

  - Global memory overview.
  - Memory usage of the top 20 memory contexts of the instance, session, and thread types.
  - The **totalsize** and **freesize** columns for each memory context.
  - Detailed information about all memory applications in each memory context, including the file where the allocated memory is located, line number, and size.

Default value: **level1**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: If this parameter is set to **level2**, the memory allocation details (file, line, and size) of each memory context are recorded, which greatly affects the performance. Therefore, exercise caution when setting this parameter.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

NOTE

- The recorded memory snapshot information can be queried by using the system function gs_get_history_memory_detail(cstring). For details about the function, see **gs_get_history_memory_detail(cstring)**.
- If the **use_workload_manager** parameter is disabled and the **bypass_workload_manager** parameter is enabled, this parameter also takes effect. The **bypass_workload_manager** parameter is of the SIGHUP type; therefore, after the reload mode is set, you need to restart the database for the setting to take effect.
- The recorded memory context is obtained after all memory contexts of the same type with the same name are summarized.

memory_log_config

Parameter description: Specifies the information as follows: when the dynamic memory usage exceeds the threshold, the dynamic memory fluctuation exceeds the threshold, or the statistical period ends, the top *N* memory contexts of each type and the memory information of the top *N* SQL statements are recorded, and memory logs are generated. This parameter takes effect only when the GUC parameters **use_workload_manager** and **enable_memory_limit** are enabled and **memory_trace_level** is not **none**.

Parameter type: string.

Unit: none

Value range:

This parameter consists of the five parts **memory_log_threshold**, **memory_rush_percent**, **memory_log_period**, **topn_memory_contexts**, and **topn_queries**, whose meanings are as follows:

- **memory_log_threshold**: specifies the percentage threshold of the dynamic memory usage. The value is an integer ranging from 0 to 100. The value **0** indicates that the function is disabled. The unit is %.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **memory_rush_percent**: specifies the percentage threshold of dynamic memory fluctuation. The value is an integer ranging from 0 to 100. The value **0** indicates that the function is disabled. The unit is %.
- **memory_log_period**: specifies the statistical period. The value is an integer ranging from 0 to *INT_MAX* (excluding *INT_MAX*). *INT_MAX* is the maximum value **2147483647** of the INT type. The value **0** indicates that the function is disabled. The unit is minute.
- **topn_memory_contexts**: specifies the top-N memory contexts of each type to be recorded. The value is an integer ranging from 0 to *INT_MAX* (excluding *INT_MAX*). The value **0** indicates that the function is disabled.
- **topn_queries**: specifies the top-N SQL statements to be recorded based on memory usage. The value is an integer ranging from 0 to *INT_MAX* (excluding *INT_MAX*). The value **0** indicates that the function is disabled.

Default value: **'90,0,0,20,10'**, indicating that the memory usage threshold is 90%, the function of triggering memory fluctuation is disabled, the function of triggering statistical period is disabled, the top 20 memory contexts of each type are recorded, and the top 10 SQL statements are recorded.

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Set this parameter based on the parameter description.

Risks and impacts of improper settings: Each part of the parameter must be separated by a comma (,). Therefore, the parameter must contain only four commas (,) and be divided into five parts. Each part must meet the requirements of the preceding value range. If any requirement is not met, the setting fails and all parameter parts do not take effect. Before modifying this parameter, make sure you understand its meaning and fully verify the change in a test environment.

resilience_memory_reject_percent

Parameter description: Specifies the dynamic memory usage percentage for escape from memory overload. This parameter takes effect only when the GUC parameters **use_workload_manager** and **enable_memory_limit** are enabled.

Parameter type: string.

Unit: none

Value range: a string of more than 0 characters.

This parameter consists of **recover_memory_percent** and **overload_memory_percent**. The meanings of the two parts are as follows:

- **recover_memory_percent**: Percentage of the dynamic memory usage when the memory recovers from overload to the maximum dynamic memory. When the dynamic memory usage is less than the maximum dynamic memory multiplied by the value of this parameter, the overload escape function is disabled and new connections are allowed. The value ranges from 0 to 100, which indicates a percentage.
- **overload_memory_percent**: Percentage of the dynamic memory usage to the maximum dynamic memory when the memory is overloaded. When the dynamic memory usage is greater than the maximum dynamic memory

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

multiplied by the value of this parameter, the current memory is overloaded. In this case, the overload escape function is triggered to kill sessions and new connections are prohibited. The value ranges from 0 to 100, which indicates a percentage.

Default value: **"0,0"**, indicating that the escape from memory overload function is disabled.

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

The following command is an example. When the memory usage exceeds 90% of the upper limit, new connections are forbidden and stacked sessions are killed. When the memory usage is less than 70% of the upper limit, session killing is stopped and new connections are allowed.

The kill policy is as follows: Idle sessions are killed first; executing sessions are killed in descending order of the memory usage.

```
gs_guc reload -Z coordinator -Z datanode -N all -I all -c "resilience_memory_reject_percent='70,90'"
```

Setting suggestion: Set the value based on service requirements.

Risks and impacts of improper settings: If the value is too small, it will frequently trigger the escape from memory overload function, causing ongoing sessions to be forcibly terminated and new connections to fail in a short period. Therefore, exercise caution when setting this parameter based on the actual memory usage.

NOTE

- You can query the maximum dynamic memory and used dynamic memory in the pv_total_memory_detail view. **max_dynamic_memory** indicates the maximum dynamic memory, and **dynamic_used_memory** indicates the used dynamic memory.
- If the **use_workload_manager** parameter is disabled and the **bypass_workload_manager** parameter is enabled, this parameter also takes effect. The **bypass_workload_manager** parameter is of the SIGHUP type; therefore, after the reload mode is set, you need to restart the database for the setting to take effect.
- The values of **recover_memory_percent** and **overload_memory_percent** can be **0** at the same time. In addition, the value of **recover_memory_percent** must be smaller than that of **overload_memory_percent**. Otherwise, the setting does not take effect.
- After the parameter is dynamically set to **"0,0"**, if session killing has been started, the killing action will not be terminated. You can wait for more than 10 seconds and then connect to the database to prevent new connections from being killed.

resilience_escape_user_permissions

Parameter description: Specifies the escape permission of users. You can set it for multiple users and separate users by commas (,). The value **sysadmin** indicates that jobs of the SYSADMIN user can be canceled by the escape function. The value **monadmin** indicates that jobs of the MONADMIN user can be canceled by the escape function. By default, this parameter is left blank, indicating that the escape function of the SYSADMIN and MONADMIN users is disabled. The value can only be **sysadmin**, **monadmin**, or an empty string.

Parameter type: string.

Unit: none

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Value range: a string of more than 0 characters.

Currently, this parameter supports only three values: **sysadmin**, **monadmin**, and **""**. The meanings of these values are as follows:

- **sysadmin**: Jobs of the SYSADMIN user can be canceled by the escape function.
- **monadmin**: Jobs of the MONADMIN user can be canceled by the escape function.
- **""**: The escape function of the SYSADMIN and MONADMIN users is disabled.

Default value: **""**, indicating that the escape function of the SYSADMIN and MONADMIN users is disabled.

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**. You can set this parameter to multiple values separated by commas (,), for example, **resilience_escape_user_permissions = 'sysadmin,monadmin'**. You can also set this parameter to only one value, for example, **resilience_escape_user_permissions = 'monadmin'**.

For example, the following command is used to enable the escape function for both the SYSADMIN and MONADMIN users:

```
gs_guc reload -Z coordinator -Z datanode -N all -I all -c
"resilience_escape_user_permissions='sysadmin,monadmin'"
```

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

NOTE

- If this parameter is set for multiple times, the latest setting takes effect.
- If this parameter is set to any value in the value range, common users support the escape function.
- If a user has both the SYSADMIN and MONADMIN role permissions, the escape function of the user can be triggered only when **resilience_escape_user_permissions** is set to **"sysadmin,monadmin"**.

start_with_max_mem

Parameter description: Specifies the maximum memory occupied by the START WITH operator. If the START WITH query statement contains a large amount of data, the memory usage may be too high due to excessive recursion depth.

Parameter type: integer.

Unit: KB

Value range: –1 to 2147483647

Default value: **-1**, indicating that the memory occupied by the START WITH operator is not limited.

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**. The value of **start_with_max_mem** can be specified without a unit, for example, **1024** (indicating 1024 KB), or with a unit, for example, **1MB** (indicating 1 MB). The unit must be KB, MB, or GB if required.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Setting suggestion: Set this parameter based on the amount of data to be queried. The default value is **-1**. If a large amount of data is queried, the memory usage may be too high. You can adjust this parameter as required to prevent a single query from occupying too much memory. For details, see **work_mem**.

Risks and impacts of improper settings: If **start_with_max_mem** is set to a non-default value or a small value, the query statement fails to be executed.

6.3.4.2 Disk Space

This section describes the disk space parameters, which are used to set limits on the disk space for storing temporary files.

sql_use_spacelimit

Parameter description: Specifies the space size for files to be written to disks when a single SQL statement is executed on a single DN. The managed space includes the space occupied by ordinary tables, temporary tables, and intermediate result sets to be written to disks. This parameter does not take effect for the initial user.

Parameter type: integer.

Unit: KB

Value range: –1 to 2147483647. The value **-1** indicates that there is no limit.

Default value: **-1**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**. If the value contains a unit, the value can be KB, MB, or GB, but cannot be TB.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after you fully understand the parameter meaning and test the parameter.

temp_file_limit

Parameter description: Specifies the maximum disk space that can be used for temporary files in a session. For example, temporary files that need to be sorted or use outer hash tables in a connection session, and temporary files occupied due to the use of cursors.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- This parameter does not apply to disk space used for temporary tables during the SQL query process.
- In the SMP scenario (**query_dop** is greater than or equal to 2), the SQL statement in the foreground session is split into several background threads (the number of split SQL statements is equal to the value of **query_dop**) for execution. When the size of temporary files generated by any thread reaches the threshold, an SQL error is reported in the frontend session. In this case, the size of temporary files may be greater than the value of this parameter set in the frontend session. (In this scenario, the peak size of temporary files occupied by a single frontend session does not exceed the value of **temp_file_limit** multiplied by the value of **query_dop**.)
- When the disk usage exceeds the read-only threshold **datastorage_threshold_value_check** and **default_transaction_read_only** is set to **on**, this parameter is taken over by the CM and is set to **0**. In this case, the modification of **temp_file_limit** does not take effect. After the disk usage is restored, the CM restores this parameter to the last value set by the user before the node becomes read-only. In addition, if disk usage goes above the read-only limit **datastorage_threshold_value_check** and **default_transaction_read_only** is **on**, clearing the disk space to reduce the disk usage to below the limit and setting **default_transaction_read_only** to **off** will be considered as bypassing CM monitoring. In this case, you need to manually change the value of **temp_file_limit**.
- If this parameter is set to the default value **-1**, after the disk usage exceeds the read-only threshold **datastorage_threshold_value_check**, the CM takes over the parameter and kills existing services. During this period, services may still be continuously flushed to disks, which may cause the disk to be full. In this case, you can delete the temporary files generated in **pgsql_tmp** in the data directory to reduce the disk usage.

Parameter type: integer.

Unit: KB

Value range: –1 to 2147483647. The value **-1** indicates that there is no limit.

Default value: **-1**

Setting method: This is a SUSET parameter. Set it based on instructions provided in **Table 6-1**. If the value contains a unit, the value can be KB, MB, or GB, but cannot be TB.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If the value is too small, frequent I/O operations will occur, causing performance deterioration. If the value is too large, too much disk space may be occupied.

6.3.4.3 Kernel Resource Usage

This section describes kernel resource parameters. Whether these parameters take effect depends on OS settings.

max_files_per_process

Parameter description: Specifies the maximum number of simultaneously open files allowed by each database thread.

Parameter type: integer.

Unit: none

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Value range: 25 to 2147483647

Default value: **1024**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: If the kernel is enforcing a proper limit, setting this parameter is not required. However, on some platforms, such as most Berkeley Software Distribution (BSD) systems, the kernel allows individual processes to open many more files than the system can support. If the message "Too many open files" is displayed, set this parameter to a smaller value. Generally, the system must meet this requirement: Number of file descriptors ≥ Maximum number of concurrent requests x Number of primary DNs on the current server x Value of **max_files_per_process** x 3.

Risks and impacts of improper settings: Set this parameter according to the actual situation. If the value is too small, the number of valid security file handles may be small. As a result, the cluster status is abnormal.

shared_preload_libraries

Parameter description: Specifies the shared libraries that need to be preloaded when the database is started. Multiple library names can be separated by commas (,). For example, **'$libdir/mylib'** will preferentially load **mylib.so** (**mylib.sl** for some platforms). Only the SYSADMIN user can modify this parameter.

NOTE

- If a specified library is not found, the GaussDB service will fail to start.
- Each GaussDB-supported library has a special mark that is checked to guarantee compatibility. Therefore, libraries that do not support GaussDB cannot be loaded in this way.

Parameter type: string.

Unit: none

Value range: a string.

Default value: **"platform_compatibility_b,security_plugin"**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: You can preload the GaussDB's stored procedure library using the '*$libdir*/pl*XXX*' syntax as described in the preceding text. *XXX* can only be **pgsql**, **perl**, **tcl**, or **python**.

By preloading a shared library and initializing it as required, the library startup time is avoided when the library is first used. However, the time to start each new server process may increase, even if that process never uses the library. Therefore, set this parameter only for libraries that will be used in most sessions.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

6.3.4.4 Cost-based Vacuum Delay

This feature is designed to reduce the I/O impact of maintenance operations such as VACUUM and ANALYZE in high-concurrency databases. The cost-based vacuum delay mechanism enables administrators to balance resource allocation among maintenance tasks and normal service operations. This feature provides the following functions:

- Non-critical delay: Maintenance operations do not need to be completed immediately and can be executed in the backend.
- Resource isolation: Maintenance tasks are prevented from occupying too many I/O resources, ensuring service query performance.

NOTICE

Certain VACUUM operations hold critical locks and should be complete as quickly as possible. In GaussDB, cost-based vacuum delays do not take effect during such operations. To avoid uselessly long delays in such cases, the actual delay is the larger of the two calculated values:

- **vacuum_cost_delay** x **accumulated_balance**/**vacuum_cost_limit**
- **vacuum_cost_delay** x 4

Context

During the execution of the **ANALYZE | ANALYSE** and **VACUUM** statements, the system maintains an internal counter that keeps track of the estimated cost of the various I/O operations that are performed. When the accumulated I/O cost reaches the threshold specified by **vacuum_cost_limit**, the thread that performs the maintenance operation sleeps for the time specified by **vacuum_cost_delay**. After the sleep ends, the counter is reset, and the operation continues. This feature is disabled by default. You need to set **vacuum_cost_delay** to a non-zero value to enable it.

vacuum_cost_delay

Parameter description: VACUUM starts the backend worker thread to vacuum dead tuples in the data table, which conflicts with the worker thread. If **vacuum_cost_delay** is set to the value of **vacuum_cost_limit** to control the impact of VACUUM on services, the VACUUM thread hibernates the time specified by **vacuum_cost_delay** and allocates resources to worker threads for execution to ensure that services are not blocked by backend VACUUM.

Parameter type: integer.

Unit: milliseconds

Value range: 0 to 100. The value **0** indicates that the cost-based vacuum delay feature is disabled, and a positive value indicates that the cost-based vacuum delay feature is enabled. In many systems, the effective resolution of the hibernation time is 10 milliseconds. Therefore, setting **vacuum_cost_delay** to a value that is not an integer multiple of 10 has the same effect as setting it to the next higher multiple of 10.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Default value: **1**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: This parameter is usually set to a small value, such as **10ms** or **20ms**. Adjusting vacuum's resource consumption is best done by changing other vacuum cost parameters.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

vacuum_cost_page_hit

Parameter description: Specifies the estimated cost for VACUUM to clean up data pages hit in a buffer.

Parameter type: integer.

Unit: none

Value range: 0 to 10000

Default value: **1**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

vacuum_cost_page_miss

Parameter description: Specifies the estimated cost for VACUUM to clean up data pages that do not hit in a buffer.

Parameter type: integer.

Unit: none

Value range: 0 to 10000

Default value: **10**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

vacuum_cost_page_dirty

Parameter description: Specifies the cost of VACUUM cleanup dirty pages. If the data page to be cleaned up is a clean page, VACUUM cleanup generates an extra cost of flushing dirty pages to disks. You can set this parameter to specify the cost of VACUUM cleanup dirty pages.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter type: integer.

Unit: none

Value range: 0 to 10000

Default value: 20

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

vacuum_cost_limit

Parameter description: Specifies the cost limit. The vacuum thread will hibernate if this limit is exceeded. When the execution cost of the VACUUM thread reaches **vacuum_cost_limit**, the thread sleeps for the time specified by **vacuum_cost_delay**.

Parameter type: integer.

Unit: none

Value range: 1 to 10000

Default value: **1000**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value. A larger value indicates a smaller I/O frequency limit of the VACUUM, a lower probability of entering the hibernation, more efficient VACUUM, and a greater impact on service I/Os.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

vacuum_defer_cleanup_age

Parameter description: Specifies the delay for the VACUUM operation to clear invalid row-store table records. The delay is calculated based on the number of executed transactions. You can set the value of **vacuum_defer_cleanup_age** to control the number of delayed transactions. That is, the VACUUM and VACUUM FULL operations do not clear a deleted tuple immediately. Instead, they clear and delete the tuple only after a certain number of transactions have been processed.

Parameter type: integer.

Unit: none

Value range: 0 to 1000000. **0** indicates no delay.

Default value: **0**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If the value is too large, VACUUM and VACUUM FULL cannot be performed in a timely manner.

6.3.4.5 Background Writer

This section describes background writer parameters. The background writer thread is used to write dirty page (new or modified data) in shared buffers to disks. It is designed to minimize or eliminate the waiting time caused by write operations (which are asynchronously performed by the background writer thread) when the database process executes user queries.

This mechanism also effectively reduces performance fluctuations caused by checkpoints. The background writer thread continuously refreshes dirty pages to disks. Therefore, when a checkpoint is triggered, only a small number of pages need to be refreshed. However, this mechanism increases the overall I/O load. In the traditional checkpoint interval, pages are refreshed only once though they may be repeatedly modified, while the background writer thread may refresh the pages multiple times in the same interval. Generally, continuous low load is better than periodic peak load. The parameters discussed in this section can be used to adjust the behavior based on actual requirements.

bgwriter_delay

Parameter description: Specifies the interval for periodically scanning dirty data in the buffer block by block. In full checkpoint mode, the amount of data written each time is controlled by the **bgwriter_lru_maxpages** parameter. After the data is written, the system sleeps for *bgwriter_delay* milliseconds and then repeats the operation. In incremental checkpoint mode, the system calculates the number of target idle buffer pages based on the specified **candidate_buf_percent_target**. If the number of candidate buffer pages is insufficient, the system scans 10 GB buffer pages every *bgwriter_delay* milliseconds. If dirty pages are found, the system flushes them to disks and adds them to the candidate linked list. If clean pages are found, the system directly adds them to the candidate linked list. In many systems, the effective resolution of the sleep delay is 10 milliseconds. Therefore, setting this parameter to a value that is not a multiple of 10 has the same effect as setting it to a value multiple of 10.

Parameter type: integer.

Unit: milliseconds

Value range: 10 to 10000

Default value: **2000** (2s)

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion:

- Incremental checkpoint mode: If the data volume is multiple times the value of **shared_buffers**, the value of **bgwriter_delay** cannot be greater than 2s. If the data volume is smaller than the value of **shared_buffers**, the value of **bgwriter_delay** can be increased to save I/O resources.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- Full checkpoint mode: Retain the default value. If the disk capability is poor, increase the value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

candidate_buf_percent_target

Parameter description: Specifies the expected percentage of the candidate linked list of clean pages to the total number of pages in the buffer when incremental checkpointing is enabled. If the proportion of pages in the linked list of clean pages is less than the value of this parameter, the pagewriter thread starts, scans the buffer pages, adds clean pages to the linked list, flushes dirty pages to disks, and then adds dirty pages to the linked list.

Parameter type: floating-point number

Unit: none

Value range: 0.1 to 0.85

Default value: **0.3**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: This parameter directly affects the number of pages flushed by the pagewriter thread. If the data volume is greater than the value of **shared_buffers** and **candidate_buf_percent_target** is set to an excessively small value, the performance is affected. If the data volume is twice or more of the value of **shared_buffers**, the value of this parameter cannot be smaller than the default value. In other scenarios, to reduce I/Os, set this parameter to a smaller value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

bgwriter_lru_maxpages

Parameter description: Specifies the maximum number of dirty pages that can be flushed by the background writer thread each time.

Parameter type: integer.

Unit: none

Value range: 0 to 1000. **0** indicates that the background writer is disabled. This setting does not affect checkpoints.

Default value: **100**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

bgwriter_lru_multiplier

Parameter description: The database kernel sets **shared_buffers** based on the current buffer size. If the value of **shared_buffers** is too small or too large when the kernel runs services, you can adjust the value of **bgwriter_lru_multiplier** to provide the optimal recommended value, the recommended value is the product of the value of this parameter and the value of **shared_buffers**. After you set this parameter to the recommended value, the setting takes effect when the database is restarted.

Parameter type: floating-point number

Unit: none

Value range: 0 to 10

Default value: **2**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion:

- The number of dirty buffers written in each round depends on the number of buffers used by server processes during recent rounds. The estimated number of buffers used in the next round is calculated using the following formula: Average number of recently used buffers x **bgwriter_lru_multiplier**. The background writer writes dirty buffers until sufficient, clean, and reusable buffers are available. The number of buffers the background writer writes in each round is always equal to or less than the value of **bgwriter_lru_maxpages**.
- Therefore, the value **1.0** of **bgwriter_lru_multiplier** indicates a just-in-time policy of writing exactly the number of dirty buffers predicted to be required. Larger values provide some cushion against spikes in demand, whereas smaller values intentionally leave more writes to be done by server processes.
- Smaller values of **bgwriter_lru_maxpages** and **bgwriter_lru_multiplier** reduce the extra I/O load caused by the background writer, but make it more likely that server processes will have to issue writes for themselves, delaying response to queries.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

pagewriter_thread_num

Parameter description: Specifies the number of threads for backend page flushing after incremental checkpointing is enabled. Data is flushed to disks based on the sequence in which dirty pages are set to dirty, clean buffer pages are generated, and recovery points for checkpointing are pushed.

Parameter type: integer.

Unit: none

Value range: 1 to 16

Default value:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- For the 8-core CPU/64 GB memory specification in hybrid deployment mode, the default value is **1**.
- For all specifications in independent deployment mode and other specifications in hybrid deployment mode, the default value is **4**.

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

dirty_page_percent_max

Parameter description: Specifies the maximum expected percentage of dirty pages to **shared_buffers** after the incremental checkpoint is enabled. When the value of this parameter is reached, the background page flush thread flushes dirty pages based on the value of **max_io_capacity**.

Parameter type: floating-point number

Unit: none

Value range: 0.1 to 1

Default value: **0.9**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

pagewriter_sleep

Parameter description: Specifies the dirty data flush period of the pagewriter page flush thread in incremental checkpoint mode.

Parameter type: integer.

Unit: milliseconds

Value range: 0 to 3600000

Default value: **2000** (2s)

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value for CNs. Do not set this parameter to a value greater than 2s for DNs. If dirty pages are generated quickly, you are advised to set this parameter to a value ranging from 100 ms to 500 ms. If this parameter is set to a large value, redo points are updated slowly, affecting Xlog recycling.

Risks and impacts of improper settings: If the value is too large, the page flushing speed decreases and redo points are pushed too slowly, affecting Xlog

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

reclamation. In addition, the instance needs to wait for the time specified by this parameter when being stopped. As a result, the process exit times out.

max_io_capacity

Parameter description: Specifies the maximum I/Os per second for the background writer to flush dirty pages in batches.

Parameter type: integer.

Unit: KB

Value range: 30720 to 10485760

Default value: **512000** (that is, 500 MB)

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**. If the value of the parameter does not contain a unit, the default unit is KB. The unit can also be MB or GB. For example, if **max_io_capacity** is set to **512000**, **512000kB**, or **500MB**, it indicates that **max_io_capacity** is 500 MB.

Setting suggestion: Set this parameter based on the service scenario and disk I/O capability of the host. For example, if the disk I/O bandwidth is 500 MB, you are advised to set the bandwidth to a value less than 500 MB. If a shorter RTO is required or a large capacity is required, you can increase the value of **max_io_capacity**, for example, 2 GB.

Risks and impacts of improper settings: If the value is too small, the dirty page flushing speed is slower than the dirty page generation speed. As a result, the dirty pages in the buffer are full and the performance deteriorates. If the value is too large, write amplification occurs, affecting the service life of the storage device.

enable_consider_usecount

Parameter description: Specifies whether the page eviction algorithm of the buffer considers the page popularity.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The page popularity is considered.
- **off**: The page popularity is not considered.

Default value: **off**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Enable this parameter in scenarios where single-page elimination is frequently performed, such as large-capacity scenarios.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

enable_buffer_evictor

Parameter description: Specifies whether to enable the intelligent eviction algorithm.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The intelligent eviction algorithm is enabled.
- **off**: The intelligent eviction algorithm is disabled.

Default value: **off**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Enable this parameter in scenarios where single-page elimination is frequently performed, such as large-capacity scenarios.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

eviction_clean_page_percent_min

Parameter description: Specifies the minimum number of clean pages reserved by the intelligent eviction algorithm. If the number of clean pages is less than the value of this parameter, the generation rate of candidate pages to be evicted is limited. If the value is set to **0**, the generation rate is not limited.

Parameter type: floating-point number

Unit: none

Value range: 0 to 0.9

Default value: **0.1**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Enable this parameter in scenarios where single-page elimination is frequently performed, such as large-capacity scenarios.

Risks and impacts of improper settings: If the value is too large, the dirty page flushing performance may deteriorate.

eviction_candidate_list_size

Parameter description: Specifies the length of the eviction queue of the intelligent eviction algorithm.

Parameter type: integer.

Unit: none

Value range: 1024 to 65536

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Default value: **2048**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Enable this parameter in scenarios where single-page elimination is frequently performed, such as large-capacity scenarios.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

pagewriter_flush_mode

Parameter description: Specifies whether to enable the ultimate dirty page flushing function.

Parameter type: enumerated type

Unit: none

Value range:

- **extre_mode**: The ultimate dirty page flushing function is enabled.
- **default_mode**: The ultimate dirty page flushing function is disabled.

Default value: **default_mode**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Enable this parameter in scenarios where single-page elimination is frequently performed, such as large-capacity scenarios.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

dw_file_num

Parameter description: Specifies the number of batch doublewrite files.

Parameter type: integer.

Unit: none

Value range: 1 to 16

Default value: **1**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: The value of this parameter is related to **pagewriter_thread_num** and cannot be greater than that of **pagewriter_thread_num**. If the value of **dw_file_num** is too large, the value is internally corrected to the value of **pagewriter_thread_num**.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

dw_file_size

Parameter description: Specifies the size of each doublewrite file.

Parameter type: integer.

Unit: MB

Value range: 32 to 256

Default value: **256**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

postmaster_parallel_init_thread_num

Parameter description: Specifies the number of parallel threads that can be used when the database is started.

Parameter type: integer.

Unit: none

Value range: 1 to 256

Default value: **16**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: This parameter indicates the number of threads for parallel initialization. Therefore, you are advised to set this parameter to a value less than or equal to the number of CPU cores minus 1.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

6.3.4.6 Asynchronous I/O

checkpoint_flush_after

Parameter description: Specifies the threshold for the number of dirty pages flushed by the checkpointer thread. If the number of pages exceeds the threshold, the thread instructs the OS to asynchronously flush the data pages cached in the file to disks. In GaussDB, the disk page size is 8 KB.

Parameter type: integer

Unit: page (8 KB)

Value range: 0 to 256. **0** indicates that the asynchronous flush function is disabled.

Default value: **256kB** (32 pages)

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**. You can set the number of pages or the size in bytes, for example, **32** or **256kB**. After the checkpointer thread continuously writes 32 disk pages, that is, 32 x 8 = 256 KB disk space, the asynchronous flush is performed. **gs_guc** does not allow you to set the number of pages as a parameter unit.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

bgwriter_flush_after

Parameter description: Specifies the threshold for the number of dirty pages flushed by the background writer thread. If the number of pages exceeds the threshold, the thread instructs the OS to asynchronously flush the data pages cached in the file to disks. In GaussDB, the disk page size is 8 KB.

Parameter type: integer

Unit: page (8 KB)

Value range: 0 to 256. **0** indicates that the asynchronous flush function is disabled.

Default value: **512kB** (64 pages)

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**. You can set the number of pages or the size in bytes, for example, **64** or **512kB**. After the background writer thread continuously writes 64 disk pages, that is, 64 x 8 = 512 KB disk space, the asynchronous flush is performed. **gs_guc** does not allow you to set the number of pages as a parameter unit.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

backend_flush_after

Parameter description: Specifies the threshold for the number of dirty pages flushed by the backend thread. If the number of pages exceeds the threshold, the thread instructs the OS to asynchronously flush the data pages cached in the file to disks. In GaussDB, the disk page size is 8 KB.

Parameter type: integer

Unit: page (8 KB)

Value range: 0 to 256. **0** indicates that the asynchronous flush function is disabled.

Default value: **0**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**. You can set the number of pages or the size in bytes, for example, **64** or **512kB**. After the backend thread continuously writes 64 disk pages, that is, 64 x 8 = 512 KB disk space, the asynchronous flush is performed. **gs_guc** does not allow you to set the number of pages as a parameter unit.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

enable_adio_function

Parameter description: Specifies whether to enable the ADIO mode.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The ADIO mode is enabled.
- **off**: The ADIO mode is disabled.

Default value: **off**

Setting method: This is a SIGHUP parameter. You can change the value of this parameter from **off** to **on** by referring to "Method 2" in **Table 6-2**. After the setting is complete, you can use the system function **gs_get_io_type()** to check whether the ADIO mode is successfully switched. If you want to change the value of this parameter from **on** to **off**, restart the instance. For details, see "Method 1" in **Table 6-2**.

Setting suggestion: If the **candidate_slots** column in the DBE_PERF.global_candidate_status system view is less than 15% of the buffer page for multiple times in a short period of time, you are advised to set this parameter to **on**.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

NOTE

If this parameter is enabled, a low configuration of **/proc/sys/fs/aio-max-nr** may stop the AIO Completer thread from starting. You are advised to increase the value of **/proc/sys/fs/aio-max-nr** to a value greater than: Maximum number of instances on the node x Maximum number of AIO threads (5 in the current version) x Maximum depth of the AIO completion queue (10,000 in the current version) + 5,000.

effective_io_concurrency

Parameter description: Specifies the number of requests that are simultaneously processed by a disk subsystem. For a RAID array, the value is the number of disk drive spindles in the array.

Parameter type: integer

Unit: none

Value range: 0 to 1000

Default value: **1**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Setting suggestion: Set this parameter to the number of disks.

Risks and impacts of improper settings: If the value is too large and the related logic is executed, the I/O resources of the entire disk may be occupied, causing I/O peak.

6.3.5 Parallel Data Import and Export

GaussDB provides a parallel data import and export function that enables a large amount of data to be imported and exported in a fast and efficient manner. This section describes parameters for importing and exporting data to GaussDB in parallel.

raise_errors_if_no_files

Parameter description: Specifies whether to distinguish between "the number of imported file records is empty" and "the imported file does not exist." If this parameter is enabled and the imported file does not exist, GaussDB displays an error message indicating that the file does not exist.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The messages of "the number of imported file records is empty" and "the imported file does not exist" are distinguished when files are imported.
- **off**: The messages of "the number of imported file records is empty" and "the imported file does not exist" are the same when files are imported.

Default value: **off**

Setting method: This is a SUSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

NOTE

The **raise_errors_if_no_files** parameter is valid only when the distributed GDS tool is used.

gds_debug_mod

Parameter description: Specifies whether to enable the debug function of Gauss Data Service (GDS). This parameter is used to better locate and analyze GDS faults. After the debug function is enabled, types of packets received or sent by GDS, peer end of GDS during command interaction, and other interaction information about GDS are written into the logs of corresponding nodes in the cluster. In this way, the state switching on the GaussDB state machine and the current state are recorded.

Parameter type: Boolean.

Unit: none

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Value range:

- **on**: The GDS debug function is enabled.
- **off**: The GDS debug function is disabled.

Default value: **off**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Enable this function only when locating GDS problems.

Risks and impacts of improper settings: If this parameter is enabled, extra logs will be generated, increasing the log I/O overhead and affecting the performance and log validity.

safe_data_path

Parameter description: Specifies the path required when the COPY, LOAD DATA, and foreign tables of the local node type, and advanced packages of non-initial users are used to read and write files. Whitelist management is implemented on related paths. Only files in the whitelisted paths can be read and written.

Parameter type: string.

Unit: none

Value range: valid directory path containing a maximum of 4096 characters.

Default value: **"copydir_default,copydir_logical_decode"**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Ensure that the path **safe_data_path** covers a limited range. Do not set a large path range.

Risks and impacts of improper settings: If **safe_data_path** is left empty and **safe_data_path** is set to a large value, malicious users may access sensitive files on the server.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- If a soft link file exists in the **safe_data_path** directory, the system processes the file based on the actual file path to which the soft link points. If the actual path is not in the **safe_data_path** directory, an error is reported.
- If a hard link file exists in the **safe_data_path** directory, it can be used properly. For security purposes, exercise caution when using hard link files. Do not create hard link files that point to other directories in the **safe_data_path** directory. Ensure that the permission on the **safe_data_path** directory is minimized.
- If the **safe_data_path** parameter is left empty, whitelist verification is disabled, which is used for compatibility with earlier versions. Exercise caution when setting this parameter after evaluating the risks and impacts.
- In the value of **safe_data_path**, different paths must be separated by commas (,). The separators cannot contain spaces or tab characters.
- **copydir_default** in the default value of this parameter is a placeholder, indicating the default path that can be used in the whitelist. The actual path is *$GAUSSLOG*/**gs_copy_data**. If the path does not exist, you can manually run the **COPY table_name FROM 'file_name'** or **COPY table_name TO 'file_name'** command to create the path, or run the **mkdir** command in the corresponding directory to create the path. When the whitelist function is enabled, you are advised not to delete this parameter.
- The default value **copydir_logical_decode** of this parameter is the path required for logical decoding. Do not delete it. Otherwise, related functions may be affected.
- When modifying the **safe_data_path** parameter, you can only add paths. Paths in the parameter value are separated using commas (,). Do not delete the default path.

enable_copy_server_files

Parameter description: Specifies whether to enable the permission to copy server files.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The permission to copy server files is enabled. Users with the SYSADMIN permission or users inherited from the built-in role gs_role_copy_files can run the **COPY FROM FILENAME** or **COPY TO FILENAME** command.
- **off**: The permission to copy server files is disabled. Only the initial user is allowed to run the **COPY FROM FILENAME** or **COPY TO FILENAME** command.

Default value: **off**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestions: Enable this function only when you need to copy server files. After this function is enabled, you are advised to set **safe_data_path** synchronously.

Risks and impacts of improper settings: After this parameter is enabled, malicious users may access sensitive files on the server if the value range of **safe_data_path** is too large.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

support_binary_copy_version

Parameter description: Specifies whether the encoding information of the current database server is included when data is exported in BINARY mode using COPY TO.

Parameter type: string.

Unit: none

Value range: **""** and **"header_encoding"**.

Table 6-14 Configuration items

Configuration Item	Behavior
"header_encoding"	When the BINARY mode of COPY TO is used to export data, the binary file header contains the encoding information of the current database server.
""	Compatibility configuration with earlier versions is performed and data is exported in the original binary format.

Default value: **"header_encoding"**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value. If compatibility with earlier versions is required, leave this parameter empty.

Risks and impacts of improper settings: If this parameter is set to an empty string, the exported result does not contain the server-side encoding information. In scenarios where the encoding information is required, you need to query and record the information.

copy_special_character_version

Parameter description: Determines the processing of invalid characters during data import and export using COPY.

Parameter type: string.

Unit: none

Value range: **""**, **"no_error"**, and **"per_byte"**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 6-15 Configuration items

Configuration Item	Behavior
"no_error"	When COPY is used to import a data file with the same encoding as that on the server, fault tolerance is performed on the data that does not meet the encoding requirements in the data file. No error is reported and the data with the original codes is directly inserted into the table.
"per_byte"	Determines how to process files encoded in GBK or ZHS16GBK when COPY is used to export text files. After the parameter is set to **"per_byte"**, one byte of data is exported at a time. Otherwise, two bytes of data are exported at a time. (One character occupies two bytes if data is encoded in GBK.)
""	The default value, which does not affect any function. Compatibility with earlier versions is supported. That is, an error is reported when invalid characters are found during COPY.

Default value: ""

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**. Use gsql to connect to the database. If you use the set method, the value is case-insensitive. If you use gs_guc, the value can only be lowercase.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

NOTE

- To ensure that the data to be imported is valid, its encoding must be validated when it is being copied. If this parameter is enabled, verification against invalid encoding will be masked, which causes invalid characters in the field. Therefore, exercise caution before enabling this parameter.
- Currently, data encoding verification is masked only when the server-side encoding is the same as the data encoding. That is, if **copy_special_character_version** is set to **"no_error"**, the database server-side encoding must be the same as the data file encoding. Otherwise, an error is reported. If no data encoding is specified, the client-side encoding is used by default.
- In binary mode, **copy_special_character_version** is set to **"no_error"**, and it takes effect only for fields of the TEXT, CHAR, VARCHAR, NVARCHAR2, or CLOB type.
- This parameter is valid only in the database with character sets encoded in UTF-8, GB18030, GB18030_2022, ZHS16GBK, or LATIN1.
- When the encoding of both the client and server is GBK or ZHS16GBK and the database contains data encoded in an invalid format, if **copy_special_character_version** is not set to **"per_byte"**, the exported data file may contain unexpected data.
- The priority of setting **copy_special_character_version** to **"no_error"** is higher than that of **COMPATIBLE_ILLEGAL_CHARS** in COPY.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

enable_log_copy_illegal_chars

Parameter description: Specifies whether to write records to the database run log if invalid characters are encountered when COPY is used to import or export data.

Parameter type: Boolean

Unit: none

Value range: **on** and **off**

Table 6-16 Configuration items

Configuration Item	Behavior
on	Each time a line of data contains invalid encoding characters, a record is written to the database run log.
off	Records related to invalid encoding characters are not written into database run logs.

Default value: **on**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value unless otherwise specified. Set this parameter to **off** only when there are requirements on database performance and disk bandwidth.

Risks and impacts of improper settings: If this parameter is set to **off**, records related to invalid encoding characters will not be written into run logs, affecting the fault locating capability.

batch_insert_index_types

Parameter description: Specifies whether to optimize the performance of batch index insertion in specific scenarios.

Parameter type: string.

Unit: none

Value range: **"rcr_ubtree"** and **""**.

Table 6-17 Configuration items

Configuration Item	Behavior
"rcr_ubtree"	The batch index insertion feature is enabled when indexes of the **rcr_ubtree** type are inserted in batches.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Configuration Item	Behavior
""	The batch index insertion feature is not enabled for any type of index.

Default value: **""**.

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value. If the performance deteriorates greatly, set this parameter to **""**.

NOTE

If any of the following scenarios meet all the specified conditions, enable the GUC parameter to improve the performance of inserting indexes in batches:

Scenario 1: Use JDBC to connect to the database and use the Java batch data insertion API executeBatch to insert indexes in batches.

Scenario 2: Run the **insert into t1 select * from t2** statement. The schemas of the **t1** and **t2** tables are the same, and **t1** contains indexes. This statement supports batch index insertion to **t1**. The stream plan must be enabled (**enable_fast_query_shipping** is set to **off**). Indexes can be inserted in batches only when table data is inserted in batches (you can run the **explain verbose** command to view the table data).

Scenario 3: Run the **copy t1 from 'file.csv' delimiter ',' csv header** statement, where **t1** and **file.csv** have the same schema, and **t1** contains indexes. This statement can be used to insert indexes in batches to the **t1** table.

Condition 1: The inserted index is a UB-tree RCR index.

Condition 2: The inserted data does not increase incrementally. (In this case, the original mechanism uses the cache, and the performance is not improved.)

Condition 3: **enable_stream_operator** is set to **on**.

Condition 4: Batch index insertion is not performed in an SMP environment.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

a_format_enable_copy_empty_lobs

Parameter description: Specifies whether empty strings can be inserted into the BLOB and CLOB types through empty string input when COPY FROM is executed in Oracle-compatible mode.

Parameter type: Boolean.

Unit: none

Value range: **on** and **off**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 6-18 Configuration items

Configuration Item	Behavior
on	In Oracle-compatible mode, empty strings can be inserted into CLOB and BLOB types using empty string input. For example, after **1,"",3** is inserted into the table, the result of the second column is empty. However, **where col2 is null** cannot be used for filtering, and the column length is 0.
off	In Oracle-compatible mode, empty strings can be inserted into CLOB and BLOB types using empty string input. An empty string is converted to NULL for storage. For example, after **1,"",3** is inserted into the table, the result of the second column is **NULL**. In this case, **where col2 is null** can be used to filter the result.

Default value: **on**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value. If compatibility with earlier versions is required, set this parameter to **off**.

NOTE

- Null string input and null value input:

  In the CSV format of COPY, **1,,3** indicates a null value, and **1,"",3** indicates a null string. When the parameter is enabled, the second column of the former is inserted as **NULL**, and the second column of the latter is inserted as an empty string. When the parameter is disabled, the second columns of the former and latter are inserted as **NULL**.
- For a newly installed database, the default value is **on**. For an upgraded database, the default value is **off** for compatibility with earlier versions.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

enable_copy_case_sensitive

Parameter description: Specifies whether to retain the case sensitivity of column names when expressions are processed during data import using gs_loader or COPY...TRANSFORM() and uppercase columns or special column names are encountered.

Parameter type: Boolean

Unit: none

Value range: **on** and **off**

Default value: **off**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value. Set this parameter to **on** if uppercase column names or special character column names exist and expressions need to be used to process the columns during data import.

NOTE

- In the **gs_loader** control file, uppercase and special character column names are converted to lowercase column names by default when expressions are used to process them. If uppercase or special character column names exist, set **enable_copy_case_sensitive** to **on** and use double quotation marks ("") in the control file to escape the column names in the control file. The following is an example:

  ```
  LOAD DATA
  CHARACTERSET UTF8
  truncate into table "IMP_COLNAME_TEST"
  FIELDS TERMINATED BY ","
  (
  id integer external,
  name char(32),
  "Column_Mixed" "TRIM(:""Column_Mixed"")",
  "Col With Space" "TRIM(:""Col With Space"")",
  "COL_UPPER" "TRIM(:""COL_UPPER"")",
  "Col""With""Quote" "TRIM(:""Col""""With""""Quote"")",
  )
  ```

- When data imported using COPY...TRANSFORM () needs to be processed using an expression, use single quotation marks ('') to identify column names in the expression. The following is an example:

  ```
  COPY "IMP_COLNAME_TEST" ( id, name, "Column_Mixed","Col With Space",
  "COL_UPPER", "Col""With""Quote", con, col_lower )
  FROM 'case.csv'
  TRANSFORM("Column_Mixed" AS TRIM(:"Column_Mixed"),"Col With Space" AS
  TRIM(:"Col With Space"),"COL_UPPER" AS TRIM(:"COL_UPPER"),"Col""With""Quote" AS
  TRIM(:"Col""With""Quote")) ;
  ```

Risks and impacts of improper settings: If this parameter is set to **off** by default, the column names in the expression are case-insensitive and are converted to lowercase letters. If the actual column names are uppercase letters, an import error may occur. If this parameter is set to **on**, the column names in the expression are used to import data.

6.3.6 Write Ahead Log

6.3.6.1 Settings

wal_level

Parameter description: Specifies the level of information to be written to the WAL. The value cannot be empty or commented out.

Parameter type: enumerated type

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Unit: none

Value range:

- **minimal**

  Advantages: Certain bulk operations (including creating tables and indexes, executing cluster operations, and copying tables) are safely skipped in logging, which improves operational efficiency.

  Disadvantages: WALs contain only basic information required for recovery from a database server crash or an emergency shutdown. Data cannot be restored from archived WALs.

- **archive**

  Adds information required for WAL archiving, supporting the database restoration from archives.

- **hot_standby**
  - Further adds information required to run SQL queries on a standby node and takes effect after the database restarts.
  - To enable read-only queries on a standby node, the **wal_level** parameter must be set to **hot_standby** or a higher level on the primary node and **hot_standby** must be enabled on the standby node. The performance difference between the **hot_standby** and **archive** levels is small.

- **logical**

  Only when this parameter is set to **logical**, logical logs can be parsed and the primary key information is recorded in Xlogs.

Default value: **hot_standby**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Set this parameter to **logical** when the logical replication function is enabled. In other scenarios, set this parameter to **hot_standby**. The parameter levels meet the following priority: **logical** > **hot_standby** > **archive** > **minimal**.

NOTICE

- To enable WAL archiving and data streaming replication between the primary and standby nodes, set this parameter to **archive**, **hot_standby**, or **logical**.
- If this parameter is set to **archive** or **minimal**, **hot_standby** must be set to **off**. In a distributed system, **hot_standby** cannot be set to **off** because this setting can affect other features of the HA system. Therefore, you are advised not to set this parameter to **archive** or **minimal**. Otherwise, the database cannot be started.

Risks and impacts of improper settings: When the read function of the standby node is enabled and the level is lower than **hot_standby**, the node cannot be started.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

fsync

Parameter description: Specifies whether the GaussDB server uses the fsync function to ensure that updated data is written to physical disks in a timely manner. For details about the implementation of the fsync function, see **wal_sync_method**.

NOTICE

- Using the fsync() function ensures that the data can be recovered to a known state when the OS or hardware crashes.
- Setting this parameter to **off** may result in unrecoverable data corruption in a system crash.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The fsync() function is used.
- **off**: The fsync() function is not used.

Default value: **on**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

wal_sync_method

Parameter description: Specifies the method for forcibly updating WAL data to disks when **fsync** is enabled.

NOTICE

If **fsync** is set to **off**, the setting of this parameter does not take effect because WAL updates will not be forcibly written to disks.

Parameter type: enumerated type

Unit: none

Value range:

- **open_datasync**: WAL files are opened using open() with the **O_DSYNC** option.
- **fdatasync**: fdatasync() is called at each commit (SUSE 10 and SUSE 11 are supported).

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **fsync_writethrough**: fsync() is called at each commit to force data in the buffer to be written to disks.
- **fsync**: fsync() is called at each commit. (SUSE 10 and SUSE 11 are supported.)
- **open_sync**: open() with the **O_SYNC** option is used to write WAL files (SUSE 10 and SUSE 11 are supported).

NOTE

- Not all platforms support the preceding parameters.
- **wal_sync_method** can be set to **fsync_writethrough** on a Windows platform, but this setting has the same effect as setting the parameter to **fsync** on the Windows platform.

Default value: fdatasync

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

synchronous_commit

Parameter description: Specifies the synchronization mode of the current transaction.

Generally, logs generated by a transaction are synchronized in the following sequence:

1. The primary node writes the logs to the local memory.
2. The primary node writes the logs in the local memory to the local file system.
3. The primary node flushes the logs in the local file system to disks.
4. The primary node sends the logs to the standby node.
5. The standby node receives the logs and saves them to the local memory.
6. The standby node writes the logs in the local memory to the local file system.
7. The standby node flushes the logs in the local file system to disks.
8. The standby node replays the logs to complete the incremental update of data files.

Parameter type: enumerated type

Unit: none

Value range:

- **on**: The primary node waits for the standby node to flush logs to disks before committing a transaction.
- **off**: The primary node commits transactions without waiting for the primary node to flush logs to disks. This mode is also called asynchronous commit.
- **local**: The primary node waits for the primary node to flush logs to disks before committing a transaction. This mode is also called local commit.
- **remote_write**: The primary node waits for the standby node to write logs to the file system before committing a transaction. (The logs do not need to be flushed to disks.)

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **remote_receive**: The primary node waits for the standby node to receive logs before committing a transaction. (The logs do not need to be written to the file system.)
- **remote_apply**: The primary node waits for the standby node to complete log replay before committing a transaction.

Default value: **on**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**. The **synchronous_commit** parameter has been taken over by the CM. In normal cases, the automatic copy upgrade function is enabled by default (that is, the CM parameter **enable_az_auto_switchover** is set to **on**). In this case, the modification of the **synchronous_commit** parameter does not take effect. Only multi-AZ scenarios are supported. To modify this parameter, you need to disable the automatic copy upgrade function (that is, set the CM parameter **enable_az_auto_switchover** to **off**). In this case, the modification of **synchronous_commit** takes effect.

Setting suggestion: Retain the default value. If you manually change the value of this parameter to a non-default value, data may be lost and this parameter cannot be put into commercial use.

Risks and impacts of improper settings: This parameter is maintained by the CM. If it is manually modified, data may be lost.

full_page_writes

Parameter description: Specifies whether the GaussDB server writes the entire content of each disk page to WALs during the first modification of that page after a checkpoint. When both **enable_incremental_checkpoint** and **enable_double_write** are enabled, **full_page_writes** is disabled.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: This feature is enabled.
- **off**: This feature is disabled.

Default value: **on**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value. After this feature is enabled, a complete page is written to a disk. During a crash and restart, the page can be correctly restored to ensure data integrity at the cost of increasing the amount of data written to WALs.

Risks and impacts of improper settings: After this feature is disabled, the OS crash may cause partial page write to the disk. As a result, the original data cannot be restored. If the server hardware (for example, a disk controller with battery power supply) or file system feature (for example, Reiser4) can effectively reduce the page write risk and the user is aware of the risk, you can disable this parameter.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

wal_log_hints

Parameter description: Specifies whether to write an entire page to WALs during the first modification of that page after a checkpoint, even for non-critical modifications of so-called hint bits.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The entire page is written to WALs.
- **off**: The entire page is not written to WALs.

Default value: **on**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Changing the value of this parameter may cause unexpected results in the cluster. Retain the default value.

wal_buffers

Parameter description: Specifies the size of shared memory for storing WALs, in multiples of **XLOG_BLCKSZ** or the actual size. **XLOG_BLCKSZ** indicates the size of an Xlog block, typically 8 KB.

Parameter type: integer.

Unit: 8 KB (**XLOG_BLCKSZ** size)

Value range: –1 to 262144 (number of Xlog blocks)

- If this parameter is set to **-1**, the **wal_buffers** size is dependent on the value of **shared_buffers**. The default value of **wal_buffers** is 1/32 of **shared_buffers**. The minimum value is **XLOG_BLCKSZ** multiplied by 8 and the maximum value is **XLOG_BLCKSZ** multiplied by 2048. If the automatically adjusted value is less than the minimum value, the value is forcibly set to the minimum value. If the value is greater than the maximum value, the value is forcibly set to the maximum value.
- If this parameter is set to a value smaller than 4 (that is, **0**, **1**, **2**, or **3**), the value **4** is forcibly used.

Default value:

- Independent deployment: 1 GB (128-core CPU/1024 GB memory, 60-core CPU/480 GB memory and 32-core CPU/256 GB memory); 512 MB (16-core CPU/128 GB memory); 256 MB (8-core CPU/64 GB memory); 128 MB (4-core CPU/32 GB memory); 64 MB (4-core CPU/16 GB memory)

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**. For example, the value **2048** indicates that **wal_buffers** is 2048 x 8 KB, and the value **20480kB** indicates that **wal_buffers** is 20480 KB. The unit must be KB, MB, or GB if required. If the value contains a unit and is not an

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

integer multiple of 8 KB, the value is automatically rounded down to an integer multiple of 8 KB.

Setting suggestion: The content of the WAL buffer is written to disks at every transaction commit. Therefore, setting an extremely large value is unlikely to bring a significant increase in system performance. However, setting this parameter to a few megabytes can improve the disk write performance on a server where a large number of transactions are committed at the same time. According to experience, the default value can meet the requirements of most cases. For different specifications, use the default values in the corresponding suggestions. You are advised to retain the default value. Do not set **wal_buffers** to an excessively large or small value, and the following condition must be true: **data_replicate_buffer_size** + **segment_buffers** + **shared_buffers** + **wal_buffers** + **temp_buffers** + **maintenance_work_mem** + **work_mem** + **query_mem** + (Standby node) **wal_receiver_buffer_size** < **max_process_memory** < Memory size of the physical machine. If the value of the memory parameter is too large and exceeds the upper limit of the physical memory, the database fails to be started because no sufficient memory can be allocated.

Risks and impacts of improper settings: The default value is the recommended value. You are advised not to change it. Before changing the values, check the specifications of the parameters and ensure that the hardware resources are sufficient. Otherwise, the cluster may be abnormal.

wal_writer_delay

Parameter description: Specifies the delay between activity rounds for the WAL writer.

Parameter type: integer.

Unit: milliseconds

Value range: 1 to 10000

Default value: **200**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If time is too long, the memory of the WAL buffer may be insufficient. If time is too short, WALs are continuously written, increasing the disk I/O load.

commit_delay

Parameter description: Specifies the duration for committed data to be stored in the WAL buffer.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTICE

- When this parameter is set to a non-zero value, the committed transaction is stored in the WAL buffer instead of being written to the WAL immediately. Then the WAL writer flushes the buffer to disks periodically.
- If system load is high, other transactions are probably ready to be committed within the delay. However, if no transaction is ready to be committed, this delay may cause unnecessary waiting.

Parameter type: integer.

Unit: μs

Value range: 0 to 100000. **0** indicates no delay.

Default value: **0**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**. The value cannot contain a unit.

Setting suggestion: For details, see the notice.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

commit_siblings

Parameter description: Specifies a threshold on the number of concurrent open transactions. If the number of concurrent open transactions is greater than the value of this parameter, a transaction that initiates a commit request will wait for a period of time specified by **commit_delay**. Otherwise, this transaction is written into WALs immediately.

Parameter type: integer.

Unit: none

Value range: 0 to 1000

Default value: **5**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

wal_block_size

Parameter description: Specifies the size of a log page in a WAL segment file.

Parameter type: integer.

Unit: byte

Value range: **8192**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Default value: **8192**

Setting method: This is a fixed INTERNAL parameter. It can be viewed but cannot be modified.

Setting suggestion: This parameter can only be viewed.

Risks and impacts of improper settings: none

wal_segment_size

Parameter description: Specifies the size of a WAL segment file. It can be specified by the multiples of **XLOG_BLCKSZ** or the actual size. **XLOG_BLCKSZ** indicates the size of an Xlog block, typically 8 KB.

Parameter type: integer.

Unit: 8 KB

Value range: **2048** (16 MB)

Default value: **16MB** (2048 x 8 KB)

Setting method: This is a fixed INTERNAL parameter. It can be viewed but cannot be modified.

Setting suggestion: This parameter can only be viewed.

Risks and impacts of improper settings: none

force_promote

Parameter description: Specifies whether to enable the forcible switchover function on the standby node.

NOTICE

When a cluster is faulty, the forcible switchover enables the cluster to recover services as soon as possible at the cost of losing some data. This is an escape method used when the cluster is unavailable. You are advised not to trigger this method frequently. You are advised not to use this function if you are not clear about the impact of data loss on services.

Parameter type: integer.

Unit: none

Value range:

- **0**: disabled.
- **1**: enabled.

Default value: **0**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**. To use the forcible standby node switchover function,

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

enable this parameter for both DNs and CM Servers. The setting takes effect after the cluster is restarted.

Setting suggestion: Do not enable this parameter.

Risks and impacts of improper settings: After this function is enabled, some data will be lost if a forcible switchover is triggered.

wal_file_init_num

Parameter description: Specifies the number of Xlog segment files created at a time when the WAL writer auxiliary thread is started.

Parameter type: integer.

Unit: none

Value range: 0 to 1000000

Default value: **10**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If the value is too large, too much disk space (**wal_file_init_num** x **wal_segment_size**) will be occupied.

wal_file_preinit_bounds

Parameter description: Specifies the maximum number of WAL segment files that can be pre-expanded by the WAL writer auxiliary thread per second during service running. The WAL segment file size is 16 MB. If this parameter is set to **0**, there is no limit.

Parameter type: integer

Unit: none

Value range: 0 to 1024

Default value: **0**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value. Set this parameter to a valid value based on the disk I/O capability. For details, see the value of **max_io_capacity**.

- If **max_io_capacity** is set to **500MB**, set this parameter to **25**.
- If **max_io_capacity** is set to **1GB**, set this parameter to **50**.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

walwriter_sleep_threshold

Parameter description: Specifies the number of times that idle Xlogs are refreshed before the Xlog flusher enters the sleep state. If the number of times reaches the threshold, the Xlog flusher enters the sleep state.

Parameter type: integer.

Unit: none

Value range: 1 to 50000

Default value: **500**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

wal_flush_timeout

Parameter description: Specifies the timeout interval for traversing **walInsertStatusTable**. It is the maximum wait time for the adaptive Xlog disk flushing I/O to traverse **walInsertStatusTable**.

Parameter type: integer.

Unit: μs

Value range: 0 to 90000000

Default value: **2**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**. The value cannot contain a unit.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If the value is too large, the Xlog flushing frequency may decrease and the Xlog processing performance may deteriorate.

xlog_file_path

Parameter description: Specifies the path of the Xlog shared disk in dual-cluster shared storage scenarios. This parameter is configured by the OM during database system initialization. You are advised not to modify the configuration.

Parameter type: string.

Unit: none

Value range: a string.

Default value: **""**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Setting suggestion: This parameter is set during installation. You are advised not to change the value.

Risks and impacts of improper settings: The database cannot be started.

xlog_file_size

Parameter description: Specifies the size of the Xlog shared disk in dual-cluster shared storage scenarios. This parameter is configured by the OM during database system initialization. You are advised not to modify the configuration.

Parameter type: integer.

Unit: byte

Value range: 134217728 to 576460752303423487

Default value: **549755813888**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**. The value cannot contain a unit.

Setting suggestion: This parameter is set during installation. You are advised not to change the value.

Risks and impacts of improper settings: Changing the value of this parameter may cause unexpected results in the cluster. Retain the default value.

xlog_lock_file_path

Parameter description: Specifies the path of the lock file preempted by the Xlog shared disk in dual-cluster shared storage scenarios. This parameter is configured by the OM during database system initialization. You are advised not to modify the configuration.

Parameter type: string.

Unit: none

Value range: a string.

Default value: **""**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: This parameter is set during installation. You are advised not to change the value.

Risks and impacts of improper settings: The database cannot be started.

max_size_for_shared_storage_xlog_write

Parameter description: Specifies the maximum amount of data that can be written to a shared disk at a time.

Parameter type: integer.

Unit: KB

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Value range: 8 to 131072

Default value: 1024

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: This parameter is set during installation. You are advised not to change the value.

Risks and impacts of improper settings: Changing the value of this parameter may cause unexpected results in the cluster. Retain the default value.

shared_storage_write_mode

Parameter description: Specifies the maximum Xlog write position of the primary cluster in shared storage (for example, OceanStor Dorado devices).

Parameter type: enumerated type

Unit: none

Value range:

- **none**: No limit.
- **standby**: maximum local Xlog LSN of the connected standby node in the cluster plus the value of **xlog_file_size** (size of the Xlog shared disk in dual-cluster shared storage scenarios).
- **disaster_standby**: maximum local LSN of the standby node connected to the standby node in the standby cluster plus the value of **xlog_file_size**.
- **disaster_standby_strict**: maximum local LSN of the standby node in the standby cluster for DR plus the value of **xlog_file_size**. (Different from **disaster_standby**, the write of this parameter is not overwritten even if the data plane network between the primary and standby clusters is isolated.)
- **standby_and_disaster_standby**: smaller value between the maximum local LSNs of the connected standby nodes in the cluster and the connected standby nodes in the standby cluster for DR plus the value of **xlog_file_size**.

Default value: **disaster_standby**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Modifying this parameter may cause the standby cluster to be rebuilt. You are advised not to manually modify this parameter.

enable_shared_storage_optimization

Parameter description: Specifies whether to enable performance optimization on shared storage (for example, OceanStor Dorado devices).

Parameter type: Boolean.

Unit: none

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Value range:

- **on**: enables performance optimization in shared storage mode.
- **off**: disables performance optimization in shared storage mode.

Default value:

- For a newly installed database: **on**.
- For a database upgraded from a version earlier than 507.0.0: **off**.
- For a database upgraded from 507.0.0 or later: original parameter value.

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this parameter is disabled, the performance of shared storage in low-concurrency scenarios will be affected.

enable_wal_insert_record_single

Parameter description: Specifies whether to enable the **Single** log insertion mode for instances on Arm-based servers. Instances on x86-based servers are not affected.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The **Single** log insertion mode is enabled.
- **off**: The **Single** log insertion mode is disabled.

Default value: **off**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion:

- In small-scale or 256-core scenarios, you are advised to enable this function to avoid invalid scheduling overhead.
- In high-concurrency multi-core scenarios, you are advised to disable this function to avoid a large number of CAS lock contentions.
- The default value of the 256-core, 2048 GB egress parameter is **on**.

Risks and impacts of improper settings: If this parameter is enabled, the performance in high-concurrency multi-core scenarios will be affected.

6.3.6.2 Checkpoints

checkpoint_segments

Parameter description: Specifies the maximum number of WAL files that can be retained in the period specified by **checkpoint_timeout**. The size of each log file is 16 MB.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter type: integer.

Unit: none

Value range: 1 to 2147483646

Default value: 1024

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value. Increasing the value of this parameter speeds up the import of a large amount of data. Set this parameter based on **checkpoint_timeout** and **shared_buffers**. This parameter affects the number of WAL files that can be reused. Generally, the maximum number of reused files in the **pg_xlog** folder is twice the value of **checkpoint_segments**. The reused files are not deleted and are renamed to the WAL segment files which will be later used.

Risks and impacts of improper settings: If the value is too small, checkpoints are frequently triggered. If the value is too large, the RTO may be increased, the number of WAL files to be retained increases, and more disk space is occupied.

checkpoint_timeout

Parameter description: Specifies the maximum time between automatic checkpoints.

Parameter type: integer.

Unit: seconds

Value range: 30 to 3600

Default value: **900** (that is, 15 minutes)

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value. If the value of **checkpoint_segments** is increased, you need to increase the value of this parameter. The increase of these two parameters further requires the increase of **shared_buffers**. Consider all these parameters during setting.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

checkpoint_completion_target

Parameter description: Specifies the ratio of the estimated completion time of each checkpoint to the value of **checkpoint_timeout**.

Parameter type: floating-point number

Unit: none

Value range: 0.0 to 1.0

Default value: **0.5**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

checkpoint_warning

Parameter description: If the checkpoint interval is less than the value of this parameter because the checkpoint file is written, a warning message is written, indicating that the value of **checkpoint_segments** needs to be increased.

Parameter type: integer.

Unit: seconds

Value range: 0 to 2147483647. **0** indicates that the warning is disabled.

Default value: **300** (5 minutes)

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

checkpoint_wait_timeout

Parameter description: Sets the longest time that the checkpoint waits for the checkpointer thread to start.

Parameter type: integer.

Unit: seconds

Value range: 2 to 3600

Default value: **60** (1 minute)

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

enable_incremental_checkpoint

Parameter description: Specifies whether to enable incremental checkpoint.

Parameter type: Boolean.

Unit: none

Value range:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **on**: The incremental checkpoint function is enabled.
- **off**: The incremental checkpoint function is disabled.

Default value: **on**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: You are advised to disable this function when the memory is small or the disk performance is poor. In other scenarios, you are advised to enable this function by default.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

NOTE

When **enable_incremental_checkpoint** is disabled and the checkpoint is manually executed, **full_page_writes** is used to generate the first Xlog. When backup and restoration are triggered, the log containing "xlog contains no data" may be generated.

enable_double_write

Parameter description: Specifies whether to enable dual-write feature. When the incremental checkpoint function **enable_incremental_checkpoint** is enabled and **enable_double_write** is enabled, the **enable_double_write** dual-write feature is used for protection and **full_page_writes** is not used to prevent partial page writes.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The dual-write function is enabled.
- **off**: The dual-write function is disabled.

Default value: **on**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Set this parameter to **on** in incremental checkpoint mode.

Risks and impacts of improper settings: Partial page writes may occur when this parameter is disabled and the incremental checkpoint function is enabled. As a result, persistent data is unavailable.

incremental_checkpoint_timeout

Parameter description: Specifies the maximum interval between automatic checkpoints when the incremental checkpoint (**enable_incremental_checkpoint**) is enabled.

Parameter type: integer.

Unit: seconds

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Value range: 1 to 3600

Default value: **60**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

enable_xlog_prune

Parameter description: Specifies whether the primary node recycles logs if the size of Xlogs exceeds the value of **max_size_for_xlog_prune** when any standby node is disconnected.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The primary node recycles logs when any standby node is disconnected.
- **off**: The primary node does not recycle logs when any standby node is disconnected.

Default value: **on**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

max_size_for_xlog_prune

Parameter description: Specifies the amount of Xlogs that are forcibly recycled.

Scenario 1: Maximum number of Xlogs retained on the primary node when the standby node is faulty. This parameter takes effect when **enable_xlog_prune** is enabled. The mechanism is as follows:

1. If all standby nodes specified by the replconninfo series GUC parameters are connected to the primary node, this parameter does not take effect.
2. This parameter takes effect when one or more standby nodes specified by the replconninfo series GUC parameters are disconnected to the primary node. If the number of Xlogs on the host is greater than the value of this parameter, the Xlogs will be forcibly recycled. The following situations are excluded:

   In synchronous commit mode (that is, the **synchronous_commit** parameter is not set to **local** or **off**), if there are standby nodes connecting to the primary node, the primary node retains the logs after the minimum log receiving location in the majority of standby nodes. In this case, the number of retained logs may be greater than the value of **max_size_for_xlog_prune**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

3. If a standby node is being built, this parameter does not take effect. All logs on the primary node are retained to prevent failures caused by log recycling during the build operation.

Scenario 2: When the PITR archive feature is enabled, the maximum number of archive Xlogs is retained. If archive Xlogs are not uploaded for a long time, the Xlogs retained locally are forcibly recycled when the size of the Xlogs exceeds the value of this parameter. In this scenario, you do not need to enable **enable_xlog_prune**.

Parameter type: integer.

Unit: KB

Value range: 0 to 2199023255551

Default value: **256GB**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**. If the value of the parameter does not contain a unit, the default unit is KB. The unit can also be MB or GB.

Setting suggestion: Set this parameter based on the available disk space. If PITR archiving is not enabled, it is recommended that the maximum value be less than or equal to 256 GB.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

- If the value is too small, the standby node may be disconnected, or a rebuild process may be triggered because the standby node cannot continuously obtain logs from the primary node when reconnecting to the primary node after build.
- When the PITR archive function is enabled, setting this parameter to a small value may trigger forcible Xlog recycling, causing subsequent XBSA archiving failures.
- If the value is too large, disk space bloat may occur when the standby node is disconnected for a long time.

max_redo_log_size

Parameter description: For a standby DN, this parameter indicates the expected log volume between the latest log replay point and the latest checkpoint position. For a primary DN, this parameter indicates the expected log volume between the latest log insertion point and the latest checkpoint position. This parameter is used to specify the page refreshing speed of checkpoints.

Parameter type: integer.

Unit: KB

Value range: 163840 to 2147483647

Default value: **1048576**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Setting suggestion: Retain the default value. It is recommended that this parameter be set to a small value if the RTO is concerned.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

checkpoint_lag_alarm_threshold

Parameter description: Specifies the threshold for triggering an alarm for checkpoint advancement lag at the recovery start point.

- For the primary instance, this threshold indicates the log volume difference between the log write position and the recovery start point.
- For the standby instance, this threshold indicates the log volume difference between the log replay position and the recovery start point.

Parameter type: integer.

Unit: GB

Value range: –1 to 2000

- **-1**: The threshold is automatically configured based on the number of CPU cores. (80 GB for fewer than 16 cores, 100 GB for 16 to 127 cores, and 128 GB for 128 or more cores.)
- **0**: The alarm for checkpoint advancement lag at the recovery start point is disabled.
- *N* (positive integer): The threshold is set to *N* GB.

Default value: **128** (192-core CPU/1536 GB memory, 128-core CPU/1024 GB memory); **100** (104-core CPU/1024 GB memory, 96-core CPU/1024 GB memory, 96-core CPU/768 GB memory, 80-core CPU/640 GB memory, 80-core CPU/512 GB memory, 72-core CPU/576 GB memory, 64-core CPU/512 GB memory, 60-core CPU/480 GB memory, 32-core CPU/256 GB memory, 16-core CPU/128 GB memory); **80** (8-core CPU/64 GB memory, 4-core CPU/32 GB memory, 4-core CPU/16 GB memory)

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

6.3.6.3 Log Replay

recovery_time_target

Parameter description: Specifies the flow control threshold for the standby node to complete log writing and replay. If the expected replay completion time of the standby node is greater than the value of this parameter, the primary node triggers log flow control and reduces the rate at which the primary node sends logs to the standby node.

Parameter type: integer.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Unit: seconds

Value range: 0 to 3600

- **0**: Log flow control is disabled.
- 1 to 3600: The standby node can write and replay logs within the period specified by the value, so that the standby node can quickly assume the primary role.

Default value: **60**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If the value is too small, the performance of the primary node will be affected. For example, if this parameter is set to **10**, there is a delay in replaying logs on the standby node compared with receiving logs on the standby node and the maximum delay is 10s. If the delay exceeds 10s, the primary node cannot send logs to the standby node, which affects the performance of the primary node. In primary and standby scenarios, transactions on the primary node can be committed only after logs on the standby node are flushed to disks. In this case, transaction execution on the primary node is restricted, affecting performance. If the value is too large, the flow control does not take effect. After flow control is disabled, the RTO/RPO may increase.

recovery_max_workers

Parameter description: Specifies the maximum number of parallel replayer threads. If the value is greater than 1, the parallel replay mode is used.

NOTICE

- This parameter takes effect only when both **recovery_parse_workers** and **recovery_redo_workers** are set to **1**, that is, the ultimate RTO is disabled.
- This parameter does not take effect when **recovery_parse_workers** or **recovery_redo_workers** is greater than 1, that is, ultimate RTO is enabled.

Parameter type: integer.

Unit: none

Value range: 0 to 20

Default value:

- For the 8-core CPU/64 GB memory specification in hybrid deployment mode, the default value is **1**.
- For all specifications in independent deployment mode and other specifications in hybrid deployment mode, the default value is **4**.

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Risks and impacts of improper settings: If this parameter is set to a large value, the CPU and memory resources will be insufficient, reducing the replay speed.

recovery_parallelism

Parameter description: Queries the actual number of parallel replayer threads.

Parameter type: integer.

Unit: none

Value range: 1 to 2147483647

Default value: **4**

Setting method: This is a POSTMASTER parameter and cannot be modified. If any of the **recovery_max_workers**, **recovery_parse_workers**, and **recovery_redo_workers** parameters is modified, **recover_parallelism** is recalculated.

Setting suggestion: This parameter is read-only and cannot be modified.

Risks and impacts of improper settings: none

queue_item_size

Parameter description: Specifies the maximum length of the task queue of each redo replayer thread.

Parameter type: integer.

Unit: none

Value range: 1 to 65535

Default value: **560**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If the value is too large, a large number of system resources will be occupied.

enable_parallel_reader

Parameter description: Specifies whether to enable the new ultimate RTO framework.

- This parameter must be used together with **recovery_readers**, **recovery_redo_workers**, **recovery_parse_workers** and **recovery_undo_workers**.
- Before enabling the new ultimate RTO framework, ensure that the value of **replication_type** is **1**.
- For details about how to enable the new ultimate RTO framework, see **Table 6-19**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 6-19 Enabling the new ultimate RTO framework

Parameter/ Mode	Parallel Replay	Ultimate RTO	New Ultimate RTO Framework
recovery_parse_workers	1	recovery_parse_workers>1 Or, recovery_redo_workers>1	recovery_parse_workers>1 Or, recovery_redo_workers>1
recovery_redo_workers	1		
enable_parallel_reader	off **NOTE** If **enable_parallel_reader** is set to **on**, the system automatically changes the value to **off** in the memory. In this case, this parameter does not take effect.	off	on

Parameter type: Boolean

Unit: none

Value range:

- **on**: The new ultimate RTO framework is enabled.
- **off**: The new ultimate RTO framework is disabled.

Default value: **off**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: You are advised not to enable this function if the number of CPU cores is less than 256.

Risks and impacts of improper settings: If the number of CPU cores is less than 256, enabling the new ultimate RTO framework may cause the cluster to fail to start.

recovery_readers

Parameter description: Specifies the number of readpage threads in the new ultimate RTO framework.

- **recovery_readers** must be used together with **enable_parallel_reader**, **recovery_redo_workers**, **recovery_parse_workers** and **recovery_undo_workers**. If you do not want to enable the new ultimate RTO framework, set **recovery_readers** to **1**.
- If **enable_parallel_reader** is set to **on** and the ultimate RTO is enabled, the value of **recovery_readers** must be greater than 1. If **enable_parallel_reader**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

is set to **on**, **recovery_readers** is set to **1**, and the value of **recovery_parse_workers** or **recovery_redo_workers** is greater than 1, the system changes the value of **enable_parallel_reader** to **false** in the memory.

Parameter type: integer

Unit: none

Value range: 1 to 50

Default value: **1**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: For details about the values of **recovery_readers**, **recovery_undo_workers**, **recovery_parse_workers**, and **recovery_redo_workers** in different CPU, memory, and deployment modes, see **Table 6-21**.

Risks and impacts of improper settings: The readpage thread has its own item for parsing Xlogs. Each time a readpage thread is added, the corresponding memory consumption increases. As services increase, if items are insufficient, item initialization will continuously happen, causing memory usage to increase. The number of items is limited. When the number of items reaches the upper limit, the memory usage does not increase significantly. However, due to operations such as ultra-large transactions may cause memory bloat of an item. Therefore, the memory usage may still increase after the number of items reaches the upper limit. Setting this parameter to a large value may cause high CPU and memory usage, which can reduce the replay speed or cause the replay to be suspended.

The new ultimate RTO framework has memory requirements. During startup, the system checks the configured values of **max_process_memory** and **shared_buffer** and calculates the maximum number of readers supported by this parameter. If the configured value of **recovery_readers** is greater than the calculated number of readers, the value of **recovery_readers** in the memory will be changed to the calculated number of readers.

parallel_max_item_count

Parameter description: Specifies the maximum number of redo items that can be used by a single readpage thread in the new ultimate RTO framework. This parameter takes effect only when the new ultimate RTO framework is used, that is, when **enable_parallel_reader** is set to **on**.

Parameter type: integer.

Unit: none

Value range: 40000 to 400000

Default value: 60000

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Set this parameter by referring to **Table 6-21**.

Risks and impacts of improper settings: The readpage thread has its own item for parsing Xlogs. Each time a readpage thread is added, the corresponding

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

memory consumption increases. As services increase, if items are insufficient, item initialization will continuously happen, causing memory usage to increase. The number of items is limited. When the number of items reaches the upper limit, the memory usage does not increase significantly. However, due to operations such as ultra-large transactions may cause memory bloat of an item. Therefore, the memory usage may still increase after the number of items reaches the upper limit. If the value is too large, CPU and memory resources will be insufficient, causing the replay performance to deteriorate. If the value is too small, the replay performance will be affected. You are advised not to set this parameter to a value less than 100000. If the replay performance is affected due to a small value, increase the value based on the actual machine configuration.

The new ultimate RTO framework has memory requirements. During startup, the system checks the configured values of **max_process_memory** and **shared_buffer** and calculates the maximum number of readers supported by this parameter. If the configured value of **recovery_readers** is greater than the calculated number of readers, the value of **recovery_readers** in the memory will be changed to the calculated number of readers.

recovery_undo_workers

Parameter description: Specifies the number of undo threads in the new ultimate RTO framework.

recovery_undo_workers must be used together with **enable_parallel_reader**, **recovery_redo_workers**, **recovery_parse_workers** and **recovery_readers**. If you do not want to enable the new ultimate RTO framework, set **recovery_undo_workers** to **1**.

Parameter type: integer

Unit: none

Value range: 1 to 50

Default value: **1**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: For details about the values of **recovery_readers**, **recovery_undo_workers**, **recovery_parse_workers**, and **recovery_redo_workers** in different CPU, memory, and deployment modes, see **Table 6-21**.

Risks and impacts of improper settings: If this parameter is set to a large value, the CPU and memory resources will be insufficient, reducing the replay speed.

recovery_parse_workers

Parameter description: Specifies the number of ParseRedoRecord threads in the ultimate RTO feature.

- It must be used together with **recovery_redo_workers**. If the value of **recovery_parse_workers** or **recovery_redo_workers** is greater than 1, ultimate RTO is enabled. If you do not want to enable ultimate RTO, set **recovery_parse_workers** to **1**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- Ensure that the value of the parameter **replication_type** is set to **1** when ultimate RTO is enabled.
- If both ultimate RTO and parallel replay are enabled, the ultimate RTO feature takes effect but the parallel replay feature does not take effect.

Parameter type: integer.

Unit: none

Value range: 1 to 16

Default value:

- Independent deployment:

  2 (128-core CPU/1024 GB memory, 60-core CPU/480 GB memory, 32-core CPU/256 GB memory, 16-core CPU/128 GB memory); **1** (8-core CPU/64 GB memory, 4-core CPU/32 GB memory, 4-core CPU/16 GB memory)

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Set **recovery_parse_workers** and **recovery_redo_workers** based on the CPU, memory, and deployment mode by referring to **Table 6-20**.

Risks and impacts of improper settings: If this parameter is set to a large value, the CPU and memory resources will be insufficient, reducing the replay speed.

NOTE

- After ultimate RTO is enabled, the total number of extra replayer threads started by the standby node = **recovery_parse_workers** × (**recovery_redo_workers** + 2) + 5. More replayer threads occupy more CPU, memory, and I/O resources. Set parameters based on the actual hardware configuration. If the parameter value is too large, the CPU and memory usage may be too high, causing system startup exceptions. In hybrid deployment scenarios, host performance may be affected.
- In the new ultimate RTO framework, the value of **recovery_parse_workers** ranges from 2 to 16. In this mode, if **recovery_parse_workers** is set to **1**, the system automatically sets it to **2** in the memory.

recovery_redo_workers

Parameter description: Specifies the number of PageRedoWorker threads corresponding to each ParseRedoRecord thread in the ultimate RTO feature. **recovery_redo_workers** must be used together with **recovery_parse_workers**. If **recovery_parse_workers** or **recovery_redo_workers** is greater than 1, ultimate RTO is enabled. If you do not want to enable ultimate RTO, retain the default value **1** of **recovery_redo_workers**.

Parameter type: integer.

Unit: none

Value range:

- Ultimate RTO: 1 to 8
- New ultimate RTO framework: 1 to 50

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

In ultimate RTO mode, if the value is greater than 8, the value is automatically changed to **8** in the memory.

Default value:

- Independent deployment:

  8 (128-core CPU/1024 GB memory, 60-core CPU/480 GB memory, 32-core CPU/256 GB memory); **3** (16-core CPU/128 GB memory, 8-core CPU/64 GB memory); **1** (4-core CPU/32 GB memory, 4-core CPU/16 GB memory)

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Set **recovery_parse_workers** and **recovery_redo_workers** based on the CPU, memory, and deployment mode by referring to **Table 6-20** and **Table 6-21**.

Table 6-20 Parameter settings for different CPUs, memory sizes, and deployment modes

No.	Number of CPUs	Memory (GB)	Hybrid Deployment or Not	recovery_parse_workers	recovery_redo_workers	Number of Replayer Threads	Remarks
1	4	-	-	1	1	Value of **recovery_max_workers**	Ultimate RTO is not recommended.
2	8	-	Yes	1	1	Value of **recovery_max_workers**	Ultimate RTO is not recommended.
3	8	64	No	1	3	10	-
4	16	128	Yes	1	2	9	-
5	16	128	No	2	3	15	-
6	32	256	Yes	2	2	13	-
7	32	256	No	2	8	25	-
8	64	512	Yes	2	4	17	-
9	64	512	No	2	8	25	Systems with larger hardware specifications should also use this recommended value.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- When the new ultimate RTO framework is enabled, you are advised to set the following parameters:
  - redo_bind_cpu_attr='cpuorderbind:0-255'
  - standby_recycle_interval=1
  - base_page_saved_interval=2000
  - pagewriter_sleep=1000
  - pagewriter_thread_num=6
  - max_io_capacity=3GB
- In the new ultimate RTO framework, if the replay speed decreases, run the following command to check the buffer status:
  ```
  select * from dbe_perf.global_candidate_status;
  ```
  If the value in the **candidate_slot** column is small, there are few clean pages in the buffer. If the value in the **get_buf_clock_sweep** column is large, worker threads are evicting pages by themselves. In this case, you can increase the value of **shared_buffer** to increase the number of buffers or improve the disk performance to accelerate the replay speed.

Risks and impacts of improper settings: If this parameter is set to a large value, the CPU and memory resources will be insufficient, reducing the replay speed.

enable_page_lsn_check

Parameter description: Specifies whether to enable the data page LSN check. During replay, the current LSN of the data page is checked to see if it is the expected one.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The data page LSN check function is enabled.
- **off**: The data page LSN check function is disabled.

Default value: **on**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this parameter is disabled, data page errors may not be quickly detected, resulting in unexpected errors.

promote_lsn_check

Parameter description: Specifies whether to verify the integrity of local log replay when the standby node is promoted to primary after replay.

Parameter type: Boolean.

Unit: none

Value range:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **on**: The local log replay verification mechanism is enabled.
- **off**: The local log replay verification mechanism is disabled.

Default value: **on**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this parameter is disabled, promoting to primary in advance due to log faults may not be intercepted, causing data loss risks.

recovery_min_apply_delay

Parameter description: Specifies the replay delay of the standby node.

Parameter type: integer.

Unit: milliseconds

Value range: 0 to 2147483647

Default value: **0** (no delay added)

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: See the notice below.

Risks and impacts of improper settings: See the notice below.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTICE

- This parameter does not take effect on the primary node. It must be set on the standby node that requires a delay. You are advised to set this parameter on the asynchronous standby node. If the delay is set on the asynchronous standby node, the RTO will take a long time after the node is promoted to primary.
- The delay time is calculated based on the transaction commit timestamp on the primary node and the current time on the standby node. Therefore, ensure that the clocks of the primary and standby nodes are synchronized.
- If the delay time is too long, the disk where the Xlog file is located on the standby node may be full. Therefore, you need to set the delay time based on the disk size.
- Operations without transactions are not delayed.
- After the primary/standby switchover, if the original primary node needs to be delayed, you need to manually set this parameter.
- When **synchronous_commit** is set to **remote_apply**, synchronous replication is affected by the delay. Each commit message is returned only after the replay on the standby node is complete.
- **hot_standby_feedback** will be delayed due to using this feature, which may cause the primary node to expand. Therefore, you need to balance the risk when using both parameters.
- After a DDL operation (such as DROP or TRUNCATE) that holds an AccessExclusive lock is performed on an object on the primary node, if the object is queried on the standby node during the delayed replay of the record on the standby node, it will be returned only after the lock is released.

dcf_truncate_dump_info_level

Parameter description: Specifies whether to print the LSN truncated by the DCF and the subsequent LSNs.

Parameter type: integer.

Unit: none

Value range: 0 to 2

- **0**: disabled.
- **1**: prints all LSNs truncated by the DCF (Xlogs whose LSN is greater than or equal to the truncated LSN).
- **2**: prints all LSNs truncated by the DCF and prints warning-level logs when the LSNs flushed to disks are greater than the truncated LSNs.

Default value: **1**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

redo_bind_cpu_attr

Parameter description: Specifies the core binding operation of the replayer thread. Only the SYSADMIN user can access this parameter.

Parameter type: string.

Unit: none

Value range: a string of more than 0 characters. The value is case-insensitive.

- **"autobind"**: The log replayer thread is automatically bound to a NUMA group. By default, the log replayer thread is bound to the last NUMA group. This parameter is valid only for Arm servers. Cores are not bound for x86 servers and small-specification servers.
- **"nobind"**: The thread is not bound to a core.
- **"nodebind: 1, 2"**: Use the CPU cores in NUMA groups 1 and 2 to bind threads.
- **"cpubind: 0-30"**: Use the CPU cores 0 to 30 to bind threads.
- **"cpuorderbind: 16-32"**: One thread is bound to one CPU core starting from core 16. If the number of cores in the range is insufficient, the remaining threads are not bound. You are advised to set the interval to a value greater than or equal to the value of **recovery_parallelism** plus 1.

Default value: **"autobind"**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: See the note below.

Risks and impacts of improper settings: The database node cannot be started.

NOTE

- This parameter is used for core binding in the Arm environment. You are advised to bind all replayer threads to the same NUMA group for better performance. In hybrid deployment scenarios, you are advised to bind the replayer threads of different nodes on the same host to different NUMA groups. If the parameters related to NUMA core binding are used in a non-Arm environment, the cluster will fail to be started.
- The core binding range specified by this parameter must be different from the core binding range specified by the **thread_pool_attr** parameter.

enable_wal_page_header_crc

Parameter description: Specifies whether to perform CRC calculation, value assignment, and verification on the WAL page header.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: CRC calculation, value assignment, and verification are enabled on the WAL page header.
- **off**: CRC calculation, value assignment, and verification are disabled on the WAL page header.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Default value: **on**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this parameter is disabled, the system may fail to check whether the WAL page header is correct. As a result, the standby node receives incorrect WALs and fails to replay and synchronize the WALs.

6.3.6.4 Archiving

archive_interval

Parameter description: Specifies the archiving interval. Log files are forcibly archived when the period specified by this parameter has elapsed.

Parameter type: integer.

Unit: seconds

Value range: 1 to 1000

Default value: **1**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If the value is too small, data will be archived frequently, occupying storage space. If the value is too large, the RPO of PITR will be affected.

time_to_target_rpo

Parameter description: In dual-cluster remote DR mode, logs of the primary cluster are archived to OBS. Specifies the time allowed from the time when the primary cluster is abnormal to the time when the primary cluster is archived to the recovery point of OBS.

Parameter type: integer.

Unit: seconds

Value range: 0 to 3600

- **0** indicates that log flow control is disabled.
- A value from 1 to 3600 indicates the duration from the time when the primary cluster is abnormal to the time when the primary cluster is archived to the recovery point of OBS. This ensures that the maximum data loss duration is within the allowed range when the primary cluster breaks down due to a disaster.

Default value: **10**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If the value is too small, the host performance is affected. If the value is too large, the flow control does not take effect.

6.3.7 HA Replication

6.3.7.1 Sending Server

max_wal_senders

Parameter description: Specifies the maximum number of concurrent connections of the Xlog sender. The value must be smaller than that of **max_connections**.

NOTICE

The prerequisite for setting **max_wal_senders** is as follows: **wal_level** must be set to **archive**, **hot_standby**, or **logical** to allow the connection to the standby node.

Parameter type: integer.

Unit: none

Value range: 0 to 1024. The recommended value range is 8 to 100.

Default value: **20**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion:

- This parameter can be set to **0** only when a single DN is used and there is no primary/standby instance.
- When HA replication, backup and restoration, and logical decoding are used, you are advised to set this parameter to: Number of current standby nodes + Number of backup connections + Number of required logical replication connections.

Risks and impacts of improper settings: If this parameter is set to a value less than the recommended value range, these functions may be unavailable or abnormal.

wal_keep_segments

Parameter description: Specifies the minimum number of Xlog files that can be retained in the **pg_xlog** directory. The standby node obtains the Xlogs from the primary node to perform streaming replication.

Parameter type: integer.

Unit: none

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Value range: 2 to 2147483647

Default value: **128**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion:

- During WAL archiving or recovery from a checkpoint on the server, the system may retain more log files than the number specified by **wal_keep_segments**.
- If the HA system uses asynchronous transmission, increase the value of **wal_keep_segments** when data greater than 4 GB is continuously imported in COPY mode. Take T6000 board as an example. If the data to be imported reaches 50 GB, you are advised to set this parameter to **1000**. You can dynamically restore the setting of this parameter after data import is complete and the log synchronization is normal.
- If the **synchronous_commit** level is lower than LOCAL_FLUSH, you are advised to set this parameter to **1000** when rebuilding the standby node to prevent rebuilding failures caused by primary node log recycling during the rebuilding.

Risks and impacts of improper settings: If the value is too large, the **pg_xlog** folder may occupy too much disk space. If the value is too small, the transaction log may have been overwritten by a new one before requested by the standby node. As a result, the request fails and the connection between the primary and standby nodes is terminated.

wal_sender_timeout

Parameter description: Specifies the maximum duration that the node waits for the receiver to receive transaction logs.

NOTICE

- If the data volume on the primary node is huge, the value of this parameter must be increased for rebuilding. For example, if the data volume on the primary node reaches 500 GB, you are advised to set this parameter to **600s**.
- This parameter cannot be set to a value larger than the value of **wal_receiver_timeout** or the timeout parameter for database rebuilding.

Parameter type: integer.

Unit: milliseconds

Value range: 0 to 2147483647

Default value: **6000**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If the value is too small, the system is more sensitive to network fluctuation and intermittent disconnection. As a result,

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

the connection between the primary and standby nodes may be abnormal. If the value is too large, the response to exceptions is slower.

max_replication_slots

Parameter description: Specifies the maximum number of log replication slots on the primary node.

Parameter type: integer.

Unit: none

Value range: 0 to 1024. The recommended value range is 8 to 100.

Default value: **20**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion:

When HA replication, backup and restoration, and logical decoding are used, you are advised to set this parameter to a value by referring to the following formula: Number of current physical streaming replication slots + Number of backup slots + Number of required logical replication slots. If the actual value is smaller than the recommended value, these functions may be unavailable or abnormal.

- Physical streaming replication slots provide an automatic method to ensure that Xlogs are not removed from a primary DN before they are received by all the standby DNs. Therefore, physical streaming replication slots are used to support the cluster HA. The number of physical streaming replication slots required by the cluster is as follows: ratio of the number of standby DNs to the number of primary DNs in a ring of DNs. If the HA cluster has 1 primary DN and 3 standby DNs, the number of physical streaming replication slots required is 3.
- Backup slot records replication information during backup execution. Full backup and incremental backup correspond to two independent backup slots.
- Plan the number of logical replication slots as follows:
  - A logical replication slot can carry changes of only one database for decoding. If multiple databases are involved, create multiple logical replication slots.
  - If logical replication is needed by multiple target databases, create multiple logical replication slots in the source database. Each logical replication slot corresponds to one logical replication link.
  - A maximum of 20 logical replication slots can be enabled for decoding on the same instance.

Risks and impacts of improper settings: If the value is too small, the standby node cannot be connected, or logical decoding and backup archiving cannot be enabled. If the value is too large, the performance will be affected. When establishing a DR relationship, ensure that **max_replication_slots** is set to the same value on both the primary and standby instances. Otherwise, the DR relationship may fail to be established.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

enable_wal_shipping_compression

Parameter description: Specifies whether to enable cross-cluster log compression in streaming DR mode.

NOTICE

This parameter applies only to a pair of WAL senders and WAL receivers for cross-cluster transmission in streaming DR and is configured in the primary cluster.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: Cross-cluster log compression is enabled in streaming DR mode.
- **off**: Cross-cluster log compression is disabled in streaming DR mode.

Default value: **off**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: You do not need to set this parameter separately. This function is enabled by default during DR setup.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

repl_auth_mode

Parameter description: Specifies the validation mode for primary/standby replication and standby node rebuilding.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTICE

- If UUID validation is enabled on the primary node and a non-null repl_uuid validation code is configured, UUID validation must also be enabled on the standby node and the same repl_uuid validation code must be configured on the standby node. Otherwise, requests for log replication between the primary and standby nodes and standby node rebuilding will be rejected by the primary node.
- The SIGHUP parameter can dynamically load new values. The modification does not affect the established primary/standby connection and takes effect for subsequent primary/standby replication requests and primary/standby rebuilding requests.
- It supports the standby node rebuild validation under the Quorum and DCF protocols and the primary/standby replication validation under the Quorum protocol. It does not support primary/standby replication validation under the DCF protocol.
- It does not support the authentication between the primary and standby nodes across clusters, including the primary/standby OceanStor Dorado and DR clusters.
- The UUID validation function is used to prevent data crosstalk and pollution caused by incorrect connection between the primary and standby nodes. It is not used for security purposes.
- This parameter cannot be automatically synchronized between the primary and standby nodes.

Parameter type: enumerated type.

Unit: none

Value range:

- **off**: UUID validation is disabled.
- **default**: indicates that UUID validation is disabled.
- **uuid**: indicates that UUID validation is enabled.

Default value: **default**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Determine whether to enable this function based on the restrictions in the notice and requirements.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

repl_uuid

Parameter description: Specifies the UUID used for primary/standby UUID validation.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTICE

- If UUID validation is enabled on the primary node and a non-null repl_uuid validation code is configured, UUID validation must also be enabled on the standby node and the same repl_uuid validation code must be configured on the standby node. Otherwise, requests for log replication between the primary and standby nodes and standby node rebuilding will be rejected by the primary node.
- The SIGHUP parameter can dynamically load new values. The modification does not affect the established primary/standby connection and takes effect for subsequent primary/standby replication requests and primary/standby rebuilding requests.
- It supports the standby node rebuild validation under the Quorum and DCF protocols and the primary/standby replication validation under the Quorum protocol. It does not support primary/standby replication validation under the DCF protocol.
- It does not support the authentication between the primary and standby nodes across clusters, including the primary/standby OceanStor Dorado and DR clusters.
- The UUID validation function is used to prevent data crosstalk and pollution caused by incorrect connection between the primary and standby nodes. It is not used for security purposes.
- This parameter cannot be automatically synchronized between the primary and standby nodes.

Parameter type: string.

Unit: none

Value range: a string. The value contains 0 to 63 characters, including letters and digits. The value is case-insensitive and is converted to lowercase letters for storage. An empty string indicates that UUID validation is disabled.

Default value: **""**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Determine whether to enable this function based on the restrictions in the notice and requirements.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

replconninfo1

Parameter description: Specifies the information about the first node to be listened on and authenticated by the current server. This parameter is automatically configured after the cluster is successfully installed.

Example:

```
replconninfo1 = "localhost=XXXX localport=XXXX localheartbeatport=XXXX localservice=XXXX
remotehost=XXXX remoteport=XXXX remoteheartbeatport=XXXX remoteservice=XXXX"
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter type: string.

Unit: none

Value range: a string. An empty string indicates that no information about the first node is configured.

Default value: ""

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: This parameter is automatically set during installation. You are advised not to change the value.

Risks and impacts of improper settings: The incorrect connection information may cause the abnormal cluster status.

replconninfo2

Parameter description: Specifies the information about the second node to be listened on and authenticated by the current server. This parameter is automatically configured after the cluster is successfully installed.

Example:

```
replconninfo2 = "localhost=XXXX localport=XXXX localheartbeatport=XXXX localservice=XXXX
remotehost=XXXX remoteport=XXXX remoteheartbeatport=XXXX remoteservice=XXXX"
```

Parameter type: string.

Unit: none

Value range: a string. An empty string indicates that no information about the second node is configured.

Default value: ""

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: This parameter is automatically set during installation. You are advised not to change the value.

Risks and impacts of improper settings: The incorrect connection information may cause the abnormal cluster status.

replconninfo3

Parameter description: Specifies the information about the third node to be listened on and authenticated by the current server. This parameter is automatically configured after the cluster is successfully installed.

Example:

```
replconninfo3 = "localhost=XXXX localport=XXXX localheartbeatport=XXXX localservice=XXXX
remotehost=XXXX remoteport=XXXX remoteheartbeatport=XXXX remoteservice=XXXX"
```

Parameter type: string.

Unit: none

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Value range: a string. An empty string indicates that no information about the third node is configured.

Default value: **""**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: This parameter is automatically set during installation. You are advised not to change the value.

Risks and impacts of improper settings: The incorrect connection information may cause the abnormal cluster status.

replconninfo4

Parameter description: Specifies the information about the fourth node to be listened on and authenticated by the current server. This parameter is automatically configured after the cluster is successfully installed.

Example:

```
replconninfo4 = "localhost=XXXX localport=XXXX localheartbeatport=XXXX localservice=XXXX
remotehost=XXXX remoteport=XXXX remoteheartbeatport=XXXX remoteservice=XXXX"
```

Parameter type: string.

Unit: none

Value range: a string. An empty string indicates that no information about the fourth node is configured.

Default value: **""**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: This parameter is automatically set during installation. You are advised not to change the value.

Risks and impacts of improper settings: The incorrect connection information may cause the abnormal cluster status.

replconninfo5

Parameter description: Specifies the information about the fifth node to be listened on and authenticated by the current server. This parameter is automatically configured after the cluster is successfully installed.

Example:

```
replconninfo5 = "localhost=XXXX localport=XXXX localheartbeatport=XXXX localservice=XXXX
remotehost=XXXX remoteport=XXXX remoteheartbeatport=XXXX remoteservice=XXXX"
```

Parameter type: string.

Unit: none

Value range: a string. An empty string indicates that no information about the fifth node is configured.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Default value: ""

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: This parameter is automatically set during installation. You are advised not to change the value.

Risks and impacts of improper settings: The incorrect connection information may cause the abnormal cluster status.

replconninfo6

Parameter description: Specifies the information about the sixth node to be listened on and authenticated by the current server. This parameter is automatically configured after the cluster is successfully installed.

Example:

```
replconninfo6 = "localhost=XXXX localport=XXXX localheartbeatport=XXXX localservice=XXXX
remotehost=XXXX remoteport=XXXX remoteheartbeatport=XXXX remoteservice=XXXX"
```

Parameter type: string.

Unit: none

Value range: a string. An empty string indicates that no information about the sixth node is configured.

Default value: ""

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: This parameter is automatically set during installation. You are advised not to change the value.

Risks and impacts of improper settings: The incorrect connection information may cause the abnormal cluster status.

replconninfo7

Parameter description: Specifies the information about the seventh node to be listened on and authenticated by the current server. This parameter is automatically configured after the cluster is successfully installed.

Example:

```
replconninfo7 = "localhost=XXXX localport=XXXX localheartbeatport=XXXX localservice=XXXX
remotehost=XXXX remoteport=XXXX remoteheartbeatport=XXXX remoteservice=XXXX"
```

Parameter type: string.

Unit: none

Value range: a string. An empty string indicates that no information about the seventh node is configured.

Default value: ""

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Setting suggestion: This parameter is automatically set during installation. You are advised not to change the value.

Risks and impacts of improper settings: The incorrect connection information may cause the abnormal cluster status.

replconninfo8

Parameter description: Specifies the information about the eighth node to be listened on and authenticated by the current server. This parameter is automatically configured after the cluster is successfully installed.

Example:

```
replconninfo8 = "localhost=XXXX localport=XXXX localheartbeatport=XXXX localservice=XXXX
remotehost=XXXX remoteport=XXXX remoteheartbeatport=XXXX remoteservice=XXXX"
```

Parameter type: string.

Unit: none

Value range: a string. An empty string indicates that no information about the eighth node is configured.

Default value: **""**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: This parameter is automatically set during installation. You are advised not to change the value.

Risks and impacts of improper settings: The incorrect connection information may cause the abnormal cluster status.

replconninfo9

Parameter description: Specifies the information about the ninth node to be listened on and authenticated by the current server. This parameter is automatically configured after the cluster is successfully installed.

Example:

```
replconninfo9 = "localhost=XXXX localport=XXXX localheartbeatport=XXXX localservice=XXXX
remotehost=XXXX remoteport=XXXX remoteheartbeatport=XXXX remoteservice=XXXX"
```

Parameter type: string.

Unit: none

Value range: a string. An empty string indicates that no information about the ninth node is configured.

Default value: **""**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: This parameter is automatically set during installation. You are advised not to change the value.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Risks and impacts of improper settings: The incorrect connection information may cause the abnormal cluster status.

replconninfo10

Parameter description: Specifies the information about the tenth node to be listened on and authenticated by the current server. This parameter is automatically configured after the cluster is successfully installed.

Example:

```
replconninfo10 = "localhost=XXXX localport=XXXX localheartbeatport=XXXX localservice=XXXX
remotehost=XXXX remoteport=XXXX remoteheartbeatport=XXXX remoteservice=XXXX"
```

Parameter type: string.

Unit: none

Value range: a string. An empty string indicates that no information about the tenth node is configured.

Default value: **""**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: This parameter is automatically set during installation. You are advised not to change the value.

Risks and impacts of improper settings: The incorrect connection information may cause the abnormal cluster status.

replconninfo11

Parameter description: Specifies the information about the eleventh node to be listened on and authenticated by the current server. This parameter is automatically configured after the cluster is successfully installed.

Example:

```
replconninfo11 = "localhost=XXXX localport=XXXX localheartbeatport=XXXX localservice=XXXX
remotehost=XXXX remoteport=XXXX remoteheartbeatport=XXXX remoteservice=XXXX"
```

Parameter type: string.

Unit: none

Value range: a string. An empty string indicates that no information about the eleventh node is configured.

Default value: **""**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: This parameter is automatically set during installation. You are advised not to change the value.

Risks and impacts of improper settings: The incorrect connection information may cause the abnormal cluster status.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

replconninfo12

Parameter description: Specifies the information about the twelfth node to be listened on and authenticated by the current server. This parameter is automatically configured after the cluster is successfully installed.

Example:

```
replconninfo12 = "localhost=XXXX localport=XXXX localheartbeatport=XXXX localservice=XXXX
remotehost=XXXX remoteport=XXXX remoteheartbeatport=XXXX remoteservice=XXXX"
```

Parameter type: string.

Unit: none

Value range: a string. An empty string indicates that no information about the twelfth node is configured.

Default value: **""**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: This parameter is automatically set during installation. You are advised not to change the value.

Risks and impacts of improper settings: The incorrect connection information may cause the abnormal cluster status.

replconninfo13

Parameter description: Specifies the information about the thirteenth node to be listened on and authenticated by the current server. This parameter is automatically configured after the cluster is successfully installed.

Example:

```
replconninfo13 = "localhost=XXXX localport=XXXX localheartbeatport=XXXX localservice=XXXX
remotehost=XXXX remoteport=XXXX remoteheartbeatport=XXXX remoteservice=XXXX"
```

Parameter type: string.

Unit: none

Value range: a string. An empty string indicates that no information about the thirteenth node is configured.

Default value: **""**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: This parameter is automatically set during installation. You are advised not to change the value.

Risks and impacts of improper settings: The incorrect connection information may cause the abnormal cluster status.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

replconninfo14

Parameter description: Specifies the information about the fourteenth node to be listened on and authenticated by the current server. This parameter is automatically configured after the cluster is successfully installed.

Example:

```
replconninfo14 = "localhost=XXXX localport=XXXX localheartbeatport=XXXX localservice=XXXX
remotehost=XXXX remoteport=XXXX remoteheartbeatport=XXXX remoteservice=XXXX"
```

Parameter type: string.

Unit: none

Value range: a string. An empty string indicates that no information about the fourteenth node is configured.

Default value: **""**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: This parameter is automatically set during installation. You are advised not to change the value.

Risks and impacts of improper settings: The incorrect connection information may cause the abnormal cluster status.

replconninfo15

Parameter description: Specifies the information about the fifteenth node to be listened on and authenticated by the current server. This parameter is automatically configured after the cluster is successfully installed.

Example:

```
replconninfo15 = "localhost=XXXX localport=XXXX localheartbeatport=XXXX localservice=XXXX
remotehost=XXXX remoteport=XXXX remoteheartbeatport=XXXX remoteservice=XXXX"
```

Parameter type: string.

Unit: none

Value range: a string. An empty string indicates that no information about the fifteenth node is configured.

Default value: **""**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: This parameter is automatically set during installation. You are advised not to change the value.

Risks and impacts of improper settings: The incorrect connection information may cause the abnormal cluster status.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

replconninfo16

Parameter description: Specifies the information about the sixteenth node to be listened on and authenticated by the current server. This parameter is automatically configured after the cluster is successfully installed.

Example:

```
replconninfo16 = "localhost=XXXX localport=XXXX localheartbeatport=XXXX localservice=XXXX
remotehost=XXXX remoteport=XXXX remoteheartbeatport=XXXX remoteservice=XXXX"
```

Parameter type: string.

Unit: none

Value range: a string. An empty string indicates that no information about the sixteenth node is configured.

Default value: **""**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: This parameter is automatically set during installation. You are advised not to change the value.

Risks and impacts of improper settings: The incorrect connection information may cause the abnormal cluster status.

replconninfo17

Parameter description: Specifies the information about the seventeenth node to be listened on and authenticated by the current server. This parameter is automatically configured after the cluster is successfully installed.

Example:

```
replconninfo17 = "localhost=XXXX localport=XXXX localheartbeatport=XXXX localservice=XXXX
remotehost=XXXX remoteport=XXXX remoteheartbeatport=XXXX remoteservice=XXXX"
```

Parameter type: string.

Unit: none

Value range: a string. An empty string indicates that no information about the seventeenth node is configured.

Default value: **""**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: This parameter is automatically set during installation. You are advised not to change the value.

Risks and impacts of improper settings: The incorrect connection information may cause the abnormal cluster status.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

replconninfo18

Parameter description: Specifies the information about the eighteenth node to be listened on and authenticated by the current server. This parameter is automatically configured after the cluster is successfully installed.

Example:

```
replconninfo18 = "localhost=XXXX localport=XXXX localheartbeatport=XXXX localservice=XXXX
remotehost=XXXX remoteport=XXXX remoteheartbeatport=XXXX remoteservice=XXXX"
```

Parameter type: string.

Unit: none

Value range: a string. An empty string indicates that no information about the eighteenth node is configured.

Default value: **""**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: This parameter is automatically set during installation. You are advised not to change the value.

Risks and impacts of improper settings: The incorrect connection information may cause the abnormal cluster status.

cross_cluster_replconninfo1

Parameter description: Specifies the information about the first node to be listened on and authenticated by the current server across clusters.

Example:

```
cross_cluster_replconninfo1 = "localhost=XXXX localport=XXXX remotehost=XXXX remoteport=XXXX"
```

Parameter type: string.

Unit: none

Value range: a string. An empty string indicates that no information about the first node is configured.

Default value: **""**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: This parameter is automatically set during installation. You are advised not to change the value.

Risks and impacts of improper settings: The incorrect connection information may cause the abnormal status of a standby cluster for DR.

cross_cluster_replconninfo2

Parameter description: Specifies the information about the second node to be listened on and authenticated by the current server across clusters.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Example:

```
cross_cluster_replconninfo2 = "localhost=XXXX localport=XXXX remotehost=XXXX remoteport=XXXX"
```

Parameter type: string.

Unit: none

Value range: a string. An empty string indicates that no information about the second node is configured.

Default value: **""**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: This parameter is automatically set during installation. You are advised not to change the value.

Risks and impacts of improper settings: The incorrect connection information may cause the abnormal status of a standby cluster for DR.

cross_cluster_replconninfo3

Parameter description: Specifies the information about the third node to be listened on and authenticated by the current server across clusters.

Example:

```
cross_cluster_replconninfo3 = "localhost=XXXX localport=XXXX remotehost=XXXX remoteport=XXXX"
```

Parameter type: string.

Unit: none

Value range: a string. An empty string indicates that no information about the third node is configured.

Default value: **""**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: This parameter is automatically set during installation. You are advised not to change the value.

Risks and impacts of improper settings: The incorrect connection information may cause the abnormal status of a standby cluster for DR.

cross_cluster_replconninfo4

Parameter description: Specifies the information about the fourth node to be listened on and authenticated by the current server across clusters.

Example:

```
cross_cluster_replconninfo4 = "localhost=XXXX localport=XXXX remotehost=XXXX remoteport=XXXX"
```

Parameter type: string.

Unit: none

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Value range: a string. An empty string indicates that no information about the fourth node is configured.

Default value: ""

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: This parameter is automatically set during installation. You are advised not to change the value.

Risks and impacts of improper settings: The incorrect connection information may cause the abnormal status of a standby cluster for DR.

cross_cluster_replconninfo5

Parameter description: Specifies the information about the fifth node to be listened on and authenticated by the current server across clusters.

Example:

```
cross_cluster_replconninfo5 = "localhost=XXXX localport=XXXX remotehost=XXXX remoteport=XXXX"
```

Parameter type: string.

Unit: none

Value range: a string. An empty string indicates that no information about the fifth node is configured.

Default value: ""

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: This parameter is automatically set during installation. You are advised not to change the value.

Risks and impacts of improper settings: The incorrect connection information may cause the abnormal status of a standby cluster for DR.

cross_cluster_replconninfo6

Parameter description: Specifies the information about the sixth node to be listened on and authenticated by the current server across clusters.

Example:

```
cross_cluster_replconninfo6 = "localhost=XXXX localport=XXXX remotehost=XXXX remoteport=XXXX"
```

Parameter type: string.

Unit: none

Value range: a string. An empty string indicates that no information about the sixth node is configured.

Default value: ""

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Setting suggestion: This parameter is automatically set during installation. You are advised not to change the value.

Risks and impacts of improper settings: The incorrect connection information may cause the abnormal status of a standby cluster for DR.

cross_cluster_replconninfo7

Parameter description: Specifies the information about the seventh node to be listened on and authenticated by the current server across clusters.

Example:

```
cross_cluster_replconninfo7 = "localhost=XXXX localport=XXXX remotehost=XXXX remoteport=XXXX"
```

Parameter type: string.

Unit: none

Value range: a string. An empty string indicates that no information about the seventh node is configured.

Default value: **""**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: This parameter is automatically set during installation. You are advised not to change the value.

Risks and impacts of improper settings: The incorrect connection information may cause the abnormal status of a standby cluster for DR.

cross_cluster_replconninfo8

Parameter description: Specifies the information about the eighth node to be listened on and authenticated by the current server across clusters.

Example:

```
cross_cluster_replconninfo8 = "localhost=XXXX localport=XXXX remotehost=XXXX remoteport=XXXX"
```

Parameter type: string.

Unit: none

Value range: a string. An empty string indicates that no information about the eighth node is configured.

Default value: **""**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: This parameter is automatically set during installation. You are advised not to change the value.

Risks and impacts of improper settings: The incorrect connection information may cause the abnormal status of a standby cluster for DR.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

enable_time_report

Parameter description: Specifies whether to record the time consumed by each redo log.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The time consumed by each redo log is recorded.
- **off**: The time consumed by each redo log is not recorded.

Default value: **off**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: You are advised not to enable the non-debugging mode because the performance deteriorates after the non-debugging mode is enabled.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

thread_top_level

Parameter description: Increases the priority of the WALWRITERAUXILIARY, WALWRITER, STARTUP, WALRECEIVER, WAL_NORMAL_SENDER, and PGSTAT threads to the highest.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The priority of the preceding threads is increased to the highest.
- **off**: The priority of the preceding threads is not increased.

Default value: **off**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

page_work_queue_size

Parameter description: Specifies the length of the blocking queue of each redo worker.

Parameter type: integer.

Unit: none

Value range: 1 to 100000

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Default value: **4096**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If the value is too small, the pipeline capability becomes invalid. If the value is too large, too much memory is occupied.

parallel_build_thread_num

Parameter description: Specifies the degree of parallelism for parallel reconstruction. When the value is **1**, the original single-thread rebuilding code is run. When the value is **n**, **n** threads are established to complete data transmission during rebuilding.

Parameter type: integer.

Unit: none

Value range: 1 to 10

Default value: **1**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion:

- Retain the default value. Set this parameter based on the service scenario and disk I/O capability only when a large number of data files need to be rebuilt, the disk I/O performance is good, and the network bandwidth, memory, and CPU resources are sufficient. Higher degree of parallelism indicates more I/O, memory, and CPU resources are occupied and faster rebuilding speed.
- The degree of parallelism is in direct proportion to the CPU and memory usage. (When there are two degrees of parallelism, the maximum CPU usage is three cores. Each time one degree of parallelism is added, the CPU usage increases by one core.)
- Assume that the build speed in a single thread is **a** MB/s. When **enable_parallel_build_compression** is set to **off**, the read I/O on the service side increases by no more than **a** MB/s each time a degree of parallelism is added. When **enable_parallel_build_compression** is set to **on**, the read I/O on the service side increases by no more than 0.7 x **a** MB/s each time a degree of parallelism is added.

Risks and impacts of improper settings:

If this function is enabled in an inappropriate environment, the parallel rebuild speed does not increase significantly and extra resources are occupied.

Each time a degree of parallelism is added, a connection is established with a new WAL Sender on the server, occupying the quota of the GUC parameter **max_wal_senders** on the server. If the degree of parallelism is too large, the parallel rebuilding fails because no connection can be established. Then, the single-thread rebuilding is performed again.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

enable_parallel_build_compression

Parameter description: Specifies whether to perform LZ4 compression during parallel data rebuilding. This parameter is valid only when **parallel_build_thread_num** is greater than 1.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: LZ4 compression is performed during parallel data rebuilding.
- **off**: LZ4 compression is not performed during parallel data rebuilding.

Default value: **off**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion:

Retain the default value. When the network bandwidth is limited, set this parameter to **on**.

Risks and impacts of improper settings:

If this function is enabled in an inappropriate environment, the parallel rebuild speed does not increase significantly and extra resources are occupied.

replay_delay

Parameter description: Specifies the replay delay for standby clusters (also referred to as DR instances) when delayed replay is enabled in DR scenarios.

RTO indicates the time required for data restoration when a disaster occurs. The RTO is calculated as follows: (Target replay point – Current replay point)/Replay rate, that is, the ratio of the number of logs to be replayed to the replay rate. The delayed replay feature enables the standby cluster to become a snapshot of the primary cluster before the replay delay. When a failover is performed to promote the standby cluster to primary, logs generated after the target replay point (Current time minus **replay_delay**) will be truncated to ensure that the RTO of the failover is not affected by the **replay_delay** parameter.

Parameter type: integer.

Unit: seconds

Value range: 0 to 4294967295. The value **0** indicates that delayed replay is disabled for standby clusters.

Default value: **0**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Set this parameter according to actual requirements.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTICE

- The replay delay can be set from minutes to years. When the following time synchronization limitations are met, the replay delay can be accurate to seconds: NTP must be used to ensure that the time synchronization precision between the primary and standby clusters is less than or equal to 100 ms, and the time synchronization precision between nodes in the standby cluster is less than or equal to 1 ms.
- After the standby cluster for DR is promoted to primary through a failover, **replay_delay** is reset to the default value **0**.

Risks and impacts of improper settings:

- If the value is too large, the standby cluster may not replay logs for a long time. As a result, logs are stacked and the disk space is used up.
- If the value is not 0, the standby cluster cannot perform switchover, DR simulation, or DR interruption and resumption.

replay_mode

Parameter description: Specifies whether to pause replay on the standby cluster when delayed replay is enabled in DR scenarios.

Parameter type: string.

Unit: none

Value range:

- **""**: Replay pause is disabled.
- **stop**: Replay is paused immediately.
- Timestamp: If this parameter is set to a timestamp, the replay is paused at the barrier point corresponding to the timestamp.

Default value: **""**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Set this parameter based on the timestamp of the barrier point.

NOTICE

After the standby cluster for DR is promoted to primary through a failover, **replay_mode** is reset to the default value **""**.

Risks and impacts of improper settings: If this parameter is set to the timestamp of a barrier that has been replayed or does not exist, the replay process is suspended.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

hadr_replconninfo_config_mode

Parameter description: Specifies the management mode of the DR link.

Parameter type: enumerated type.

Unit: none

Value range:

- **local_file**: The DR link management mode is based on GUC configuration.
- **cluster_manager**: The DR link management mode is based on cluster management configuration.

Default value: **local_file**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: This parameter is automatically set during the DR process. You are advised not to change the value.

Risks and impacts of improper settings: The DR link attribute setting becomes invalid.

hadr_source_info

Parameter description: Specifies the link information of the cluster at the log sender for the cluster at the log receiver in the streaming DR scenario.

Parameter type: string.

Unit: none

Value range: a string. **""** indicates that the link information of the cluster at the log sender is not configured.

Default value: **""**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: This parameter is automatically set in the DR process. You are advised not to change the value. The value of the **hadr_source_info** of the cluster at the log receiver must match **dest_name** configured for the cluster at the log sender.

Risks and impacts of improper settings: If **hadr_source_info** of the main standby node is not correctly configured, the cluster at the log receiver cannot connect to the cluster at the log sender.

6.3.7.2 Primary Node

synchronous_standby_names

Parameter description: Specifies a comma-separated list of names of potential standby nodes that support synchronous replication.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTICE

- The current synchronous standby node is on the top of the list. If the current synchronous standby node is disconnected, it will be replaced immediately with the next-highest-priority standby node. Name of the next-highest-priority standby node is added to the list.
- The standby node name can be specified by setting the environment variable **PGAPPNAME**.

Parameter type: string.

Unit: none

Value range: If this parameter is set to *****, the name of any standby node that provides synchronous replication is matched. The value can be configured in the following format:

- ANY *num_sync* (*standby_name* [, ...])
- [FIRST] *num_sync* (*standby_name* [, ...])
- *standby_name* [, ...]

NOTE

- In the preceding command, *num_sync* indicates the number of standby nodes that need to wait for responses from the transaction, *standby_name* indicates the name of the standby node, and FIRST and ANY specify the policies for selecting standby nodes for synchronous replication from the listed servers.
- **ANY N (dn_instanceId1, dn_instanceId2,...)** indicates that any *N* host names in the brackets are selected as the name list of standby nodes for synchronous replication. For example, **ANY 1(dn_instanceId1, dn_instanceId2)** indicates that either of **dn_instanceId1** or **dn_instanceId2** is used as the standby node for synchronous replication.
- **FIRST N (dn_instanceId1, dn_instanceId2, ...)** indicates that the first N primary node names in the brackets are selected as the standby node name list for synchronous replication based on the priority. For example, **FIRST 1 (dn_instanceId1, dn_instanceId2)** indicates that **dn_instanceId1** is selected as the standby node for synchronous replication.
- The meanings of **dn_instanceId1, dn_instanceId2, ...** are the same as those of **FIRST 1 (dn_instanceId1, dn_instanceId2, ...)**.

If you use the gs_guc tool to set this parameter, perform the following operations:

```
gs_guc reload -Z datanode -N @NODE_NAME@ -D @DN_PATH@ -c "synchronous_standby_names='ANY 1(dn_instanceId1, dn_instanceId2)'"
```

or

```
gs_guc reload -Z datanode -N @NODE_NAME@ -D @DN_PATH@ -c "synchronous_standby_names='ANY 1(AZ1, AZ2)'"
```

Default value: *****

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Risks and impacts of improper settings: If the synchronization standby list is incorrect, the primary and standby synchronization majority protocol becomes invalid.

NOTICE

This parameter is maintained by the CM. If it is manually modified, data may be lost.

most_available_sync

Parameter description: Specifies whether to block the transaction commit on the primary node when the primary-standby synchronization fails.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The transaction commit on the primary node is not blocked when the synchronization fails.
- **off**: The transaction commit on the primary node is blocked when the synchronization fails.

Default value: **off**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: After this function is enabled, the primary node does not wait for the standby node to commit for verification. If the host is in the single-primary state, the committing is successful, not the majority write is successful.

Risks and impacts of improper settings: Customers need to exercise caution when enabling this function based on their application scenarios.

enable_stream_replication

Parameter description: Specifies whether data and logs are synchronized between the primary and standby nodes.

NOTICE

- This parameter is used for testing performance with standby DNs and without standby DNs. If this parameter is set to **off**, tests on abnormal scenarios, such as switchover and faults, cannot be performed to prevent inconsistency between the primary and standby nodes.
- This is a restricted parameter, and you are advised not to set it to **off** in normal service scenarios.

Parameter type: Boolean.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Unit: none

Value range:

- **on**: Synchronization between the primary and standby nodes is enabled.
- **off**: Synchronization between the primary and standby nodes is disabled.

Default value: **on**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this parameter is disabled, the multi-copy capability of the cluster will be unavailable, reducing availability and causing backup failures. Therefore, you are advised not to disable this parameter.

enable_mix_replication

Parameter description: Specifies how WAL files and data are replicated between the primary and standby nodes.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The WAL file and data page mixed replication mode is enabled.
- **off**: The WAL file and data page mixed replication mode is disabled.

Default value: **off**

Setting method: This parameter is a POSTMASTER parameter. Its default value is **off** and cannot be modified.

Setting suggestion: Retain the default value. This parameter cannot be modified in normal service scenarios. That is, the WAL file and data page mixed replication mode is disabled by default.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

enable_wal_replication_compression

Parameter description: Specifies whether to enable the Xlog compression function during physical replication between the primary and standby DNs.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The log compression function is enabled.
- **off**: The log compression function is disabled.

Default value: **off**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: This parameter applies only to a pair of WAL Sender and WAL Receiver threads for data transmission between the primary and standby DNs. Configure this parameter on the primary DN. You are advised not to enable this parameter in scenarios with small Xlogs and delay sensitivity.

Risks and impacts of improper settings: After this parameter is enabled, performance and resources are consumed. Therefore, you need to set **wal_replication_compression_thread_settings** and **wal_replication_compression_settings** properly.

- Impact on performance: For details, see the description of the **wal_replication_compression_settings** parameter.
- Configurations in different resource scenarios: For details, see the description of the **wal_replication_compression_thread_settings** parameter.

NOTICE

This parameter has the following limitations:

- The compression algorithm cannot be modified during the upgrade.
- DCF is not supported.
- Currently, standby clusters for DR are not supported.
- You are advised not to enable this function in small specifications (for example, 4 or 8 cores).

wal_replication_compression_thread_settings

Parameter description: Specifies the number of parallel compression threads and single-thread queue depth of the primary and standby clusters. This parameter takes effect only when **enable_wal_replication_compression** is enabled.

Parameter type: string.

Unit: none

Value range: a string of two integers separated by a comma (,). The value ranges of both integer parameters are 1 to 16.

Default value: **'1,6'**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: This parameter and **walsender_max_send_size** are used together to specify the memory usage of the compression thread. You need to use this parameter with caution. You are advised to set this parameter to a small value for low-performance machines.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Risks and impacts of improper settings: If this parameter is set to a large value, a large amount of dynamic memory is occupied. As a result, the process cannot be started or the service fails to apply for memory.

wal_replication_compression_settings

Parameter description: Specifies the algorithm rule used for Xlog compression of the primary and standby clusters.

Parameter type: string.

Unit: none

Value range: The parameter value consists of the compression algorithm and compression parameter. The format is '*string*,*int*', for example, **'zstd,5'**. Other formats are incorrect, which will cause the setting failure. The first parameter (compression algorithm) can be set to **lz4** or **zstd**. Other values are invalid.

- If the first parameter is set to **lz4**, the second parameter is the acceleration factor and the value ranges from 1 to 300.
- If the first parameter is set to **zstd**, the second parameter is the compression level and the value ranges from 1 to 15.

Default value: **'lz4,3'**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion:

- A larger acceleration factor of the LZ4 algorithm indicates a lower compression ratio and better performance.
- A higher compression level of the zstd algorithm indicates a higher compression ratio and poorer performance.
- Increasing the compression ratio will reduce the network bandwidth, but the TPS performance will also deteriorate. You are advised to set the compression ratio to the minimum compression ratio that meets the bandwidth requirements.
- The zstd algorithm has a higher compression ratio and more performance degradation, while the lz4 algorithm has a lower compression ratio and less performance degradation.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

data_replicate_buffer_size

Parameter description: Specifies the amount of memory used by queues when the sender sends data pages to the receiver. The value of this parameter affects the buffer size used during the replication from the primary node to the standby node.

Parameter type: integer.

Unit: KB

Value range: 4096 to 1072693248

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Default value: **131072**, that is, 128 MB.

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value. Do not set this parameter to an excessively large or small value. The following condition must be met: **data_replicate_buffer_size** + **segment_buffers** + **shared_buffers** + **wal_buffers** + **temp_buffers** + **maintenance_work_mem** + **work_mem** + **query_mem** + **wal_receiver_buffer_size** (standby node) < **max_process_memory** < Memory size of the physical machine.

Risks and impacts of improper settings: If the value of the memory parameter is too large and exceeds the upper limit of the physical memory, the database cannot be started because it cannot apply for sufficient memory.

walsender_max_send_size

Parameter description: Specifies the size of the log or data sending buffer on the primary node.

Parameter type: integer.

Unit: KB

Value range: 8 to 2147483647

Default value: **8192** (8 MB)

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If the value is too large, too much memory is occupied. If the value is too small, the synchronization performance between the primary and standby nodes deteriorates.

wal_buffer_reserve_percent

Parameter description: Specifies the ratio of the WAL buffer reservation window on the primary node. The window retains the log data that has been flushed to disks in the buffer. If this parameter is set to a valid non-zero value, this parameter takes effect only when the value of **wal_buffers** is greater than or equal to 1 GB.

Parameter type: floating-point number

Unit: none

Value range: 0.0 to 0.5

Default value: **0.25**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

ha_module_debug

Parameter description: Specifies the replication status log of a specific data block during data replication.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The status of each data block is recorded in logs during data replication.
- **off**: The status of each data block is not recorded in logs during data replication.

Default value: **off**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Printing logs occupies unnecessary disk, CPU, and I/O bandwidth. Therefore, you are advised not to enable this function.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

sync_config_strategy

Parameter description: Specifies the policy for synchronizing configuration files between the primary node and standby node, and between the standby node and cascaded standby node.

NOTICE

If this parameter is configured after an upgrade from a version earlier than 503.0.0 to 503.0.0, this parameter cannot be identified after a rollback. Do not set this parameter during the upgrade to 503.0.0.

Parameter type: enumerated type.

Unit: none

Value range:

- **all_node**: If this parameter is set to **all_node** for the primary node, the primary node is allowed to proactively synchronize configuration files to all standby nodes. If this parameter is set to **all_node** for a standby node, the standby node is allowed to send synchronization requests to its primary node, and the standby node is allowed to proactively synchronize configuration files to all cascaded standby nodes. If this parameter is set to **all_node** for a cascaded standby node, the current cascaded standby node is allowed to send synchronization requests to its standby node.
- **only_sync_node**: If this parameter is set to **only_sync_node** for the primary node, the primary node is only allowed to proactively synchronize configuration files to all standby nodes. If this parameter is set to

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

only_sync_node for a standby node, the standby node is allowed to send synchronization requests to its primary node, and the standby node is not allowed to proactively synchronize configuration files to all cascaded standby nodes. If this parameter is set to **only_sync_node** for a cascaded standby node, the current cascaded standby node is allowed to send synchronization requests to its standby node.

- **none_node**: If this parameter is set to **none_node** for the primary node, the primary node is not allowed to proactively synchronize configuration files to all standby nodes. If this parameter is set to **none_node** for a standby node, the standby node is not allowed to send synchronization requests to its primary node, and the standby node is not allowed to proactively synchronize configuration files to all cascaded standby nodes. If this parameter is set to **none_node** for a cascaded standby node, the current cascaded standby node is not allowed to send synchronization requests to its standby node.

Default value: all_node

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: After this function is disabled, the primary node stops synchronizing GUC parameters to the standby node. In this case, exercise caution when setting this parameter to a value other than **all_node**.

Risks and impacts of improper settings: If this parameter is set to **none_node**, GUC parameters will not be synchronized between the primary and standby nodes. In this case, exercise caution when setting this parameter.

hadr_recovery_time_target

Parameter description: Specifies whether the standby database instance completes log writing and replay in streaming DR mode.

Parameter type: integer.

Unit: seconds

Value range: 0 to 3600

- **0** indicates that log flow control is disabled.
- 1 to 3600 indicates that the standby node can write and replay logs within the time specified by **hadr_recovery_time_target**. This ensures that logs can be written and replayed within the time specified by **hadr_recovery_time_target** during the switchover between the primary and standby database instances. In this case, the standby database instance can be quickly switched to the primary database instance.

Default value: **0**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**. The value cannot contain a unit.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If the value is too small, frequent flow control will affect host performance. If the value is too large or the parameter is disabled, the RTO of the standby node will exceed the expectation if the standby

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

node does not replay data in a timely manner. As a result, the RTO and RPO of HA will be decreased.

hadr_recovery_point_target

Parameter description: Specifies the RPO time allowed for the standby database instance to flush logs to disks in streaming DR mode.

Parameter type: integer.

Unit: seconds

Value range: 0 to 3600

- **0** indicates that log flow control is disabled.
- 1 to 3600 indicates that the standby node can flush logs to disks within the time specified by **hadr_recovery_point_target**. This ensures that logs can be replayed within the time specified by **hadr_recovery_point_target** during the switchover between the primary and standby database instances. In this case, the standby database instance is switched to primary.

Default value: **0**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**. The value cannot contain a unit.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If the value is too small, frequent flow control will affect host performance. If the value is too large or the parameter is disabled, the RTO of the standby node will exceed the expectation if the standby node does not replay data in a timely manner. As a result, the RTO and RPO of HA will be decreased.

hadr_super_user_record_path

Parameter description: Specifies the path for storing encrypted files of the **hadr_disaster** user in the standby cluster in streaming DR mode.

Parameter type: string.

Unit: none

Value range: a string.

Default value: **""**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: The value is automatically set by the streaming DR password transfer tool and does not need to be manually added. You are advised not to change the value.

Risks and impacts of improper settings: If the settings are incorrect, the standby cluster status will be abnormal, and the primary cluster cannot be connected. As a result, data cannot be synchronized.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

check_sync_standby

Parameter description: Specifies whether to check the standby node. After the **synchronous_standby_names** parameter is correctly configured in the primary and standby scenarios, if the synchronous standby node is faulty, the write service on the primary node reports a write failure.

NOTE

- This parameter cannot be synchronized in job work and autonomous transactions. Otherwise, the check may not take effect.
- If the standby node check is not configured for a specified user or session and the standby node is faulty when the forcible synchronization commit mode is enabled, the write operation on a table causes the query on the same table by another user or in another session to hang. In this case, you need to recover the standby node or manually terminate the hung client.
- The standby node check function cannot be enabled in scenarios (such as VACUUM ANALYZE and gs_clean) where non-write operations trigger log writing. If the standby node does not meet the requirements for synchronizing configurations to the standby node, services will be hung in this scenario. In this case, you need to manually terminate the services.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The standby node check is enabled.
- **off**: The standby node check is disabled.

Default value: **off**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

enable_wal_sender_crc_check

Parameter description: Specifies whether to enable CRC for the WAL sender thread. CRC is performed before the primary node sends logs. If this parameter is enabled, the performance may deteriorate by less than 5%.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The check function is enabled.
- **off**: The check function is disabled.

Default value: **on**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Setting suggestion: This parameter ensures log validity. Determine whether to enable this function based on scenario requirements.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

NOTE

In DCF mode, the thread for sending logs is dcf_rep_appendlog. If **enable_wal_sender_crc_check** is enabled, CRC can be performed before the dcf_rep_appendlog thread sends logs in DCF mode.

syncrep_wait_proceed_timeout

Parameter description: Specifies the time threshold for timeout detection after the primary thread receives a termination signal when waiting for the majority confirmation during transaction commit. If the duration for which the flushing location of the majority of standby nodes is not updated exceeds the threshold, the primary node process exits.

Parameter type: integer.

Unit: seconds

Value range: 0 to 1000. **0** indicates that timeout detection is not performed after the termination signal is received.

Default value: **0**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value. If this timeout detection needs to be enabled, set this parameter to a value greater than or equal to the duration of the automatic copy reduction process. You are advised to set this parameter to a value greater than or equal to 60.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing. If the value is too small, the host process may exit in advance during the automatic copy reduction.

async_build

Parameter description: Specifies whether to use the asynchronous build process to rebuild a faulty DN. If this function is enabled, the asynchronous process is used for rebuilding. If the number of remaining copies is less than the majority, the service write capability can be preferentially restored. If this function is disabled, the synchronous logic is used for rebuilding. If the number of remaining copies is less than the majority, services can be restored only after data and logs are completely synchronized. After this function is enabled, if the standby DN to be rebuilt is required to participate in majority commit, the standby DN to be rebuilt must be in the synchronization list configured by the **synchronous_standby_names** parameter, and at least one DN in the synchronization list must be alive except the DN to be rebuilt.

Parameter type: Boolean.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Unit: none

Value range:

- **on**: The function of participating in majority commit in asynchronous build is enabled.
- **off**: The function of participating in majority commit in asynchronous build is disabled.

Default value: **on**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Set this parameter to ensure quick recovery of services in fault scenarios. For example, in four-copy deployment, when two DNs are faulty, blocked services are written to new services because the majority cannot meet the requirements. After the function of asynchronous build to participate in majority commit is enabled, new services can be written during the rebuilding of the faulty DN.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

NOTICE

1. The service recovery time is determined by the Xlog difference between each building instance and the primary node and the network rate. For example, if the Xlog difference is 1 GB and the network rate is 100 MB/s, the service should be recovered about 10s after the building starts to transmit Xlogs.
2. Data reliability of new transactions in the building state may be temporarily lost. That is, when available copies cannot meet the majority commit condition, the building receives logs to meet the majority commit condition, but the building instance does not have complete data. If the remaining copies cannot work and cannot be restored, the new data written during the building process may fail to be restored. After the building instance is restored or the automatic copy reduction capability of the CM is triggered, the risk can be eliminated. For example, in the four-copy scenario, if only one primary copy and one standby copy are normal, and the other two copies are in the building or to-be-repaired state, building receiving logs allows the transactions in the primary node to meet the majority commit condition. However, if the primary and standby copies in the normal state are damaged and cannot be restored, the new logs generated during the fault may fail to be restored.
3. This parameter can be set independently on each node of the cluster and takes effect only when it is set to **on** on both the primary and standby nodes. It is recommended that the parameter settings be the same on all nodes in the cluster.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

6.3.7.3 Standby Node

hot_standby

Parameter description: Specifies whether the standby node is allowed to accept connections and queries after it is restored to the minrecovery point.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTICE

- If this parameter is set to **on**, **wal_level** must be set to **hot_standby** or higher. Otherwise, the database startup fails.
- In a distributed system, **hot_standby** cannot be set to **off** because this setting can affect other features of the HA system.
- If the **hot_standby** parameter was disabled and the **wal_level** parameter was set to a value smaller than that of **hot_standby**, perform the following operations to ensure that the logs to be replayed on the standby node can be queried on the standby node before enabling the **hot_standby** parameter again:
  1. Change the value of **wal_level** of the primary and standby nodes to the value of **hot_standby** or a higher value, and restart the instances for the change to take effect.
  2. Perform the checkpoint operation on the primary node and query the **pg_stat_get_wal_senders()** function to ensure that the value of **receiver_replay_location** of each standby node is the same as that of **sender_flush_location** of the primary node. Ensure that the value adjustment of **wal_level** is synchronized to the standby nodes and takes effect, and the standby nodes do not need to replay low-level logs.
  3. Set the **hot_standby** parameter of the primary and standby nodes to **on**, and restart the instances for the setting to take effect.
- If the read on standby function is enabled, conflicts between replay and query on the standby node may cause the query to cancel. The error information is as follows:
  - ERROR: canceling statement due to conflict with recovery.
  - ERROR: terminating connection due to conflict with recovery.
- During the standby node read in serial and parallel replay modes, when the primary node rebuilds indexes online, an error may be reported when the standby node is read. Try again later. Error information:
  - ERROR: could not open relation with OID xxx during recovery delete object, please try again later.
  - ERROR: Catalog is missing xxx attribute(s) for relid xxx.
  - ERROR: cache lookup failed for index xxx, refilenode:xxx, name:"xxx".
  - ERROR: could not find pg_class entry for xxx.
  - ERROR: could not open block during recovery delete object, please try again later.
- During the standby node read in the case of ultimate RTO, the VM with small memory configuration may report an error indicating insufficient memory. You can enable the GUC parameter **exrto_standby_read_opt** (enabled by default) to effectively reduce the memory and I/O overhead.
- The standby node does not support autonomous transactions.
- In the case of parallel replay and read on standby in ultimate RTO mode, Astore tables do not support the generation of the IndexOnlyScan execution plan.
- In the scenario where read on standby is enabled with ultimate RTO, if the **READ COMMITTED** transaction isolation level is required, the

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

exrto_transaction_isolation_force_rr parameter must be set to **off**. When the **exrto_transaction_isolation_force_rr** parameter is set to **on**, only the **REPEATABLE READ** transaction isolation level is supported in the scenario where read on standby is enabled with ultimate RTO. When the standby node is read at the **REPEATABLE READ** isolation level, pay attention to the following two conditions: If neither of the two conditions is met, the newly replayed data cannot be read after the session is established.

  - In scenarios where applications connect to the database through drivers, the autocommit function must be enabled.
  - In scenarios where autocommit needs to be disabled, if the latest replayed data needs to be read during the execution of a long transaction, you need to manually commit the current query transaction and then perform a new query.

- Use sysbench to test the read performance of the standby node in typical scenarios: The primary node executes 100 concurrent update services. The primary and standby nodes both execute 200 concurrent read services at the same time. When the I/O and CPU are not limited, the read performance of the standby node in serial replay mode is not lower than 80% of that of the primary node, and the read performance of the standby node in ultimate RTO deteriorates by no more than 10% compared with that of the standby node in serial replay mode.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The standby node is allowed to accept connections and queries after it is restored to the minrecovery point.
- **off**: The standby node is not allowed to accept connections and queries after it is restored to the minrecovery point.

Default value: **on**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: After the read function of the standby node is enabled, certain resources, including the CPU, memory, disk space, and I/O usage, are consumed even if the standby node does not respond to services. If there is no read service on the standby node, you are advised to disable this parameter.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

max_standby_archive_delay

Parameter description: Specifies the wait period before queries on the standby node are canceled. A query conflict occurs when you use the standby node to read data in hot standby mode. In the current version, the setting does not take effect and is controlled by the **max_standby_streaming_delay** parameter.

Parameter type: integer.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Unit: milliseconds

Value range: –1 to 2147483647. **-1** indicates that the standby node waits until the conflicting queries are complete.

Default value: **3000** (that is, 3s)

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

max_standby_streaming_delay

Parameter description: Specifies the wait period before queries on the standby node are canceled when the queries conflict with WAL data receiving through streaming replication in hot standby mode. If this parameter is set to a large value or the service load is heavy, an error may be reported, indicating that queries conflict with conflict.

Parameter type: integer.

Unit: milliseconds

Value range: –1 to 2147483647

NOTICE

-1 indicates that the standby node waits until the conflicting queries are complete. In the scenario where serial or parallel replay is enabled, if the system detects that the query thread and replayer thread are in the deadlock state, the system still cancels the query to prevent replay blocking.

0 indicates that the standby node immediately cancels the query when a conflict between replay and query occurs.

Default value: **3000** (that is, 3s)

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Set this parameter based on service requirements. The default value is recommended. A larger value indicates a higher query service priority on the standby node, but affects replay on the standby node. A smaller value indicates that long queries are more likely to be canceled, but the replay priority is higher.

Risks and impacts of improper settings: If the value is too large and long queries conflict with replay, replay may be blocked for a long time, affecting the RTO and RPO of the standby node.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

wal_receiver_status_interval

Parameter description: Specifies the maximum interval for notifying the primary node of the WAL receiver status.

Parameter type: integer.

Unit: seconds

Value range: 0 to 2147483

Default value: **5**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this parameter is set to **0**, the standby node does not send information, such as the log receiving location, to the primary node. As a result, the transaction commit on the primary node may be blocked, and the switchover may fail. In normal service scenarios, you are advised not to set this parameter to **0**.

hot_standby_feedback

Parameter description: Specifies that the minimum transaction ID of a query performed on the standby node is sent to the primary node to avoid query conflicts.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The ID of the oldest transaction active on standby nodes will be sent to the primary node.
- **off**: The ID of the oldest transaction active on standby nodes will not be sent to the primary node.

Default value: **off**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this parameter is set to **on**, the deletion of source version data on the primary node is restricted by the transactions that are being read by the standby node. That is, the primary node can delete only the changes whose transaction IDs are smaller than those reported by the standby node. Therefore, the performance of the primary node will be affected when this parameter is enabled. If replay conflicts with query on the standby node and a query error is reported, you are advised to increase the value of **max_standby_streaming_delay**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

wal_receiver_timeout

Parameter description: Specifies the maximum wait period for a standby node to receive data from the primary node.

Parameter type: integer.

Unit: milliseconds

Value range: 0 to 2147483647

Default value: **6000** (that is, 6s)

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If the value is too small, the walreceiver thread is frequently disconnected when the network fluctuates.

wal_receiver_connect_timeout

Parameter description: Specifies the maximum timeout interval for the standby server to connect to the primary server.

Parameter type: integer.

Unit: seconds

Value range: 0 to 2147483

Default value: **2**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

wal_receiver_connect_retries

Parameter description: Specifies the maximum attempts that a standby node connects to the primary node.

Parameter type: integer.

Unit: none

Value range: 1 to 2147483647

Default value: **1**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

wal_receiver_buffer_size

Parameter description: Specifies the memory buffer size for the standby nodes to store the received Xlog files.

Parameter type: integer.

Unit: KB

Value range: 4096 to 1047552

Default value: **65536** (that is, 64 MB)

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

primary_slotname

Parameter description: Specifies the slot name of the primary node corresponding to a standby node. This parameter is used for verifying the primary-standby relationship.

Parameter type: string.

Unit: none

Value range: a string.

Default value: **""**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this parameter is incorrectly set, the standby node may fail to connect to the primary node, and the cluster status may be abnormal.

max_standby_base_page_size

Parameter description: Specifies the maximum storage space of base page files on the standby node after the ultimate RTO function is enabled.

Parameter type: integer.

Unit: KB

Value range: 1048576 to 562949953421311

Default value: **268435456** (that is, 256 GB)

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Set this parameter according to the actual size of the physical disk.

Risks and impacts of improper settings: If the value is too small, the probability of read errors on the standby node increases.

max_standby_lsn_info_size

Parameter description: Specifies the maximum size of LSN info files on the standby node after the ultimate RTO function is enabled.

Parameter type: integer.

Unit: KB

Value range: 1048576 to 562949953421311

Default value: **268435456** (that is, 256 GB)

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Set this parameter according to the actual size of the physical disk.

Risks and impacts of improper settings: If the value is too small, the probability of read errors on the standby node increases.

max_keep_csn_info_size

Parameter description: Specifies the maximum size of CSN info linked lists allowed by each DN on the standby node after the ultimate RTO function is enabled.

Parameter type: integer.

Unit: KB

Value range: 16384 to 131072

Default value: **16384** (that is, 16 MB)

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

base_page_saved_interval

Parameter description: Specifies the interval for generating base pages on the standby node after the ultimate RTO function is enabled. For the same page, a base page is generated each *n* (specified by this parameter) times.

Parameter type: integer.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Unit: none

Value range: 5 to 2000

Default value: **400**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If the interval is too long, a large number of Xlogs need to be replayed each time the standby node reads data, and the performance deteriorates. If the interval is too short, more disk space is occupied and the forcible recycling point is reached more quickly.

standby_force_recycle_ratio

Parameter description: Specifies the percentage of files read by the standby node to trigger forcible recycling after the ultimate RTO function is enabled. When the total size of base page files exceeds the value of **max_standby_base_page_size** x **standby_force_recycle_ratio** or the total size of LSN info files exceeds the value of **max_standby_lsn_info_size** x **standby_force_recycle_ratio**, forcible recycling is triggered and some queries are canceled. When the value of **standby_force_recycle_ratio** is **0**, forcible recycling is not started, and the setting of **max_standby_base_page_size** and **max_standby_lsn_info_size** does not take effect.

Parameter type: floating-point number

Unit: none

Value range: 0.0 to 1.0

Default value: **0.8**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

standby_recycle_interval

Parameter description: Specifies the interval for the standby node to recycle read files after the ultimate RTO function is enabled. The thread for recycling read resources on the standby node attempts to clear read files on the standby node at the interval specified by this parameter.

Parameter type: integer.

Unit: seconds

Value range: 0 to 86400. The value **0** indicates that historical pages are not recycled and the recycling of Xlogs on the standby node is affected. As a result, the standby node occupies too much disk space.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Default value: **10**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If the interval is too long, historical pages cannot be recycled in a timely manner, which may cause excessive disk usage.

standby_max_query_time

Parameter description: Specifies the maximum query time supported on the standby node after the ultimate RTO function is enabled. If the query time exceeds the value of this parameter, the query will be canceled.

NOTE

The time when the query is canceled is affected by the interval parameter **standby_recycle_interval** of the recycling thread and the time when the snapshot is obtained. Therefore, the actual execution time of the query on the standby node must be greater than the value of this parameter.

Parameter type: integer.

Unit: seconds

Value range: 0 to 86400. The value **0** indicates that when the recycling thread recycles historical pages, if the queried snapshot is earlier than the current recycling point, the query is canceled immediately.

Default value: **600**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Set the value based on service requirements.

Risks and impacts of improper settings: If this parameter is set to a large value, the recycling thread cannot calculate the recycling point. As a result, the recycling of historical versions and Xlogs may be blocked, increasing the disk space usage.

exrto_transaction_isolation_force_rr

Parameter description: Specifies whether to forcibly set the transaction to the **REPEATABLE READ** isolation level in the scenario where read on standby is enabled with ultimate RTO.

Parameter type: Boolean

Unit: none

Value range:

- **on**: In the scenario where read on standby is enabled with ultimate RTO, the transaction is forcibly set to the **REPEATABLE READ** isolation level.
- **off**: In the scenario where read on standby is enabled with ultimate RTO, the transaction can be set to any isolation level.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTICE

In the scenario where read on standby is enabled with ultimate RTO, you need to ensure that the value of **exrto_transaction_isolation_force_rr** is **off**, and then set the transaction isolation level using the **transaction_isolation** parameter.

Default value:

- For a newly installed database, the default value is **off**.
- If the GUC parameter does not exist in the source version, the default value is **on**. If the GUC parameter exists in the source version, the original setting is retained.

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

exrto_standby_read_opt

Parameter description: Specifies whether to support read optimization of the standby node with ultimate RTO. This parameter is not synchronized between the primary and standby nodes.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The optimization is enabled.
- **off**: The optimization is disabled.

Default value: **on**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

walrcv_writer_crc_check_level

Parameter description: Specifies whether to enable Xlog verification on the standby node in the primary/standby clusters in the streaming DR scenario. By default, the parameter is enabled only in the standby cluster.

Parameter type: integer.

Unit: none

Value range: 0 to 3

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **0**: The verification is disabled.
- **1**: The verification takes effect in the standby cluster.
- **2**: The verification on the standby node in the primary cluster takes effect.
- **3**: The verification on all standby nodes in the primary cluster and nodes in the standby cluster take effect.

Default value: **1**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: This parameter is automatically set in the DR establishment process. If the verification fails, the primary and standby nodes are disconnected, and the status of the standby cluster is abnormal for a short period of time. The status can be restored after the standby cluster is restarted.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

standby_read_use_az_info

Parameter description: Specifies whether the GTM-lite standby node uses AZ information to read data. The standby node in the same AZ as the CN is preferentially selected. This parameter is disabled by default.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: enabled.
- **off**: disabled.

Default value: **off**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Set this parameter based on service requirements. After this function is enabled, all available standby DNs need to be traversed before being selected, which may cause query performance deterioration.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

standby_read_use_load_balance

Parameter description: Specifies whether the GTM-lite standby node uses the load balancing function to randomly select DNs that meet the consistency point (and AZ information). This function is disabled by default.

Parameter type: Boolean.

Unit: none

Value range:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **on**: enabled.
- **off**: disabled.

Default value: **off**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Set this parameter based on service requirements. After this function is enabled, all available standby DNs need to be traversed before being selected, which may cause query performance deterioration.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

enable_standby_bufferpool

Parameter description: Specifies whether to enable the function of reading data from an independent buffer on the standby node with ultimate RTO.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: enabled.
- **off**: disabled.

Default value: **on**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

NOTE

When this function is enabled, it takes effect only when **enable_incremental_checkpoint** is enabled and the difference between the value of **standby_shared_buffers_fraction** and that of **standby_bufferpool_scale** is greater than or equal to 0.1.

standby_bufferpool_scale

Parameter description: Specifies the percentage of the **shared_buffers** memory buffer used by the independent buffer after the function of independent buffer for read on the standby node with ultimate RTO is enabled.

Parameter type: floating-point number

Unit: none

Value range: 0.1 to 0.9

Default value: **0.5**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this parameter is set to an improper value, page refreshing will be accelerated.

wal_replication_ssl

Parameter description: Specifies whether to enable SSL communication between primary and standby nodes. This parameter is used together with the GUC parameter **ssl**. SSL encrypted transmission is used only when both parameters are set to **on**. If SSL encrypted transmission is disabled, the communication performance between primary and standby nodes can be improved.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: enabled.
- **off**: disabled.

Default value: **on**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this parameter is set to an improper value, the communication security between the primary and standby nodes deteriorates.

6.3.7.4 Logical Replication

max_changes_in_memory

Parameter description: Specifies the maximum number of DML statements cached in memory for a single transaction during logical decoding.

Parameter type: integer.

Unit: none

Value range: 1 to 2147483647

Default value: **4096**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If the value is too large, a large amount of dynamic memory is occupied when large transactions are decoded. If the value is too small, the decoding efficiency decreases.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

max_cached_tuplebufs

Parameter description: Specifies the upper limit of the total tuple information cached in the memory during logical decoding.

Parameter type: integer.

Unit: none

Value range: 1 to 2147483647

Default value: **8192**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value. You are advised to set this parameter to a value greater than or equal to twice of **max_changes_in_memory**.

Risks and impacts of improper settings: If the value is too large, a large amount of dynamic memory is occupied when large transactions are decoded. If the value is too small, the decoding efficiency decreases.

logical_decode_options_default

Parameter description: Specifies the global default parameters when a logical decoding task is started.

Parameter type: string.

Unit: none

Value range: Currently, the following logical decoding options can be specified: **parallel-decode-num**, **parallel-queue-size**, **max-txn-in-memory**, **max-reorderbuffer-in-memory**, **exclude-users**, **skip-generated-columns**, **decode-sequence**, **max-control-memory-size**, **max-toast-memory-size**, **max-queue-cache-num**, **desc-memory-limit**, **data-limit**, and **enable-cn-decode**. For details about the options, see "Feature Usage Guidelines > Logical Replication > Logical Decoding (Non-Multi-Primary) > Logical Decoding Options" in *Developer Guide*.

NOTICE

- Multiple key=value pairs in a string are separated by commas (,), for example, **"parallel-decode-num=4,parallel-queue-size=128,exclude-users=userA,skip-generated-columns=on"**.
- The **exclude-users** option specified by **logical_decode_options_default** is different from the logical decoding startup option **exclude-users**. You are not allowed to specify multiple blacklisted users.
- **decode-sequence** configured in **logical_decode_options_default** can only be set to **false**.

Default value: **""**. An empty string indicates that the default value of the program is used.

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTICE

The setting of this SIGHUP parameter does not affect the logical decoding process that has been started. The setting of this parameter will be used as the default configuration for subsequent logical decoding startup. If the same configuration item exists in the decoding task startup command, the default value of the corresponding option of **logical_decode_options_default** does not take effect. Instead, the value specified in the startup command is used.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

logical_decode_options_extend

Parameter description: Specifies the global default parameters when a logical decoding task is started. This parameter can be set at the PDB level.

Parameter type: string.

Unit: none

Value range: a string that contains XIDs, separated by slashes (/), for example, **"skip-xid-list=9737819/9737823"**. Valid XIDs range from 3 to 18446744073709551615.

Default value: **""**, indicating that the preset default value is used.

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**. Currently, the following logical decoding options can be specified: **skip-xid-list**. For details about the options, see "Feature Usage Guidelines > Logical Replication > Logical Decoding (Non-Multi-Primary) > Logical Decoding Options" in *Developer Guide*.

NOTICE

The setting of this parameter does not affect the logical decoding process that has been started. The setting of this parameter will be used as the default configuration for subsequent logical decoding startup. If the same configuration item exists in the decoding task startup command, the default value of the corresponding option of **logical_decode_options_extend** does not take effect. Instead, the value specified in the startup command is used.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after you fully understand the parameter meaning and test the parameter. If the XIDs are incorrectly set, transactions may be skipped unexpectedly, causing data loss during decoding.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

logical_sender_timeout

Parameter description: Specifies the maximum waiting time for the sender to wait for the receiver to receive logical logs.

Parameter type: integer.

Unit: milliseconds

Value range: 0 to 2147483647

Default value: **30000** (30s)

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

enable_logicalrepl_xlog_prune

Parameter description: Specifies whether to enable the function of forcibly invalidating a logical replication slot. When the GUC parameters **enable_logicalrepl_xlog_prune** is set to **on**, **max_size_for_xlog_retention** is greater than 0, and the number of retained log segments (16 MB for each log segment) exceeds the value of **max_size_for_xlog_retention** due to the current logical replication slot, or **max_size_for_xlog_retention** is less than 0 and the disk usage reaches (–**max_size_for_xlog_retention**)/100, the logical replication slot will be forcibly invalidated, **restart_lsn** is set to **7FFFFFFF/FFFFFFFF**, and the replication slot does not block the recycling of Xlogs.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The function of forcibly invalidating a logical replication slot is enabled.
- **off**: The function of forcibly invalidating a logical replication slot is disabled.

Default value: **off**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Determine whether to enable this function based on service requirements.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

enable_logical_replication_ddl

Parameter description: Specifies whether the logical decoding supports DDL statements, reverse parsing, and log generation.

Parameter type: Boolean.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Unit: none

Value range:

- **on**: Logical replication supports DDL statements, reversely parses DDL execution results, and generates DDL WALs.
- **off**: DDL statements are not supported, reverse parsing is not performed, and WALs are not generated.

Default value: **on**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

max_keep_log_seg

Parameter description: Flow control parameter. In logical replication, physical logs are parsed and converted into logical logs locally on the DN. When the number of physical log files that are not parsed is greater than the value of this parameter, flow control is triggered.

Parameter type: integer.

Unit: none

Value range: 0 to 2147483647. **0** indicates that the flow control function is disabled.

Default value: **0**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Determine whether to perform flow control based on service requirements.

Risks and impacts of improper settings: If the value is too large, flow control will not be triggered.

logical_replication_dictionary_retention_time

Parameter description: Specifies the retention period of data in the system catalogs related to GS_TXN_LSN_TIME and the data dictionary.

Parameter type: integer

Unit: days (d)

Value range: 1 to 3650

Default value: **365**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Setting suggestion: Set this parameter based on service requirements.

Risks and impacts of improper settings: If the value is too small, the available interval for decoding the positioning point is too small. If the value is too large, the decoding performance is affected.

logical_replica_identity_force

Parameter description: Specifies the record level of old tuples for global logical replication.

Parameter type: enumerated type

Unit: none

Value range:

- **'full'**: All columns are recorded as replica identifiers.
- **'unique'**: The replica identifier is the primary key and unique key.
- **'default'**: The replica identifier is selected by default (primary key or none).
- **'nothing'**: There is no replica identifier for recording this relationship.
- **'none'**: The global control parameter does not take effect.

Default value: **'none'**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

NOTE

To reset **logical_replica_identity_force** that has been set to a non-default value to **'none'**, you need to restore the GUC parameter to the default value.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

6.3.8 Query Planning

This section describes the method configuration, cost constants, planning algorithm, and some configuration parameters for the optimizer.

NOTE

- Two parameters are involved in the optimizer:
  - *INT_MAX* indicates the maximum value of the INT data type. The value is **2147483647**.
  - *DBL_MAX* indicates the maximum value of the FLOAT data type.
- In addition to customer services, global query planning parameters also affect database O&M and monitoring services, such as WDR generation, scale-out, redistribution, and data import and export.

6.3.8.1 Optimizer Method Configuration

These configuration parameters provide a crude method of influencing the query plans chosen by the query optimizer. If the default plan chosen by the optimizer

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

for a particular query is not optimal, a temporary solution is to use one of these configuration parameters to force the optimizer to choose a different plan. Better ways include adjusting the optimizer cost constants, manually running **ANALYZE**, increasing the value of the **default_statistics_target** parameter, and increasing the amount of the statistics collected in specific columns using **ALTER TABLE SET STATISTICS**.

enable_bitmapscan

Parameter description: Specifies the query optimizer's use of bitmap-scan plan types.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: used.
- **off**: not used.

Default value: **on**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: After this function is disabled, the bitmap scan operator is disabled globally, which may cause performance deterioration in some scenarios. Exercise caution when modifying the parameter to avoid risks caused by misoperations.

force_bitmapand

Parameter description: Specifies whether the query optimizer forcibly uses BitmapAnd plan types.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: used.
- **off**: not used.

Default value: **off**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: After this parameter is enabled, the optimizer forcibly performs bitmap and index scan when the conditions for using the bitmap and index scan operator are met. In some scenarios, the query performance may be affected. Exercise caution when modifying the parameter to avoid risks caused by misoperations.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

enable_hashagg

Parameter description: Specifies the query optimizer's use of Hash aggregation plan types.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: used.
- **off**: not used.

Default value: **on**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this parameter is disabled, the Hash aggregation operator cannot be used in some scenarios, affecting the query rewriting logic and deteriorating the query performance. Exercise caution when modifying the parameter to avoid risks caused by misoperations.

enable_hashjoin

Parameter description: Specifies whether the optimizer uses hash join plan types.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: used.
- **off**: not used.

Default value: **on**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: After this function is disabled, the Hash Join operator cannot be used globally and other Join plans are preferentially generated. As a result, the performance may deteriorate in some scenarios. Exercise caution when modifying the parameter to avoid risks caused by misoperations.

enable_indexscan

Parameter description: Specifies whether the optimizer uses index-scan plan types.

Parameter type: Boolean.

Unit: none

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Value range:

- **on**: used.
- **off**: not used.

Default value: **on**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: After this function is disabled, the index scan operator is disabled globally, which may cause performance deterioration in some scenarios. Exercise caution when modifying the parameter to avoid risks caused by misoperations.

enable_indexonlyscan

Parameter description: Specifies whether the optimizer uses index-only-scan plan types.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: used.
- **off**: not used.

Default value: **on**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: After this function is disabled, the index-only-scan operator cannot be used globally. Some plans that require only index scan but do not require table return cannot be generated. As a result, the performance may deteriorate in some scenarios. Exercise caution when modifying the parameter to avoid risks caused by misoperations.

enable_gsiscan

Parameter description: Specifies whether the query optimizer uses global secondary-index-only scan plan types.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: used.
- **off**: not used.

Default value: **on**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: In scenarios where global secondary indexes are available, if this parameter is disabled, only global secondary index scan plans cannot be generated, which may affect the query performance.

enable_gsitablescan

Parameter description: Specifies whether the query optimizer uses the global secondary index table scan plan types.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: used.
- **off**: not used.

Default value: **on**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: In scenarios where global secondary indexes are available, if this parameter is disabled, only global secondary index scan plans cannot be generated, which may affect the query performance.

gsi_fastpath_level

Parameter description: Specifies whether the optimizer executes the determination system of simple query rules of GSI. The simple query rules of GSI are as follows:

- A single table, no subquery, no sublink, or the target table is not a view.
- The query statement cannot generate an execution plan for an ordinary index.
- The query statement cannot generate the IndexOnlyScan execution plan of GSI.
- Query statements do not contain scan hints, such as TableScan and IndexScan.
- The WHERE condition contains an equivalent condition that contains the index key of the candidate GSI (unique and not a partial GSI index).

Parameter type: enumerated type.

Unit: none

Value range:

- **strict**: The equivalent condition contains all GSI index keys.
- **partial**: The equivalent condition contains partial index keys (leftmost match) of GSI. The performance may not be optimal.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **none**: disabled.

Default value: **strict**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Improper settings may affect plan generation in some GSI scenarios, affecting query performance.

NOTE

If you want to use **partial**:

```
gaussdb=# CREATE TABLE t1(a INT, b INT, c INT);
gaussdb=# CREATE GLOBAL UNIQUE INDEX t1_gsi ON t1(b,c);
-- Q1
gaussdb=# SELECT * FROM t1 WHERE b=1;
-- Q2
gaussdb=# SELECT * FROM t1 WHERE b=1 LIMIT 1;
```

In the preceding scenario, the GSI is created on the **b** and **c** columns. When **gsi_fastpath_level** is set to **partial**, the GSI non-stream return plan can be generated for query statements Q1 and Q2. The uniqueness of an index is ensured by the **b** and **c** columns. For query statement Q1, multiple results may be returned. The performance of the GSI non-stream return plan may not be optimal. For query statement Q2, the limit 1 condition is included, the performance of the GSI non-stream return plan is still optimal.

enable_default_gsi

Parameter description: (1) Specifies whether to create a global secondary index (GSI) by default when the primary key constraint or unique constraint is added to a column that does not contain a distribution key during table creation. (2) Specifies whether a GSI can be created for a hash bucket table.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: (1) A GSI is created by default when the primary key constraint or unique constraint is added to a column that does not contain a distribution key during table creation. (2) A GSI can be created for a hash bucket table.
- **off**: (1) A GSI is not created by default when the primary key constraint or unique constraint is added to a column that does not contain a distribution key during table creation. The table fails to be created. (2) A GSI cannot be created for a hash bucket table.

Default value: **on**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value. You need to determine whether to enable this parameter based on the actual application scenario.

Risks and impacts of improper settings:

- Setting this parameter to **off**: (1) The primary key constraint or unique constraint cannot be added to columns that do not contain distribution keys

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

during table creation. You are advised to add distribution keys by reconstructing services. (2) GSIs cannot be created for hash bucket tables.

- If this parameter is set to **on**: (1) GSIs are created by default. PRIMARY KEY constraints or UNIQUE constraints can be added to columns that do not contain distribution keys in the table. Note that if GSIs are created on the table, DML operations may cause potential performance deterioration. (2) Some indexes and GSIs in the form of expression indexes on hash bucket tables are rebuilt offline during redistribution. During the rebuilding, services are blocked. GSIs that are not partial indexes or expression indexes are rebuilt online during redistribution, and services are not blocked. GSIs are valid during scale-out and redistribution.

enable_gsi_iud_returning

Parameter description: Specifies whether to enable the RETURNING functionality when INSERT, UPDATE, and DELETE operations are performed on a base table with GSIs.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: enable.
- **off**: disabled.

Default value: **on**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this parameter is disabled when INSERT, UPDATE, or DELETE operations are performed on a base table with GSIs, the RETURNING functionality will not be supported.

enable_gsi_distkey_update

Parameter description: Specifies whether to enable the functionality of updating the distribution key of a GSI (UPDATE, UPSERT, and MERGE INTO).

Parameter type: Boolean.

Unit: none

Value range:

- **on**: enable.
- **off**: disabled.

Default value: **on**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Risks and impacts of improper settings: If this parameter is disabled, the distribution key of the GSI cannot be updated.

enable_gsi_dml_lp_opt

Parameter description: Specifies whether the optimizer executes the determination system of simple DML rules of the GSI to optimize the execution of simple DML statements. The simple DML optimization rules of the GSI are as follows:

- For INSERT statements, only the following simple INSERT statements are supported:
  - Only a single VALUES clause is supported. Multiple VALUES clauses are not supported.
  - The values in VALUES must be constants or parameters (expressions are not supported).
  - The RETURNING clause, subqueries in any form, and UPSERT statements are not supported.
  - The target table must be a single table that has no more than one GSI. The GSI must be an ordinary GSI (expression indexes or partial indexes are not supported) and cannot contain columns of user-defined types.
- Other DML statements: Not supported currently.
- This parameter must be set on both CNs and DNs.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: enable.
- **off**: disabled.

Default value: **on**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this parameter is disabled, GSI DML Light Proxy optimization is not supported, which may cause performance deterioration in some GSI DML scenarios.

enable_material

Parameter description: Specifies whether the query optimizer uses materialization. It is impossible to suppress materialization entirely, but setting this parameter to **off** prevents the optimizer from inserting materialized nodes.

Parameter type: Boolean.

Unit: none

Value range:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **on**: used.
- **off**: not used.

Default value: **on**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: After this function is disabled, the optimizer is prohibited from inserting entity nodes. As a result, the Material operator cannot be generated in some scenarios, and the performance may deteriorate in some scenarios.

enable_mergejoin

Parameter description: Specifies whether the optimizer uses merge-join plan types.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: used.
- **off**: not used.

Default value: **off**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this parameter is enabled, the optimizer generates a merge join path for joins that meet the conditions. As a result, the selected join operator in this scenario may not be the optimal one.

enable_nestloop

Parameter description: Specifies whether the query optimizer uses nested-loop join plan types to fully scan internal tables. It is impossible to eliminate nested-loop joins. However, if this parameter is disabled, the optimizer prefers other methods when other methods exist.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: used.
- **off**: not used.

Default value: **off**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this parameter is enabled, the optimizer generates a nested-loop join path for joins that meet the conditions. As a result, the selected join operator in this scenario may not be the optimal one.

enable_index_nestloop

Parameter description: Specifies whether the optimizer uses the nested-loop join plan type to scan the parameterized indexes of inner tables.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: used.
- **off**: not used.

Default value: **on**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this parameter is disabled, parameterized paths cannot be generated in some scenarios. Generally, parameterized paths can improve query performance. Therefore, you are advised to enable this parameter.

enable_remote_param

Parameter description: Specifies whether to use the XC parameterized path feature. If this parameter is enabled, an XC parameterized path plan can be generated.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: used.
- **off**: not used.

Default value:

- **on**: default value of the newly installed database.
- **off**: default value after an upgrade from a version earlier than 505.2.0.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

> **NOTE**
>
> This parameter was introduced in version 505.2.0 and its default value was changed from **off** to **on** in version 507.0.0. After an upgrade from a version earlier than 505.2.0, the value of this parameter is **off**. If this parameter exists and has been set before the upgrade, the original value will be retained after the upgrade.

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: In correlated sublink and nested-loop scenarios, if the outer table is small and the inner table is large, and the inner table has an index that meets the leftmost prefix matching rule in the join condition, you are advised to set this parameter to **on**. In this configuration, if the cost model selects a parameterized path, the performance can be improved.

Risks and impacts of improper settings: In correlated sublink and nested-loop scenarios, if the outer table is large and the inner table is small, setting this parameter to **on** and selecting a parameterized path for the cost model may cause performance deterioration.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTICE

- The conditions for generating an XC parameterized path are as follows:
  - The condition cannot contain expressions that cannot be pushed down (for example, a function whose PROVOLATILE attribute is volatile).
  - The condition can match an index according to the leftmost matching rule.
  - The WHERE condition of an outer join does not support parameterization.
- XC parameterization supports the following scenarios:
  - A parameterized path for nested loops can be generated, and the join condition can be pushed down to the inner table RemoteQuery (including single-table RemoteQuery and RemoteJoinQuery) so that the query result of the outer table can be passed to the inner table as a parameter.
  - A parameterized path for subplans can be generated, and the Coordinator Qual on the subplan can be pushed down to the RemoteQuery of the subplan so that the result of the parent query of the subplan can be passed to the inner table as a parameter.
- The limitations on using the XC parameterized path feature are as follows:
  - Only XC plans are supported. Stream and FQS plans are not supported.
  - A plan with the parameter **rescan** is generated for the base table only when the index parameterized path is generated for the base table.
  - The nested loop parameterized path supports only the scenario where the inner table is **RemoteQuery**.
  - The nested-loop parameterized path does not support pushing parameters down to subqueries.
  - The predpush hint is not supported.
  - In an M-compatible database, if the **max_datanode_for_plan** parameter is set to a value greater than 0, the DN plan of the parameterized path cannot be displayed.
  - Dynamic DN pruning for remote queries is not supported.

enable_remote_pbe_reuse

Parameter description: Specifies whether to reuse the PBE packets of DNs delivered by the CN as planned by the XC. After this function is enabled, the packets sent by the CN to the DN in the XC plan are changed from unnamed packets to packets with the **_disqry_sys_cached** prefix. The packets are reused during execution, improving query performance.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: used.
- **off**: not used.

Default value: **on**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this parameter is disabled, the XC plan query performance will be affected in some scenarios.

enable_seqscan

Parameter description: Specifies whether the query optimizer uses sequential scan plan types. It is impossible to eliminate sequential scan. However, if this parameter is disabled, the optimizer prefers other methods when other methods exist.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: used.
- **off**: not used.

Default value: **on**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this parameter is disabled, the optimizer tends to select other scan methods and lowers the priority of sequential scan methods. In some scenarios, the query performance may be affected.

enable_sort

Parameter description: Specifies whether the optimizer uses sort methods. It is impossible to eliminate explicit sorting. However, if this parameter is disabled, the optimizer prefers other methods when other methods exist.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: used.
- **off**: not used.

Default value: **on**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this parameter is disabled, the optimizer prefers other methods and lowers the priority of the sorting method. Therefore, you are advised to enable this parameter.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

enable_tidscan

Parameter description: Specifies whether the optimizer uses Tuple ID (TID) scan plan types.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: used.
- **off**: not used.

Default value: **on**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this parameter is disabled, the optimizer prefers other methods and lowers the priority of the TID scan method. Therefore, you are advised to enable this parameter.

enable_kill_query

Parameter description: In CASCADE mode, when a user is deleted, all the objects belonging to the user are deleted. This parameter specifies whether the queries of the objects belonging to the user can be unlocked when the user is deleted.

Parameter type: Boolean.

Unit: none

Value range:

- **on** indicates that the unlocking is allowed.
- **off** indicates that the unlocking is not allowed.

Default value: **off**

Setting method: This is a SUSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: After this parameter is enabled, when a user is deleted, the query of the user may be exposed, affecting system consistency and security.

enable_stream_concurrent_update

Parameter description: Specifies the optimizer's use of streams in concurrent update scenarios. This parameter is restricted by the **enable_stream_operator** parameter. If concurrent update conflicts occur, an error may be reported. This parameter can be used to control the conflict.

Parameter type: Boolean.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Unit: none

Value range:

- **on** indicates that the optimizer can generate stream plans for the UPDATE statement.
- **off** indicates that the optimizer can generate only non-stream plans for the UPDATE statement.

Default value: **on**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this parameter is disabled, the optimizer prefers other methods and generates only non-stream plans for update statements. Therefore, you are advised to enable this parameter.

enable_stream_operator

Parameter description: Specifies whether the optimizer uses stream. When the **enable_stream_operator** parameter is disabled, a large number of logs indicating that the stream plans cannot be pushed down are recorded. If you do not need these logs, you are advised to disable **enable_unshipping_log** when disabling **enable_stream_operator**. During bare metal installation, this parameter is set to **off**.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: used.
- **off**: not used.

Default value:

- Independent deployment: **off**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this parameter is set to an improper value, the optimizer cannot generate stream plans, which may deteriorate the query performance.

enable_stream_recursive

Parameter description: Specifies whether to push **WITH RECURSIVE** join queries to DNs for processing.

Parameter type: Boolean.

Unit: none

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Value range:

- **on** indicates that WITH RECURSIVE join queries will be pushed down to DNs.
- **off** indicates that WITH RECURSIVE join queries will not be pushed down.

Default value: **on**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this parameter is disabled, the query performance may deteriorate.

max_recursive_times

Parameter description: Specifies the maximum number of WITH RECURSIVE iterations.

Parameter type: integer.

Unit: none

Value range: 0 to 2147483647

Default value: **200**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Set this parameter based on service requirements.

Risks and impacts of improper settings: This parameter is used to prevent an infinite loop of the WITH RECURSIVE statement by using nocycle in hierarchical queries to exit the loop. If you want to adjust the value, make sure you understand the parameter meaning and adjust the value with caution to avoid risks caused by misoperations.

enforce_a_behavior

Parameter description: Specifies the rule matching modes of regular expressions.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The A matching rule is used.
- **off**: The POSIX matching rule is used.

Default value: **on**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Set this parameter based on the actual service scenario.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Risks and impacts of improper settings: The regular expression in the query statement cannot be matched as expected.

enable_vector_engine

Parameter description: Specifies whether the optimizer uses vectorized engine.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: used.
- **off**: not used.

Default value: **on**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this parameter is disabled, the optimizer may fail to generate vectorized query plans for specific scenarios, affecting query performance.

enable_broadcast

Parameter description: Specifies whether the query optimizer uses broadcast distribution method when it evaluates the cost of stream.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: used.
- **off**: not used.

Default value: **on**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: The accuracy of stream plan generation and the query performance are affected.

enable_change_hjcost

Parameter description: Specifies whether the optimizer excludes inner table running costs when selecting the hash join cost path. If it is set to **on**, tables with a few records and high running costs are more possible to be selected.

Parameter type: Boolean.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Unit: none

Value range:

- **on**: used.
- **off**: not used.

Default value: **off**

Setting method: This is a SUSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: The hash join cost may be incorrectly estimated, affecting the accuracy of generating hash join plans.

best_agg_plan

Parameter description: Specifies the type of hash aggregation plan generated by the optimizer. The optimizer can generate three plans for the aggregation operation in a stream:

1. hashagg+gather(redistribute)+hashagg
2. redistribute+hashagg(+gather)
3. hashagg+redistribute+hashagg(+gather)

Parameter type: integer.

Unit: none

Value range: 0 to 3.

- **0**: The optimizer generates the optimal plan based on the estimated costs of the three plans.
- **1**: The first plan is forcibly generated.
- **2**: The second plan is forcibly generated if the **group by** column can be redistributed. Otherwise, the first plan is generated.
- **3**: The third plan is forcibly generated if the **group by** column can be redistributed. Otherwise, the first plan is generated.

Default value: **0**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: This parameter affects the hashagg generation mode. You are advised to use the default value. If this parameter is set to another value, the corresponding hashagg generation mode is preferred. If this parameter is set to an improper value, the query performance in some scenarios may be affected.

agg_redistribute_enhancement

Parameter description: When the aggregate operation is performed, which contains multiple **group by** columns and all of the columns are not in the

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

distribution key, you need to select one **group by** column for redistribution. This parameter specifies the policy of selecting a redistribution key.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The column that can be redistributed with the most distinct value evaluated is selected for redistribution.
- **off**: The first column that can be redistributed is selected for redistribution.

Default value: **off**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this parameter is enabled, the plan generation time increases, but a more reasonable redistribution key may be selected.

enable_absolute_tablespace

Parameter description: Specifies whether the tablespace can use the absolute path.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: An absolute path can be used.
- **off**: No absolute path can be used.

Default value: **on**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this parameter is disabled, absolute paths cannot be used when tablespaces are created. You are advised to set this parameter based on service requirements. No other risk exists.

enable_valuepartition_pruning

Parameter description: Specifies whether the DFS partitioned table is dynamically or statically optimized.

Parameter type: Boolean.

Unit: none

Value range:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **on**: The DFS partitioned table is dynamically or statically optimized.
- **off**: The DFS partitioned table is not dynamically or statically optimized.

Default value: **on**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: After this parameter is disabled, the query performance of DFS partitioned tables may deteriorate.

expected_computing_nodegroup

Parameter description: Specifies a compute node group or the way to choose such a group. The node group mechanism is internal. You do not need to set it. During join or aggregation operations, a node group can be selected in four modes. In each mode, the specified candidate compute node groups are listed for the optimizer to select the most appropriate one for the current operator.

Parameter type: string.

Unit: none

Value range:

- **optimal**: The list of candidate compute node groups consists of the node groups where the operator's operation objects are located and the node group that combines all DNs in the node groups on which the current user has the COMPUTE permission.
- **query**: The list of candidate compute node groups consists of the node groups where the operator's operation objects are located and the node group that combines all DNs in the node groups where base tables involved in the query are located.
- *Node group name* (when **enable_nodegroup_debug** is set to **off**): The list of candidate compute node groups consists of the node groups where the operator's operation objects are located and the specified node group.
- *Node group name* (when **enable_nodegroup_debug** is set to **on**): A specific node group is used as the compute node group.

Default value: **query**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: The optimizer may fail to select a better compute node group, affecting query performance.

enable_nodegroup_debug

Parameter description: Specifies whether the optimizer assigns computing workloads to a specific node group when multiple node groups exist in an environment. The node group mechanism is internal. You do not need to set it.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

This parameter takes effect only when **expected_computing_nodegroup** is set to a specific node group.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: Computing workloads are assigned to the node group specified by **expected_computing_nodegroup**.
- **off**: No node group is specified for computing.

Default value: **off**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: The query performance may be affected.

enable_default_index_deduplication

Parameter description: Specifies whether to deduplicate and compress tuples with duplicate key values for a B-tree index by default. The deduplication and compression functions do not take effect for primary key indexes and unique indexes. When there are a large number of indexes with duplicate key values, the deduplication and compression function can effectively reduce the space occupied by indexes. If the WITH (**deduplication** set to **on**/**off**) syntax is used during index creation, the deduplication parameter is preferentially used to determine whether to use deduplication and compression for the index.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The deduplication and compression function is enabled for B-tree indexes.
- **off**: The deduplication and compression function is disabled for B-tree indexes.

Default value: **off**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value. You can enable this parameter for non-unique indexes, high index key value repetition, and large index space usage.

Risks and impacts of improper settings: In scenarios where non-unique indexes are used and index key values are seldom repeated or unique, the deduplication and compression function slightly deteriorates the index insertion performance.

expr_engine

Parameter description: Specifies the execution mode of an expression.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter type: enumerated type.

Unit: none

Value range:

- **EXPR_TREE**: The recursive engine of the expression is used.

Default value: **EXPR_TREE**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: This parameter can only be set to **EXPR_TREE**.

Risks and impacts of improper settings: none

NOTE

The current version does not support expression execution optimization. Therefore, this parameter can only be set to the default value **EXPR_TREE**.

sql_result_check

Parameter description: Specifies the self-verification function of expression results.

Parameter type: enumerated type.

Unit: none

Value range:

- **off**: The expression-based result verification functionality is disabled.
- **single_select**: In the type range that supports expression result verification, if the verification of a column of the numeric precision type fails, an alarm is generated. If the verification of a column of other types fails, an error is thrown.

Default value: **off**

Setting method: This is a SUSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: When **single_check** is used, the query execution time increases slightly.

stream_multiple

Parameter description: Specifies the weight used by the optimizer to calculate the final cost of stream operators. The base stream cost is multiplied by this weight to obtain the final cost.

NOTE

This parameter is applicable only to Redistribute and Broadcast streams.

Parameter type: floating-point

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Unit: none

Value range: 0 to *DBL_MAX*

Default value: **1**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value and adjust the value based on the deployment environment.

Risks and impacts of improper settings: The optimizer may incorrectly estimate the overhead of the stream operator, affecting the query performance.

qrw_inlist2join_optmode

Parameter description: Specifies whether to enable inlist-to-join query rewriting.

Parameter type: string.

Unit: none

Value range:

- **disable**: The inlist-to-join query rewriting is disabled.
- **cost_base**: cost-based inlist-to-join query rewriting. That is, whether to use inlist-to-join query rewriting is automatically evaluated based on the cost.
- **rule_base**: The rule-based inlist-to-join query rewriting is forcibly enabled.
- A positive integer (1 to 2147483647) indicates the threshold of inlist-to-join query rewriting. If the number of elements in the list is greater than the threshold, the rewriting is performed.

Default value: **cost_base**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value. Use other values only when manual optimization is required in abnormal scenarios or when the query performance of the plan selected by the optimizer is low.

Risks and impacts of improper settings: Whether the optimizer performs inlist-to-join query rewriting is affected. No better plan is generated due to improper settings.

NOTICE

The following data types can use the inlist-to-join query rewrite function: TINYINT, SMALLINT, INTEGER, BIGINT, NUMERIC, FLOAT4, FLOAT8, BOOLEAN, CHAR, BPCHAR, VARCHAR, NVARCHAR, TEXT, DATE, TIME, TIMEZ, TIMESTAMP, TIMESTAMPTZ, SMALLDATETIME, INTERVAL, TINTERVAL, UNSIGNED TINYINT, UNSIGNED SMALLINT, UNSIGNED INTEGER, and UNSIGNED BIGINT.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

skew_option

Parameter description: Specifies whether an optimization policy is used.

Parameter type: enumerated type.

Unit: none

Value range: **off**, **normal**, and **lazy**

- **off** indicates that the policy is disabled.
- **normal** indicates that a radical policy is used. All possible skews are optimized.
- **lazy** indicates that a conservative policy is used. Uncertain skews are ignored.

Default value: **normal**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Whether the optimizer optimizes skew is affected. The plan generation performance or query execution performance is affected due to improper settings.

default_limit_rows

Parameter description: Specifies the default estimated number of limit rows for generating genericplan.

Parameter type: floating-point

Unit: none

Value range: –100 to *DBL_MAX*. The recommended value range is 0.1 to 10000. If the value is beyond this range, service risks may occur.

- If this parameter is set to a non-negative number, the value is used as the estimated number of limit rows.
- If this parameter is set to a negative value, the value is used as the default estimated number in percentage. A negative value is converted to the default percentage, that is, **–5** indicates 5%.

Default value: **-10**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: The genericplan query performance of the limit operator may be affected.

check_implicit_conversions

Parameter description: Specifies whether to check candidate index paths generated for index columns that have implicit type conversion in a query. For

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

details about the application scenarios of this parameter, see "Checking the Implicit Conversion Performance" in *SQL Optimization Guide*.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: A check will be performed for candidate index paths generated for index columns that have implicit type conversion in a query.
- **off**: No check will be performed.

Default value: **off**

NOTE

- When this parameter is set to **on**, you need to set **enable_fast_query_shipping** to **off** so that the mechanism for identifying implicit data type conversion in index columns can take effect.
- This parameter is used to check implicit conversion performance issues. Disable this parameter in the formal production environment.

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impact of improper settings: If the check is not performed, the regular expression in the query statement may not be matched as expected.

cost_weight_index

Parameter description: Specifies the cost weight of index_scan.

Parameter type: floating-point

Unit: none

Value range: 1e-6 to 1e+10

Default value: **1**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: This parameter specifies whether the optimizer uses index_scan. The optimizer may use a non-optimal plan due to improper settings, affecting query performance.

try_vector_engine_strategy

Parameter description: Specifies the policy for processing row-store tables by using the vectorized engine. By setting this parameter, queries containing row-store tables can be converted to vectorized execution plans for calculation, improving the execution performance of complex queries in AP-like scenarios.

Parameter type: enumerated type.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Unit: none

Value range:

- **off**: This function is disabled. That is, row-store tables will not be converted into vectorized execution plans for execution.
- **force**: The base table to be queried is a row-store table as long as queries do not contain types or expressions that are not supported by the vectorized engine. Queries are forcibly converted to vectorized execution plans for execution. In this case, the performance may deteriorate in different query scenarios.
- **optimal**: On the basis of **force**, the optimizer determines whether to convert a query statement into a vectorized execution plan based on the query complexity to avoid performance deterioration after the conversion.

Default value: **off**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Whether the optimizer uses a vectorized execution plan is affected. The query performance may be affected in some scenarios due to improper settings.

enable_opfusion_reuse

Parameter description: Specifies whether to reuse the opfusion obj memory.

Parameter type: Boolean.

Unit: none

Value range:

- **on** indicates that the opfusion obj memory is reused when conditions are met.
- **off**: This function is disabled.

Default value: **on**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this parameter is disabled, plans may be regenerated and the query performance may deteriorate.

enable_iud_fusion

Parameter description: Specifies whether to optimize the IUD statements.

Parameter type: Boolean.

Unit: none

Value range:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **on** indicates that the input is optimized during type conversion.
- **off**: This function is disabled.

Default value: **off**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value. You can enable this function if the IUD statement performance needs to be optimized.

Risks and impacts of improper settings: If this parameter is enabled, the optimizer cost increases without significant risk.

enable_cached_operator

Parameter description: Specifies whether to enable the cache feature for operators in execution state.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: Operators can be executed in cache mode.
- **off**: This function is disabled.

Default value: **on**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this parameter is disabled, the operator execution status cannot be cached, affecting the query performance.

enable_smp_partitionwise

Parameter description: Specifies whether to enable the Partition-wise Join capability in the SMP scenario.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The Partition-wise Join capability is enabled in the SMP scenario.
- **off**: The Partition-wise Join capability is disabled in the SMP scenario.

Default value:

- **on**: default value of the newly installed database.
- **off**: This parameter is added in 505.2.0. If a database is upgraded from a version earlier than 505.2.0, the value of this parameter is **off**. If this parameter exists and is set before the upgrade, the default value remains unchanged after the upgrade.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: The data query performance in the SMP scenario may be affected.

force_smp_partitionwise_scan

Parameter description: Specifies whether to enable the Partition-wise Scan parallel scan mode globally after the Partition-wise Join switch **enable_smp_partitionwise** is turned on in the SMP scenario.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The Partition-wise Scan parallel scan mode is enabled in the SMP scenario.
- **off**: The Partition-wise Scan parallel scan mode is disabled in the SMP scenario.

Default value: **off**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: The performance of reading partitioned table data in the SMP scenario may be affected.

enable_nestagg

Parameter description: Specifies whether to enable nested aggregate function. Nested aggregation is a double aggregation syntax similar to sum(min(col)).

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The nested aggregate function is enabled.
- **off**: The nested aggregate function is disabled.

Default value: **on**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: The nested aggregate function is affected.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

enable_index_skip_scan

Parameter description: Specifies whether to enable the index skip scan feature. If this feature is disabled, a full table scan is performed when a user uses a composite index for query and the leading column is empty. If this feature is enabled, when a user uses a combination index for query and the leading column is empty, the database determines whether to perform index skip scanning based on the proportion of the number of distinct values (NDV). A lower proportion of NDV indicates greater advantage of index skip scan. When the proportion of the NDV is high, the cost of index skip scan may be higher than that of full table scan. As a result, the database still uses full table scan.

NOTE

- Leading columns cannot be separated. For example, after an index is created for columns **(a,b,c,d)** of table **t1**, you cannot run the **SELECT * FROM t1 WHERE b =** *xxx* **AND d =** *xxx* statement for query.
- The leading columns cannot be a range.
- Expression indexes are not supported.
- Only RCR B-tree and UB-tree indexes are supported.
- Only IndexScan and IndexOnlyScan are supported. BitmapIndexScan is not supported.
- SQL Bypass is no longer evolved. Therefore, this feature does not apply to SQL Bypass.
- SMP is not supported.
- Hash bucket tables are not supported.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The index skip scan feature is enabled.
- **off**: The index skip scan feature is disabled.

Default value: **off**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If the index skip scan feature is disabled, index scan cannot be used when a combination index is used for query and the leading column is empty. As a result, the query efficiency is reduced.

enable_gsi_stream_dml

Parameter description: Specifies whether to enable the stream feature for DML operations on base tables that have global secondary indexes.

Parameter type: Boolean.

Unit: none

Value range:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **on**: The stream optimization is enabled for DML operations on base tables with global secondary indexes. That is, stream plans can be generated.
- **off**: The stream optimization is disabled for DML operations on base tables with global secondary indexes. That is, stream plans cannot be generated.

Default value: **on**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this parameter is disabled, the performance may deteriorate.

enable_partition_statistic

Parameter description: Specifies whether to use partition-level statistics in the optimizer phase. A scenario where partition-level statistics can be used is as follows: In a Cplan, the partitioned table involved in the query is statically pruned to a single partition, including pruning a partitioned table to a single partition.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: Partition-level statistics can be used.
- **off**: Partition-level statistics cannot be used.

Default value: **on**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: The statistics of a partitioned table when the partitioned table is statically pruned to a single partition are affected, and the plan generation is affected.

dist_query_adaptive_mode

Parameter description: Specifies the mode selected by the distributed adaptive plan. The value can be **auto** (default), **plan**, **sql**, or **off**. If the parameter value is not **off**, the cost of the Remote Query operator is calculated.

Parameter type: enumerated type.

Unit: none

Value range:

- **auto**: The distributed plan is adaptively selected based on the cost or rule. If a rule exists (the **dist_query_adaptive_rows** parameter is not set to **0**), the rule has a higher priority than cost-based selection.
- **plan**: The distributed plan of the delivered plan is forcibly executed.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **sql**: The distributed plan of the delivered statement is forcibly executed.
- **off**: Adaptive selection of distributed plans is disabled.

Default value:

- **auto**: default value of the newly installed database.
- **off**: This parameter is introduced in 507.0.0. After an upgrade from an earlier version, the value of this parameter is **off**. If this parameter exists and has been set before the upgrade, the original value will be retained after the upgrade.

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: The optimizer's selection of the generation plan will be affected, and the query performance will be affected in some scenarios. Exercise caution when modifying the parameter to avoid risks caused by misoperations.

NOTE

The process of adaptive selection of distributed plans is as follows: First, a distributed plan (stream plan) for the delivered plan is generated. By analyzing the characteristics of the stream plan, the system determines whether to trigger the adaptive selection of distributed plans. If adaptive optimization is required, a new distributed plan for the delivered statement is generated.

- Cost-based adaptive constraints on distributed plans:
  - Only the SELECT statement supports adaptive selection of distributed plans.
  - If a statement contains a stream hint, adaptive distributed optimization cannot be enabled for the plan.
  - If a stream plan contains only the Stream Gather operator and no other stream operators, adaptive distributed optimization cannot be enabled for the plan.
  - If a stream plan is an SMP plan, adaptive distributed optimization cannot be enabled for the plan.
  - If a stream plan does not contain the join operation or related sublinks, adaptive distributed optimization cannot be enabled for the plan.
  - If the cost of a stream plan is relatively low, adaptive distributed optimization cannot be enabled for the plan.
  - When the memory or CPU usage of a CN is higher than 80%, if the distributed plan generated by the distributed adaptive plan for the delivered statement is a non-parameterized path plan, the system falls back to the stream plan. This constraint is controlled by the **opt_behavior_knob** option **DIST_QUERY_ADAPTIVE_FALLBACK** and is enabled by default.
- Rule-based adaptive constraints on distributed plans:
  - Only the SELECT statement supports adaptive selection of distributed plans.
  - If a statement contains a stream hint, adaptive distributed optimization cannot be enabled for the plan.
  - If a stream plan contains only the Stream Gather operator and no other stream operators, adaptive distributed optimization cannot be enabled for the plan.
  - If a stream plan is an SMP plan, adaptive distributed optimization cannot be enabled for the plan.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

dist_query_adaptive_rows

Parameter description: Selects a distributed plan rule based on the number of rows of the stream operator. If the total number of rows of all stream operators (except the Stream Gather operator) is less than or equal to the value of this parameter, the distributed plan of the delivered statement is selected. If the total number of rows is greater than the value of this parameter, the distributed plan of the delivered plan is selected.

Parameter type: integer.

Unit: none

Value range: [0,2147483647]

Default value: **0** (indicating that the rule is disabled). This parameter is introduced in 507.0.0. After an upgrade from an earlier version, the value of this parameter is **0**. If this parameter exists and has been set before the upgrade, the original value will be retained after the upgrade.

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Set this parameter when there are a large number of DNs. Adjust the value based on the service data scale. It is recommended that the value be less than or equal to 500.

Risks and impacts of improper settings: The optimizer's selection of the generation plan will be affected, and the query performance will be affected in some scenarios. Exercise caution when modifying the parameter to avoid risks caused by misoperations.

NOTE

The Stream operator needs to establish connections with all DNs to transmit data. In scenarios with a large number of DNs and high concurrency, data communication bottlenecks may occur. Therefore, it is recommended that this parameter be used in services where the number of primary DNs in the cluster is greater than 8 and the number of concurrent requests is greater than 100. Before using this parameter, test and adjust its value based on service requirements.

enable_constraint_optimization

Parameter description: Specifies whether to enable the query optimization function based on informative constraints. When this function is enabled, the optimizer can use the constraint information on the table to generate a more efficient query execution plan. The main scenarios are as follows: external data source scan optimization, redundant NOT NULL constraint elimination, and scan and connection optimization that contain the UNIQUE constraint.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The query optimization function based on information constraints is enabled.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **off**: The query optimization function based on information constraints is disabled.

Default value: **on**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Improper settings may affect the query performance in some scenarios.

6.3.8.2 Optimizer Cost Constants

This section describes the optimizer cost constants. The cost variables described here are measured on an arbitrary scale. Only their relative values matter, therefore scaling them all up or down by the same factor will result in no change in the optimizer's choices. By default, they use the cost of fetching sequential pages as the basic unit. That is, **seq_page_cost** is set to **1.0** and the other cost variables are set with reference to the parameter. However, you can use a different scale, such as actual execution time in milliseconds.

seq_page_cost

Parameter description: Specifies the optimizer's estimated cost of a disk page fetch that is part of a series of sequential fetches.

Parameter type: floating-point number

Unit: none

Value range: 0 to *DBL_MAX*

Default value: **1**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: This parameter affects the performance overhead evaluation of sequentially fetching disk pages in a query. If this parameter is incorrectly set, the optimizer's selection of the generation plan is affected, and the query performance is affected in some scenarios. Exercise caution when modifying the parameter to avoid risks caused by misoperations.

random_page_cost

Parameter description: Specifies the optimizer's estimated cost of an out-of-sequence disk page fetch.

Parameter type: floating-point number

Unit: none

Value range: 0.1 to *DBL_MAX*. The recommended value range is 0.1 to 10. If the value is beyond this range, service risks may occur.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Default value: **4**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: See the parameter description.

Risks and impacts of improper settings: This parameter affects the performance overhead evaluation of randomly fetching disk pages in a query. If this parameter is incorrectly set, the optimizer's selection of the generation plan is affected, and the query performance is affected in some scenarios. Exercise caution when modifying the parameter to avoid risks caused by misoperations.

NOTE

- Although the server allows you to set **random_page_cost** to a value less than that of **seq_page_cost**, it is not physically sensitive to do so. Setting them equal makes sense if the database is entirely cached in RAM because in that case there is no penalty for fetching pages out of sequence. Also, in a heavily-cached database you should lower both values relative to the CPU parameters, since the cost of fetching a page already in RAM is much smaller than it would normally be.
- For tables and indexes in a specified tablespace, you can set a tablespace parameter with the same name to overwrite the database-level parameter value. That is, the priority of the tablespace-level parameter is higher than that of the database-level parameter.
- Reducing this value relative to **seq_page_cost** will cause the system to prefer index scans and raising it will make index scans relatively more expensive. You can increase or decrease both values together to change the disk I/O costs relative to CPU costs.
- The value **1.1** is suitable for SSDs. If HDDs are used, you are advised to change the value to **4**.

cpu_tuple_cost

Parameter description: Specifies the optimizer's estimated cost of processing each row during a query.

Parameter type: floating-point number

Unit: none

Value range: 0 to *DBL_MAX*

Default value: **0.01**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: This parameter affects the evaluation of the performance overhead for processing a row of data in a query. If this parameter is incorrectly set, the optimizer's selection of the generation plan is affected, and the query performance is affected in some scenarios. Exercise caution when modifying the parameter to avoid risks caused by misoperations.

cpu_index_tuple_cost

Parameter description: Specifies the optimizer's estimated cost of processing each index entry during an index scan.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter type: floating-point number

Unit: none

Value range: 0 to *DBL_MAX*

Default value: 0.005

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: This parameter affects the performance cost evaluation of index scan in a query. If this parameter is incorrectly set, the optimizer's selection of the generation plan is affected, and the query performance is affected in some scenarios. Exercise caution when modifying the parameter to avoid risks caused by misoperations.

cpu_operator_cost

Parameter description: Specifies the optimizer's estimated cost of processing each operator or function executed during a query.

Parameter type: floating-point number

Unit: none

Value range: 0 to *DBL_MAX*

Default value: **0.0025**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: This parameter affects the performance overhead evaluation of operators or functions in a query. If this parameter is incorrectly set, the optimizer's selection of the generation plan is affected, and the query performance is affected in some scenarios. Exercise caution when modifying the parameter to avoid risks caused by misoperations.

effective_cache_size

Parameter description: Specifies the optimizer's assumption about the effective size of the disk cache that is available to a single query.

Set this parameter based on the following factors: the GaussDB's shared buffer space, the kernel's disk buffer space, and the estimated number of concurrent queries on different tables that share the available space.

This parameter does not affect the size of the shared memory allocated during actual GaussDB running. It is used only for estimation in the plan generation phase. The value is in the unit of disk page. Usually the size of each page is 8192 bytes.

Parameter type: integer.

Unit: page (8 KB)

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Value range: 1 to 2147483647

Default value:

Independent deployment:

CN: **4GB** (128-core CPU/1024 GB memory); **2GB** (60-core CPU/480 GB memory); **1GB** (32-core CPU/256 GB memory and 16-core CPU/128 GB memory); **512MB** (8-core CPU/64 GB memory); **256MB** (4-core CPU/32 GB memory); **128MB** (4-core CPU/16 GB memory)

DN: **152GB** (128-core CPU/1024 GB memory); **70GB** (60-core CPU/480 GB memory); **38GB** (32-core CPU/256 GB memory); **20GB** (16-core CPU/128 GB memory); **8GB** (8-core CPU/64 GB memory); **4GB** (4-core CPU/32 GB memory); **2GB** (4-core CPU/16 GB memory)

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**. For example, the value **200** indicates 200 pages, that is, 200 x 8 KB. The value **200MB** indicates 200 MB. The unit must be KB, MB, or GB if required.

Setting suggestion: A larger value indicates that the optimizer prefers index scan, and a smaller value indicates that the optimizer prefers full table scanning. Generally, the value is half of the value of **shared_buffers**. More radically, you can set the value to three-fourths of the value of **shared_buffers**. If the memory is sufficient, a larger value indicates better performance.

Risks and impacts of improper settings: The optimizer's selection of the generation plan will be affected, and the query performance will be affected in some scenarios. Exercise caution when modifying the parameter to avoid risks caused by misoperations.

allocate_mem_cost

Parameter description: Specifies the query optimizer's estimated cost of creating a hash table for memory space using hash join. This parameter is used for optimization when the hash join estimation is inaccurate.

Parameter type: floating-point number

Unit: none

Value range: 0 to *DBL_MAX*

Default value: **0**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value. Adjust this parameter only when the Hash Join estimation is inaccurate.

Risks and impacts of improper settings: Hash Join estimation may be inaccurate, affecting query performance in some scenarios. Exercise caution when modifying the parameter to avoid risks caused by misoperations.

6.3.8.3 Genetic Query Optimizer

This section describes parameters related to genetic query optimizer. The genetic query optimizer (GEQO) is an algorithm that plans queries by using heuristic

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

searching. This algorithm reduces planning time for complex queries and the costs of producing plans are sometimes inferior to those found by the normal exhaustive-search algorithm.

geqo

Parameter description: Specifies whether to enable the genetic query optimization.

NOTE

If this parameter is modified by running the **gs_guc reload** command and the connection of a session on the current node is not from the client but from another node in the cluster to which the node belongs, this parameter does not take effect immediately on the session after the **gs_guc reload** command is executed. The setting takes effect only after the connection node is disconnected and then reconnected.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: used.
- **off**: not used.

Default value: **on**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Generally, do not disable the parameter during the execution. **geqo_threshold** provides more subtle control of GEQO.

Risks and impacts of improper settings: If the **geqo** parameter is disabled, dynamic planning is still used to enumerate all combinations when a query statement involves a large number of tables. As a result, the optimizer generates a plan with high cost.

geqo_threshold

Parameter description: Specifies the number of **FROM** items. Genetic query optimization is used to plan queries when the number of statements executed is greater than this value.

NOTE

- For simpler queries, it is best to use the regular, exhaustive-search planner; but for queries with many tables, it is better to use GEQO to manage the queries.
- A **FULL OUTER JOIN** construct counts as only one **FROM** item.

Parameter type: integer.

Unit: none

Value range: 2 to 2147483647

Default value: **12**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value. If the performance overhead of dynamic planning is acceptable, increase the value of this parameter. If the performance overhead of dynamic planning is unacceptable, decrease the value of this parameter.

Risks and impacts of improper settings: If the value is too large, the cost of enumerating all plans in dynamic planning may be unacceptable. If the value is too small, the plan accuracy may be affected.

geqo_effort

Parameter description: Specifies the trade-off between planning time and query plan quality in GEQO.

Parameter type: integer.

Unit: none

Value range: 1 to 10

Default value: **5**

NOTE

- **geqo_effort** does not do anything directly. This parameter is only used to compute the default values for the other variables that influence GEQO behavior. You can also manually set other parameters.
- Larger values increase the time spent in query planning, but also increase the probability that an efficient query plan is chosen.

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If the value is too large, the query planning cost may be high. If the value is too small, the quality of the generated query plan may be poor.

geqo_pool_size

Parameter description: Specifies the pool size used by GEQO, that is, the number of individuals in the genetic population.

Parameter type: integer.

Unit: none

Value range: 0 to 2147483647

Default value: **0**

NOTE

If this parameter is set to **0**, GaussDB selects a proper value based on **geqo_effort** and the number of tables. In other cases, the value of the parameter is at least **2**, and the useful value typically ranges from 100 to 1000.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If the value is too large, the query planning cost may be high. If the value is too small, the quality of the generated query plan may be poor.

geqo_generations

Parameter description: Specifies the number of iterations of the GEQO.

Parameter type: integer.

Unit: none

Value range: 0 to 2147483647

Default value: **0**

NOTE

If it is set to **0**, a suitable value is chosen based on **geqo_pool_size**. In other cases, the value of this parameter is at least **1**, and useful values are typically from **100** to **1000**.

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If the value is too large, the query planning cost may be high. If the value is too small, the quality of the generated query plan may be poor.

geqo_selection_bias

Parameter description: Specifies the selection bias used by GEQO. The selection bias is the selective pressure within the population.

Parameter type: floating-point number

Unit: none

Value range: 1.5 to 2

Default value: **2**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If the parameter is set to a large value, the GEQO algorithm may focus on some excellent plans more quickly than exploring diversity in feasible plans. This may reduce the possibility that the algorithm finds the global optimal solution, but can improve the speed of finding a feasible better solution.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

geqo_seed

Parameter description: Specifies the initial value of the random number generator used by GEQO to select random paths through the join order search space.

Parameter type: floating-point number

Unit: none

Value range: 0 to 1

Default value: **0**

NOTE

Varying the value changes the set of join paths explored, and may result in a better or worse best path being found.

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Different values bring different randomness, which may affect the quality of connection path generation.

6.3.8.4 DSL Rule Engine

enable_dsl_ruleengine

Parameter description: Specifies whether to enable the DSL rule engine. If this function is enabled, the optimizer applies DSL rules to rewrite SQL statements equivalently.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: enabled.
- **off**: disabled.

Default value: **on**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this parameter is disabled, the built-in rules provided by the DSL rule engine cannot be used for query rewriting optimization. As a result, the generated query plan may not be optimal.

dsl_engine_max_iteration

Parameter description: Specifies the maximum number of iterations applied by the DSL rule engine in an SQL rewriting.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter type: integer.

Unit: none

Value range: 1 to 100

Default value: **10**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If the value is too large, the DSL rule engine cost may be high. If the value is too small, the generated query plan may not be optimal.

dsl_rulelist

Parameter description: Specifies whether to enable or disable a session-level DSL rule. The DSL rule whose status needs to be changed is specified by rule name, and the rule status is indicated by **on** or **off**.

Parameter type: string.

Unit: none

Value range:

- Rule name: The rule name is obtained from the **rulename** column in the GS_DSL_REWRITERULE system catalog.
- Status:
  - **on**: The rule is enabled.
  - **off**: The rule is disabled.

```
gaussdb=# SHOW dsl_rulelist;
 dsl_rulelist
--------------

(1 row)

gaussdb=# SET dsl_rulelist = 'compute_const:on';
SET
gaussdb=# SHOW dsl_rulelist;
    dsl_rulelist
--------------------
 compute_const:on
(1 row)
```

Default value: **''**, indicating that whether the rule is enabled is controlled by the **enabled** column in the GS_DSL_REWRITERULE system catalog.

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: If you need to manually set this parameter, determine whether the enabled or disabled rule meets the requirements.

Risks and impacts of improper settings: If a rule is set to **off**, the generated query plan may not be optimal.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

6.3.8.5 Other Optimizer Options

cost_model_version

Parameter description: Specifies the version of the optimizer cost model. It can be regarded as a protection parameter to disable the latest optimizer cost model and keep consistent with the plan of the version corresponding to the specified value. If the function is the same as that of other GUC parameters, see the description of the corresponding GUC parameter for the effective priority.

Parameter type: integer.

Unit: none

Value range: **0**, **1**, **2**, **3**, **4**, **5**, **6**, **7**, and **8**

- **0**: The latest cost estimation model is used. In the current version, it is equivalent to **8**.
- **1**: The original cost estimation model is used.
- **2**: The enhanced COALESCE expression, hash join cost, and semi/anti join cost are used for estimation on the basis of **1**.
- **3**: The boundary correction estimator is used to estimate the NDV on the basis of **2**. The hint of index scan can be applied to index-only scan.
- **4**: Partition-level statistics are used for cost estimation on the basis of **3**.
- **5**: The cost estimation of outer join calculation filter is enhanced on the basis of **4**, making the cost-based query rewriting more accurate. The calculation of filter conditions of the outer table in the outer join during selectivity calculation is optimized, which can be controlled by the **enable_poisson_outer_optimization** parameter.
- **6**: The following functions are added on the basis of **5**:
  - When a subquery is used to update multiple columns, multiple subplans can be optimized to only one. This function can also be enabled or disabled using **enable_shared_set_update**.
  - In the query rewriting phase, redundant DISTINCT and GROUP BY conditions in IN non-correlated sublinks and redundant LIMIT conditions in Exists simple sublinks can be eliminated, eliminate redundant LIMIT conditions in expression-related sublinks with agg and redundant projection columns in subqueries.
  - FQS plans can be generated when sublinks meet the distribution key join conditions of inner and outer tables.
  - FQS plans can be generated using INSERT, UPDATE, and DELETE statements in views, in addition, the involved DNs can be tailored based on the simple filter criteria of the distribution key. (For SELECT view statements, the FQS plan is supported in versions earlier than **6**, but DNs cannot be tailored. In versions later than **6**, DNs can also be tailored.)
  - In the query rewriting phase, redundant left join and right join in sublinks can be eliminated, self-joins on primary keys or NOT NULL UNIQUE keys can be eliminated, and outer joins on primary and foreign keys can be converted into inner joins.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

  - In the query rewriting phase, simple IN/ANY correlated sublinks that meet the conditions can be switched from semi join to inner join in the scenario where semi join can be performed.
  - Static statistics can be used. The number of rows and pages can be directly read from the PG_CLASS system catalog, and the base table sampling is skipped. This function can also be enabled or disabled using **opt_use_static_stats**.
  - Correlated sublinks of IN boosting in the query rewriting phase is supported. When this parameter takes effect, this function is controlled by the **pullup_in_related** option of the GUC parameter **rewrite_rule**.
  - Cost-based expansion of OR conditions into set operations such as UNION ALL or UNION is supported. When this parameter takes effect, this function is controlled separately by the **enable_or_expand** option of the GUC parameter **costbased_rewrite_rule**.
  - When the bitmap index scan plan is generated for the record array in (whether the multi-column composite type expression exists in the given array set) condition, the generated execution plan may not be globally optimal due to too many predicates. After this parameter is enabled, this scenario can be optimized and indexes that cover more columns are more likely to be retained.
- **7**: The following functions are added on the basis of **6**:
  - For equi-join predicates whose left and right operands are ordinary columns, the selectivity cache function can be used in the path generation phase to accelerate the calculation process and improve the optimizer performance. This function can also be controlled by specifying **enable_sel_cache**.
  - Predicates whose left and right operands are ordinary columns or predicates whose left and right operands are ordinary columns and constant values and are connected by operators such as =, <>, >, >=, <, and <= are supported. These predicates are only placed after WHERE and do not contain subquery lifting and join pushdown. Predicate deduction and reduction can be performed based on deduction rules to simplify predicate logic and improve query performance. This function can be controlled separately by the **PREDICATE_INFER_ENHANCE** option of **opt_behavior_knob**.
  - In M-compatible database, a parallel execution plan can be generated for count(DISTINCT *Multiple columns*) to improve query performance.
  - Redundant ORDER BY elimination is enhanced to improve query performance.
  - In ORA-compatible mode, the FQS can be pushed down to DNs for execution in recursive queries using START WITH CONNECT BY on replication tables.
  - The DSL rule engine can be used in the query rewriting phase to improve query performance. By default, the engine contains query rewriting rules in four scenarios. For details about the rules, see "Table Built-in rules" in "Feature Usage Guidelines > DSL Rule Engine > Overall Process of the DSL Rule Engine" in *Developer Guide*.
- **8**: The following functions are added on the basis of **7**:
  - In some scenarios (xmlagg does not contain the ORDER BY clause, xmlagg contains the ORDER BY clause and the GROUP BY statement

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

exists in the same-layer query, and xmlagg is located inside a correlated subquery), the aggregate function xmlagg can be pushed down to DNs for execution, improving query performance.

- DSL query rewriting rules can be added in version 507.0.0 to improve query performance. For details about the new rules, see the corresponding content of scenarios 5 to 9 under "Table Built-in rules" in "Feature Usage Guidelines > DSL Rule Engine > Overall Process of the DSL Rule Engine" in *Developer Guide*.
- Partition-wise join is supported in more scenarios to optimize query performance. For details about the new capabilities, see "Feature Usage Guidelines > Partitioned Table > Query Optimizations on Partitioned Tables > Partition-wise Join" in *Developer Guide*.

Default value: **0**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: When upgrading the database, you are advised to set this parameter the same as that of the source version. When installing a new environment, you are advised to set this parameter to the default value.

Risks and impacts of improper settings: If this parameter is modified, many SQL plans may be changed. Therefore, exercise caution when changing this parameter.

enable_fast_query_shipping

Parameter description: Specifies whether to use the distributed framework for a query planner.

Parameter type: Boolean.

Unit: none

Value range:

- **on** indicates that the distributed framework is not used. Execution plans are generated on CNs and DNs separately.
- **off** indicates that the distributed framework is used. Execution plans are generated on CNs and then sent to DNs for execution.

Default value: **on**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this parameter is disabled, the generated plan may not use the distributed cluster performance more efficiently. You are advised to enable this parameter.

enable_trigger_shipping

Parameter description: Specifies whether the trigger can be pushed to DNs for execution.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter type: Boolean.

Unit: none

Value range:

- **on** indicates that the trigger can be pushed to DNs for execution.
- **off** indicates that the trigger cannot be pushed to DNs. It must be executed on CNs.

Default value: **on**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this parameter is disabled, the performance load is concentrated on the CN, and the cluster performance cannot be maximized. You are advised to enable this parameter.

enable_remotejoin

Parameter description: Specifies whether JOIN operation plans can be pushed to DNs for execution.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: JOIN operation plans can be pushed to DNs for execution.
- **off**: JOIN operation plans cannot be pushed to DNs for execution.

Default value: **on**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If there is a large amount of data in the JOIN table, the data has been distributed on different DNs based on the JOIN condition, and the DNs have sufficient compute resources to efficiently complete the JOIN operation locally, disabling this parameter may deteriorate the query performance.

enable_remotegroup

Parameter description: Specifies whether the execution plans of GROUP BY and AGGREGATE can be pushed to DNs for execution.

Parameter type: Boolean.

Unit: none

Value range:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **on**: The execution plans of GROUP BY and AGGREGATE can be pushed to DNs for execution.
- **off**: The execution plans of GROUP BY and AGGREGATE cannot be pushed to DNs for execution.

Default value: **on**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If the query involves grouping of a large amount of data and the data is distributed on multiple data nodes, disabling this parameter may deteriorate the query performance.

enable_remotelimit

Parameter description: Specifies whether the execution plan specified in the LIMIT clause can be pushed to DNs for execution.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The execution plan specified in the LIMIT clause can be pushed down to DNs for execution.
- **off**: The execution plan specified in the LIMIT clause cannot be pushed to DNs for execution.

Default value: **on**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If the query involves quick tailoring of a large amount of data and data is distributed on multiple nodes, disabling this parameter may cause query performance deterioration.

enable_remotesort

Parameter description: Specifies whether the execution plan of the ORDER BY clause can be pushed to DNs for execution.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The execution plan of the ORDER BY clause can be pushed to DNs for execution.
- **off**: The execution plan of the ORDER BY clause cannot be pushed to DNs for execution.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Default value: **on**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If the query involves sorting of a large amount of data and the data is distributed on multiple data nodes, disabling this parameter may cause performance deterioration.

enable_rep_table_strict_shipping

Parameter description: Specifies the behavior when the pushdown necessary and sufficient conditions of a replication table fail to be determined during DML operations on the replication table.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: When DML operations are performed on replication tables, the tables cannot be pushed down if the pushdown conditions fail to be determined.
- **off**: When DML operations are performed on replication tables, the pushdown is not disabled and only prompt information is printed in logs if the pushdown conditions of replication tables fail to be determined.

Default value: **on**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

enable_csqual_pushdown

Parameter description: Specifies whether to push down filter criteria for a rough check during query.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: A rough check is performed with filter criteria pushed down during query.
- **off**: A rough check is performed without filter criteria pushed down during query.

Default value: **on**

Setting method: This is a SUSET parameter. Set it based on instructions provided in **Table 6-1**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If a query involves filtering of a large amount of data and the data is distributed on different nodes, disabling pushdown of filter criteria may cause performance deterioration.

explain_dna_file

Parameter description: Specifies the object file to be exported when **explain_perf_mode** is set to **run**.

Parameter type: string.

Unit: none

Value range: absolute path plus the file name in .csv format.

Default value: **""**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value. Set this parameter based on the service scenario if necessary.

Risks and impacts of improper settings: Improper settings may cause file write overhead.

explain_perf_mode

Parameter description: Specifies the display format of the **explain** command.

Parameter type: enumerated type

Unit: none

Value range: **normal**, **pretty**, **summary**, and **run**

- **normal** indicates that the default printing format is used.
- **pretty** indicates a new format improved by using GaussDB. The new format contains a plan node ID, directly and effectively analyzing performance.
- **summary** indicates that the analysis result on this information is printed in addition to the printed information specified by **pretty**.
- **run** indicates that the system exports the printed information specified by **summary** as a CSV file for further analysis.

Default value: **pretty**

NOTE

The pretty mode supports only plans that contain stream operators and does not support plans that deliver statements to DNs. Therefore, the display format is affected by the **enable_stream_operator** parameter. When **enable_stream_operator** is set to **off**, the plan containing the stream operator cannot be generated.

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Setting suggestion: Retain the default value. You can set another value if necessary.

Risks and impacts of improper settings: Different formats affect the amount of information provided by EXPLAIN.

analysis_options

Parameter description: Specifies whether to enable function options in the corresponding options to use the corresponding location functions, including data verification and performance statistics. For details, see the description of the value range.

Parameter type: string.

Unit: none

Value range:

Each time this parameter is set, the current value is changed through the set operation.

```
gaussdb=# show analysis_options;
                    analysis_options
------------------------------------------------------------
 ALL,on(),off(LLVM_COMPILE,HASH_CONFLICT,STREAM_DATA_CHECK)
(1 row)

gaussdb=# SET analysis_options = 'on(LLVM_COMPILE)';
SET
gaussdb=# show analysis_options;
                    analysis_options
------------------------------------------------------------
 ALL,on(LLVM_COMPILE),off(HASH_CONFLICT,STREAM_DATA_CHECK)
(1 row)

gaussdb=# SET analysis_options = 'on(HASH_CONFLICT)';
SET
gaussdb=# show analysis_options;
                    analysis_options
------------------------------------------------------------
 ALL,on(LLVM_COMPILE,HASH_CONFLICT),off(STREAM_DATA_CHECK)
(1 row)
gaussdb=# SET analysis_options = 'off(ALL)';
SET
gaussdb=# show analysis_options;
                    analysis_options
------------------------------------------------------------
 ALL,on(),off(LLVM_COMPILE,HASH_CONFLICT,STREAM_DATA_CHECK)
(1 row)
```

- **LLVM_COMPILE**: The codegen compilation time of each thread is displayed on the explain performance page.
- **HASH_CONFLICT**: The log file in the **gs_log** directory of the DN process displays the hash table statistics, including the hash table size, hash chain length, and hash conflict information.
- **STREAM_DATA_CHECK**: A CRC check is performed on data before and after network data transmission.

Default value: **off(ALL)**, which indicates that no location function is enabled.

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If manual setting is required, check whether the expected result meets the requirements.

cost_param

Parameter description: Specifies use of different estimation methods in specific customer scenarios, allowing the cost model estimation more accurate. You can change the parameter values to enable different methods. This parameter can control multiple methods at the same time. Each method is controlled by a number. If the result of the AND operation between the parameter value and the number corresponding to the method is not 0, the method is enabled.

- When **cost_param & 1** is set to a value other than 0, an improved mechanism is used for connecting the selectivity of non-equi-joins. This method is more accurate for estimating the selectivity of joins between two identical tables. At present, if **cost_param & 1** is set to a value other than 0, the path is not used. That is, a better formula is selected for calculation.
- When **cost_param & 2** is set to a value other than 0, the selectivity is estimated based on multiple filter criteria. The lowest selectivity among all filter criteria, but not the product of the selectivities for two tables under a specific filter criterion, is used as the total selectivity. This method is more accurate when a close join exists between the columns to be filtered.
- When **cost_param & 4** is not 0, the selected debugging model is not recommended when the stream node is evaluated.

Parameter type: integer.

Unit: none

Value range: 0 to 2147483647

Default value: **0**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Set this parameter after determining the scenario where the selectivity needs to be adjusted.

Risks and impacts of improper settings: The estimated cost may not meet the expectation. You are advised to confirm the parameter settings after thorough tests.

enable_partitionwise

Parameter description: Specifies whether to select an intelligent algorithm for joining partitioned tables.

Parameter type: Boolean.

Unit: none

Value range:

- **on** indicates that an intelligent algorithm is selected.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **off** indicates that an intelligent algorithm is not selected.

Default value: **off**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Before enabling this function, ensure that SMP is enabled. Otherwise, the performance of the join operation on partitioned tables in non-SMP scenarios may be affected.

partition_page_estimation

Parameter description: Specifies whether to optimize the estimation of partitioned table pages based on the pruning result.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The pruning result is used to optimize the page estimation.
- **off**: The pruning result is not used to optimize the page estimation.

Default value:

- **on**: default value for a newly installed database.
- **off**: For an upgrade from a version earlier than 506.0.0 to the current version, the default value of this parameter is **off**. If this parameter exists before the upgrade, the default value is **off** after the upgrade regardless of its setting.

  In the PDB scenario, if this parameter is not set, the global settings will apply.

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

enable_partition_pseudo_predicate

Parameter description: Specifies whether to rewrite pseudo-predicates to calculate the selectivity of query in a specified partition.

Parameter type: Boolean.

Unit: none

Value range:

- **on** indicates that pseudo-predicate rewriting is used.
- **off** indicates that pseudo-predicate rewriting is not used.

Default value: **off**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

partition_iterator_elimination

Parameter description: Specifies whether to eliminate the partition iteration operator to improve execution efficiency when the partition pruning result of a partitioned table is a partition.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The partition iteration operator is eliminated.
- **off**: The partition iteration operator is not eliminated.

Default value: **on**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this parameter is disabled, the query performance may deteriorate.

rewrite_rule

Parameter description: Specifies the optional query rewriting rules that are enabled. Some query rewriting rules are optional. Enabling them cannot always improve the query efficiency. In a specific customer scenario, you can set the query rewriting rules through this GUC parameter to achieve optimal query efficiency.

This parameter specifies the combination of query rewriting rules. For example, if there are multiple rewriting rules **rule1**, **rule2**, **rule3**, and **rule4**, you can perform settings as follows:

```
set rewrite_rule=rule1;          -- Enable query rewriting rule rule1
set rewrite_rule=rule2, rule3;     -- Enable query rewriting rules rule2 and rule3
set rewrite_rule=none;         -- Disable all optional query rewriting rules
```

Parameter type: enumerated type

Unit: none

Value range:

- **none**: No optional query rewriting rules are used.
- **lazyagg**: The Lazy Agg query rewriting rules are used to eliminate aggregation operations in subqueries.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **magicset**: The Magic Set query rewriting rules are used to join subqueries which have aggregation operators with the main query in advance to reduce repeated scanning of sublinks.
- **partialpush**: The Partial Push query rewriting rules are used. For statements that cannot be pushed down, push down some subqueries to DNs for execution and the rest to CNs for execution.
- **uniquecheck**: The Unique Check query rewriting rules are used to optimize the subquery statements in target columns without agg and check whether the number of returned rows is 1.
- **disablerep**: The Disable Replicate query rewriting rules are used. The performance may deteriorate after a replication table is optimized. Therefore, after this rule is enabled, subqueries cannot be optimized.
- **intargetlist**: The In Target List query rewriting rules are used to improve subqueries in the target column.
- **predpushnormal**: The predicate push query rewriting rule is used. (The predicate condition is pushed down to the subquery, and the BROADCAST operator may be added to support distributed execution.) After **predpush** is enabled, no vectorized plan is generated.
- **predpushforce**: The predicate push query rewriting rules are used to push down predicate conditions to subqueries and use indexes to accelerate the query. After predpush is enabled, no vectorized plan is generated.
- **predpush**: The optimal plan between **predpushnormal** and **predpushforce** is selected based on the cost. After **predpush** is enabled, no vectorized plan is generated.
- **disable_pullup_expr_sublink**: The optimizer is not allowed to pull up sublinks of the expr_sublink type. For details about sublink classification and pull-up principles, see "Typical SQL Optimization Methods > Optimizing Subqueries" in *SQL Optimization Guide*.
- **enable_sublink_pullup_enhanced**: Enhanced sublink query rewriting rules are used, including unrelated sublink pull-up of the WHERE and HAVING clauses and WinMagic rewriting optimization.
- **disable_pullup_not_in_sublink**: The optimizer is not allowed to pull up sublinks related to NOT IN. For details about sublink classification and pull-up principles, see "Typical SQL Optimization Methods > Optimizing Subqueries" in *SQL Optimization Guide*.
- **disable_rownum_pushdown**: The filter criterion ROWNUM in the parent query cannot be pushed down to the subquery.
- **disable_windowagg_pushdown**: The filter criterion of the window function in the parent query cannot be pushed down to the subquery.
- **cse_rewrite_opt**: The common expression CSE is used to replace the common expression in the Having subquery with windowAgg.
- **groupby_pushdown_subquery**: The Group By clause and aggregate function are pushed down to the subquery.
- **enable_sublink_pullup_rownum**: The optimizer can be used to pull up sublinks when the SQL statement contains the ROWNUM pseudocolumn.
- **disable_in_sublink_reduce_distinct**: Redundant DISTINCT and GROUP BY conditions cannot be eliminated in IN/ANY non-correlated sublink pullup scenarios.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **disable_sublink_reduce_limit**: Redundant LIMIT conditions (for example, LIMIT conditions that do not affect query results in simple Exists sublinks) in sublinks that meet constraints cannot be eliminated.
- **pullup_in_related**: Simple IN/ANY or NOT IN sublinks that meet the conditions can be promoted to semi join or anti join.
- **disable_reduce_unused_targetlist**: Redundant function calculation in the subquery projection column cannot be eliminated.
- **disable_sublink_outer_join_elimination**: Redundant left/right joins in sublinks that meet the conditions cannot be eliminated.
- **disable_fk_pk_outer_join_to_inner_join**: An outer join on a primary foreign key cannot be converted to an inner join.
- **disable_self_join_elimination**: The self-joins on primary keys or NOT NULL UNIQUE keys cannot be eliminated.
- **enable_corr_any_sublink_semijoin_to_innerjoin**: In the query rewriting phase, simple IN/ANY correlated sublinks that meet the conditions can be switched from semi join to inner join in the scenario where semi join can be performed.
- **disable_reduce_orderby**: Redundant ORDER BY statements that meet the conditions are not eliminated.
- **enable_not_in_sublink_reduce_distinct**: Redundant DISTINCT and GROUP BY conditions can be eliminated when non-correlated sublinks of NOT IN type are pulled up.

Default value: **magicset,groupby_pushdown_subquery,pullup_in_related**.

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value. If other rewriting is necessary, you are advised to specify the query rewriting scenario and enable only the corresponding rewriting rule.

Risks and impacts of improper settings: The cost of rewriting statements in some scenarios may not be optimal. You are advised to use the corresponding rules after thorough tests.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- When **cost_model_version** is greater than or equal to 6 or is set to **0** and **disable_in_sublink_reduce_distinct** is not set in GUC parameters, the function of eliminating redundant DISTINCT and GROUP BY for IN non-correlated sublinks takes effect.
- When **cost_model_version** is greater than or equal to 6 or is set to **0** and **disable_sublink_reduce_limit** is not set in GUC parameters, the function of eliminating redundant LIMIT for Exists sublinks takes effect.
- When **cost_model_version** is greater than or equal to 6 or is set to **0** and **disable_reduce_unused_targetlist** is not set in GUC parameters, the function of eliminating redundant projection columns in a subquery takes effect.
- When **cost_model_version** is greater than or equal to 6 or is set to **0** and **pullup_in_related** is set in GUC parameters, the IN-correlated sublink improvement function takes effect.
- When **cost_model_version** is greater than or equal to 6 or is set to **0** and **disable_sublink_outer_join_elimination** is not set in GUC parameters, the function of eliminating redundant left/right joins in the sublink takes effect.
- When **cost_model_version** is greater than or equal to 6 or is set to **0** and **disable_fk_pk_outer_join_to_inner_join** is not set in GUC parameters, the function of converting outer joins to inner joins on primary and foreign keys takes effect.
- When **cost_model_version** is greater than or equal to 6 or is set to **0** and **disable_self_join_elimination** is not set in the GUC parameter, the function of eliminating self-join on the primary key or NOT NULL UNIQUE key takes effect.
- When **cost_model_version** is greater than or equal to 6 or is set to **0** and **enable_corr_any_sublink_semijoin_to_innerjoin** is set in GUC parameters, the switching of simple IN/ANY-correlated sublinks from semi join to inner join takes effect.
- When **cost_model_version** is greater than or equal to 6 or is set to **0** and **enable_not_in_sublink_reduce_distinct** is set in GUC parameters, the function of eliminating redundant DISTINCT and GROUP BY for NOT IN non-correlated sublinks takes effect.

costbased_rewrite_rule

Parameter description: Specifies whether to enable the cost-based evaluation policy for a specified query rewriting rule. Some query rewriting rules support cost-based evaluation of whether to rewrite SQL statements. In this way, the kernel can generate better query plans and improve SQL execution efficiency.

This parameter is mutually exclusive with the GUC parameter **rewrite_rule**. If both **costbased_rewrite_rule** and **rewrite_rule** are set, the rule configuration related to **rewrite_rule** does not take effect.

This parameter can be used to set multiple cost-based query rewriting rules. The parameters are not mutually exclusive. For example, if there are multiple rewriting rules **rule1**, **rule2**, **rule3**, and **rule4**, you can perform settings as follows:

```
set costbased_rewrite_rule= rule1;          -- Enable the cost-based evaluation policy of query rewriting rule rule1.
set costbased_rewrite_rule= rule2,rule3;    -- Enable the cost-based evaluation policy for query rewriting rules rule2 and rule3.
set costbased_rewrite_rule=none;            -- Disable the cost-based evaluation policy for all optional query rewriting rules.
```

Parameter type: string.

Unit: none

Value range:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **none**: No cost-based query rewriting policy is used.
- **pullup_subquery**: The cost-based query rewriting policy is enabled for the rewriting rules of simple subquery expansion.
- **pullup_sublink_any_exists**: The cost-based query rewriting policy is enabled for the rewriting rules of non-correlated sublinks of the ANY type and related sublinks of the [NOT] EXISTS type in a single or AND condition.
- **pullup_not_in_sublink**: The cost-based query rewriting policy is enabled for the rewriting rules of non-correlated sublinks of the NOT IN type in a single or AND condition. This option is mutually exclusive with the **disable_pullup_not_in_sublink** option of the GUC parameter **rewrite_rule**. When this option is enabled, the **disable_pullup_not_in_sublink** option of **rewrite_rule** does not take effect.
- **pullup_expr_sublink**: The rewriting scenarios of expression sublinks, non-correlated sublinks of the ANY type, and related sublinks of [NOT] the EXISTS type in the OR condition take effect. This option is mutually exclusive with the **disable_pullup_expr_sublink**, **enable_sublink_pullup_enhanced**, and **magicset** options of the GUC parameter **rewrite_rule**. When this option is enabled, the corresponding options of **rewrite_rule** do not take effect.
- **intargetlist**: The cost-based query rewriting policy is enabled for the rewriting rules of the sublinks of related expression in the TargetList. This option is mutually exclusive with the **intargetlist** and **magicset** options of the GUC parameter **rewrite_rule**. When this option is enabled, the **intargetlist** and **magicset** options of **rewrite_rule** does not take effect.
- **enable_sublink_pullup_enhanced**: The cost-based query rewriting policy is enabled for the rewriting rules of expression sublinks in the enhanced scenario. This option is affected by the **pullup_expr_sublink** option. This option takes effect only when the **pullup_expr_sublink** option is enabled for the expression sublink rewriting scenario in the AND condition. It is mutually exclusive with the **enable_sublink_pullup_enhanced** option of the GUC parameter **rewrite_rule**. When this option is enabled, the **enable_sublink_pullup_enhanced** option of **rewrite_rule** does not take effect.
- **enable_or_expand**: The OR condition is expanded based on the cost and rewritten into a set operation such as UNION ALL or UNION.

Default value:

- **intargetlist,pullup_expr_sublink,pullup_not_in_sublink,enable_sublink_pullup_enhanced,enable_or_expand** for a newly installed database.
- **none** for a database upgraded from a version earlier than 505.2.0 to the current version, or the same value as that before for upgrade from 505.2.0 to a later version (for example, 505.2.1), as this parameter is available since 505.2.0.

NOTE

- For details about parameter application scenarios, see "Optimization Cases > Case: Adjusting the GUC Parameter costbased_rewrite_rule for Cost-based Query Rewriting" in *SQL Optimization Guide*.
- When **cost_model_version** is greater than or equal to 6 or is set to **0** and **enable_or_expand** is set in GUC parameters, the functions expanded based on costs by OR conditions take effect.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Simple subquery expansion (specified by the **pullup_subquery** parameter), ANY non-correlated sublinks, and [NOT] EXISTS related sublinks (specified by the **pullup_sublink_any_exists** parameter) are rewritten based on the default rules to generate an execution plan. Enabling the cost rewriting policy brings some performance overhead, therefore, you are advised not to enable the cost-based rewriting policy for such rules.

In the query rewriting phase of the optimizer, after this parameter is enabled, more candidate plans are generated compared with the rule-based rewriting model. Therefore, extra time is consumed. In this mode, each time the cost-based rewriting policy is used, the plan generation time is doubled compared with the rule-based rewriting policy, but the execution performance may be better. Therefore, if the SQL statement uses a good execution plan generated based on the rule-based rewriting policy, you are advised to disable this parameter.

Risks and impacts of improper settings: If the rewriting rules related to this parameter are disabled, rewriting is performed based on rules. If the cost evaluation is missing, the generated plans in some scenarios may be poor, affecting the query performance.

costbased_rewrite_rule_max_iterations

Parameter description: In the plan generation phase of an SQL statement, if the number of conditions that meet the cost evaluation in the same rule exceeds the value of this parameter, the cost-based evaluation policy is disabled for the conditions that exceed the threshold in the current request and converted to the rule-based rewriting policy. This parameter takes effect when the cost-based evaluation policy is enabled in the query rewriting phase.

Parameter type: integer.

Unit: none

Value range: 0 to 1000

Default value: **10**

NOTE

- This parameter is affected by the GUC parameter **costbased_rewrite_rule**. This parameter takes effect when the value of **costbased_rewrite_rule** is a value other than **none**.
- If this parameter is set to **0**, the cost-based rewriting policy is disabled for the current SQL statement.

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Adjust the value based on service requirements. If the value is too large or too small, extra performance overhead may occur, affecting the final query performance.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

costbased_rewrite_rule_timeout

Parameter description: In the plan generation phase of an executed SQL statement, if the overall cost evaluation time using each rule exceeds the timeout interval specified by this parameter, the cost-based evaluation policy is disabled for subsequent processes of the current request and the rule-based rewriting policy is used. This parameter takes effect when the cost-based evaluation policy is enabled in the query rewriting phase.

Parameter type: integer.

Unit: milliseconds

Value range: –1 to 300000

Default value: **-1**

NOTE

- This parameter is affected by the GUC parameter **costbased_rewrite_rule**. This parameter takes effect when the value of **costbased_rewrite_rule** is a value other than **none**.
- If this parameter is set to **0**, the cost-based rewriting policy is disabled for the current SQL statement.
- If this parameter is set to **-1**, the timeout interval control is disabled for the current SQL statement.

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Adjust the value based on service requirements. If the value is too large or too small, extra performance overhead may occur, affecting the final query performance.

optrbo_max_or_expr_numbers

Parameter description: Specifies the maximum number of times that OR can be used for expansion.

Parameter type: integer.

Unit: none

Value range: 2 to 100

Default value: **10**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Set this parameter based on service requirements. If the value is too large, queries with many OR conditions may be rewritten, affecting the query performance.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

enable_pbe_optimization

Parameter description: Specifies whether the optimizer optimizes the query plan for statements executed in parse bind execute (PBE) mode. The optimization principle is to use gplan for FQS.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The optimizer optimizes the query plan for statements executed in PBE mode and the gplan is used for FQS.
- **off** indicates that the optimization is not performed.

Default value: **on**

Setting method: This is a SUSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value. If you do not use gplan for FQS, set this parameter to **off**.

Risks and impacts of improper settings: If this parameter is disabled, the cplan may be used in some scenarios.

enable_light_proxy

Parameter description: Specifies whether the optimizer optimizes the execution of simple queries on CNs. This parameter does not take effect if the character set of the application side does not match that of the kernel side. You are advised to set the character set to UTF-8 when creating a database.

Parameter type: Boolean.

Unit: none

Value range:

- **on** indicates that the optimizer optimizes the execution of simple queries on CNs.
- **off** indicates that the optimization is not performed.

Default value: **on**

Setting method: This is a SUSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this parameter is disabled, the execution pressure of simple queries may be concentrated on the CN.

NOTE

This parameter does not take effect if it is set using SET in a stored procedure.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

enable_global_plancache

Parameter description: Specifies whether to share the cache for the execution plans of statements in PBE queries and stored procedures. If this parameter is set to **on**, the memory usage of the CNs and DNs in high concurrency scenarios can be reduced.

Parameter type: Boolean.

Unit: none

Value range:

- **on** indicates that cache sharing is enabled for the execution plans of statements in PBE queries and stored procedures.
- **off** indicates no sharing.

Default value: **off**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value. The value of this parameter must be the same on CNs and DNs.

Risks and impacts of improper settings: If this parameter is set to different values on CNs and DNs, the packets delivered by CNs to DNs do not match. As a result, errors are reported. After this parameter is enabled, frequent DDL operations may cause plan invalidation, affecting the CPU overhead and performance.

enable_plancache_mprotect

Parameter description: Specifies whether to enable plan write protection in the execution phase.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: Plan write protection is enabled in the execution phase.
- **off**: Plan write protection is disabled in the execution phase.

Default value: **off**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: This parameter applies to the debugging version and is mainly used for fault locating, troubleshooting, and debugging. In the production environment, use the default value to avoid affecting normal services.

Risks and impacts of improper settings:

- If this parameter is enabled, the database kernel strictly protects the generated execution plan and forbids any modifications to the plan in the execution phase.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- This parameter uses mprotect for memory protection. If this parameter is enabled, extra time is required when the memory is frequently used or modified in a large scale under heavy load.
- If the mprotect resources are insufficient due to insufficient memory or the execution plan is modified, the process will be restarted for protection.

disable_gpc_store

Parameter description: Specifies whether to prevent subsequent execution plans from being stored in the global plan cache when **enable_global_plancache** is set to **on**.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The subsequent execution plan cannot be stored in the global plan cache.
- **off**: The subsequent execution plan can be stored in the global plan cache.

Default value: **off**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If **enable_global_plancache** is set to **off**, this setting of this GUC parameter does not take effect. After this parameter is set, subsequent execution plans are not stored in the global shared cache, which may increase the memory overhead of the current session. Exercise caution when setting this parameter.

enable_stream_pbe

Parameter description: Specifies whether the optimizer uses cache to optimize the STREAM distributed plan on DNs.

NOTE

- When **enable_global_plancache** is set to **on**, stream PBE optimization is not supported.
- The optimization functionality of **enable_stream_pbe** takes effect only when the **enable_stream_operator** parameter is enabled.
- If a version that does not support stream PBE is upgraded to a version that supports stream PBE, the stream PBE optimization execution mode is not supported during the upgrade that has not been committed.

Parameter type: Boolean.

Unit: none

Value range:

- **on** indicates that the optimizer uses the cache to optimize the STREAM distributed plan on DNs.
- **off** indicates that the optimization is not performed.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Default value: **on**

Setting method: This is a SUSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this parameter is disabled, the cost of generating a plan may increase.

gpc_clean_timeout

Parameter description: Specifies the retention period of a shared plan that is not used. When **enable_global_plancache** is enabled, if a plan in the shared plan list is not used within the period specified by **gpc_clean_timeout**, the plan is cleared at a specified interval.

Parameter type: integer.

Unit: seconds

Value range: 300 to 86400

Default value: **1800**, that is, 30 minutes

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If the value is too large, the GPC may occupy too much memory. You are advised to set this parameter to a proper value after thorough tests.

enable_gpc_grayrelease_mode

Parameter description: Specifies whether to enable GPC in a distributed cluster. The cluster needs to be restarted to enable GPC. If you want to enable GPC without restarting the cluster, use **enable_gpc_grayrelease_mode**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTICE

Perform operations in a distributed cluster.

To enable GPC:

1. Enable **enable_gpc_grayrelease_mode** on all DNs.
2. Enable **enable_gpc_grayrelease_mode** on all CNs.
3. Enable the GPC parameter which is a POSTMASTER parameter. You need to reload the parameter and then kill the node in polling mode for GPC on the restarted node to take effect.

To disable GPC:

1. Ensure that **enable_gpc_grayrelease_mode** is set to **on**, reload and then disable the GPC parameter, and kill the node in polling mode for GPC on the restarted node to take effect.
2. Disable **enable_gpc_grayrelease_mode** on all CNs.
3. Disable **enable_gpc_grayrelease_mode** on all DNs.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: GPC is enabled in scrolling mode.
- **off**: GPC is disabled.

Default value: **off**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this parameter is enabled, the logic for sending and receiving PBE packets is affected. Therefore, you must set this parameter in strict accordance with the parameter description to avoid improper errors.

enable_opfusion

Parameter description: Specifies whether to optimize simple queries.

NOTE

This parameter is used to optimize the query performance of DNs. You can set **max_datanode_for_plan** to view the execution plan of a query DN. If the execution plan of the DN contains **[Bypass]**, the query can be optimized on the DN.

The limitations on simple queries are as follows:

- Only index scan and index-only scan are supported, and the filter criteria of all WHERE statements are on indexes.
- Only single tables can be added, deleted, modified, and queried. JOIN and USING operations are not supported.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- Only row-store tables are supported. Partitioned tables and tables with triggers are not supported.
- Information statistics features of active SQL statements and queries per second (QPS) are not supported.
- Tables that are being scaled out or in are not supported.
- System columns cannot be queried or modified.
- Only simple SELECT statements are supported. For example:
  ```
  SELECT c3 FROM t1 WHERE c1 = ? and c2 =10;
  ```
  Only columns in the target table can be queried. Columns **c1** and **c2** are index columns, which can be followed by constants or parameters. You can use **for update**.
- Only simple INSERT statements are supported. For example:
  ```
  INSERT INTO t1 VALUES (?,10,?);
  ```
  Only one VALUES is supported. The type in VALUES can be a constant or a parameter. RETURNING is not supported.
- Only simple DELETE statements are supported. For example:
  ```
  DELETE FROM t1 WHERE c1 = ? and c2 = 10;
  ```
  Columns **c1** and **c2** are index columns, which can be followed by constants or parameters.
- Only simple UPDATE statements are supported. For example:
  ```
  UPDATE t1 SET c3 = c3+? WHERE c1 = ? and c2 = 10;
  ```
  The values modified in column **c3** can be constants, parameters, or a simple expression. Columns **c1** and **c2** are index columns, which can be followed by constants or parameters.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: used.
- **off**: not used.

Default value: **on**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: After this parameter is disabled, the SQL bypass feature will not be used. SQL bypass uses simplified execution paths for simple CRUD statements to reduce the execution overhead caused by condition filtering, projection column calculation, and operator initialization and execution. After this parameter is disabled, the simple CRUD statements specified in the parameter description will use the common execution process, which affects the performance in the corresponding scenarios.

sql_beta_feature

Parameter description: Specifies the SQL engine's optional beta features to be enabled, including optimization of row count estimation and query equivalence

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

estimation. These optional features provide optimization for specific scenarios, but performance deterioration may occur in some scenarios for which testing is not performed. In a specific customer scenario, you can set the query rewriting rules through this GUC parameter to achieve optimal query efficiency.

This parameter determines the combination of the SQL engine's beta features, for example, feature1, feature2, feature3, and feature4, as follows:

```
set sql_beta_feature=feature1;          -- Enable the beta feature 1 of the SQL engine.
set sql_beta_feature=feature2,feature3;    -- Enable the beta features 2 and 3 of the SQL engine.
set sql_beta_feature=none;          -- Disable all optional SQL engine beta features.
```

Parameter type: string.

Unit: none

Value range:

- **none**: uses none of the beta optimizer features.
- **sel_semi_poisson**: uses Poisson distribution to calibrate the equivalent semi-join and anti-join selectivity.
- **sel_expr_instr**: uses the matching row count estimation method to provide more accurate estimation for **instr(col, 'const') > 0, = 0, = 1**.
- **param_path_gen**: generates more possible parameterized paths.
- **rand_cost_opt**: optimizes the random read cost of tables that have a small amount of data.
- **param_path_opt**: uses the bloating ratio of the table to optimize the analysis information of indexes.
- **page_est_opt**: optimizes the **relpages** estimation for the analysis information of table indexes.
- **no_unique_index_first**: disables optimization of the primary key index scan path first.
- **join_sel_with_cast_func**: supports type conversion functions when the number of join rows is estimated.
- **canonical_pathkey**: The regular path key is generated in advance (**pathkey**: a set of ordered key values of data).

  NOTE

  After this option is enabled, the semantics of the output data of statements such as ORDER BY may be different from that of the standard ones in the case of outer join. Contact Huawei technical support to determine whether to enable this parameter.
- **index_cost_with_leaf_pages_only**: specifies whether index leaf nodes are included when the index cost is estimated.
- **partition_opfusion**: supports lightweight cache of some data structures of partitioned tables during database running and lightweight processing. It does not take effect in the current version.
- **a_style_coerce**: enables the Decode type conversion rule to be compatible with the Oracle Database. For details, see "Type Resolution for CASE in ORA-compatible Mode" in **UNION, CASE, and Related Constructs**.
- **plpgsql_stream_fetchall**: enables the function of obtaining all tuple results when the SQL statements which use streams are executed on the for loop or cursor in a stored procedure.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **partition_fdw_on**: supports the creation of SQL statements related to GaussDB foreign tables based on partitioned tables.
- **predpush_same_level**: enables the **predpush** hint to control parameterized paths at the same layer.
- **disable_bitmap_cost_with_lossy_pages**: disables the computation of the cost of lossy pages in the bitmap path cost.
- **enable_upsert_execute_gplan**: allows execution through **gplan** in the PBE scenario, if the UPDATE clause in the ON DUPLICATE KEY UPDATE statement contains parameters.
- **disable_text_expr_flatten**: disables the function of automatically inlining expressions during comparison between text and numeric types (numeric, bigint).

Default value:
"sel_semi_poisson,sel_expr_instr,rand_cost_opt,param_path_opt,page_est_opt"

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value. This parameter specifies multiple query optimization and compatibility behaviors. The settings of some options are risky. Therefore, you are advised to use this parameter with caution. If you want to adjust the value, make sure you understand the parameter meaning and adjust the value with caution to avoid risks caused by misoperations.

Risks and impacts of improper settings: Sufficient tests are required. Otherwise, unexpected risks may occur.

enable_global_stats

Parameter description: Specifies the current statistics mode.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The global statistics collection mode is used.
- **off**: The statistics of the first node in the cluster are collected. In this case, the quality of the generated query plan may be affected. However, the information collection performance is optimal. Therefore, exercise caution when disabling this parameter.

Default value: **on**

Setting method: This is a SUSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this parameter is disabled, the query plan generation quality in the cluster environment may be affected.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

default_statistics_target

Parameter description: Specifies the default statistics target for table columns without a column-specific target set by running **ALTER TABLE SET STATISTICS**. This parameter affects only the target number of sampled rows in the statistics. The actual number of sampled rows is also affected by the memory parameter **maintenance_work_mem**.

Parameter type: integer.

Unit: none

Value range: –100 to 10000

- If this parameter is set to a positive value, it indicates the expected number of buckets in the statistics histogram. The number of sampled rows is **default_statistics_target** multiplied by 300.
- If this parameter is set to a negative value, it indicates the statistical target in percentage. The negative value is converted to the corresponding percentage. For example, **-5** indicates 5%. The number of sampled rows is the total number of rows multiplied by 5%.

Default value: **100**

NOTE

- A larger positive number than the default value increases the time required to do **ANALYZE**, but might improve the quality of the optimizer's estimates.
- Changing settings of this parameter may result in performance deterioration. If query performance deteriorates, you can:
  1. Restore to the default statistics.
  2. Use hints to force the optimizer to use the optimal query plan. For details, see "Hint-based Optimization" in *SQL Optimization Guide*.
- If this GUC parameter is set to a negative value, the number of samples is greater than or equal to 2% of the total data volume, and the number of records in user tables is less than 1.6 million, the time taken by running **ANALYZE** will be longer than that when this parameter uses its default value.
- If this GUC parameter is set to a negative value, AUTOANALYZE does not take effect.

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value. Before changing settings of this parameter, perform a comprehensive evaluation based on the specific workload and query mode. For tables whose data features are not evenly distributed or whose data volume is large, you may need to manually adjust the value of this parameter.

Risks and impacts of improper settings:

- If the value of **default_statistics_target** is too large, the time and resource consumption of the ANALYZE operation may increase because more sample data needs to be collected to generate statistics. This can result in increased overhead for database maintenance, especially on large tables.
- If the value of **default_statistics_target** is too small, the accuracy of statistics may be reduced. As a result, the query optimizer's capability of generating efficient query plans is affected, and the query performance deteriorates.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

default_gsi_statistics_target

Parameter description: Specifies the default statistics target for global secondary indexes.

Parameter type: integer.

Unit: none

Value range: –100 to 3000000

- If this parameter is set to a positive number, it indicates the number of samples of statistics.
- If this parameter is set to a negative value, it indicates the statistical target in percentage. The negative value is converted to the corresponding percentage. For example, **-5** indicates 5%.

Default value: **0**

NOTE

- The default value **0** indicates that the default sampling rate is used for sampling.
- Changing settings of this parameter may result in performance deterioration. If query performance deteriorates, you can:
  1. Restore to the default statistics.
  2. Use hints to force the optimizer to use the optimal query plan. For details, see "Hint-based Optimization" in *SQL Optimization Guide*.

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value. Before changing settings of this parameter, perform a comprehensive evaluation based on the specific workload and query mode. For tables whose data features are not evenly distributed or whose data volume is large, you may need to manually adjust the value of this parameter.

Risks and impacts of improper settings:

- If the value of **default_gsi_statistics_target** is too large, the time and resource consumption of the ANALYZE operation may increase because more sample data needs to be collected to generate statistics. This may increase the overhead of database maintenance.
- If the value of **default_gsi_statistics_target** is too small, the accuracy of statistics may be reduced. As a result, the query optimizer's capability of generating efficient query plans is affected, and the query performance deteriorates.

opt_mcv_buckets_global

Parameter description: Specifies the maximum number of buckets for storing the most common values (MCVs) for columns that are not specified in **ALTER TABLE <table> ALTER COLUMN <attr> SET (OPT_MCV_BUCKETS = <val>)**. This parameter only specifies the upper limit of the number of stored MCVs. The actual number of MCVs is determined by the actual sampling data distribution. This parameter can be set at the PDB level.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter type: integer.

Unit: none

Value range: 0 to 10000. If this parameter is set to **0**, the number of MCVs is automatically calculated based on the number of sampled rows.

Default value:

- For a newly installed database: **100**.
- For a database upgraded from an earlier version that does not support this GUC parameter, the default value is **0** after the upgrade. If the earlier version supports this GUC parameter, the default value is retained after the upgrade.
- In the PDB scenario, if this parameter is not set, the global setting is inherited.

NOTE

- The parameter modification takes effect only for subsequent ANALYZE operations. The old statistics of existing tables are not automatically updated. You need to manually run the **ANALYZE** *Table name*; command to collect statistics again or wait for the statistics collection to be automatically triggered.
- If a single column in a table requires a higher upper limit of buckets, you can use the column-level customized statistics parameter to increase the upper limit. The syntax is as follows:

```
ALTER TABLE <table> ALTER COLUMN <attr> SET (OPT_MCV_BUCKETS = <val>)
```

  After the setting, the column is not restricted by the global parameter **opt_mcv_buckets_global**.
- This parameter is invalid during the upgrade observation period.

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value. Before changing settings of this parameter, perform a comprehensive evaluation based on the specific workload and query mode. For a table with a large number of MCVs in the data distribution, you may need to manually adjust the value of this parameter.

Risks and impacts of improper settings:

- If the value of **opt_mcv_buckets_global** is too large, more MCVs will be collected, which may increase the time and resources consumed by the ANALYZE operation. As a result, the database maintenance overhead increases, especially for large tables.
- If the value of **opt_mcv_buckets_global** is too small, the accuracy of cost estimation may be reduced. As a result, the query optimizer's capability of generating efficient query plans is affected, and the query performance deteriorates.

auto_statistic_ext_columns

Parameter description: Collects statistics about multiple columns based on the first **auto_statistic_ext_columns** columns of the composite index in the data table. For example, if a composite index is (a,b,c,d,e) and the GUC parameter is set to **3**, statistics about multiple columns are generated on columns (a,b) and (a,b,c). Multi-column statistics can enable the optimizer to estimate the cardinality more accurately when combined conditions are used for query.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- The system catalog does not take effect.
- The statistics take effect only when the types of all columns support the comparison functions '=' and '<'.
- System pseudocolumns in indexes, such as **tableoid** and **ctid**, are not collected.
- By default, distinct values, MCVs without NULL, and MCVs with NULL are collected. Intelligent statistics are not collected for automatically created multi-column statistics. Only MCVs and MCVs with NULL are collected.
- If the index for creating multi-column statistics is deleted and no other index contains the multi-column combination, the multi-column statistics will be deleted in the next ANALYZE operation.
- If the value of this parameter decreases, the new index generates multi-column statistics based on the value of this parameter. The generated multi-column statistics that exceed the value of this parameter will not be deleted.
- If you want to disable the multi-column statistics on a specific combination only, you can retain the value of this parameter and run the DDL command **ALTER TABLE** *tablename* **disable statistics** *((column list))* to disable the statistics on multiple columns in a specific combination.
- Multi-column statistics with weak correlation will be skipped when multi-column statistics are automatically created. If the product of the number of distinct values (NDV) of a single column is close to 80% of the NDV of multiple columns, the multi-column correlation is weak. If the NDV of manually or automatically created multi-column statistics is **-1**, the correlation does not need to be determined.
- If the percentage sampling mode is used in distributed deployment, multi-column statistics will not be automatically created on CNs.
- After the function of automatically creating multi-column statistics is enabled, the overhead of the statistics calculation phase increases. When there are a large number of composite indexes, the ANALYZE performance slightly decreases.

Parameter type: integer.

Unit: none

Value range: 1 to 4. **1** indicates that statistics about multiple columns are not automatically collected.

Default value:

- For a newly installed database: **4**.
- For a database upgraded from a version earlier than 506.1.0: **1**.
- For a database upgraded from 506.1.0 or later: original parameter value.

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value. When adjusting the value of this parameter, consider the following factors:

- Table size and data characteristics, such as multi-column correlation.
- Query mode, especially the columns and indexes involved in the query.
- Available system resources, such as CPU, memory, and storage space.

Risks and impacts of improper settings:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- If the value is too large, ANALYZE operations may be performed frequently, which increases the database maintenance overhead, especially for large tables.
- If the value is too small, the correlation between columns in the table may not be fully captured. As a result, the query optimizer cannot generate the optimal query plan.

constraint_exclusion

Parameter description: Specifies the query optimizer's use of table constraints to optimize queries.

Parameter type: enumerated type

Unit: none

Value range:

- **on** indicates that constraints for all tables are examined.
- **off** indicates that constraints for any table are not examined.
- **partition** indicates that only constraints for inheritance child tables and **UNION ALL** subqueries are examined.

Default value: **partition**

NOTE

- When **constraint_exclusion** is set to **on**, the optimizer compares query conditions with the table's **CHECK** constraints, and omits scanning tables for which the conditions contradict the constraints.
- Currently, **constraint_exclusion** is enabled by default only for cases that are often used to implement table partitioning. If this parameter is enabled for all tables, extra planning is imposed on simple queries, which has no benefits. If you have no partitioned tables, disable the parameter.

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value. If table constraints are frequently used in service queries and these constraints help optimize the query, it may be beneficial to keep enabling this parameter. Otherwise, if these constraints are not helpful for query optimization, disabling this parameter may improve performance.

Risks and impacts of improper settings: The query performance may be affected.

cursor_tuple_fraction

Parameter description: Specifies the optimizer's estimated fraction of a cursor's rows that are retrieved.

Parameter type: floating-point.

Unit: none

Value range: 0 to 1

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Default value: **0.1**

NOTE

Smaller values of this setting bias the optimizer towards using **fast start** plans for cursors, which will retrieve the first few rows quickly while perhaps taking a long time to fetch all rows. Larger values put more emphasis on the total estimated time. At the maximum setting of **1.0**, cursors are planned exactly like regular queries, considering only the total estimated time and how soon the first rows might be delivered.

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value. If most rows in the table are frequently accessed, you can increase the value of this parameter.

Risks and impacts of improper settings: The performance may deteriorate.

from_collapse_limit

Parameter description: Specifies whether the optimizer merges subqueries into upper queries based on the resulting FROM list. The optimizer merges subqueries into upper queries if the resulting FROM list would have no more than this many items.

Parameter type: integer.

Unit: none

Value range: 1 to 2147483647

Default value: **8**

NOTE

Smaller values reduce planning time but may lead to inferior execution plans.

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value. If multiple subqueries need to be processed frequently in a query and these subqueries can be effectively combined to improve query performance, you can increase the value of this parameter. Otherwise, if merging subqueries deteriorates performance or increases the time for the optimizer to generate an execution plan, you can reduce the value.

Risks and impacts of improper settings: The performance may deteriorate.

join_collapse_limit

Parameter description: Specifies whether the optimizer rewrites JOIN constructs (except FULL JOIN) into the FROM list based on the number of the items in the result list.

Parameter type: integer.

Unit: none

Value range: 1 to 2147483647

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Default value: **8**

NOTE

- Setting this parameter to **1** prevents join reordering. As a result, the join order specified in the query will be the actual order in which the relations are joined. The query optimizer does not always choose the optimal join order. Therefore, advanced users can temporarily set this parameter to **1**, and then specify the join order they desire explicitly.
- Smaller values reduce planning time but lead to inferior execution plans.

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value. Decreasing the value reduces the planning time but may reduce the plan generation quality. Increasing the value increases the planning time but may generate a better plan.

Risks and impacts of improper settings: The trade-off between the planning time and the plan generation quality. Improper settings may cause the effect of one party to be unacceptable.

plan_mode_seed

Parameter description: This is a debugging parameter. Currently, it supports only **OPTIMIZE_PLAN** and **RANDOM_PLAN**.

Parameter type: integer.

Unit: none

Value range: –1 to 2147483647

- **0**: **OPTIMIZE_PLAN** mode. In this mode, the dynamic planning algorithm is used to estimate the cost and generate the optimal plan.
- **-1**: **RANDOM_PLAN** mode. In this mode, a plan is randomly generated, and the seed value for generating a random number is not specified. The optimizer randomly generates an integer value within the range of 1 to 2147483647 and generates a random execution plan based on the random number.
- Integer within the range of 1 to 2147483647: **RANDOM_PLAN** mode. In this mode, a plan is randomly generated, and the seed value of the seed identifier for generating a random number is specified by the user. The optimizer generates a random execution plan based on the seed value.

Default value: **0**

NOTE

If this parameter is not set to 0, the specified plan hint does not take effect.

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: When this parameter is set to the **RANDOM_PLAN** mode, the optimizer randomly generates an execution plan. The execution plan may not be the optimal one, which affects the query performance. Therefore, you are advised to set this parameter to **0** during normal service operations or O&M, such as upgrade, scale-out, and scale-in.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Risks and impacts of improper settings: The performance may deteriorate.

enable_random_datanode

Parameter description: Specifies whether the query of the replication table is conducted on a random DN. A complete replication table is stored on each DN for random retrieval to release the pressure on nodes.

Parameter type: Boolean.

Unit: none

Value range:

- **on** indicates that the function of querying the replication table on a random DN is enabled.
- **off** indicates that the function of querying the replication table on a random DN is disabled.

Default value: **on**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this parameter is disabled, the node pressure may increase sharply.

hashagg_table_size

Parameter description: Specifies the hash table size during the execution of the HASH JOIN operation.

Parameter type: integer.

Unit: none

Value range: 0 to 1073741823. **0** indicates that the database automatically adjusts the size of the hash table as required.

Default value: **0**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value. In actual applications, if you encounter specific query scenarios, for example, aggregation operations that process a large amount of data, you may need to manually adjust this parameter to optimize performance.

Risks and impacts of improper settings: Increasing the size of the hash table can reduce the disk I/O in the Hash Agg operation because more data can be retained in the memory. However, if the size of the hash table is too large, too much memory may be occupied, resulting in insufficient memory. If this parameter is set to a small value, the memory may not be effectively used, resulting in more disk I/O operations and decreasing the query speed.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

enable_codegen

Parameter description: Specifies whether code optimization can be enabled. Currently, the code optimization uses the LLVM optimization.

Parameter type: Boolean.

Unit: none

Value range:

- **on** indicates that code optimization is enabled.
- **off** indicates that code optimization is disabled.

Default value: **off**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this parameter is enabled, resource usage may increase in expression query scenarios.

codegen_compile_thread_num

Parameter description: Specifies the number of Codegen compilation threads.

Parameter type: integer.

Unit: none

Value range: 1 to 8

Default value: **1**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value. Change the value when the number of concurrent services is large and the service performance bottleneck occurs during expression execution.

Risks and impacts of improper settings: If the number of threads is too large, the system performance may deteriorate. However, when there are a large number of concurrent services, you can increase the number of threads to improve the throughput performance.

llvm_max_memory

Parameter description: Specifies the maximum memory occupied by IRs (including cached and in-use IRs) generated during Codegen compilation. The memory used by Codegen is not applied for by preoccupation. It is a part of **max_dynamic_memory** and is restricted by the **llvm_max_memory** parameter.

Parameter type: integer.

Unit: KB

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Value range: 0 to 2147483647. If the value exceeds the specified value, the original recursive execution logic, instead of the Codegen execution logic, is used. When the upper limit is reached and a downgrade is triggered, decreasing the value of **llvm_max_memory** cannot immediately release the memory occupied by extra IRs. The memory occupied by IRs is released after the corresponding SQL statements are executed.

Default value: **131072**, that is, 128 MB.

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**. For example, if this parameter is set to **100** without a unit, it indicates 100 KB. If this parameter is set to **16MB**, it indicates 16 MB. The unit must be KB, MB, or GB if required.

Setting suggestion: Retain the default value. Change the value when the value of **llvm_used_memory** in the pv_total_memory_detail view reaches the upper limit of the default value and the service performance bottleneck lies in the expression execution process.

Risks and impacts of improper settings:

- If the parameter is set to an excessively small value, the system does not use the Codegen execution logic, affecting the use of functions.
- If the parameter is set to an excessively large value, LLVM compilation may occupy too many resources of other threads. As a result, the overall system performance deteriorates.

enable_codegen_print

Parameter description: Specifies whether the LLVM IR function can be printed in logs.

Parameter type: Boolean.

Unit: none

Value range:

- **on** indicates that the IR function can be printed in logs.
- **off** indicates that the IR function cannot be printed in logs.

Default value: **off**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value. Enable this function when locating faults.

Risks and impacts of improper settings: If this parameter is enabled, a large number of logs are generated, occupying disk I/O resources. As a result, the read and write performance of the database system foreground query deteriorates.

codegen_cost_threshold

Parameter description: The LLVM compilation takes some time to generate executable machine code. Therefore, LLVM compilation is beneficial only when the

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

actual execution cost is more than the sum of the cost required for generating machine code and the optimized execution cost. Parameter **codegen_cost_threshold** specifies a threshold. If the estimated execution cost exceeds the threshold, LLVM optimization is performed. codegen uses **plan_rows** of the execution operator as the cost to compare with the value of **codegen_cost_threshold**. You can run the **explain** command to view the value of **plan_rows**.

Parameter type: integer.

Unit: none

Value range: 0 to 2147483647

Default value: **100000**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value. You can change the value only when you need to change the threshold for triggering the codegen mechanism.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

enable_bloom_filter

Parameter description: Specifies whether the Bloom filter optimization can be used.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The Bloom filter optimization can be used.
- **off**: The Bloom filter optimization cannot be used.

Default value: **on**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

bloom_filter_build_max_rows

Parameter description: Specifies the maximum data threshold on the build side of the hash join for creating a Bloom filter when Bloom filter optimization is enabled. If the data volume on the build side is greater than the value of this parameter, no Bloom filter is created.

Parameter type: integer.

Unit: none

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Value range: 1 to 2147483647

Default value: **2000000**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**. This parameter takes effect only when the **enable_bloom_filter** parameter is enabled.

Setting suggestion: If the storage and compute resources are sufficient, you can increase the value of this parameter to achieve better performance.

Risks and impacts of improper settings: When the storage and compute resources are insufficient, **query_dop** is high (greater than 16), and the value is too large (greater than 2000000), the system performance may deteriorate.

bloom_filter_apply_threshold

Parameter description: Specifies the minimum data threshold on the apply side of the hash join for creating a Bloom filter when Bloom filter optimization is enabled. If the data volume on the apply side is less than the value of this parameter, no Bloom filter is created.

Parameter type: integer.

Unit: none

Value range: 1 to 2147483647

Default value: **10000**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**. This parameter takes effect only when the **enable_bloom_filter** parameter is enabled.

Setting suggestion: Set this parameter to an integer ranging from 1000 to 20000.

Risks and impacts of improper settings:If this parameter is set to a large value (greater than 20000), scenarios where performance can be optimized after Bloom filter is added will be lost. If this parameter is set to a small value (smaller than 1000), Bloom filter is added for queries with a small amount of data. As a result, the performance deteriorates.

NOTE

- After the **enable_bloom_filter** and **bloom_filter_build_max_rows** parameters are enabled or set, the bloom filter can be generated only when the bloom filter implementation or principle restrictions are met.
- Limitations on the bloom filter implementation and principles:
  - The build side must be inside the hash join.
  - The apply side must be IMCVScan.
  - Left join, full join, and left anti join are not supported.
  - Bloom filter crosses operators that cannot be pushed down during apply/build, such as Func Agg and Limit.
  - Bloom filter calls the semi join API for estimation. Bloom filter can be created only when the outer table selectivity is less than 2/3. The outer table selectivity is calculated based on statistics. For details, see "Feature Usage Guidelines > CBO > Technical Principle > Statistics" in *Developer Guide*.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

You can confirm the build and apply nodes by observing the plan. For the hash join node in the plan, the lower subnode is on the build side, and the upper subnode is on the apply side. The following plan is used as an example, in which **Imcv Scan on public.row_hashjoin_table_01 a** is on the build side and **Imcv Scan on public.row_hashjoin_table_02 b** is on the apply side:

```
                                QUERY PLAN
-------------------------------------------------------------------------------------------------
 Row Adapter  (cost=3033.82..3033.82 rows=59804 width=48)
   Output: a.c_int, a.c_bigint, a.c_smallint, b.c_int, b.c_bigint, b.c_smallint
   ->  Vector Sonic Hash Join  (cost=374.00..3033.82 rows=59804 distinct=[200, 600] width=48)
         Output: a.c_int, a.c_bigint, a.c_smallint, b.c_int, b.c_bigint, b.c_smallint
         Hash Cond: (b.c_int = a.c_int)
         Generate Bloom Filter On Expr: a.c_int
         Generate Bloom Filter On Index: 0
         ->  Imcv Scan on public.row_hashjoin_table_02 b  (cost=0.00..924.00 rows=75852 width=24)
               Output: b.c_int, b.c_bigint, b.c_smallint
               Filter: (b.c_int > 2400)
               Filter By Bloom Filter On Expr: b.c_int
               Filter By Bloom Filter On Index: 0
         ->  Imcv Scan on public.row_hashjoin_table_01 a  (cost=0.00..299.00 rows=6000 width=24)
               Output: a.c_int, a.c_bigint, a.c_smallint
               Filter: (a.c_int > 2400)
```

enable_extrapolation_stats

Parameter description: Specifies whether the extrapolation logic is used for data of date type based on historical statistics. If this logic is used, the estimation accuracy can be improved for tables whose statistics are not collected in a timely manner. However, the estimation may be too large due to inference errors. This parameter must be enabled when date-type data is periodically inserted.

Parameter type: Boolean.

Unit: none

Value range:

- **on** indicates that the extrapolation logic is used.
- **off** indicates that the extrapolation logic is not used.

Default value:

- For a newly installed database, the default value is **on**.
- If the GUC parameter does not exist in the source version, the default value is **on**. If the GUC parameter exists in the source version, the original setting is retained.

Setting method: This is a SUSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value. Before enabling **enable_extrapolation_stats**, you should evaluate the frequency of data changes and the query mode. Enabling this parameter may be helpful if the data changes quickly and process incomplete statistics are required frequently for the query optimizer. Before official launch, adequate testing should be conducted in the test environment to determine the specific impact of enabling extrapolation statistics on performance. After extrapolation statistics are enabled, closely monitor the query performance and the accuracy of database statistics to ensure that no performance problem is introduced or the accuracy of statistics is greatly reduced.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Risks and impacts of improper settings: If this parameter is enabled, the query performance may deteriorate due to inference errors.

query_dop

Parameter description: Specifies the user-defined degree of parallelism (DOP).

Parameter type: integer.

Unit: none

Value range: –64 to 64

- A value ranging from 1 to 64 indicates that the fixed SMP is enabled and the system will use the specified DOP.
- **0** indicates that the SMP adaptation is enabled, and the system will dynamically select the optimal DOP based on resource usage and plan characteristics.
- A value ranging from –64 to –1 indicates that the SMP adaptation is enabled, and the system limits the DOP that can be adaptively selected.

NOTE

- After enabling parallel queries, ensure you have sufficient CPU, memory, network, and I/O resources to achieve the optimal performance.
- To prevent performance deterioration caused by an overly large value of **query_dop**, the system calculates the maximum number of available CPU cores for a DN and uses the number as the upper limit for this parameter. If the value of **query_dop** is greater than 4 and also the upper limit, the system resets **query_dop** to the upper limit.

Default value: **1**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value. When resources such as the CPU, memory, I/O, and network bandwidth are sufficient, a higher degree of parallelism indicates the better performance improvement.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

enable_analyze_check

Parameter description: Specifies whether it is allowed to check whether statistics were collected about tables whose **reltuples** and **relpages** are displayed as **0** in pg_class during plan generation.

Parameter type: Boolean

Unit: none

Value range:

- **on** indicates that the tables will be checked.
- **off** indicates that the tables will not be checked.

Default value: **off**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Setting method: This is a SUSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value. Enabling the check may cause plan generation overhead, but ensures that statistics have been collected. If most tables whose **reltuples** and **relpages** are **0** in pg_class do not need to collect additional statistics, you can disable the check.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

enable_sonic_hashagg

Parameter description: Specifies whether to use the Hash Agg operator designed for column-oriented hash tables when certain constraints are met.

Parameter type: Boolean.

Unit: none

Value range:

- **on** indicates that the Hash Agg operator designed for column-oriented hash tables is used when certain constraints are met.
- **off** indicates that the Hash Agg operator designed for column-oriented hash tables is not used.

NOTE

- If **enable_sonic_hashagg** is enabled and the Hash Agg operator designed based on the column-oriented hash table is used when the query meets the constraint condition, the memory usage of the Hash Agg operator can be reduced. However, in scenarios where **enable_codegen** is enabled and the performance is significantly improved, the performance of the operator may deteriorate.
- When **enable_sonic_hashagg** is enabled and the hash agg operator designed based on the column-oriented hash table is used when the query meets the limitation, the operator is displayed as **Sonic Hash Aggregation** in the execution plan and execution information of Explain Analyze/Performance; when the query does not meet the limitation, the operator is displayed as **Hash Aggregation**. For details, see "Introduction to the SQL Execution Plan > Execution Plan Details" in *SQL Optimization Guide*.

Default value: **on**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this parameter is disabled, the query performance may deteriorate in this scenario.

enable_sonic_hashjoin

Parameter description: Specifies whether to use the hash join operator designed for column-oriented hash tables when certain constraints are met.

Parameter type: Boolean.

Unit: none

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Value range:

- **on** indicates that the hash join operator designed for column-oriented hash tables is used when certain constraints are met.
- **off** indicates that the hash join operator designed for column-oriented hash tables is not used.

NOTE

- Currently, the parameter can be used only for Inner Join.
- When **enable_sonic_hashjoin** is enabled, the memory usage of query using the Hash Inner operator can be reduced. However, in scenarios where the code generation technology can significantly improve performance, the performance of the operator may deteriorate.
- When **enable_sonic_hashjoin** is enabled and the hash join operator designed based on the column-oriented hash table is used when the query meets the limitation, the operator is displayed as **Sonic Hash Join** in the execution plan and execution information of Explain Analyze/Performance; when the query does not meet the limitation, the operator is displayed as **Hash Join**. For details, see "Introduction to the SQL Execution Plan > Execution Plan Details" in *SQL Optimization Guide*.

Default value: **on**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this parameter is disabled, the query performance may deteriorate in this scenario.

vector_engine_features

Parameter description: Specifies whether to enable the optional features of the vectorized engine. Enabling these features may not improve the execution performance. In specific service scenarios, you can use this GUC parameter to set vectorized engine features to achieve optimal execution performance.

This parameter is used to set the combination of vectorized engine feature switches. For example, if there are multiple features **rule1**, **rule2**, **rule3**, and **rule4**, you can perform settings as follows:

```
set vector_engine_features='rule1';          -- Enable the vectorized engine feature rule1.
set vector_engine_features='rule2,rule3';    -- Enable the vectorized engine features rule2 and rule3.
set vector_engine_features=none;             -- Disable all optional vectorized engine features.
```

Parameter type: enumerated type

Unit: none

Value range:

- **none**: does not use any optional vectorized engine feature.
- **enable_ca_hashjoin**: uses the Ca Hash Join operator designed for Cache-Aware HashTable.
- **enable_ca_hashagg**: uses the Ca Hash Agg operator designed for Cache-Aware HashTable.

Default value: **enable_ca_hashjoin, enable_ca_hashagg**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-2**.

Setting suggestion: Retain the default value. If necessary, you are advised to enable only the corresponding feature after determining the execution scenario.

Risks and impacts of improper settings: If a feature is disabled, the execution performance may deteriorate in some scenarios. You are advised to enable the feature after thorough tests.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- When **enable_ca_hashjoin** is set in the GUC parameter, this switch depends on the basic switch **enable_hashjoin**. When **enable_hashjoin** is disabled, no hash join exists in the plan, and **enable_ca_hashjoin** is invalid.
  - This switch applies only to the following scenarios:
    - Join keys
      - Join key of the same type. For example, **int** = **varchar** is not supported.
      - Non-expression join key. For example, **a** – 1 = **b** is not supported.
      - For details about the data types supported by join keys, see **Table 6-22**.
    - Join types
      - Inner Join: supported.
      - Right Join: partially supported. It is not supported in the case of join conditions and is supported in other cases.
      - Semi Join: partially supported. It is supported in non-projection scenarios and only when outer table data is output. It is not supported in projection scenarios or when inner table data is output.
      - Anti Join: partially supported. It is supported in non-projection scenarios and only when outer table data is output. It is not supported in projection scenarios or when inner table data is output.
      - Right Semi Join: partially supported. It is supported only when inner table data is output.
      - Right Anti Join: partially supported. It is supported only when inner table data is output.
      - Full Join: not supported.
      - Left Join: not supported.
    - Others
      - It is supported only when the number of columns in the output data of an inner table is less than or equal to 64.
  - When **enable_ca_hashjoin** is enabled, the query meets the specified condition, and the Ca Hash Join operator designed for Cache-Aware Hash Table is used, the operator is displayed as **Vector Ca Hash Join** in the execution plan and execution information of Explain Analyze/Performance. If the specified condition is not met, the operator is displayed as **Vector Sonic Hash Join** or **Vector Hash Join**. For details, see "Introduction to the SQL Execution Plan > Execution Plan Details" in *SQL Optimization Guide*.
- When **enable_ca_hashagg** is set in the GUC parameter, this switch depends on the basic switch **enable_hashagg**. When **enable_hashagg** is disabled, no HashAgg exists in the plan, and **enable_ca_hashagg** is invalid.
  - This switch applies only to the following scenarios:
    - Non-numeric type supported by the original vectorized AGG.
    - The number of aggregate functions cannot exceed 21.
    - Columns returned by lower-layer operators include only columns used as HashKey, columns used for aggregation, and columns irrelevant to HashAgg. For example, if **SELECT col1::numeric FROM test_table GROUP BY col1;** is used, the lower-layer operators may return **col1** and **col1::numeric**, and only **col1** is used as the hash key.
    - **unique_check** of the AGG node is **false**. (Currently, it may be **true** only in some subqueries.)
    - For details about the data types supported by join keys, see **Table 6-22**.
  - When **enable_ca_hashagg** is enabled, the query meets the specified condition, and the Ca Hash Agg operator designed for Cache-Aware Hash Table is used, the operator is displayed as **Vector Ca Hash Aggregate** in the execution plan and

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

execution information of Explain Analyze/Performance. If the specified condition is not met, the operator is displayed as **Vector Sonic Hash Aggregate** or **Vector Hash Aggregate**. For details, see "Introduction to the SQL Execution Plan > Execution Plan Details" in *SQL Optimization Guide*.

Table 6-22 Data types supported by join keys

Category	Data Type
Numeric types	TINYINT [UNSIGNED]
	SMALLINT [UNSIGNED]
	MEDIUMINT [UNSIGNED]
	BIGINT [UNSIGNED]
	FLOAT4
	FLOAT8
Date/Time types	DATE
	DATEA
	SMALLDATETIME
	ABSTIME
	INTERVAL
	RELTIME
	TIME [WITHOUT TIME ZONE]
	TIMESTAMP [WITHOUT TIME ZONE]
Character types	BPCHAR
	CHAR
	VARCHAR
	TEXT
Other data types	BOOL
	OID

enable_sonic_optspill

Parameter description: Specifies whether to optimize the number of files to be written to disks for the hash join operator designed for column-oriented hash tables. If this parameter is enabled, the number of files written to disks does not increase significantly when the hash join operator writes a large number of files to disks.

Parameter type: Boolean.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Unit: none

Value range:

- **on** indicates that the number of files to be written to disks for the hash join operator designed for column-oriented hash tables is optimized.
- **off** indicates that the number of files to be written to disks for the hash join operator designed for column-oriented hash tables is not optimized.

Default value: **on**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this parameter is disabled, the query performance may deteriorate in this scenario.

plan_cache_mode

Parameter description: Specifies the policy for generating an execution plan in the prepared statement.

Parameter type: enumerated type

Unit: none

Value range: **auto**, **force_generic_plan**, and **force_custom_plan**

- **auto**: The optimizer automatically selects a custom plan or generic plan.
- **force_generic_plan** indicates that the generic plan is forcibly used (soft parse). The generic plan is a plan generated after you run a prepared statement. The plan policy binds parameters to the plan when you run the **EXECUTE** statement to execute the plan. The advantage of this scheme is that repeated optimizer overheads can be avoided in each execution. The disadvantage is that the plan may not be optimal when data skew occurs for the bound parameters and may result in poor plan execution performance. The bound parameters bind the types of parameters set for the first time. If the type of a parameter set to the same placeholder is different from the previous time, an error is reported.
- **force_custom_plan** indicates that the custom plan is forcibly used (hard parse). The custom plan is a plan generated after you run a prepared statement where parameters in the EXECUTE statement are embedded. The custom plan generates a plan based on specific parameters in the EXECUTE statement. This scheme generates a preferred plan based on specific parameters each time and has good execution performance. The disadvantage is that the plan needs to be regenerated before each execution, resulting in a large amount of repeated optimizer overhead.

NOTE

This parameter is valid only for prepared statements. It is used when the parameterized field in a prepared statement has severe data skew.

Default value: **auto**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Set this parameter based on the actual service scenario.

Risks and impacts of improper settings: The plan generation overhead may increase or the plan generation quality may deteriorate.

enable_router

Parameter description: Specifies whether to enable the manual pushdown function so that supported query statements can be pushed down to specific DNs for execution.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: used.
- **off**: not used.

Default value: **off**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: You need to manually set the pushdown node to be enabled for a specific distribution key.

Risks and impacts of improper settings: After this function is enabled, if the distribution key is incorrectly set, data may be stored on an incorrect DN. Therefore, exercise caution when enabling this function.

router

Parameter description: Specifies the detailed attributes of the router function. This parameter is valid only when **enable_router** and **enable_light_proxy** are enabled. This parameter is used to calculate the DN where the given distribution key is located based on the hash distribution key of the table. After the router is set, the supported SQL statements are pushed down to the DN for execution.

Parameter type: string.

Unit: none

Value range:

This parameter consists of two parts: **'schema_name.table_name,"distribute_keys"'** (pay attention to the double quotation marks). The meanings are as follows:

- **schema_name.table_name**: indicates the schema name and table name. If schema_name is not set, the default value current_schema is used.
- **distribute_keys**: Values of all distribution keys in the distributed table are separated by commas (,). The sequence of the values must be the same as that of the distribution keys in the table.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Default value: ""

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: You need to manually set the pushdown node to be enabled for a specific distribution key.

Risks and impacts of improper settings: If **router** is incorrectly set, data may be stored to an incorrect DN, causing unpredictable problems. Therefore, exercise caution when setting this parameter.

enable_force_vector_engine

Parameter description: Specifies whether to forcibly generate vectorized execution plans for a vectorized execution operator if the operator's child node is a non-vectorized operator. When this parameter is set to **on**, vectorized execution plans are forcibly generated.

Parameter type: Boolean.

Unit: none

Value range:

- **on** indicates that vectorized operators are forcibly generated.
- **off** indicates that the vectorized operator optimizer determines whether to perform vectorization.

Default value: **off**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value. You are advised to enable this function in vectorized service scenarios.

Risks and impacts of improper settings: If this parameter is enabled, the query performance may deteriorate.

enable_auto_explain

Parameter description: Specifies whether to enable the function of automatically printing execution plans. This parameter is used to locate slow stored procedures or slow queries and is valid only for the currently connected CN. It does not affect the execution of other CNs.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: enabled.
- **off**: disabled.

Default value: **off**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value. If you want to view the execution plan, enable this parameter. However, this causes the current system performance to deteriorate.

Risks and impacts of improper settings: After this function is enabled, the current system performance may deteriorate.

auto_explain_level

Parameter description: Specifies the log level for automatically printing execution plans.

Parameter type: enumerated type

Unit: none

Value range:

- **log**: Logs of the **log** level or higher will be printed.
- **notice**: Logs of the **notice** level or higher will be printed.

Default value: **log**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

auto_explain_log_min_duration

Parameter description: Specifies the minimum duration of execution plans that are automatically printed. Only execution plans whose duration is greater than the value of **auto_explain_log_min_duration** will be printed. For example, if this parameter is set to **0**, all executed plans are printed. If this parameter is set to **3000**, all executed plans are printed if the execution of a statement takes more than 3000 ms.

Parameter type: integer.

Unit: milliseconds

Value range: 0 to 2147483647

Default value: **0**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**. For example, if this parameter is set to **100** without a unit, it indicates 100 ms. If this parameter is set to **2min**, it indicates 2 minutes. The unit must be **ms**, **s**, **min**, **h**, or **d** if required.

Setting suggestion: Retain the default value. You can adjust the value based on service requirements to output slow query statements.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Risks and impacts of improper settings: If the value is too small, too much output content may be generated.

auto_explain_analyze_options

Parameter description: Specifies whether to display the runtime plan information when execution plans are automatically printed. This parameter is used to view the actual execution plans of FQS and PGXC plan pushdown statements in DN logs. It is valid only for the currently connected CN and does not affect the execution of other CNs.

NOTE

- This parameter can be used only when **enable_auto_explain** is enabled. The constraint of **enable_auto_explain** is inherited. EXPLAIN statements are not printed. Only the statement plans that are normally executed can be printed.
- Plan logs on DNs take effect only when **enable_auto_explain** is set to **true** and **auto_explain_level** is set to **log**.
- If this parameter is set to any value except **None**, the ANALYZE function is included, and the basic runtime plan information is displayed.
- Stream, SMP, and SQL Bypass plans are not supported. If no runtime information is displayed for the plan, check whether the Stream, SMP, and SQL Bypass plans are generated.
- Only the plan information of the current node can be displayed on each node. For example, the CN does not display the plan information of DNs in logs or on the client.
- In the current version, AUTO EXPLAIN does not display CPU plan information at runtime. The CPU option is reserved.

Parameter type: enumerated type

Unit: none

Value range:

- **None**: automatically prints execution plan and does not display the runtime plan information.
- **Analyze**: collects basic runtime plan information, including **rows** and **time**.
- **Buffers**: collects runtime information about **rows**, **time**, and **buffer**.
- **Cpu**: collects runtime information about **rows**, **time**, and **cpu**.

Default value: **None**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value. If you want to view the execution plan information, enable this parameter. However, this causes the current system performance to deteriorate.

Risks and impacts of improper settings: After this function is enabled, the current system performance may deteriorate.

max_datanode_for_plan

Parameter description: Specifies the number of execution plans displayed on DNs when FQS plans are generated. The number of plans that are displayed on DNs is

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

determined by the smaller value between the number of DNs on the cluster and the value of this parameter.

Parameter type: integer.

Unit: none

Value range: 0 to 8192

Default value: **0**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Change the value when you need a more detailed multi-node execution plan.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

enable_inner_unique_opt

Parameter description: Specifies whether to optimize Inner Unique for nested-loop join, hash join, and sort merge join, that is, whether to reduce the number of matching times when the attribute corresponding to the inner table in the join condition meets the UNIQUE constraint.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: used.
- **off**: not used.

Default value: **on**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this parameter is disabled, the query performance of the corresponding scenarios may deteriorate.

enable_indexscan_optimization

Parameter description: Specifies whether to optimize B-tree index scan (IndexScan and IndexOnlyScan) in the Astore.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: used.
- **off**: not used.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Default value: **on**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this parameter is disabled, the query performance of the corresponding scenarios may deteriorate.

enable_uniq_idx_a_compat

Parameter description: Specifies whether composite unique indexes are compatible with Oracle Database for **NULL** values.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: compatible.
- **off**: incompatible.

Default value: **off**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: This parameter is applicable only to ORA-compatible databases. Retain the default value.

Risks and impacts of improper settings: Improper settings may affect compatibility or increase query planning overheads.

create_gsi_opt

Parameter description: Specifies the GSI creation mode. Other modes except **none** take effect only after the **enable_stream_operator** parameter is enabled.

Parameter type: enumerated type

Unit: none

Value range:

- **none**: PGXC is used.
- **build**: The STREAMING and GSI BUILD operators are used.
- **parallel**: The STREAMING and GSI BUILD operators and the parallel sorting mode are used. (The **parallel_workers** parameter of the base table needs to be set.)

Default value: **build**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Risks and impacts of improper settings: The performance of creating global secondary indexes may deteriorate.

session_sequence_cache

Parameter description: Specifies the **sequence** value applied for one-time interaction in the current session. The unused values are automatically discarded after the session ends.

Parameter type: integer.

Unit: none

Value range: 1 to 2147483647

Default value: **10**

NOTE

The default value is **10**. In high-concurrency scenarios, the performance of single and batch insertion is good.

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: When using **sequence** to import data in batches, you can increase the value of this parameter to improve the insertion speed and high concurrency performance. When a single data record is inserted concurrently, set this parameter to **1** to reduce the sequence change. If you have high requirements on continuity, you need to specify the required cache when creating a sequence. If the value of this parameter is greater than that of cache, the value automatically becomes invalid.

Risks and impacts of improper settings: If the value is too large, the performance of inserting a single record may deteriorate. If the value is too small, the performance of inserting records in batches may deteriorate.

enable_invisible_indexes

Parameter description: Specifies whether the optimizer can use invisible indexes.

NOTE

After an index is set to invisible, the performance of query statements may be affected. If you do not want to change the index visibility status and want to use invisible indexes, set **enable_invisible_indexes** to **on**.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The optimizer can use invisible indexes.
- **off**: The optimizer cannot use invisible indexes.

Default value: **off**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If invisible indexes are used but this parameter is not enabled, invisible indexes may be ignored. Therefore, a better plan may not be considered.

enable_dynamic_samplesize

Parameter description: Specifies whether to dynamically adjust the number of sampled rows. For a large table with more than one million rows, the number of sampled rows is dynamically adjusted during statistics collection to improve statistics accuracy.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: indicates that the function is enabled.
- **off**: indicates that the function is disabled.

Default value: **on**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this parameter is disabled, the accuracy of statistics may decrease.

NOTE

The function of dynamically adjusting the number of sampled rows supports only absolute sampling.

default_statistic_granularity

Parameter description: Specifies which partition-level statistics of a partitioned table are collected by default when **PARTITION_MODE** is not specified. This parameter does not take effect for non-partitioned tables.

Parameter type: enumerated type

Unit: none

Value range:

- **all**: Statistics of the entire table and partition are collected.
- **global**: Statistics of the entire table are collected.
- **partition**: Statistics of the partition are collected.
- **global_and_partition**: Statistics about the entire table and partitions are collected.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **all_complete**: Statistics about the entire table and partitions are collected. Compared with the scenario where the value is **all**, the sampling rate is higher, which may cause longer time required for collecting statistics.

Default value: **global**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value. If partition-level statistics need to be collected, you can set this parameter as required. However, the **ANALYZE** performance may be affected.

Risks and impacts of improper settings: You need to balance the maintenance overhead and the accuracy of statistics. Improper settings may cause high costs for one party.

NOTE

In upgrade scenarios, the value of this GUC parameter after the upgrade must be the same as that before the upgrade.

enable_fast_numeric_agg

Parameter description: Specifies whether to enable aggregation optimization for the numeric data type.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The aggregation optimization is enabled for the numeric data type.
- **off**: The aggregation optimization is disabled for the numeric data type.

Default value: **on**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this parameter is disabled, the query performance of the corresponding scenarios may deteriorate.

enable_poisson_outer_optimization

Parameter description: Specifies whether to use Poisson to correct the selectivity of the filter condition in the outer table in outer join when the selectivity is calculated in the plan generation phase.

Parameter type: Boolean.

Unit: none

Value range:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **on**: Poisson is not used to modify the selectivity of the filter condition of the outer table in the outer join. That is, the filter condition of the outer table is not calculated as pushdown.
- **off**: The selectivity is calculated based on the filter condition of the outer table in the outer join.

Default value: **off** for an upgraded cluster and **on** for a newly installed cluster.

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: A good execution plan may not be selected, and slow SQL statements may occur.

NOTE

The related functions take effect only when the GUC parameter **cost_model_version** is greater than or equal to 5 or is set to **0** and **enable_poisson_outer_optimization** is set to **on**.

enable_predreorder_by_rank

Parameter description: Specifies whether to reorder multiple filter criteria of a single base table based on their selectivity and calculation cost during plan generation to reduce the execution overhead.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: Multiple filter criteria are reordered based on their selectivity and calculation cost during plan generation.
- **off**: Multiple filter criteria are not reordered based on their selectivity and calculation cost during plan generation.

Default value: **on**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this function is disabled, some plans cannot be optimized.

NOTE

The related functions take effect only when **cost_model_version** is greater than or equal to 6 or is set to **0** and **enable_predreorder_by_rank** is set to **on**.

enable_shared_set_update

Parameter description: Specifies whether the optimizer generates a subplan for each column to be updated when a subquery is used to update multiple columns

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

in an UPDATE statement. When this parameter is enabled, only one subplan is generated and shared among multiple columns.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: Only one subplan is generated based on the subquery.
- **off**: A subplan is generated for each column to be updated.

Default value: **on**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this function is disabled, the query execution efficiency of updating multiple columns using subqueries may be reduced, and the query optimization and execution overhead may increase.

NOTE

- The related functions take effect only when **cost_model_version** is greater than or equal to 6 or is set to **0** and **enable_shared_set_update** is set to **on**.
- When **enable_shared_set_update** is set to **on** and a shared set update plan is generated, if the statement contains an IMCV table, no IMCV SCAN plan will be generated.

cursor_sharing

Parameter description: Specifies whether to enable automatic parametrization or reuse of the same statement plan.

Parameter type: enumerated type

Unit: none

Value range:

- **force**: enables automatic parameterization and reuse of the same statement plan. If the automatic parameterization conditions are met, the automatic parameterization cache is used preferentially. If the conditions are not met, the same statement plan reuse cache is used. For example, in MySQL- or M-compatible mode, parameterization is not supported and **cursor_sharing** is automatically set to **exact**.
- **exact**: enables only the same statement plan reuse function.
- **off**: disables both the automatic parameterization and same statement plan reuse functions.

Default value: **off**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Risks and impacts of improper settings: If this parameter is set to **force**, some constants in the statement will be replaced by parameters. The SQL plan may be changed, the plan performance may deteriorate, the syntax tree may be affected, the value of **unique_sql_id** may change, and the SQL patch may become invalid.

If this parameter is set to **force** or **exact**, the memory usage may increase. In addition, if the plan template cannot be reused, the performance cannot be improved through plan reuse. Before setting this parameter, check whether the service model is suitable. When the upper limit of the plan memory is controlled, if a large number of different SQL templates are stored, the plan cache memory usage is too high and reaches the upper limit, triggering the planned memory eviction. As a result, the performance deteriorates and even drops to zero in extreme scenarios.

Before modifying this parameter, make sure you understand its meaning and fully verify the change in a test environment.

NOTE

- After automatic parameterization is enabled, its execution mechanism is the same as that of manually binding parameters.
- After automatic parameterization is enabled, the query statement is automatically rewritten in parameterized form. Therefore, the WARNING or ERROR information (such as the prompt text and line number) displayed during the execution may be different from that when automatic parameterization is disabled. This is expected.

opt_use_static_stats

Parameter description: After this function is enabled, statistics such as the number of rows and number of pages can be directly read from the PG_CLASS system catalog, instead of being obtained by sampling pages of the base table. This parameter is used to manually verify the plan generation effect of the optimizer on the premise that the statistics are given.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: Statistics are directly read from PG_CLASS.
- **off**: The base table is sampled to obtain statistics such as the number of rows and pages in the default mode.

Default value: **off**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this function is enabled, the optimizer does not detect the actual table size. The statistics are based only on the PG_CLASS system catalog.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

The related functions take effect only when **cost_model_version** is greater than or equal to 6 or is set to **0** and **opt_use_static_stats** is set to **on**.

enable_sel_cache

Parameter description: When this function is enabled, the selectivity cache is used for the equi-join predicates whose left and right operands are ordinary columns and have been pushed down through deduction by the optimizer in the path generation phase. The cache is used to accelerate the repeated calculation of the predicate selectivity in the path search phase.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: This function is used.
- **off**: This function is not used.

Default value:

- **on**: default value of the newly installed database.
- **off**: For an upgrade from a version earlier than 506.1.0 to the current version, the default value of this parameter is **off**. If this parameter exists before the upgrade, the default value is **off** after the upgrade regardless of its setting.

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this function is disabled, the performance may deteriorate during path generation of the optimizer.

NOTE

- Results of multi-column statistics cannot be cached.
- The related functions take effect only when **cost_model_version** is greater than or equal to 7 or is set to **0** and **enable_sel_cache** is set to **on**.
- A cache is built to accelerate selectivity calculation only when an equi-join predicate composed of ordinary columns is encountered.
- If the left and right operands contain type conversion and the converted types are forcibly converted in binary mode, this function can also be used to accelerate calculation. For details, see the description of **castmethod** in **PG_CAST**.
- If both **enable_hashjoin** and **enable_mergejoin** are disabled, this function does not take effect.

stats_history_record_limit

Parameter description: Specifies the maximum number of historical statistics that can be retained for each object (including tables, columns, partitions, and indexes). When collecting statistics about an object, the system saves the statistics to the historical statistics table. When the number of statistics about the object in

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

the historical statistics table reaches the threshold and new statistics are collected, the earlier statistics are deleted.

Parameter type: integer.

Unit: none

Value range: 0 to 100

Default value: **10**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestions: The default value is recommended. If you need to record statistics of more historical versions, increase the value of this parameter. However, the performance of ANALYZE may be affected.

Risks and impacts of improper settings: If the value is too large, the ANALYZE performance may be affected.

stats_history_retention_time

Parameter description: Specifies the retention period of historical statistics about each object (including tables, columns, partitions, and indexes). When collecting statistics about an object, the system saves the statistics to the historical statistics table. If the retention period of the statistics about the object in the historical statistics table exceeds the threshold, the system deletes the statistics that exceed the retention period when collecting new statistics.

Parameter type: floating-point.

Unit: days (d)

Value range: **-1** or a value ranging from 0 to 365000. **-1** indicates that the history statistics are not cleared over time.

Default value: **31**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestions: The default value is recommended. If you need to record statistics of earlier versions, increase the value of this parameter. However, the performance of ANALYZE may be affected.

Risks and impacts of improper settings: If the value is too large, the ANALYZE performance may be affected.

opt_behavior_knob

Parameter description: Specifies the behavior change of the optimizer in specific scenarios for manual query optimization.

Parameter type: string.

Unit: none

Value range: All behavior changes in specific scenarios are enabled. You can use SHOW opt_behavior_knob to check the changes.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

ALL,on(ROWID_OPT,DIST_QUERY_ADAPTIVE_FALLBACK,XC_REMOTE_JOIN_PARAM,MERGE_INTO_SHIP,SUBLINK_QUERY_SHIP,SUBPLAN_SORTED_PATH_FIX,PARAM_PATH_SKIP_CACHING_VARRATIO,PREFER_UNIQUE_INDEX,PREFER_LONGER_INDEX,PPI_COST_MODEL1,PREDICATE_INFER_ENHANCE,HIERARCHY_QRY_CHECK_SUBLINK_PULLUP,ACTUAL_RANGE_BY_INDEX,FIX_PART_INDEX_SCAN_COST,OPT_KNOB_20260703_1,OPT_KNOB_20260807_1,OPT_KNOB_20260728_1,OPT_KNOB_20260812_1),off()

- **PARAM_PATH_SKIP_CACHING_VARRATIO**: specifies whether to skip the caching of the selectivity of related predicates during cardinality estimation when parameterized paths are generated, ensuring the accuracy of upper-layer join cardinality estimation.
- **SUBPLAN_SORTED_PATH_FIX**: specifies the path selection related to the sorted path of sublinks, preventing paths with low costs from being directly eliminated and ensuring the accuracy of path selection.
- **DIST_QUERY_ADAPTIVE_FALLBACK**: specifies whether to roll back a plan to a stream plan if the following conditions are met: CN resources are insufficient (memory or CPU usage exceeds 80%); the plan generated by the distributed adaptive plan is a distributed plan for delivering statements; and the plan is a non-parameterized path plan.
- **XC_REMOTE_JOIN_PARAM**: specifies whether an outer table can pass parameters to an inner table for execution when the inner table is a remote join operator.
- **MERGE_INTO_SHIP**: specifies the pushdown of the MERGE INTO statement. In the MERGE INTO USING SELECT FROM dual table scenario, the MERGE INTO statement can be pushed down to DNs to execute the CN lightweight/FQS plan.
- **SUBLINK_QUERY_SHIP**: specifies whether to push down the sublink FQS. When the pushdown conditions are met, the sublink can be pushed down to DNs for execution.
- **ROWID_OPT**: specifies whether to enable the ROWID system column predicate condition rewriting, ORDER BY statement rewriting, max/min optimization, distribution pruning, and partition pruning. For details, see "Feature Usage Guidelines > ROWID Table > Operation Guide > DML" in *Developer Guide*.
- **PREFER_UNIQUE_INDEX**: specifies whether the rule that the unique index scan path is preferred takes effect. This parameter is compatible with **no_unique_index_first** in **sql_beta_feature**. The relationship between the two parameters is OR. The rule that the unique index scan path is preferred takes effect when **no_unique_index_first** is not set in **sql_beta_feature** or **PREFER_UNIQUE_INDEX** is enabled. Only the equivalent scenario is supported. The priority of this rule is lower than that of **PREFER_LONGER_INDEX**.
- **PREFER_LONGER_INDEX**: specifies whether the rule that the longest and leftmost index scan path is preferred takes effect. Only the equivalent scenario is supported. The priority of this rule is higher than that of **PREFER_UNIQUE_INDEX**.
- **PPI_COST_MODEL1**: specifies the cost correction in the scenario where the LOCAL index parameterized path is used. This prevents the plan from being suboptimal due to small cost estimation when the LOCAL index is selected and the query condition does not contain the partition key. If the database is upgraded from an earlier version that does not support this parameter, this function is enabled by default and the parameter does not take effect during the observation period. After the observation period ends, the function is automatically disabled.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **PREDICATE_INFER_ENHANCE**: controls predicate inference and reduction, simplifies predicate logic, and improves query performance. For details, see the description of predicate inference and reduction in **cost_model_version**.
- **HIERARCHY_QRY_CHECK_SUBLINK_PULLUP**: controls the behavior of pulling up sublinks at the same level in hierarchical queries. When this parameter is enabled, a stricter check is performed on sublink pulling up. After an upgrade from an earlier version that does not support this parameter to the current version, this function is disabled by default and does not take effect during the upgrade observation period.
- **ACTUAL_RANGE_BY_INDEX**: controls whether the optimizer directly queries the actual maximum or minimum value through an index when estimating the selectivity of a range condition and finds that the condition falls on the leftmost or rightmost end of the statistical histogram. This prevents estimation deviation caused by outdated statistics.
- **FIX_PART_INDEX_SCAN_COST**: specifies whether to correct the estimated cost of local index scans on partitioned tables to prevent the plan from being suboptimal due to estimation deviation. If the database is upgraded from an earlier version that does not support this parameter, this function is enabled by default and the parameter does not take effect during the observation period. After the observation period ends, the function is automatically disabled.
- **OPT_KNOB_20260703_1**: specifies whether the optimizer counts the null ratio when using multi-column statistics to calculate the NDV. If this function is enabled, the null ratio is not counted, and a more accurate cardinality estimation can be obtained. If the database is upgraded from an earlier version that does not support this parameter, this function is enabled by default and the parameter does not take effect during the observation period. After the observation period ends, the function is automatically disabled.
- **OPT_KNOB_20260807_1**: specifies whether to correct the optimizer's estimation on the number of index pages in a partitioned table to prevent the plan from being suboptimal due to estimation deviation. If the database is upgraded from an earlier version that does not support this parameter, this function is enabled by default and the parameter does not take effect during the observation period. After the observation period ends, the function is automatically disabled.
- **OPT_KNOB_20260728_1**: controls the optimizer agg cost model. When this function is enabled, the hypergeometric distribution probability algorithm is used. When this function is disabled, the proportional scaling algorithm is used. This affects the estimation of the number of agg rows in hashagg and avoids poor planning due to estimation deviation. If the database is upgraded from an earlier version that does not support this parameter, this function is enabled by default and the parameter does not take effect during the observation period. After the observation period ends, the function is automatically disabled.
- **OPT_KNOB_20260812_1**: specifies whether to correct the cost when the optimizer generates a nested-loop join path and the foreign table contains the sort operator. This prevents suboptimal plans caused by estimation deviation. If the database is upgraded from an earlier version that does not support this parameter, this function is enabled by default and the parameter does not take effect during the observation period. After the observation period ends, the function is automatically disabled.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Default value:

- For a newly installed database:

  'ALL,on(ROWID_OPT,DIST_QUERY_ADAPTIVE_FALLBACK,XC_REMOTE_JOIN_PARAM,MERGE_INTO_SHIP,SUBLINK_QUERY_SHIP,SUBPLAN_SORTED_PATH_FIX,PARAM_PATH_SKIP_CACHING_VARRATIO,PREFER_UNIQUE_INDEX,PREFER_LONGER_INDEX,PPI_COST_MODEL1,PREDICATE_INFER_ENHANCE,HIERARCHY_QRY_CHECK_SUBLINK_PULLUP,ACTUAL_RANGE_BY_INDEX,FIX_PART_INDEX_SCAN_COST,OPT_KNOB_20260703_1,OPT_KNOB_20260807_1,OPT_KNOB_20260728_1,OPT_KNOB_20260812_1),off()'.
- For the **PPI_COST_MODEL1**, **FIX_PART_INDEX_SCAN_COST**, **HIERARCHY_QRY_CHECK_SUBLINK_PULLUP**, **OPT_KNOB_20260703_1**, **OPT_KNOB_20260807_1**, **OPT_KNOB_20260728_1**, and **OPT_KNOB_20260812_1** parameters: If the database is upgraded from an earlier version that does not support these parameters, this function is enabled by default and the parameters do not take effect during the observation period. After the observation period ends, the function is automatically disabled.
- In the PDB scenario, if this parameter is not set, the global setting is inherited.

Setting method: This is a USERSET parameter, and you are advised not to use the gs_guc tool to set it. The setting method is as follows:

First, you can run **SHOW opt_behavior_knob** to check which behavior changes are controllable. For example, the query output result is as follows:

```
gaussdb=# SHOW opt_behavior_knob;
              opt_behavior_knob
-------------------------------------------------

ALL,on(ROWID_OPT,DIST_QUERY_ADAPTIVE_FALLBACK,XC_REMOTE_JOIN_PARAM,MERGE_INTO_SHIP,SUBLINK_QUERY_SHIP,SUBPLAN_SORTED_PATH_FIX,PARAM_PATH_SKIP_CACHING_VARRATIO,PREFER_UNIQUE_INDEX,PREFER_LONGER_INDEX,PPI_COST_MODEL1,PREDICATE_INFER_ENHANCE,HIERARCHY_QRY_CHECK_SUBLINK_PULLUP,ACTUAL_RANGE_BY_INDEX,FIX_PART_INDEX_SCAN_COST,OPT_KNOB_20260703_1,OPT_KNOB_20260807_1,OPT_KNOB_20260728_1,OPT_KNOB_20260812_1),off()
(1 row)
```

Controllable behavior changes are identified by uppercase letters, and the special ID **ALL** is used for setting all behavior changes. You can set it to **on** or **off** to specify whether the behavior change takes effect. To disable the behavior change of skipping cache selectivity for parameterized paths, run the following commands:

```
gaussdb=# SET opt_behavior_knob = 'off(PARAM_PATH_SKIP_CACHING_VARRATIO)';
gaussdb=# SHOW opt_behavior_knob;
              opt_behavior_knob
-------------------------------------------------

ALL,on(ROWID_OPT,DIST_QUERY_ADAPTIVE_FALLBACK,XC_REMOTE_JOIN_PARAM,MERGE_INTO_SHIP,SUBLINK_QUERY_SHIP,SUBPLAN_SORTED_PATH_FIX,PREFER_UNIQUE_INDEX,PREFER_LONGER_INDEX,PPI_COST_MODEL1,PREDICATE_INFER_ENHANCE,HIERARCHY_QRY_CHECK_SUBLINK_PULLUP,ACTUAL_RANGE_BY_INDEX,FIX_PART_INDEX_SCAN_COST,OPT_KNOB_20260703_1,OPT_KNOB_20260807_1,OPT_KNOB_20260728_1,OPT_KNOB_20260812_1),off(PARAM_PATH_SKIP_CACHING_VARRATIO)
(1 row)
```

The behavior change of skipping cache selectivity for parameterized paths is disabled, and other behavior changes remain unchanged.

The **ALL** identifier can be used to quickly enable or disable all behavior changes.

```
gaussdb=# SET opt_behavior_knob = 'off(ALL)';
SET
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gaussdb=# SHOW opt_behavior_knob;
              opt_behavior_knob
-------------------------------------------------

ALL,on(),off(ROWID_OPT,DIST_QUERY_ADAPTIVE_FALLBACK,XC_REMOTE_JOIN_PARAM,MERGE_INTO_SHIP,
SUBLINK_QUERY_SHIP,SUBPLAN_SORTED_PATH_FIX,PARAM_PATH_SKIP_CACHING_VARRATIO,PREFER_UNIQ
UE_INDEX,PREFER_LONGER_INDEX,PPI_COST_MODEL1,PREDICATE_INFER_ENHANCE,HIERARCHY_QRY_CHE
CK_SUBLINK_PULLUP,ACTUAL_RANGE_BY_INDEX,FIX_PART_INDEX_SCAN_COST,OPT_KNOB_20260703_1,OPT
_KNOB_20260807_1,OPT_KNOB_20260728_1,OPT_KNOB_20260812_1)
(1 row)

gaussdb=# SET opt_behavior_knob = 'on(ALL)';
SET
gaussdb=# SHOW opt_behavior_knob;
              opt_behavior_knob
-------------------------------------------------

ALL,on(ROWID_OPT,DIST_QUERY_ADAPTIVE_FALLBACK,XC_REMOTE_JOIN_PARAM,MERGE_INTO_SHIP,SUBLI
NK_QUERY_SHIP,SUBPLAN_SORTED_PATH_FIX,PARAM_PATH_SKIP_CACHING_VARRATIO,PREFER_UNIQUE_I
NDEX,PREFER_LONGER_INDEX,PPI_COST_MODEL1,PREDICATE_INFER_ENHANCE,HIERARCHY_QRY_CHECK_S
UBLINK_PULLUP,ACTUAL_RANGE_BY_INDEX,FIX_PART_INDEX_SCAN_COST,OPT_KNOB_20260703_1,OPT_KN
OB_20260807_1,OPT_KNOB_20260728_1,OPT_KNOB_20260812_1),off()
(1 row)
```

Setting suggestion: Retain the default value. Disable specified behavior changes as required.

Risks and impacts of improper settings: If one or all behavior changes are disabled, the optimizer may output an unexpected plan, which may affect the system performance.

NOTE

The related functions take effect only when **cost_model_version** is greater than or equal to **5** or is set to **0** and **opt_behavior_knob** is set to **on**.

exec_behavior_knob

Parameter description: Specifies the behavior change of the executor in specific scenarios.

Parameter type: string.

Unit: none

Value range: You can run the **SHOW exec_behavior_knob** command to view the parameter values.

```
ALL,on(SHOW_BATCH_ERROR_DETAIL,INDEXBY_FUNC_OPTIMIZE,SYS_CB_PATH_NULL_CTRL,PGXC_MERGE_
UPDATE,SORT_KEYS_CACHE,PLSQL_RETURN_EXCEPTION),off(AUTO_INCR_LP_INSERT)
```

- **SHOW_BATCH_ERROR_DETAIL**: In the batch execution scenario, if an exception is thrown during cyclic execution, the number of current batches and the bound parameter values in the error batch are printed.
- **INDEXBY_FUNC_OPTIMIZE**: When the first/last/prior/next function of a set variable with an index is called in a stored procedure, the red-black tree is used to optimize performance. After this function is enabled, the memory usage increases to maintain the red-black tree, and the performance deteriorates in some scenarios.
- **SYS_CB_PATH_NULL_CTRL**: specifies whether to perform special processing when the hierarchical query system function SYS_CONNECT_BY_PATH is executed and a NULL value is read. After this function is enabled, an empty

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

value is output for NULL values. Otherwise, the string **"null"** is output. If the database is upgraded from an earlier version that does not support this parameter, this function is enabled by default and the parameter does not take effect during the observation period. After the observation period ends, the function is automatically disabled.

- **AUTO_INCR_LP_INSERT**: specifies whether to enable light proxy pushdown optimization in simple insertion scenarios where the partition key is an auto-increment column. If it is disabled, the execution plan displayed using EXPLAIN changes from light proxy to PGXC in this scenario. As a result, the performance deteriorates in some scenarios.
- **PGXC_MERGE_UPDATE**: specifies whether to allow multiple updates to the same row of data when the MERGE INTO syntax is executed for a single SQL statement in a PGXC plan. If this parameter is enabled and the **enable_cid_sync** parameter is also enabled, an error is reported.
- **SORT_KEYS_CACHE**: specifies whether to enable the multi-column information cache mechanism of the Sort operator to improve sorting performance. When this function is enabled, information about the sorting key can be dynamically cached, improving the sorting performance of the row executor.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

The Sort operator has the following limitations on multi-column information cache:

- Full sorting only

  This feature is optimized for full sorting scenarios where the row executor performs high-frequency cross comparison. For top-N queries with the LIMIT clause, heap sort is usually used and the overall number of comparisons is small. Therefore, the cost-effectiveness of caching multiple columns of data is low. In this case, this feature does not take effect. If the query with the LIMIT clause uses quick sort, this feature can be enabled. For example, the execution plan output is as follows:

```
gaussdb=# EXPLAIN ANALYZE SELECT * FROM test_sort ORDER BY 1 LIMIT 1;
                                                        QUERY PLAN
---------------------------------------------------------------------------------------------------------------------------
--------
 [Parameterized]
 Limit  (cost=46.03..46.03 rows=1 width=4) (actual time=0.098..0.098 rows=1 loops=1)
   ->  Sort  (cost=46.03..52.04 rows=1 width=4) (actual time=0.095..0.095 rows=1 loops=1)
         Sort Key: a
         Sort Method: top-N heapsort  Memory: 25kB
         ->  Seq Scan on test_sort  (cost=0.00..34.02 rows=2402 width=4) (actual
time=0.045..0.050 rows=10 loops=1)
 Total runtime: 0.397 ms
(7 rows)
gaussdb=# EXPLAIN ANALYZE SELECT * FROM test_sort ORDER BY 1 LIMIT 6;
                                                        QUERY PLAN
---------------------------------------------------------------------------------------------------------------------------
--------
 [Parameterized]
 Limit  (cost=77.08..77.09 rows=6 width=4) (actual time=0.132..0.137 rows=6 loops=1)
   ->  Sort  (cost=77.08..83.08 rows=6 width=4) (actual time=0.127..0.129 rows=6 loops=1)
         Sort Key: a
         Sort Method: quicksort  Memory: 25kB
         ->  Seq Scan on test_sort  (cost=0.00..34.02 rows=2402 width=4) (actual
time=0.060..0.070 rows=10 loops=1)
 Total runtime: 0.551 ms
(7 rows)
```

- Unique key scenario

  On a single DN, secondary comparison will not be performed when there is only one column in the sort key or the data of the first sort key is unique (only the actual data needs to be unique and the UNIQUE constraint is not necessary). In this case, this feature does not take effect.

- Memory overflow protection

  If the memory required by the original sorted data exceeds the working memory (**work_mem**) configured in the system, the data needs to be spilled to disks for processing. Alternatively, if the overall memory usage exceeds the working memory plus the additional memory overhead caused by multi-column caching, the multi-column caching feature automatically becomes invalid.

- Limit on the number of sort keys

  To prevent the cache structure from bloating excessively, the system disables this feature when the total number of sort keys in a query statement exceeds 32.

- **PLSQL_RETURN_EXCEPTION**: specifies whether the EXCEPTION statement can capture the type conversion errors reported by the RETURN statement in the stored procedure in ORA-compatible mode. For details, see **Error Trapping Statements**.

  NOTE

  For an upgrade from a version that does not support this parameter, the setting of this parameter does not take effect during the upgrade observation period. After the upgrade is committed, the setting takes effect and this option is set to **off** by default.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Default value:

- For a newly installed database:

  'ALL,on(SHOW_BATCH_ERROR_DETAIL,INDEXBY_FUNC_OPTIMIZE,SYS_CB_PATH_NULL_CTRL,PGXC_MERGE_UPDATE,SORT_KEYS_CACHE,PLSQL_RETURN_EXCEPTION),off(AUTO_INCR_LP_INSERT)'.
- This parameter is added in the 507.0.0 version. If the database is upgraded from a version earlier than 507.0.0, the default value is as follows:

  'ALL,on(SHOW_BATCH_ERROR_DETAIL),off(INDEXBY_FUNC_OPTIMIZE,SYS_CB_PATH_NULL_CTRL,AUTO_INCR_LP_INSERT,PGXC_MERGE_UPDATE,SORT_KEYS_CACHE,PLSQL_RETURN_EXCEPTION)'.
- For an upgrade from a version later than 507.0.0 to this version, the original behavior change is the same as that in the source version, and the new behavior change is disabled by default.

Setting method: This is a USERSET parameter, and you are advised not to use the gs_guc tool to set it. The setting method is as follows:

First, you can run **SHOW exec_behavior_knob** to check which behavior changes are controllable. For example, the query output result is as follows:

```
gaussdb=# SHOW exec_behavior_knob;
        exec_behavior_knob
----------------------------------------

ALL,on(SHOW_BATCH_ERROR_DETAIL,INDEXBY_FUNC_OPTIMIZE,SYS_CB_PATH_NULL_CTRL,PGXC_MERGE_
UPDATE,SORT_KEYS_CACHE,PLSQL_RETURN_EXCEPTION),off(AUTO_INCR_LP_INSERT)
(1 row)
```

Controllable behavior changes are identified by uppercase letters, and the special ID **ALL** is used for setting all behavior changes. You can set it to **on** or **off** to specify whether the behavior change takes effect. To disable the **SHOW_BATCH_ERROR_DETAIL** behavior change, run the following commands:

```
gaussdb=# SET exec_behavior_knob='off(SHOW_BATCH_ERROR_DETAIL)';
gaussdb=# SHOW exec_behavior_knob;
        exec_behavior_knob
----------------------------------------

ALL,on(INDEXBY_FUNC_OPTIMIZE,SYS_CB_PATH_NULL_CTRL,PGXC_MERGE_UPDATE,SORT_KEYS_CACHE,PLS
QL_RETURN_EXCEPTION),off(SHOW_BATCH_ERROR_DETAIL,AUTO_INCR_LP_INSERT)
(1 row)
```

The behavior change of **SHOW_BATCH_ERROR_DETAIL** is disabled, and other behavior changes remain unchanged.

The **ALL** identifier can be used to quickly enable or disable all behavior changes.

```
gaussdb=# SET exec_behavior_knob='off(ALL)';
SET
gaussdb=# SHOW exec_behavior_knob;
        exec_behavior_knob
----------------------------------------

ALL,on(),off(SHOW_BATCH_ERROR_DETAIL,INDEXBY_FUNC_OPTIMIZE,SYS_CB_PATH_NULL_CTRL,AUTO_INC
R_LP_INSERT,PGXC_MERGE_UPDATE,SORT_KEYS_CACHE,PLSQL_RETURN_EXCEPTION)
(1 row)
gaussdb=# SET exec_behavior_knob = 'on(ALL)';
SET
gaussdb=# SHOW exec_behavior_knob;
        exec_behavior_knob
----------------------------------------
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
ALL,on(SHOW_BATCH_ERROR_DETAIL,INDEXBY_FUNC_OPTIMIZE,SYS_CB_PATH_NULL_CTRL,AUTO_INCR_LP
_INSERT,PGXC_MERGE_UPDATE,SORT_KEYS_CACHE,PLSQL_RETURN_EXCEPTION),off()
(1 row)
```

When **SHOW_BATCH_ERROR_DETAIL** is enabled, the default values of the parameters that are not explicitly specified in the configuration file are loaded. By default, the **SHOW_BATCH_ERROR_DETAIL** and **SYS_CB_PATH_NULL_CTRL** parameters are enabled. Therefore, when the behavior change of **SHOW_BATCH_ERROR_DETAIL** is enabled, the **SYS_CB_PATH_NULL_CTRL** parameter is enabled, and the **INDEXBY_FUNC_OPTIMIZE**, **AUTO_INCR_LP_INSERT**, **PGXC_MERGE_UPDATE**, and **PLSQL_RETURN_EXCEPTION** parameters are disabled.

```
gs_guc reload -Z datanode -N all -I all -c "exec_behavior_knob='on(SHOW_BATCH_ERROR_DETAIL)'"
gaussdb=# SHOW exec_behavior_knob;
         exec_behavior_knob
-----------------------------------------

ALL,on(SHOW_BATCH_ERROR_DETAIL,SYS_CB_PATH_NULL_CTRL),off(INDEXBY_FUNC_OPTIMIZE,AUTO_INC
R_LP_INSERT,PGXC_MERGE_UPDATE,SORT_KEYS_CACHE,PLSQL_RETURN_EXCEPTION)
(1 row)
```

Setting suggestion:

- **SORT_KEYS_CACHE**: Set this parameter based on the **work_mem** and data distribution configured in the current service system.

  NOTICE

  Enabling multi-column cache increases the memory usage of the Sort operator proportionally. The increased memory size is in strict linear relationship with the number of data rows and the number of extra cached columns. The relationship is evaluated using the following formula:

  Extra memory increment ≈ Total number of rows x 10 x (Total number of sort keys – 1) bytes

  (Note: 10 is the estimated byte overhead base for single-column cache.)

  - Recommended scenarios for enabling:

    High duplicity in leading columns: When the leading columns in ORDER BY have many duplicate values (such as low-cardinality fields like status and department), the optimization payoff of multi-column comparison becomes increasingly pronounced as data duplication grows.

    Trailing columns positioned later internally: When the subsequent columns used for secondary comparison are located further back in the physical table layout (that is, with larger column indexes), the optimization benefit scales directly with the size of the column index.
  - Recommended scenarios for disabling:

    Insufficient memory resources: If the **work_mem** configured for the system is small or the overall memory resources of the database are insufficient, you are advised not to enable this feature.
- Others: You are advised to use the default value.

Risks and impacts of improper settings: Disabling one or all options will change the behavior of the corresponding options.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

enable_cid_sync

Parameter description: If this function is enabled, non-read-only statements delivered to DNs use the CID on the CN during the execution of a top-level distributed PGXC plan. This ensures the visibility of tuple modified in the current transaction.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: This function is enabled.
- **off**: This function is disabled.

Default value:

- For a newly installed database: **on**.
- For a database upgraded from an earlier version that does not support this GUC parameter, the default value is **off** after the upgrade. If the earlier version supports this GUC parameter, the default value is retained after the upgrade.

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this function is disabled, the visibility of tuples modified in the current transaction may be affected when a distributed PGXC plan involves delivering multiple statements in a row of SQL statements.

enable_startwith_prior_enhance

Parameter description: Specifies whether to enhance the control over columns modified by PRIOR. If this parameter is enabled, the PRIOR keyword can be used to modify columns in the SELECT query column, DISTINCT clause, WHERE clause, GROUP BY clause, HAVING clause, WINDOW clause, and ORDER BY clause in the SELECT statement with the CONNECT BY clause to display the parent row column value. In addition, an error is reported in the following scenarios:

(1) In the SELECT statement with the CONNECT BY clause, PRIOR is used to modify columns in the ON condition and ORDER SIBLINGS BY clause.

(2) In a statement without the CONNECT BY clause, PRIOR is used to modify columns.

(3) In a clause (SELECT query column, DISTINCT clause, WHERE clause, GROUP BY clause, HAVING clause, WINDOW clause, or ORDER BY clause) that supports PRIOR, PRIOR is used to modify the pseudo columns **LEVEL**, **CONNECT_BY_ISCYCLE**, and **CONNECT_BY_ISLEAF**.

If this parameter is disabled, using the PRIOR keyword to modify a column outside the CONNECT BY clause is equivalent to not adding the PRIOR keyword. In this case, the current row and column values are displayed.

Parameter type: Boolean.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Unit: none

Value range:

- **on**: enabled.
- **off**: disabled.

Default value: **on**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value. Disable this function when restoring the behavior of the compatibility with earlier versions.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

ustore_consistent_read_opt

Parameter description: Specifies the consistent read policy for Ustore sequential scans.

Parameter type: enumerated type

Unit: none

Value range:

- **pbrcr**: page-based row-level consistent read policy.
- **fast_pbrcr**: page-based row-level consistent read policy that optimizes the page lock logic and undo traversal algorithm.

Default value: **pbrcr**

Setting method: This is a SUSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

parser_ignore_hints

Parameter description: Specifies whether to disable the parsing of hints.

Parameter type: Boolean

Unit: none

Value range:

- **on**: The processing of hints is disabled in the parsing phase, so that hints in statements do not take effect. When this parameter is enabled, the effect of SQL patches is affected, but outlines and SPM baselines are not affected.
- **off**: Hints are processed normally in the parsing phase.

Default value: **off**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: After this parameter is enabled, statements that have been optimized using hints or SQL patches may be rolled back to poor query plans, resulting in performance deterioration.

enable_partition_statistics_min_rows

Parameter description: Specifies whether to use the **partition_statistics_min_rows** option set for a partitioned table when **partition_mode** is set to **ALL** for the ANALYZE operation on the partitioned table.

Parameter type: Boolean

Unit: none

Value range:

- **on**: The value of **partition_statistics_min_rows** specified for a partitioned table can be used as the minimum number of rows sampled in a non-empty partition.
- **off**: The value of **partition_statistics_min_rows** specified for a partitioned table cannot be used as the minimum number of rows sampled in a non-empty partition.

Default value:

- For a newly installed database: **on**.
- For a database upgraded from an earlier version that does not support this GUC parameter, the default value is **off** after the upgrade. If the earlier version supports this GUC parameter, the default value is retained after the upgrade.

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this parameter is disabled, the partition-level statistics obtained by the ANALYZE operation with **partition_mode** set to **ALL** may be inaccurate. For details, see **ANALYZE | ANALYSE**.

6.3.9 Error Reporting and Logging

6.3.9.1 Logging Destination

log_destination

Parameter description: GaussDB supports several methods of logging server messages. Set this parameter to a list of desired log destinations separated by commas. (For example, **log_destination** can be set to **"stderr,csvlog"**.)

Parameter type: string.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Unit: none

Value range: **"stderr"**, **"csvlog"**, **"syslog"**, and **"eventlog"**.

- **"stderr"** indicates that logs are printed to the screen.
- **"csvlog"** indicates that logs are output in comma separated value (CSV) format. The prerequisite for generating logs in CSV format is that **logging_collector** must be set to **on**. For details, see **Using CSV Log Output**.
- **"syslog"** indicates that logs are recorded using the syslog of the OS. GaussDB can record logs using syslog from **LOCAL0** to **LOCAL7**. For details, see **syslog_facility**. To record logs using syslog, add the following information to syslog daemon's configuration file:
  local0.* */var/log/gaussdb*
- **"eventlog"** indicates that logs are recorded using the event log component. This function is supported only in the Windows OS.

Default value: **"stderr"**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

logging_collector

Parameter description: Specifies whether to enable the logger thread to collect logs. This thread captures log messages sent to **stderr** or **csvlog** and redirects them into log files.

This method is more effective than recording logs to syslog because some types of messages cannot be displayed in syslog output, such as messages indicating the loading failures of dynamic link libraries and error messages generated by scripts.

NOTICE

It is possible to log to **stderr** without using the parameter **logging_collector** and the log messages will go to where the server's **stderr** is directed. However, this method is only suitable for low log volumes due to difficulties in rotating log files.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The log collection is enabled.
- **off**: The log collection is disabled.

Default value: **on**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: When this parameter is disabled, CSV logs cannot be used to record logs.

log_directory

Parameter description: Specifies the directory for storing log files when **logging_collector** is set to **on**. The value can be an absolute path, or relative to the data directory. The **log_directory** parameter can be dynamically modified using the **gs_guc reload** command. Only the SYSADMIN user can access this parameter.

NOTICE

- If **log_directory** is set to an invalid path, the cluster cannot be started.
- If you modify the **log_directory** parameter using the **gs_guc reload** command, and the specified path is valid, the log files are output to this new path. If the specified path is invalid, the log files are output to the valid path set last time and the database operation is not affected. The invalid value of **log_directory** is still written into the configuration file.
- In the sandbox environment, the path cannot contain **/var/chroot**. For example, if the absolute path of log is **/var/chroot/var/lib/log/Ruby/gs_log/cn_log**, you only need to set the path to **/var/lib/log/Ruby/gs_log/cn_log**.

NOTE

- Valid path: Users have read and write permissions on the path.
- Invalid path: Users do not have read or write permission on the path.

Parameter type: string.

Unit: none

Value range: a string.

Default value: specified during installation

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

log_filename

Parameter description: Specifies the names of generated log files when **logging_collector** is set to **on**. The value is treated as a strftime pattern, so %-escapes can be used to specify time-varying file names. Only the SYSADMIN user can access this parameter.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTICE

- You are advised to use %-escapes to specify the log file names for efficient management of log files.
- If **log_destination** is set to **csvlog**, log files are output in CSV format with timestamped names, for example, **server_log.1093827753.csv**.

Parameter type: string.

Unit: none

Value range: a string.

Default value: **gaussdb-***%Y-%m-%d_%H%M%S***.log**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

log_file_mode

Parameter description: Specifies the permissions of log files when **logging_collector** is set to **on**. The value of **log_file_mode** is usually a number in the format acceptable to the **chmod** and **umask** system calls.

NOTICE

- Before setting this parameter, set **log_directory** to store the logs to a directory other than the data directory.
- Do not make the log files world-readable because they might contain sensitive data.

Parameter type: integer.

Unit: none

Value range: an octal integer ranging from 0000 to 0777 (that is, 0 to 511 in the decimal format).

NOTE

- **0600** indicates that log files are readable and writable only to the server administrator.
- **0640** indicates that log files are readable and writable to members of the administrator's group.

Default value: 0600

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

log_truncate_on_rotation

Parameter description: Specifies the writing mode of the log files when **logging_collector** is set to **on**.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: GaussDB overwrites the existing log files of the same name on the server.
- **off**: GaussDB appends the logging messages to the existing log files of the same name on the server.

Default value: **off**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

log_rotation_age

Parameter description: Specifies the interval for creating a log file when **logging_collector** is set to **on**. If the duration from the time when the last log file was created to the current time is greater than the value of **log_rotation_age**, a new log file will be generated.

NOTE

Assume that you want logs to be kept for 7 days, a log file generated each day to be named **server_log.Mon** on Monday, **server_log.Tue** on Tuesday, and so forth, and this week's log files to be overwritten by next week's log files.

Setting method: Set **log_filename** to **server_log.%a**, **log_truncate_on_rotation** to **on**, and **log_rotation_age** to **1440**.

Parameter type: integer.

Unit: minute

Value Range: 0 to 35791394. **0** indicates that the time-based creation of new log files is disabled.

Default value: **1440** (that is, 1 day)

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

log_rotation_size

Parameter description: Specifies the maximum size of a server log file when **logging_collector** is set to **on**. If the total size of messages in a log file exceeds the maximum size, a log file will be generated.

Parameter type: integer.

Unit: KB

Value Range: 0 to 2097151. **0** indicates that the capacity-based creation of new log files is disabled.

Default value: 20480 (20 MB)

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

syslog_facility

Parameter description: Specifies the syslog facility to be used when **log_destination** is set to **syslog**.

Parameter type: enumerated type.

Unit: none

Value range: **local0**, **local1**, **local2**, **local3**, **local4**, **local5**, **local6**, and **local7**.

Default value: local0

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

syslog_ident

Parameter description: Specifies the identifier of GaussDB messages in syslog logs when **log_destination** is set to **syslog**.

Parameter type: string.

Unit: none

Value range: a string.

Default value: **"postgres"**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

event_source

Parameter description: This parameter takes effect only in a Windows environment. It specifies the identifier of GaussDB messages in logs when **log_destination** is set to **eventlog**.

Parameter type: string.

Unit: none

Value range: a string.

Default value: **"PostgreSQL"**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

6.3.9.2 Logging Time

client_min_messages

Parameter description: Specifies the level of messages sent to the client. All messages at or above the specified level are sent.

Parameter type: enumerated type

Unit: none

Value range: The message levels are **debug5**, **debug4**, **debug3**, **debug2**, **debug1**, **log**, **info**, **notice**, **warning**, **error**, **fatal**, and **panic** in ascending order. For details about the parameters, see **Table 6-23**.

NOTICE

- In general, the lower the set level, the more messages will be sent to the client.
- For client log messages, if **client_min_messages** is set to **fatal** or **panic**, its effective value will be forcibly adjusted to **error**. Regardless of the level set in **client_min_messages**, messages at the **info** level are always sent to the client.
- When a client is connected to a CN, debug (**debug5**, **debug4**, **debug3**, **debug2**, and **debug1**) and log messages are not sent to the client due to security and performance reasons. To view these two types of logs, view the server logs of the CN.

Default value: **notice**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

log_min_messages

Parameter description: Specifies the level of messages written to server logs. All messages at or above the specified level are written.

Parameter type: enumerated type

Unit: none

Value range: The message levels are **debug5**, **debug4**, **debug3**, **debug2**, **debug1**, **log**, **info**, **notice**, **warning**, **error**, **fatal**, and **panic** in ascending order. For details about the parameters, see **Table 6-23**.

NOTICE

- In general, the lower the set level, the more messages will be written into server logs.
- For server log messages, if **log_min_messages** is set to a level not higher than **error**, all messages at the **log** level will be written into server logs.
- Frequent printing affects system performance and stability. Therefore, the debug levels 1–5 are generally used for onsite fault locating. You are advised to enable these levels by module (see **logging_module**) and promptly reset the levels afterward.

Default value: **warning**

Setting method: This is a SUSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

log_min_error_statement

Parameter description: Specifies the level of messages corresponding to SQL statements written to server logs. All SQL statements corresponding to messages at or above the specified level are written.

Parameter type: enumerated type

Unit: none

Value range: The message levels are **debug5**, **debug4**, **debug3**, **debug2**, **debug1**, **log**, **info**, **notice**, **warning**, **error**, **fatal**, and **panic** in ascending order. For details about the parameters, see **Table 6-23**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTICE

- In general, the lower the set level, the more SQL statements will be written into server logs.
- For SQL messages in server logs, if the level is set to **error** or lower, the SQL statements corresponding to messages at the **log** level will be written into server logs.
- If an SQL statement contains personal information and you do not need to record the SQL statement that reports an error, you can set **log_min_error_statement** to **panic**.

Default value: **error**

Setting method: This is a SUSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

log_min_duration_statement

Parameter description: When the execution time of an SQL statement is greater than or equal to the value of this parameter, the SQL statement and its execution time are recorded.

Setting **log_min_duration_statement** makes it easy to trace query statements that need to be optimized. For clients using extended query protocols, the time required for parsing, binding, and executing steps are logged independently.

Parameter type: integer.

Unit: milliseconds

NOTICE

When you use this parameter together with **log_statement**, the SQL statements that have been logged by **log_statement** will not be repeatedly logged. If syslog is not used, you are advised to use **log_line_prefix** to record PIDs or session IDs so that statement messages and execution time messages can be associated based on PIDs or session IDs.

Value range: –1 to 2147483647

- **-1** indicates that this function is disabled.
- **0** indicates that all SQL statements and their execution time are recorded.
- Positive integer indicates that an SQL statement and its execution time are recorded when the execution time of the SQL statement is greater than or equal to the value of this parameter.

Default value: **3000 (that is, 3s)**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Setting method: This is a SUSET parameter. Set it based on instructions provided in **Table 6-1**. If the value is an integer, the default unit is ms. If the value contains a unit, the unit must be ms, s, min, h, or d. For example, if the value is **600** without a unit, **log_min_duration_statement** indicates 600 ms. If the value is **10min**, **log_min_duration_statement** indicates 10 minutes.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If the value is out of the range or the value contains a unit other than ms, s, min, h, and d, an error message is displayed.

backtrace_min_messages

Parameter description: Specifies the level of messages corresponding to function stack information written to server logs. All stack information corresponding to messages at or above the specified level is written.

Parameter type: enumerated type

Unit: none

Value range: The message levels are **debug5**, **debug4**, **debug3**, **debug2**, **debug1**, **log**, **info**, **notice**, **warning**, **error**, **fatal**, and **panic** in ascending order. For details about the parameters, see **Table 6-23**.

NOTICE

- In general, the lower the level, the more stack information is written to the server logs.
- This parameter is used to locate faults on site. Frequent printing of function stacks affects system overhead and stability. Therefore, you are advised to set **backtrace_min_messages** to **fatal** or **panic** during fault locating.

Default value: **panic**

Setting method: This is a SUSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing. If the level is too low, concurrent thread stack printing may affect service execution in high-concurrency scenarios. For example, if this parameter is set improperly when a large number of concurrent connections are established, the processing efficiency of the connection thread pool will be slowed down, or even the database instance will become unreachable.

Table 6-23 explains message severities used by GaussDB. When logs are output to syslog or eventlog (only in the Windows environment, this parameter is not involved in GaussDB), GaussDB performs the conversion as shown in the following table.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 6-23 Message severity levels

Severity	Description	System Log	Event Log
debug[1-5]	Provides detailed debug information.	DEBUG	INFORMATION
log	Reports information of interest to administrators, for example, checkpoint activity.	INFO	INFORMATION
info	Provides information implicitly requested by users, for example, output from **VACUUM VERBOSE**.	INFO	INFORMATION
notice	Provides information that might be helpful to users, for example, truncation of long identifiers and index created as part of the primary key.	NOTICE	INFORMATION
warning	Provides warnings of likely problems, for example, COMMIT outside a transaction block.	NOTICE	WARNING
error	Reports an error that causes a command to terminate.	WARNING	ERROR
fatal	Reports the reason that causes a session to terminate.	ERR	ERROR
panic	Reports an error that caused all database sessions to terminate.	CRIT	ERROR

6.3.9.3 Logging Content

debug_print_parse

Parameter description: Specifies whether to print parsing tree results.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The printing is enabled.
- **off**: The printing is disabled.

Default value: **off**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

debug_print_rewritten

Parameter description: Specifies whether to print query rewriting results.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The printing is enabled.
- **off**: The printing is disabled.

Default value: **off**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

debug_print_plan

Parameter description: Specifies whether to print the query execution plan to logs.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The query execution plan is printed to logs.
- **off**: The query execution plan is not printed to logs.

Default value: **off**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTICE

- Debugging information about **debug_print_parse**, **debug_print_rewritten**, and **debug_print_plan** is printed only when the log level is set to **log** or higher. When these parameters are set to **on**, their debugging information will be recorded in server logs and will not be sent to client logs. You can change the log level by setting **client_min_messages** and **log_min_messages**.
- Do not call the **gs_encrypt_aes128** and **gs_decrypt_aes128** functions when **debug_print_plan** is set to **on**, preventing the risk of sensitive information disclosure. You are advised to filter parameter information of the **gs_encrypt_aes128** and **gs_decrypt_aes128** functions in the log files generated when **debug_print_plan** is set to **on** before providing the log files to external maintenance engineers for fault locating. After you finish using the logs, delete them as soon as possible.

debug_pretty_print

Parameter description: If this parameter is enabled, logs generated by **debug_print_parse**, **debug_print_rewritten**, and **debug_print_plan** are indented and output in a longer format that is easy to read.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The indentation is enabled.
- **off**: The indentation is disabled.

Default value: **on**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

log_checkpoints

Parameter description: Specifies whether the statistics on checkpoints and restart points are recorded in the server logs. When this parameter is set to **on**, statistics on checkpoints and restart points are recorded in the log messages, including the number of buffers written and the time spent in writing them.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: Statistics on checkpoints and restart points are recorded in the server logs.
- **off**: Statistics on checkpoints and restart points are not recorded in the server logs

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Default value: **off**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

log_connections

Parameter description: Specifies whether to record logs of connection requests from the client. Logs include the IP address, port number, username, database name, and duration of key steps in the GaussDB connection setup process.

NOTE

Some client programs (such as gsql) attempt to connect to the database twice when determining whether a password is required. Therefore, the log message may contain duplicate "connection receive" (indicating that a connection request is received).

Parameter type: Boolean.

Unit: none

Value range:

- **on** indicates that the logs are recorded.
- **off** indicates that the logs are not recorded.

Default value: **off**

Setting method: This is a BACKEND parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

log_disconnections

Parameter description: Specifies whether to record disconnection request information of the client.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The information is recorded.
- **off**: The information is not recorded.

Default value: **off**

Setting method: This is a BACKEND parameter. Set it based on instructions provided in **Table 6-1**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

log_duration

Parameter description: Specifies whether to record the duration of every completed SQL statement. For clients using extended query protocols, the time required for parsing, binding, and executing steps are logged independently.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The execution time of all completed SQL statements is recorded.
- **off**: The execution time of SQL statements is not recorded.

NOTE

If this parameter is set to **on** or **log_min_duration_statement** is set to **0**, the execution time of each completed SQL statement is recorded. The difference is that **log_min_duration_statement** forcibly records SQL statements.

Default value: **off**

Setting method: This is a SUSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

log_error_verbosity

Parameter description: Specifies the content output to the server log for each message that is logged.

Parameter type: enumerated type.

Unit: none

Value range:

- **terse**: The record excludes the DETAIL, HINT, QUERY, and CONTEXT error information.
- **verbose**: The record includes the SQLSTATE error code, the source code file name, function name, and number of the line in which the error occurs.
- **default**: The record includes the DETAIL, HINT, QUERY, and CONTEXT error information, and excludes the SQLSTATE error code, the source code file name, function name, and number of the line in which the error occurs.

Default value: **default**

Setting method: This is a SUSET parameter. Set it based on instructions provided in **Table 6-1**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Setting suggestion: Set this parameter according to the requirement for the detail level of the log message.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

log_hostname

Parameter description: By default, connection log messages only show the IP address of the connecting host. If this parameter is enabled, the host name is also recorded. It may take some time to parse the host name. Therefore, the database performance may be affected.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The host name is recorded.
- **off**: The host name is not recorded.

Default value: **off**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: The database performance may be affected when this parameter is enabled.

log_line_prefix

Parameter description: Specifies the prefix format of each log. A prefix is a printf-style string that is output at the beginning of each line of the log. The escape character starting with **%** indicates the status information. For details, see **Table 6-24**.

Table 6-24 Escape characters

Escape Character	Status Information
%a	Application name.
%u	Username.
%d	Database name.
%r	Remote host name or IP address and remote port. If **log_hostname** is set to **off**, only the IP address and remote port are displayed.
%h	Remote host name or IP address. If **log_hostname** is set to **off**, only the IP address is displayed.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Escape Character	Status Information
%p	Thread ID.
%t	Timestamp without milliseconds (no time zone in the Windows OS).
%m	Timestamp with milliseconds.
%n	Node to which an error is reported.
%i	Command tag: type of command executed in the current session.
%e	SQLSTATE error code.
%c	Session ID. For details, see the note below the table.
%l	Number of the log line for each session or thread, starting at 1.
%s	Thread startup time.
%v	Virtual transaction ID (backend ID/local XID).
%x	Transaction ID (**0** indicates that no transaction ID is assigned).
%q	Produces no output. If the current thread is a backend thread, this escape sequence is ignored and subsequent escape sequences are processed. Otherwise, this escape sequence and subsequent escape sequences are all ignored.
%S	Session ID.
%T	Trace ID.
%%	The character %.

NOTE

The %c escape character prints a session ID consisting of two 4-byte hexadecimal numbers separated by a period (.). The two hexadecimal numbers indicate the thread startup time and thread ID, respectively. Therefore, %c can also be used to record the thread startup time and thread ID, which saves space. For example, you can use the following query to generate such a hexadecimal session ID from pg_stat_activity:

```
SELECT to_hex(EXTRACT(EPOCH FROM backend_start)::integer) || '.' ||
       to_hex(pid)
FROM pg_stat_activity;
```

- If you set a nonempty value for **log_line_prefix**, you should usually make its last character be a space, to provide visual separation from the rest of the log line. A punctuation character can be used, too.
- Syslog generates its own timestamp and thread ID information. Therefore, you do not need to include those escape characters when you are logging in to syslog.

Parameter type: string.

Unit: none

Value range: a string.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Default value: **'%m %n %u %d %h %p %S %x %a '**

NOTE

%m %n %u %d %h %p %S %x %a indicates the session start timestamp, error reporting node, username, database name, remote host name or IP address, thread ID, session ID, transaction ID, and application name.

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Set this parameter based on the requirements for log status information.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

log_lock_waits

Parameter description: When the time for a session to wait for a lock exceeds the value of **deadlock_timeout**, this parameter specifies whether to record the message in the database log. This helps determine whether the lock wait event causes problems such as deadlock.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The information is recorded.
- **off**: The information is not recorded.

Default value: **off**

Setting method: This is a SUSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

log_statement

Parameter description: Specifies which SQL statements are recorded. For clients using extended query protocols, logging occurs when an execute message and values (enclosed by a pair of single quotation marks) of bound parameters are received.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTICE

- Statements that contain simple syntax errors are not logged even if **log_statement** is set to **all** because logging occurs only after basic parsing has been completed and the statement type is determined. If an extended query protocol is used, statements that fail before the execution phase (during parsing or planning) are not logged, either. Set **log_min_error_statement** to **ERROR** or lower to log such statements.
- If this parameter is set to a value other than **none**, the statement audit function is enabled. The database administrator can access server logs to view SQL execution records.

Parameter type: enumerated type.

Unit: none

Value range:

- **none**: No SQL statement is recorded.
- **ddl**: All data definition statements, such as CREATE, ALTER, and DROP, are recorded.
- **mod**: All DDL statements and data modification statements, such as INSERT, UPDATE, DELETE, TRUNCATE, and COPY FROM, are recorded.
- **all**: All statements, including the PREPARE, EXECUTE, and EXPLAIN ANALYZE statements, are recorded.

Default value: **none**

Setting method: This is a SUSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Set this parameter based on whether SQL statements need to be recorded.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

log_temp_files

Parameter description: Specifies whether to record the deletion information about temporary files whose size is greater than the value of this parameter. Temporary files can be created for sorting, hashing, and storing temporary querying results. If the recording is enabled, a log entry is generated for each temporary file when it is deleted.

Parameter type: integer.

Unit: KB

Value range: –1 to 2147483647

- A positive value indicates that the deletion information of temporary files whose size is larger than the value specified by **log_temp_files** is recorded.
- **0** indicates that the delete information of all temporary files is recorded.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **-1** indicates that the delete information of any temporary files is not recorded.

Default value: **-1**

Setting method: This is a SUSET parameter. Set it based on instructions provided in **Table 6-1**. If the value is an integer, the default unit is KB. If the value contains a unit, the unit must be KB, MB, or GB. For example, if the value is **16384** without a unit, **log_temp_files** indicates 16384 KB. If the value is **16MB**, **log_temp_files** indicates 16 MB.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this parameter is set to a value other than –1, more temporary files that meet the recording requirements indicate more logs are recorded, affecting the system performance. If the value is out of the range or the value contains a unit other than KB, MB, and GB, an error message is displayed.

log_timezone

Parameter description: Specifies the time zone used for timestamps written in the server log. Different from **TimeZone**, this parameter takes effect for all sessions in the database.

Parameter type: string.

Unit: none

Value range: a string. You can obtain it by querying the **PG_TIMEZONE_NAMES** view.

Default value: Set this parameter based on the OS time zone.

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

NOTE

The default value will be changed when **gs_initdb** is used to set system environments.

logging_module

Parameter description: Specifies whether module logs are output on the server. This parameter depends on the setting of the **log_min_messages** parameter. Module logs whose levels are lower than the value of **log_min_messages** will not be printed.

Parameter type: string.

Unit: none

Value range:

ALL,on(),off(COMMAND,DFS,GUC,GSCLEAN,HDFS,ORC,SLRU,MEM_CTL,AUTOVAC,CACHE,ADIO,SSL,GDS,TBLSPC,WLM,OBS,INDEX,EXECUTOR,OPFUSION,GPC,GSC,VEC_EXECUTOR,STREAM,LLVM,OPT,OPT_REWRITE,CB

```

Table 6-25 Description of some logging_module modules

Module	Description
COMM_IPC	Specifies whether to print the packet sending and receiving status between nodes. This is a switch for locating communication performance problems.
COMM_PARAM	Specifies whether to print the **session** parameter settings during node communication. This is a switch for locating communication performance problems.

NOTICE

CN_RETRY and **BYTECODE** do not take effect in the current version.

Default value: **"off(ALL)"**. That is, all module logs are disabled by default.

Setting method: This is a session-level parameter, and you are advised not to use the gs_guc tool to set it.

You can run **SHOW logging_module** to check which modules are controllable. For example, the query output result is as follows:

```
gaussdb=# show logging_module;
logging_module
-------------------
```

```
ER,INSTR,WDR_SNAPSHOT,GSMONITOR,WDR_REPORT,ASP_REPORT,BLACKBOX,INCRE_CKPT,INCRE_BG_WRI
TER,DBL_WRT,RTO_RPO,HEARTBEAT,COMM_IPC,COMM_PARAM,TIMESERIES,SCHEMA,GTT,SEGMENT_PAGE,L
IGHTPROXY,HOTKEY,THREAD_POOL,OPT_AI,WALRECEIVER,USTORE,UPAGE,UBTREE,UNDO,TIMECAPSULE,GE
N_COL,DCF,AI4DB,DB4AI,ABO,MOD_ABOFEEDBACK,ASCEND,PLDEBUGGER,ADVISOR,SEC,SEC_FE,SEC_LEGER,
SEC_POLICY,SEC_SDD,SEC_TDE,COMM_FRAMEWORK,COMM_PROXY,COMM_POOLER,COMM_STATUS,VACU
UM,JOB,SPI,NEST_COMPILE,RESOWNER,GSSTACK,LOGICAL_DECODE,GPRC,DISASTER_READ,STANDBY_READ,
SQL_APPLY,REPSYNC,SQLPATCH,PARTITION,UBT_NEWPAGE,GS_DEPENDENCY,GPI,LWLOCK,LOCK,UNIQUE_S
QL,GSI,GLC,SRF,DBLINK,BARRIER_CREATOR,EXRTO_PAGE_P,SEQ_TUP_P,BT_TUP_P,DISPATCH_VERIFY,HBKT,HB
KT_CBI,DBE_STATS,DBE_XMLGEN,MESSAGE_QUEUE,DBE_ALERT,UPDATE_DIST_COL,GS_ILM,GSPERF,PARAME

B,EXEC_CACHE,ROWID,WAL_IMAGE_CHECK,CHECK_XLOG_GEN,SHARE_STORAGE,MOD_TOOLKIT,RESULT_CH
ECK)
(1 row)
```

Controllable modules are identified by uppercase letters, and the special ID **ALL** is used for setting all module logs. You can control the output of module logs by setting the parameter to **on** or **off**. Enable log output for SSL:

```
gaussdb=# set logging_module='on(SSL)';
SET
gaussdb=# show
logging_module;
      logging_module
-------------------
```

```

ECK)
(1 row)

gaussdb=# set logging_module='on(ALL)';
SET
gaussdb=# show
logging_module;
       logging_module
-------------------
```

Parameter type: Boolean.

Unit: none

Value range:

- **on**: Logs are printed.
- **off**: Logs are not printed.

Default value: **off**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

opfusion_debug_mode

Parameter description: Checks whether simple queries are optimized for debugging. If this parameter is set to **log**, you can view the specific reasons why queries are not optimized in the DN execution plans.

Parameter type: enumerated type.

Unit: none

Value range:

- **off**: This function is disabled.
- **log**: This function is enabled. You can view the specific reasons why queries are not optimized in the DN execution plans.

NOTICE

- You need to set **max_datanode_for_plan** to view the DN execution plans.
- To view the reasons why queries are not optimized in the log, set the parameter to **log**, **log_min_messages** to **debug4**, and **logging_module** to **'on(OPFUSION)'**. Note that a large number of log messages may be generated. Therefore, execute only a small number of jobs during debugging.

Default value: **off**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

enable_debug_vacuum

Parameter description: Specifies whether to allow output of some VACUUM-related logs for problem locating. This parameter is used only by developers. Common users are advised not to use it.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: enabled.
- **off**: disabled.

Default value: **off**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

enable_err_stack

Parameter description: Specifies whether to print stack information for errors whose **ACTION** is "Contact Huawei technical support."

Parameter type: Boolean.

Unit: none

Value range:

- **on**: enabled.
- **off**: disabled.

Default value: **on**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

enable_show_err_code

Parameter description: Specifies whether to display error codes for frontend connections such as gsql.

Parameter type: Boolean.

Unit: none

Value range:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **on**: enabled.
- **off**: disabled.

Default value: **off**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

6.3.9.4 Using CSV Log Output

Prerequisites

- The **log_destination** parameter is set to **csvlog**.
- The **logging_collector** parameter is set to **on**.

Definition of csvlog

Log lines are emitted in comma separated values (CSV) format.

An example table definition for storing CSV-format log output is shown as follows:

```
CREATE TABLE gaussdb_log
(
log_time timestamp(3) with time zone,
node_name text,
user_name text,
database_name text,
process_id bigint,
connection_from text,
"session_id" text,
session_line_num bigint,
command_tag text,
session_start_time timestamp with time zone,
virtual_transaction_id text,
transaction_id bigint,
query_id bigint,
module text,
error_severity text,
sql_state_code text,
message text,
detail text,
hint text,
internal_query text,
internal_query_pos integer,
context text,
query text,
query_pos integer,
location text,
application_name text
);
```

For details, see **Table 6-26**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 6-26 Meaning of each csvlog field

Field	Description	Field	Description
log_time	Timestamp in milliseconds	module	Log module
node_name	Node name	error_severity	ERRORSTATE code
user_name	Username	sql_state_code	SQLSTATE code
database_name	Database name	message	Error message
process_id	Thread ID	detail	Detailed error message
connection_from	Port number of the client host	hint	Prompt message
session_id	Session ID	internal_query	Internal query (This field is used to query the information leading to errors if any.)
session_line_num	Number of lines in each session	internal_query_pos	Pointer for an internal query
command_tag	Command tag	context	Environment
session_start_time	Start time of a session	query	Character count at the position where errors occur
virtual_transaction_id	Regular transaction	query_pos	Pointer at the position where errors occur
transaction_id	Transaction ID	location	Position where errors occur in the GaussDB source code if **log_error_verbosity** is set to **verbose**.
query_id	Query ID	application_name	Application name

Run the **COPY FROM** command to import a log file to this table.

```
COPY postgres_log FROM '/opt/data/gs_log/logfile.csv' WITH csv;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

The log name (**logfile.csv**) here needs to be replaced with the name of a log generated.

Simplifying Input

Simplify importing CSV log files by performing the following operations:

- Set **log_filename** and **log_rotation_age** to provide a consistent and predictable naming solution for log files. By doing this, you can predict when an individual log file is complete and ready to be imported.
- Set **log_rotation_size** to **0** to disable size-based log rollback, as it makes the log file name difficult to predict.
- Set **log_truncate_on_rotation** to **on** so that old log data cannot be mixed with the new one in the same file.

6.3.10 Alarm Reporting

During the running of cluster, error can be reported and informed to users in a timely manner. You can view system_alarm logs in *$GAUSSLOG*/**cm**, *$GAUSSLOG*/**gs_log/gtm**, *$GAUSSLOG*/**gs_log**, or *$GAUSSLOG*/**roach/agent**.

enable_alarm

Parameter description: Specifies whether to enable the alarm reporting thread to report possible fault scenarios in the database.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The alarm reporting thread is enabled.
- **off**: The alarm reporting thread is disabled.

Default value: **on**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this parameter is disabled, users cannot perceive some fault scenarios in the database.

NOTE

This parameter takes effect only on CNs and DNs.

connection_alarm_rate

Parameter description: Specifies the ratio restriction on the maximum number of allowed parallel connections to the database. The maximum number of concurrent connections to the database is **max_connections** x **connection_alarm_rate**. When the number of concurrent connections exceeds

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

max_connections x **connection_alarm_rate**, the backend prints the connection information log (**connection_log**), you can view the pg_stat_activity view and thread pool view LOCAL_THREADPOOL_STATUS in logs. (To view the pg_stat_activity view, you need to enable the tracing function. To view the thread pool view LOCAL_THREADPOOL_STATUS, you need to enable the thread pool function.)

Parameter type: floating-point number

Unit: none

Value range: 0 to 1

Default value: **0.9**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

alarm_report_interval

Parameter description: Specifies the interval at which an alarm is reported.

Parameter type: integer.

Unit: seconds (s)

Value range: 0 to 2147483647

Default value: **10**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**. The value cannot contain a unit.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings:

- If the value is too large and the same alarm is detected for multiple times within the specified alarm reporting interval, key alarms will be lost.
- If the value is too small and the same alarm is detected continuously within the specified alarm reporting interval, the alarm is reported frequently.

alarm_component

Parameter description: Certain alarms are suppressed during alarm reporting. That is, the same alarm will not be repeatedly reported by an instance within the period specified by **alarm_report_interval**. Its default value is **10s**. In this case, the parameter specifies the location of the alarm component that is used to process alarm information. Only the SYSADMIN user can access this parameter.

Parameter type: string.

Unit: none

Value range: valid file name.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- If **--alarm-type** in the gs_preinstall script is set to **5**, no third-party component is connected and alarms are written into system_alarm logs. In this case, the value of **alarm_component** is **/opt/huawei/snas/bin/snas_cm_cmd**.
- If **--alarm-type** in the gs_preinstall script is set to **1**, a third-party component is connected. In this case, the value of **alarm_component** is the absolute path of the executable program of the third-party component.

Default value: **"/opt/huawei/snas/bin/snas_cm_cmd"**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**. The value cannot contain a unit.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

table_skewness_warning_threshold

Parameter description: Specifies the threshold for triggering a table skew alarm.

Parameter type: floating-point number

Unit: none

Value range: 0 to 1

Default value: **1**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value. You can adjust the value based on the sensitivity to table skew in service scenarios.

Risks and impacts of improper settings: If this parameter is set to a small value, the system may be more sensitive to table skew. There is no significant risk.

table_skewness_warning_rows

Parameter description: Specifies the number of rows for triggering a table skew alarm.

Parameter type: integer.

Unit: none

Value range: 0 to 2147483647

Default value: **100000**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value. You can adjust the value based on the sensitivity to table skew in service scenarios.

Risks and impacts of improper settings: If this parameter is set to a small value, the system may be more sensitive to table skew. There is no significant risk.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

6.3.11 Statistics During the Database Running

6.3.11.1 Query and Index Statistics Collector

The query and index statistics collector is used to collect statistics during database running. The statistics include the times of inserting and updating a table and index, the number of disk blocks and tuples, and the time required for the last cleanup and analysis on each table. The statistics can be viewed by querying the system view pg_stats and the system catalog pg_statistic. The following parameters are used to set the statistics collection feature in the server scope:

track_activities

Parameter description: Specifies whether to collect statistics about the commands that are being executed in each session. For a stored procedure, if this parameter is enabled, you can view the PERFORM statement, stored procedure calling statement, SQL statement, and OPEN CURSOR statement that are being executed in the stored procedure in the pg_stat_activity view.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The statistics collection function is enabled.
- **off**: The statistics collection function is disabled.

Default value: **on**

Setting method: This is a SUSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this parameter is set to **off**, the space recycling capability of the storage engine is affected, causing space expansion.

track_counts

Parameter description: Specifies whether to collect statistics about database activities. Database statistics are required when the autovacuum process checks for databases that need to be vacuumed. Therefore, the default value is set to **on**.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The statistics collection function is enabled.
- **off**: The statistics collection function is disabled.

Default value: **on**

Setting method: This is a SUSET parameter. Set it based on instructions provided in **Table 6-1**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this parameter is set to **off**, the space recycling capability of the storage engine is affected, causing space expansion.

track_procedure_sql

Parameter description: Specifies whether the SQL statements that are being executed in the stored procedure are printed in the **query** column in the pg_stat_activity system view.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: When a stored procedure is called, the statements that are being executed by the stored procedure are printed in the query column of pg_stat_activity.
- **off**: When a stored procedure is called, only statements for calling the stored procedure are printed in the query column of pg_stat_activity.

Default value: **on**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

track_io_timing

Parameter description: Specifies whether to collect statistics about I/O timing in the database. The I/O timing statistics can be queried by using the **pg_stat_database** parameter. When this parameter is enabled, the collector repeatedly queries the OS information at the current time, which may cause significant cost on some platforms. Therefore, the default value is **off**.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The statistics collection function is enabled.
- **off**: The statistics collection function is disabled.

Default value: **off**

Setting method: This is a SUSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

track_functions

Parameter description: Specifies whether to collect statistics of the number and duration of function calls.

NOTE

When the SQL functions are set to inline functions queried by the calling, these SQL functions cannot be traced no matter the parameter is enabled or not.

Parameter type: enumerated type

Unit: none

Value range:

- **pl**: Only procedural language functions are traced.
- **all**: SQL language functions are traced.
- **none**: The function tracing function is disabled.

Default value: **none**

Setting method: This is a SUSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

track_activity_query_size

Parameter description: Specifies byte counts of the current running commands used to trace each active session. If the actual number of bytes in a command is greater than the value of this parameter, the command is truncated.

Parameter type: integer

Unit: bytes

Value range: 100 to 102400

Default value: 1024

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Set this parameter based on the actual service scenario.

Risks and impacts of improper settings: Setting a larger value will increase the shared memory usage. If the value is too large, the memory of other modules may be insufficient. Before modifying this parameter, make sure you understand its meaning and fully verify the change in a test environment.

update_process_title

Parameter description: Specifies whether to control statistics updated with a thread name each time the server receives a new SQL statement.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

The thread name can be viewed on Windows task manager by running the **ps** command.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The statistics collection function is enabled.
- **off**: The statistics collection function is disabled.

Default value: **off**

Setting method: This parameter is a fixed INTERNAL parameter and cannot be modified.

Setting suggestion: This parameter can only be viewed.

Risks and impacts of improper settings: none

stats_temp_directory

Parameter description: Specifies the directory for storing temporary statistics. Only the SYSADMIN user can access this parameter.

NOTE

If a RAM-based file system directory is used, the actual I/O cost can be lowered and the performance can be improved.

Parameter type: string.

Unit: none

Value range: valid directory.

Default value: **"pg_stat_tmp"**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

enable_gsstat_cache

Parameter description: Specifies whether to enable cache acceleration for PgStat functions.

PgStat functions include pg_stat_get_numscans, pg_stat_get_tuples_returned, pg_stat_get_tuples_fetched, pg_stat_get_tuples_inserted, pg_stat_get_tuples_updated, pg_stat_get_tuples_deleted, pg_stat_get_tuples_hot_updated, pg_stat_get_live_tuples, pg_stat_get_dead_tuples, pg_stat_get_autovacuum_count, pg_stat_get_autoanalyze_count, pg_stat_get_blocks_fetched, pg_stat_get_blocks_hit, pg_timestamp stat_get_last_autoanalyze_time, pg_timestamp stat_get_last_autovacuum_time, and pg_timestamp stat_get_last_updated.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The cache acceleration function is enabled for PgStat functions.
- **off**: The cache acceleration function is disabled for PgStat functions.

Default value: **off**

Setting method: This is a SUSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: If this parameter is disabled and the query of PgStat-related views using the preceding functions is slow, you are advised to enable this parameter.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

gsstat_cache_size

Parameter description: Specifies the maximum memory occupied by cache acceleration when the statistics of a specific partition are obtained.

Parameter type: integer

Unit: Megabytes

Value range: 1 to 10240

Default value: 1024

Setting method: This is a SUSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Set this parameter based on the actual service scenario.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

track_thread_wait_status_interval

Parameter description: Specifies the interval of collecting the thread status information.

Parameter type: integer

Unit: minute

Value range: 0 to 1440

Default value: **30**

Setting method: This is a SUSET parameter. Set it based on instructions provided in **Table 6-1**. For example, if this parameter is set to **100** without a unit, it indicates 100 minutes. If this parameter is set to **1d**, it indicates 1 day. The unit must be **min**, **h**, or **d** if required.

Setting suggestion: Retain the default value.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

enable_save_datachanged_timestamp

Parameter description: Specifies whether to record the time when **INSERT**, **UPDATE**, **DELETE**, or **EXCHANGE**/**TRUNCATE**/**DROP PARTITION** is performed on table data.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The time when an operation is performed on table data will be recorded.
- **off**: The time when an operation is performed on table data will not be recorded.

Default value: **on**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

plan_collect_thresh

Parameter description: Collects statistics about the plans that are being executed in each session.

Parameter type: integer

Unit: none

Value range: –1 to 2147483647

- **–1**: Plans that are being executed are not collected.
- **0**: If the current SQL execution time is greater than or equal to the value of **log_min_duration_statement** and the total number of tuples processed by all operators in the plan is greater than or equal to 10000, the system starts to collect plans in running state. Each time the total number of tuples processed by all operators exceeds 10000, a collection is performed.
- Value greater than **0**: When the total number of tuples incrementally returned by all operators in a plan is greater than or equal to the value of this parameter, plans that are being executed are collected once.

Default value: **0**

Setting method: This is a SUSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

track_sql_count

Parameter description: Specifies whether to collect statistics about the statements (SELECT, INSERT, UPDATE, MERGE INTO, and DELETE) that are being executed in a session.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The statistics collection function is enabled.
- **off**: The statistics collection function is disabled.

Default value: **on**

Setting method: This is a SUSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

NOTE

If this parameter is disabled, the query result is 0.

6.3.11.2 Hotspot Key Statistics

In the distributed architecture, if applications access a node in a short period of time, the resource usage of the node is too high, affecting the normal running of the database. GaussDB provides the function of quickly detecting hotspot keys to quickly determine whether there are hotspot keys and the distribution of hotspot keys.

enable_hotkeys_collection

Parameter description: Specifies whether to automatically collect statistics on the accessed key values in the database.

NOTE

- If you set parameters using gs_guc set, you need to restart the database for the GUC parameters to take effect. During the restart, hotspot key information is cleared.
- When the GUC parameter is disabled, the query result of the hotspot key is empty and a message is displayed indicating that the GUC parameter is disabled. However, when the function is disabled, the hotspot key clearance API can still be used.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The statistics collection function is enabled.
- **off**: The statistics collection function is disabled.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Default value: **off**

Setting method: This is a SUSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Enable this parameter when the hotspot detection function is required.

Risks and impacts of improper settings: If this function is enabled, the TPC-C performance slightly deteriorates by less than 5%, and each instance occupies 500 MB memory resources.

6.3.12 Workload Management

If database resource usage is not controlled, concurrent tasks may preempt resources. As a result, the OS will be overloaded and cannot respond to user tasks; or even crash and cannot provide any services to users. The workload and management of GaussDB balance the database workload based on available resources to prevent database overloads.

use_workload_manager

Parameter description: Specifies whether to enable the resource and management function. This parameter must be set to a same value on CNs and DNs.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The resource management function is enabled.
- **off**: The resource management function is disabled.

Default value: **on**

Setting method: This is a SUSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this resource management function is disabled, many resource management functions will be affected. Therefore, you are advised not to disable this function.

NOTE

- If method 2 in **Table 6-1** is used to change the parameter value, the new value takes effect only for the threads that are started after the change. In addition, the new value does not take effect for new jobs that are executed by background threads and reused threads. You can make the new value take effect for these threads by using **kill session** or restarting the node.
- After the value of **use_workload_manager** changes from **off** to **on**, statistics about storage resources when **use_workload_manager** was **off** are not collected. To collect statistics about such resources, run the following SQL statement:

```
SELECT gs_wlm_readjust_user_space(0);
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

enable_control_group

Parameter description: Specifies whether to enable the Cgroup function. This parameter must be set to a same value on CNs and DNs.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The Cgroups function is enabled.
- **off**: The Cgroups function is disabled.

Default value: **on**

Setting method: This is a SIGHUP parameter. Set it based on the corresponding setting method in **Table 6-1**. When you change the parameter value using method 2 listed in the table, the new value takes effect only for the thread that is started after the change.

Setting suggestion: The modification does not take effect for background threads and new jobs that are reused by threads. If you want such threads to identify parameter changes in real time, kill sessions or restart nodes.

Risks and impacts of improper settings: If this parameter and the resource management function (**use_workload_manager**) are enabled at the same time, the user resource management function takes effect, deteriorating the performance of jobs executed by users.

enable_cgroup_switch

Parameter description: Specifies whether a statement is automatically switched to the TopWD group when the statement is executed by control group type.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: A statement is automatically switched to the TopWD group when the statement is executed by control group type.
- **off**: A statement is not automatically switched to the TopWD group when the statement is executed by control group type.

Default value: **off**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

NOTE

This parameter is valid only when **enable_control_group** is set to **on**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

cgroup_name

Parameter description: Specifies the name of the Cgroup in use and changes the priority of items in the queue of the Cgroup.

If you set **cgroup_name** and then **session_respool**, the Cgroup associated with **session_respool** takes effect. If you reverse the order, the Cgroup associated with **cgroup_name** takes effect.

If the workload Cgroup level is specified during the **cgroup_name** change, the database does not check the Cgroup level. The level ranges from 1 to 10.

Parameter type: string.

Unit: none

Value range: name of an existing Cgroup.

Default value: **"DefaultClass:Medium"**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Do not use both **cgroup_name** and **session_respool**.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

NOTE

DefaultClass:Medium indicates the **Medium** Cgroup that belongs to the **Timeshare** Cgroup under the **DefaultClass** Cgroup.

enable_backend_control

Parameter description: Specifies whether the database permanent thread is bound to the **DefaultBackend** and **HaBackend** Cgroups. This parameter must be set to a same value on CNs and DNs.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: Permanent threads are bound to the **DefaultBackend** and **HaBackend** Cgroups.
- **off**: Permanent threads are not bound to the **DefaultBackend** and **HaBackend** Cgroups.

Default value: **on**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

This parameter is valid only when **enable_control_group** is set to **on**. The **HaBackend** Cgroup is used to control the CPU usage of heartbeat threads and WAL-related background threads to ensure high cluster availability.

enable_vacuum_control

Parameter description: Specifies whether the database permanent thread autovacuum worker is bound to the **Vacuum** Cgroup. This parameter must be set to a same value on CNs and DNs.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The autovacuum worker thread is bound to the **Vacuum** Cgroup.
- **off**: The autovacuum worker thread is not bound to the **Vacuum** Cgroup.

Default value: **on**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

NOTE

This parameter is valid only when **enable_control_group** is set to **on**.

enable_perm_space

Parameter description: Specifies whether to enable the perm space function. This parameter must be set to a same value on CNs and DNs.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The perm space management is enabled.
- **off**: The perm space management is disabled.

Default value: **on**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

parctl_min_cost

Parameter description: Specifies the execution cost threshold of a statement. If the execution cost of a statement exceeds the specified value, the statement is subject to the concurrent limit of a resource pool.

Parameter type: integer.

Unit: none

Value range: –1 to 2147483647

- If the value is **-1** or the cost of executing a statement is less than 10, the statement is not subject to the concurrency limit of the resource pool.
- If the value is greater than or equal to **0**, **enable_dynamic_workload** is set to **off**, and the cost of executing a statement exceeds the value and is greater than or equal to 10, the statement is subject to the concurrency limit of the resource pool.

Default value: **100000**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

cpu_collect_timer

Parameter description: Specifies how frequently CPU data is collected during statement execution on DNs.

Parameter type: integer.

Unit: seconds

Value range: 1 to 2147483647

Default value: **30**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**. The value cannot contain a unit.

Setting suggestion: A database administrator should set a proper collection frequency based on system resources (for example, CPU, I/O, and memory resources). A small value will affect the execution efficiency and a large value will reduce the accuracy of exception handling.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

memory_tracking_mode

Parameter description: Specifies the memory information recording mode.

Parameter type: enumerated type

Unit: none

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Value range:

- **none**: Memory statistics are not collected.
- **peak**: Memory statistics on the peak value of the query level are collected. The value is recorded in the database log and can also be output by using **explain analyze**.
- **normal**: Memory statistics are collected in real time but no file is generated.
- **executor**: A statistics file is generated, containing the context information of all allocated memory used on the execution layer.
- **fullexec**: A statistics file is generated, containing the information about all memory contexts requested by the execution layer.

Default value: **none**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

memory_detail_tracking

Parameter description: Specifies the memory context allocation priority of a thread and the plannodeid of the query for which the current thread is running. This parameter is used only in the debug version.

Parameter type: string.

Unit: none

Value range: a string.

Default value: **""**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value. You are not allowed to set this parameter.

Risks and impacts of improper settings: none

enable_resource_track

Parameter description: Specifies whether to enable the real-time resource monitoring function. This parameter must be set to a same value on CNs and DNs.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The resource monitoring is enabled.
- **off**: The resource monitoring is disabled.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Default value: **on**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

enable_resource_record

Parameter description: Specifies whether resource monitoring records are archived. If this parameter is set to **on**, records in the history views (GS_WLM_SESSION_HISTORY and GS_WLM_OPERATOR_HISTORY) are archived to the corresponding info views (GS_WLM_SESSION_INFO and GS_WLM_OPERATOR_INFO) at an interval of 3 minutes. After being archived, the records are deleted from the history views. This parameter must be set to a same value on CNs and DNs.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The resource monitoring records are archived.
- **off**: The resource monitoring records are not archived.

Default value: **off**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

enable_logical_io_statistics

Parameter description: Specifies whether to enable the logical I/O statistics function during resource monitoring. If this function is enabled, the **read_kbytes**, **write_kbytes**, **read_counts**, **write_counts**, **read_speed**, and **write_speed** fields in the PG_TOTAL_USER_RESOURCE_INFO view will collect statistics on the byte count, number of times, and speed of logical read and write. Fields related to logical read and write in the system catalogs GS_WLM_USER_RESOURCE_HISTORY and GS_WLM_INSTANCE_HISTORY will collect statistics on the logical read and write of related users and instances.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The logical I/O statistics function is enabled.
- **off**: The logical I/O statistics function is disabled.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Default value: **on**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

enable_instance_metric_persistent

Parameter description: Specifies whether the instance resource monitoring data is dumped. When this parameter is enabled, the instance monitoring data is saved to the system catalog GS_WLM_INSTANCE_HISTORY.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The instance resource monitoring data is dumped.
- **off**: The instance resource monitoring data is not dumped.

Default value: **on**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

instance_metric_retention_time

Parameter description: Specifies the retention days of the historical monitoring data of instance resources. This parameter is valid only when **enable_instance_metric_persistent** is set to **on**.

Parameter type: integer.

Unit: days

Value range: 0–3650

- If this parameter is set to **0**, the historical monitoring data of instance resources is permanently stored.
- If the value is greater than **0**, the historical monitoring data of instance resources is stored for the specified number of days.

Default value: **7**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**. The unit must be **d** if required.

Setting suggestion: Retain the default value.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

resource_track_level

Parameter description: Specifies the resource monitoring level of the current session. This parameter is valid only when **enable_resource_track** is set to **on**.

Parameter type: enumerated type

Unit: none

Value range:

- **none**: Resources are not monitored.
- **query**: Resources used at the query level are monitored.
- **operator**: Resources used at the query and operator levels are monitored.

Default value: **query**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

resource_track_cost

Parameter description: Specifies the minimum execution cost for resource monitoring on statements in the current session. This parameter is valid only when **enable_resource_track** is set to **on**.

Parameter type: integer.

Unit: none

Value range: –1 to 2147483647

- **-1** indicates that resource monitoring is disabled.
- A value ranging from 0 to 9 indicates that statements whose execution cost is greater than or equal to 10 will be monitored.
- A value greater than or equal to **10** indicates that statements whose execution cost exceeds this value will be monitored.

Default value: **100000**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

resource_track_duration

Parameter description: Specifies the minimum statement execution time that determines whether information about jobs of a statement recorded in the real-time view will be dumped to a historical view after the statement is executed. Job information will be dumped from the real-time view (with the suffix **statistics**) to a historical view (with the suffix **history**) if the statement execution time is no less than this value. This parameter is valid only when **enable_resource_track** is set to **on**.

Parameter type: integer.

Unit: seconds

Value range: 0 to 2147483647

- **0** indicates that historical information about all statements recorded in the real-time resource monitoring view are archived.
- If the value is greater than **0**, historical information about a statement whose execution time exceeds this value will be archived.

Default value: **60**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**. For example, if the value is **3600** without a unit, **resource_track_duration** indicates 3600s. If the value is **1h**, **resource_track_duration** indicates 1 hour. The unit must be **s**, **min**, **h**, or **d** if required.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

dynamic_memory_quota

Parameter description: Specifies the memory quota in adaptive load scenarios, that is, the proportion of maximum available memory to total system memory.

Parameter type: integer.

Unit: none

Value range: 1 to 100

Default value: **80**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

disable_memory_protect

Parameter description: Specifies whether to stop memory protection. To query system views when system memory is insufficient, set this parameter to **on** to stop

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

memory protection. This parameter is used only to diagnose and debug the system when system memory is insufficient. Set it to **off** in other scenarios.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: Memory protection is disabled.
- **off**: Memory protection is enabled.

Default value: **off**

Setting method: This parameter is a USERSET parameter and is valid only for the current session. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

query_band

Parameter description: Specifies the user-defined job type of the current session.

Parameter type: string.

Unit: none

Value range: a string.

Default value: **""**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

memory_fault_percent

Parameter description: Specifies the ratio of memory allocation failures during the memory fault test. This parameter is used only in the DEBUG version.

Parameter type: integer.

Unit: none

Value range: 0 to 2147483647

Default value: **0**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

enable_bbox_dump

Parameter description: Specifies whether to enable the black box function and whether to generate core files when the core mechanism is not configured in the system. This function is valid only for CNs or DNs. For CM Agent, CM Server, GTM, and fenced UDF, the system core mechanism must be configured to capture core files.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The black box function is enabled.
- **off**: The black box function is disabled.

Default value: **on**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

NOTE

The generation of core files by the black box function depends on the open ptrace API of the OS. If the permission is insufficient (errno = 1), ensure that the **/proc/sys/kernel/yama/ptrace_scope** configuration is correct.

bbox_dump_count

Parameter description: Specifies the maximum number of core files that are generated by GaussDB and can be stored in the path specified by **bbox_dump_path**. If the number of core files exceeds this value, old core files will be deleted. This parameter is valid only when **enable_bbox_dump** is set to **on**.

NOTE

When core files are generated concurrently, the number of files may be larger than the value of **bbox_dump_count**.

Parameter type: integer.

Unit: none

Value range: 1 to 20

Default value: **8**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

bbox_dump_path

Parameter description: Specifies the path where the black box core files are generated. This parameter is valid only when **enable_bbox_dump** is set to **on**.

Parameter type: string.

Unit: none

Value range: valid file path.

Default value: **""**. The default path where the black box core files are generated is **"/proc/sys/kernel/core_pattern"**. If the path is not a directory or you do not have the write permission on the directory, black box core files will be generated under the data directory of the database.

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

bbox_blanklist_items

Parameter description: Specifies the anonymized data items of black box core files. This parameter is valid only when **enable_bbox_dump** is set to **on**.

Parameter type: string.

Unit: none

Value range: a string of sensitive data items separated by commas (,).

Currently, the following data items can be anonymized:

- **SHARED_BUFFER**: data buffer.
- **XLOG_BUFFER**: redo log buffer.
- **DW_BUFFER**: doublewrite data buffer.
- **XLOG_MESSAGE_SEND**: buffer for sending primary/standby replication logs.
- **WALRECEIVER_CTL_BLOCK**: buffer for receiving primary/standby replication logs.
- **DATA_MESSAGE_SEND**: buffer for sending primary/standby replication data.
- **DATA_WRITER_QUEUE**: buffer for receiving primary/standby replication data.
- **BUCKET_XLOG_MESSAGE_SEND**: buffer for sending replay logs during bucket scale-out.

Default value: **""**. It indicates that all supported sensitive data items of the core files generated by the black box are anonymized.

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

enable_ffic_log

Parameter description: Specifies whether to enable the first failure information capture (FFIC) function. This function is valid only for CNs or DNs. For CM Agent, CM Server, GTM, and fenced UDF, the system core mechanism must be configured to capture core files.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The FFIC function is enabled.
- **off**: The FFIC function is disabled.

Default value: **on**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

enable_dynamic_workload

Parameter description: Specifies whether to enable the memory adaptation function.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The memory adaptation function is enabled.
- **off**: The memory adaptation function is disabled.

Default value: **off**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- If memory adaptation is enabled, you do not need to use **work_mem** to optimize the operator memory usage. The system will generate a plan for each statement based on the current workload, estimating the memory used by each operator and by the entire statement. In a concurrency scenario, statements are queued based on the system workload and their memory usage.
- In some cases, the optimizer cannot accurately estimate the number of rows and thereby underestimates or overestimates memory usage. If the memory usage is underestimated, the allocated memory will be automatically increased during statement running. If the memory usage is overestimated, system memory resources will not be fully used, and the number of statements waiting in a queue will increase, which probably results in low performance. In this case, you need to identify the statements whose estimated memory usage is much greater than the actual DN peak memory and optimize the performance by setting **query_mem**. For details, see "Adjusting Key Parameters During SQL Optimization" in *SQL Optimization Guide*.

enable_reaper_backend

Parameter description: Specifies whether the signal sent by a worker thread when it exits is collected by a separate thread.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: This function is enabled.
- **off**: This function is disabled.

Default value: **on**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

bypass_workload_manager

Parameter description: Specifies whether to enable independent I/O management and control. This parameter must be used together with CNs and DNs.

If **use_workload_manager** is not set to **on**, this parameter can be used to enable the I/O control independently. After the I/O control is enabled, you can set **io_limits** or **io_priority** to configure control details.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The I/O control is enabled.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **off**: The I/O control is disabled.

Default value: **on**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

io_limits

Parameter description: Specifies the upper limit of input/output operations per second (IOPS).

Parameter type: integer.

Unit: none

Value range: 0 to 1073741823

Default value: **0**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

io_priority

Parameter description: Specifies the I/O priority for jobs that consume many I/O resources. It takes effect when the I/O usage reaches 50%.

Parameter type: enumerated type

Unit: none

Value range:

- **None**: no limitation.
- **Low**: The IOPS is reduced to 10% of the original value.
- **Medium**: The IOPS is reduced to 20% of the original value.
- **High**: The IOPS is reduced to 50% of the original value.

Default value: **None**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

io_control_unit

Parameter description: Specifies the unit used to count the number of I/Os during I/O control in row-store scenarios. This parameter must be set to a same value on CNs and DNs.

Set a certain number of I/Os as one unit. This unit is used during the I/O control.

Parameter type: integer.

Unit: none

Value range:1000 to 1000000

Default value: **6000**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

session_respool

Parameter description: Specifies the resource pool associated with the current session.

If you set **cgroup_name** and then **session_respool**, the Cgroup associated with **session_respool** takes effect. If you reverse the order, the Cgroup associated with **cgroup_name** takes effect.

If the workload Cgroup level is specified during the **cgroup_name** change, the database does not check the Cgroup level. The level ranges from 1 to 10.

Parameter type: string.

Unit: none

Value range: name of the resource pool set by running **create resource pool**.

Default value: **"invalid_pool"**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Do not use both **cgroup_name** and **session_respool**.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

session_statistics_memory

Parameter description: Specifies the memory size of a real-time query view.

Parameter type: integer.

Unit: KB

Value range: 5120 to 2147483647

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Default value: 5120 (that is, 5 MB)

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**. For example, if the value is **16384** without a unit, **session_statistics_memory** indicates 16384 KB. If the value is **16MB**, **session_statistics_memory** indicates 16 MB. The unit must be KB, MB, or GB if required.

Setting suggestion: You are advised to set this parameter to a value less than or equal to 50% of the value of **max_process_memory**.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

session_history_memory

Parameter description: Specifies the memory size of a historical query view.

Parameter type: integer.

Unit: KB

Value range: 10240 to 2147483647

Default value: **10240** (that is, 10 MB)

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**. For example, if the value is **16384** without a unit, **session_history_memory** indicates 16384 KB. If the value is **16MB**, **session_history_memory** indicates 16 MB. The unit must be KB, MB, or GB if required.

Setting suggestion: You are advised to set this parameter to a value less than or equal to 50% of the value of **max_process_memory**.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

enable_transaction_parctl

Parameter description: Specifies whether to control transaction block statements and stored procedure statements.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: Transaction block statements and stored procedure statements are controlled.
- **off**: Transaction block statements and stored procedure statements are not controlled.

Default value: **on**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

topsql_retention_time

Parameter description: Specifies the retention period of historical TopSQL data in the **gs_wlm_session_query_info_all** and **gs_wlm_operator_info** tables.

Parameter type: integer.

Unit: days

Value range: 0–3650

- If it is set to **0**, the data is stored permanently.
- If the value is greater than **0**, the data is stored for the specified number of days.

Default value: **0**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**. The value cannot contain a unit.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

transaction_pending_time

Parameter description: Specifies the maximum queuing time of transaction block statements and stored procedure statements. This parameter is valid only when **enable_transaction_parctl** is set to **on**.

Parameter type: integer.

Unit: seconds

Value range: –1 to 1073741823.

- **-1** or **0** indicates that no queuing timeout is specified for transaction block statements and stored procedure statements. The statements can be executed when resources are available.
- A value greater than **0** indicates that if transaction block statements and stored procedure statements have been queued for a time longer than the specified value, they are forcibly executed regardless of the current resource situation.

Default value: **0**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**. The value cannot contain a unit.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

node_group_mode

Parameter description: Displays the current node group mode.

Parameter type: string.

Unit: none

Value range: name of the node group mode.

Default value: **"node group"**

Setting method: This is a fixed INTERNAL parameter. It can be viewed but cannot be modified.

Setting suggestion: This parameter can only be viewed.

Risks and impacts of improper settings: none

resilience_ctrlslot_available_maxpercent

Parameter description: Specifies the maximum percentage of threads in the thread pool that can be occupied by slow SQL statements. This parameter is valid only for SELECT statements executed by non-SYSADMIN/MONADMIN users.

Parameter type: integer.

Unit: none

Value range: 0 to 100

Default value: **100**, indicating that slow SQL statements can occupy all threads in the thread pool.

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

resilience_ctrlstmt_detect_timelimit

Parameter description: Specifies the execution time of a normal SQL statement after which it is marked as a slow SQL statement. The value **0** indicates that slow SQL statements are not identified. A value greater than 0 indicates that the SQL statement is marked as a slow SQL statement when its execution time exceeds the value of this parameter. This parameter is valid only for SELECT statements executed by non-SYSADMIN/MONADMIN users.

Parameter type: integer.

Unit: milliseconds

Value range: 0 to 2147483647. **0** indicates that the slow SQL detection function is disabled.

Default value: **0**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**. For example, if the value is **6000** without a unit, **resilience_ctrlstmt_detect_timelimit** indicates 6000 ms. If the value is **6s**, **resilience_ctrlstmt_detect_timelimit** indicates 6s. The unit must be **ms**, **s**, **min**, **h**, or **d** if required.

Setting suggestion: Set this parameter based on the average SQL execution duration of the real-time database.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

resilience_ctrlstmt_control_iopslimit

Parameter description: Specifies the maximum IOPS that can be used by slow SQL statements after normal SQL statements are marked as slow SQL statements. This parameter is valid only for SELECT statements executed by non-SYSADMIN/MONADMIN users.

Parameter type: string.

Unit: none

Value range: **"Low"**, **"Medium"**, **"High"**, **"None"**, or a value ranging from 0 to 2147483647. The lower the level, the stricter the control.

- **"Low"**: low level.
- **"Medium"**: medium level.
- **"High"**: high level.
- **"None"**: Logical I/O control for slow SQL statements is disabled.
- 0 to 2147483647: A smaller value indicates stricter and a larger value indicates looser.

Default value: **"None"**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**. If this parameter is set to a number, the value must be a character string, for example, **resilience_ctrlstmt_control_iopslimit = '1024'**.

Setting suggestion: Set this parameter to a small value when I/O access is full and to a large value when I/O access is idle.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

session_max_dynamic_memory

Parameter description: Specifies the upper limit of the session-level memory. If the session memory usage exceeds the value of this parameter, an error is reported and the session is interrupted. This parameter is valid only when **enable_memory_limit** is set to **on**.

Parameter type: integer.

Unit: KB

Value range: –1 to 2147483647

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Default value: **-1**, indicating no control.

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**. The value cannot contain a unit.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: The parameter cannot be set to a small value. If the value is too small, the session fails to execute statements due to insufficient memory. If the parameter is set to a value by using method 3 in **Table 6-2** but the value cannot be set larger due to insufficient memory, you can only exit the session to eliminate the limit. If the value is less than 16 MB, a message is displayed.

max_concurrency

Parameter description: Specifies the upper limit of global concurrency.

Parameter type: integer.

Unit: none

Value range: –1 to 2147483647

Default value: **-1**, indicating no control.

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: A database administrator needs to adjust the value of this parameter based on the usage of system resources (such as CPU, I/O, and memory resources) to maximize the number of concurrent jobs and prevent system breakdown caused by excessive concurrent jobs.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

enable_workload_rule

Parameter description: Specifies whether to enable the SQL statement concurrency control.

Parameter type: Boolean.

Unit: none

Value range:

- **on** indicates that the SQL statement concurrency control is enabled.
- **off** indicates that the SQL statement concurrency control is disabled.

Default value: **on**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: If the SQL statement concurrency control function is not required, set this parameter to **off**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

enable_sysadmin_workload_rule

Parameter description: Specifies whether to enable the SQL statement concurrency control for administrators. This parameter is invalid for superusers, who are never subject to concurrency control rules.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The SQL statement concurrency control for administrators is enabled.
- **off**: The SQL statement concurrency control for administrators is disabled.

Default value: **off**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value **off**. Set this parameter to **on** only when you need to limit the concurrency of SQL statements executed by administrators.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

workload_uncontrolled_users

Parameter description: Specifies the user whitelist for workload management. Workload management is not performed on users in the whitelist. Currently, this parameter takes effect only for SQL statement concurrency control.

Parameter type: string.

Unit: none

Value range: a list of users separated by commas (,), for example, **user1, user2, user3**.

Default value: **""**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Set this parameter based on service requirements. If the users without the SYSADMIN permission do not want to be restricted by workload management when running SQL statements, they can add this parameter.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

enable_emergency_access

Parameter description: Specifies whether to enable the UDS O&M channel, which is called emergency channel.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The emergency channel is enabled.
- **off**: The emergency channel is disabled.

Default value: **on**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after you fully understand the parameter meaning and test the parameter to avoid unexpected results.

max_plancache_memory_ratio

Parameter description: Specifies the dynamic memory usage percentage threshold of the plan cache in session-level prepare statements and **cursor_sharing**.

Parameter type: integer.

Unit: none

Value range: 0 to 100

The value is an integer ranging from 0 to 100, indicating the percentage threshold of the upper limit of the plan cache in the current session to the expected memory reserved for each session. The value **0** indicates that the function is disabled.

The expected dynamic memory size reserved for each session complies with the rules described in **Table 6-27**.

Table 6-27 Dynamic memory reserved for each session

CurConnCount/ max_connections	Dynamic Memory Reserved for Each Session
0 ~ 30%	max_dynamic_memory / (max_connections * 30%)
30% ~ 60%	max_dynamic_memory / (max_connections * 60%)
60% ~ 100%	max_dynamic_memory / (max_connections * 100%)

CurConnCount indicates the number of current sessions. **max_connections** indicates the maximum number of concurrent sessions, which is specified by the GUC parameter **max_connections**. **max_dynamic_memory** indicates the maximum dynamic memory of the system.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

When the system detects that the ratio of the memory occupied by the plan cache to the memory reserved for sessions reaches or exceeds the percentage threshold specified by **max_plancache_memory_ratio**, the cache eviction mechanism is triggered. This mechanism releases plan cache entries using the least recently used (LRU) algorithm until the current plan cache memory usage falls below the threshold. When the cached entries are evicted, the system automatically generates a new execution plan to ensure that the query can be executed properly.

Default value:

- Independent deployment:

  CN: **60** (60-core CPU/480 GB memory, 32-core CPU/256 GB memory, 16-core CPU/128 GB memory); **30** (8-core CPU/64 GB memory); **50** (4-core CPU/32 GB memory); **40** (4-core CPU/16 GB memory)

  DN: **60** (60-core CPU/480 GB memory, 32-core CPU/256 GB memory, 16-core CPU/128 GB memory); **50** (8-core CPU/64 GB memory; 4-core CPU/32 GB memory); **30** (4-core CPU/16 GB memory)

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: If this parameter is set to a small percentage, planned cache eviction and rebuilding are frequently triggered, which may cause performance deterioration. Exercise caution when setting this parameter based on the actual memory usage. In the hybrid deployment scenario, you need to adjust the parameter settings based on the memory allocated to a single process. This parameter controls only the dynamic memory usage of the plan cache in session-level prepare statements and **cursor_sharing**. Other memory is not controlled.

The current parameter settings are based on the memory configuration, number of connections, and performance. If the plan memory usage is too high, **max_dynamic_memory** may be used up, or memory eviction may be triggered, causing performance deterioration. In this special scenario, you are advised to adjust the memory ratio based on services.

In addition, if the GUC parameter **enable_opfusion** is set to **on**, the session-level opfusion memory is not specified by this parameter. As a result, this memory may not be controlled. If this problem occurs, you are advised to decrease the value of the GUC parameter **max_plancache_memory_ratio** to alleviate this problem.

Risks and impacts of improper settings: If the ratio set by this parameter is too small, the plan cache eviction and rebuild are frequently triggered, which may deteriorate the performance. If the ratio set by this parameter is too large, memory resources may be insufficient and resources may be unavailable. Before modifying this parameter, make sure you understand its meaning and fully verify the change in a test environment.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- This parameter takes effect only when the parameter **enable_memory_limit** is enabled.
- The maximum dynamic memory (**max_dynamic_memory**) can be queried in the pv_total_memory_detail view. The GUC parameter **max_connections** indicates the maximum number of connections.
- Cache eviction is triggered only when the memory size reaches or exceeds the upper limit after the execution plan is created or rebuilt. When a new session is connected and the percentage changes in the range described in **Table 6-27** (for example, from 29% to 31%), the memory reserved for each session changes accordingly. Note that eviction is not triggered.
- After the version upgrade, this parameter is disabled by default, that is, the value is **0**.

global_plancache_memory_ratio

Parameter description: Specifies the percentage threshold of the dynamic memory occupied by the global shared plan cache. The value **0** indicates that the GPC memory control is disabled.

Parameter type: integer

Unit: none

Value range: 0 to 80

Default value:

- Independent deployment:

  CN: **30** (60-core CPU/480 GB memory, 32-core CPU/256 GB memory, 16-core CPU/128 GB memory); **20** (8-core CPU/64 GB memory); **30** (4-core CPU/32 GB memory); **20** (4-core CPU/16 GB memory)

  DN: **30** (60-core CPU/480 GB memory, 32-core CPU/256 GB memory, 16-core CPU/128 GB memory, 8-core CPU/64 GB memory, 4-core CPU/32 GB memory); **30** (4-core CPU/16 GB memory)

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: If the percentage specified by this parameter is too small, the plan cache may fail to be shared. Set this parameter based on the actual memory usage.

You are advised to adjust the parameter settings based on the memory specifications. For details, see the egress parameter settings.

In the hybrid deployment scenario, you need to adjust the parameter settings based on the memory allocated to a single process.

The current parameter settings are based on the memory configuration and performance. If the plan memory usage is too high, **max_dynamic_memory** may be used up, or memory eviction may be triggered, causing performance deterioration. In this special scenario, you are advised to adjust the memory ratio based on services.

Risks and impacts of improper settings: If the percentage specified by this parameter is too small, a large number of plan caches cannot be shared. If the percentage is too large, memory resources may be insufficient and there is still a

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

risk that resources are unavailable. Before modifying this parameter, make sure you understand its meaning and fully verify the change in a test environment.

NOTE

This parameter takes effect only when the parameter **enable_memory_limit** is enabled.

current_logic_cluster

Parameter description: Displays the name of the current logical database instance.

Parameter type: string.

Unit: none

Value range: logical database instance name.

Default value: ""

Setting method: This is a fixed INTERNAL parameter. It can be viewed but cannot be modified.

Setting suggestion: This parameter can only be viewed.

Risks and impacts of improper settings: none

6.3.13 Autovacuum

The autovacuum thread includes the VACUUM and ANALYZE processes to recycle the record space marked as deleted and update statistics about the table. The **autovacuum_naptime** parameter specifies the interval between them. The default interval is 10 minutes. You can set the interval based on the actual situation. The interval cannot be completely accurate. It depends on the hardware conditions and load of the environment. If a large amount of data needs to be vacuumed, the heavy load may delay the process. It also depends on the values of **autovacuum_naptime** and **autovacuum_max_workers**. **autovacuum_naptime** specifies the execution interval. A smaller value indicates a shorter execution interval. However, data vacuuming and statistics calculation will increase the CPU usage, memory usage, and I/O overhead. **autovacuum_max_workers** specifies the maximum number of concurrent autovacuum threads. A larger value makes the parameter more compatible with **autovacuum_naptime**, but the CPU usage, memory usage, and I/O overhead also increase.

autovacuum

Parameter description: Specifies whether to start the autovacuum thread in the database. Ensure that the **track_counts** parameter is set to **on** before starting the autovacuum thread.

Parameter type: Boolean.

Unit: none

Value range:

- **on** indicates that the autovacuum thread is started.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **off** indicates that the autovacuum thread is not started.

Default value: **on**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion:

- Set the **autovacuum** parameter to **on** if you expect the system to automatically clear up two-phase transactions after recovering from faults.
- If **autovacuum** is set to **on** and **autovacuum_max_workers** to **0**, the system does not perform autovacuum. Instead, the system automatically vacuum two-phase transactions after recovering from faults.
- If **autovacuum** is set to **on** and the value of **autovacuum_max_workers** is greater than **0**, the system will automatically vacuum the two-phase transactions and processes after recovering from faults.

Risks and impacts of improper settings: If this parameter is disabled in an Astore table, too many inactive rows will exist in the table, which may affect the query performance.

autovacuum_mode

Parameter description: Specifies whether the autoanalyze and autovacuum function are enabled. This parameter is valid only when **autovacuum** is set to **on**.

Parameter type: enumerated type.

Unit: none

Value range:

- **analyze** indicates that only autoanalyze is performed.
- **vacuum** indicates that only autovacuum is performed.
- **mix** indicates that both autoanalyze and autovacuum are performed.
- **none** indicates that neither autoanalyze nor autovacuum is performed.

Default value: **mix**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

autoanalyze_timeout

Parameter description: Specifies the timeout interval of autoanalyze. If the duration of autoanalyze on a table exceeds the value of **autoanalyze_timeout**, the autoanalyze operation is automatically canceled.

The timeout check cannot be completely accurate. In principle, the statistics on each CN must be consistent. Therefore, the synchronization between CNs will not

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

be interrupted even if the synchronization times out. As a result, the actual execution time may exceed the user-defined time.

Parameter type: integer.

Unit: seconds

Value range: 0 to 2147483. The value **0** indicates that no timeout occurs.

Default value: **300**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**. The value cannot contain a unit.

Setting suggestion: Set the value depending on the database load and performance requirements. If the database load is light, you can set **autoanalyze_timeout** to a larger value so that the automatic analysis operation can be completed in sufficient time. If the database is heavily loaded, set **autoanalyze_timeout** to a smaller value so that automatic analysis can be completed in a short period of time. This prevents other important database operations from being affected.

Risks and impacts of improper settings: The AUTOANALYZE operation consumes certain system resources. If the value is too large, system resources may be excessively consumed, affecting database performance. If the value is too small, the AUTOANALYZE operation may fail to be completed. As a result, the statistics may be inaccurate, affecting the execution plan and performance of the query.

autovacuum_io_limits

Parameter description: Specifies the upper limit of I/Os triggered by the autovacuum thread per second.

Parameter type: integer.

Unit: none

Value range: –1 to 1073741823. **-1** indicates that the default Cgroup is used.

Default value: **-1**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion:

- If the disk I/O resources of server are sufficient, you can set **autovacuum_io_limits** to a large value, which allows the autovacuum thread to complete the cleanup operation more quickly.
- If the disk I/O resources of the server are limited, you can set **autovacuum_io_limits** to a small value. This limits the disk I/O resources used by the autovacuum thread to avoid impact on other threads.

Risks and impacts of improper settings:

- If the value is too large, the autovacuum thread may use too many disk I/O resources, affecting the performance of other threads.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- If the value is too small, the autovacuum thread may fail to effectively clear table data. As a result, table data is excessively expanded, affecting database performance.

log_autovacuum_min_duration

Parameter description: Records each step performed by the autovacuum process to the server log when the execution time of the autovacuum process is greater than or equal to a certain value. This parameter helps track the autovacuum behavior.

For example, set the **log_autovacuum_min_duration** parameter to **250ms** to record the information about the autovacuum commands running longer than or equal to 250 ms.

Parameter type: integer.

Unit: ms

Value range: –1 to 2147483647

- **0** indicates that all autovacuum actions are recorded in the log.
- **-1** indicates that all autovacuum actions are not recorded in the log.
- A value greater than or equal to 0 indicates that a message is recorded when an autovacuum action is skipped due to a lock conflict. (The reason for skipping autovacuum is recorded for audit.)

Default value: **-1**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**. For example, if the value is **600** without a unit, **log_autovacuum_min_duration** indicates 600 ms. If the value is **10min**, **log_autovacuum_min_duration** indicates 10 minutes. The unit must be **ms**, **s**, **min**, **h**, or **d** if required.

Setting suggestion: The default value is **-1**. If you want to monitor the performance of automatic VACUUM operations, set **log_autovacuum_min_duration** to a value greater than 0 to record the automatic VACUUM operations whose duration exceeds the value of this parameter.

Risks and impacts of improper settings: If this parameter is set to **0** or the value is too small, a large number of logs may be recorded, affecting system performance. If this value is too large, the system may not detect that the automatic clearance time is too long in a timely manner, causing insufficient clearance speed or exceptions.

autovacuum_max_workers

Parameter description: Specifies the maximum number of autovacuum threads running at the same time.

Parameter type: integer.

Unit: none

Value range: The minimum value is **0**, indicating that autovacuum is not automatically performed. Theoretically, the maximum value is **1024**. If the value is

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

greater than 1024, the value is automatically changed to **1024**. However, the value may still exceed the actual upper limit. The actual upper limit of this parameter is related to the GUC parameters **max_connections** and **job_queue_processes**. The calculation formula is as follows: 262143 – **max_inner_tool_connections** – **max_connections** – **max_concurrent_autonomous_transactions** – **job_queue_processes** – Number of auxiliary threads – Number of launcher threads of autovacuum [x(1] – 1. The number of auxiliary threads and the number of launcher threads of autovacuum are specified by two macros and their default values are **20** and **2**, respectively.

Default value: **3**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If the value is too large, more autovacuum processes are created and more CPU and memory resources are occupied. Therefore, you are advised not to set this parameter to a large value. Otherwise, memory cannot be allocated or too many CPU resources are occupied, causing database startup errors or affecting services. If the value is too small, the autovacuum thread may fail to clear and recycle tablespaces that are no longer used in a timely manner, causing database expansion and performance deterioration. The actual value of this parameter needs to be evaluated based on the actual upper limit of the value range. Generally, the value can reach **1024**. If the value exceeds the actual upper limit, the setting fails. This parameter takes effect for new threads but does not take effect for running threads.

autovacuum_naptime

Parameter description: Specifies the interval between activity rounds for the autovacuum process.

Parameter type: integer.

Unit: seconds

Value range: 1 to 2147483

Default value: **600** (that is, 10 minutes)

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**. For example, if the value is **600** without a unit, **autovacuum_naptime** indicates 600s. If the value is **10min**, **autovacuum_naptime** indicates 10 minutes. The unit must be **s**, **min**, **h**, or **d** if required.

Setting suggestion: Retain the default value when only Ustore tables are used. For Astore tables, the setting value depends on the user's database environment and application load. If a large number of tables are updated or deleted in the database environment, you are advised to set this parameter to a short interval to ensure that useless data is deleted in a timely manner and the database space is sufficient. If there are few update or delete operations in the database environment, you can set this parameter to a long interval to reduce the overhead of the automatic cleanup thread.

Risks and impacts of improper settings:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- If **autovacuum_naptime** is set to a short interval, the overhead of the autovacuum thread may be too high, affecting the database performance.
- If **autovacuum_naptime** is set to a long interval, useless data may be accumulated, occupying database space and affecting database performance.

autovacuum_vacuum_threshold

Parameter description: Specifies the reference value for triggering VACUUM operations on Astore and Ustore tables. Threshold for triggering VACUUM is calculated as follows: Value of **autovacuum_vacuum_threshold** + Value of **reltuples** (Number of tuples in the table) x **autovacuum_vacuum_scale_factor**. When the total number of deleted and updated records in a table exceeds the threshold, the VACUUM operation is executed on this table.

Parameter type: integer.

Unit: none

Value range: 0 to 2147483647

Default value: **50**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings:

- If the value is too small, VACUUM operations are frequently performed, increasing system overhead and deteriorating system performance.
- If the value is too large, too many dead rows exist in the table, affecting the query performance.

autovacuum_analyze_threshold

Parameter description: Specifies the reference value for triggering ANALYZE operations on Astore and Ustore tables. Threshold for triggering ANALYZE is calculated as follows: Value of **autovacuum_analyze_threshold** + Value of **reltuples** (Number of tuples in the table) x **autovacuum_analyze_scale_factor**. When the total number of deleted, inserted, and updated records in a table exceeds the threshold, the ANALYZE operation is executed on this table. If a global secondary index exists in a table, the ANALYZE operation is performed on the global secondary index only when the total number of deleted, inserted, and updated records in the table exceeds the threshold 20 times.

Parameter type: integer.

Unit: none

Value range: 0 to 2147483647

Default value: **50**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Risks and impacts of improper settings:

- If the value is too small, ANALYZE operations are frequently performed, increasing system overhead and deteriorating system performance.
- If the value is too large, the statistics in the table may be outdated. As a result, the query plan is inaccurate and the query performance is affected.

autovacuum_vacuum_scale_factor

Parameter description: Specifies the scale factor for triggering VACUUM operations on Astore and Ustore tables. Threshold for triggering VACUUM is calculated as follows: Value of **autovacuum_vacuum_threshold** + Value of **reltuples** (Number of tuples in the table) x **autovacuum_vacuum_scale_factor**. When the total number of deleted and updated records in a table exceeds the threshold, the VACUUM operation is executed on this table.

Parameter type: floating-point number

Unit: none

Value range: 0.0 to 100.0

Default value: **0.2**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: The value of this parameter depends on the load and usage of a table. If the write load is high, set this parameter to a smaller value so that the table can be cleared more frequently to prevent performance deterioration. If the read load is high, set this parameter to a larger value to avoid unnecessary waste of resources during read.

Risks and impacts of improper settings:

- If the value is too small, the autovacuum thread may clear tables too frequently, causing performance deterioration.
- If the value is too large, the table may not be cleared in a timely manner. As a result, the table size becomes large and occupies too much disk space.

autovacuum_analyze_scale_factor

Parameter description: Specifies the scale factor for triggering ANALYZE operations on Astore and Ustore tables. Threshold for triggering ANALYZE is calculated as follows: Value of **autovacuum_analyze_threshold** + Value of **reltuples** (Number of tuples in the table) x **autovacuum_analyze_scale_factor**. When the total number of deleted, inserted, and updated records in a table exceeds the threshold, the ANALYZE operation is executed on this table.

Parameter type: floating-point number

Unit: none

Value range: 0.0 to 100.0

Default value: **0.1**, that is, 10% of the number of tuples in the table.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings:

- If the value is too small, ANALYZE operations are frequently performed, increasing system overhead and deteriorating system performance.
- If the value is too large, the frequency of performing ANALYZE operations may be too low and the statistics in the table may be outdated. As a result, the query plan is inaccurate and the query performance is affected.

autovacuum_analyze_window

Parameter description: Specifies one or more time windows from Monday to Sunday. In the specified time window, **autovacuum_analyze_window_scale_factor** is used as the scale factor to trigger the ANALYZE operation on the Astore and Ustore tables.

Parameter type: string.

Unit: none

Value range: an empty string or a string consisting of one or more specified time windows separated by commas (,).

NOTE

- The string of a specified time window is in the format of *key=value*.
- The key of a time window must be **MONDAY_WINDOW**, **TUESDAY_WINDOW**, **WEDNESDAY_WINDOW**, **THURSDAY_WINDOW**, **FRIDAY_WINDOW**, **SATURDAY_WINDOW**, or **SUNDAY_WINDOW**, which is case-insensitive.
- The value of a time window is in the format of *HH:MM-HH:MM*, which is separated by a hyphen (-). The left part is the start time of the window, and the right part is the end time of the window. The value cannot contain spaces. The minimum time is **00:00**, and the maximum time is **23:59**.
- If the end time of a time window is earlier than the start time, the time window crosses days. For example, **"MONDAY_WINDOW=22:00-02:00"** indicates that the time window starts from 22:00 on Monday to 02:00 on Tuesday.
- Time windows of multiple days cannot overlap. For example, if **"MONDAY_WINDOW=22:00-05:00,TUESDAY_WINDOW=03:00-09:00"** cannot be set, you can set it to **"MONDAY_WINDOW=22:00-02:59,TUESDAY_WINDOW=03:00-09:00"**.
- This parameter is not controlled by the parameter **autovacuum_mode**. As long as this parameter is set successfully, statistics are collected in the specified time window.
- Only one window can be configured for a day. If multiple windows are configured for a day, only the last configured window takes effect.
- The time window is determined based on the local system time. When changing the system time or time zone, check whether the time window specified by this parameter needs to be modified.

Default value: **""**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Setting suggestion: Retain the default value or adjust the value based on service requirements.

Risks and impacts of improper settings: The interval of a single time window must be greater than the value of **autovacuum_naptime**. Otherwise, the time window may not take effect.

autovacuum_analyze_window_scale_factor

Parameter description: Specifies the scale factor for triggering ANALYZE operations on Astore and Ustore tables in the time window. Threshold for triggering ANALYZE is calculated as follows: Value of **autovacuum_analyze_threshold** + Value of **reltuples** (Number of tuples in the table) x Value of **autovacuum_analyze_window_scale_factor**. When the total number of deleted, inserted, and updated records in a table exceeds the threshold, the ANALYZE operation is executed on this table.

Parameter type: floating-point number

Unit: none

Value range: 0.0 to 100.0

Default value: **0.1**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings:

- If the value is too small, ANALYZE operations are frequently performed in the time window, increasing system overhead and deteriorating system performance.
- If the value is too large, the frequency of performing ANALYZE operations in the time window may be too low and the statistics in the table may be outdated. As a result, the query plan is inaccurate and the query performance is affected.

autovacuum_freeze_max_age

Parameter description: Specifies the number of transactions after which the VACUUM operation is forcibly performed for the **pg_class.relfrozenxid64** column in Astore and Ustore tables. The system starts the AUTOVACUUM thread even if automatic cleanup is disabled. After the forcible VACUUM operation is complete, the system deletes old files that can be deleted from the **pg_clog** and **pg_csnlog** subdirectories to prevent the **pg_clog** and **pg_csnlog** directories from expanding infinitely.

Parameter type: integer.

Unit: none

Value range: 100000 to 576460752303423487

Default value: **4000000000**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value. If a large number of update and deletion operations are frequently performed on the Astore table in the database, you are advised to set this parameter to a small value to recycle garbage in a timely manner. If the Astore table in the database is seldom updated or deleted, you can set this parameter to a large value to reduce the frequency of automatic space recycling.

Risks and impacts of improper settings:

- If the value is too small, automatic space recycling is frequently performed, increasing system overhead and deteriorating system performance.
- If this parameter is set to a large value, automatic space recycling is delayed. As a result, a large amount of invalid data may occupy disk space, affecting database performance.

autovacuum_vacuum_cost_delay

Parameter description: Specifies the value of the cost delay used in the autovacuum operation.

Parameter type: integer.

Unit: ms

Value range: –1 to 100. **-1** indicates that the regular **vacuum_cost_delay** is used.

Default value: **20**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

autovacuum_vacuum_cost_limit

Parameter description: Sets the value of the cost limit used in the autovacuum operation.

Parameter type: integer.

Unit: none

Value range: –1 to 10000. **-1** indicates that the regular **vacuum_cost_limit** is used.

Default value: **-1**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

twophase_clean_workers

Parameter description: Specifies the maximum number of concurrent cleanup operations that can be performed by the gs_clean tool.

Parameter type: integer.

Unit: none

Value range: 1 to 10

Default value: **3**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

clog_keep_xids

Parameter description: Specifies the number of transactions retained in a Clog transaction file.

Parameter type: integer.

Unit: none

Value range: 0 to 576460752303423487

- If the value is **0**, the original recycling logic is used and no extra transaction files are retained.
- If the value is not 0 and is within the value range, the new recycling logic is used. (The number of retained transactions is calculated based on the latest transaction ID. The retention mechanism is triggered only when the new parameter value range contains the transaction files to be recycled based on the original recycling logic.)

Default value: **0**

Description: Evaluate the disk space and ensure that sufficient disk space is reserved in the environment. The method for estimating the disk space of each node is as follows:

The number of retained transactions is calculated based on the latest transaction ID. The retention mechanism is triggered only when the new parameter value range contains the transaction files to be recycled based on the original recycling logic.

Space reserved by Clog (bytes): **clog_keep_xids**/4

Space reserved by Clog (hash bucket) (bytes): Number of databases x Number of buckets x (**clog_keep_xids**/4)

For example, if **clog_keep_xids** is set to **4294967295**, the space occupied in common scenarios is 1073741823 bytes (4294967295/4), about 1 GB.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value. (Calculate the disk space usage based on the preceding formula. If the disk space is sufficient and the hash bucket service does not exist, you are advised to set this parameter to **8589934590**. If the hash bucket service exists, you are advised to set this parameter to **8388607**.)

Risks and impacts of improper settings: If the parameter is set improperly, the disk space usage may be high. All nodes are involved. Exercise caution when evaluating the risk.

csnlog_keep_xids

Parameter description: Specifies the number of transactions retained in a CSNlog transaction file.

Parameter type: integer.

Unit: none

Value range: 0 to 576460752303423487

- If the value is **0**, the original recycling logic is used and no extra transaction files are retained.
- If the value is not 0 and is within the value range, the new recycling logic is used. (The number of retained transactions is calculated based on the latest transaction ID. The retention mechanism is triggered only when the new parameter value range contains the transaction files to be recycled based on the original recycling logic.)

Default value: **0**

Description: Evaluate the disk space and ensure that sufficient disk space is reserved in the environment. The method for estimating the disk space of each node is as follows:

The number of retained transactions is calculated based on the latest transaction ID. The retention mechanism is triggered only when the new parameter value range contains the transaction files to be recycled based on the original recycling logic.

csnlog_keep_xids space estimation:

Space occupied by retained CSNlog files (bytes): **csnlog_keep_xids** x 8

For example, if **csnlog_keep_xids** is set to **4294967295**, 34359738360 bytes (4294967295 x 8) are occupied, which is about 34 GB.

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value. (Calculate the disk space usage based on the preceding formula. If the disk space is sufficient, you are advised to set this parameter to **252645135**.)

Risks and impacts of improper settings: If the parameter is set improperly, the disk space usage may be high. All nodes are involved. Exercise caution when evaluating the risk.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

defer_csn_cleanup_time

Parameter description: Specifies the local recycling interval.

Parameter type: integer.

Unit: ms

Value range: 0 to 2147483647

Default value: **5000** (5s)

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value. Generally, if the system load is light, you can set **defer_csn_cleanup_time** to a long time. If the system load is heavy, you can set **defer_csn_cleanup_time** to a short time. In this case, the system can maintain good performance even when it is busy.

Risks and impacts of improper settings: The **defer_csn_cleanup_time** parameter is used to specify when to delete expired CSN information. It specifies how long the system retains expired CSN information. If this parameter is set to a small value, the system may frequently clear expired CSN information, which deteriorates system performance. If the value is too large, the system may occupy too much memory. As a result, the system slows down or breaks down.

multixact_keep_mxids

Parameter description: Specifies the number of transactions retained in a multixact transaction file.

Parameter type: integer.

Unit: none

Value range: 0 to 576460752303423487

- If the value is **0**, the original recycling logic is used and no extra transaction files are retained.
- If the value is not 0 and is within the value range, the new recycling logic is used. (The number of retained transactions is calculated based on the latest multixact ID. The retention mechanism is triggered only when the new parameter value range contains the transaction files to be recycled based on the original recycling logic.)

Default value: **0**

Description: Evaluate the disk space and ensure that sufficient disk space is reserved in the environment. The method for estimating the disk space of each node is as follows:

The number of retained transactions is calculated based on the latest transaction ID. The retention mechanism is triggered only when the new parameter value range contains the transaction files to be recycled based on the original recycling logic.

multixact_keep_mxids space estimation:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Space reserved for multixact (bytes): **multixact_keep_mxids** x 8 + **multixact_keep_mxids** x **members** x 8

For example, when **multixact_keep_mxids** is set to **4294967295** and there are three concurrent requests (three members) in the multixact scenario, the total size that resources are occupied is calculated as follows:

(4294967295 x 8 + 4294967295 x 3 x 8) = 137438953440 bytes, about 137 GB.

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value. (Calculate the disk space usage based on the preceding formula. If the disk space is sufficient, you are advised to set this parameter to **63161283**.)

Risks and impacts of improper settings: If the parameter is set improperly, the disk space usage may be high. All nodes are involved. Exercise caution when evaluating the risk.

6.3.14 Default Settings of Client Connection

6.3.14.1 Statement Behavior

This section describes related default parameters involved in the execution of SQL statements.

search_path

Parameter description: Specifies the order in which schemas are searched when an object is referenced with no schema specified.

Parameter type: string.

Unit: none

Value range: a character string consisting of one or more schema names. Different schema names are separated by commas (,).

NOTE

- When this parameter is set to **'"$user",public'**, shared use of a database (where no users have private schemas, and all share use of public), private per-user schemas, and combinations of them are supported. Other effects can be obtained by modifying the default search path setting, either globally or per-user.
- When this parameter is set to a null character string (''), the system automatically converts it into a pair of double quotation marks ("").
- If the content contains double quotation marks, the system considers them as insecure characters and converts each double quotation mark into a pair of double quotation marks.

Default value: **'"$user",public'**

NOTE

$user indicates the name of the schema with the same name as the current session user. If the schema does not exist, **$user** will be ignored.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion:

- If schemas of temporary tables exist in the current session, the schemas can be listed in the search path by using the alias **pg_temp**, for example, **'pg_temp,public'**. The schema of temporary tables has the highest search priority and is always searched before all the other schemas specified in **pg_catalog** and **search_path**. Therefore, do not explicitly specify **pg_temp** to be searched after other schemas in **search_path**. If **pg_temp** is specified in **search_path**, this setting will not take effect and an error message will be displayed. If the alias **pg_temp** is used, the temporary schema will be searched only for tables, views, and data types, and not for functions or operators.
- The system catalog schema, pg_catalog, has the second highest search priority and is the first to be searched among all the schemas, excluding **pg_temp**, specified in **search_path**. Therefore, do not explicitly specify **pg_catalog** to be searched after other schemas in **search_path**. If **pg_catalog** is specified in **search_path**, this setting will not take effect and an error message will be displayed.
- When an object is created without a specific target schema, the object will be placed in the first valid schema listed in **search_path**. An error is reported if the search path is empty.
- The current effective value of the search path can be examined through the SQL function current_schema(). This is different from examining the value of **search_path** because the current_schema() function displays the first valid schema name in **search_path**.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

current_schema

Parameter description: Specifies the current schema.

Parameter type: string.

Unit: none

Value range: a character string consisting of one or more schema names. Different schema names are separated by commas (,).

Default value: **'"$user",public'**

NOTE

$user indicates the name of the schema with the same name as the current session user. If the schema does not exist, **$user** will be ignored.

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

default_tablespace

Parameter description: Specifies the default tablespace of the created objects (tables and indexes) when a **CREATE** command does not explicitly specify a tablespace.

NOTE

- The value of this parameter is either the name of a tablespace, or an empty string that indicates the use of the default tablespace of the current database. If a non-default tablespace is specified, users must have CREATE privilege for it. Otherwise, creation attempts will fail.
- This parameter is not used for temporary tables. For them, **temp_tablespaces** is used instead.
- This parameter is not used when users create databases. By default, a new database inherits its tablespace setting from the template database.

Parameter type: string.

Unit: none

Value range: Specifies the name of an existing tablespace or an empty string. An empty string indicates that the default tablespace is used.

Default value: ""

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

temp_tablespaces

Parameter description: Specifies one or more tablespaces to which temporary objects (temporary tables and their indexes) will be created when a CREATE command does not explicitly specify a tablespace. Temporary files for sorting large data sets are created in these tablespaces.

The value of this parameter can be a list of names of tablespaces. When there is more than one name in the list, GaussDB chooses a random tablespace from the list upon the creation of a temporary object each time. However, within a transaction, successively created temporary objects are placed in successive tablespaces in the list. If the element selected from the list is an empty character string, GaussDB will automatically use the default tablespace of the current database instead.

Parameter type: string.

Unit: none

Value range: name of an existing tablespace or an empty string. An empty string indicates that all temporary objects are created only in the default tablespace of the current database. For details, see **default_tablespace**.

Default value: ""

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

default_storage_nodegroup

Parameter description: Specifies the node group where a table is created by default. This parameter takes effect only for ordinary tables.

Parameter type: string.

Unit: none

Value range: an existing Node Group name or **"installation"**.

Default value: **"installation"**

- **"installation"** indicates that tables will be created in the node group created during database installation.
- Other character strings indicate that tables will be created in the node group specified by this parameter.

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

check_function_bodies

Parameter description: Specifies whether to enable validation of the function body string during the execution of **CREATE FUNCTION**. Verification is occasionally disabled to avoid problems, such as forward references when you restore function definitions from a dump. After the function is enabled, the syntax of the PL/SQL in the stored procedure is verified, including the data type, statement, and expression. The SQL statements in the stored procedure are not checked in the CREATE phase. Instead, they are checked during running.

NOTE

In O-compatible mode, if **check_function_bodies** is set to **off**, a deadlock occurs when a stored procedure or function with a user-defined type and autonomous transaction is called. Set **check_function_bodies** to **on**. After a function or stored procedure is rebuilt, the function or stored procedure can be called properly.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: Validation of the function body string is enabled during the execution of CREATE FUNCTION.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **off**: Validation of the function body string is disabled during the execution of CREATE FUNCTION.

Default value: **on**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

default_transaction_isolation

Parameter description: Specifies the default isolation level of each transaction.

NOTE

The current version does not support the setting of the default transaction isolation level. The default value is **read committed**. Do not change the value.

Parameter type: enumerated type.

Unit: none

Value range:

- **read committed**: The transaction is read and committed.
- **read uncommitted**: The transaction is read but not committed.
- **repeatable read**: The transaction can be read repeatedly.
- **serializable**: Currently, this isolation level is not supported in GaussDB. It is equivalent to **repeatable read**.

Default value: read committed

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

default_transaction_read_only

Parameter description: Specifies whether each new transaction is in read-only state.

Parameter type: Boolean.

Unit: none

Value range:

- **on** indicates that the transaction is in read-only state.
- **off** indicates that the transaction is not in read-only state.

Default value: **off**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this parameter is set to **on**, DML cannot be performed and transactions cannot be written.

default_transaction_deferrable

Parameter description: Specifies the default deferrable status of each new transaction. It currently has no effect on read-only transactions or those running at isolation levels lower than serializable.

GaussDB does not support the serializable isolation level. Therefore, the parameter takes no effect.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: delayed by default.
- **off**: no delay by default.

Default value: **off**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

session_replication_role

Parameter description: Specifies the behavior of replication-related triggers and rules for the current session.

NOTE

Modifying this parameter will discard all the cached execution plans.

Parameter type: enumerated type.

Unit: none

Value range:

- **origin**: The current session is the data source. Triggers are executed, and foreign keys, constraints, and rules are checked. This value is the default setting for all common sessions and applies to common database operations.
- **replica**: The current session is the data receiver (for example, the secondary database). Only triggers, foreign keys, and rules in ENABLE REPLICA mode are enabled. Triggers, rules, and foreign keys in other modes are disabled.
- **local**: The system detects the role that has logged in to the database when using the function to copy operations and performs related operations. This

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

value is used in specific replication function scenarios and is used less frequently. The behavior of this value is the same as that of **origin**.

Default value: **origin**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

statement_timeout

Parameter description: If the statement execution time (starting from the time the server receives the command) is longer than the duration specified by the parameter, error information is displayed and the statement exits.

Parameter type: integer.

Unit: milliseconds

Value range: 0 to 2147483647

Default value: **0**, indicating that the timeout error reporting function is disabled.

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**. For example, if the value is **2000** without a unit, **statement_timeout** indicates 2000 ms. If the value is **2s**, **statement_timeout** indicates 2s. The unit must be **ms**, **s**, **min**, **h**, or **d** if required.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

vacuum_freeze_min_age

Parameter description: Specifies whether VACUUM replaces the **xmin** column (minimum time) of a record with **FrozenXID** when scanning a table (in the same transaction).

Parameter type: integer.

Unit: none

Value range: 0 to 576460752303423487

NOTE

By default, regardless of the value configured, VACUUM will limit the effective value within 50% of **autovacuum_freeze_max_age**.

Default value: **2000000000**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Risks and impacts of improper settings: If this parameter is set to a large value, the freeze time is delayed and the recycling efficiency is reduced.

vacuum_freeze_table_age

Parameter description: Specifies when VACUUM scans the whole table and freezes old tuples. VACUUM performs a full table scan if the difference between the current transaction ID and the value of **pg_class.relfrozenxid64** is greater than the specified time.

Parameter type: integer.

Unit: none

Value range: 0 to 576460752303423487

NOTE

By default, regardless of the value configured, VACUUM will limit the effective value within 95% of **autovacuum_freeze_max_age**. Therefore, a periodic manual VACUUM has a chance to run before an anti-wraparound autovacuum is launched for the table.

Default value: **4000000000**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this parameter is set to a large value, tablespace expansion may occur.

bytea_output

Parameter description: Specifies the output format for values of the bytea type.

Parameter type: enumerated type.

Unit: none

Value range:

- **hex** indicates the binary data is converted to the two hexadecimal digits per byte.
- **escape** uses ASCII character sequences to represent binary strings, and converts those binary strings that cannot be represented as ASCII characters into special escape sequences. When **sql_compatibility** is set to **'B'**, **b_format_version** is set to **'5.7'**, and **b_format_dev_version** is set to **'s1'**, the binary data is not escaped. Instead, the original bytes are returned.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTICE

When **sql_compatibility** is set to **'B'**, **b_format_version** is set to **'5.7'**, and **bytea_output** is set to **'escape'**, the following rules are used for querying data in a new table where data in hex format is inserted using the escape string E'\\x' based on the value of **b_format_dev_version**:

- When **b_format_dev_version** is set to **'s1'**, if the client-side character set is the same as the server-side character set, no error is reported during the query. If the client-side character set is different from the server-side character set and the encoding of the inserted data is invalid in the server-side character set, an error is reported during the query.
- When **b_format_dev_version** is set to **'s2'** and the encoding of the inserted data is invalid in the client-side character set, an error is reported during the query.

Default value: **hex**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

xmlbinary

Parameter description: Specifies the encoding format of binary values in XML files.

NOTE

Currently, this parameter does not support data of the XML type.

Parameter type: enumerated type.

Unit: none

Value range:

- **base64**: The Base64 encoding format is used.
- **hex**: The hex encoding format is used.

Default value: **base64**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

xmloption

Parameter description: Specifies whether XML data is treated as a document or a normal string when it is implicitly converted or serialized.

NOTE

Currently, this parameter does not support data of the XML type.

Parameter type: enumerated type.

Unit: none

Value range:

- **document** indicates an HTML document.
- **content** indicates a common string.

Default value: **content**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

max_compile_functions

Parameter description: Specifies the maximum number of compilation results of stored procedures and functions that can be stored on a node, including system stored procedures and user-defined stored procedures and functions. If the compilation result exceeds the value of this parameter, the system automatically triggers memory eviction and deletes unused common stored procedures and functions.

Parameter type: integer.

Unit: none

Value range: 1 to 2147483647.

Default value: 1000

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value to reduce memory usage and improve system performance.

Risks and impacts of improper settings: If the number of compilation results exceeds the value of this parameter and the system cannot find the stored procedures and functions that can be deleted, a large amount of memory is occupied, causing performance deterioration.

gin_pending_list_limit

Parameter description: Specifies the threshold for merging the pending lists of GINs and UGINs when **fastupdate** is enabled for GINs or UGINs. If the pending

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

list grows larger than this maximum size, it is cleaned up by moving the entries in it to the main index data structure in batches. This setting can be overridden for a single index by changing index storage parameters.

Parameter type: integer.

Unit: KB

Value range: 64 to 2147483647

Default value: **4096**, that is, 4 MB.

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**. For example, if the value is **1024** without a unit, **gin_pending_list_limit** indicates 1024 KB. If the value is **1MB**, **gin_pending_list_limit** indicates 1 MB. The unit must be KB, MB, or GB if required.

Setting suggestion: Set this parameter to a proper value based on the update frequency to improve the performance of synchronizing indexes.

Risks and impacts of improper settings:

- If this parameter is set to a value greater than **work_mem**, the performance of synchronizing incremental data and scanning data may deteriorate.
- If this parameter is set to a small value, **pending_list** is frequently merged, affecting DML execution performance.

6.3.14.2 Locale and Formatting

This section describes parameters related to the time format setting.

DateStyle

Parameter description: Specifies the display format for date and time values, as well as the rules for interpreting ambiguous date input values.

This variable contains two independent components: the output format declaration (ISO, Postgres, SQL, or German) and the input/output order of year/month/day (DMY, MDY, YMD, Euro, European, US, NonEuro, NonEuropean, or Default). The two components can be set separately or together. The keywords Euro and European are synonyms for DMY. The keywords US, NonEuro, and NonEuropean are synonyms for MDY.

Parameter type: string.

Unit: none

Value range: combination of the output format declaration and the input/output order of year/month/day. (The two components can be set separately.)

- Output format declaration: ISO, Postgres, SQL, or German.
- Input/Output order of year/month/day: DMY (Euro, European), MDY (US, NonEuro, NonEuropean), or YMD

Default value: **"ISO, MDY"**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

gs_initdb will initialize this parameter so that its value is the same as that of **lc_time**.

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**. If this parameter is modified by running the **gs_guc reload** command and the connection of a session on the current node is not from the client but from another node in the cluster to which the node belongs, this parameter does not take effect immediately on the session after the **gs_guc reload** command is executed. The setting takes effect only after the connection node is disconnected and then reconnected.

Setting suggestion: The ISO format is recommended.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

IntervalStyle

Parameter description: Specifies the display format for interval values.

Parameter type: enumerated type.

Unit: none

Value range:

- **sql_standard**: Output matching SQL standards will be generated.
- **postgres**: Output matching PostgreSQL 8.4 will be generated. It is valid when the **DateStyle** parameter is set to **ISO**.
- **postgres_verbose**: Output matching PostgreSQL 8.4 will be generated. It is valid when the **DateStyle** parameter is set to **non_ISO**.
- **iso_8601**: Output matching the time interval "format with designators" defined in ISO 8601 will be generated.
- **oracle**: The numtodsinterval function generates output matching the Oracle format. For details, see **numtodsinterval(num, interval_unit)**.

NOTE

The **IntervalStyle** parameter also affects the interpretation of ambiguous interval input.

Default value: **postgres**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**. If this parameter is modified by running the **gs_guc reload** command and the connection of a session on the current node is not from the client but from another node in the cluster to which the node belongs, this parameter does not take effect immediately on the session after the **gs_guc reload** command is executed. The setting takes effect only after the connection node is disconnected and then reconnected.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

TimeZone

Parameter description: Specifies the time zone for displaying and interpreting timestamps.

Parameter type: string.

Unit: none

Value range: You can query the PG_TIMEZONE_NAMES view to check the value range. For details, see **PG_TIMEZONE_NAMES**.

Default value: **"PRC"**

NOTE

gs_initdb will set a time zone value that is consistent with the system environment.

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**. If this parameter is modified by running the **gs_guc reload** command and the connection of a session on the current node is not from the client but from another node in the cluster to which the node belongs, this parameter does not take effect immediately on the session after the **gs_guc reload** command is executed. The setting takes effect only after the connection node is disconnected and then reconnected.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

timezone_abbreviations

Parameter description: Specifies the time zone abbreviations that will be accepted by the server.

Parameter type: string.

Unit: none

Value range: **"India"**, **"Australia"**, and **"Default"**.

Default value: **"Default"**

NOTE

- **"Default"** indicates an abbreviation of the universal time zone, which is applicable to most cases. There are also other values, such as **"Australia"** and **"India"** that can be defined for a particular time zone installation.
- You are advised not to modify the corresponding value file. After the time zone abbreviation file is rewritten or replaced, the modification cannot be updated in real time. In some scenarios, you need to restart the database cluster for the modification to take effect.

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

extra_float_digits

Parameter description: Adjusts the number of digits displayed for floating-point values, including float4, float8, and geometric data types. The parameter value is added to the standard number of digits (FLT_DIG or DBL_DIG, according to the actual situation).

Parameter type: integer.

Unit: none

Value range: –15 to 3

NOTE

- If the value is greater than 0, some key data bits are included, but the included data bits may not be valid. As a result, the output digits may not be completely valid. This function is applicable to scenarios where floating-point data needs to be accurately restored during dumping.
- If the value is less than or equal to 0, unnecessary data bits are eliminated to ensure that the output digits are valid.
- In M-compatible databases, **extra_float_digits** affects only the number of data bits displayed for the float4 data type without scale. The number of data bits displayed for the float8 data type and the float4 data type with scale is not affected by the GUC parameter.
- In the scenario where JDBC and ODBC are used to establish a connection, the default value of **extra_float_digits** is **0**.

Default value: **3**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

float_shortest_precision

Parameter description: Specifies whether to enable the minimum precision method to replace sprintf() to serialize floating point numbers. The minimum precision method is used to improve performance of a floating-point number serialization system function, that is, shorten execution time of a single thread of two system functions float4out() and float8out().

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The minimum precision method is enabled.
- **off**: The minimum precision method is disabled.

Default value: **off**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: You are advised to set this parameter for new sites or sites that have performance requirements for floating-point serialization.

Risks and impacts of improper settings: After this parameter is enabled, the precision of valid float digits varies according to the value of **extra_float_digits**. The value range of **extra_float_digits** is –15 to 3, the number of valid digits required for each value is as follows.

Value of extra_float_digits	Number of Required Valid Digits	
	Float4	Float8
-15	1	1
-14	1	1
-13	1	2
-12	1	3
-11	1	4
-10	1	5
-9	1	6
-8	1	7
-7	1	8
-6	1	9
-5	1	10
-4	2	11
-3	3	12
-2	4	13
-1	5	14
0	6	15
1	7	16
2	8	17
3	9	18

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- For the original logic that calls snprintf_s(), the number of required valid digits does not mean that all output digits are valid.
  1. When the value of **extra_float_digits** is greater than 0, the output digits are not guaranteed to be completely valid.
  2. When the value of **extra_float_digits** is less than or equal to 0, the output digits are completely valid.
- For the new logic that uses the minimum precision method, only valid digits are output.
  1. When the value of **extra_float_digits** is greater than 0, it is not guaranteed that the number of output digits reaches the number of required valid digits, but all output digits are valid.
  2. When the value of **extra_float_digits** is less than or equal to 0, the output digits are completely valid.

client_encoding

Parameter description: Specifies the client-side encoding (character set).

Parameter type: string.

Unit: none

Value range: all PG-compatible encoding types. **UTF8** indicates that the database encoding is used.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- You can run the **locale -a** command to check the system-supported locales and the corresponding encodings, and select one as required. The sorting rules may vary according to OSs or versions of the same OS. When application services are logically migrated between these OSs, differences and changes in OS sorting rules may cause differences in database functions such as indexes, partitions, and sorting operators. For example, data result sets returned by a same range query statement are different, or query results returned by a same sorting query statement are different. The application service needs to check whether the service data contains related characters based on the locale differences released by the OS.
- By default, **gs_initdb** will initialize the setting of this parameter based on the current system environment. You can also run the **locale** command to check the current configuration environment.
- To use consistent encoding for communication within the cluster, you are advised to retain the default value of **client_encoding**. Modification to this parameter in the **gaussdb.conf** file (by using the gs_guc tool, for example) does not take effect.
- **client_encoding** can be set to **GB18030_2022**. When **client_encoding** is set to **gb18030_2022**, ensure that the GB18030 character set supported by the client OS has been upgraded to version 2022.
- If the encoding format of the database character set is UTF8, the encoding format of the region supported by the current system is GB18030, the GB18030 character set supported by the client OS has been upgraded to version 2022, and the database contains historical data stored before the GB18030 character set is upgraded, the following situations may occur:
  1. When **client_encoding** is set to **gb18030**, the character encoding of historical data in the UTF8 database returned to the client is the same as that before the client character set is upgraded. However, the font of 38 characters whose mapping changes during the character set upgrade is the same as that in version 2022.
  2. When **client_encoding** is set to **gb18030_2022**, the character encoding of historical data in the UTF8 database returned to the client are the same as that after the upgrade of the client character set and the font of characters are the same as that before the upgrade. This is because the versions of the GB18030 character set are not completely compatible, which may cause data inconsistency. Therefore, if the GB18030 character set needs to be upgraded on the client and historical data exists, you need to convert the historical data before the upgrade.
- **client_encoding** can be set to **ZHS16GBK**. The following table lists the setting methods of **server_encoding** and **client_encoding** corresponding to all ways that ZHS16GBK, GB18030, and GB18030_2022 character sets can be transformed.

server_encoding	client_encoding	locale	Setting Method
zhs16gbk	utf8	utf8	The database automatically obtains the value of **locale**.

server_encoding	client_encoding	locale	Setting Method
utf8	zhs16gbk	gbk	• Users use gsql to manually set **client_encoding** to **zhs16gbk**. • When JDBC is used for connection, the URL parameter is used to set **characterEncoding** to **zhs16gbk**.
zhs16gbk	zhs16gbk	gbk	• When gsql is used for connection, the database automatically obtains the value of **locale**. After internal processing, **client_encoding** is automatically set to **zhs16gbk**. • When JDBC is used for connection, the URL parameter is used to set **characterEncoding** to **zhs16gbk**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

server_encoding	client_encoding	locale	Setting Method
zhs16gbk	gb18030	gb18030	• When gsql is used for connection, the database automatically obtains the value of **locale**. • When JDBC is used for connection, the URL parameter is used to set **characterEncoding** to **gb18030**.
gb18030	zhs16gbk	gbk	• gsql does not support this setting. • When JDBC is used for connection, the URL parameter is used to set **characterEncoding** to **zhs16gbk**.
zhs16gbk	gb18030-2022	gb18030	• When gsql is used for connection, users manually set **client_encoding** to **gb18030_2022**. • When JDBC is used for connection, the URL parameter is used to set **characterEncoding** to **gb18030_2022**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

server_encoding	client_encoding	locale	Setting Method
gb18030-2022	zhs16gbk	gbk	• gsql does not support this setting. • When JDBC is used for connection, the URL parameter is used to set **characterEncoding** to **zhs16gbk**.
gb18030	utf8	utf8	The database automatically obtains the value of **locale**.
utf8	gb18030	gb18030	• The database automatically obtains the value of **locale**. • When JDBC is used for connection, the URL parameter is used to set **characterEncoding** to **gb18030**.
gb18030_2022	utf8	utf8	The database automatically obtains the value of **locale**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

server_encoding	client_encoding	locale	Setting Method
utf8	gb18030_2022	gb18030	• When gsql is used for connection, users manually set **client_encoding** to **gb18030_2022**. • When JDBC is used for connection, the URL parameter is used to set **characterEncoding** to **gb18030_2022**.
gb18030	gb18030	gb18030	• The database automatically obtains the value of **locale**. • When JDBC is used for connection, the URL parameter is used to set **characterEncoding** to **gb18030**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

server_encoding	client_encoding	locale	Setting Method
gb18030_2022	gb18030_2022	gb18030	• When gsql is used for connection, the database automatically obtains the value of **locale**. After internal processing, **client_encoding** is automatically set to **gb18030_2022**. • When JDBC is used for connection, the URL parameter is used to set **characterEncoding** to **gb18030_2022**.

Default value: **"UTF8"**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Set this parameter based on frontend services. Try to keep the encoding consistent on the client and server to improve efficiency. You are advised to set this parameter to **"SQL_ASCII"** or **"UTF8"**.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

lc_messages

Parameter description: Specifies the language in which messages are displayed.

Parameter type: string.

Unit: none

Value range: The value range is related to the system. You can run the **locale -a** command to view the value range.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- You can run the **locale -a** command to check the system-supported locales and the corresponding encodings, and select one as required.
- On some systems, this value range does not exist. Setting this variable will still work, but there will be no effect. In addition, translated messages for the desired language may not exist. In this case, you can still see the English messages.
- By default, **gs_initdb** will initialize the setting of this parameter based on the current system environment. You can also run the **locale** command to check the current configuration environment.

Default value: **"C"**

Setting method: This is a SUSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

lc_monetary

Parameter description: Specifies the display format of monetary values. It affects the output of functions such as to_char(). Acceptable values are system-related.

Parameter type: string.

Unit: none

Value range: The value range is related to the system. You can run the **locale -a** command to view the value range.

NOTE

- You can run the **locale -a** command to check the system-supported locales and the corresponding encodings, and select one as required.
- By default, **gs_initdb** will initialize the setting of this parameter based on the current system environment. You can also run the **locale** command to check the current configuration environment.
- If this parameter is modified by running the **gs_guc reload** command and the connection of a session on the current node is not from the client but from another node in the cluster to which the node belongs, this parameter does not take effect immediately on the session after the **gs_guc reload** command is executed. The setting takes effect only after the connection node is disconnected and then reconnected.

Default value: **"C"**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

lc_numeric

Parameter description: Specifies the display format of numbers. It affects the output of functions such as **to_char**.

Parameter type: string.

Unit: none

Value range: The value range is related to the system. You can run the **locale -a** command to view the value range.

NOTE

- You can run the **locale -a** command to check the system-supported locales and the corresponding encodings, and select one as required.
- By default, **gs_initdb** will initialize the setting of this parameter based on the current system environment. You can also run the **locale** command to check the current configuration environment.
- If this parameter is modified by running the **gs_guc reload** command and the connection of a session on the current node is not from the client but from another node in the cluster to which the node belongs, this parameter does not take effect immediately on the session after the **gs_guc reload** command is executed. The setting takes effect only after the connection node is disconnected and then reconnected.

Default value: **"C"**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

lc_time

Parameter description: Specifies the display format of time and locale. It affects the output of functions such as to_char().

Parameter type: string.

Unit: none

Value range: The value range is related to the system. You can run the **locale -a** command to view the value range.

NOTE

- You can run the **locale -a** command to check the system-supported locales and the corresponding encodings, and select one as required.
- By default, **gs_initdb** will initialize the setting of this parameter based on the current system environment. You can also run the **locale** command to check the current configuration environment.
- If this parameter is modified by running the **gs_guc reload** command and the connection of a session on the current node is not from the client but from another node in the cluster to which the node belongs, this parameter does not take effect immediately on the session after the **gs_guc reload** command is executed. The setting takes effect only after the connection node is disconnected and then reconnected.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Default value: **"C"**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

lc_time_names

Parameter description: Specifies the language used to display names and abbreviations of dates and months. The output of the DATE_FORMAT(), DAYNAME(), and MONTHNAME() functions is affected. The performance of STR_TO_DATE() and GET_FORMAT() is not affected.

Parameter type: string.

Unit: none

Value range: IETF language tags in simple format, such as **en_US** or **zh_CN**.

Default value: **"en_US"**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Switch the language based on service requirements.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

default_week_format

Parameter description: Specifies the default **mode** value of the week() function. The following table lists the value range and description.

default_week_format	First Day of a Week	Range	First Week Definition
0	Sunday	0 to 53	The first week that contains a Sunday in this year.
1	Monday	0 to 53	The first week that contains four or more days in this year.
2	Sunday	1 to 53	The first week that contains a Sunday in this year.
3	Monday	1 to 53	The first week that contains four or more days in this year.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

default_week_format	First Day of a Week	Range	First Week Definition
4	Sunday	0 to 53	The first week that contains four or more days in this year.
5	Monday	0 to 53	The first week that contains a Monday in this year.
6	Sunday	1 to 53	The first week that contains four or more days in this year.
7	Monday	1 to 53	The first week that contains a Monday in this year.

NOTE

For week 1 of a year, the number 1 indicates a week number. The week number of the first week of a year may be 0, depending on the value of **week_format**, as shown in the third column.

Parameter type: integer.

Unit: none

Value range: –2147483648 to 2147483647

- If the value is less than 0, it is forcibly changed to **0**.
- If the value is greater than 7, it is forcibly changed to **7**.

Default value: **0**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Select a mode based on service requirements.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

6.3.14.3 Other Default Parameters

This section describes the default database loading parameters.

dynamic_library_path

Parameter description: Specifies the path that the system will search for a shared database file that is dynamically loadable. When a dynamically loadable module needs to be opened and the file name specified in the **CREATE FUNCTION** or **LOAD** command does not contain a directory, the system will search this path for the required file. Only the SYSADMIN user can access this parameter.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter type: string.

Unit: none

Value range: a list of absolute paths separated by colons (;) in Windows.

When the name of a path starts with the special variable *$libdir*, the variable will be replaced with the directory in which the module provided by GaussDB is installed. For example:

```
dynamic_library_path = '/usr/local/lib/gaussdb:/opt/testgs/lib:$libdir'
```

NOTE

If the value of this parameter is set to an empty character string, the automatic path search is turned off.

Default value: **"$libdir"**

Setting method: This is a SUSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: The dynamic library search paths specified by **local_preload_libraries** and **shared_preload_libraries** also depend on this parameter. If this parameter is left blank or set to an invalid path, the dynamic libraries fail to be loaded, which will result in abnormal database services.

gin_fuzzy_search_limit

Parameter description: Specifies the upper soft limit of the size of the set returned by the UGIN or GIN. If this parameter is not set to the default value, an error is reported during UGIN scan.

Parameter type: integer.

Unit: none

Value range: 0 to 2147483647

Default value: **0**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

enable_astore_gin

Parameter description: Specifies whether to enable the GIN function. If this function is enabled, Astore supports GIN creation. If this function is disabled, the GIN function is unavailable.

Parameter type: Boolean.

Unit: none

Value range:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **on**: Astore supports the GIN function.
- **off**: Astore does not support the GIN function.

Default value: **on**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value and adjust the value based on service requirements.

Risks and impacts of improper settings: none

enable_astore_gist

Parameter description: Specifies whether to enable the GiST function. If this function is enabled, Astore supports GiST creation. If this function is disabled, the GiST function is unavailable.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: Astore supports the GiST function.
- **off**: Astore does not support the GiST function.

Default value: **on**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value and adjust the value based on service requirements.

Risks and impacts of improper settings: none

local_preload_libraries

Parameter description: Specifies one or more shared libraries that are to be preloaded at connection start. If multiple shared libraries are separated with commas (,). All library names (except the names in double quotation marks) are converted to lower case.

- Any user can change this option. Therefore, library files that can be loaded are restricted to those saved in the **plugins** subdirectory of the standard library installation directory. It is the database administrator's responsibility to ensure that libraries in this directory are all safe. Entries in **local_preload_libraries** can specify the library directory explicitly, for example, **$libdir/plugins/mylib**, or just specify the library name, for example, **mylib**. (**mylib** is equivalent to **$libdir/plugins/mylib**.)
- Unlike **shared_preload_libraries**, there are no differences in performance between loading a module at session start or doing this during the session. The intent of this feature is to allow debugging or performance-measurement libraries to be loaded into specific sessions without an explicit LOAD command. For example, debugging can be enabled under a given username by setting this parameter to **ALTER USER SET**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- Every GaussDB-supported library has a "magic block" that is checked to guarantee compatibility. For this reason, non-GaussDB-supported libraries cannot be loaded in this way.

Parameter type: string.

Unit: none

Value range: a list of shared libraries separated by commas (,), or an empty string.

Default value: ""

Setting method: This is a BACKEND parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If the specified library is not found, the connection fails. If the configuration is incorrect (for example, the length exceeds the limit or the directory is invalid), the process cannot be started properly.

enable_driver_param_sync

Parameter description: Specifies whether the GUC parameters specified when the driver creates a database connection are synchronized from CNs to DNs.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: enabled.
- **off**: disabled.

Default value: **off** for an upgraded database instance and **on** for a newly installed database instance.

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value. For an upgraded database, you are advised to manually set this parameter to **on** after evaluating the impact on services.

Risks and impacts of improper settings: If this parameter is set to **off**, after the **RESET ALL** command is executed, the parameter values set on CNs when the driver creates a connection are restored to the values set during connection, and the parameter values on DNs are restored to the default values. In this case, the parameter values on CNs and DNs are different. Therefore, you are advised to manually set this parameter to **on** for an upgraded database after evaluating the impact on services to avoid parameter inconsistency.

6.3.15 Lock Management

In GaussDB, a deadlock may occur when concurrently executed transactions compete for resources. This section describes parameters used for managing transaction locks.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

deadlock_timeout

Parameter description: Specifies the deadlock timeout interval. When the applied lock exceeds the preset value, the system will check whether a deadlock occurs. This parameter takes effect only for common locks.

Parameter type: integer.

Unit: ms

Value range: 1 to 2147483647

Default value: **1000** (that is, 1s)

Setting method: This is a SUSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion:

- The check for deadlock is relatively expensive. Therefore, the server does not check it when waiting for a lock every time. Deadlocks seldom occur when the system is running. Therefore, the system just needs to wait on the lock for a while before checking for deadlocks. Increasing the value of **deadlock_timeout** reduces the time wasted in deadlock check, but slows down reporting of real deadlock errors. On a heavily loaded server, you may need to set **deadlock_timeout** to a larger value. It is recommended that this value exceed the transaction time to avoid deadlock check before locks are released.
- When **log_lock_waits** is set to **on**, **deadlock_timeout** determines the wait time threshold beyond which lock wait information is written to the logs during query execution. To study the lock delay, you can set **deadlock_timeout** to a value smaller than the normal value.

Risks and impacts of improper settings: If the value is too large, the speed of reporting deadlock errors is slowed down. If the value is too small, deadlock detection starts before the lock is released.

NOTE

Only partial deadlocks caused by a single node can be detected. Distributed global deadlocks involving multi-node collaboration cannot be detected.

lockwait_timeout

Parameter description: Specifies the maximum wait time for a single lock in the application process of all lock types except **update_lockwait_timeout** and **ddl_lockwait_timeout**. If the waiting time of the preceding locks exceeds the value of this parameter, the system reports an error. This parameter takes effect only for common locks.

Parameter type: integer.

Unit: ms

Value range: 0 to 2147483647

Default value: **1200000** (20 minutes)

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**. For example, if the value is **900** without a unit, **lockwait_timeout** indicates 900 ms. If the value is **20min**, **lockwait_timeout** indicates 20 minutes. The unit must be **ms**, **s**, **min**, **h**, or **d** if required.

Setting suggestion: Retain the default value. Set this parameter based on the lock conflict timeout interval in the service scenario. If the value is less than 1s and not 0, the preceding locks will wait for at least 1s before reporting timeout. To make all lock types wait indefinitely, set this parameter to **0**. (**update_lockwait_timeout** and **ddl_lockwait_timeout** do not specify whether to wait indefinitely.)

Risks and impacts of improper settings: If a lock conflict occurs when the preceding locks are requested, a large value of this parameter will prolong the blocking time, and a small value will increase the number of timeout errors.

update_lockwait_timeout

Parameter description: Specifies the maximum waiting time for applying for a transaction ID lock or a tuple lock when concurrent updates are allowed in a row. If the time spent in waiting for a lock exceeds the specified time, an error is reported. This parameter takes effect only for common locks.

Parameter type: integer.

Unit: ms

Value range: 0 to 2147483647

Default value: **120000** (2 minutes)

Setting method: This is a SUSET parameter. Set it based on instructions provided in **Table 6-1**. For example, if the value is **900** without a unit, **update_lockwait_timeout** indicates 900 ms. If the value is **2min**, **update_lockwait_timeout** indicates 2 minutes. The unit must be **ms**, **s**, **min**, **h**, or **d** if required.

Setting suggestion: Retain the default value. Set the value based on the workload of transactions that concurrently update the same row. In most TP workloads, transactions complete in less than 2 minutes, so the wait time for concurrent update transactions to commit is usually short. In this case, the default value of 2 minutes rarely causes lock timeouts. If many concurrent transactions update the same row and execution time exceeds 2 minutes, you can increase this value to reduce false lock timeout errors. If the value is less than 1s, the preceding locks will wait for at least 1s before reporting timeout.

Risks and impacts of improper settings: During concurrent data update in the same row, if a lock conflict occurs when the transaction ID lock or tuple lock is applied for, the blocking time is prolonged if the value is too large; more transaction ID locks or tuple locks may time out if the value is too small.

ddl_lockwait_timeout

Parameter description: Specifies the maximum waiting time for a single lock when some DDL services apply for advanced object locks (level-5 to level-8 locks) on table objects, index objects, and stored procedures/packages/functions. If the time spent in waiting for a lock exceeds the specified time, an error is reported.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter type: integer.

Unit: ms

Value range: 0 to 2147483647

Default value: **120000** (2 minutes)

Setting method: This is a SUSET parameter. Set it based on instructions provided in **Table 6-1**. For example, if the value is **900** without a unit, **ddl_lockwait_timeout** indicates 900 ms. If the value is **2min**, **ddl_lockwait_timeout** indicates 2 minutes. The unit must be **ms**, **s**, **min**, **h**, or **d** if required.

Setting suggestion: Retain the default value. Set this parameter to the expected maximum waiting time based on the DDL service requirements on the timeout interval of the preceding advanced locks. If the value is less than 1s, the preceding locks will wait for at least 1s before reporting timeout.

Risks and impacts of improper settings: If a lock conflict occurs when the preceding advanced locks are requested for DDL services, a large value of this parameter will prolong the blocking time, and a small value will increase the number of advanced lock timeout errors.

max_locks_per_transaction

Parameter description: Specifies the average number of object locks that each transaction can hold when the number of database connections reaches the maximum.

NOTE

This parameter does not strictly limit the maximum number of object locks that can be held by each transaction. If the number of connections does not reach the maximum value (**max_connections**), the average number of object locks that can be held by each transaction increases.

Parameter type: integer.

Unit: none

Value range: 10 to 2147483647

Default value: **256**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion:

- The maximum number of hash tables that can be locked by a shared lock at any time is calculated based on an assumption: **max_locks_per_transaction** × (**max_connections** + **max_prepared_transactions**) and **max_locks_per_transaction** ≥ Number of concurrent service transactions × Number of object locks added by each service transaction/(**max_connections** + **max_prepared_transactions**). In this case, an upper limit is determined for this parameter.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- Within the specified range, objects can be locked simultaneously at any time. You may need to increase the value of this parameter if many different tables are modified in a single transaction.
- Increasing the value of this parameter may cause GaussDB to request more System V-shared memory than the OS's default configuration allows, leading to database startup failure. You are advised to set this parameter to a value less than or equal to **max_process_memory** x 10%/(**max_connections** + **job_queue_processes** + **autovacuum_max_workers** + **max_inner_tool_connections** + **max_concurrent_autonomous_transactions** + 1280 + **max_prepared_transactions** x **TWOPHASE_PART**)/(512 bytes). **1280** is the estimated number of reserved auxiliary threads and other threads. The unit of **max_process_memory** must be converted into bytes.
- When running a standby node, you must set this parameter to a value that is no less than that on the primary node. Otherwise, queries will not be allowed on the standby node.
- If this parameter is set to a smaller value and the standby node is faulty before the restart, the standby node fails to be restored. You are advised to set the parameters to the original values and restart the system to restore the environment.
- In specification degradation and DR scenarios, you are advised not to perform DDL operations frequently when modifying this parameter. Otherwise, a memory error will be reported.

Risks and impacts of improper settings: If the value is too large, the database may fail to be started.

max_pred_locks_per_transaction

Parameter description: Specifies the average number of predicate locks that each transaction can hold when the number of database connections reaches the maximum.

NOTE

This parameter does not strictly limit the maximum number of predicate locks that can be held by each transaction. If the number of connections does not reach the maximum value (**max_connections**), the average number of predicate locks that can be held by each transaction increases.

Parameter type: integer.

Unit: none

Value range: 10 to 2147483647

Default value: **64**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion:

- The size of the shared predicate lock table is calculated under the condition that a maximum of *N* independent objects need to be locked at any time. *N* = **max_pred_locks_per_transaction** x (**max_connections** + **max_prepared_transactions**). Within the specified range, objects can be

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

locked simultaneously at any time. You may need to increase this value if many different tables are modified in a single transaction. This parameter can only be set at server start.

- Increasing the value of this parameter may cause GaussDB to request more System V-shared memory than the OS's default configuration allows.

Risks and impacts of improper settings: If the value is too large, the database may fail to be started.

gs_clean_timeout

Parameter description: Transactions in GaussDB are committed in two phases. An unfinished two-phase transaction may hold a table-level lock, keeping tables from being locked by other connections. In this case, the database needs to call the gs_clean tool to clean unfinished two-phase transactions in cluster. **gs_clean_timeout** is used to specify the interval for the CN to call the gs_clean tool. gs_clean can periodically clear residual temporary tables.

Parameter type: integer.

Unit: seconds

Value range: 0 to 2147483

Default value: **60**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**. For example, if the value is **1** without a unit, **gs_clean_timeout** indicates 1s. If the value is **1min**, **gs_clean_timeout** indicates 1 minute. The unit must be **s**, **min**, **h**, or **d** if required.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this parameter is set to a large value, the interval for clearing two-phase transactions and residual temporary tables is prolonged. As a result, other connections may fail to be locked before the clearing.

partition_lock_upgrade_timeout

Parameter description: Specifies the timeout for attempts to upgrade an exclusive lock (read allowed) to an access exclusive lock (read/write blocked) on a partitioned table during the execution of some query statements. If there are concurrent read transactions running, the lock upgrade will need to wait. **partition_lock_upgrade_timeout** sets the waiting timeout for lock upgrade attempts.

Example: When you perform **MERGE PARTITION** and **CLUSTER PARTITION** on a partitioned table, temporary tables are used for data rearrangement and file exchange. To concurrently perform as many operations as possible on the partitions, exclusive locks are acquired for the partitions during data rearrangement and access exclusive locks are acquired during file exchange. The locking mode is attempt locking. If the locking is successful, a response is returned immediately. If the locking fails, the system waits for 50 ms and attempts to lock the next time. The locking timeout interval is specified by the session-level parameter **partition_lock_upgrade_timeout**.

Parameter type: integer.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Unit: seconds

Value range: –1 to 3000. **-1** indicates infinite waiting. That is, the system continuously attempts to upgrade the lock until the upgrade is successful.

Default value: **1800**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this parameter is set to **-1**, services may be blocked when the lock cannot be upgraded for a long time.

fault_mon_timeout

Parameter description: Specifies the period for detecting lightweight deadlocks.

Parameter type: integer.

Unit: minute

Value range: 0 to 1440

Default value: **5**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this parameter is set to a large value, deadlocks cannot be detected in a timely manner, which slows down the speed of reporting deadlock errors.

enable_online_ddl_waitlock

Parameter description: Specifies whether to block DDL operations to wait for the release of cluster locks, such as **pg_advisory_lock** and **pgxc_lock_for_backup**.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: enabled.
- **off**: disabled.

Default value: **off**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: This parameter is mainly used in online OM operations and you are advised not to modify the settings.

Risks and impacts of improper settings: Changing the value of this parameter may cause unexpected results in the cluster. Retain the default value.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

xloginsert_locks

Parameter description: Specifies the number of locks on concurrent write-ahead logging. This parameter is used to improve the efficiency of writing write-ahead logs.

Parameter type: integer.

Unit: none

Value range: 1 to 1000. If the CPU uses the NUMA architecture, the value must be an integer multiple of the number of NUMA nodes.

Default value: 16

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: When the concurrency pressure of the Arm CPU architecture is high, performance jitter may occur due to atomic operation competition. You can decrease the value of this parameter for stable running performance.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

num_internal_lock_partitions

Parameter description: Specifies the number of internal lightweight lock partitions. It is mainly used for performance optimization in various scenarios.

NOTE

- The parameter content is organized in the KV format of keywords and numbers. Different types of locks are separated by commas (,).
- The sequence does not affect the setting result. For example, **"CLOG_PART=256,CSNLOG_PART=512"** is equivalent to **"CSNLOG_PART=512,CLOG_PART=256"**.
- If you set the same keyword repeatedly, the last setting takes effect. For example, if the setting is **"CLOG_PART=256,CLOG_PART=2"**, the value of **CLOG_PART** is **2**.

Parameter type: string.

Unit: none

Value range:

- **CLOG_PART**: number of Clog file controllers. The value ranges from 1 to 256.
- **CSNLOG_PART**: number of CSNlog file controllers. The value ranges from 1 to 512.
- **LOG2_LOCKTABLE_PART**: the base-2 logarithm of the number of regular lock table partitions. The minimum value is **4**, that is, the number of lock partitions is 16. The maximum value is **12**, that is, the number of lock partitions is 4096.
- **TWOPHASE_PART**: number of partitions of the two-phase transaction lock. The value ranges from 1 to 64.
- **FASTPATH_PART**: maximum number of locks that each thread can obtain without using the main lock table. The value ranges from 20 to 10000.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **FASTPATH_PART_PER_SHARD**: size of a single FASTPATH partition when each thread applies for a lock through FASTPATH. The value ranges from 20 to 10000.
- **FASTPATH_PROCEDURE_PART**: maximum number of stored procedure object locks that can be applied for by each thread without using the main lock table. The value ranges from 0 to 10000.

Default value:
"CLOG_PART=256,CSNLOG_PART=512,LOG2_LOCKTABLE_PART=4,TWOPHASE_PART=1,FASTPATH_PART=20,FASTPATH_PART_PER_SHARD=20,FASTPATH_PROCEDURE_PART=100"

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion:

- **CLOG_PART**: Increasing the value of this parameter improves the Clog writing efficiency and transaction commit performance, but increases the memory usage. Decreasing the value of this parameter reduces the memory usage, but may increase the conflict of writing Clogs and affect the performance.
- **CSNLOG_PART**: Increasing the value of this parameter improves the CSNlog writing efficiency and transaction commit performance, but increases the memory usage. Decreasing the value of this parameter reduces the memory usage, but may increase the conflict of writing CSNlogs and affect the performance.
- **LOG2_LOCKTABLE_PART**: Increasing the value can improve the degree of parallelism of obtaining locks in the normal process, but may increase the memory usage. When wait events occur in **LockMgrLock**, you can increase the value to improve the performance.
- **TWOPHASE_PART**: Increasing the value of this parameter increases the number of concurrent two-phase transaction commits but increases the memory usage. If an error indicating insufficient slots is reported for a two-phase transaction (the "Maximum number of prepared transactions reached, please increase max_parepared_transactions (currently max_parepared_transactions) or wait gs_clean to clean reserved prepared transactions." log is generated on the CN or DN), you are advised to increase the value of this parameter to avoid severe transaction lock conflicts.
- **FASTPATH_PART**: When a partitioned table is read, updated, inserted, or deleted and a wait event is **LockMgrLock**, you can increase the value of this parameter to prevent **LockMgrLock** from being obtained, improving performance. It is recommended that the value be greater than or equal to that calculated using the following formula: Number of partitions x (1 + Number of local indexes) + Number of global indexes + 10. Increasing the value will increase the memory usage. The incremental FASTPATH memory (unit: bytes) is calculated as follows: (Incremental FASTPATH/20 x 8 + Incremental FASTPATH x 12) x Thread pool size.
- **FASTPATH_PART_PER_SHARD**: size of a FASTPATH partition. If the value is large, it takes a long time to traverse FASTPATH partitions, which may deteriorate the performance. You are advised to use the default value.
- **FASTPATH_PROCEDURE_PART**: If the wait event of a stored procedure is **LockMgrLock**, you can increase the value of this parameter to prevent **LockMgrLock** from being obtained, improving performance. It is

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

recommended that the value be greater than the maximum depth of nested stored procedure calls. Increasing the value will increase the memory usage. The incremental memory (unit: bytes) is calculated as follows: (Incremental value/20 x 8 + Incremental value x 12) x Thread pool size.

Risks and impacts of improper settings: The database performance may be affected.

enable_wait_exclusive_lock

Parameter description: Specifies whether to enable the hang detection and cure function for the exclusive lock of ProcArrayLock.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: enabled.
- **off**: disabled.

Default value: **on**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

barrier_lock_timeout

Parameter description: Specifies the timeout interval for holding a barrier lock.

Parameter type: integer.

Unit: seconds

Value range: 0 to 3600

Default value: **30**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

track_activity_history_query_number

Parameter description: Specifies the maximum number of historical commands in a transaction that can be printed in the log after a deadlock occurs.

Parameter type: integer.

Unit: none

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Value range: 1 to 1000

Default value: **1**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Set this parameter based on the number of commands in a single transaction. You are advised to set this parameter to a value less than 10. The database pre-allocates memory. The memory size is the value of **track_activity_query_size** multiplied by the maximum number of threads and then multiplied by the value of **track_activity_history_query_number**. **max_connections** is the factor that affects the maximum number of threads. If **max_connections** is set to a large value, the maximum number of estimated threads increases (the maximum number of threads may exceed 500,000). As a result, a large memory is allocated. In this case, exercise caution when increasing the number specified by **track_activity_history_query_numbers**.

Risks and impacts of improper settings: If the value is too large, a large number of logs will be printed and a large memory is allocated when a deadlock occurs.

enable_xid_abort_check

Parameter description: Specifies whether to verify transaction ID rollback is enabled when a transaction is committed.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: enabled.
- **off**: disabled.

Default value: **on**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

enable_partition_ddl_lowlevel_lock

Parameter description: Locks a partitioned table during the execution of the DDL statements (ADD, DROP, TRUNCATE, EXCHANGE, MOVE, and RENAME). This parameter specifies the lock level of a table. If this parameter is set to **on**, a level-4 lock is added to the table, and DDL/DML operations can be concurrently performed on other partitions of the table. If this parameter is set to **off**, a level-8 lock is added to the table, and DDL/DML operations cannot be concurrently performed on other partitions of the table.

Parameter type: Boolean.

Unit: none

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Value range:

- **on**: enabled.
- **off**: disabled.

Default value: **off** for an upgraded database instance and **on** for a newly installed database instance.

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this parameter is set to **on**, DDL/DML operations can be concurrently performed on other partitions of a table, which has high performance. However, due to factors such as network delay, the execution sequences of concurrent DDL and DML operations on different DNs may be different, causing distributed deadlocks between DNs. If this parameter is set to **off**, DDL/DML operations cannot be concurrently performed on other partitions of the table. This has no performance advantage but no deadlock risk.

6.3.16 Version and Platform Compatibility

6.3.16.1 Compatibility with Earlier Versions

This section describes the parameters that control the backward compatibility and external compatibility of GaussDB. A backward compatible database supports applications of earlier versions. This section describes parameters used for controlling backward compatibility of a database.

array_nulls

Parameter description: Specifies whether the array input parser recognizes unquoted NULL as a null array element. This parameter is not supported in M-compatible mode.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: Null values can be entered in arrays.
- **off**: Old behaviors are backward compatible. Arrays containing the value **NULL** can still be created when this parameter is set to **off**.

Default value: **on**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

backslash_quote

Parameter description: Determines whether a single quotation mark can be represented by \' in a string text.

NOTE

When the string text meets the SQL standards, \ has no other meanings. This parameter only affects the handling of non-standard-conforming string texts, including escape string syntax (E'...').

Parameter type: enumerated type.

Unit: none

Value range:

- **on**: The use of \' is always allowed.
- **off**: The use of \' is not allowed.
- **safe_encoding**: The use is allowed only when client-side encoding does not contain a backslash (\) at the end of a multibyte character for an ASCII value.

Default value: **safe_encoding**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

escape_string_warning

Parameter description: Specifies whether to warn against backslash (\) escapes used in ordinary character strings.

- If you need to use a backslash (\) as an escape, you can use escape string syntax (E'...'). This is because the default behavior of ordinary character strings treats the backslash as an ordinary character in each SQL standard.
- This variable can be enabled to help locate codes that need to be changed.
- If E'...' is used as an escape, logs may be incomplete in some scenarios.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: Warn against backslash escapes used in ordinary character strings.
- **off**: Do not warn against backslash escapes used in ordinary character strings.

Default value: **on**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

quote_all_identifiers

Parameter description: Specifies whether to forcibly quote all identifiers even if they are not keywords when the database generates SQL. This will affect the output of **EXPLAIN** and the results of functions, such as pg_get_viewdef. For details, see the **--quote-all-identifiers** parameter in **gs_dump for Exporting Database Information**.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The forcible quoting is enabled.
- **off**: The forcible quoting is disabled.

Default value: **off**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

sql_inheritance

Parameter description: Specifies the access policy of an inherited table. This parameter is set to be compatible with earlier versions.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: Subtables can be accessed.
- **off**: Subtables cannot be accessed. That is, the ONLY keyword is used by default.

Default value: **on**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

standard_conforming_strings

Parameter description: Specifies whether ordinary string texts ('...') regard backslashes (\) as ordinary texts as specified in the SQL standard in a non-M-

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

compatible database. Applications can check this parameter to determine how string texts will be processed. You are advised to use the escape string syntax (E'...') to escape characters. This syntax takes precedence over this parameter. Even if this parameter is set to **on**, backslashes (\) in escape strings are still interpreted as escape characters. The setting of this parameter does not take effect in an M-compatible database.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: Backslashes are regarded as ordinary texts as specified in the SQL standard.
- **off**: Backslashes are regarded as escape characters in the string literal value.

Default value: **on**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

synchronize_seqscans

Parameter description: Specifies whether parallel sequence scans are synchronized with each other.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The scan may start from the middle of the table and then overwrite all rows in surround mode. The purpose is to keep synchronization with the scan that is being executed. This synchronization mechanism can improve the performance of parallel sequence scanning, but queries without using ORDER BY may return out-of-order results.
- **off**: The synchronization behavior of order scans is disabled. Each scan starts from the start position of the table. This ensures that queries without using ORDER BY return results that are consistent with the physical storage sequence, but parallel scanning efficiency may be reduced.

Default value: **on**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

enable_beta_features

Parameter description: Specifies whether to enable some features that are not officially released and are used only for POC verification, such as GDS table join.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The features are enabled for compatibility with earlier versions.
- **off**: The features are disabled.

Default value: **off**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Exercise caution when enabling these extended features because they may cause errors in some scenarios.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

enable_recordtype_check_strict

Parameter description: Specifies whether to perform strict check on the record type in PL/SQL. For details, see the following description.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The record type created during compilation of stored procedures, functions, and packages is checked for unsupported functions, and the record type created by provided stored procedures and functions is checked for the NOT NULL function.
- **off**: The backward compatibility is performed and the record type is not checked.

Default value: **on**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this parameter is set to **off**, some *record* variables that specify the NOT NULL constraint and define the default value of a column do not take effect during value assignment.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- If the current database version is directly installed, the default value of this parameter is **on**. For a database upgraded from an earlier version, if the source version does not support this parameter, the default value of this parameter is **off** after the upgrade. If the source version supports this parameter, the current setting of this parameter is retained after the upgrade.
- After this parameter is enabled, the following three changes occur:
  - For the record type created in a stored procedure or function, the NOT NULL constraint of the columns takes effect.
  - If **NOT NULL** or **DEFAULT** is specified for a column of the record type created in a package, a compilation error is reported. Variables created by accessing the package.rec type do not support **NOT NULL** and **DEFAULT**.
  - If **NOT NULL** or **DEFAULT** is specified for a column of another type with a nested record type, a compilation error is reported. For a variable nested with the record type, the record element of the variable does not support **NOT NULL** and **DEFAULT**.

plsql_block_concat_typename

Parameter description: Specifies the combination mode of user-defined type names in PL/SQL subblocks.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: A user-defined type in the PL/SQL subblock is used. The name of the user-defined type in the SQL statement is in the format of *OID*.[*m.n*···].*typename*, where *OID* is the OID of the stored procedure, *typename* is the name of the user-defined type, and *m* and *n* are sequence numbers of subblocks. When a plurality of layers of subblocks are nested, a plurality of layers of sequence numbers are required. If there is only a single layer of subblocks, only *m* is required.
- **off**: The backward compatibility in original mode is used. The name format is *OID*.*typename*.

Default value:

- If a new version is directly installed, the default value is **on**.
- For a database upgraded from an earlier version, if the source version does not support the GUC parameter, the default value is **off**. If the source version supports the GUC parameter, the default value is **on**.

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If the value is **off** and the user-defined types in a subblock have the same name, the SQL statement cannot distinguish the user-defined types of different subblocks.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

default_with_oids

Parameter description: Specifies whether **CREATE TABLE** and **CREATE TABLE AS** include an **OID** field in newly-created tables if neither **WITH OIDS** nor **WITHOUT OIDS** is specified. It also determines whether OIDs will be included in tables created by **SELECT INTO**.

Parameter type: Boolean.

Unit: none

Value range:

- **on** indicates that **CREATE TABLE** and **CREATE TABLE AS** can include an **OID** column in newly-created tables.
- **off** indicates that **CREATE TABLE** and **CREATE TABLE AS** cannot include any **OID** column in newly-created tables.

Default value: **off**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: It is not recommended that OIDs be used in user tables. Therefore, this parameter is set to **off** by default. When OIDs are required for a particular table, **WITH OIDS** needs to be specified during the table creation.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

system_view_version

Parameter description: Determines the version of the system view. For details, see **Table 1 System view version parameters**. All versions are backward compatible. For example, when **system_view_version** is set to **3**, all features of version 2 and version 1 are also supported.

Parameter type: integer.

Unit: none

Value range: 0 to 9999

Default value: **1**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: In the upgrade scenario, do not change the value. In the installation scenario, set this parameter to the latest version listed in **Table 1 System view version parameters**.

Risks and impacts of improper settings: The behavior of some columns in the system view is changed. For details, see **Table 1 System view version parameters**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 6-28 System view version parameters

Value	Description
0	Default behavior.
1	When no prepared transaction exists in GaussDB, the value of the **PREPARECOUNT** column in the V$GLOBAL_TRANSACTION view changes from **NULL** to **0**.

enable_subtype_inherit_notnull_constraint

Parameter description: Specifies whether the NOT NULL constraint of subtype takes effect when subtype is used as a subelement of the set type and array type.

Parameter type: Boolean

Unit: none

Value range:

- **on**: When subtype is used as a subelement of the set type and array type, the NOT NULL constraint of subtype takes effect and no null value can be assigned to the element.
- **off**: When subtype is used as a subelement of the set type and array type, the NOT NULL constraint of subtype does not take effect and a null value can be assigned to the element.

Default value: **on**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this parameter is set to **off** and subtype is used as a subelement of the set type and array type, the NOT NULL constraint of subtype does not take effect.

NOTE

If the current database version is directly installed, the default value of this parameter is **on**. For a database upgraded from an earlier version, if the source version does not support this parameter, the default value of this parameter is **off** after the upgrade. If the source version supports this parameter, the current setting of this parameter is retained after the upgrade.

enable_create_rule_on_select_to_table

Parameter description: Specifies whether the operation is successful when an "ON SELECT TO ... DO INSTEAD" rule named "_RETURN" is created on a table to convert the table to a view.

Parameter type: Boolean.

Unit: none

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Value range:

- **on**: The "ON SELECT TO ... DO INSTEAD" rule named "_RETURN" is successfully created on the table to convert the table to a view.
- **off**: The "ON SELECT TO ... DO INSTEAD" rule named "_RETURN" fails to be created on the table to convert the table to a view.

Default value: **off**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Creating an "ON SELECT TO ... DO INSTEAD" rule named "_RETURN" on a table to convert the table to a view is an insecure operation and may cause unexpected errors. Views created in this way cannot be recompiled after they become invalid. Before modifying this parameter, make sure you understand its meaning and fully verify the change in a test environment.

6.3.16.2 Platform and Client Compatibility

Many platforms use the database system. External compatibility of the database system provides great convenience for platforms.

a_format_date_timestamp

Parameter description: Specifies whether to return the date and time. In ORA-compatible mode, when a transaction is started, the functions current_date(), current_timestamp(), and localtimestamp() return the timestamp when the current SQL statement is started.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: Returns the timestamp when the current SQL statement is started.
- **off**: Returns the date or date and time when the transaction is started.

Default value: **off**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value. This parameter can be enabled when the system time needs to be returned when a transaction is started.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

NOTE

When the value of **a_format_version** is **10c** and the value of **a_format_dev_version** is **s7**, this GUC parameter can be enabled. For details, see **a_format_dev_version**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

compatiable_o_function_version

Parameter description: Specifies the version number to change the logic for selecting overloaded system functions. This parameter takes effect only in ORA-compatible mode.

Parameter type: string

Unit: none

Value range:

- **"auto"**: indicates that the overloaded system functions added from 507.1.0 are selected.
- *Specific version number*: If the version number is 507.1.0 or later, the overloaded system functions added from 507.1.0 to the specified version are selected.

Default value: **"auto"**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Adjusting this parameter will change the logic for selecting overloaded system functions, which may result in the selection of incorrect overloaded system functions. Exercise caution when performing this operation.

NOTE

If the selected version is 507.1.0.SPC1100, set this parameter to **507.1.0.1100**. If the selected version is 507.1.0 (without an SPC version number), set this parameter to **507.1.0.0**.

convert_string_to_digit

Parameter description: Specifies the implicit conversion priority, which specifies whether to preferentially convert strings into numbers.

Parameter type: Boolean.

Unit: none

Value range:

- **on** indicates that strings are preferentially converted into numbers.
- **off** indicates that strings are not preferentially converted into numbers.

Default value: **on**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this parameter is modified, the internal data type conversion rule will be modified, causing unexpected behavior. Exercise caution when performing this operation.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

character_set_connection

Parameter description: Specifies the character set of constant strings. If this parameter is modified, **collation_connection** is changed to the default collation of the character set.

- This parameter takes effect when **sql_compatibility** is set to **'MYSQL'**, **b_format_version** is set to **'5.7'**, and **b_format_dev_version** is set to **'s2'**.
- This parameter takes effect in M-compatible mode.

Parameter type: string

Unit: none

Value range:

- Character sets supported in the compatibility mode whose **sql_compatibility** is set to **'MYSQL'**. For details, see **COLLATE collation**.
- In M-compatible mode, the value range is the supported character set. For details, see "SQL Reference > Character Sets and Collations" in *M Compatibility Developer Guide*.

Default value: same as the value of **server_encoding**.

Setting method: This is a USERSET parameter, which can only be set using method 3, and cannot be set using the GUC tools. For details about how to set this parameter, see **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If the configured character set is inconsistent with the current environment, transcoding may be performed for multiple times, affecting performance.

collation_connection

Parameter description: Specifies the collation of a constant string. If this parameter is modified, **character_set_connection** is changed to the default character set of the collation.

- This parameter takes effect when **sql_compatibility** is set to **'MYSQL'**, **b_format_version** is set to **'5.7'**, and **b_format_dev_version** is set to **'s2'**.
- This parameter takes effect in M-compatible mode.

Parameter type: string

Unit: none

Value range:

- Collations supported in the compatibility mode whose **sql_compatibility** is set to **'MYSQL'**. For details, see **COLLATE collation**.
- In M-compatible mode, the value range is the supported collations. For details, see "SQL Reference > Character Sets and Collations" in *M Compatibility Developer Guide*.

Default value: default collation of the current **server_encoding**. If it has no default collation, the value is **default**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Setting method: This is a USERSET parameter, which can only be set using method 3, and cannot be set using the GUC tools. For details about how to set this parameter, see **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If the configured collation is inconsistent with the current environment, transcoding may be performed for multiple times, affecting performance.

character_set_results

Parameter description: Specifies the character set of the returned result.

- This parameter takes effect when **sql_compatibility** is set to **'MYSQL'**, **b_format_version** is set to **'5.7'**, and **b_format_dev_version** is set to **'s2'**.
- This parameter takes effect in M-compatible mode.

Parameter type: string

Unit: none

Value range:

- Character sets supported in the compatibility mode whose **sql_compatibility** is set to **'MYSQL'**. For details, see **COLLATE collation**.
- In M-compatible mode, the value range is the supported character set. For details, see "SQL Reference > Character Sets and Collations" in *M Compatibility Developer Guide*.
- You can also set this parameter to **null** or **''**. In this case, the character set of the database is output.

Default value: same as the value of **client_encoding**.

Setting method: This is a USERSET parameter, which can only be set using method 3, and cannot be set using the GUC tools. For details about how to set this parameter, see **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If the configured character set is inconsistent with the current environment, garbled characters may be displayed.

enable_multiple_charset

Parameter description: Specifies whether tables, columns, and schemas whose character sets are different from the character set of the current database can be created in M-compatible mode.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: You can create tables, columns, and schemas whose character sets are different from the character set of the current database.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **off**: You cannot create tables, columns, and schemas whose character sets are different from the character set of the current database.

Default value: **on**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Set this parameter based on service requirements.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

enable_view_invalidation

Parameter description: Specifies whether to enable or disable the view invalidation function. After this parameter is enabled, if the object on which a view depends is changed, the upper-layer views that depend on the object become invalid.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The view invalidation function is enabled.
- **off**: The view invalidation function is disabled.

Default value: **off**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after you fully understand the parameter meaning and test the parameter to avoid unexpected results.

NOTE

For details about how to recompile an invalid view, see "Feature Usage Guidelines > Recompilation upon Invalidation" in *Developer Guide*.

enable_proc_exec_check

Parameter description: Specifies whether to check the validity of dependent objects when a stored procedure is executed. After this parameter is enabled, if the dependent object is invalid, the current stored procedure is not executed and an error is reported.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The validity check is performed when the stored procedure is executed.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **off**: The validity check is not performed when the stored procedure is executed.

Default value: **on**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Set this parameter based on the actual scenario.

Risks and impacts of improper settings: Change the parameter value after you fully understand the parameter meaning and test the parameter to avoid unexpected results.

NOTE

If the version is upgraded from an earlier version to 507.0 or later, this parameter is set to **off** by default. If the newly installed version is 507.0 or later, this parameter is set to **on** by default.

enable_show_view_original_definition

Parameter description: Specifies whether to display the original SELECT statement entered by a user when the view definition is queried in an ORA-compatible database.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The original SELECT statement entered by the user is displayed when the view definition is queried.
- **off**: The SELECT statement is displayed by reversely parsing the QUERY TREE statement when querying the view definition.

Default value: **off**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Set this parameter based on service requirements.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

NOTE

In ORA-compatible mode, this parameter affects the display result of functions or views (for example, \d+, dba_views, all_views, user_views, information_schema.views, pg_views, and pg_get_viewdef) that query view information.

fixed_date

Parameter description: Specifies the value of **sysdate** that can be fixed in an ORA-compatible database.

Parameter type: string

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Unit: none

Value range: all formats supported by timestamp. The value range is the time range (0001 to 9999) represented by **datea**. The date cannot be set to a negative value, which indicates the BC time. To indicate BC time, append **'BC'** to the end of the time.

Default value: **""**

Setting method: This is a SUSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Set this parameter based on service requirements.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing. This parameter cannot be enabled in the production environment and is used only for debugging.

mapping_date_to_datea

Parameter description: Specifies whether to replace the date type with the datea type in ORA-compatible mode.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The date type is replaced with the datea type.
- **off**: The behavior of the date type is retained in the default state.

Default value: **on** for a newly installed database. If the GUC parameter does not exist in the basic version to be upgraded, the default value is **off**. If the GUC parameter exists in the basic version to be upgraded, the original setting is retained.

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value. The value can be specified during database installation. If the value is not specified, the default value **on** is used, indicating that the date type is replaced by the datea type. You can enable or disable this parameter during installation as follows:

```
gs_install --dn-guc="mapping_date_to_datea=off" --cn-guc="mapping_date_to_datea=off" --gsinit-parameter="-- mapping_date_to_datea off"
```

Risks and impacts of improper settings: In ORA-compatible mode, the range, precision, and format of the date type may not be as expected.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- This parameter does not take effect during the upgrade observation period.
- This parameter is specified during database installation. You are advised not to modify this parameter after the database is started. If you modify the parameters during database running, the system views, system catalogs, and data related to the date type before the modification remain unchanged. The new object replaces the date type with the datea type.
- In the upgrade scenario, if the value of this parameter is changed after the upgrade is committed, the data created in the source version remains unchanged. For example, if this parameter is set to **off** in an earlier version and is set to **on** in a later version, the date type data created in the earlier version is still mapped to the timestamp type. To use the new datea type, create an object again according to the description in the data type.

nls_date_format

Parameter description: In Oracle-compatible mode, it is used for format control during the conversion between the DATEA type and the character type.

Parameter type: string

Unit: none

Value range: For details about the formats supported by **nls_date_format**, see **Table 1-12**. The following characters can be used as separators: hyphen (-), slash (/), comma (,), period (.), percent (%), colon (:), or a string enclosed in double quotation marks ("").

Default value: **"DD-MON-RR"**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Set this parameter based on service requirements. You are advised not to change the value frequently.

Risks and impacts of improper settings: The format verification may fail when the datea type is entered. As a result, an error is reported, or the entered time is not as expected.

nls_timestamp_format

Parameter description: Specifies the default timestamp format.

Parameter type: string

Unit: none

Value range: a string.

Default value: **"DD-Mon-YYYY HH:MI:SS.FF AM"**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

nls_timestamp_tz_format

Parameter description: Specifies the default timestamp with time zone format in Oracle-compatible mode.

Parameter type: string

Unit: none

Value range: a string.

Default value: **"DD-Mon-YYYY HH:MI:SS.FF AM"**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

NOTE

This parameter is valid only when **a_format_version** is set to **10c** and **a_format_dev_version** is set to **s1**.

nls_nchar_characterset

Parameter description: Specifies the national character set. This parameter is used together with the nchr(cvalue int|bigint) system function.

Parameter type: string.

Unit: none

Value range: **"AL16UTF16"** and **"UTF8"** (case-insensitive).

Default value: **"AL16UTF16"**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

NOTE

- The database does not support the national character set. This parameter is used only to be compatible with the Oracle Database and obtain the national character set for users.
- This GUC parameter applies only to the nchr(cvalue int|bigint) function.

group_concat_max_len

Parameter description: This parameter is used together with the group_concat() function to limit the length of the return value. If the length exceeds the limit, the return value is truncated and an error or alarm is generated. If **sql_mode** is set to

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

a value containing **STRICT_TRANS_TABLES**, an error is reported in the DML statement. In other scenarios, an alarm is reported.

Parameter type: integer.

Unit: none

Value range: 0 to 9223372036854775807. Currently, the maximum length that takes effect is 1073741823. If the length exceeds this limit, the out of memory error is reported.

Default value: 1024

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this parameter is set to a small value, the result returned by group_concat() may be truncated.

lastval_supported

Parameter description: Specifies whether the lastval() function can be used.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The lastval() function can be used and the nextval() function cannot be pushed down.
- **off**: The lastval() function cannot be used and the nextval() function can be pushed down.

Default value: **off**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

max_function_args

Parameter description: Specifies the maximum number of parameters allowed for a function.

Parameter type: integer.

Unit: none

Value range: **8192**

Default value: **8192**

Setting method: This is a fixed INTERNAL parameter. It can be viewed but cannot be modified.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Setting suggestion: This parameter can only be viewed.

Risks and impacts of improper settings: none

lower_case_table_names

Parameter description: Specifies whether the user table names (including table aliases), user view names, schema names (internal database names), and values of the columns corresponding to the preceding objects in the information_schema system view are case-sensitive in an M-compatible database. In the current version, the value of this parameter is **0** and cannot be changed.

Parameter type: integer.

Unit: none

Value range:

- **0**: User table names, user view names, and schema names (internal database names) are stored in system catalogs in the capitalization style specified in the CREATE TABLE, CREATE VIEW, and CREATE SCHEMA (CREATE DATABASE) statements. In the information_schema system view, the values of the columns corresponding to the preceding objects are case-sensitive.
- **1**: User table names are stored in lowercase in system catalogs. Names are case-insensitive. During storage and query operations, all user table names are converted to lowercase. This behavior also applies to schema names (internal database names), table aliases, user view names, and values of the corresponding columns in the information_schema system view.

Default value: **0**

Setting method: This is a fixed INTERNAL parameter. It can be viewed but cannot be modified.

Setting suggestion: This parameter can only be viewed.

Risks and impacts of improper settings: none

max_subpro_nested_layers

Parameter description: Specifies the maximum nesting depth of nested subprocedures.

Parameter type: integer.

Unit: none

Value range: 0 to 100

NOTE

When this parameter is set to **0**, nested subprocedures are not allowed.

Default value: **3**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Set this parameter based on the maximum nesting depth.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

transform_null_equals

Parameter description: Specifies whether expressions of the form **expr=NULL** (or **NULL=expr**) are treated as **expr IS NULL**. The correct SQL-standard-compliant behavior of **expr=NULL** is to always return **NULL** (unknown). Filtered forms in Microsoft Access generate queries that appear to use **expr=NULL** to test for null values. After you enable this option, you can use this API to access the database.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: Expressions of the form **expr=NULL** (or **NULL=expr**) are treated as **expr IS NULL** They return true if expr evaluates to the **NULL** value, and false otherwise.
- **off**: **expr=NULL** always returns **NULL** (unknown).

Default value: **off**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

NOTE

New users are always confused about the semantics of expressions involving **NULL** values. Therefore, **off** is used as the default value.

support_extended_features

Parameter description: Specifies whether extended database features are supported.

Parameter type: Boolean.

Unit: none

Value range:

- **on** indicates that extended database features are supported.
- **off** indicates that extended database features are not supported.

Default value: **off**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

sql_compatibility

Parameter description: Specifies the type of mainstream database with which the SQL syntax and statement behavior of the database is compatible.

Parameter type: enumerated type

Unit: none

Value range:

- **ORA**: Oracle-compatible.
- **TD**: Teradata-compatible.
- **MYSQL**: MySQL-compatible.
- **PG**: PG-compatible.
- **M**: M-compatible database.

Default value: **MYSQL**

Setting method: This is a fixed INTERNAL parameter. It can be viewed but cannot be modified.

Setting suggestion: This parameter can only be viewed.

Risks and impacts of improper settings: none

NOTE

- This parameter can be set only when you run the **CREATE DATABASE** command to create a database.
- In the database, this parameter must be set to a specific value. It can be set to **ORA** or **TD** and cannot be changed randomly. Otherwise, the setting is not consistent with the database behavior.
- In distributed database scenarios in M-compatible mode, if an alarm is generated on a CN, WARNING information is generated. If an alarm is generated on a DN, WARNING information cannot be generated.

b_format_behavior_compat_options

Parameter description: Specifies a MySQL-compatible database configuration item.

Parameter type: string

Unit: none

Value range: Currently, only B-compatible configuration items listed in **Table 1 MySQL-compatible configuration items** are supported. Use commas (,) to separate multiple compatibility configuration items.

Default value: **""**

NOTE

If **b_format_version** is not set to **''**, **b_format_behavior_compat_options** will be set to **"all"** and cannot be modified.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 6-29 MySQL-compatible configuration items

Configuration Item	Behavior
default_collation	Specifies whether to enable compatibility with earlier versions of the default collation. • If this item is not specified, the character set or collation of a column of the character type is not explicitly specified, and the collation of a table is empty, the column uses the default collation. • If this item is specified, the collation of a column of the character type inherits the collation of a table (if it is not empty). If the collation of a table is empty, the default collation corresponding to the database is used.
all	Determines whether to enable all syntax. **all** cannot be specified together with other configuration items. In the table, specifying all configuration items except **all** that are separated by commas is equivalent to specifying **all**.

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Determines whether some MySQL-compatible features are available. If you want to modify this parameter, make sure you understand its meaning and modify it with caution to avoid risks caused by misoperations.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

m_format_behavior_compat_options

Parameter description: Specifies the configuration items of an M-compatible database.

Parameter type: string

Unit: none

Value range: Currently, only B-compatible configuration items listed in **Table 2 M-compatible configuration items** are supported. Use commas (,) to separate multiple compatibility configuration items.

Default value:

- For a newly installed database, the value is **"grant_database_nomapping"**.
- For a database upgraded from an earlier version, if the earlier version does not support this GUC parameter, the default value is **""** after the upgrade. If the earlier version supports this GUC parameter, the default value is retained after the upgrade.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 6-30 M-compatible configuration items

Configuration Item	Behavior

grant_database_nomapping	Configuration item of the GRANT | REVOKE ON DATABASE syntax behavior in the M-compatible database.
	• If this configuration item is not set, the GRANT | REVOKE ON DATABASE syntax is mapped to the GRANT | REVOKE ON SCHEMA behavior to grant or revoke the specified user or role's permission to access schema-level objects.
	• If this configuration item is set, the GRANT | REVOKE ON DATABASE syntax retains the behavior of the GRANT | REVOKE ON DATABASE syntax in the non-M-compatible database (that is, original GaussDB) of the default compatibility, and grants or revokes the access permission of a specified user or role on database objects.
	-- Create a user and a database.
	\c postgres
	DROP USER IF EXISTS testUser cascade;
	DROP DATABASE IF EXISTS m_db;
	CREATE USER testUser WITH PASSWORD '********';
	CREATE DATABASE m_db DBCOMPATIBILITY='M';
	\c m_db
	
	-- The option is not enabled and the schema is mapped to the GRANT SCHEMA. A message is displayed, indicating that the schema cannot be found.
	m_db=# SET m_format_behavior_compat_options='';
	SET
	m_db=# GRANT CREATE ON DATABASE m_db TO testUser;
	ERROR: schema "m_db" does not exist
	m_db=# SET SESSION AUTHORIZATION testUser PASSWORD '********';
	SET
	m_db=> CREATE SCHEMA s1;
	ERROR: Permission denied for database m_db.
	DETAIL: N/A.
	m_db=> \c -
	
	-- Enable the option. The CREATE SCHEMA permission is granted.
	m_db=# SET m_format_behavior_compat_options='grant_database_nomapping';
	SET
	m_db=# GRANT CREATE ON DATABASE m_db TO testUser;
	GRANT
	m_db=# SET SESSION AUTHORIZATION testUser PASSWORD '********';
	SET
	m_db=> CREATE SCHEMA s1;

	m_db=> \c -
	
	-- Clean up.
	\c postgres
	DROP USER IF EXISTS testUser cascade;
	DROP DATABASE IF EXISTS m_db;

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

system_function_version

Parameter description: Specifies the configuration item of the database system function behavior.

Parameter type: string

Unit: none

Value range: Currently, only compatibility configuration items listed in **Table 6-31** are supported. Use commas (,) to separate multiple compatibility configuration items, for example, **"SET system_function_version='get_hash_value_fix,pbe_trunc_fix,empty_array_fix';"**.

Default value:

- During installation: **get_hash_value_fix,pbe_trunc_fix,empty_array_fix,regex_like_m_fix,parse_phrase_fix**
- During upgrade: **""**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 6-31 Compatibility configuration items

Configuration Item	Behavior

get_hash_value_fix	Specifies whether to enable the **dbe_utility.get_hash_value** compatibility with earlier versions.
	● If this configuration item is not set, the last four bytes of the character string entered by the user are ignored. As a result, the hash values of the character strings less than four bytes are the same.
	● If this configuration item is set, the problem is resolved to ensure that the hash values are correct.
	gaussdb=# SET system_function_version = '';
	gaussdb=# SELECT dbe_utility.get_hash_value(1, 1024, 1024);
	get_hash_value
	---------------- 	
	1444
	(1 row)
	
	gaussdb=# SELECT dbe_utility.get_hash_value(2, 1024, 1024);
	get_hash_value
	---------------- 	
	1444
	(1 row)
	
	gaussdb=# SET system_function_version = 'get_hash_value_fix';
	gaussdb=# SELECT dbe_utility.get_hash_value(1, 1024, 1024);
	get_hash_value
	---------------- 	
	1785
	(1 row)
	
	gaussdb=# SELECT dbe_utility.get_hash_value(2, 1024, 1024);
	get_hash_value
	---------------- 	
	1538
	(1 row)

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Configuration Item	Behavior

pbe_trunc_fix	Specifies whether to enable the compatibility with earlier versions of the lpad/rpad/chr/round/trunc/ add_months/instrb function in the PBE scenario.
	● If this configuration item is not set, the decimal points of the input parameters of the preceding functions are rounded off to integers in the PBE scenario.
	● If this configuration item is set, the decimal points of the input parameters of the preceding functions are truncated to integers in the PBE scenario to ensure that the result is the same as the result in ORA-compatible mode.
	`gaussdb=# SET a_format_version='10c';`
	`gaussdb=# SET a_format_dev_version='s1';`
	`gaussdb=# PREPARE pround1 AS SELECT round(123.456,$1);`
	`gaussdb=# EXECUTE pround1('2.6');`
	`round`
	`---------`
	`123.456`
	`(1 row)`
	
	`gaussdb=# SET system_function_version = 'pbe_trunc_fix';`
	`gaussdb=# PREPARE pround1 AS SELECT round(123.456,$1);`
	`gaussdb=# EXECUTE pround1('2.6');`
	`round`
	`---------`
	`123.46`
	`(1 row)`
	NOTE
	This parameter is valid only in an ORA-compatible database.

empty_array_fix	Specifies whether to enable the compatibility with earlier versions of empty arrays.
	● If this configuration item is not set, the empty array constructed by the array_positions function is different from that constructed by **'{}'::int[]**.
	● If this configuration item is set, the empty array constructed by the array_positions function is the same as that constructed by **'{}'::int[]**.
	`gaussdb=# SET system_function_version = 'empty_array_fix';`
	`SET`
	`gaussdb=# SELECT array_eq(array_positions(array[1, 1, 1], 3),`
	`'{}'::int[]);`
	`array_eq`
	`----------`
	`t`
	`(1 row)`
	
	`gaussdb=# SET system_function_version = '';`
	`SET`
	`gaussdb=# SELECT array_eq(array_positions(array[1, 1, 1], 3),`
	`'{}'::int[]);`
	`array_eq`
	`----------`
	`f`
	`(1 row)`

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Configuration Item	Behavior
regex_like_m_fix	Specifies the compatibility with earlier versions switch that controls the behavior of the regex_like_m function. (The regexp_like function calls regex_like_m, which is also affected.) ● If this configuration item is not set, the matching result is incorrect when multiple rows are matched and the regular expression rule contains |. ● If this configuration item is set, the matching result is correct when multiple rows are matched and the regular expression rule contains |. gaussdb=# SET system_function_version = 'regex_like_m_fix'; SET gaussdb=# SELECT 'abc' FROM dual WHERE regex_like_m('111 2 222','^1+$\|^2+$'); ?column? ---------- abc (1 row) gaussdb=# SET system_function_version = ''; SET gaussdb=# SELECT 'abc' FROM dual WHERE regex_like_m('111 2 222','^1+$\|^2+$'); ?column? ---------- (0 row) **NOTE** This parameter takes effect only for the database upgraded from a version where the matching result is incorrect. For a newly installed database, the behavior is the same as that when this parameter is set, regardless of whether this parameter is set.
parse_phrase_fix	Specifies whether to parse phrase operators in tsquery. ● If this parameter is not set, phrase operators are not parsed in operations such as **to_tsquery** that involve tsquery parsing. ● If this parameter is set, phrase operators are parsed in operations such as **to_tsquery** that involve tsquery parsing. gaussdb=# SET system_function_version = 'parse_phrase_fix'; SET gaussdb=# SELECT to_tsquery('hello <-> world'); to_tsquery ---------- 'hello' <-> 'world' (1 row) gaussdb=# SET system_function_version = ''; SET gaussdb=# SELECT to_tsquery('hello <-> world'); ERROR: syntax error in tsquery: "hello <-> world" CONTEXT: referenced column: to_tsquery

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**. During the upgrade, the parameter is left empty by default. If you need to enable the setting, you are advised to modify the GUC configuration file to ensure that the setting is not lost when the database is restarted.

Setting suggestion: Specifies whether some system function compatibility features are available. If you want to modify this parameter, make sure you understand its meaning and modify it with caution.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

behavior_compat_options

Parameter description: Specifies the database compatibility configuration item.

Parameter type: string

Unit: none

Value range: Currently, only compatibility configuration items listed in **Table 6-32** are supported. Use commas (,) to separate multiple compatibility configuration items, for example, **set behavior_compat_options='end_month_calculate,display_leading_zero'**.

Default value:

- For a newly installed database, the default value is **"enable_bpcharlikebpchar_compare,enable_crosstype_integer_operator,forbid_skip_tableof_empty_str_elem,enable_ora_joinop_in_updatestmt"**.
- For a database upgraded from an earlier version, if the earlier version does not support this GUC parameter, the default value is **""** after the upgrade. If the earlier version supports this GUC parameter, the default value is retained after the upgrade.

NOTE

When **a_format_version** is set to **10c** and **a_format_dev_version** is set to **s7**, some compatibility configuration items are supported. For details about the parameters, see **a_format_dev_version**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 6-32 Compatibility configuration items

Configuration Item	Behavior
display_leading_zero	Specifies how floating-point numbers are displayed. It controls the display of zeros before the decimal point of all character string types (such as char, character, nchar, varchar, character varying, varchar2, nvarchar2, text, and clob) and arbitrary-precision types (such as float4, float8, and numeric) in the numeric type, specifies whether the length of the number calculated by **length** contains zeros before the decimal point. ● If this item is not specified, for a non-zero decimal number between –1 and +1, the 0 before the decimal point is not displayed. For example: `gaussdb=# SELECT 0.1231243 as a, 0.1231243::numeric as b,0.1231243::integer(10,3) as c, length(0.1242343) as d;` ` a	b	c	d` `----------+----------+------+---` `.1231243	.1231243	.123	8` `(1 row)` ● If this item is specified, for a non-zero decimal number between –1 and +1, the 0 before the decimal point is displayed. For example: `gaussdb=# select 0.1231243 as a, 0.1231243::numeric as b,0.1231243::integer(10,3) as c, length(0.1242343) as d;` ` a	b	c	d` `----------+----------+-------+---` `0.1231243	0.1231243	0.123	9` `(1 row)`

end_month_calculate	Specifies the calculation logic of the add_months function.
	This parameter does not take effect in M-compatible databases.
	Assume that the two parameters of the add_months function are **param1** and **param2**, and that the month of **param1** and **param2** is **result**.
	● If this item is not specified, and the **Day** of **param1** indicates the last day of a month shorter than **result**, the **Day** in the calculation result will equal that in **param1**. For example:
	`gaussdb=# select add_months('2018-02-28',3) from sys_dummy;`
	`add_months`
	`---------------------`
	`2018-05-28 00:00:00`
	`(1 row)`
	● If this item is specified, and the **Day** of **param1** indicates the last day of a month shorter than **result**, the **Day** in the calculation result will equal that in **result**. For example:
	`gaussdb=# select add_months('2018-02-28',3) from sys_dummy;`
	`add_months`
	`---------------------`
	`2018-05-31 00:00:00`
	`(1 row)`

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Configuration Item	Behavior
compat_analyze_sample	Specifies the sampling behavior of the ANALYZE operation. If this item is specified, the sample collected by the ANALYZE operation will be limited to around 30,000 records, controlling CN memory consumption and maintaining the stability of ANALYZE.
bind_schema_tablespace	Binds a schema with the tablespace with the same name. If a tablespace name is the same as *schema_name*, **default_tablespace** will also be set to *schema_name* if **search_path** is set to *schema_name*.
bind_procedure_searchpath	Specifies the search path of the database objects in a stored procedure for which no schema name is specified. If the schema name is implicitly specified for a stored procedure, the schema to which the stored procedure belongs is searched preferentially. If the stored procedure is not found, the following operations are performed: ● If this item is not specified, the system reports an error and exits. ● If this item is specified, the search continues based on the settings of **search_path**. If the issue persists, the system reports an error and exits.
skip_insert_gs_source	If this parameter is enabled, no data is inserted into the dbe_pldeveloper.gs_source table when the PL/SQL objects are created.
a_hash_bpchar	If this parameter is enabled, the hashbpchar function retains spaces at the end of a string to calculate the hash value.

correct_to_number	Specifies the compatibility of the to_number() result.
	● If this item is not set, the result of the to_number() function is the same as that in the Oracle Database by default.
	`gaussdb=# select '' AS to_number_14, to_number('34,50','999,99');`
	`ERROR:  invalid data.`
	`CONTEXT:  referenced column: to_number`
	● If this item is specified, the result of the to_number() function is the same as that of pg11.
	`gaussdb=# select '' AS to_number_14, to_number('34,50','999,99');`
	` to_number_14 | to_number`
	`---------------+-----------`
	`  |  3450`
	`(1 row)`

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Configuration Item	Behavior

unbind_divide_bound	Specifies the range check on the result of integer division.
	This parameter does not take effect in M-compatible databases.
	● If this item is not specified, the range of the division result is verified. For example, an out-of-bounds error is reported because the output result of *INT_MIN*/**(-1)** is greater than *INT_MAX*.
	`gaussdb=# select (-2147483648)::int4 / (-1)::int4;`
	`ERROR:  integer out of range`
	● If this item is specified, the range of the division result does not need to be verified. For example, the output result of *INT_MIN*/**(-1)** is *INT_MAX*+**1**.
	`gaussdb=# select (-2147483648)::int4 / (-1)::int4;`
	`  ?column?`
	`------------`
	` 2147483648`
	`(1 row)`

convert_string_digit_to_numeric	Specifies whether to convert numeric constants of the character string type to those of the numeric type before these two types are compared.
	This parameter does not take effect in M-compatible databases.
	● If this item is not specified, the numeric constants of the character string type are not converted to those of the numeric type.
	● If this item is specified, the numeric constants of the character string type are converted to those of the numeric type.
	`gaussdb=# create table test1 (c1 int, c2 varchar);`
	`gaussdb=# insert into test1 values (2, '1.1');`
	`gaussdb=# set behavior_compat_options='';`
	`gaussdb=# select * from test1 where c2 > 1;`
	`ERROR:  invalid input syntax for type bigint: "1.1"`
	
	`gaussdb=# set behavior_compat_options='convert_string_digit_to_numeric';`
	`gaussdb=# select * from test1 where c2 > 1;`
	` c1 | c2`
	`----+-----`
	`  2 | 1.1`
	`(1 row)`
	
	`gaussdb=# drop table test1;`

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Configuration Item	Behavior

return_null_string	Specifies how to display the empty result (empty string '') of the lpad() and rpad() functions.
	This parameter does not take effect in M-compatible databases.
	● If this item is not specified, the empty string is displayed as **NULL**.
	`gaussdb=# select length(lpad('123',0,'*')) from sys_dummy;`
	`length`
	`--------`
	`(1 row)`
	● If this item is specified, the empty string is displayed as single quotation marks ('').
	`gaussdb=# select length(lpad('123',0,'*')) from sys_dummy;`
	`length`
	`--------`
	`0`
	`(1 row)`

compat_concat_variadic	Specifies the compatibility of variadic results of the concat() and concat_ws() functions. The MySQL database does not have the variadic type. Therefore, this option has no impact on the MySQL database.
	● If this item is not set and the concat function parameter is of the variadic type, the results of the Oracle and Teradata databases in compatibility mode are the same by default.
	`gaussdb=# select concat(variadic NULL::int[]) is null;`
	` ?column?`
	`----------`
	` t`
	`(1 row)`
	● If this item is set and the concat function parameter is of the variadic type, different result formats of the ORA and TD databases in compatibility mode are retained.
	`-- In the Oracle Database:`
	`gaussdb=# select concat(variadic NULL::int[]) is null;`
	` ?column?`
	`----------`
	` t`
	`(1 row)`
	`-- In the TD database:`
	`gaussdb=# select concat(variadic NULL::int[]) is null;`
	` ?column?`
	`----------`
	` f`
	`(1 row)`

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Configuration Item	Behavior
merge_update_multi	Controls the UPDATE operation if a data record in the destination table conflicts with multiple source data records when MERGE INTO ... WHEN MATCHED THEN UPDATE (see **MERGE INTO**) and INSERT ... ON DUPLICATE KEY UPDATE (see **INSERT**) are used. • If this item is specified and the preceding scenario exists, the system performs multiple UPDATE operations on the conflicting row. • If this item is not specified (the default value is retained), an error is reported, indicating that the MERGE or INSERT operation fails.
plstmt_implicit_savepoint	Determines whether the execution of an UPDATE statement in a stored procedure has an independent subtransaction. If this parameter is set, the implicit savepoint is enabled before executing each UPDATE statement in the stored procedure, and the subtransaction is rolled backed to the latest savepoint in the EXCEPTION block by default, ensuring that only the modification of failed statements is rolled back. This option is used to be compatible with the EXCEPTION behavior of the Oracle Database.
hide_tailing_zero	Configuration item for numeric display. • If this item is specified, the trailing zeros after the decimal point are hidden in all scenarios where numeric values are output, even if the precision format is specified. • If this item is not specified, numeric data is displayed in the specified precision. For example: gaussdb=# set behavior_compat_options='hide_tailing_zero'; gaussdb=# select cast(123.123 as numeric(15,10)) as a, to_char(cast(123.123 as numeric(15,10)), '999D999999'); a | to_char ---------+---------- 123.123 | 123.123 (1 row) gaussdb=# set behavior_compat_options=''; gaussdb=# select cast(123.123 as numeric(15,10)) as a, to_char(cast(123.123 as numeric(15,10)), '999D999999'); a | to_char ----------------+------------- 123.1230000000 | 123.123000 (1 row)

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Configuration Item	Behavior
truncate_numeric_tail_zero	Configuration item for numeric display. ● If this item is specified, the trailing zeros after the decimal point are hidden in all numeric output scenarios except explicit precisions, such as to_char(numeric, format). ● If this item is not specified, numeric data is displayed in the default precision. For example: gaussdb=# set behavior_compat_options='truncate_numeric_tail_zero'; gaussdb=# select cast(123.123 as numeric(15,10)) as a, to_char(cast(123.123 as numeric(15,10)), '999D999999'); a | to_char ---------+------------- 123.123 | 123.123000 (1 row) gaussdb=# set behavior_compat_options=''; gaussdb=# select cast(123.123 as numeric(15,10)) as a, to_char(cast(123.123 as numeric(15,10)), '999D999999'); a | to_char ----------------+------------- 123.1230000000 | 123.123000 (1 row)

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Configuration Item	Behavior

char_coerce_compat	Controls the behavior when char(n) types are converted to other variable-length string types. This parameter is valid only when the **sql_compatibility** parameter is set to **ORA**. After this parameter is enabled, spaces at the end are not omitted in implicit conversion, explicit conversion, or conversion by calling the text(bpchar) function.
	● If this item is specified, spaces at the end are not omitted in conversion. In addition, if the length of the char(n) type exceeds that of other variable-length string types, an error is reported.
	● If this item is not specified, spaces at the end are omitted when the char(n) type is converted to another variable-length string type.
	gaussdb=# set behavior_compat_options='';
	gaussdb=# create table tab_1(col1 varchar(3));
	gaussdb=# create table tab_2(col2 char(3));
	gaussdb=# insert into tab_2 values(' ');
	gaussdb=# insert into tab_1 select col2 from tab_2;
	gaussdb=# select * from tab_1 where col1 is null;
	col1
	------ 	
	
	(1 row)
	gaussdb=# select * from tab_1 where col1=' ';
	col1
	------ 	
	(0 rows)
	gaussdb=# delete from tab_1;
	gaussdb=# set behavior_compat_options = 'char_coerce_compat';
	gaussdb=# insert into tab_1 select col2 from tab_2;
	gaussdb=# select * from tab_1 where col1 is null;
	col1
	------ 	
	(0 rows)
	gaussdb=# select * from tab_1 where col1=' ';
	col1
	------ 	
	
	(1 row)
	
	gaussdb=# drop table tab_1;
	gaussdb=# drop table tab_2;

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Configuration Item	Behavior
aformat_regexp_match	Determines the matching behavior of regular expression functions. When this parameter is set and **sql_compatibility** is set to **ORA** or **MYSQL**, the meanings of the options supported by the **flags** parameter of the regular expression are as follows: 1. By default, the character **'\n'** cannot be matched. 2. If **flags** contains the **n** option, **'.'** can match the character **'\n'**. 3. The regexp_replace(source, pattern replacement) function replaces all matching substrings. 4. The regexp_replace(source, pattern, replacement, flags) function returns **null** when the value of **flags** is **null**. 5. When the value of **sql_compatibility** is **ORA** and the value of **flags** in the regexp_replace(source, pattern, replacement, flags) function is **''**, the return value is **null**. Otherwise, the meanings of the options supported by the **flags** parameter of the regular expression are as follows: 1. By default, the character **'\n'** can be matched. 2. The **n** option in **flags** indicates that the multi-line matching mode is used. 3. The regexp_replace(source, pattern replacement) function replaces only the first matched substring. 4. If the value of **flags** is **null**, the return value of the regexp_replace(source, pattern, replacement, flags) function is the character string after replacement. 5. When the value of **sql_compatibility** is **ORA** and the value of **flags** in the regexp_replace(source, pattern, replacement, flags) function is **''**, the return value is the character string after replacement. **NOTICE** You are advised not to change the status of this parameter during service execution. The status change of this parameter may change the return result of the regexp_replace function with the same input parameter. If the regexp_replace function is referenced in the expression index, the status change of this parameter may cause data exceptions.
disable_emptystr2null	In the ORA-compatible parameter binding scenario, if this parameter is enabled, the function of converting the values of parameters of the character type from an empty string to **null** by default, if any, is disabled. text, clob, blob, raw, bytea, varchar, nvarchar2, bpchar, char, name, byteawithoutorderwithqualcol, and byteawithoutordercol. This parameter is reserved for emergency. Do not set it unless necessary.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Configuration Item	Behavior

select_into_return_null	If this parameter is enabled in PG-compatible mode, **NULL** values can be assigned to the variables in the stored procedure statement **SELECT** *select_expressions* **INTO [STRICT]** *target* **FROM...** without specifying **STRICT** when the query result is empty.
	After this parameter is enabled, if the returned result set is empty, the **NULL** value is assigned to the variable. For example:
	gaussdb=# SET behavior_compat_options = 'select_into_return_null';
	SET
	gaussdb=# CREATE TABLE t1 (a int, b int) DISTRIBUTE BY hash(a);
	CREATE TABLE
	gaussdb=# DECLARE
	gaussdb-# var int;
	gaussdb-# BEGIN
	gaussdb$# SELECT b INTO var FROM t1;
	gaussdb$# RAISE INFO '%', var;
	gaussdb$# END;
	gaussdb$# /
	INFO: <NULL>
	ANONYMOUS BLOCK EXECUTE
	gaussdb=# DROP TABLE t1;
	DROP TABLE

plsql_security_definer	• After this parameter is enabled, the definer permission is used by default when a stored procedure is created. • The default permission on a package is SECURITY INVOKER. To change the default permission to SECURITY DEFINER, set this parameter.
proc_outparam_override	• Determines the overloading of output parameters of a stored procedure. After this parameter is enabled, the stored procedure can be properly created and called even if only the output parameters of the stored procedure are different. Currently, this parameter can be used only when gsql and JDBC are used to connect to the database. If this parameter is enabled for other tools to connect to the database, stored procedures with the **out** parameter cannot be called. • It supports the functions that contain the **out** output parameter and returns data of the record type. Besides, a value is assigned to the **out** parameter. • Setting **behavior_compat_options** to **'proc_outparam_override'** is applicable only in ORA-compatible mode.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Configuration Item	Behavior

proc_uncheck_default_param	When a function is called, the system does not check whether the default parameter is omitted.
	• If this item is not specified and a function with default parameters is called, input parameters are added to the function from left to right. If inputs of non-default parameters are missing, an error is reported. For example:
	gaussdb=# create or replace function test(f1 int, f2 int default 20, f3 int, f4 int default 40, f5 int default 50) return int
	gaussdb-# as
	gaussdb$# begin
	gaussdb$# raise info 'f1:%',f1;
	gaussdb$# raise info 'f2:%',f2;
	gaussdb$# raise info 'f3:%',f3;
	gaussdb$# raise info 'f4:%',f4;
	gaussdb$# raise info 'f5:%',f5;
	gaussdb$# return 1;
	gaussdb$# end;
	gaussdb$# /
	CREATE FUNCTION
	gaussdb=# select test(1,2);
	ERROR: function test(integer, integer) does not exist
	LINE 1: select test(1,2);
	^
	HINT: No function matches the given name and argument types. You might need to add explicit type casts.
	CONTEXT: referenced column: test
	
	gaussdb=# drop function test;
	• If this item is set and a function with default parameters is called, the inputs are added to the function from left to right. The number of default inputs matches the number of default parameters. If any input of a non-default parameter is missing, the parameter will be filled with a misplaced default value. For example:
	gaussdb=# create or replace function test(f1 int, f2 int default 20, f3 int, f4 int default 40, f5 int default 50) return int
	gaussdb-# as
	gaussdb$# begin
	gaussdb$# raise info 'f1:%',f1;
	gaussdb$# raise info 'f2:%',f2;
	gaussdb$# raise info 'f3:%',f3;
	gaussdb$# raise info 'f4:%',f4;
	gaussdb$# raise info 'f5:%',f5;
	gaussdb$# return 1;
	gaussdb$# end;
	gaussdb$# /
	CREATE FUNCTION
	gaussdb=# select test(1,2);
	INFO: f1:1
	CONTEXT: referenced column: test
	INFO: f2:2
	CONTEXT: referenced column: test
	INFO: f3:20
	CONTEXT: referenced column: test
	INFO: f4:40
	CONTEXT: referenced column: test
	INFO: f5:50
	CONTEXT: referenced column: test
	test

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Configuration Item	Behavior
	------ 1 (1 row) gaussdb=# drop function test; As shown above, f3 is filled with an incorrect default value. **NOTE** In this scenario, a non-default parameter is filled with the previous default value.
dynamic_sql_compat	After this parameter is enabled: ● Duplicate parameters in the SQL statement template are not regarded as the same parameter, but match variables in the USING clause in sequence. ● If a stored procedure is called during dynamic statement execution, the IN and OUT attributes of the stored procedure and the USING clause are checked. ● Application scenarios: Execute immediate, open cursor for, return query, and for var in execute sql binding parameters. **NOTE** If a stored procedure is called when a dynamic statement executes an anonymous block statement, only the **IN** parameters are corrected. If **OUT** parameters need to be checked, set the **proc_outparam_override** parameter.
dynamic_sql_check	After this parameter is enabled, an error is reported during dynamic statement execution if the number of different template parameters in the dynamic statement template SQL is different from that of variables in the USING clause. Application scenarios: Execute immediate, open cursor for, return query, and for var in execute sql binding parameters. **NOTE** ● If the **dynamic_sql_compat** option is enabled, the **dynamic_sql_check** option does not take effect. ● If a stored procedure is called when a dynamic statement executes an anonymous block statement, only the **IN** parameters are checked. If **OUT** parameters need to be checked, set the **proc_outparam_override** parameter. ● If a stored procedure is called when a dynamic statement executes an anonymous block statement and the parameter is enabled, the **IN** and **OUT** attributes in a stored procedure and the USING clause are not checked.

Configuration Item	Behavior

enable_funcname_with_argsname	If the parameter is enabled, the projection alias displays the complete function when SELECT is used to call a function.
	• If this item is not specified, the projection alias displays only the function name when SELECT is used to call a function. For example:
	gaussdb=# select power(2,3);
	power
	------- 	
	8
	(1 row)
	
	gaussdb=# select count(*) from db_ind_columns;
	count
	------- 	
	611
	(1 row)
	
	gaussdb=# select count(index_name) from db_ind_columns;
	count
	------- 	
	611
	(1 row)
	
	gaussdb=# select left('abcde', 2);
	left
	------ 	
	ab
	(1 row)
	
	gaussdb=# select pg_client_encoding();
	pg_client_encoding
	-------------------- 	
	UTF8
	(1 row)
	• If this item is specified, the projection alias displays the complete function when SELECT is used to call a function. For example:
	gaussdb=# set behavior_compat_options =
	'enable_funcname_with_argsname';
	SET
	gaussdb=# select power(2,3);
	power(2,3)
	------------ 	
	8
	(1 row)
	
	gaussdb=# select count(*) from db_ind_columns;
	count(*)
	---------- 	
	611
	(1 row)
	
	gaussdb=# select count(index_name) from db_ind_columns;
	count(index_name)
	------------------- 	
	611
	(1 row)
	
	gaussdb=# select left('abcde', 2);
	left('abcde',2)
	----------------- 	

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Configuration Item	Behavior

	ab
	(1 row)
	
	gaussdb=# select pg_client_encoding();
	pg_client_encoding()
	---------- 	
	UTF8
	(1 row)
	• Currently, only the projection aliases in the func_name(args_list), func_name(), and func_name(*) formats can display complete functions. The **args** parameter can only be a character constant, numeric constant, column name, or function. A column name can contain a table name, but func_name(*) cannot have a table name before the asterisk. A function name can contain a schema or package name. The parameter cannot be an expression. The parameter can contain only the DISTINCT keyword. If the parameter contains other keywords, the function cannot be displayed completely.
	• When the input parameter of the function is in the following scenarios, the projection alias does not display the complete function:
	-- Create a database in ORA-compatible mode.
	gaussdb=# CREATE DATABASE ora_db DBCOMPATIBILITY = 'ORA' ENCODING = 'UTF8';
	CREATE DATABASE
	gaussdb=# \c ora_db
	ora_db=# SET behavior_compat_options = 'enable_funcname_with_argsname';
	SET
	-- The input parameter of the function contains null values or empty strings in ORA-compatible mode.
	ora_db=# SELECT length(null);
	length
	-------- 	
	
	(1 row)
	
	ora_db=# SHOW sql_compatibility;
	sql_compatibility
	------------------- 	
	ORA
	(1 row)
	
	ora_db=# SELECT length('');
	length
	-------- 	
	
	(1 row)
	
	-- The input parameter of the function is a forcible type cast with double colons.
	ora_db=# SELECT length('abc'::text);
	length
	-------- 	
	3
	(1 row)
	
	-- The input parameter of the function is of a specified type.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Configuration Item	Behavior

	ora_db=# SELECT length(text'abc');
	 length
	-------- 	
	 3
	(1 row)
	
	-- The input parameter of the function is a PBE placeholder.
	ora_db=# PREPARE p1 AS SELECT length($1);
	PREPARE
	ora_db=# EXECUTE p1('abc');
	 length
	-------- 	
	 3
	(1 row)
	
	ora_db=# DEALLOCATE p1;
	DEALLOCATE
	
	-- The input parameter of the function is an array constructor.
	ora_db=# SELECT array_ndims(ARRAY[1, 2, 3]);
	 array_ndims
	------------- 	
	 1
	(1 row)
	• The projection alias varies with the clause following the function:
	– When the input parameter of the function contains other clauses (such as the ORDER BY clause), the projection alias displays only the function name.
	– When a function is followed by an OVER or WITHIN clause, the projection alias displays the function name and input parameter, but the OVER or WITHIN clause is not displayed.
	– When a function is followed by the KEEP clause, the projection alias displays the function name, but the input parameter and KEEP clause are not displayed.
	gaussdb=# \c ora_db
	ora_db=# SET behavior_compat_options =
	'enable_funcname_with_argsname';
	SET
	ora_db=# DROP TABLE IF EXISTS tbl;
	ora_db=# CREATE TABLE tbl (id int, lower_col text, col1 int, col2
	numeric);
	ora_db=# INSERT INTO tbl VALUES (1, 'hello', 42, 3.14);
	
	-- The input parameter contains the ORDER BY clause.
	ora_db=# SELECT string_agg(lower_col, '1' ORDER BY id) FROM tbl;
	 string_agg
	------------ 	
	 hello
	(1 row)
	
	-- OVER clause
	ora_db=# SELECT min(col1) OVER(PARTITION BY id ORDER BY col2)
	FROM tbl;
	 min(col1)
	----------- 	
	 42

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Configuration Item	Behavior

	(1 row)
	
	-- WITHIN clause
	ora_db=# SELECT listagg(lower_col, ',') WITHIN GROUP(ORDER BY id) FROM tbl;
	 listagg(lower_col,',')
	----------------------- 	
	 hello,world,test
	(1 row)
	
	-- KEEP clause.
	ora_db=# SELECT min(col1) KEEP (DENSE_RANK FIRST ORDER BY col2) FROM tbl;
	 min
	----- 	
	 42
	(1 row)
	
	ora_db=# DROP TABLE IF EXISTS tbl;
	• Some functions can both be called by syntax or as system functions, causing the difference in the display of projection aliases. For details about these functions, see **Table 1-29**.
	– When a function is called only by function name, the projection alias does not display the complete function.
	– When a function is called with the pg_catalog prefix or double quotation marks, the projection alias displays the complete function.
	• If the projection column contains functions that can only be called by syntax, the projection alias does not display the complete function. For details about these functions, see **Table 1-29**. The projection alias of a function that can only be called by syntax may not display the function name itself. Instead, it displays the output identifier derived by the function during syntax parsing.
	– If the outermost function is a function that can only be called by syntax, only the name of the function is displayed in the projection alias.
	– If the outermost function supports the display of projection alias, but its parameters contain functions that can only be called by syntax, only the name of the outermost function is displayed.
	• If some secure encryption and decryption functions and masking functions are displayed completely by projection aliases, it may bring security problems. Therefore, only function names are displayed here, including: gs_encrypt_aes128, gs_decrypt_aes128, gs_encrypt, gs_decrypt, gs_encrypt_bytea, gs_decrypt_bytea, aes_encrypt, aes_decrypt, pg_create_physical_replication_slot_extern, creditcardmasking, basicemailmasking, fullemailmasking,

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Configuration Item	Behavior

	alldigitsmasking, shufflemasking, randommasking, regexpmasking, gs_digest, desencrypt, desdecrypt, es3encrypt, and des3decrypt functions.
	• Parameter passed using => is not supported for the projection alias to display the complete function. The projection alias cannot contain double quotation marks (""), for example, **select "power"(2,3)**.
	• To enable the projection alias to display the complete function, this function is not affected by parameters such as removing 0 at the end.
	• If a projection alias contains more than 63 bytes, the excess part will be truncated.
	• If the **args** parameter is a numeric constant, the projection alias cannot display leading zeros.
	`gaussdb=# SET behavior_compat_options = 'enable_funcname_with_argsname';`
	`SET`
	`gaussdb=# SELECT abs(0010);`
	`abs(10)`
	`---------`
	`10`
	`(1 row)`
	• In the following special scenarios, the projection alias is different:
	– Scenario 1: Some functions can be called as a system function or called by syntax. For details about these functions, see **Table 1-29**. In scenarios where functions can be called without parentheses, the pg_catalog prefix is omitted when the functions are called.
	– Scenario 2: When XMLType is called with the pg_catalog prefix or enclosed in double quotation marks, it is treated as a system function, and the projection alias can display the complete function. When only XMLType is used for calling, it is treated as a syntax function, and the projection alias does not display the complete function.
	`gaussdb=# \c ora_db`
	`ora_db=# SET behavior_compat_options = 'enable_funcname_with_argsname';`
	`SET`
	`-- Scenario 1 (the current user is omm):`
	`ora_db=# SELECT pg_catalog.current_user;`
	`current_user`
	`--------------`
	`omm`
	`(1 row)`
	
	`-- Scenario 2:`
	`ora_db=# SELECT pg_catalog.xmltype('<a>1</a>');`
	`pg_catalog.xmltype('<a>1</a>')`
	`--------------------------------`

	<a>1
	(1 row)
	
	ora_db=# SELECT xmltype('<a>1');
	xmltype
	---------- 	
	<a>1
	(1 row)
	
	ora_db=# \c postgres
	gaussdb=# DROP DATABASE ora_db;

proc_outparam_transfer_length	After this parameter is enabled, the length of the **out** output parameter can be passed to the stored procedure and function, and an error will be reported in the inner stored procedure or function if any. For example:
	gaussdb=# SET behavior_compat_options='proc_outparam_override,proc_outparam_transfer_length';
	SET
	gaussdb=# CREATE OR REPLACE PROCEDURE out_param_test1(m in int, v inout varchar2,v1 inout varchar2) is
	gaussdb$# begin
	gaussdb$# v := 'aaaddd';
	gaussdb$# v1 := 'aaaddd';
	gaussdb$# end;
	gaussdb$# /
	CREATE PROCEDURE
	gaussdb=# CREATE OR REPLACE PROCEDURE call_out_param_test1 is
	gaussdb$# v varchar2(5) := 'aabbb';
	gaussdb$# v1 varchar2(6) := 'aabb';
	gaussdb$# begin
	gaussdb$# out_param_test1(5,v,v1);
	gaussdb$# end;
	gaussdb$# /
	CREATE PROCEDURE
	gaussdb=# CALL call_out_param_test1();
	ERROR: value too long for type character varying(5)
	CONTEXT: PL/SQL function out_param_test1(integer,character varying,character varying) line 3 at assignment
	PL/SQL function call_out_param_test1() line 4 at SQL statement
	
	gaussdb=# DROP PROCEDURE call_out_param_test1;
	gaussdb=# DROP PROCEDURE out_param_test1;

compat_cursor	Specifies the compatibility of error code variables. In this option is set in the ORA-compatible mode, error code variables (*SQLCODE* and *SQLSTATE*) are modified. In earlier versions, they are valid only for the currently executed function; while in this version, they are valid for the subfunctions called by this function.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Configuration Item	Behavior

tableof_elem_constraints	After this parameter is enabled:
	1. For the collection type, the validity of elements will be verified.
	2. If the index is of the varchar collection type, the validity of the index length is also verified.
	For details about behavior differences and examples, see **Collections**.
	NOTE
	• Do not switch and use this parameter in the same session.
	• After a database is upgraded:
	  • For collection types that have been defined in stored procedures or packages, enabling the **tableof_elem_constraints** parameter does not take effect. You need to rebuild the collection type. That is, you need to rebuild the stored procedure or package by performing the CREATE OR REPLACE or DROP+CREATE operation. The parameter takes effect only after the collection type is rebuilt.
	  • If a collection type is created using the syntax: CREATE TYPE type_name IS TABLE OF data_type, you need to drop the type and rebuild it for the function to take effect.
	The following is an example of verifying the validity of elements:
	If this parameter is not enabled, the elements are not verified when the following stored procedure is called:
	`gaussdb=# CREATE OR REPLACE procedure p1 is`
	`gaussdb$#  type t1 is table of varchar(5);`
	`gaussdb$#  v t1 := t1();`
	`gaussdb$# begin`
	`gaussdb$#  v.extend();`
	`gaussdb$#  v(1) := '123456';`
	`gaussdb$#  raise info '%', v;`
	`gaussdb$# end;`
	`gaussdb$# /`
	`CREATE PROCEDURE`
	`gaussdb=# CALL p1();`
	`INFO:  {123456}`
	` p1`
	`----`
	`(1 row)`
	`gaussdb=# DROP procedure p1;`
	If this parameter is enabled, the elements are verified and an error may be reported when the following stored procedure is called:
	`gaussdb=# SET behavior_compat_options = 'tableof_elem_constraints';`
	`SET`
	`gaussdb=# CREATE OR REPLACE procedure p1 is`
	`gaussdb$#  type t1 is table of varchar(5);`
	`gaussdb$#  v t1 := t1();`
	`gaussdb$# begin`
	`gaussdb$#  v.extend();`
	`gaussdb$#  v(1) := '123456';`

Configuration Item	Behavior

	gaussdb$# raise info '%', v;
	gaussdb$# end;
	gaussdb$# /
	CREATE PROCEDURE
	gaussdb=# CALL p1();
	ERROR: value too long for type character varying(5)
	CONTEXT: PL/SQL function p1() line 5 at assignment
	The following is an example of verifying the index value:
	If this parameter is not enabled, no error is reported when the index value exceeds the defined length.
	gaussdb=# CREATE OR REPLACE procedure p1 is
	gaussdb$# type t1 is table of int index by varchar(5);
	gaussdb$# v t1;
	gaussdb$# begin
	gaussdb$# v('123456') := 1;
	gaussdb$# raise info '%', v;
	gaussdb$# end;
	gaussdb$# /
	CREATE PROCEDURE
	gaussdb=# CALL p1();
	INFO: {indexbyType:varchar,"123456"=>1}
	p1
	---- 	
	
	(1 row)
	
	gaussdb=# DROP procedure p1;
	If this parameter is enabled, an error is reported when the index value exceeds the defined length.
	gaussdb=# SET behavior_compat_options = 'tableof_elem_constraints';
	SET
	gaussdb=# CREATE OR REPLACE procedure p1 is
	gaussdb$# type t1 is table of int index by varchar(5);
	gaussdb$# v t1;
	gaussdb$# begin
	gaussdb$# v('123456') := 1;
	gaussdb$# raise info '%', v;
	gaussdb$# end;

Configuration Item	Behavior
allow_rownum_alias	After this parameter is enabled, ROWNUM can be used as a column alias in SQL statements using the AS syntax. ROWNUM is used as a common identifier and cannot be used as a pseudocolumn. This parameter does not take effect in M-compatible databases. **NOTE** You are advised not to change the status of this parameter during service execution. When the parameter is enabled, database objects (such as table names, column names, and database names) are created using ROWNUM as the name in the database. If the parameter is disabled, ambiguity occurs and the behavior is unpredictable. When the parameter is disabled, the behavior of using ROWNUM as a pseudocolumn in the database becomes invalid after the parameter is enabled and the behavior is unpredictable.

current_sysdate	If this parameter is enabled, the current OS time is obtained when the **sysdate** command is executed. After the parameter is disabled, **sysdate** returns the system date and time when the current SQL statement is executed.
	`gaussdb=# set behavior_compat_options='current_sysdate';`
	`SET`
	`gaussdb=# select sysdate;`
	`current_sysdate`
	`---------------------`
	`2023-06-20 20:15:27`
	`(1 row)`
	After the GUC parameter **mapping_date_to_datea** is enabled, **sysdate** returns the datea type by default in ORA-compatible mode. In this case, **current_sysdate** does not take effect.
	`gaussdb=# set behavior_compat_options='';`
	`SET`
	`gaussdb=# show mapping_date_to_datea;`
	`mapping_date_to_datea`
	`----------------------`
	`on`
	`(1 row)`
	`gaussdb=# set NLS_DATE_FORMAT = 'YYYY-MM-DD HH24:MI:SS';`
	`SET`
	`gaussdb=# begin`
	`gaussdb$# dbe_output.print_line('time1:' || sysdate);`
	`gaussdb$# pg_sleep(2);`
	`gaussdb$# dbe_output.print_line('time2:' || sysdate);`
	`gaussdb$# end;`
	`gaussdb$# /`
	`time1:2025-02-27 10:45:57`
	`time2:2025-02-27 10:45:59`

Configuration Item	Behavior

enable_case_when_alias	If this parameter is enabled, the aliases of the CASE WHEN and DECODE syntaxes are character strings starting with __unnamed_.
	Example:
	gaussdb=# set behavior_compat_options='enable_case_when_alias';
	SET
	gaussdb=# create table test(c1 varchar2);
	CREATE TABLE
	gaussdb=# insert into test values('x');
	INSERT 0 1
	gaussdb=# select decode(c1,'x','0','default') from test;
	__unnamed_decode__
	-------------------- 	
	0
	(1 row)
	
	gaussdb=# select (case c1 when 'x' then '0' else 'default' end) from test;
	__unnamed_case_when__
	---------------------- 	
	0
	(1 row)
	
	gaussdb=# drop table test;

plsql_rollback_keep_user	Specifies whether ROLLBACK and ROLLBACK TO SAVEPOINT in PL/SQL change the current user, and whether SAVEPOINT in ROLLBACK TO a definer-privileged function changes the current user. If this parameter is enabled, ROLLBACK does not change the current user.
	Example:
	gaussdb=# create user plsql_rollback1 password '********';
	gaussdb=# create user plsql_rollback2 password '********';
	gaussdb=# grant plsql_rollback1 to plsql_rollback2;
	gaussdb=# create or replace procedure plsql_rollback1.p1 () authid definer
	gaussdb-# as
	gaussdb$# va int;
	gaussdb$# begin
	gaussdb$# raise info 'current usr:%', current_user;
	gaussdb$# rollback;
	gaussdb$# raise info 'current usr:%', current_user;
	gaussdb$# end;
	gaussdb$# /
	CREATE PROCEDURE
	gaussdb=# set session AUTHORIZATION plsql_rollback2 PASSWORD '********';
	SET
	gaussdb=> set behavior_compat_options = 'plsql_rollback_keep_user';
	SET
	gaussdb=> call plsql_rollback1.p1 ();

enable_crosstype_integer_operator	Enables or disables the cross-type integer operator.
	• This parameter is enabled by default for a newly installed database.
	• After the database of a version earlier than 505.1.0 is upgraded, this parameter is disabled by default.
	• Involved operators: =, <>, <, >, <=, and >=
	• After this parameter is enabled, the involved cross-type integers can be compared directly without implicit conversion. Here is an example that uses (int1 op int2):
	ora_db=# SET max_datanode_for_plan=1;
	SET
	ora_db=# DROP TABLE IF EXISTS implicit_index;
	DROP TABLE
	ora_db=# CREATE TABLE implicit_index(c1 int1);
	NOTICE: The 'DISTRIBUTE BY' clause is not specified. Using 'c1' as the distribution column by default.
	HINT: Please use 'DISTRIBUTE BY' clause to specify suitable data distribution column.
	CREATE TABLE
	ora_db=# SET behavior_compat_options='enable_crosstype_integer_operator';
	SET
	ora_db=# EXPLAIN (COSTS OFF) SELECT * FROM implicit_index WHERE c1 > 1::int2;
	QUERY PLAN
	---------- 	
	Data Node Scan
	Node/s: All datanodes
	
	Remote SQL: SELECT c1 FROM public.implicit_index WHERE c1 > 1::smallint
	Datanode Name: datanode1-- The node information is about the execution plan node of the current test instance, which may be different from the actual information. The actual execution information is subject to the actual information.
	Seq Scan on implicit_index
	Filter: (c1 > 1::smallint)
	
	(8 rows)
	
	ora_db=# SET behavior_compat_options='';
	SET
	ora_db=# EXPLAIN (COSTS OFF) SELECT * FROM implicit_index WHERE c1 > 1::int2;
	QUERY PLAN
	---------- 	
	Data Node Scan
	Node/s: All datanodes
	
	Remote SQL: SELECT c1 FROM public.implicit_index WHERE c1::bigint > 1::smallint
	Datanode Name: datanode1-- The node information is about the execution plan node of the current test instance, which may be different from the actual information. The actual execution information is subject to the actual information.
	Seq Scan on implicit_index
	Filter: ((c1)::bigint > 1::smallint)
	
	(8 rows)
	
	ora_db=# DROP TABLE implicit_index;
	DROP TABLE

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Configuration Item	Behavior

	NOTE
	• This parameter takes effect only when **sql_compatibility** is set to **ORA**.
	• If this parameter is enabled, the execution plan of operators involved in the following scenarios will be affected:
	  • (int1 op int2)
	  • (int1 op int4)
	  • (int1 op int8)
	  • (int1 op int16)
	  • (int1 op numeric)
	  • (int2 op int1)
	  • (int2 op int16)
	  • (int2 op numeric)
	  • (int4 op int1)
	  • (int4 op int16)
	  • (int4 op numeric)
	  • (int8 op int1)
	  • (int8 op int16)
	  • (int8 op numeric)
	  • (int16 op int1)
	  • (int16 op int2)
	  • (int16 op int4)
	  • (int16 op int8)
	  • (numeric op int1)
	  • (numeric op int2)
	  • (numeric op int4)
	  • (numeric op int8)

forbid_package_function_with_prefix	After this parameter is enabled, an error is reported if a function with a prefix is created in a package.
	For example:
	`gaussdb=# SET behavior_compat_options='forbid_package_function_with_prefix';`
	`SET`
	`gaussdb=# CREATE SCHEMA schema1;`
	`gaussdb=# CREATE OR REPLACE package pck1`
	`  IS`
	`  procedure schema1.proc1();`
	`  END pck1;`
	`  /`
	`ERROR:  not support procedure name use *.* format in package at or near ";"`
	`CONTEXT:  compilation of PL/pgSQL package "pck1" near line 2`
	
	`gaussdb=# DROP SCHEMA schema1;`

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Configuration Item	Behavior
time_constexpr_compact	If this parameter is enabled, in a scenario where the time expression is executed, the type automatically returned is with timezone or without timezone depending on whether the constant carries the time zone. Currently, the timestamp and time types are supported. -- Execute a timestamp expression without a time zone. gaussdb=# SELECT timestamp '1999-03-15 8:00:00'; timestamp --------------------- 1999-03-15 08:00:00 (1 row) -- The type timestamp with time zone is returned after a timestamp expression with a time zone is executed. gaussdb=# SELECT timestamp '1999-03-15 8:00:00 -8:00:00'; timestamptz ------------------------ 1999-03-16 00:00:00+08 (1 row)
enable_use_ora_timestamptz	After it is enabled, the date and time obtained by the TIMESTAMP AT TIME ZONE syntax are the same as those in ORA-compatible database. GaussDB can display only the session time zone, and the ORA-compatible database can display the entered time zone. If the time zones are different, the displayed results are different. After the date and time are converted to the same time zone, the same time point is displayed. -- Before enabling a parameter gaussdb=# SELECT timestamp '2024-03-20 01:30:00' at time zone 'Europe/Moscow' FROM dual; timezone ---------------------- 2024-03-20 06:30:00+08 (1 row) -- After enabling a parameter gaussdb=# SET behavior_compat_options='enable_use_ora_timestamptz'; SET gaussdb=# SELECT timestamp '2024-03-20 01:30:00' at time zone 'Europe/Moscow' FROM dual; timezone ---------------------- 2024-03-20 01:30:00+08 (1 row) **NOTE** This parameter is valid only in an ORA-compatible database.

Configuration Item	Behavior

search_path_behavior_optimization	Enables or disables the path search enhancement function for stored procedures.
	● This parameter is disabled by default for a newly installed database.
	● If this option is enabled, the capability of the **bind_procedure_searchpath** option is included. In a stored procedure, schemas in the session-level **search_path** setting are bound to form a schema list. If no schema is explicitly specified for an object in a stored procedure, the object is searched in the schema list in sequence. If both **bind_procedure_searchpath** and **search_path_behavior_optimization** are enabled, **search_path_behavior_optimization** is used by default.
	● The differences between enabling the option and only enabling the **bind_procedure_searchpath** option are that the refresh logic of *$user* in the search path compilation product changes and the pg_temp schema in the search path compilation product changes.
	● After this option is enabled, the behavior changes are as follows:
	– The SECURITY DEFINER function is called in nested mode to refresh the search path. In the compilation product, *$user* is the owner of the innermost nested function.
	– The namespace of the local temporary table is not added to the search path compilation product.
	– Stored procedures or functions cannot use local temporary tables *%type* and *%rowtype*. (This limitation does not apply to the scenario where local temporary tables *%type* and *%rowtype* are used as input and output parameters.) For example:
	`gaussdb=# SET behavior_compat_options='search_path_behavior_optimization';`
	`SET`
	
	`-- Create the local temporary table **temp_table**.`
	`gaussdb=# CREATE TEMP TABLE tmp_table(c1 int);`
	`CREATE TABLE`
	
	`-- An error is reported when the local temporary table *%rowtype* is used in the stored procedure.`
	`gaussdb=# CREATE or REPLACE PROCEDURE test_temp_tab_proc AS`
	`gaussdb$# a tmp_table%ROWTYPE;`
	`gaussdb$# BEGIN`
	`gaussdb$# NULL;`
	`gaussdb$# END;`
	`gaussdb$# /`
	`ERROR: UNSUPPORTED FEATURE with temporary table when setting behavior_compat_options: search_path_behavior_optimization.`
	`CONTEXT: compilation of PL/pgSQL function "test_temp_tab_proc" near line 2`

Configuration Item	Behavior
aformat_null_test	It does not take effect in distributed scenarios.

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Adjust the parameter value based on the database-compatible objects.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

NOTE

Some options of this parameter affect the cache plan. If this parameter is modified in the prepared statement, the execution result does not change.

a_format_version

Parameter description: Specifies the compatibility configuration item of the database platform.

Parameter type: string

Unit: none

Value range: **Table 6-33** lists the supported compatibility configuration items.

Default value: **"10c"**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

Table 6-33 Compatibility configuration item

Configuration Item	Behavior
10c	The ORA platform is compatible with the 10C version. **a_format_version** and **a_format_dev_version** are used together. For details about behavior control, see **Table 6-34**.

a_format_dev_version

Parameter description: Specifies the database platform minor version compatibility configuration item.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter type: string

Unit: none

Value range: **Table 6-34** lists the supported compatibility configuration items.

Default value: **"s7"**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 6-34 Compatibility configuration items

Configuration Item	Behavior
s1	• A minor version of ORA-compatible iteration, which affects the following functions: round(date, fmt), nvl2, lpad, rpad, add_months, months_between, regexp_replace, regexp_count, empty_clob, instrb, trunc(numeric, int), greatest, least, mod, round(number, int), cast, to_date, to_timestamp, chr, to_char, to_number, and to_timestamp_tz. – round(date, fmt): This function, with input parameters of the TIMESTAMP WITHOUT TIME ZONE type, takes effect only when the value of **a_format_version** is **10c** and that of **a_format_dev_version** is **s1** in an ORA-compatible database. – nvl2: This function takes effect when **a_format_version** is **10c** and **a_format_dev_version** is **s1** in ORA-compatible mode. – lpad: When **a_format_version** is **10c** and **a_format_dev_version** is **s1** in ORA-compatible mode: – The **length** parameter indicates the display length of a character string. The display length of a single character is processed based on ORA-compatible requirements. – During the function execution, if the remaining length is 1 and the next character is of the full-width type (2 bytes), a space character is added to the left of the string. – If the value of **length** is a decimal, the value is truncated instead of being rounded off. – The **string** and **fill** parameters do not comply with the encoding specifications. – rpad: When **a_format_version** is **10c** and **a_format_dev_version** is **s1** in ORA-compatible mode: – The **length** parameter indicates the display length of a character string. The display length of a single character is processed based on ORA-compatible requirements. – During the function execution, if the remaining length is 1 and the next character is of the full-width type (2 bytes), a space character is added to the right of the string. – If the value of **length** is a decimal, the value is truncated instead of being rounded off. – The **string** and **fill** parameters do not comply with the encoding specifications. – If the length of the **string** parameter exceeds 1 GB after padding, an error is reported. – add_months: When the GUC parameter **mapping_date_to_datea** is set to **off**, the database parses

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Configuration Item	Behavior
	the date type in the input parameter into the TIMESTAMP(0) WITHOUT TIME ZONE type. In this case, the return value is of the timestamp type. When the input parameter type of the function is parsed as TIMESTAMP(0) WITHOUT TIME ZONE, the function is in Oracle-compatible mode, and **a_format_version** is set to **10c** and **a_format_dev_version** is set to **s1**: – If the calculation result is greater than 9999, an error will be reported. – If the input parameter **n** is a decimal, it will be truncated rather than rounded off. – months_between: When the GUC parameter **mapping_date_to_datea** is set to **off**, the database parses the date type in the input parameter to the TIMESTAMP(0) WITHOUT TIME ZONE type. This function takes effect in the scenario where this function input parameter is parsed to the TIMESTAMP(0) WITHOUT TIME ZONE type in Oracle-compatible mode, the value of **a_format_version** is **10c**, and that of **a_format_dev_version** is **s1**. – regexp_replace: When the function is in ORA-compatible mode, **a_format_version** is set to **10c**, and **a_format_dev_version** is set to **s1**, the default value of **occurrence** is **0**, indicating that all matched substrings are replaced. In addition, the **pattern** parameter that ends with a backslash (\) is valid. – regexp_count: When the function is in ORA-compatible mode, the value of **a_format_version** is **10c**, and the value of **a_format_dev_version** is **s1**, the **pattern** parameter ending with a backslash (\) is valid. – empty_clob: This function takes effect when **a_format_version** is **10c** and **a_format_dev_version** is **s1** in ORA-compatible mode. – instrb: This function takes effect when **a_format_version** is **10c** and **a_format_dev_version** is **s1** in ORA-compatible mode. – trunc(numeric, int): When **a_format_version** is **10c** and **a_format_dev_version** is **s1** in ORA-compatible mode, if the input parameter s is a decimal, the parameter is truncated instead of being rounded off. – greatest: When **a_format_version** is **10c** and **a_format_dev_version** is **s1** in ORA-compatible mode: – If any parameter is null, the function will return null. – If the first parameter is of the numeric type, the function converts this parameter and other parameters to the numeric type, and then compares them. If the

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Configuration Item	Behavior
	parameters cannot be converted, an error message is displayed. If the first parameter is of another type, the function converts other parameters to the type of the first parameter for comparison. If the parameters cannot be converted, an error message is displayed. – least: When **a_format_version** is **10c** and **a_format_dev_version** is **s1** in ORA-compatible mode: – If any parameter is null, the function will return null. – If the first parameter is of the numeric type, the function converts this parameter and other parameters to the numeric type, and then compares them. If the parameters cannot be converted, an error message is displayed. If the first parameter is of another type, the function converts other parameters to the type of the first parameter for comparison. If the parameters cannot be converted, an error message is displayed. – mod: When **a_format_version** is **10c** and **a_format_dev_version** is **s6** in ORA-compatible mode, this function supports overloading with mod(text, int). When the mod function is called with (text, int) as the input type, mod(text, int) will take precedence. – round(numeric, int): – When the control parameter **s** is a decimal: In ORA-compatible databases where **a_format_version** is **10c** and **a_format_dev_version** is **s1**, the function truncates **s** to the integer. In other setups, it will round off **s** to the nearest integer. – If the value of **a_format_version** is **10c** and the value of **a_format_dev_version** is **s1**, the round function supports round(timestamp, text) overloading. When **(text, text)** or **(text, '')** is used as the input parameter to call the round function, round(timestamp, text) is preferred. – cast: When **a_format_version** is **10c** and **a_format_dev_version** is **s1** in ORA-compatible mode, this function supports the optional syntax DEFAULT z ON CONVERSION ERROR and optional parameter **fmt**. – to_date: When **a_format_version** is **10c** and **a_format_dev_version** is **s1** in ORA-compatible mode, if the year exceeds 9999, the system may not report an error. For example, executing **to_date('99999-12-12', 'yyyy-mm-dd hh24:mi:ss')** will yield **9999-09-12 12:00:00**. Any numbers that come after 9999 (the maximum allowed year) will be interpreted as the next **fmt**. – to_timestamp: When **a_format_version** is **10c** and **a_format_dev_version** is **s1** in ORA-compatible mode, **fmt**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Configuration Item	Behavior
	supports FF[7-9]. When FF[7-9] is applied, the number of characters that can be converted from the target position in the string is limited by the number following FF, with only 6 characters ultimately being retained in the conversion result. – chr: When **a_format_version** is **10c** and **a_format_dev_version** is **s1** in ORA-compatible mode, the value is truncated instead of being rounded off if the value of *integer* is a decimal. – to_char(numeric/smallint/integer/bigint/double precision/ real[, fmt]): When **a_format_version** is **10c** and **a_format_dev_version** is **s1** in ORA-compatible mode, the function supports the $, C, TM, TM9, TME, and U formats. However, it does not support TH, PL, or SG. – to_number: When **a_format_version** is **10c** and **a_format_dev_version** is **s1** in ORA-compatible database, the supported formats are described in the to_number function description in *Developer Guide*. – to_timestamp_tz: This function takes effect when **a_format_version** is **10c** and **a_format_dev_version** is **s1** in ORA-compatible mode. ● Data type casting: A decimal character string is rounded off when it is converted to an integer (int1/int2/int4/int8/int16). ● Data type conversion: Implicit conversions from timestamp with time zone to timestamp without time zone and datea, and from timestamp to datea are supported.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Configuration Item	Behavior
s2	• Compatible minor version of platform ORA, which affects functions, such as dump, to_single_byte, to_multi_byte, nls_upper, nls_lower, initcap, ascii2, asciistr, unistr, vsize, cosh, remainder, sinh, tanh, nanvl, current_date, current_timestamp, dbtimezone, numtodsinterval, numtoyminterval, new_time, sessiontimezone, sys_extract_utc, tz_offset, to_binary_double, to_binary_float, to_dsinterval, to_yminterval, lnnvl, and ora_hash. – dump: This function takes effect when **a_format_version** is **10c** and **a_format_dev_version** is **s2** in ORA-compatible mode. – to_single_byte: This function takes effect when **a_format_version** is **10c** and **a_format_dev_version** is **s2** in ORA-compatible mode. – to_multi_byte: This function takes effect when **a_format_version** is **10c** and **a_format_dev_version** is **s2** in ORA-compatible mode. – nls_upper: This function is supported when **a_format_version** is **10c** and **a_format_dev_version** is **s2** in ORA-compatible mode. – nls_lower: This function is supported when **a_format_version** is **10c** and **a_format_dev_version** is **s2** in ORA-compatible mode. – initcap: When **a_format_version** is **10c** and **a_format_dev_version** is **s2** in ORA-compatible mode, if a case-insensitive character, such as Chinese, is followed by a case-sensitive character, only the first letter of the case-sensitive character is capitalized. Therefore, you are advised to set **a_format_version** to **10c** and **a_format_dev_version** to **s2**. – ascii2: This function takes effect when **a_format_version** is **10c** and **a_format_dev_version** is **s2** in ORA-compatible mode. – asciistr: This function takes effect when **a_format_version** is **10c** and **a_format_dev_version** is **s2** in ORA-compatible mode. – unistr: This function takes effect when **a_format_version** is **10c** and **a_format_dev_version** is **s2** in ORA-compatible mode. – vsize: This function takes effect when **a_format_version** is **10c** and **a_format_dev_version** is **s2** in ORA-compatible mode. – cosh: This function takes effect when **a_format_version** is **10c** and **a_format_dev_version** is **s2** in ORA-compatible mode.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Configuration Item	Behavior
	– remainder: This function takes effect when **a_format_version** is **10c** and **a_format_dev_version** is **s2** in ORA-compatible mode. – sinh: This function takes effect when **a_format_version** is **10c** and **a_format_dev_version** is **s2** in ORA-compatible mode. – tanh: This function takes effect when **a_format_version** is **10c** and **a_format_dev_version** is **s2** in ORA-compatible mode. – nanvl: This function takes effect when **a_format_version** is **10c** and **a_format_dev_version** is **s2** in ORA-compatible mode. – current_date: When **a_format_version** is **10c** and **a_format_dev_version** is **s2** in ORA-compatible mode, the return type of this function is timestamp. – current_timestamp: When **a_format_version** is **10c** and **a_format_dev_version** is **s2** in ORA-compatible mode, the precision parameter supports integer values of the numeric type. Otherwise, only int input is supported. – dbtimezone: This function takes effect when **a_format_version** is **10c** and **a_format_dev_version** is **s2** in ORA-compatible mode. – numtodsinterval: When **a_format_version** is **10c** and **a_format_dev_version** is **s2** in ORA-compatible mode, an error is reported if **interval_unit** is set to **'DAY'** and **num** is set to a value greater than **1000000000**. – numtoyminterval: This function takes effect when **a_format_version** is **10c** and **a_format_dev_version** is **s2** in ORA-compatible mode. – new_time: When the GUC parameter **mapping_date_to_datea** is set to **off**, the database parses the date type in the input parameter to the TIMESTAMP(0) WITHOUT TIME ZONE type. In this case, the return value is of the timestamp type. This function takes effect in the scenario where this function input parameter is parsed to the TIMESTAMP(0) WITHOUT TIME ZONE type in Oracle-compatible mode, the value of **a_format_version** is **10c**, and that of **a_format_dev_version** is **s2**. – sessiontimezone: This function takes effect when **a_format_version** is **10c** and **a_format_dev_version** is **s2** in ORA-compatible mode. – sys_extract_utc: This function takes effect when **a_format_version** is **10c** and **a_format_dev_version** is **s2** in ORA-compatible mode.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Configuration Item	Behavior
	– tz_offset: This function takes effect when **a_format_version** is **10c** and **a_format_dev_version** is **s2** in ORA-compatible mode. – to_binary_double: This function takes effect when **a_format_version** is **10c** and **a_format_dev_version** is **s2** in ORA-compatible mode. – to_binary_float: This function takes effect when **a_format_version** is **10c** and **a_format_dev_version** is **s2** in ORA-compatible mode. – to_dsinterval: This function takes effect when **a_format_version** is **10c** and **a_format_dev_version** is **s2** in ORA-compatible mode. – to_yminterval: This function takes effect when **a_format_version** is **10c** and **a_format_dev_version** is **s2** in ORA-compatible mode. – lnnvl: This function takes effect when **a_format_version** is **10c** and **a_format_dev_version** is **s2** in ORA-compatible mode. – ora_hash: This function takes effect only when **a_format_version** is **10c** and **a_format_dev_version** is **s2** in ORA-compatible mode. ● Supports all behaviors when the compatibility configuration item is set to **s1**.
s3	● Compatible minor version of platform ORA. If the parameter is enabled, nested calling of functions without parameters is supported. ● Supports all behaviors when the compatibility configuration item is set to **s2**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Configuration Item	Behavior
s4	• Compatible minor version of platform ORA, which affects functions such as nchr(cvalue int|bigint), to_timestamp_tz, getclobval(xml), and getstringval(xml). – nchr(cvalue int|bigint): This function takes effect when **a_format_version** is **10c** and **a_format_dev_version** is **s4** in ORA-compatible mode. – to_timestamp_tz(string [DEFAULT return_value ON CONVERSION ERROR], fmt, nlsparam): This function takes effect when **a_format_version** is **10c** and **a_format_dev_version** is **s4** in ORA-compatible mode. – getclobval(xml): This function takes effect when **a_format_version** is **10c** and **a_format_dev_version** is **s4** in ORA-compatible mode. – getstringval(cml): This function takes effect when **a_format_version** is **10c** and **a_format_dev_version** is **s4** in ORA-compatible mode. • Supports all behaviors when the compatibility configuration item is set to **s3**.
s5	• Compatible minor version of the ORA platform. If the parameter is enabled, the composite type with the same name as a function is preferentially parsed. The sys_guid() function is affected. – This function takes effect only when **a_format_version** is **10c** and **a_format_dev_version** is **s5** in ORA-compatible mode. • Supports all behaviors when the compatibility configuration item is set to **s4**.
s6	• The ORA platform is compatible with the iteration minor version. The parameter is enabled, and the function mod(text, int) is affected. – mod(text, int): When **a_format_version** is **10c** and **a_format_dev_version** is **s6** in ORA-compatible mode, the mod function supports overloading with mod(text, int). When the mod function is called with (text, int) as the input type, mod(text, int) will take precedence. • Supports all behaviors when the compatibility configuration item is set to **s5**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Configuration Item	Behavior
s7	• The ORA platform is compatible with the minor iteration version and this parameter is enabled. • When this parameter is enabled, the following behavior is compatible: 1. Supports all behaviors when the GUC parameter **behavior_compat_options** is set to '**display_leading_zero, end_month_calculate, plstmt_implicit_savepoint, truncate_numeric_tail_zero, char_coerce_compat, aformat_regexp_match, compat_cursor, plsql_security_definer, proc_outparam_override, dynamic_sql_compat, proc_outparam_transfer_length, tableof_elem_constraints, current_sysdate, plsql_rollback_keep_user, enable_bpcharlikebpchar_compare, show_full_error_lineno, enable_crosstype_integer_operator, forbid_package_function_with_prefix, enable_case_when_alias, time_constexpr_compact, enable_use_ora_timestamptz, forbid_skip_tableof_empty_str_elem, sys_function_without_brackets**'. 2. Supports all behaviors when the GUC parameter **a_format_date_timestamp** is set to **on**. • Supports all behaviors when the compatibility configuration item is set to **s6**. • If this parameter needs to be set in the scenario where the JDBC driver is used to connect to the database, the JDBC driver must be updated accordingly.

b_format_version

Parameter description: Specifies the database platform compatibility behavior configuration item that controls the compatibility with earlier versions in MySQL-compatible mode.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTICE

- **b_format_version** takes effect only when **sql_compatibility** is set to **MySQL**.
- If this parameter is set to a non-empty string, **b_format_behavior_compat_options** is set to **"ALL"** and **bytea_output** is set to **"escape"** simultaneously. If this parameter is set to an empty string, **b_format_behavior_compat_options** and **bytea_output** are set to the original values.
- This parameter must be set on both CNs and DNs.
- To ensure data consistency, after a table with a table collation or column collation is created, this parameter must be used together with **b_format_version='5.7'** and **b_format_dev_version='s2'**, and cannot be changed during the running of the production environment.

Parameter type: string

Unit: none

Value range: an empty string **""** or **"5.7"**

Default value: **""**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Set this parameter together with **b_format_dev_version** immediately after the installation and deployment. You do not need to change the value unless necessary.

Risks and impacts of improper settings: The behaviors of some SQL statements are affected, causing compatibility issues.

b_format_dev_version

Parameter description: Specifies the database platform minor version compatibility configuration item.

NOTICE

- **b_format_dev_version** takes effect only when **sql_compatibility** is set to **MYSQL** and **b_format_version** is set to **"5.7"**.
- This parameter must be set on both CNs and DNs.
- To ensure data consistency, after a table with a table collation or column collation is created, this parameter must be used together with **b_format_version='5.7'** and **b_format_dev_version='s2'**, and cannot be changed during the running of the production environment.

Parameter type: string

Unit: none

Value range: an empty string **""** or a compatibility configuration item in **Table 6-35**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 6-35 Compatibility configuration items

Configuration Item	Behavior
s1	1. The following parameters are influenced: If this parameter is enabled, the **datetime** option in the **disable_keyword_options** parameter is removed, indicating that DATETIME is used as a non-reserved keyword. *datetime* can be used as a table name, column name, or alias, but cannot be used as a function name, stored procedure name, or parameter name of a function or stored procedure. 2. The following functions are influenced: curdate, from_days, date_format, str_to_date, current_date, datediff, timestampdiff, date_add, subtime, month, time_to_sec, to_days, to_seconds, dayname, monthname, convert_tz, sec_to_time, addtime, adddate, date_sub, timediff, last_day, weekday, from_unixtime, unix_timestamp, subdate, day, year, weekofyear, dayofmonth, dayofyear, week, yearweek, dayofweek, time_format, hour, minute, second, microsecond, quarter, utc_date, get_format, extract, makedate, period_add, timestamppadd, period_diff, utc_time, utc_timestamp, sysdate, current_timestamp, maketime, curtime, current_time, localtime, localtimestamp, now, lc_time_names, default_week_format, json_object, and substring. 3. The following types are influenced: a. Be compatible with the integer type tinyint with the value range changed to –128 to 127. b. Be compatible with the character string types char and varchar. The precision *n* of char(*n*) and varchar(*n*) is changed from the byte length to the character length. c. Be compatible with the text types tinytext, mediumtext, and longtext. These types are mapped to the text type after the parameter is enabled. d. Be compatible with binary types tinyblob, blob, mediumblob, and longblob. These types are mapped to the bytea type after the parameter is enabled. e. Be compatible with floating-point types double, float, and real. Among them, double is mapped to the float8 type, double(p, s) is mapped to the numeric type, float(p, s) is mapped to the numeric type, real is mapped to float8, and real(p, s) is mapped to the numeric type. f. Be compatible with high-precision types numeric, dec, and decimal. If the precision and scale are not specified, the default precision is changed to **10** and the scale is changed to **0**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Configuration Item	Behavior
	g. Be compatible with time types datetime, timestamp, time, and date. Replace datetime[(*p*)] with a timestamp without time zone[(*p*)]. Replace timestamp[(p)] with a timestamp with time zone[(p)]. The input, output, range, and precision specifications of these types are changed. For details, see related sections in **Data Types**. h. Be compatible with integer types tinyint, smallint, int, and bigint. The display width and ZEROFILL attributes of these types take effect after the parameter is enabled. 4. The following syntax is influenced: The column constraint ON UPDATE update_expr can be specified. 5. The following operators are influenced: a. An error is reported when the || operator between bytea types is used. b. The REGEXP operator is supported. 6. The following GUC parameter is influenced: When the **bytea_output** parameter is set to **'escape'**, the processing logic changes. For details, see **bytea_output**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Configuration Item	Behavior
s2	The compatibility behavior controlled by s1 is included. In addition, the following impacts are included: 1. The following parameters are influenced: a. When this option is enabled, **standard_conforming_strings** and **escape_string_warning** are set to **off**. b. The **collation_connection** and **character_set_connection** parameters take effect only when this option is enabled. 2. The following functions are affected: a. The like operator does not report an error when an escape character is at the end of the matching string. b. The priorities of the collation rules of the character set and collation are changed. For details, see **Rules for Combining Character Sets and Collations**. c. After the parameter is enabled, the collation of foreign keys cannot be inconsistent with that of columns. 3. The following syntax is influenced: a. The CREATE TABLE table_name LIKE source_table syntax is supported. b. The syntaxes CREATE TABLE table_name LIKE source_table and CREATE TABLE table_name (LIKE source_table) cannot specify **INCLUDING** and **EXCLUDING** options. By default, **INCLUDING ALL** is specified. c. The LOAD DATA syntax is supported. d. The syntaxes for changing table names, such as ALTER TABLE and RENAME TABLE, have impact in the following scenario: If the character string corresponding to the new table name starts with **"#MySQL50#"** and is followed by other characters, **"#MySQL50#"** will be ignored. If the old and new table names are the same, no error will be reported. e. The collate clause can be specified by set names.

Default value: **""**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Set this parameter together with **b_format_version** immediately after the installation and deployment. You do not need to change the value unless necessary.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Risks and impacts of improper settings: The behaviors of some SQL statements are affected, causing compatibility issues.

m_format_dev_version

Parameter description: Specifies the database platform minor version compatibility configuration item.

NOTE

m_format_dev_version takes effect only when **sql_compatibility** is set to **M**.

Parameter type: string

Unit: none

Value range: compatibility configuration items in **Table 6-36**. Currently, you can set the value to **s1** only.

Table 6-36 Compatibility configuration items

Configuration Item	Behavior
s1	The following syntax is influenced: 1. Disable the SELECT FETCH FIRST ROWS ONLY syntax. 2. The TRUNCATE CASCADE/RESTRICT syntax is disabled. 3. USING INDEX TABLESPACE tablespace_name syntax cannot be specified when a primary key is defined using CREATE TABLE. 4. The semantics of CASCADE/RESTRICT syntax in DROP TABLE/VIEW/COLUMN is ignored, and the default behavior is RESTRICT. 5. If the CREATE TABLE REFERENCES syntax is used as a column constraint, its semantics is changed to ignore the foreign key definition.

Default value: **"s1"**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Set this parameter immediately after the installation and deployment. You do not need to change the value unless necessary.

Risks and impacts of improper settings: The behaviors of some SQL statements are affected, causing compatibility issues.

sql_mode

Parameter description: Specifies the SQL behavior control configuration item in MySQL-compatible and M-compatible modes.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- **sql_mode** takes effect when **sql_compatibility** is set to **MYSQL**, **b_format_version** is set to **'5.7'**, and **b_format_dev_version** is set to **'s1'**, or when **sql_mode** takes effect only when **sql_compatibility** is set to **M**.
- When **SHOW sql_mode** and **SELECT @@sql_mode** are used for query, the values are displayed in uppercase based on the sequence as follows: **REAL_AS_FLOAT**, **ANSI_QUOTES**, **ONLY_FULL_GROUP_BY**, **NO_UNSIGNED_SUBTRACTION**, **NO_AUTO_VALUE_ON_ZERO**, **NO_BACKSLASH_ESCAPES**, **STRICT_TRANS_TABLES**, **STRICT_ALL_TABLES**, **NO_ZERO_IN_DATE**, **NO_ZERO_DATE**, **ALLOW_INVALID_DATES**, **ERROR_FOR_DIVISION_BY_ZERO**, **TRADITIONAL**, **NO_AUTO_CREATE_USER**, **NO_ENGINE_SUBSTITUTION**, and **PAD_CHAR_TO_FULL_LENGTH**.

Parameter type: string

Unit: none

Value range:

- MySQL-compatible mode: an empty string **""** or a value in the range of **'strict_trans_tables,only_full_group_by,no_zero_in_date,no_zero_date,error_for_division_by_zero,no_auto_create_user,no_engine_substitution,pad_char_to_full_length,no_auto_value_on_zero'**.
- M-compatible mode: parameters supported in MySQL-compatible mode, **no_unsigned_subtraction**, **ansi_quotes**, **allow_invalid_dates**, **real_as_float**, **strict_all_tables**, and **traditional**.

The meaning of each option value is described in **Table 6-37**.

Table 6-37 Compatibility configuration items

Configuration Item	Behavior	MySQL-compatible Parameter Configuration	M-compatible Parameter Configuration
strict_trans_tables	Currently, only data types and system functions in MySQL-compatible and M-compatible databases can be verified. If this parameter is set, its format and range are strictly verified. If an invalid value is entered or the value exceeds the range, an error is reported during parsing. If this parameter is not set, the format and range of the input parameter are loosely verified. If an invalid value is entered or the value exceeds the range, a warning is reported during parsing and the value after loose processing is returned. Troubleshooting: 1. Abnormal data When a string, rather than a numeric value, is inserted, the string is truncated from the first non-digit character, for example, **'1a'** is truncated to **1**. If the target type is a time type, the zero value of the corresponding data is returned. 2. Exceeding the maximum range The maximum or minimum value of the corresponding data is returned.	It can be set and canceled independently.	It can be set and canceled independently.
only_full_group_by	Projection columns that contain non-GROUP BY keys and that are not constants and aggregate functions are not allowed.	It can be set and canceled independently.	It can be set and canceled independently.
no_zero_in_date	The year, month, and day of the DATE cannot be **0**.	It can be set and canceled independently, but it does not take effect.	It can be set and canceled independently.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Configuration Item	Behavior	MySQL-compatible Parameter Configuration	M-compatible Parameter Configuration
no_zero_date	The value of DATE cannot be **0** (**0000-00-00**).	It can be set and canceled independently, but it does not take effect.	It can be set and canceled independently.
error_for_division_by_zero	The value cannot be divided by 0.	It can be set and canceled independently, but it does not take effect.	It can be set and canceled independently.
no_auto_create_user	This item has no actual function. It is used only for compatibility that an error is not reported when the SET SQL_MODE statement contains this option.	It can be set and canceled independently.	It can be set and canceled independently.
no_engine_substitution	This item has no actual function. It is used only for compatibility that an error is not reported when the SET SQL_MODE statement contains this option.	It can be set and canceled independently.	It can be set and canceled independently.
pad_char_to_full_length	Be used for formatted output of CHAR columns in a table. If there are CHAR columns, a string with spaces at the end is output. Otherwise, a string without spaces at the end is output.	It can be set and canceled independently.	It can be set and canceled independently.
no_auto_value_on_zero	If this option is included, the value **0** inserted into the **AUTO_INCREMENT** column does not trigger auto-increment.	It can be set and canceled independently.	It can be set and canceled independently.
no_unsigned_subtraction	Unsigned numbers cannot be subtracted. If unsigned integers are subtracted and the result is negative, an error is returned.	It can be set and canceled independently, but it does not take effect.	It can be set and canceled independently.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Configuration Item	Behavior	MySQL-compatible Parameter Configuration	M-compatible Parameter Configuration
ansi_quotes	The ANSI_QUOTES mode is enabled, in which double quotation marks are treated as identifier quotes, not string quotes.	It can be set and canceled independently, but it does not take effect. Double quotation marks ("") are always considered as identifier reference symbols.	It can be set and canceled independently.
allow_invalid_dates	If this option is enabled, MySQL allows invalid dates to be inserted, for example, '0000-00-00'.	It can be set and canceled independently, but it does not take effect.	It can be set and canceled independently.
real_as_float	By default, the REAL type is regarded as the DOUBLE type. If this option is enabled, the REAL type is regarded as the FLOAT type.	It can be set and canceled independently, but it does not take effect.	It can be set and canceled independently.
strict_all_tables	The effect is the same as that of **strict_trans_tables**.	It can be set and canceled independently.	It can be set and canceled independently.
traditional	The effect is the same as that of setting **strict_trans_tables**, **strict_all_tables**, **no_zero_in_date**, **no_zero_date**, **error_for_division_by_zero**, **no_auto_create_user**, and **no_engine_substitution** together.	It can be set and canceled independently. **NOTE** Whether this parameter takes effect depends on whether the MySQL-compatible mode is supported.	It can be set and canceled independently.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Default value: **"strict_trans_tables,only_full_group_by,no_zero_in_date,no_zero_date,error_for_division_by_zero,no_auto_create_user,no_engine_substitution"**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

auto_increment_increment

Parameter description: Specifies the auto-increment step of an auto-increment column. The auto-increment value is calculated by the following formula: **auto_increment_offset** + *N* × **auto_increment_increment**. *N* is a positive integer.

Parameter type: integer.

Unit: none

Value range: 1 to 65535

Default value: **1**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Set this parameter as required.

Risks and impacts of improper settings: The self-increment value may not meet the expectation. If the parameter value is smaller than that of **auto_increment_offset**, an error occurs when the values in the auto-increment column automatically increase.

auto_increment_offset

Parameter description: Specifies the initial value of an auto-increment column. The auto-increment value is calculated by the following formula: **auto_increment_offset** + *N* × **auto_increment_increment**. *N* is a positive integer.

Parameter type: integer.

Unit: none

Value range: 1 to 65535

Default value: **1**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Set this parameter as required.

Risks and impacts of improper settings: The self-increment value may not meet the expectation. If the parameter value is greater than that of **auto_increment_increment**, an error occurs when the values in the auto-increment column automatically increase.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

auto_increment_cache

Parameter description: Specifies the number of reserved auto-increment cache values when auto-increment is triggered by batch insertion or import of auto-increment columns. When auto-increment values are reserved, the auto-increment counter value is updated to the maximum auto-increment cache value. Before the cache values are used up, the auto-increment counter value remains unchanged, and the triggered auto-increment uses the cache values.

NOTE

- The reserved cache values are valid only in the statement. If the reserved auto-increment cache values are used up and subsequent INSERT statements trigger auto-increment based on the auto-increment counter, the values in the auto-increment column in the table are discontinuous.
- When auto-increment is triggered by parallel import or insertion of auto-increment columns, the cache value reserved for each parallel thread is used only in the thread. If the cache value is not used up, the values of auto-increment columns in the table are discontinuous.
- When you add an auto-increment column to a table with data or modify a column to an auto-increment column, the existing data triggers auto-increment. The reserved auto-increment cache value is also affected by this parameter.
- This parameter does not affect the auto-increment column in the local temporary table.

Parameter type: integer.

Unit: none

Value range: 0 to 2147483647

- If this parameter is set to **0**, the auto-increment cache values are automatically reserved.
  - When auto-increment is triggered for the first time, if the number of rows to be inserted into the auto-increment column is known, the number is the reserved value.
    - For example, the number of rows to be inserted cannot be obtained as the value of auto-increment that is triggered by INSERT INTO table SELECT ... or COPY FROM. When the ALTER TABLE statement is executed to rewrite table data, if auto-increment is triggered, reltuples in the statistics is used as the number of rows to be reserved. INSERT INTO table VALUES(...),(...),... is distributed to different DNs. Therefore, in some execution plans, DNs cannot obtain the number of rows to be inserted.
  - If the number of rows is unknown, 2^n values are reserved each time. For example, one value is reserved in the first auto-increment, two values are reserved in the second auto-increment, four values are reserved in the third auto-increment, and eight values are reserved for in fourth auto-increment. However, if the number of reserved values exceeds 65535, 65535 values are reserved.
- If this parameter is not set to **0**, the number of reserved cache values is the value of this parameter.
  - When auto-increment is triggered for the first time, if the number of rows to be inserted into the auto-increment column is known, the number is the reserved value.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

  - If the number of rows is unknown, the value of **auto_increment_cache** is the number of auto-increment values reserved each time.

Default value: **0**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: The default value is recommended. However, if the auto-increment values are discontinuous in this case, you can adjust the parameter value based on the amount of data to be inserted in batches.

Risks and impacts of improper settings: A larger parameter value indicates better batch insertion performance and more likely to generate discontinuous self-increment values.

auto_increment_mode

Parameter description: When creating a table in an M-compatible database, if **LOCAL** and **GLOBAL** are not specified in the **AUTO_INCREMENT** column, you can use the **auto_increment_mode** parameter to specify the column as a global or local auto-increment column.

Parameter type: string

Unit: none

Value range:

- **'global'**: global auto-increment column.
- **'local'**: local auto-increment column.

Default value: **'global'**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Set this parameter as required.

Risks and impacts of improper settings: The self-increment value may not meet the expectation.

disable_keyword_options

Parameter description: Specifies database compatibility behavior. Multiple items are separated by commas (,). An identifier with this parameter set will not be used as a keyword.

Parameter type: string

Unit: none

Value range: The keywords vary depending on compatibility modes of databases. For details, see **Table 6-38**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Default value:

- In non-M-compatible database: **"datetime,regexp,rlike,zerofill"**
- In M-compatible database: **""**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this parameter is enabled, some functions used as keywords will become invalid. Exercise caution when setting this parameter. If the keyword to be shielded does not exist in the to-be-shielded keyword array of the current compatibility mode database but exists in other compatibility mode databases, WARNING is generated. If the keyword to be shielded does not exist in other compatibility mode databases, ERROR is generated.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

In MySQL-compatible mode, whether **datetime**, **regexp**, **rlike**, and **zerofill** are reserved keywords is determined by the system and cannot be modified or deleted by users. Specifically, in the initial state, the system adds **datetime**, **regexp**, **rlike**, and **zerofill** to the **disable_keyword_options** parameter. In this case, **datetime**, **regexp**, **rlike**, and **zerofill** are not reserved keywords. After **b_format_version** is set to **'5.7'** and **b_format_dev_version** is set to **'s1'** (or a version later than s1), the system deletes **datetime**, **regexp**, **rlike**, and **zerofill** from **disable_keyword_options**. In this case, **datetime**, **regexp**, **rlike**, and **zerofill** can be used as reserved keywords.

disable_plsql_keyword_options

Parameter description: Specifies the database compatibility behavior, that is, whether to use an identifier as a non-keyword. Values of this parameter are separated by commas (,).

Parameter type: string

Unit: none

Value range: **PIPE**, **PIPELINED**, **RANGE**, **REPLACE**, and **SUBTYPE**.

Default value: **""**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

NOTE

- If this parameter is enabled, some functions used as keywords will become invalid. Exercise caution when setting this parameter.
- To cancel the function of shielding the PL/SQL keyword, leave this parameter empty.

td_compatible_truncation

Parameter description: Specifies whether to enable features compatible with a Teradata database. You can set this parameter to **on** when connecting to a database compatible with the Teradata database, so that when you perform the INSERT operation, overlong strings are truncated based on the allowed maximum length before being inserted into char- and varchar-type columns in the target table. This ensures all data is inserted into the target table without errors reported.

NOTE

- The string truncation function cannot be used if the INSERT statement includes a foreign table.
- If multi-byte character data (such as Chinese characters) is inserted into a database with the character set byte encoding (such as SQL_ASCII and LATIN1), and the character data crosses the truncation position, the string is truncated based on its bytes instead of characters. Unexpected result will occur in tail after the truncation. To ensure correct truncation behavior, it is advisable to use character-based encoding such as UTF-8 as the database's character set.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter type: Boolean.

Unit: none

Value range:

- **on** indicates that overlong strings are automatically truncated.
- **off** indicates that overlong strings are not automatically truncated.

Default value: **off**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

uppercase_attribute_name

Parameter description: Specifies whether to return column names in uppercase to the client. This parameter is used only in ORA-compatible mode.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: Column names are returned to the client in uppercase.
- **off**: Column names are not returned to the client in uppercase.

Default value: **off**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- Do not run **gs_guc set**, **gs_guc reload**, **alter database set**, or **alter user set** or modify **gaussdb.conf** to modify this parameter globally.
- When this parameter is enabled and an alias with quotation marks is specified for a projection column, whether the column name is returned in uppercase is also controlled by the **uppercase_attribute_name_respect_quote** parameter.
- After this parameter is enabled, the column name is converted to uppercase only when the column name is in lowercase. The uppercase column name is returned to the client. When the column name is case-insensitive, the column name is not converted to uppercase.

```
gaussdb=# SET uppercase_attribute_name=off;
SET
gaussdb=# SELECT 1 AS ab, 2 AS Ab, 3 AS AB, 4 AS "ab", 5 AS "Ab", 6 AS "AB";
 ab | ab | ab | ab | Ab | AB
----+----+----+----+----+----
  1 |  2 |  3 |  4 |  5 |  6
(1 row)

gaussdb=# SET uppercase_attribute_name=on;
SET
gaussdb=# SELECT 1 AS ab, 2 AS Ab, 3 AS AB, 4 AS "ab", 5 AS "Ab", 6 AS "AB";
 AB | AB | AB | AB | Ab | AB
----+----+----+----+----+----
  1 |  2 |  3 |  4 |  5 |  6
(1 row)
```

uppercase_attribute_name_respect_quote

Parameter description: Specifies whether to retain the original case of quoted column aliases after the **uppercase_attribute_name** parameter is enabled when the column aliases are returned to the client. This parameter is used only in ORA-compatible mode. This parameter can be set at the PDB level.

Parameter type: enumerated type

Unit: none

Value range:

- **off**: The quoted column aliases that are in lowercase are converted to uppercase and returned. The quoted column aliases that are in uppercase or mixed case are returned in the original case.
- **select_alias**: In the scenario where the outermost layer is a SELECT query and the projection column specifies an alias with quotation marks, the original case is retained. In other scenarios, the behavior is the same as that of **off**.

Default value: **off**. In the PDB scenario, if this parameter is not set, the global setting is inherited.

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- For an upgrade from a version that does not support this parameter to the current version, this parameter does not take effect if the upgrade is not committed.
- Do not run **gs_guc set**, **gs_guc reload**, **alter database set**, or **alter user set** or modify **gaussdb.conf** to modify this parameter globally.
- This parameter takes effect only when **uppercase_attribute_name** is enabled. If this parameter is set to **select_alias**, only SELECT statements are affected, and scenarios such as PBE, CREATE VIEW, and DECLARE CURSOR are not affected.

enable_object_special_character

Parameter description: Determines whether the value of the **schema** parameter in the control file can contain any special characters in ["$'\] when the CREATE EXTENSION statement is executed and "@extschema@" is used in the script file.

Parameter type: Boolean.

Unit: none

Value range:

- **on** indicates that the value can contain any special characters in ["$'\].
- **off** indicates that the value cannot contain any special characters in ["$'\].

Default value:

- **off**: default value of the newly installed database.
- **on**: This parameter is added in 505.0. If a database is upgraded from a version earlier than 505.0, the value of this parameter is **on**. If this parameter exists and is set before the upgrade, the default value remains unchanged after the upgrade.

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Extensions are for internal use only. Only advanced packages or extensions in the database can be operated.

Risks and impacts of improper settings: Changing the value of this parameter may cause unexpected results in the cluster. Retain the default value.

enable_implicit_cast_str2num

Parameter description: Specifies whether a string can be converted to a NUMERIC type when a comparison or arithmetic operator is performed between an integer data type and a string data type.

NOTE

This parameter is valid only when **a_format_version** is set to **'10c'** and **a_format_dev_version** is set to **'s1'**.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: enabled.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Comparison operators (>, >=, <, <=, =, and <>): The string data type is implicitly converted to the NUMERIC type. If the **enable_crosstype_integer_operator** option of the **behavior_compat_options** parameter is disabled, the integer data type is implicitly converted to the NUMERIC type.

Arithmetic operators (+, -, *, /,%, and ^): Both integer and string data types are implicitly converted to the NUMERIC type.

- **off**: disabled. The string data type will be implicitly converted to the integer data type.

Default value: **on**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

a_format_disable_func

Parameter description: Disables a specified system function. The value of this parameter consists of multiple system function OIDs separated by commas (,). The system function for which this parameter is set cannot be called. When a system function cannot meet user requirements and a user-defined function with the same name is required, you can use this function.

Parameter type: string

Unit: none

Value range: a string consisting of multiple system function OIDs separated by commas (,).

Default value: **""**

Setting method: This is a SUSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

enable_convert_illegal_char

Parameter description: Specifies whether invalid characters in the command output are not verified and are displayed as placeholders.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The parameter is enabled. Invalid sequences are replaced by the symbols specified by the **convert_illegal_char_mode** parameter.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **off**: The parameter is disabled. If the query result contains invalid characters, an error is reported after verification.

Default value: **off**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value. Enable this parameter only when the data contains special characters and errors should not be reported for special characters.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

1. When the database character set is utf8, zhs16gbk, gb18030, gb18030-2022, or latin1, **enable_convert_illegal_char=on** takes effect. If the character set of the database client is different from that of the database server, invalid characters are displayed as placeholders.
2. Special character range: The special characters mentioned in this document include only fully abnormal encoding and hybrid encoding. The \u0000 character is not supported. If the character code contains the \u0000 character, the character is truncated at \u0000, which affects data integrity.
3. In the PBE scenario, if the character set of the database client is the same as that of the server, the bound parameters do not require encoding conversion. However, the validity of the bound parameters still needs to be verified, and invalid characters in the bound parameters need to be processed during the verification. When the **enable_convert_illegal_char** parameter is disabled, invalid characters (excluding \u0000) in the bound parameters are replaced with placeholders (characters specified by the **convert_illegal_char_mode** parameter). When the **enable_convert_illegal_char** parameter is enabled, the original characters are retained.
4. If the character sets of the database client and server are different, when **enable_convert_illegal_char** is set to **off**, the database replaces special characters (excluding \x0000) that exceed the current character set codes with **\x3F** (displayed as **?**) and writes the special characters into the database; when **enable_convert_illegal_char** is set to **on**, only the dbe_raw.cast_to_varchar2() function can be used to insert the original invalid character into the database and display the character as a placeholder.
5. If the character sets of the database client and server are the same, when **enable_convert_illegal_char** is set to **off**, the database replaces special characters (excluding \x0000) that exceed the current character set codes with **\x3F** (displayed as **?**) and writes the special characters into the database; when **enable_convert_illegal_char** is set to **on**, only the dbe_raw.cast_to_varchar2() function can be used to insert the original invalid character into the database.
6. Only encoding processing between the client character set and the server character set is supported. The behavior of encoding verification that is not between the client character set and the server character set is the same as that when the parameter is disabled.
7. When the GUC parameter is enabled, the behaviors of the special characters in the functions and advanced package functions listed in the following table are as follows:
   - When the character sets of the client and server are the same, no error is reported during the query of special characters. The behavior is the same as that before the GUC parameter is enabled.
   - If the character sets of the client and server are different, special characters are displayed as placeholders, which use question marks (?) by default.
   - You are advised not to use functions to process character strings that contain special characters. The functions listed in the following table do not report errors when processing character strings that contain special characters, and the correctness of the results cannot be ensured.

fix_func_selection

Parameter description: Specifies whether to optimize the function matching policy.

The catlist sequence issue occurs in this case: If a user-defined function conflicts with a system function, the function selected by the database depends on the registration sequence of the system function in the database system.

Parameter type: string

Unit: none

Value range: **""** and **"catlist"**.

- **""**: No optimization is performed. The value is the same as that in versions earlier than 505.1.0.
- **"catlist"**: The catlist sequence is optimized. System functions are always preferentially selected and executed.

Default value:

- **"catlist"**: default value of the newly installed database
- **""**: default value of the database in versions earlier than 505.1.0 after the database is upgraded.

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

max_allowed_packet

Parameter description: Specifies the upper limit of the return value of a string function in M-compatible database. If the actual result exceeds the upper limit, an alarm is generated and **NULL** is returned.

Parameter type: integer.

Unit: bytes

Value range: 1024 to 1073741824. The value must be a multiple of 1024. Otherwise, the value is rounded down to the nearest multiple.

Default value: **4194304**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

div_precision_increment

Parameter description: Specifies the database configuration item in M-compatible mode. This parameter specifies the precision improvement value of the division result. That is, the number of decimal places in the division result is equal to the number of decimal places in the divisor plus the value of this parameter.

Parameter type: integer.

Unit: none

Value range: 0 to 30

Default value: **4**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

enable_m_format_hook

Parameter description: Specifies the database configuration item in M-compatible mode. This parameter specifies whether the hook in M-compatible mode takes effect.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The M-compatible database allows the corresponding parser and executor hooks to be mounted.
- **off**: The M-compatible database does not mount the corresponding parser and executor hooks.

Default value: **on**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: This parameter is used only for external tools that are not fully adapted and cannot be used by users.

Risks and impacts of improper settings: none

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

gs_format_behavior_compat_options

Parameter description: Selects configuration items of GaussDB internal system functions.

Parameter type: string

Unit: none

Value range: Currently, only compatibility configuration items listed in **Table 6-40** are supported. Compatibility configuration items are separated by commas (,).

Default value: **""**

Table 6-40 gs_format_behavior compatibility configuration items

Configuration Item	Behavior
sqrt_karatsuba	• If this parameter is set, the Karatsuba square root algorithm is used when the sqrt function is called. The Karatsuba algorithm has higher performance but its precision may be different from that of the Newton iteration algorithm in rare cases. • If this parameter is not set, the default Newton iteration algorithm is used to calculate the square root for the sqrt algorithm.

allow_textconcat_null	• If this parameter is set, the value of the corresponding character string is returned when a character string is combined with the **null** value in PG-compatible mode.
	`-- Run the following command in PG-compatible mode:`
	`gaussdb=# set gs_format_behavior_compat_options='allow_textconcat_null';`
	`SET`
	`gaussdb=# select 'a' || null || 'b';`
	` ?column?`
	`----------`
	` ab`
	`(1 row)`
	• If this parameter is not set, **NULL** is returned when a character string is combined with the **null** value in PG-compatible mode.

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Determines whether some compatibility features are available. If you want to modify this parameter, make sure you understand its meaning and modify it with caution to avoid risks caused by misoperations.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

support_zero_character

Parameter description: Specifies whether the database cancels the verification of the zero character and correctly processes it without truncating the character when the data contains the character whose Unicode code is \u0000 (referred to as the zero character).

Parameter type: Boolean.

Unit: none

Value range:

- **on**: enabled. The database cancels the verification of the zero character and can correctly insert and process the zero character so that the data is not truncated during processing.
- **off**: disabled. The database retains the verification of the zero character. When some functions process the zero character, an error is reported or data is truncated.

Default value: **off**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value. Enable this parameter only when the data contains the zero character and the zero character need to be correctly processed.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- This parameter takes effect only when the ORA-compatible database is used and **support_zero_character** is set to **on** for all nodes.
- If you want to write zero characters to the database, ensure that **support_zero_character** is set to **on** and the setting takes effect so that the zero characters can be properly inserted and stored.
- When **support_zero_character** is set to **on** and the data type is CHAR(n), CHARACTER(n), NCHAR(n), VARCHAR(n), CHARACTER VARYING(n), VARCHAR2(n), NVARCHAR2(n), TEXT, or CLOB, the database can correctly insert and process zero characters. If the string data contains zero characters and is explicitly converted to JSON/JSONB, XML, XMLTYPE, numeric, currency, time, geometric, network address, bit string, text (for search), HLL, range, object identifier, ledger database, aclitem, or vector type, the string will be truncated at the zero character. If the string is explicitly converted to the UUID type, an error is reported at the zero character.
- The database supports only the following methods of writing the zero characters:
  - When the database is connected through JDBC, the zero character can be written to the database in text mode.
  - Use the dbe_raw.cast_to_varchar2 function to directly write the zero character code to the database.
  - Use the copy tool to write the zero character code to the database.
- When the GUC parameter is enabled and different character sets are converted, the zero character is directly returned and no error is reported.
- The gsql client version must match the database version. When the GUC parameter is enabled, if the data received by gsql contains zero characters, gsql converts the zero characters to spaces and then prints the data. If the gsql tool of a version earlier than 505.2.0 is used to connect to the database, data containing zero characters is still truncated.
- When the GUC parameter is enabled, the zero characters can be properly processed by the functions listed in **Table 6-41** and will not be truncated.
- The input parameters of some advanced package APIs are schema names or object names, which cannot contain zero characters theoretically. Therefore, zero character verification is added to the functions in **Table 6-42**. When the input parameters contain zero characters, an error is reported. (In earlier versions, data after the zero characters is truncated.)
- When **support_zero_character** is set to **on**, if the processed data does not contain zero characters, the function performance does not deteriorate significantly. If the processed data contains zero characters, the performance deterioration of the initcap, upper, lower, nls_upper, and nls_lower functions is closely related to the number of zero characters in the data. That is, the more zero characters there are, the more severe the performance deterioration.
- When **support_zero_character** is set to **on**, if the logical decoding tool reads zero characters in the data, zero characters are converted to spaces and then printed. (In earlier versions, data after the zero characters is truncated.)

enable_case_intervaltonumeric

Parameter description: Specifies whether INTERVAL can be converted to NUMERIC in CASE statements. This parameter takes effect only in ORA-compatible mode.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: INTERVAL can be converted to NUMERIC in the CASE statement.
- **off**: INTERVAL cannot be converted to NUMERIC in the CASE statement.

Default value: **off**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this parameter is set to **on** and then modified to **off**, an error may be reported for the existing CASE statement.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

enable_ecpg_cursor_duplicate_operation

Parameter description: Specifies whether to allow ECPG to control a cursor can be opened or closed repeatedly in ORA-compatible mode. This parameter is valid only when ECPG is connected to ORA-compatible databases.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: A cursor can be opened or closed repeatedly when ECPG connects to an ORA-compatible database.
- **off**: A cursor cannot be opened or closed repeatedly when ECPG connects to an ORA-compatible database.

Default value: **on**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this parameter is set to **off**, an error will be reported when a cursor is opened or closed repeatedly.

NOTE

If the current database version is directly installed, the default value of this parameter is **on**. For a database upgraded from an earlier version, if the source version does not support this parameter, the default value of this parameter is **off** after the upgrade. If the source version supports this parameter, the current setting of this parameter is retained after the upgrade.

format_pg_to_timestamp

Parameter description: Controls the behavior of the to_timestamp(string [, fmt]) function in PG-compatible mode. After this parameter is enabled, unsupported formats are automatically skipped. The current version does not support formats such as FF, FF7, FF8, FF9, RR, RRRR, SYYYY, x and X. Dates earlier than 294277-01-01 00:00:00 and negative years (converted to BC) are supported. FF1 to FF6 round off the milliseconds that exceed the precision. When the same items in the time and date conflict (for example, the days specified by DDD and DD are different), a time in the correct format is returned and no error is reported. For details about the conflict behavior, see **Table 6-43**.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The preceding functions are enabled.
- **off**: The preceding functions are disabled.

Default value: **on**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this parameter is enabled, a format that is not supported by GaussDB will become invalid.

Table 6-43 to_timestamp fmt conflicts

Type	Description
SSSSS conflicts with time.	Retain minutes and hours of time and the seconds part of SSSSS.
W and J conflict with time and date.	Priority: Overwrite J, W, and mmdd in sequence. W: indicates Wednesday by default. Default behavior: Overwrite mmdd with W.
SSSSS conflicts with SS.	Retain SS and discard SSSSS.
DDD conflicts with a date.	Discard DDD.

synonym_priv_strict_check

Parameter description: Specifies whether to check access to objects associated with a synonym when you search for an object using the synonym.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The access permission on the objects associated with the synonyms is checked when searching for objects by synonyms.
- **off**: The access permission on the objects associated with the synonyms is not checked when searching for objects by synonyms.

Default value:

- If a new version is directly installed, the default value is **on**.
- For a database upgraded from an earlier version, if the source version does not support the GUC parameter, the default value is **off**. If the source version supports the GUC parameter, the default value is **on**.

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If the parameter is set to **off**, the access permission on the objects associated with the synonyms is not checked when searching for objects by synonyms, which may cause unauthorized operations.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

forbid_public_funcname_same_with_sysfunc

Parameter description: Specifies whether to forbid PUBLIC functions to have the same name as system functions in pg_catalog when creating functions and RENAME functions.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: When creating a function or rename a function, the name of the PUBLIC function cannot be the same as that of a system function in pg_catalog.
- **off**: When creating a function or rename a function, the name of the PUBLIC function can be the same as that of a system function in pg_catalog.

Default value:

- If a new version is directly installed, the default value is **on**.
- For a database upgraded from an earlier version, if the source version does not support the GUC parameter, the default value is **off**. If the source version supports the GUC parameter, the default value is **on**.

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this parameter is set to **off**, the PUBLIC function can have the same name as a system function in pg_catalog.

a_format_func_col_name

Parameter description: Specifies the system function compatibility configuration item in the ORA-compatible database.

Parameter type: string

Unit: none

Value range: Currently, only information in **Table 6-44** are supported. Compatibility configuration items are separated by commas (,).

Default value: **""** (an empty string)

Table 6-44 System function compatibility configuration items

Configuration Item	Behavior
user	After this parameter is enabled, the name of the projection column returned by **SELECT user;** is **user**.

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Setting suggestion: Adjust the parameter value based on the database-compatible objects.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

enable_cursor_with_hold

Parameter description: Specifies whether a cursor has the WITH HOLD function in ORA-compatible mode. After **enable_cursor_with_hold** is enabled, if the WITHOUT HOLD keyword is not specified and the SELECT clause does not contain the FOR UPDATE or FOR SHARE clause when a cursor is created, the WITH HOLD function is used by default.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: If the WITHOUT HOLD keyword is not specified and the SELECT clause does not contain the FOR UPDATE or FOR SHARE clause when a cursor is created, the WITH HOLD function is used by default. In this case, **CURSOR cursor_name FOR query;** is equivalent to **CURSOR cursor_name WITH HOLD FOR query;**.
- **off**: If WITH HOLD or WITHOUT HOLD is not specified when a cursor is created, WITHOUT HOLD is used by default.

Default value: **off**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**. This parameter can be set only in a session.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If the value is **on**, all cursors are not released, which may cause memory bloat in sessions.

modify_function_property

Parameter description: Specifies the attributes of related system functions in non-M-compatible mode.

Parameter type: string

Unit: none

Value range: Currently, only the configuration items listed in **Table 6-45** are supported. Compatibility configuration items are separated by commas (,).

Default value: **"3257,5562,4164,4073"** for a newly installed database. If the GUC parameter does not exist in the basic version to be upgraded, the default value is **""**. If the GUC parameter exists in the basic version to be upgraded, the original setting is retained.

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Risks and impacts of improper settings: The attributes of system functions are affected.

Table 6-45 System function configuration items

OID Corresponding to the System Function	Description
3257	Modifies the variability of the pg_catalog.current_timestamp(numeric) function. When the configuration item exists in the GUC parameter, the variability of the function is **'stable'**. When the configuration item does not exist, the variability of the function is **'immutable'**.
4073	Modifies the variability of the pg_catalog.text_timestamp(text) function. When the configuration item exists in the GUC parameter, the variability of the function is **'stable'**. When the configuration item does not exist, the variability of the function is **'immutable'**.
4164	Modifies the variability of the pg_catalog.text_date(text) function. When the configuration item exists in the GUC parameter, the variability of the function is **'stable'**. When the configuration item does not exist, the variability of the function is **'immutable'**.
5562	Modifies the variability of the pg_catalog.DBTimezone() function. When the configuration item exists in the GUC parameter, the variability of the function is **'stable'**. When the configuration item does not exist, the variability of the function is **'immutable'**.

enable_check_insertall_target

Parameter description: Specifies whether to check the validity of the target table attributes of the INSERT ALL syntax in ORA-compatible mode.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The validity of the target table attributes of the INSERT ALL syntax is checked. The target table cannot be a replication table or a table with a global secondary index (GSI). The distribution modes of all target tables must be the same.
- **off**: The validity of the target table attributes of the INSERT ALL syntax is not checked.

Default value: **on** for a newly installed database. If the GUC parameter does not exist in the basic version to be upgraded, the default value is **off**. If the GUC

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

parameter exists in the basic version to be upgraded, the original setting is retained.

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this parameter is set to **off**, the data inserted into the target table may not meet the expectation.

forbid_hold_cursor_with_forupdate

Parameter description: Specifies whether to report an error when the cursor cyclic or for loop query statement with the FOR UPDATE/FOR SHARE feature in a stored procedure accesses the cursor in the next cycle after the transaction is committed or rolled back.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The error reporting behavior described in the parameter description is reported.
- **off**: The error reporting behavior described in the parameter description is not reported.

Default value: **on**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this parameter is set to **off**, an error may be reported when the stored procedure is executed during transaction commit/rollback, or the FOR UPDATE/FOR SHARE feature may be lost when the cursor is accessed cyclically next time after the commit/rollback.

NOTE

If the current database version is directly installed, the default value of this parameter is **on**. For a database upgraded from an earlier version, if the source version does not support this parameter, the default value of this parameter is **off** after the upgrade. If the source version supports this parameter, the current setting of this parameter is retained after the upgrade.

adjust_systemview_priority

Parameter description: Specifies whether to preferentially access the user-defined view with the same name in Oracle-compatible mode.

Parameter type: Boolean.

Unit: none

Value range:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **on**: enabled. The user-defined views with the same name are preferentially accessed.
- **off**: disabled. The system views with the same name are preferentially accessed.

Default value: **off**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this parameter is set to **on**, the user-defined views with the same name are preferentially accessed.

using_danger_feature

Parameter description: Specifies whether to enable dangerous features.

Parameter type: string.

Unit: none

Value range: Only the information in **Table 6-46** is supported. Use commas (,) to separate multiple values.

Default value: **"none"**, indicating that dangerous features are disabled.

Table 6-46 Dangerous feature configuration items

Dangerous Feature Configuration Item	Behavior Control
operator_class	If this option is set, system administrators are allowed to create operator classes. When an operator class is created, the input parameter type of the specified function must be the same as the index type or the type can be properly converted. Otherwise, unpredictable consequences may occur.
alter_function	• If this option is set, you can modify the names, owners, and schemas of functions in m_schema, information_schema, sqladvisor, sys, pg_toast, dbe_sql_util, and the schemas to which advanced packages belong. • If this option is not set, the preceding modification is not allowed.

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Risks and impacts of improper settings: Change the parameter value after you fully understand the parameter meaning and test the parameter to avoid unexpected results.

NOTE

- If the current database version is directly installed, the default value of this parameter is **"none"**. For an upgrade from an earlier version to the current version, if the source version does not support this parameter, the default value of this parameter is **"operator_class, alter_function"**. If the source version supports this parameter, the current setting of this parameter is retained after the upgrade.
- When **"none"** is set together with other configuration items, **"none"** does not take effect.

disable_operator

Parameter description: Specifies the operators to be disabled. The operators specified by this parameter cannot be called. This functionality can be used when a system operator cannot meet user requirements and a user-defined operator is required.

Parameter type: string

Unit: none

Value range: a string consisting of multiple operator OIDs separated by commas (,). You can obtain the operator OID by querying the **PG_OPERATOR** system catalog.

Default value: **""**

Setting method: This is a SUSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after you fully understand the parameter meaning and test the parameter to avoid unexpected results.

enable_xmltype_ignore_format

Parameter description: Specifies whether to use the content format for XMLType data verification.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The parameter is enabled and XMLType data can be verified in content format.
- **off**: The parameter is disabled and XMLType data can be verified in document format.

Default value: **off**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: This parameter is reserved for emergency. Do not set it unless necessary.

Risks and impacts of improper settings: Change the parameter value after you fully understand the parameter meaning and test the parameter to avoid unexpected results.

NOTE

When the **enable_xmltype_ignore_format** parameter is enabled, the content format can be used to verify input data only in the following scenarios:

- Convert the unknown and unspecified types to the XMLType type. For details about the conversion principle, see **Type Conversion**.
- Call the XMLType function, for example, xmltype('123').

enable_force_create_obj

Parameter description: Specifies whether to enable the one-off import function for views. After this parameter is enabled, a view can still be successfully created even if the objects it depends on are absent or the required query permissions are missing.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The one-off import function is enabled for views.
- **off**: The one-off import function is disabled for views.

Default value: **off**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Set this parameter based on the actual scenario. You are advised to enable the corresponding function in normal cases.

Risks and impacts of improper settings: Change the parameter value after you fully understand the parameter meaning and test the parameter to avoid unexpected results.

distribute_default_compatibility

Parameter description: Specifies the default compatibility mode when the **DBCOMPATIBILITY** and **TEMPLATE** keywords are not specified in the CREATE DATABASE operation.

Parameter type: enumerated type

Unit: none

Value range:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **ora**: The default mode for creating a database is ORA-compatible.
- **mysql**: The default mode for creating a database is MySQL-compatible.

Default value:

- For a newly installed database: **ora**.
- For a database upgraded from a version earlier than 507.0.0: **mysql**.
- For a database upgraded from 507.0.0 or later: original parameter value.

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Set this parameter based on service requirements. This parameter can be specified during database installation. If the specified value is **NULL**, an error will be reported. If the specified value is not within the value range, the default value **ora** will be used. You can set this parameter during installation as follows:

```
gs_install -X /data/software/XmlConfig/Dist_3C3D3REP.xml --init-password --gsinit-parameter="--distribute_default_compatibility ora"
```

Risks and impacts of improper settings: Change the parameter value after you fully understand the parameter meaning and test the parameter to avoid unexpected results.

load_data_behavior_compat_options

Parameter description: Specifies the behavior of importing data using the LOAD DATA syntax. This database configuration item is used when **sql_compatibility** is set to **'MYSQL'** or in the M-compatible database.

Parameter type: enumerated type

Unit: none

Value range: See **Table 6-47**.

Table 6-47 Configuration items of load_data_behavior_compat_options

Configuration Item	Behavior
none	No compatibility configuration item is used. When **none** is used together with other compatibility configuration items, **none** does not take effect. For example, **SET load_data_behavior_compat_options='none,new_escape_string'** is equivalent to **SET load_data_behavior_compat_options='new_escape_string'**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Configuration Item	Behavior
new_escape_string	Specifies the escape sequences supported when LOAD DATA is used to import data. The default escape character is a backslash (\). ● If the **new_escape_string** option is not set, the following escape sequences are supported: – **\a[b[c]]**: **a**, **b**, and **c** in the escape sequence are octal digits (0 to 7), indicating a value consisting of octal digits. The system parses the value into the corresponding byte value. For example, the octal value of **\141** is 141, which corresponds to the decimal value 97, indicating the ASCII character (the ASCII code of character **a** is 97). – **\xhh**: In the escape sequence, **h** indicates a hexadecimal digit (0 to 9, a to f, or A to F). **hh** indicates a value consisting of two hexadecimal digits. The system parses the value into the corresponding byte value. For example, the hexadecimal value of **\x6a** is **6A**, which corresponds to the decimal value **106**, indicating the ASCII character **'j'** (the ASCII code of character **'j'** is 106). – **\r**: carriage return character. – **\n**: newline character. – **\b**: backspace character. – **\v**: vertical tab character. – **\t**: horizontal tab character. – **\f**: form feed character. – **\0**: zero character. ● If the **new_escape_string** option is set, the following escape sequences are supported: – **\r**: carriage return character. – **\n**: newline character. – **\b**: backspace character. – **\t**: horizontal tab character. – **\0**: zero character. – **\Z**: ASCII 26(Control Z). Specifies whether to escape the specified line terminator when LOAD DATA is used to import data. ● If **new_escape_string** is not set and the line terminator is specified as follows, it will be escaped to the corresponding control character: – **0x0A** or **\n**: newline character. – **0x0D0A** or **\r\n**: carriage return character and newline character. – **0x0D** or **\r**: carriage return character.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Configuration Item	Behavior
	– **0x09** or **\t**: horizontal tab character. – **0x0B** or **\v**: vertical tab character. – **0x0C** or **\f**: form feed character. • If the **new_escape_string** option is set, the specified line terminator is not escaped.

Configuration Item	Behavior
fixed_row_column_division	When LOAD DATA is used to import data, you can use this option to adjust the row and column splitting behavior of the source data file. The processing methods in the following scenarios are controlled by this option: ● When the end of a line in the source data file does not contain a line separator (**lines_terminated_by**) and the data in the last column of the last line starts with an enclosure character (**enclosed_by**): – If this option is not set, one byte will be lost during the import. – If this option is set, no data will be lost during the import. ● When the escape character is followed by a column delimiter (**fields_terminated_by**): – If this option is not set, the column delimiter will not be escaped to a common character. – If this option is set, the column delimiter will be escaped to a common character. ● When the escape character is followed by an enclosure: – If this option is not set, the enclosure will not be escaped to a common character. – If this option is set, the enclosure will be escaped to a common character. ● When the escape character is followed by an unspecified line separator: – If this option is not set, the line separator will not be escaped to a common character. – If this option is set, the line separator will be escaped to a common character. ● When no line separator is specified: – If this option is not set, the line separator is the first matched **'\r\n'**, **'\n'**, or **'\r'** in the file. – If this option is set, the line separator is **'\n'**. ● When the escape character and the enclosure are the same character: – If this option is not set, escape sequences such as **'\t'** and **'\n'** will be escaped. – If this option is set, escape sequences such as **'\t'** and **'\n'** will not be escaped. ● In M-compatible mode, when the **LOCAL** option is specified for remote transmission: – If this option is not set, the specified line starting character (**lines_starting_by**) will not take effect. If the source data

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Configuration Item	Behavior
	contains a whole line of the '\.' string, '\.' and the subsequent data will not be imported. – If this option is set, the specified line starting character will take effect. If the source data contains a whole line of the '\.' string, '\.' and the subsequent data will be imported.

Default value:

- For a newly installed database, the value is **"new_escape_string, fixed_row_column_division"**.
- For a database upgraded from an earlier version, if the earlier version does not support this GUC parameter, the default value is **"none"** after the upgrade. If the earlier version supports this GUC parameter, the default value is retained after the upgrade.

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after you fully understand the parameter meaning and test the parameter to avoid unexpected results.

modify_function_property_json

Parameter description: Specifies the properties of a system function in JSON format.

- **oid**: OID of the target system function. The value ranges from 0 to 10000.
- **compatibility**: database compatibility mode. The value can be **A**, **M**, or **OTHER**.
- **property_list**: function property list. Multiple properties can be configured.
  - **property_name**: property name. Currently, **proshippable** and **provolatile** are supported.
  - **property_value**: property value. The value must be within the value range of the corresponding property. The value range of **proshippable** is **t** and **f**, and the value range of **provolatile** is **i**, **s**, and **v**.

Parameter type: string

Unit: none

Value range: 0 to 50,000 characters for configuration file modification; 0 to 4,099 characters for gs_guc setting.

Default value:

- For a newly installed database:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

'[{"oid": 4162,"compatibility":"A", "property_list": [{"property_name": "provolatile", "property_value": "s"}]},
{"oid": 4163,"compatibility":"A", "property_list": [{"property_name": "provolatile", "property_value": "s"}]},
{"oid": 4186,"compatibility":"A", "property_list": [{"property_name": "provolatile", "property_value": "s"}]},
{"oid": 4187,"compatibility":"A", "property_list": [{"property_name": "provolatile", "property_value": "s"}]},
{"oid": 4905,"compatibility":"A", "property_list": [{"property_name": "provolatile", "property_value": "s"}]},
{"oid": 4906,"compatibility":"A", "property_list": [{"property_name": "provolatile", "property_value": "s"}]},
{"oid": 4907,"compatibility":"A", "property_list": [{"property_name": "provolatile", "property_value": "s"}]},
{"oid": 4908,"compatibility":"A", "property_list": [{"property_name": "provolatile", "property_value": "s"}]},
{"oid": 4909,"compatibility":"A", "property_list": [{"property_name": "provolatile", "property_value": "s"}]},
{"oid": 4910,"compatibility":"A", "property_list": [{"property_name": "provolatile", "property_value": "s"}]},
{"oid": 4911,"compatibility":"A", "property_list": [{"property_name": "provolatile", "property_value": "s"}]},
{"oid": 4912,"compatibility":"A", "property_list": [{"property_name": "provolatile", "property_value": "s"}]},
{"oid": 4913,"compatibility":"A", "property_list": [{"property_name": "provolatile", "property_value": "s"}]},
{"oid": 4914,"compatibility":"A", "property_list": [{"property_name": "provolatile", "property_value": "s"}]},
{"oid": 6286,"compatibility":"A", "property_list": [{"property_name": "provolatile", "property_value": "s"}]},
{"oid": 6287,"compatibility":"A", "property_list": [{"property_name": "provolatile", "property_value": "s"}]},
{"oid": 6288,"compatibility":"A", "property_list": [{"property_name": "provolatile", "property_value": "s"}]},
{"oid": 6289,"compatibility":"A", "property_list": [{"property_name": "provolatile", "property_value": "s"}]},
{"oid": 6307,"compatibility":"A", "property_list": [{"property_name": "provolatile", "property_value": "v"}]},
{"oid": 4079,"compatibility":"M", "property_list": [{"property_name": "provolatile", "property_value": "s"}]}]'.

- If the GUC parameter does not exist in the source version, the default value is "".
- If the GUC parameter exists in the source version, retain the original setting.

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Risks and impacts of improper settings: The attributes of system functions are affected.

NOTE

If the values of **modify_function_property** and **modify_function_property_json** conflict, the value of **modify_function_property** prevails.

illegal_character_strict_check

Parameter description: Specifies whether to enable the check for invalid characters.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: Invalid characters are checked. If the byte sequence of a character string cannot be completely parsed into valid characters based on the encoding rules (that is, the actual byte length is insufficient to form a complete character), the character string is considered invalid, and an error is reported.
- **off**: Invalid characters are not checked.

Default value:

- For a newly installed database: **on**.
- For a database upgraded from an earlier version that does not support this GUC parameter, the default value is **off** after the upgrade. If the earlier version supports this GUC parameter, the default value is retained after the upgrade.

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Do not set this parameter unless necessary.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

disable_unsupported_copy_load_options

Parameter description: Specifies the behavior of handling operations that may cause exceptions in the non-recommended syntax COPY/LOAD DATA during data import and export.

Parameter type: Boolean.

Value range:

- **on**: Operations that may cause exceptions in the non-recommended syntax are disabled.
- **off**: Operations that may cause exceptions in the non-recommended syntax are not disabled.

Default value:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- For a newly installed database: **on**.
- For a database upgraded from an earlier version that does not support this GUC parameter, the default value is **off** after the upgrade. If the earlier version supports this GUC parameter, the default value is retained after the upgrade.

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

6.3.16.3 Product Version of the Cloud Service

This section describes the version parameters of the cloud service.

product_version

Parameter description: Specifies the version of a cloud service product.

Parameter type: string.

Unit: none

Value range: none

Default value: ""

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: The following rules must be met to avoid errors.

- The value can contain a maximum of 50 characters.
- The value cannot contain vertical bars (|), semicolons (;), ampersands (&), dollar signs ($), ampersands (>), ampersands (<), ampersands (`), backslashes (\), exclamation marks (!), or newline characters.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

hotpatch_version

Parameter description: Specifies the hot patch version of a cloud service product.

Parameter type: string.

Unit: none

Value range: none

Default value: ""

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: The following rules must be met to avoid errors.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- The value can contain a maximum of 1500 characters.
- The value cannot contain vertical bars (|), semicolons (;), ampersands (&), dollar signs ($), ampersands (>), ampersands (<), ampersands (`), backslashes (\), exclamation marks (!), or newline characters.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

6.3.17 Fault Tolerance

This section describes parameters used for controlling how the server processes an error occurring in the database system.

exit_on_error

Parameter description: If this function is enabled, errors of the ERROR level will be escalated to PANIC errors, and core stacks will be generated. It is mainly used to locate problems and test services.

Parameter type: Boolean

Unit: none

Value range:

- **on**: Errors of the ERROR level will be escalated to PANIC errors.
- **off**: Errors of the ERROR level will not be escalated.

Default value: **off**

Setting method: This is a SUSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

restart_after_crash

Parameter description: If this parameter is enabled and a backend thread crashes, GaussDB automatically reinitializes the backend thread.

Parameter type: Boolean

Unit: none

Value range:

- **on**: GaussDB can automatically reinitialize a backend thread when the backend thread breaks down. In some circumstances (for example, when a management tool, such as xCAT, is used to manage GaussDB), setting this parameter to **on** maximizes the availability of the database.
- **off**: A management tool is enabled to obtain control permission and take proper measures when a backend thread crashes.

Default value: **on**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

omit_encoding_error

Parameter description: If this parameter is enabled and the client character set of the database is encoded in UTF-8 format, character encoding conversion errors will be recorded in logs. Additionally, converted characters that have conversion errors will be ignored and replaced by question marks (?).

Parameter type: Boolean

Unit: none

Value range:

- **on**: Characters that have conversion errors will be ignored and replaced by question marks (?), and error information will be recorded in logs.
- **off**: Characters that have conversion errors cannot be converted and error information will be directly displayed.

Default value: **off**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

NOTE

If this parameter is modified by running the **gs_guc reload** command and the connection of a session on the current node is not from the client but from another node in the cluster to which the node belongs, this parameter does not take effect immediately on the session after the **gs_guc reload** command is executed. The setting takes effect only after the connection node is disconnected and then reconnected.

cn_send_buffer_size

Parameter description: Specifies the size of the data buffer used for data transmission on CNs.

Parameter type: integer.

Unit: KB

Value range: 8–128

Default value: **8**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**. For example, if this parameter is set to **100** without a unit,

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

it indicates 100 KB. If this parameter is set to **128kB**, it indicates 128 KB. The unit must be KB if required.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

max_cn_temp_file_size

Parameter description: Specifies the maximum size of temporary files used by the CN when the SQL statement automatic retry function is enabled. The value **0** indicates that temporary files are not used.

Parameter type: integer.

Unit: KB

Value range: 0 to 10485760

Default value: 5242880 (that is, 5 GB)

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**. For example, if this parameter is set to **100** without a unit, it indicates 100 KB. If this parameter is set to **16MB**, it indicates 16 MB. The unit must be KB, MB, or GB if required.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

data_sync_retry

Parameter description: Specifies whether to keep running the database when updated data fails to be written into disks by using the fsync function. In some OSs, no error is reported even if **fsync** fails after the second attempt. As a result, data is lost.

Parameter type: Boolean

Unit: none

Value range:

- **on**: The retry mechanism is used to continue running the database after fsync fails to synchronize data to the disk.
- **off**: A PANIC-level error is reported and the database is stopped after fsync fails.

Default value: **off**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

remote_read_mode

Parameter description: Specifies whether to enable the remote read function. This function allows pages on the standby node to be read when reading pages on the primary node fails.

Parameter type: enumerated type

Unit: none

Value range: **off**, **non_authentication**, and **authentication**

- **off**: The remote read function is disabled.
- **non_authentication**: The remote read function is enabled but certificate authentication is not required.
- **authentication**: The remote read function is enabled and certificate authentication is required.

Default value: **authentication**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

6.3.18 Connection Pool Parameters

When a connection pool is used to access the database, database connections are established and then stored in the memory as objects during system running. When you need to access the database, no new connection is established. Instead, an existing idle connection is selected from the connection pool. After you finish accessing the database, the database does not disable the connection but puts it back into the connection pool. The connection can be used for the next access request.

pooler_port

Parameter description: Specifies the O&M management port of internal tools, such as cm_agent and cm_ctl. This port is used by the initial user or system administrator to connect to the database through the client.

Parameter type: integer.

Unit: none

Value range: 1 to 65535.

Default value: **5433** (The actual value is the specified value of the **port** GUC parameter plus 1.)

Setting method: This is a fixed INTERNAL parameter. It can be viewed but cannot be modified.

Setting suggestion: This parameter can only be viewed.

Risks and impacts of improper settings: none

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

pooler_maximum_idle_time

Parameter description: Specifies the maximum amount of time that the connections can remain idle in a pool before being removed. After that, the automatic connection clearing mechanism is triggered to reduce the number of connections on each node to the value of **minimum_pool_size**.

Parameter type: integer.

Unit: seconds

Value range: 0 to 2147483647

Default value: **600** (that is, 10 minutes)

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**. For example, if this parameter is set to **100** without a unit, it indicates 100s. If this parameter is set to **20min**, it indicates 20 minutes. If the unit is required, the value must be **s**, **min**, **h**, or **d**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If the value is too large, the frequency of clearing idle connections in the pooler connection pool decreases and the recycling rate decreases. If the value is too small, the frequency of clearing idle connections in the pooler connection pool increases. As a result, services frequently establish connections, affecting performance.

minimum_pool_size

Parameter description: Specifies the minimum number of remaining connections on the node corresponding to each pooler connection pool after automatic pooler connection cleanup. This parameter is used by the automatic pooler connection cleanup function.

Parameter type: integer.

Unit: none

Value range: 1 to 65535

Default value: **50**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If the value is too large, the number of clearing idle connections in the pooler connection pool decreases and the recycling rate decreases. If the value is too small, the number of clearing idle connections in the pooler connection pool increases. As a result, services frequently establish connections, affecting performance.

max_pool_size

Parameter description: Specifies the maximum number of connections between the connection pool and another CN/DN. You may need to adjust this parameter when the cluster scale changes, for example, when nodes are added or removed.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter type: integer

Unit: none

Value range: 0 to 65535. This parameter does not take effect on DNs and can be set to **0** only on DNs.

Default value:

- Independent deployment:

  CN: **32768** (128-core CPU/1024 GB memory, 60-core CPU/480 GB memory); **16384** (32-core CPU/256 GB memory); **8192** (16-core CPU/128 GB memory); **4096** (8-core CPU/64 GB memory); **2048** (4-core CPU/32 GB memory); **1000** (4-core CPU/16 GB memory)

  DN: **0**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Set this parameter based on the default value of different instance specifications. The value of this parameter must be greater than the value of **max_connections**. During the adjustment, the connections consumed by internal threads must be reserved.

Risks and impacts of improper settings: When the number of concurrent services is large, the connections from the CN to other CNs/DNs in the connection pool are consumed. If this parameter is set to a small value, an error is reported when the number of connections reaches the upper limit. As a result, services fail. When a CN is started, it allocates memory in advance based on the parameter value. Therefore, if the parameter value increases, the system consumes more memory resources. However, in general, the impact on the CN memory is small.

persistent_datanode_connections

Parameter description: Specifies whether to release the connection for the current session.

Parameter type: Boolean

Unit: none

Value range:

- **on** indicates that the connection for the current session will not be released.
- **off** indicates that the connection for the current session will be released.

Default value: **off**

Setting method: This is a BACKEND parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: After this parameter is enabled, a session may hold a connection but does not run a query. As a result, other queries cannot apply for a connection and an error is reported.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

max_coordinators

Parameter description: Specifies the maximum number of CNs in a cluster. This parameter may need to be modified when the cluster scale changes, for example, nodes are added or deleted. During scale-out, ensure that the value of this parameter is greater than the number of CNs in the target cluster. Otherwise, the scale-out will fail. If this parameter is set to a large value during scale-in, more memory resources are consumed when the CN is started. However, in general, the impact on the CN memory is small.

Parameter type: integer.

Unit: none

Value range: 2 to 1024

Default value: **128**

Setting method: This is a POSTMASTER parameter. You are advised not to modify it. If you need to modify it, set it based on instructions provided in **Table 6-1**.

Setting suggestion: Set this parameter based on the actual cluster specifications.

Risks and impacts of improper settings: If this parameter is set to a value less than the number of CNs in the cluster, node creation will fail. When a CN is started, it allocates memory in advance based on the parameter value. Therefore, if the parameter value increases, the system consumes more memory resources. However, in general, the impact on the CN memory is small.

max_datanodes

Parameter description: Specifies the maximum number of DNs in a cluster. This parameter may need to be modified when the cluster scale changes, for example, nodes are added or deleted. During scale-out, ensure that the value of this parameter is greater than the total number of DN shards in the target cluster. Otherwise, the scale-out will fail. If this parameter is set to a large value during scale-in, more memory resources are consumed when the CN is started. However, in general, the impact on the CN memory is small.

Parameter type: integer.

Unit: none

Value range: 2 to 65535

Default value: **256**

Setting method: This is a POSTMASTER parameter. You are advised not to modify it. If you need to modify it, set it based on instructions provided in **Table 6-1**.

Setting suggestion: Set this parameter based on the actual cluster specifications.

Risks and impacts of improper settings: If this parameter is set to a value less than the number of DNs in the cluster, node creation will fail. When a CN is started, it allocates memory in advance based on the parameter value. Therefore, if the parameter value increases, the system consumes more memory resources. However, in general, the impact on the CN memory is small.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

cache_connection

Parameter description: Specifies whether to recycle the connections of a connection pool.

Parameter type: Boolean

Unit: none

Value range:

- **on**: The connections of a connection pool will be recycled.
- **off**: The connections of a connection pool will not be recycled.

Default value: **on**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this parameter is disabled, the connections held by the session are cleared after the session execution statement ends. As a result, the service frequently establishes connections, affecting the performance. After this parameter is enabled in the multi-database scenario, if the memory size is small and the value of **max_connections** is large, the memory may be insufficient and DNs cannot be started.

enable_force_reuse_connections

Parameter description: Specifies whether a session forcibly reuses a new connection.

Parameter type: Boolean

Unit: none

Value range:

- **on** indicates that the new connection is forcibly used.
- **off** indicates that the current connection is used.

Default value: **off**

Setting method: This is a BACKEND parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: After this parameter is enabled, the **reset** parameter is forcibly sent to existing connections each time before a statement is executed, which affects the performance.

pooler_connect_max_loops

Parameter description: Specifies whether to enable the connection retries to enhance stability of setting up connections in switchover scenarios. If a service fails to connect to the primary node, it will retry by attempting to connect to the standby node. If the standby node is successfully promoted to primary, the retry

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

attempt will succeed. This parameter is used by the pooler connection retry function. This parameter specifies the total number of retry attempts. If this parameter is set to **0**, retry is disabled. The service only establishes a connection to the primary node.

Parameter type: integer.

Unit: none

Value range: 0 to 20

Default value: **1**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: This parameter is an HA parameter. If this parameter is set to **0**, the retry function is disabled, reducing the HA capability. If this parameter is set to a value greater than 1, the number of retries increases.

pooler_connect_interval_time

Parameter description: Specifies the interval between retries when **pooler_connect_max_loops** is set to a value greater than 1. This parameter is used by the pooler connection retry function. You are advised to set this parameter to a value slightly greater than the time required for switchover in the current cluster.

Parameter type: integer.

Unit: seconds

Value range: 0 to 7200

Default value: **15**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**. For example, if this parameter is set to **100** without a unit, it indicates 100s. If this parameter is set to **20min**, it indicates 20 minutes. If the unit is required, the value must be **s**, **min**, **h**, or **d**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: This parameter is an HA parameter. If this parameter is set to a large value, the retry period is prolonged and the HA capability is reduced.

pooler_timeout

Parameter description: Specifies the timeout interval of communication between each connection in a CN's connection pool and another CN/DN.

Parameter type: integer.

Unit: seconds

Value range: 0 to 7200

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Default value: **600** (that is, 10 minutes)

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**. For example, if this parameter is set to **100** without a unit, it indicates 100s. If this parameter is set to **20min**, it indicates 20 minutes. If the unit is required, the value must be **s**, **min**, **h**, or **d**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If the value is too small, an error is reported during data transmission and reception when the network fluctuates. If the value is too large, an error is reported during data transmission and reception when the network is disconnected. As a result, the HA capability is reduced.

pooler_connect_timeout

Parameter description: Specifies the timeout interval of connecting a CN's connection pool to another CN/DN in the same cluster.

Parameter type: integer.

Unit: seconds

Value range: 0 to 7200

Default value: **60** (1 minute)

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**. For example, if this parameter is set to **100** without a unit, it indicates 100s. If this parameter is set to **20min**, it indicates 20 minutes. If the unit is required, the value must be **s**, **min**, **h**, or **d**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If the value is too small, an error is reported during connection setup when the network fluctuates. If the value is too large, an error is reported during connection setup when the network is disconnected. As a result, the HA capability is reduced.

pooler_cancel_timeout

Parameter description: Specifies the timeout interval of canceling a connection by a CN's connection pool during error processing. If similar timeout occurs when an exception of the subtransaction or stored procedure is captured, the transaction containing the subtransaction or the stored procedure rolls back. If the source data from the COPY FROM operation is not consistent with that of the table definition in the target table, and the parameter value is not **0**, an error is reported.

Parameter type: integer.

Unit: seconds

Value range: 0 to 7200. **0** (not recommended) indicates that this function is disabled and no timeout limit is set.

Default value: **15**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**. For example, if this parameter is set to **100** without a unit, it

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

indicates 100s. If this parameter is set to **20min**, it indicates 20 minutes. If the unit is required, the value must be **s**, **min**, **h**, or **d**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If the value is too small, an error is reported for cancel actions when the network fluctuates. If the value is too large, an error is reported for cancel actions when the network is disconnected. As a result, the HA capability is reduced.

6.3.19 Cluster Transaction Parameters

This section describes the settings and value ranges of transaction parameters for the cluster.

transaction_isolation

Parameter description: Specifies the isolation level of the current transaction. For a new transaction that is started, the isolation level is fixed to the value of **default_transaction_isolation**.

Parameter type: string.

Unit: none

Value range: The value is a string of case-sensitive and space-sensitive characters. Only the following values are supported:

- **"serializable"**: Currently, GaussDB does not support this isolation level. Setting this isolation level has the same effect as **"repeatable read"**.
- **"read committed"**: Only data of committed transactions is read. Uncommitted data cannot be read.
- **"read uncommitted"**: The performance is the same as that of **"read committed"**.
- **"repeatable read"**: Only the data committed before a transaction starts is read. Uncommitted data or data committed in other concurrent transactions cannot be read.
- **"default"**: The value is the same as that of **default_transaction_isolation**.

Default value: **"default"**. If the default value of **default_transaction_isolation** is **"read committed"**, the output of the following command is **"read committed"**:

```
show transaction_isolation;
```

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

transaction_read_only

Parameter description: Specifies whether the current transaction is a read-only transaction.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter type: Boolean

Unit: none

Value range:

- **on**: The current transaction is a read-only transaction.
- **off**: The current transaction is a read/write transaction.

Default value: **off**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

autocommit

Parameter description: Specifies whether to enable the automatic commit mode. If this parameter is set to **on**, sessions will be committed automatically and each individual statement is implicitly committed. If this parameter is set to **off**, you must run COMMIT to commit a transaction or run ROLLBACK to cancel a transaction. If **autocommit** is changed from **off** to **on**, all unfinished transactions are automatically committed.

Parameter type: Boolean

Unit: none

Value range:

- **on**: The automatic commit mode is enabled.
- **off**: The automatic commit mode is disabled.

Default value: **on**

Setting method: This parameter is a USERSET parameter. You can set it based on instructions provided in **Table 6-1**. The gs_guc tool cannot be used to set this parameter.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this parameter is set to **off**, DDL or DCL statements executed in a transaction will not be automatically committed.

NOTE

- When **dbcompatibility** is set to **'M'**, this parameter can be set to **off**. Otherwise, this parameter is set to **on**.
- In GaussDB, this parameter cannot be queried in the pg_settings view. You can run the **SHOW autocommit;** command to view the value of this parameter.
- If the **autocommit** parameter is used, the internal automatic commit mode must be enabled. You can run **\echo :AUTOCOMMIT** to check whether the internal automatic commit mode is enabled. If the automatic commit mode is not used, run **\set AUTOCOMMIT on** to enable the automatic commit mode.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

xc_maintenance_mode

Parameter description: Specifies whether the system is in maintenance mode.

Parameter type: Boolean

Unit: none

Value range:

- **on**: The maintenance mode is used.
- **off**: The maintenance mode is not used.

NOTICE

Exercise caution when enabling this function. You need to avoid data inconsistencies in the cluster.

Default value: **off**

Setting method: This is a SUSET parameter. Set it based on method 3 provided in **Table 6-2**.

Setting suggestion: This parameter is used by maintenance personnel to locate faults. You are advised not to enable this parameter.

Risks and impacts of improper settings: Changing the value of this parameter may cause unexpected results in the cluster. Retain the default value.

allow_concurrent_tuple_update

Parameter description: Specifies whether to allow concurrent update.

Parameter type: Boolean

Unit: none

Value range:

- **on**: Concurrent updates are allowed.
- **off**: Concurrent updates are not allowed.

Default value: **on**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

gtm_host

Parameter description: Specifies the IP address of the primary GTM process. This parameter is visible only to the SYSADMIN user. The IP address can be an IPv4 or IPv6 address.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter type: string.

Unit: none

Value range: a string

Default value: IP address of the primary GTM.

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

gtm_port

Parameter description: Specifies the listening port of the primary GTM process. This parameter is visible only to the SYSADMIN user.

NOTE

This parameter is specified in the configuration file during installation. Do not modify this parameter unless absolutely necessary. Otherwise, database communication will be affected.

Parameter type: integer.

Unit: none

Value range: 1 to 65535

Default value: specified during installation.

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If the port number is changed, the database communication will be affected.

gtm_host1

Parameter description: Specifies the IP address of the standby GTM process. This parameter is visible only to the SYSADMIN user. The IP address can be an IPv4 or IPv6 address.

Parameter type: string.

Unit: none

Value range: a string

Default value: IP address of the standby GTM.

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

gtm_port1

Parameter description: Specifies the listening port of the standby GTM process. This parameter is visible only to the SYSADMIN user.

NOTE

This parameter is specified in the configuration file during installation. Do not modify this parameter unless absolutely necessary. Otherwise, database communication will be affected.

Parameter type: integer.

Unit: none

Value range: 1 to 65535

Default value: The value is specified during installation if the standby node 1 is deployed. Otherwise, the default value is **6665**.

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If the port number is changed, the database communication will be affected.

gtm_backup_barrier

Parameter description: Specifies whether to create a restoration point for the GTM starting point.

Parameter type: Boolean

Unit: none

Value range:

- **on**: A restoration point is created.
- **off**: No restoration point is created.

Default value: **off**

Setting method: This is a SUSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

gtm_conn_check_interval

Parameter description: Sets the intervals between two consecutive performed checks on the connections between local threads and the primary GTM for the CN.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter type: integer.

Unit: seconds

Value range: 0 to 2147483

Default value: **10**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

enable_show_any_tuples

Parameter description: This parameter is available only in a read-only transaction and is used for analysis. When this parameter is set to **on**, all versions of tuples in the table are displayed.

Parameter type: Boolean

Unit: none

Value range:

- **on**: All versions of tuples in the table are displayed.
- **off**: No versions of tuples in the table are displayed.

Default value: **off**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

NOTE

In the TOAST scenario, if DML operations (mainly INSERT+UPDATE or INSERT+DELETE) are performed before and after the REINDEX operation, and the read-only transaction is started and the GUC parameter is enabled after the REINDEX operation, historical data in the TOAST table or TOAST index table can be queried separately in the released version. However, when historical data in the TOAST column is queried in the main table, the error message "missing chunk number xxx" is displayed.

gtm_connect_timeout

Parameter description: Specifies the GTM connection timeout. If the connection time of the GTM exceeds its value, the connection times out and exits.

Parameter type: integer.

Unit: seconds

Value range: 1 to 2147483647

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Default value: **2**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

gtm_connect_retries

Parameter description: Specifies the number of GTM reconnection attempts.

Parameter type: integer.

Unit: none

Value range: 1 to 2147483647

Default value: **30**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

gtm_rw_timeout

Parameter description: Specifies the GTM response timeout. If the time spent waiting for GTM responses exceeds its value, the operation times out and exits.

Parameter type: integer.

Unit: seconds

Value range: 1 to 2147483647

Default value: **60** (1 minute)

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

enable_redistribute

Parameter description: Specifies whether unmatched nodes are redistributed.

Parameter type: Boolean

Unit: none

Value range:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **on** indicates that unmatched nodes are redistributed.
- **off** indicates that unmatched nodes are not redistributed.

Default value: **off**

Setting method: This is a SUSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

replication_type

Parameter description: Specifies whether the current database is deployed in standalone or one-primary-multiple-standby mode.

Parameter type: integer.

Unit: none

Value range: 0 to 3

- **0**: reserved parameter.
- **1**: one-primary-multiple-standby mode, covering all scenarios. This mode is recommended.
- **2**: single primary mode. In this mode, the standby node cannot be expanded.
- **3**: reserved parameter.

Default value: **1**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**. This parameter is used for CM deployment and cannot be set.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

pgxc_node_name

Parameter description: Specifies the name of a node.

When a standby node requests to replicate logs on the primary node, if the **application_name** parameter is not set, the **pgxc_node_name** parameter is used as the name of the streaming replication slot of the standby node on the primary node. The streaming replication slot is named in the following format: *Value of this parameter_IP address of the standby node_Port number of the standby node*. The IP address and port number of the standby node are obtained from the IP address and port number of the standby node specified by the **replconninfo** parameter. The maximum length of a streaming replication slot name is 61 characters. If the length of the concatenated string exceeds 61 characters, the truncated **pgxc_node_name** will be used for concatenation to ensure that the length of the streaming replication slot name is less than or equal to 61 characters.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter type: string.

Unit: none

Value range: a string

Default value: current node name.

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: After the modification, the cluster will fail to be connected.

enable_twophase_commit

Parameter description: Currently, the cloud database uses the GTM-free mode to solve the SDS replacement problem. To prevent unreliability caused by service abuse, the GUC parameter **enable_twophase_commit** is used to enable or disable distributed two-phase write transactions.

Parameter type: Boolean

Unit: none

Value range:

- **on** indicates that distributed two-phase commit is allowed in the GTM-free mode.
- **off** indicates that distributed two-phase commit is not allowed in the GTM-free mode.

Default value: **on**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

application_type

Parameter description: valid only when **enable_gtm_free** is set to **on**. This parameter specifies the service type of a user.

Parameter type: enumerated type.

Unit: none

Value range:

- **not_perfect_sharding_type** indicates a service across nodes. If this value is used, statements across nodes can be executed.
- **perfect_sharding_type** indicates a service on a single node. If an SQL statement requires multiple nodes, an error is reported and the corresponding

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

SQL statement is recorded in the system log. If this value is used, you can run the **/*+ multinode */ hint** command to allow SQL statements to be executed on multiple nodes. The multinode hint can be added after the select, insert, update, delete, and merge keywords.

Default value: **perfect_sharding_type**

Setting method: This parameter is a USERSET parameter and cannot be set using gs_guc. It can be set using either of the following methods:

- Use the **gsql** client to perform session-level configuration.
- When JDBC is used to connect to the database, set the **ApplicationType** parameter for the connection string.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

gtm_host2

Parameter description: Specifies the IP address of the GTM 2 if the standby GTM 2 is deployed. This parameter is visible only to the SYSADMIN user. The IP address can be an IPv4 or IPv6 address.

Parameter type: string.

Unit: none

Value range: a string

Default value: IP address of the GTM 2 if the GTM 2 is deployed. Otherwise, the value is **""**.

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

gtm_host3

Parameter description: Specifies the IP address of the GTM 3 if the standby GTM 3 is deployed. This parameter is visible only to the SYSADMIN user. The IP address can be an IPv4 or IPv6 address.

Parameter type: string.

Unit: none

Value range: a string

Default value: IP address of the GTM 3 if the GTM 3 is deployed. Otherwise, the value is **""**.

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

gtm_host4

Parameter description: Specifies the IP address of the GTM 4 if the standby GTM 4 is deployed. This parameter is visible only to the SYSADMIN user. The IP address can be an IPv4 or IPv6 address.

Parameter type: string.

Unit: none

Value range: a string

Default value: IP address of the GTM 4 if the GTM 4 is deployed. Otherwise, the value is **""**.

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

gtm_host5

Parameter description: Specifies the IP address of the GTM 5 if the standby GTM 5 is deployed. This parameter is visible only to the SYSADMIN user. The IP address can be an IPv4 or IPv6 address.

Parameter type: string.

Unit: none

Value range: a string

Default value: IP address of the GTM 5 if the GTM 5 is deployed. Otherwise, the value is **""**.

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

gtm_host6

Parameter description: Specifies the IP address of the GTM 6 if the standby GTM 6 is deployed. This parameter is visible only to the SYSADMIN user. The IP address can be an IPv4 or IPv6 address.

Parameter type: string.

Unit: none

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Value range: a string

Default value: IP address of the GTM 6 if the GTM 6 is deployed. Otherwise, the value is **""**.

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

gtm_host7

Parameter description: Specifies the IP address of the GTM 7 if the standby GTM 7 is deployed. This parameter is visible only to the SYSADMIN user. The IP address can be an IPv4 or IPv6 address.

Parameter type: string.

Unit: none

Value range: a string

Default value: IP address of the GTM 7 if the GTM 7 is deployed. Otherwise, the value is **""**.

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

gtm_port2

Parameter description: Specifies the listening port of the standby GTM 2 if the standby GTM 2 is deployed. This parameter is visible only to the SYSADMIN user.

Parameter type: integer.

Unit: none

Value range: 1 to 65535

Default value: The value is specified during installation if the GTM 2 is deployed. Otherwise, the value is **6666**.

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If the port number is changed, the database communication will be affected.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

gtm_port3

Parameter description: Specifies the listening port of the standby GTM 3 if the standby GTM 3 is deployed. This parameter is visible only to the SYSADMIN user.

Parameter type: integer.

Unit: none

Value range: 1 to 65535

Default value: The value is specified during installation if the GTM 3 is deployed. Otherwise, the value is **6666**.

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If the port number is changed, the database communication will be affected.

gtm_port4

Parameter description: Specifies the listening port of the standby GTM 4 if the standby GTM 4 is deployed. This parameter is visible only to the SYSADMIN user.

Parameter type: integer.

Unit: none

Value range: 1 to 65535

Default value: The value is specified during installation if the GTM 4 is deployed. Otherwise, the value is **6666**.

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If the port number is changed, the database communication will be affected.

gtm_port5

Parameter description: Specifies the listening port of the standby GTM 5 if the standby GTM 5 is deployed. This parameter is visible only to the SYSADMIN user.

Parameter type: integer.

Unit: none

Value range: 1 to 65535

Default value: The value is specified during installation if the GTM 5 is deployed. Otherwise, the value is **6666**.

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If the port number is changed, the database communication will be affected.

gtm_port6

Parameter description: Specifies the listening port of the standby GTM 6 if the standby GTM 6 is deployed. This parameter is visible only to the SYSADMIN user.

Parameter type: integer.

Unit: none

Value range: 1 to 65535

Default value: The value is specified during installation if the GTM 6 is deployed. Otherwise, the value is **6666**.

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If the port number is changed, the database communication will be affected.

gtm_port7

Parameter description: Specifies the listening port of the standby GTM 7 if the standby GTM 7 is deployed. This parameter is visible only to the SYSADMIN user.

Parameter type: integer.

Unit: none

Value range: 1 to 65535

Default value: The value is specified during installation if the GTM 7 is deployed. Otherwise, the value is **6666**.

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If the port number is changed, the database communication will be affected.

enable_defer_calculate_snapshot

Parameter description: Delays the calculation of **xmin** and **oldestxmin** of a snapshot. The calculation is triggered only after 1000 transactions are executed or the calculation interval is 1s.

Parameter type: Boolean

Unit: none

Value range:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **on** indicates that snapshots **xmin** and **oldestxmin** are calculated with a delay.
- **off** indicates that snapshots **xmin** and **oldestxmin** are calculated in real time.

Default value: **on**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this parameter is set to **on**, the snapshot calculation overhead can be reduced in high load scenarios. However, **oldestxmin** is updated slowly, affecting dead tuple collection. If this parameter is set to **off**, **xmin** and **oldestxmin** can be updated in real time, but the overhead for calculating snapshots increases.

seqscan_csn_cache_num

Parameter description: Specifies the size of the CSN cache. The cache is used only when the Seq Scan scans the heap table page through the MVCC snapshot to determine the visibility.

Parameter type: integer.

Unit: none

Value range: 0 to 1000. If this parameter is set to **0**, the CSN cache mechanism is not used.

Default value: **100**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

reject_gtm_address

Parameter description: Specifies the IP address of the GTM that is rejected for connection.

Parameter type: string.

Unit: none

Value range: The substrings are separated by commas (,). The format of each substring is *IP[:port]*.

NOTE

[:port] is optional.

Default value: **""**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Setting suggestion: This parameter is automatically set by the CM component in a specific process. Manual modification is not recommended.

Risks and impacts of improper settings: Improper settings may cause communication failures between the cluster and GTM, affecting cluster transactions.

verify_clog_csnlog_mode

Parameter description: Specifies the log level and alarm output for data correctness verification errors on the Clog and CSNlog pages.

Parameter type: enumerated type.

Unit: none

Value range:

- **off**: The error reporting and alarm output are disabled.
- **warning**: The warning-level error reporting and alarm output are enabled.
- **error**: The error-level error reporting and alarm output are enabled.
- **panic**: The panic-level error reporting and alarm output are enabled.

Default value:

- When a version that supports this function is installed, the default value is **warning**.
- When a version that does not support this parameter is upgraded to a version that supports this parameter, the default value is **off**. After the upgrade is complete, you need to manually set this parameter.

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Set this parameter based on the actual requirements. If this parameter is set to **error** or **panic**, services or even database running will be affected when the page is faulty.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

6.3.20 Dual-Cluster Replication Parameters

enable_slot_log

Parameter description: Specifies whether to enable primary/standby synchronization for replication slots. Only logical replication slots, archive slots, and backup slots are involved.

Parameter type: Boolean

Unit: none

Value range:

- **on**: Primary/standby synchronization is enabled for replication slots.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **off**: Primary/standby synchronization is disabled for replication slots.

Default value: **on**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Enable the function of creating archive/backup slots on the primary node and disable the function of creating archive/backup slots on the standby node.

Risks and impacts of improper settings: Functions (except replication and synchronization between the primary and standby nodes) such as backup, archiving, and building, will be affected.

RepOriginId

Parameter description: This is a session-level GUC parameter. In bidirectional logical replication, set it to a non-zero value to avoid infinite data replication.

Parameter type: integer.

Unit: none

Value range: 0 to 2147483647

Default value: **0**

Setting method: This is a USERSET parameter. Set it based on method 3 provided in **Table 6-2**.

Setting suggestion: In two-way logical replication scenarios, set this parameter to a non-zero value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

auto_csn_barrier

Parameter description: Specifies whether the barrier logging function is enabled for the primary cluster and GTM-lite cluster for streaming DR.

Parameter type: Boolean

Unit: none

Value range:

- **on**: enabled.
- **off**: disabled.

Default value: **off**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: This function is automatically enabled during the DR process. You are advised not to manually disable this function. To enable the read function of the standby node in the GTM-lite cluster, set this parameter to **on**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Risks and impacts of improper settings: If this function is disabled, the data read consistency between the standby cluster for the DR and the standby node of the GTM-lite cluster will be affected.

stream_cluster_run_mode

Parameter description: Specifies whether a CN or DN belongs to the primary or standby cluster in a dual-cluster streaming DR scenario.

Parameter type: enumerated type

Unit: none

Value range:

- **cluster_primary** indicates that the node is in the primary cluster.
- **cluster_standby** indicates that the node is in the standby cluster.

Default value: **cluster_primary**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: This parameter specifies the status of a standby cluster for DR. It is used in internal processes and can be read by users. You are advised not to modify this parameter.

Risks and impacts of improper settings: Manual modification will cause standby clusters to be abnormal.

hadr_process_type

Parameter description: Specifies a process ID of a streaming replication-based remote DR solution or intra-city dual-DC HA solution.

Parameter type: enumerated type

Unit: none

Value range:

- **none**: There is no process.
- **failover** indicates that a standby cluster for DR is promoted to primary.
- **switchover_promote** indicates that a standby cluster is promoted to primary during the cluster switchover.
- **switchover_demote** indicates that a primary cluster is demoted to a standby cluster during the cluster switchover.
- **dorado_failover** indicates that an OceanStor Dorado standby cluster is promoted to primary.
- **dorado_switchover_demote** indicates that a primary cluster is demoted to a standby cluster during the OceanStor Dorado cluster switchover.
- **dorado_failover_abnormal** indicates that a standby cluster is promoted to primary when a shared disk of the OceanStor Dorado primary cluster is faulty.
- **dorado_failover_in_standby_stream** indicates that an OceanStor Dorado standby cluster is upgraded to an OceanStor Dorado primary cluster (also the

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

remote DR-standby cluster) when the remote cluster in the streaming replication-based remote DR solution is the primary cluster.

- **dorado_failover_abnormal_in_standby_stream** indicates that the intra-city dual-DC HA solution supports streaming replication-based remote DR. In this solution, the remote cluster is the primary cluster for remote DR and the shared disk of the OceanStor Dorado primary cluster (also the standby cluster for remote DR) is faulty, the OceanStor Dorado standby cluster is switched to the OceanStor Dorado primary cluster (also the remote DR standby cluster).

Default value: **none**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: This parameter specifies the status of a standby cluster for DR. It is used in internal processes and can be read by users. You are advised not to modify this parameter.

Risks and impacts of improper settings: Manual modification will cause standby clusters to be abnormal.

cluster_name

Parameter description: Specifies the name of the current cluster.

NOTICE

cluster_name cannot be set to **"invalid_cluster_uuid"**.

Parameter type: string.

Unit: none

Value range: valid cluster name.

Default value: **""**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: This parameter is used in the DR process. The standby cluster for DR identifies the cluster based on this parameter. You are advised not to modify this parameter.

Risks and impacts of improper settings: The manual modification may cause DR function exceptions.

hadr_primary_cluster_name

Parameter description: Specifies the name of the cluster at the current physical log sender in the current DR.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTICE

If **hadr_primary_cluster_name** of the main standby cluster at the log receiver is set to **invalid_cluster_uuid**, log synchronization with the cluster at the log sender is not started, and the cluster at the log receiver remains disconnected.

Parameter type: string.

Unit: none

Value range: valid cluster name.

Default value: **""**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: This parameter identifies a cluster of the log receiver. It is used in DR processes and can be read by users. You are advised not to modify this parameter.

Risks and impacts of improper settings: The manual modification may cause DR function exceptions.

hadr_standby_cluster_num

Parameter description: Specifies the number of standby clusters for streaming DR.

NOTICE

- The **hadr_standby_cluster_num** parameter is invalid in the streaming replication-based remote DR solution (one primary cluster + one standby cluster).
- This parameter is invalid when **hadr_replconninfo_config_mode** is set to **cluster_manager**, that is, the DR link between the log sender cluster and the log receiver cluster is configured through cluster management.

Parameter type: integer.

Unit: none

Value range: 0 to 2147483647

Default value: **0**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: This parameter specifies the status of a standby cluster for DR. It is used in DR processes and can be read by users. You are advised not to modify this parameter.

Risks and impacts of improper settings: The manual modification may cause DR function exceptions.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

switchover_abort_timeout

Parameter description: Specifies the timeout threshold. If the time for the primary node to exit the thread exceeds the timeout threshold after the message interaction between the primary and standby nodes is complete, the process is terminated unexpectedly.

Parameter type: integer.

Unit: milliseconds

Value range: 0 to 2147483647. **0** indicates that the timeout abort function is not used.

Default value: **10000**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If the value is too small, the primary node may exit unexpectedly during the switchover.

6.3.21 Developer Options

allow_system_table_mods

Parameter description: Specifies whether the structure of a system catalog and the name of a system schema can be modified.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The structure of the system catalog or the name of the system schema can be modified.
- **off**: The structure of the system catalog or the name of the system schema cannot be modified.

Default value: **off**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: You are advised not to modify this parameter.

Risks and impacts of improper settings: If this parameter is enabled, system catalogs may be damaged or even the database cannot be started.

allow_create_sysobject

Parameter description: Specifies whether objects such as functions, stored procedures, and synonyms can be created or modified in the system schema. The system schema refers to the schema provided by the database after initialization, excluding the public schema. The OID of the system schema is usually smaller than 16384.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The initial user and system administrators can create or modify objects such as functions, stored procedures, and synonyms in the system schema. For details about whether other users are allowed to create these objects, see the permission requirements of the corresponding schema.
- **off**: All users are not allowed to create or modify objects such as functions, stored procedures, and synonyms in the system schema.

Default value: **off**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Set this parameter to **off** to improve system security. If you do not need to create or modify objects in the system schema, you are advised to set this parameter to **off**.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

NOTE

If the database is newly installed or the GUC parameter does not exist in the basic version to be upgraded, the default value is **off**. If the GUC parameter exists in the basic version to be upgraded, the original setting is retained.

debug_assertions

Parameter description: Specifies whether to enable various assertion checks. To use this parameter, the macro USE_ASSERT_CHECKING must be defined (through the configure option **--enable-cassert**) during the GaussDB compilation.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: Various assertion checks are enabled.
- **off**: Various assertion checks are disabled.

Default value: **off**

NOTE

If you compile GaussDB with the assertion check enabled, **debug_assertions** is set to **on** by default.

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: This function helps debugging. When an exception or breakdown occurs, enable this function to locate program errors.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

ignore_checksum_failure

Parameter description: Specifies whether to ignore data check errors.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: Data check errors are ignored.
- **off**: Data check errors are reported.

Default value: **off**

Setting method: This is a SUSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: You are advised not to modify this parameter.

Risks and impacts of improper settings: If this parameter is enabled, the system ignores the failure (but still generates an alarm). Continuing execution may result in breakdown, damaged data being transferred or stored, failure of data recovery from remote nodes, or other serious problems.

ignore_system_indexes

Parameter description: Specifies whether to ignore system indexes when reading system catalog (but still update the indexes when modifying the tables).

NOTE

This parameter is useful for recovering data from tables whose system indexes are damaged.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: System indexes are ignored.
- **off**: System indexes are not ignored.

Default value: **off**

Setting method: This is a BACKEND parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

ignore_invalid_pages

Parameter description: Specifies whether to trigger a PANIC error when an invalid page is detected at the end of replay.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: Invalid pages are ignored at the end of replay. When an invalid page is detected, no PANIC error is triggered and only WARNING logs are recorded.
- **off**: Invalid pages are not ignored at the end of replay. When an invalid page is detected, a PANIC error is triggered.

Default value: **off**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If a PANIC error occurs during page verification in the database and services need to be quickly restored, you can set this parameter to **on** to restore the services. However, this behavior may cause abnormal termination, data loss, and incorrect data synchronization to other standby nodes.

post_auth_delay

Parameter description: Specifies the delay in the connection to the server after a successful authentication. Developers can attach a debugger to the server startup process.

Parameter type: integer.

Unit: seconds

Value range: 0 to 2147

Default value: **0**, indicating no delay.

Setting method: This is a BACKEND parameter. Set it based on instructions provided in **Table 6-1**. For example, if the value is **60** without a unit, **post_auth_delay** indicates 60s. If the value is **1min**, **post_auth_delay** indicates 1 minute. The unit must be **s**, **min**, **h**, or **d** if required.

Setting suggestion: This parameter is used only for commissioning and fault locating. To prevent impact on service running, ensure that the default value **0** is used in the production environment.

Risks and impacts of improper settings: If this parameter is set to a non-zero value, the cluster status may be abnormal due to a long authentication delay.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

pre_auth_delay

Parameter description: Specifies the period of delaying authentication after the connection to the server is started. Developers can attach a debugger to the authentication procedure.

Parameter type: integer.

Unit: seconds

Value Range: 0 to 60

Default value: **0**, indicating no delay.

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**. For example, if the value is **60** without a unit, **pre_auth_delay** indicates 60s. If the value is **1min**, **pre_auth_delay** indicates 1 minute. The unit must be **s**, **min**, **h**, or **d** if required.

Setting suggestion: This parameter is used only for commissioning and fault locating. To prevent impact on service running, ensure that the default value **0** is used in the production environment.

Risks and impacts of improper settings: If this parameter is set to a non-zero value, the cluster status may be abnormal due to a long authentication delay.

trace_notify

Parameter description: Specifies whether to enable the function of generating debugging output for the **LISTEN** and **NOTIFY** commands. The level of **client_min_messages** or **log_min_messages** must be **DEBUG1** or lower so that such output can be recorded in the logs on the client or server separately.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The output function is enabled.
- **off**: The output function is disabled.

Default value: **off**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

trace_recovery_messages

Parameter description: Specifies whether to enable logging of recovery-related debugging output. If it is not enabled, no log is recorded This parameter allows users to overwrite the normal setting of **log_min_messages**, but only for specific messages. This is intended for the use in debugging the standby node.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter type: enumerated type.

Unit: none

Value range: **debug5**, **debug4**, **debug3**, **debug2**, **debug1**, and **log**. For details about the parameters, see **Table 6-23**.

Default value: **log**

NOTE

- **log** indicates that recovery-related debugging information will not be logged.
- Except the default value **log**, each of the other values indicates that recovery-related debugging information at the specified level will also be logged. Common settings of **log_min_messages** enable logs to be unconditionally recorded into server logs.

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: You are advised to change the value of this parameter only when commissioning the standby node. In other cases, you are advised to use the default value.

Risks and impacts of improper settings: If this parameter is set to a value other than **log**, a large number of logs will be printed, occupying certain I/O resources.

trace_sort

Parameter description: Specifies whether to print information about resource usage during sorting operations. This option can be used only when the **TRACE_SORT** macro is defined during GaussDB compilation. Currently, **TRACE_SORT** can only be set to the default value and cannot be adjusted.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: Information about resource usage in sorting operations is printed.
- **off**: Information about resource usage in sorting operations is not printed.

Default value: **off**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

zero_damaged_pages

Parameter description: Specifies whether to terminate the current transaction after a damaged page header that causes GaussDB to report an error is detected.

Parameter type: Boolean.

Unit: none

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Value range:

- **on**: The system generates a warning instead of throwing an error, clears the damaged page, and continues processing. This behavior will destroy data, including all the rows on the damaged page. However, it allows you to bypass the error and retrieve rows from any undamaged pages that may be present in the table. Therefore, it is useful for restoring data if corruption has occurred due to a hardware or software error.
- **off**: The system does not fill zeros in damaged pages.

Default value: **off**

Setting method: This is a SUSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: In most cases, you are advised not to set it to **on** if you want to restore data from damaged pages.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

string_hash_compatible

Parameter description: Specifies whether to use the same method to calculate char-type hash values and varchar- or text-type hash values. Based on the setting of this parameter, you can determine whether a redistribution is required when a distribution key is converted from a char-type data distribution into a varchar- or text-type data distribution.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The same calculation method is used and a redistribution is not required.
- **off**: Different calculation methods are used and a redistribution is required.

NOTE

Calculation methods differ in the length of input strings used for calculating hash values. (For a char-type hash value, spaces following a string are not counted as the length. For a text- or varchar-type hash value, the spaces are counted.) The hash value affects the calculation result of queries. To avoid query errors, do not modify this parameter during database running once it is set.

Default value: **off**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

remotetype

Parameter description: Specifies the remote connection type.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter type: enumerated type.

Unit: none

Value range: **application**, **coordinator**, **datanode**, **gtm**, **gtmproxy**, **internaltool**, and **gtmtool**

Default value: **application**

Setting method: This is a BACKEND parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

max_user_defined_exception

Parameter description: Specifies the maximum number of exceptions. The default value cannot be changed.

Parameter type: integer.

Unit: none

Value range: Currently, only the fixed value **1000** is supported.

Default value: **1000**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: This parameter can only be viewed.

Risks and impacts of improper settings: none

enable_fast_numeric

Parameter description: Specifies whether to enable optimization for numeric data calculation. Calculation of numeric data is time-consuming. Numeric data is converted into int64- or int128-type data to improve numeric data calculation performance.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: Optimization for numeric data calculation is enabled.
- **off**: Optimization for numeric data calculation is disabled.

Default value: **on**

Setting method: This is a SUSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Risks and impacts of improper settings: If this parameter is disabled, the performance of query statements of the numeric type may deteriorate.

enable_numeric_optimization

Parameter description: Specifies whether to enable optimization for numeric data calculation.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: enables NUMERIC data type optimization in the vectorized engine.
- **off**: disables NUMERIC data type optimization in the vectorized engine.

Default value: **off**

Setting method: This is a fixed INTERNAL parameter. It can be viewed but cannot be modified.

Setting suggestion: This parameter can only be viewed.

Risks and impacts of improper settings: none

NOTE

The current version does not support this optimization. Currently, only the default value of **enable_numeric_optimization** can be viewed.

enable_fast_vecop

Parameter description: Specifies whether to enable vectorized calculation optimization. The calculation of the Timestamp, int32, int64, and float8 types in the vectorization engine is optimized, the calling cost is reduced, and automatic vectorization calculation is supported.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The vectorized operation optimization is enabled.
- **off**: The vectorized operation optimization is disabled.

Default value: **on**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this parameter is disabled, the calculation performance of the Timestamp, int32, int64, and float8 types in the vectorization engine will be affected.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

enable_compress_spill

Parameter description: Specifies whether to enable the compression function of writing data to disk.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The compression function is enabled.
- **off**: The compression function is disabled.

Default value: **on**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

resource_track_log

Parameter description: Specifies the log level of self-diagnosis. Currently, this parameter takes effect only on multi-column statistics.

Parameter type: enumerated type.

Unit: none

Value range:

- **summary**: Brief diagnosis information is displayed.
- **detail**: Detailed diagnosis information is displayed.

Currently, the two parameter values differ only when there is an alarm about multi-column statistics not collected. If the parameter is set to **summary**, such an alarm will not be displayed. If it is set to **detail**, such an alarm will be displayed.

Default value: **summary**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

enable_parallel_ddl

Parameter description: Specifies whether multiple CNs can concurrently perform DDL operations on the same database object.

Parameter type: Boolean.

Unit: none

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Value range:

- **on**: DDL operations can be concurrently performed without distributed deadlocks.
- **off**: DDL operations cannot be concurrently performed as distributed deadlocks may occur.

Default value: **on**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

support_batch_bind

Parameter description: Specifies whether to batch bind and execute PBE statements through APIs such as JDBC, ODBC, and libpq.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: Batch binding and execution are used.
- **off**: Batch binding and execution are not used.

Default value: **on**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

numa_distribute_mode

Parameter description: Specifies the distribution of some shared data and threads among NUMA nodes. This parameter is used to optimize the performance of large-scale Arm servers with multiple NUMA nodes. Generally, you do not need to set this parameter.

Parameter type: string.

Unit: none

Value range: **"none"** and **"all"**.

- **"none"**: This feature is disabled.
- **"all"**: Some shared data and threads are distributed to different NUMA nodes to reduce the number of remote access times and improve performance. Currently, this function applies only to Arm servers with multiple NUMA

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

nodes. All NUMA nodes must be available for database processes. You cannot select only some NUMA nodes.

NOTE

- In the current version, **numa_distribute_mode** cannot be set to **"all"** on the x86 platform.
- If this parameter is enabled and CPU scaling is performed, you need to run the **gs_cgroup -u -T Gaussdb -f New CPU core range** command to update the Cgroup core binding information. Ensure that the range of available cores in the Cgroup is the same as the range of available CPU cores after scaling. Otherwise, the cluster fails to be started.

Default value: **"none"**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

log_pagewriter

Parameter description: Specifies whether to display the page refresh information of threads and details about incremental checkpoints after incremental checkpoints are enabled.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: Detailed information is displayed.
- **off**: Detailed information is not displayed.

Default value: **off**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: You are advised not to set this parameter to **on**.

Risks and impacts of improper settings: If this parameter is set to **on**, more information will be displayed, affecting performance.

advance_xlog_file_num

Parameter description: Specifies the number of Xlog files that are periodically initialized in advance in the backend.

Parameter type: integer.

Unit: none

Value range: 0 to 1000000. The value **0** indicates that initialization is not performed in advance. For example, the value **10** indicates that the background

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

thread periodically initializes 10 Xlog files in advance based on the write location of the current Xlog.

Default value: **0**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Use this parameter to prevent the Xlog file initialization from affecting the performance during transaction commit. However, such a fault may occur only when the system is overloaded. Therefore, you do not need to set this parameter.

Risks and impacts of improper settings: If the value is too large, too much disk space is occupied. As a result, the disk usage is abnormal. Therefore, you need to consider the actual disk size when adjusting this parameter. The disk space occupied by this parameter can be calculated using the following formula: **advance_xlog_file_num** x **wal_segment_size** (16 MB). It is recommended that the pre-allocated space be less than or equal to 10% of the available space. If the value is too large, the cluster may be unavailable and cannot be restored.

comm_sender_buffer_size

Parameter description: Specifies the size of the buffer for each interaction between CNs and DNs and between DNs in the stream plan. In some cases, different values affect the stream performance. After the value is set, the cluster needs to be restarted for the reset to take effect.

Parameter type: integer.

Unit: KB

Value range: 1 to 1024

Default value: **8**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**. The value cannot contain a unit.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If the value is too small, data is frequently transmitted and received, the delay is short, but the throughput is low. If the value is too large, the throughput increases but the delay increases.

ustore_attr

Parameter description: This parameter is used to control the information statistics of Ustore tables, rollback type, UB-tree index type, and data verification during the running of key modules (including data, indexes, rollback segments, and replay). This parameter helps R&D engineers locate faults.

Parameter type: string.

Unit: none

Value range: This parameter is set in key-value mode. The mapping between keys and values is as follows: If multiple key-value pairs are used, use semicolons (;) to

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

separate them. For example, **ustore_attr='ustore_verify_level=FAST;ustore_verify_module=UPAGE:UBTREE:UNDO:REDO'**.

- **ustore_verify_level**: verification level.

  Value range: a string of case-insensitive characters. For details, see the following table.

  Table 6-48 Parameter value meaning of ustore_verify_level

Parameter Value	Description
NONE	**NONE** indicates that the verification function is disabled. You are advised to enable this function to test performance.
FAST	**FAST** indicates fast verification. The verification content is small and the impact on performance is minimized.
COMPLETE	**COMPLETE** indicates complete verification. The verification content is the largest and the performance is greatly affected.
NORMAL	This level has the same function as the **FAST** level and is reserved only for compatibility with earlier versions. The **FAST** level is recommended.
SLOW	This level has the same function as the **COMPLETE** level and is reserved only for compatibility with earlier versions. The **COMPLETE** level is recommended.

  Default value: **FAST**

- **ustore_verify_module**: module that controls verification.

  Value range: The value can be one or more of **UPAGE**, **UBTREE**, **UNDO**, **REDO**, and **ROACH**, or it can be **ALL** or **NULL** (case-insensitive). When multiple values of **UPAGE**, **UBTREE**, **UNDO**, **REDO**, and **ROACH** are used, separate them with colons (:). For example, **ustore_verify_module=UPAGE:UBTREE:UNDO:REDO**.

  Table 6-49 Parameter value meaning of ustore_verify_module

Parameter Value	Description
UPAGE	Indicates that data page verification is enabled.
UBTREE	Indicates that UB-tree index verification is enabled.
UNDO	Indicates that rollback segment data verification is enabled.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter Value	Description
REDO	Indicates that data page verification for the REDO process is enabled.
ROACH	This parameter is invalid in the current version. The verification has been removed from the underlying logic. Although **ustore_verify_module** can be set to **roach**, the setting does not take effect.
ALL	Indicates that data verification is enabled for the UPAGE, UBTREE, UNDO, REDO, and ROACH modules.
NULL	Indicates that data verification for the UPAGE, UBTREE, UNDO, REDO, and ROACH modules is disabled.

Default value: **UPAGE:UBTREE:UNDO**

- **index_trace_level**: specifies whether to enable index tracing and controls the printing level. After this function is enabled, information about index tuples that meet the conditions is printed based on the printing level during index scan.

  Value range: The values are described in the following table.

  Default value: **NO**

  Table 6-50 Parameter value meaning of index_trace_level

Parameter Value	Description
NO	No additional information is printed.
NORMAL	Information about visible index tuples is printed, including: ● ID and offset of the index page where the current index tuple is located ● Current tuple status ● TID and partOid corresponding to the current tuple ● xmin and xmax information corresponding to the current tuple ● Current tuple content (if **enable_log_tuple** is set to **on**).
VISIBILITY	On the basis of **NORMAL**, the information about the index tuples that do not pass the visibility check is printed and whether the index tuples are visible is marked.
SHOWHIKEY	On the basis of **VISIBILITY**, the system tries to print the information about the HIKEY tuple on the page.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter Value	Description
ALL	Information about all tuples on the scanned index page is printed.

- **enable_log_tuple**: specifies whether to print the contents of related tuples when printing log-level prompts for troubleshooting and locating.

  Value range: **on** or **off** (case-insensitive)

  Default value: **off**
- **enable_ustore_sync_rollback**: specifies whether to enable synchronous rollback for Ustore tables.

  Value range: Boolean

  Default value: **true**
- **enable_ustore_async_rollback**: specifies whether to enable asynchronous rollback for Ustore tables.

  Value range: Boolean

  Default value: **true**
- **enable_ustore_page_rollback**: specifies whether to enable page rollback for Ustore tables.

  Value range: Boolean

  Default value: **true**
- **enable_ustore_partial_seqscan**: specifies whether to enable partial scan for Ustore tables.

  Value range: Boolean

  Default value: **false**
- **enable_candidate_buf_usage_count**: specifies whether to enable buffer usage statistics.

  Value range: Boolean

  Default value: **false**
- **ustats_tracker_naptime**: specifies the interval for collecting statistics on Ustore tables.

  Value range: 1 to 1073741

  Default value: **20**, in seconds.
- **umax_search_length_for_prune**: specifies the maximum search depth of the prune operation on the Ustore table.

  Value range: 1 to 1073741

  Default value: **10**
- **ustore_td_reservation_timeout**: specifies the maximum timeout interval for a DML statement to wait for TD on the Ustore table page.

  Value range: 0 to 120000

  Default value: **60000**, in milliseconds.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- When setting **ustore_attr**, do not leave spaces or other characters before and after the equal sign (=) between key and value, for example, **ustore_attr='ustore_verify_level = FAST;'**. Otherwise, the parameter is invalid during kernel code verification and the parameter setting fails.
- The online verification function is enabled by default. To disable the online verification function, set **ustore_attr** to **""**.

Default value:
"ustore_verify_level=FAST;ustore_verify_module=UPAGE:UBTREE:UNDO"

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Exercise caution when setting the **ustore_attr** parameter. You are advised to modify it with the assistance of engineers.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

index_txntype

Parameter description: Determines whether the index type of UB-tree is PCR or RCR. PCR supports flashback query based on indexes, but RCR does not. An empty string is equivalent to RCR in most scenarios. In the reindex scenario, the new index keeps the original index type, which is not affected by this parameter.

Parameter type: string.

Unit: none

Value range: **""**, **"PCR"**, or **"RCR"**

Default value: **""**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: If the PCR index is required, set this parameter to **"PCR"**. Otherwise, you are advised not to change the value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

default_index_kind

Parameter description: Specifies the default behavior of creating indexes for partitioned tables.

Parameter type: integer.

Unit: none

Value range: 0 to 2

- **0**: The global partitioned index function is disabled for distributed deployment.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **1**: A local index is created by default.
- **2**: A global index is created by default.

Default value: **2**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this parameter is set to **0**, global partitioned indexes cannot be created.

enable_auto_segment_remain_cleanup

Parameter description: Specifies whether to enable automatic clearing of residual segment-page data.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: Residual segment-page data is automatically cleared.
- **off**: Residual segment-page data is not automatically cleared.

Default value: **on**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Do not switch the clearing mode randomly. Otherwise, residual segment-page data may fail to be cleared or other exceptions may occur.

enable_stream_noblock_memcopy

Parameter description: Specifies whether to enable memory copy optimization for the stream operator in the vectorized engine. If this parameter is enabled, data of the local stream operator in the vectorized engine is sent in non-waiting mode, improving the execution efficiency of the local stream operator.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: Memory copy optimization is enabled for the stream operator.
- **off**: Memory copy optimization is disabled for the stream operator.

Default value: **on**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Risks and impacts of improper settings: If this parameter is set to **off**, the execution efficiency of the local stream operator may decrease.

enable_remove_redundant_update_col

Parameter description: Specifies whether to optimize the pseudo-update of distribution keys. For details about this parameter, see **Pseudo-update of Distribution Keys**.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The pseudo-update of distribution keys is optimized.
- **off**: The pseudo-update of distribution keys is not optimized.

Default value: **off**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Set this parameter based on service requirements.

Risks and impacts of improper settings: If this parameter is set to **on**, the pseudo-update of distribution keys is optimized. As a result, the performance deteriorates slightly in real update scenarios. Set this parameter to **off** if it is not used.

convert_illegal_char_mode

Parameter description: Specifies the placeholders of invalid characters that can be displayed on the client when the **enable_convert_illegal_char** parameter is enabled.

Parameter type: string.

Unit: none

Value range: 95 characters whose decimal codes range from 32 to 126 in the ASCII coding table.

Default value: **"?"**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

default_segment

Parameter description: Specifies whether to create a segment-page table by default.

Parameter type: Boolean.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Unit: none

Value range:

- **on**: A segment-page table is created by default when the segment field is not specified.
- **off**: A page table is created by default when the segment field is not specified.

Default value: **off**

Setting method: This is a SUSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

pldebugger_timeout

Parameter description: Specifies the timeout interval for the pldebugger server to wait for a response from the debug end.

Parameter type: integer.

Unit: seconds

Value range: 1 to 86400

Default value: **900** (that is, 15 minutes)

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**. For example, if the value is **3600** without a unit, **pldebugger_timeout** indicates 3600s. If the value is **1h**, **pldebugger_timeout** indicates 1 hour. The unit must be **s**, **min**, **h**, or **d** if required.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

6.3.22 Auditing

6.3.22.1 Audit Switch

audit_enabled

Parameter description: Specifies whether to enable the traditional audit.

Parameter type: Boolean.

Unit: none

Value range:

- **on** indicates that the auditing function is enabled.
- **off** indicates that the auditing function is disabled.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Default value: **on**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Enabling the audit function affects the database performance. The impact depends on the audit recording frequency. If this parameter is set to **on**, set other audit items based on service and tracing requirements. If this parameter is set to **off**, historical operations cannot be traced using audit logs. To ensure system stability, do not disable the audit function during frequent audit operations.

audit_directory

Parameter description: Specifies the storage directory of audit files. The path can be relative to the **data** directory or an absolute path. Only the SYSADMIN user can access this parameter.

Parameter type: string.

Unit: none

Value range: valid target path.

Default value: **"pg_audit"**. If **om** is used for cluster deployment, audit logs are stored in *$GAUSSLOG*/**pg_audit/***Instance name*.

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If the value is an invalid path or a path whose space is full, the audit function cannot be used. Different directories for storing audit files must be set for different CNs or DNs. Otherwise, audit logs will be abnormal.

NOTE

- Valid path: Users have read and write permissions on the path.
- Invalid path: Users do not have read or write permission on the path.

audit_data_format

Parameter description: Audits the format of log files. Currently, only the binary or TXT format is supported. Only the SYSADMIN user can access this parameter.

Parameter type: string.

Unit: none

Value range:

- **BIN**: binary format.
- **text**: TEXT format.

Default value: **"binary"**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Currently, only the binary or TEXT format is supported. If the format is invalid, the default value is used.

audit_rotation_interval

Parameter description: Specifies the interval of creating an audit log file. When the difference between the current time and the time when the last audit log is created exceeds the value of this parameter, the server generates a new audit log file. A random delay is introduced to the performance interval.

Parameter type: integer.

Unit: minute

Value range: 1 to 35791394 (*INT_MAX*/60)

Default value: 1d (that is, 1440 minutes)

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**. For example, if the value is **1440** without a unit, **audit_rotation_interval** indicates 1440 minutes. If the value is **2d**, **audit_rotation_interval** indicates 2 days, that is, 2880 minutes. The unit must be **min**, **h**, or **d** if required.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If the value is too small, there will be too many files in the audit directory. If the value is too large, a single audit file will be too large. Do not adjust this parameter unless necessary. Otherwise, **audit_resource_policy** may not take effect. To control the storage space and time of audit logs, use parameters such as **audit_resource_policy**, **audit_space_limit**, and **audit_file_remain_time**.

audit_rotation_size

Parameter description: Specifies the maximum size of an audit log file (the actual file size may exceed the upper limit by 1 MB to 10 MB). If the total number of messages in an audit log exceeds the value of this parameter, the server will generate a new audit log file.

Parameter type: integer.

Unit: KB

Value range: 1024 to 1048576

Default value: **10MB** (that is, 10240 KB)

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**. For example, if the value is **131072** without a unit, **audit_rotation_size** indicates 131072 KB. If the value is **128MB**, **audit_rotation_size** indicates 128 MB. The unit must be KB, MB, or GB if required.

Setting suggestion: Retain the default value.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Risks and impacts of improper settings: If the value is too small, there will be too many files in the audit directory. If the value is too large, a single audit file will be too large. Do not adjust this parameter unless necessary. Otherwise, **audit_resource_policy** may not take effect. To control the storage space and time of audit logs, use parameters such as **audit_resource_policy**, **audit_space_limit**, and **audit_file_remain_time**. If the space occupied by a single record in an audit log file exceeds the value of this parameter, the log file is regarded as an invalid log file.

audit_resource_policy

Parameter description: Specifies the policy for determining whether audit logs are preferentially stored by space or time.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The space-first policy is used, with the maximum storage space set by **audit_space_limit**.
- **off**: The time-first policy is used, with the minimum storage duration set by **audit_file_remain_time**.

Default value: **on**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: When the space-first policy is selected, do not adjust the GUC parameters related to the time policy: **audit_rotation_interval** and **audit_file_remain_time**. When the time-first policy is selected, do not adjust the GUC parameters related to the space policy: **audit_rotation_size**, **audit_space_limit**, and **audit_file_remain_threshold**.

Risks and impacts of improper settings: This parameter must be used together with other GUC parameters related to the corresponding policy. If this parameter is set to an improper value, the audit log storage policy does not meet expectations.

audit_file_remain_time

Parameter description: Specifies the minimum duration required for recording audit logs. This parameter is valid only when **audit_resource_policy** is set to **off**.

Parameter type: integer.

Unit: days (d)

Value range: 0 to 730. The value **0** indicates no time limit.

Default value: **90**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**. The value cannot contain a unit.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Setting suggestion: Set this parameter according to the actual situation. If **audit_resource_policy** is set to **on**, do not change the value of this parameter.

Risks and impacts of improper settings: This parameter takes effect only when **audit_resource_policy** is set to **off**. If the value is too small, only a small number of audit logs are retained and the audit tracing duration is shortened. If the value is too large, too many audit logs are stored in the audit directory, affecting the audit query and deletion performance and occupying disk space.

audit_space_limit

Parameter description: Specifies the total disk space occupied by audit files.

Parameter type: integer.

Unit: KB

Value range: 1024 to 1073741824 (1024 GB)

Default value: **1GB** (that is, 1048576 KB)

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**. For example, if the value is **131072** without a unit, **audit_space_limit** indicates 131072 KB. If the value is **128MB**, **audit_space_limit** indicates 128 MB. The unit must be KB, MB, or GB if required.

Setting suggestion: Set this parameter based on the actual available space of the instance and the number of audit logs to be saved.

Risks and impacts of improper settings: This parameter takes effect only when **audit_resource_policy** is set to **on**. If the value is too small, only a small number of audit logs are retained and the audit tracing duration is shortened. If the value is too large, too many audit logs are stored in the audit directory, affecting the audit query and deletion performance and occupying disk space.

NOTE

- This parameter takes effect only for a single process instance folder in the **pg_audit** directory. By default, the total disk space occupied by audit files on each CN or DN is 1 GB.
- In the multi-audit thread scenario, the minimum disk space occupied by audit files is the product of values of **audit_thread_num** and **audit_rotation_size**. Ensure that the value of **audit_space_limit** is greater than the product of values of **audit_thread_num** and **audit_rotation_size**.

audit_file_remain_threshold

Parameter description: Specifies the maximum number of audit files in the audit directory.

Parameter type: integer.

Unit: none

Value range: 100 to 1048576

Default value: **1048576**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value and do not modify this parameter unless necessary. To control the storage space and time of audit logs, use the **audit_resource_policy**, **audit_space_limit**, and **audit_file_remain_time** parameters.

Risks and impacts of improper settings: If this parameter is set improperly, **audit_resource_policy** may not take effect.

audit_thread_num

Parameter description: Specifies the number of threads used for auditing.

Parameter type: integer.

Unit: none

Value range: 1 to 48

Default value: **1**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: When **audit_dml_state** is enabled and high performance is required, you are advised to set this parameter to a larger value to ensure that audit messages can be processed and recorded in a timely manner. In other cases, you are advised to retain the default value.

Risks and impacts of improper settings: A larger number of threads indicates a greater impact on system performance and more CPU and I/O resources are occupied.

6.3.22.2 User and Permission Audit

audit_login_logout

Parameter description: Specifies whether to audit a user's login (including login success and failure) and logout.

Parameter type: integer.

Unit: none

Value range: 0 to 7

- **0**: The function of auditing users' logins and logouts is disabled.
- **1**: Only successful user logins are audited.
- **2**: Only failed user logins are audited.
- **3**: Only successful and failed user logins are audited.
- **4**: Only user logouts are audited.
- **5**: Only user logouts and successful logins are audited.
- **6**: Only user logouts and failed logins are audited.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **7**: Successful user logins, failed user logins, and logouts are audited.

Default value: **7**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: A smaller value indicates fewer types of user login and logout behaviors to be audited and higher risks of untraceable user login and logout behaviors. A larger value indicates more types of user login and logout behaviors to be recorded. When a large number of user login and logout behaviors exist, the database performance is affected.

audit_database_process

Parameter description: Specifies whether to audit the database startup, stop, switchover, and recovery.

Parameter type: integer.

Unit: none

Value range: **0** and **1**

- **0**: The function of auditing database startup, stop, switchover, and recovery is disabled.
- **1**: The function of auditing database startup, stop, switchover, and recovery is enabled.

Default value: **1**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this parameter is set to **0**, database startup, stop, switchover, and recovery may fail to be traced.

audit_user_locked

Parameter description: Specifies whether to audit the users' locking and unlocking.

Parameter type: integer.

Unit: none

Value range: **0** and **1**

- **0**: The function of auditing user's locking and unlocking is disabled.
- **1**: The function of auditing user's locking and unlocking is enabled.

Default value: **1**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this parameter is set to **0**, user locking and unlocking behaviors may not be traced.

audit_user_violation

Parameter description: Specifies whether to audit the access violation operations of a user.

Parameter type: integer.

Unit: none

Value range: **0** and **1**

- **0**: The function of auditing the access violation operations of a user is disabled.
- **1**: The function of auditing the access violation operations of a user is enabled.

Default value: **1**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Set this parameter to **1** if unauthorized operations need to be audited.

Risks and impacts of improper settings: If this parameter is set to **0**, unauthorized audit operations may fail to be traced. If this parameter is set to **1**, a large number of unauthorized operations may affect database performance.

audit_grant_revoke

Parameter description: Specifies whether to audit the granting and revoking of user permissions.

Parameter type: integer.

Unit: none

Value range: **0** and **1**

- **0**: The function of auditing user permission granting and revoking operations is disabled.
- **1**: The function of auditing user permission granting and revoking operations is enabled.

Default value: **1**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this parameter is set to **0**, user permission granting and revoking behaviors may not be traced. If this parameter is

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

set to **1**, the database performance will be affected when a large number of permissions are granted and revoked.

audit_security_label

Parameter description: Specifies whether to audit the creation, deletion, and application of user security labels.

Parameter type: integer.

Unit: none

Value range: **0** or **1**

- **0**: The creation, deletion, and application of user security labels are not audited.
- **1**: The creation, deletion, and application of user security labels are audited.

Default value: **0**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this parameter is set to **0**, the creation, deletion, and application of user security labels cannot be traced. If this parameter is set to **1**, the database performance will be affected when a large number of user security labels are created, deleted, and applied.

audit_internal_event

Parameter description: Specifies whether to audit the connections and operations of internal tools cm_agent, gs_clean, and WDRXdb, and whether to audit the connections from CNs on DNs for the initial user.

Parameter type: Boolean

Unit: none

Value range:

- **on**: indicates that the logins, logouts, and operations of internal tools CM Agent, gs_clean, and WDRXdb are audited, and logins and logouts from CNs are audited on DNs for the initial user.
- **off**: indicates that the logins, logouts, and operations of internal tools CM Agent, gs_clean, and WDRXdb are not audited, and logins and logouts from CNs are not audited on DNs for the initial user.

Default value: **off**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value to save space occupied by audit logs and improve audit log query performance.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Risks and impacts of improper settings: If this parameter is enabled, login and logout operations between internal tools or nodes on the database server will be recorded, causing performance deterioration.

full_audit_users

Parameter description: Specifies the full audit user list. Audit logs are recorded for all auditable operations performed by users in the list.

Parameter type: string.

Unit: none

Value range: a string. Use commas (,) to separate multiple usernames.

Default value: **""**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Set this parameter when all behaviors of a specific user need to be recorded and audited.

Risks and impacts of improper settings: If there are too many users in the list, all operations performed by these users are recorded in audit logs, causing database performance deterioration.

no_audit_client

Parameter description: Specifies the names and IP addresses of clients that do not need to be audited. The IP addresses can be IPv6 addresses. The parameter format is *client name*@*IP address*, which is the same as that of the **client_conninfo** column in the gs_query_audit function, for example, **cm_agent@127.0.0.1 or gs_clean@127.0.0.1**.

Parameter type: string.

Unit: none

Value range: a character string. Use commas (,) to separate multiple configuration items.

Default value: **""**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Audit logs are generated for communication among tools or nodes in the database server. To save space occupied by audit logs and improve the query performance of audit logs, you can configure the **no_audit_client** parameter not to audit the low-risk scenarios.

Risks and impacts of improper settings: If the settings are incorrect, operations performed on a client may fail to be audited. As a result, risky operations cannot be traced.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

If the executed SQL statement meets the configuration requirements of **full_audit_users** and **no_audit_client**, the **no_audit_client** is preferentially configured.

6.3.22.3 Operation Auditing

audit_system_object

Parameter description: Specifies whether to audit the operations such as CREATE, DROP, and ALTER on database objects. Database objects include databases, users, schemas, and tables. You can change the value of this parameter to audit only the operations on required database objects.

Parameter type: integer.

Unit: none

Value range: 0 to 1073741823

- **0** indicates that the operations such as CREATE, DROP, and ALTER are not audited.
- A non-zero value indicates that the operations such as CREATE, DROP, and ALTER on a certain or some database objects are audited.

Value description:

The value of this parameter is calculated by 30 binary bits. The 30 binary bits represent 30 types of database objects. If the corresponding binary bit is set to **0**, the operations such as CREATE, DROP, and ALTER on corresponding database objects are not audited. If it is set to **1**, the operations such as CREATE, DROP, and ALTER are audited. For details about the audit contents represented by these 30 binary bits, see **Table 6-51**.

When SQL patches are audited and **audit_dml_state_select** is enabled, an SQL patch operation will be audited twice and recorded as DML and DDL operations in the audit log, respectively. If a remote API is called, the DDL logs are generated on the node corresponding to the input parameter, instead of on the node where the statement is issued.

Default value: **67121159** (decimal), corresponding to 00 0100 0000 0000 0011 0000 0000 0111 in binary, indicating that DDL operations on DATABASE, SCHEMA, USER, NODE GROUP, and SQLPatch are audited.

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Set the type of database objects to be audited based on service requirements. In the scenario where the primary node is forcibly selected from the primary and standby nodes, you are advised to set **audit_system_object** to the maximum value to audit all objects in table 1.

Risks and impacts of improper settings: A larger number of object types to audit indicates a greater impact on system performance, and more CPU and I/O resources are occupied.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 6-51 Meaning of each value for the **audit_system_object** parameter

Binary Bit	Description	Value Range
Bit 0	Specifies whether to audit the CREATE, DROP, and ALTER operations on databases.	• **0** indicates that the CREATE, DROP, and ALTER operations on these objects are not audited. • **1** indicates that the CREATE, DROP, and ALTER operations on these objects are audited.
Bit 1	Specifies whether to audit the CREATE, DROP, and ALTER operations on schemas.	• **0** indicates that the CREATE, DROP, and ALTER operations on these objects are not audited. • **1** indicates that the CREATE, DROP, and ALTER operations on these objects are audited.
Bit 2	Specifies whether to audit the CREATE, DROP, and ALTER operations on users and user mappings.	• **0** indicates that the CREATE, DROP, and ALTER operations on these objects are not audited. • **1** indicates that the CREATE, DROP, and ALTER operations on these objects are audited.
Bit 3	Specifies whether to audit the CREATE, DROP, ALTER, TRUNCATE, VACUUM, and ANALYZE operations on tables.	• **0** indicates that the CREATE, DROP, ALTER, TRUNCATE, VACUUM, and ANALYZE operations on these objects are not audited. • **1** indicates that the CREATE, DROP, ALTER, TRUNCATE, VACUUM, and ANALYZE operations on these objects are audited.
Bit 4	Specifies whether to audit the CREATE, DROP, and ALTER operations on indexes.	• **0** indicates that the CREATE, DROP, and ALTER operations on these objects are not audited. • **1** indicates that the CREATE, DROP, and ALTER operations on these objects are audited.
Bit 5	• Specifies whether to audit the CREATE, DROP, and ALTER operations on views. • Specifies whether to audit the CREATE and DROP operations on MATVIEW objects.	• **0** indicates that the CREATE, DROP, and ALTER operations on views and the CREATE and DROP operations on MATVIEW objects are not audited. • **1** indicates that the CREATE, DROP, and ALTER operations on views and the CREATE and DROP operations on MATVIEW objects are audited.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Binary Bit	Description	Value Range
Bit 6	Specifies whether to audit the CREATE, DROP, and ALTER operations on triggers.	• **0** indicates that the CREATE, DROP, and ALTER operations on these objects are not audited. • **1** indicates that the CREATE, DROP, and ALTER operations on these objects are audited.
Bit 7	Specifies whether to audit the CREATE, DROP, and ALTER operations on procedures/functions.	• **0** indicates that the CREATE, DROP, and ALTER operations on these objects are not audited. • **1** indicates that the CREATE, DROP, and ALTER operations on these objects are audited.
Bit 8	Specifies whether to audit the CREATE, DROP, and ALTER operations on tablespaces.	• **0** indicates that the CREATE, DROP, and ALTER operations on these objects are not audited. • **1** indicates that the CREATE, DROP, and ALTER operations on these objects are audited.
Bit 9	Specifies whether to audit the CREATE, DROP, and ALTER operations on resource pools.	• **0** indicates that the CREATE, DROP, and ALTER operations on these objects are not audited. • **1** indicates that the CREATE, DROP, and ALTER operations on these objects are audited.
Bit 10	Specifies whether to audit the CREATE, DROP, and ALTER operations on workloads.	• **0** indicates that the CREATE, DROP, and ALTER operations on these objects are not audited. • **1** indicates that the CREATE, DROP, and ALTER operations on these objects are audited.
Bit 11	Specifies whether to audit the CREATE, DROP, and ALTER operations on server objects.	• **0** indicates that the CREATE, DROP, and ALTER operations on these objects are not audited. • **1** indicates that the CREATE, DROP, and ALTER operations on these objects are audited.
Bit 12	Reserved.	-
Bit 13	Specifies whether to audit the CREATE and DROP operations on node groups.	• **0** indicates that the CREATE and DROP operations on these objects are not audited. • **1** indicates that the CREATE and DROP operations on these objects are audited.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Binary Bit	Description	Value Range
Bit 14	Specifies whether to audit the CREATE, DROP, and ALTER operations on ROW LEVEL SECURITY objects.	• **0** indicates that the CREATE, DROP, and ALTER operations on these objects are not audited. • **1** indicates that the CREATE, DROP, and ALTER operations on these objects are audited.
Bit 15	Specifies whether to audit the CREATE, DROP, and ALTER operations on types.	• **0** indicates that the CREATE, DROP, and ALTER operations on types are not audited. • **1** indicates that the CREATE, DROP, and ALTER operations on types are audited.
Bit 16	Specifies whether to audit the CREATE, DROP, and ALTER operations on text search objects (CONFIGURATION and DICTIONARY).	• **0** indicates that the CREATE, DROP, and ALTER operations on text search objects are not audited. • **1** indicates that the CREATE, DROP, and ALTER operations on text search objects are audited.
Bit 17	Specifies whether to audit the CREATE, DROP, and ALTER operations on directories.	• **0** indicates that the CREATE, DROP, and ALTER operations on directories are not audited. • **1** indicates that the CREATE, DROP, and ALTER operations on directories are audited.
Bit 18	Specifies whether to audit the CREATE, DROP, and ALTER operations on synonyms.	• **0** indicates that the CREATE, DROP, and ALTER operations on synonyms are not audited. • **1** indicates that the CREATE, DROP, and ALTER operations on synonyms are audited.
Bit 19	Specifies whether to audit the CREATE, DROP, and ALTER operations on sequences.	• **0** indicates that the CREATE, DROP, and ALTER operations on sequences are not audited. • **1** indicates that the CREATE, DROP, and ALTER operations on sequences are audited.
Bit 20	Specifies whether to audit the CREATE, ALTER, and DROP operations on CMKs and CEKs.	• **0** indicates that the CREATE, ALTER, and DROP operations on CMKs and CEKs are not audited. • **1** indicates that the CREATE, ALTER, and DROP operations on CMKs and CEKs are audited.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Binary Bit	Description	Value Range
Bit 21	Specifies whether to audit the CREATE, DROP, and ALTER operations on packages.	• **0** indicates that the CREATE, DROP, and ALTER operations on packages are not audited. • **1** indicates that the CREATE, DROP, and ALTER operations on packages are audited.
Bit 22	Reserved	-
Bit 23	Reserved	-
Bit 24	Specifies whether to audit the ALTER and DROP operations on the gs_global_config objects.	• **0** indicates that the ALTER and DROP operations on the **gs_global_config** objects are not audited. • **1** indicates that the ALTER and DROP operations on the gs_global_config objects are audited.
Bit 25	Specifies whether to audit the CREATE, DROP, and ALTER operations on FOREIGN DATA WRAPPER objects. Currently, this function is not supported.	• **0** indicates that the CREATE, DROP, and ALTER operations on FOREIGN DATA WRAPPER objects are not audited. • **1** indicates that the CREATE, DROP, and ALTER operations on FOREIGN DATA WRAPPER objects are audited.
Bit 26	Specifies whether to audit the CREATE, ENABLE, DISABLE, and DROP operations on SQL patches.	• **0** indicates that the CREATE, ENABLE, DISABLE, and DROP operations on SQL patches are not audited. • **1** indicates that the CREATE, ENABLE, DISABLE, and DROP operations on SQL patches are audited.
Bit 27	Reserved	-
Bit 28	Specifies whether to audit the CREATE, ALTER, and DROP operations on database links.	• **0** indicates that the CREATE, ALTER, and DROP operations on database links are not audited. • **1** indicates that the CREATE, ALTER, and DROP operations on database links are audited.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Binary Bit	Description	Value Range
Bit 29	Specifies whether to audit the CREATE, DROP, and ALTER operations on resource labels, masking policies, and audit policies.	• **0** indicates that the CREATE, ALTER, and DROP operations on resource labels, masking policies, and audit policies are not audited. • **1** indicates that the CREATE, ALTER, and DROP operations on resource labels, masking policies, and audit policies are audited.

audit_dml_state

Parameter description: Specifies whether to audit the INSERT, UPDATE, DELETE, and MERGE operations on all tables.

Parameter type: integer.

Unit: none

Value range: **0** and **1**

- **0**: The INSERT, UPDATE, DELETE, and MERGE operations on a specific table are not audited.
- **1**: The INSERT, UPDATE, DELETE, and MERGE operations on a specific table are audited.

Default value: **0**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this parameter is set to **1**, audit logs are frequently recorded when INSERT, UPDATE, DELETE, and MERGE operations are frequently performed in the database. As a result, the database performance deteriorates.

audit_dml_state_select

Parameter description: Specifies whether to audit the SELECT operation.

Parameter type: integer.

Unit: none

Value range: **0** and **1**

- **0**: The SELECT auditing function is disabled.
- **1**: The SELECT auditing function is enabled.

Default value: **0**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this parameter is set to **1**, audit logs are frequently recorded when the SELECT operation is frequently performed in the database. As a result, the database performance deteriorates.

audit_function_exec

Parameter description: Specifies whether to record the audit information during the execution of the stored procedures, anonymous blocks, or user-defined functions (excluding system functions).

Parameter type: integer.

Unit: none

Value range: **0** and **1**

- **0**: The stored procedures, anonymous blocks, or user-defined functions (excluding system functions) are not audited.
- **1**: The stored procedures, anonymous blocks, or user-defined functions (excluding system functions) are audited.

Default value: **0**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this parameter is set to **1**, audit logs are frequently recorded when the database frequently executes stored procedures, anonymous blocks, or user-defined functions. As a result, the database performance deteriorates.

audit_system_function_exec

Parameter description: Specifies whether to record audit logs when system functions in the whitelist are executed.

Parameter type: integer.

Unit: none

Value range: **0** and **1**

- **0**: The function of auditing the execution of system functions is disabled.
- **1**: The function of auditing system function execution is enabled.

Default value: **0**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Risks and impacts of improper settings: If this parameter is set to **1**, audit logs are frequently recorded when the database frequently executes system functions in the whitelist. As a result, the database performance deteriorates.

The following table lists the whitelist of system functions that can be recorded and audited.

set_working_grand_version_num_manually	set_config	pg_terminate_backend	pg_cancel_backend	pg_cancel_session	pg_cancel_invalid_query
pg_reload_conf	pg_rotate_logfile	pg_terminate_session	pg_terminate_backend	pg_start_backup	pg_stop_backup
pg_create_restore_point	pg_switch_xlog	pg_cbm_get_merged_file	pg_cbm_recycle_file	pg_enable_delay_ddl_recycle	pg_disable_delay_ddl_recycle
pg_cbm_rotate_file	gs_roach_enable_delay_ddl_recycle	gs_roach_disable_delay_ddl_recycle	gs_roach_stop_backup	pg_last_xlog_receive_location	pg_xlog_replay_pause
pg_xlog_replay_resume	gs_roach_switch_xlog	gs_pitr_archive_slot_force_advance	gs_pitr_clean_history_global_barriers	gs_download_obs_file	gs_upload_obs_file
gs_set_obs_file_context	gs_set_obs_delete_location	gs_hadr_do_switchover	gs_set_obs_delete_location_with_slotname	gs_streaming_dr_in_switchover	pg_advisory_lock
pg_advisory_lock_shared	pg_advisory_unlock	pg_advisory_unlock_shared	pg_advisory_unlock_all	pg_advisory_xact_lock	pg_advisory_xact_lock_shared
pg_try_advisory_lock	pg_try_advisory_lock_shared	pg_try_advisory_xact_lock	pg_try_advisory_xact_lock_shared	gs_get_hadr_key_cn	pg_create_physical_replication_slot_extern

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

sqladvisor.init	sqladvisor.set_weight_params	sqladvisor.set_cost_params	sqladvisor.assign_table_type	gs_repair_file	local_clear_bad_block_info
gs_repair_page	clean_abnormal_sql	abnormal_sql_manage_allowlist	dsl_add_rule	dsl_del_rule	dsl_set_rule
dsl_reload_rule	pgxc_fenced_udf_process	pgxc_terminate_all_fenced_udf_process	-	-	-

NOTE

In the audit record of the system function execution event, the value of the **object_name** column is the system function name and does not contain function parameters.

audit_copy_exec

Parameter description: Specifies whether to audit the COPY operation.

Parameter type: integer.

Unit: none

Value range: **0** and **1**

- **0**: The function of auditing the COPY operation is disabled.
- **1**: The function of auditing the COPY operation is enabled.

Default value: **1**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this parameter is set to **1**, audit logs are frequently recorded when the COPY operation is frequently performed in the database. As a result, the database performance deteriorates.

audit_set_parameter

Parameter description: Specifies whether to audit the SET operation.

Parameter type: integer.

Unit: none

Value range: **0** and **1**

- **0**: The function of auditing the SET operation is disabled.
- **1**: The function of auditing the SET operation is enabled.

Default value: **0**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this parameter is set to **1**, audit logs are frequently recorded when the SET operation is frequently performed in the database. As a result, the database performance deteriorates.

audit_xid_info

Parameter description: Specifies whether to record the transaction ID of the SQL statement in the **detail_info** column of the audit log.

Parameter type: integer.

Unit: none

Value range: **0** and **1**

- **0**: The function of recording transaction IDs in the audit log is disabled.
- **1**: The function of recording transaction IDs in the audit log is enabled.

Default value: **0**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

NOTE

If this function is enabled, the **detail_info** information in the audit log starts with *xid*. For example:

```
detail_info: xid=14619 , create table t1(id int);
```

If transaction IDs do not exist, **xid=NA** is recorded.

audit_rollback

Parameter description: Specifies whether to audit the rollback operation. This parameter can be set at the PDB level.

Parameter type: integer

Unit: none

Value range: **0** and **1**

- **0**: Rollback is not audited.
- **1**: Rollback is audited.

Default value: **0**. In the PDB scenario, if this parameter is not set, the global setting is inherited.

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: After this function is enabled, rollback operations will be recorded in the audit log.

audit_sql_error

Parameter description: Specifies whether to audit SQL statements that fail to be executed. This parameter can be set at the PDB level.

Parameter type: integer

Unit: none

Value range: **0** and **1**

- **0**: The function of auditing SQL statements that fail to be executed is disabled.
- **1**: The function of auditing SQL statements that fail to be executed is enabled.

Default value: **0**. In the PDB scenario, if this parameter is not set, the global setting is inherited.

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: After this function is enabled, SQL statements that fail to be executed will be recorded in the audit log.

6.3.23 Transaction Monitoring

The automatic rollback transaction can be monitored and its statement problems can be located by setting the transaction timeout warning. In addition, the statements with long execution time can also be monitored.

transaction_sync_naptime

Parameter description: For data consistency, when the local transaction's status differs from that in the snapshot of GTM, other transactions will be blocked. You need to wait for a few minutes until the transaction status of the localhost is consistent with that of the GTM. The gs_clean tool is automatically triggered for cleansing when the waiting period on the CN exceeds that of **transaction_sync_naptime**. The tool will shorten the blocking time after it completes the cleansing.

Parameter type: integer.

Unit: second

Value range: 0 to 2147483

NOTE

If the value of this parameter is set to **0**, gs_clean will not be automatically called for the cleansing before the blocking arrives the duration. Instead, the gs_clean tool is called by **gs_clean_timeout**. The default value is 5 minutes.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Default value: **30**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If the value is too large, the time for the CN to trigger clearing is prolonged, and the blocking time in the case of inconsistency is longer.

transaction_sync_timeout

Parameter description: For data consistency, when the local transaction's status differs from that in the snapshot of GTM, other transactions will be blocked. You need to wait for a few minutes until the transaction status of the localhost is consistent with that of the GTM. An exception is reported when the waiting duration on the CN exceeds the value of **transaction_sync_timeout**. Roll back the transaction to avoid system blocking due to long time of thread response failures (for example, sync lock).

Parameter type: integer.

Unit: second

Value range: 0 to 2147483

NOTE

- If the value is **0**, no error is reported when the blocking times out or the transaction is rolled back.
- If the value is not 0, the value of this parameter must be greater than that of **gs_clean_timeout**. Otherwise, unnecessary transaction rollback will probably occur due to a block timeout caused by residual transactions that have not been deleted by gs_clean on the DN.

Default value: **600** (10 minutes)

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

6.3.24 GTM Parameters

GTM parameters can be set in the **gtm.conf** file or using gs_guc.

nodename

Parameter description: Specifies the name of the primary or standby GTM.

Parameter type: string.

Unit: none

Value range: a string, which complies with the identifier naming convention

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Default value: **""**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

port

Parameter description: Specifies the host port number listened by the primary or standby GTM.

Parameter type: integer.

Unit: none

Value range: 0 to 2147483647. The recommended value range is 1024 to 65535.

Default value: **6666**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

log_file

Parameter description: Specifies a log file name.

Parameter type: string.

Unit: none

Value range: a string, which complies with the identifier naming convention

Default value: **"gtm-***%Y-%m-%d_%H%M%S***.log"**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

active_host

Parameter description: Specifies the IP address of a target GTM. For the primary GTM, it is the IP address of the standby GTM; for the standby GTM, it is the IP address of the primary GTM. The IP address can be an IPv4 or IPv6 address.

Parameter type: string.

Unit: none

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Value range: a string, which complies with the identifier naming convention

Default value: **""**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

local_host

Parameter description: Specifies the HA local address. Set this parameter based on the cluster configuration file. You do not need to manually set this parameter. The IP address can be an IPv4 or IPv6 address.

Parameter type: string.

Unit: none

Value range: a string, which complies with the identifier naming convention

Default value: **""**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

active_port

Parameter description: Specifies the port number of the target GTM server.

Parameter type: integer.

Unit: none

Value range: 0 to 2147483647. The recommended value range is 1024 to 65535.

Default value: **0**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impact of improper settings: This parameter is specified in the configuration file during installation. Do not modify this parameter unless necessary. Otherwise, database communications will be affected after the modification.

local_port

Parameter description: Specifies the local port for HA.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter type: integer.

Unit: none

Value range: 0 to 2147483647. The recommended value range is 1024 to 65535.

Default value: **0**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impact of improper settings: This parameter is specified in the configuration file during installation. Do not modify this parameter unless necessary. Otherwise, database communications will be affected after the modification.

standby_connection_timeout

Parameter description: Specifies the timeout interval between the primary and standby GTMs. A larger value enhances the fault tolerance capability of the network between the primary and standby GTMs, but increases the duration for reporting disconnection between them.

Parameter type: integer.

Unit: seconds

Value range: 5 to 2147483647

Default value: **5**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impact of improper settings: If the value is too large, disconnection faults may not be detected in a timely manner.

keepalives_count

Parameter description: Specifies the maximum number of unresponsive keepalive signals that can be waited before the GTM server is disconnected from the client on an OS that supports the **TCP_KEEPCNT** socket option. This parameter takes effect only on the standby GTM.

Parameter type: integer.

Unit: none

Value range: 0 to 2147483647

Default value: **0**, indicating that the connection is immediately broken if no keepalive signal from the client is received by the GTM.

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

keepalives_idle

Parameter description: Specifies the interval for sending keepalive signals if no data is sent after the GTM server is connected to the client on the OS that supports the **TCP_KEEPIDLE** socket option.

Parameter type: integer.

Unit: seconds

Value range: 0 to 2147483647

Default value: **0**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

keepalives_interval

Parameter description: Specifies the interval at which the GTM server sends active signals on the OS that supports the **TCP_KEEPINTVL** socket option.

Parameter type: integer.

Unit: seconds

Value range: 0 to 2147483647

Default value: **0**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

synchronous_backup

Parameter description: Specifies whether to enable synchronization for backing up data to the standby GTM.

Parameter type: enumerated type.

Unit: none

Value range:

- **on**: Synchronization is enabled.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **off**: Synchronization is disabled.
- **auto**: Automatic synchronization is enabled.

Default value: **auto**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

query_memory_limit

Parameter description: Specifies the limit of memory available for queries. This parameter applies only to the default resource group. For other resource groups, the memory available for queries is not limited.

Parameter type: floating-point.

Unit: none

Value range: 0.0 to 1.0

Default value: **0.25**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

wlm_max_mem

Parameter description: Specifies the maximum memory for GTM execution.

Parameter type: integer.

Unit: MB

Value range: 512 to 2147483647

Default value: **2048**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

config_file

Parameter description: Specifies the name of a GTM configuration file. Only the SYSADMIN user can access this parameter.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter type: string.

Unit: none

Value range: valid file name.

Default value: **"gtm.conf"**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

data_dir

Parameter description: Specifies the GTM data file directory.

Parameter type: string.

Unit: none

Value range: valid path of a directory.

Default value: **""**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

listen_addresses

Parameter description: Specifies the TCP/IP address of the client for a server to listen on. The IP address can be an IPv4 or IPv6 address.

Parameter type: string.

Unit: none

Value range:

- Host name or IP address. Multiple values are separated with commas (,). IPv4 and IPv6 addresses are supported.
- An asterisk (*), indicating all IP addresses.
- If the parameter is not specified, the server does not listen on any IP address. In this case, only UDS can be used for database connections.

Default value: **"*"**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

log_directory

Parameter description: Specifies the directory for storing log files when **logging_collector** is set to **on**. The value can be an absolute path, or relative to the data directory.

NOTICE

- If the value of **log_directory** in the configuration file is an invalid path (that is, the user does not have the permission to read or write this path), the cluster cannot be restarted.
- If the value of **log_directory** is changed to a valid path (that is, the user has the permission to read and write this path), logs are generated in the new path. If the specified path is invalid, log files are generated in the last valid path and the database running is not affected. The invalid value is still written into the configuration file.

Parameter type: string.

Unit: none

Value range: valid path of a directory.

Default value: **gtm_log**, indicating that server logs will be generated in the **gtm_log/** directory under the data directory.

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

log_min_messages

Parameter description: Specifies the level of messages written to GTM log files in the server log folder. When a message of the same or higher level is generated, the message is recorded in the log file. Therefore, a lower level indicates that more messages are recorded in the run log of the server.

Parameter type: enumerated type.

Unit: none

Value range: The message levels are **debug5**, **debug4**, **debug3**, **debug2** (**debug**), **debug1**, **info**, **notice**, **warning**, **error**, **log**, **fatal**, and **panic** in ascending order. For details about the parameters, see **Table 6-23**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- The message level **debug** is equivalent to **debug2**.
- For **log_min_messages**, the log message level is higher than **error** and lower than **fatal**.

Default value: **warning**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

alarm_component

Parameter description: Certain alarms are suppressed during alarm reporting. That is, the same alarm will not be repeatedly reported by an instance within the period specified by **alarm_report_interval**. Its default value is **10s**. In this case, the parameter specifies the location of the alarm component that is used to process alarm information.

Parameter type: string.

Unit: none

Value range:

- If **--alarm-type** in the gs_preinstall script is set to **5**, no third-party component is connected and alarms are written into the **system_alarm** log. In this case, the value of **alarm_component** is **/opt/huawei/snas/bin/snas_cm_cmd**.
- If **--alarm-type** in the gs_preinstall script is set to **1**, a third-party component is connected. In this case, the value of **alarm_component** is the absolute path of the executable program of the third-party component.

Default value: **"/opt/huawei/snas/bin/snas_cm_cmd"**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

alarm_report_interval

Parameter description: Specifies the interval at which an alarm is reported.

Parameter type: integer.

Unit: seconds

Value range: 0 to 2147483647

Default value: **10**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

standby_only

Parameter description: Specifies whether to forcibly synchronize information to standby nodes. In the mode with one primary and multiple standby nodes, information is only forcibly synchronized to the ETCD.

Parameter type: integer.

Unit: none

Value range:

- **0**: Information is not forcibly synchronized to standby nodes.
- **1**: Information is forcibly synchronized to standby nodes.

Default value: **0**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

gtm_max_trans

Parameter description: Specifies the maximum number of connections accepted by the GTM. You are advised not to change the value.

Parameter type: integer.

Unit: none

Value range: 256 to 200000

Default value: **8192**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value. If you have to, set this parameter to a value no less than the maximum number of connections plus 100.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

enable_connect_control

Parameter description: Specifies whether the GTM connection control is enabled to check whether a connection IP address is within the cluster.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: Checks whether a connection IP address is within the cluster. If it is not, the access is rejected.
- **off**: Does not check whether a connection IP address is within the cluster.

Default value: **on**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

gtm_authentication_type

Parameter description: Specifies the port authentication mode of the GTM module.

Parameter type: enumerated type.

Unit: none

Value range:

- **trust**: Port authentication is not configured.
- **gss**: Kerberos port authentication is used.

> **NOTICE**
>
> Note that you can change the value to **gss** only after the Kerberos server and client are successfully installed. Otherwise, the GTM cannot communicate properly, affecting the cluster status.

Default value: **trust**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

gtm_krb_server_keyfile

Parameter description: Specifies the location of the key file on the Kerberos server. The value must be an absolute path. The file is usually stored in the *${GAUSSHOME}*/**kerberos** directory and ends with keytab. The file name is the same as the name of the user who runs the cluster. This parameter is used

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

together with **gtm_authentication_type**. If **gtm_authentication_type** is changed to **gss**, this parameter must be configured as the correct path. Otherwise, the cluster status will be affected.

Parameter type: string.

Unit: none

Value range: valid file path.

Default value: **""**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

enable_gtm_free

Parameter description: Specifies whether the GTM-free mode is enabled. In large concurrency scenarios, the snapshots delivered by the GTM increase in number and size. The network between the GTM and the CN becomes the performance bottleneck. The GTM-free mode is used to eliminate the bottleneck. In this mode, the CN communicates with DNs instead of the GTM. The CN sends queries to each DN, which locally generates snapshots and XIDs, ensuring external write consistency but not external read consistency.

NOTICE

When the GTM-free mode is used, you are advised to set **application_type** to **perfect_sharding_type** so that you can find SQL statements that may cause data inconsistency. Otherwise, the system does not intercept statements that may cause data inconsistency.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The GTM-free mode is enabled and the cluster ensures eventual read consistency.
- **off**: The GTM-free mode is disabled.

Default value: **off**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Data inconsistency may occur in GTM-free mode.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

gtm_option

Parameter description: Specifies the GTM mode. This parameter must be configured on all GTMs, CNs, and DNs. The value must be the same. There are three GTM modes: GTM, GTM-lite, and GTM-free. The GTM and GTM-lite modes take effect only when the **enable_gtm_free** parameter is set to **off**. The current version does not support switching between different GTM modes for installed clusters. For details about the three GTM modes, see "Feature Usage Guidelines > GTM > GTM Modes" in *Developer Guide*.

Parameter type: integer.

Unit: none

Value range: 0 to 2

- **0**: GTM mode.
- **1**: GTM-lite mode.
- **2**: GTM-free mode.

Default value: **1**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

csn_sync_interval

Parameter description: Specifies the interval for synchronizing CSN between the primary and standby GTMs.

Parameter type: integer.

Unit: seconds

Value range: 1 to 2147483647

Default value: **1**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

restore_duration

Parameter description: Specifies the restoration duration of XID or CSN on the GTM, that is, the number of XIDs or CSNs for restoration.

Parameter type: integer.

Unit: none

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Value range: 1000000 to 2147483647

Default value: **1000000**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

gtm_enable_threadpool

Parameter description: Specifies whether to enable the GTM thread pool function. The setting takes effect only after the GTM is restarted.

Parameter type: Boolean.

Unit: none

Value range:

- **true**: The GTM thread pool function is enabled.
- **false**: The GTM thread pool function is disabled.

Default value: **true**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

gtm_num_threads

Parameter description: Specifies the number of worker threads in the thread pool when the thread pool function **gtm_enable_threadpool** is enabled.

Parameter type: integer.

Unit: none

Value range: 0 to 16384. The value is related to the size of **gtm_max_trans** and cannot exceed the result of (Value of **gtm_max_trans** – 1 – Number of auxiliary threads). The number of auxiliary threads is **2** in the current version.

Default value: **1024**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

check_gtm_primary_time

Parameter description: Specifies the interval at which GTM checks the consistency between its primary node and ETCD primary node.

Parameter type: integer.

Unit: seconds

Value range: 0 to 2147483647. The value **0** indicates that the detection function is disabled.

Default value: **2**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Set this parameter based on service requirements.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

seq_cache_coefficient

Parameter description: Specifies the sequence cache coefficient on the GTM. The cache coefficient is used to calculate the sequence recovery value.

Parameter type: integer.

Unit: none

Value range: 3 to 20000

Default value: **20000**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value. The minimum value cannot be less than the number of nodes.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

gtm_dcf_run_mode

Parameter description: Specifies the DCF running mode of the DCC when GTM uses DCC.

Parameter type: integer.

Unit: none

Value range: 0 to 2. The value **0** indicates that the election function is enabled, the value **1** indicates that the manual election is performed, and the value **2** indicates that the election function is disabled.

Default value: **2**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Setting suggestion: This parameter is set by the CM. You are advised not to manually set or change the value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing. Unnecessary switchovers may occur or the primary and standby status may be abnormal.

gtm_dcc_id

Parameter description: Specifies the DCC ID of the instance when GTM uses DCC.

Parameter type: integer.

Unit: none

Value range: 1 to 127

Default value: **0**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: This parameter is set and maintained by the OM and cannot be modified.

Risks and impacts of improper settings: none

gtm_dcf_extreme_mode

Parameter description: Specifies whether to enable the maximum availability mode for DCF of DCC when GTM uses DCC.

Parameter type: integer.

Unit: none

Value range: 0 to 2. The value **0** indicates the maximum protection mode, the value **1** indicates the maximum availability mode, and the value **2** indicates the maximum performance mode.

Default value: **0**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: This parameter is set by the CM. You are advised not to manually set or change the value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing. Service consistency may be affected.

gtm_dcf_static_leader_timeout

Parameter description: Specifies the timeout period for GTM to wait for the static primary DCF node or the original primary node to be promoted to primary when DCC is used. This parameter is mainly used in the cluster startup phase.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter type: integer.

Unit: none

Value range: 0 to 2147483647

Default value: **0**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: This parameter is set by the CM or OM. You are advised not to manually set or change the value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing. The cluster may fail to be started.

gtm_dcc_config

Parameter description: Specifies the DCC cluster configuration when GTM uses DCC.

Parameter type: string.

Unit: none

Value range: a JSON string that contains valid information.

Default value: **""**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: This parameter is set and maintained by the OM and cannot be modified.

Risks and impacts of improper settings: none

gtm_dcc_data_dir

Parameter description: Specifies the DCC data directory when GTM uses DCC.

Parameter type: string.

Unit: none

Value range: a valid absolute path.

Default value: **""**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: This parameter is set and maintained by the OM and cannot be modified.

Risks and impacts of improper settings: none

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

gtm_dcf_sync_nodes

Parameter description: Specifies the synchronization mode between DCCs when GTM uses DCC.

Parameter type: string.

Unit: none

Value range:

- **ANY num_sync:standby1,standby2**: specifies the policy for replicating the standby node. **ANY** *N*:**1,2,**... indicates that logs are synchronized to any *N* standby nodes after the colon (:).
- **FIRST num_sync:standby1,standby2**: specifies the policy for replicating the standby node. **FIRST** *N*:**1,2,**... indicates that logs are synchronized based on the sequence following the colon (:).

num_sync indicates the number of logs to be synchronized to the standby node, and **standby** indicates the standby node ID.

Default value: **""**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: This parameter is set by the CM or OM. You are advised not to manually set or change the value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing. Unnecessary switchovers may occur or the primary and standby status may be abnormal.

gtm_dcf_candidate_nodes

Parameter description: Specifies the list of primary node candidates of DCC when GTM uses DCC.

Parameter type: string.

Unit: none

Value range: numbers separated by commas (,).

Default value: **""**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: This parameter is set by the CM or OM. You are advised not to manually set or change the value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing. Unnecessary switchovers may occur or the primary and standby status may be abnormal.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

gtm_dcc_log_level

Parameter description: Specifies the DCC log printing level when GTM uses DCC.

Parameter type: string.

Unit: none

Value range:

- **"NONE"**: The log function is disabled. It cannot be used together with the following log levels.
- **"RUN_ERR|RUN_WAR|RUN_INF|DEBUG_ERR|DEBUG_WAR|DEBUG_INF|TRACE|PROFILE|OPER"**: The log function of specified levels is enabled.

Default value: **"RUN_ERR|RUN_WAR|DEBUG_ERR|OPER|RUN_INF|PROFILE"**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Set this parameter based on service requirements.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

gtm_ddb

Parameter description: Specifies whether GTM uses ETCD or DCC.

Parameter type: string.

Unit: none

Value range: **etcd** or **dcc**.

Default value: **etcd**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: This parameter is set by OM during cluster installation and cannot be manually modified after installation.

Risks and impacts of improper settings: none

6.3.25 Upgrade Parameters

IsInplaceUpgrade

Parameter description: Specifies whether an upgrade is ongoing. This parameter is an upgrade parameter and cannot be modified. Only the SYSADMIN user can access the parameter.

Parameter type: Boolean

Unit: none

Value range:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **on**: An upgrade is ongoing.
- **off**: No upgrade is ongoing.

Default value: **off**

Setting method: This is a SUSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: This parameter can only be viewed.

Risks and impacts of improper settings: none

inplace_upgrade_next_system_object_oids

Parameter description: Specifies the OID of a new system object during the in-place upgrade. This parameter is used for upgrade and cannot be modified by users.

Parameter type: string.

Unit: none

Value range: a string.

Default value: **""**

Setting method: This is a SUSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: This parameter can only be viewed.

Risks and impacts of improper settings: none

om_operation_mode

Parameter description: Specifies whether the cluster is in the O&M or running state. This parameter is used for internal component interaction and cannot be used by users.

Parameter type: enumerated type.

Unit: none

Value range:

- **upgrade_system_object_mode**: The upgrade is in the system object update phase.
- **running_mode**: The normal running phase of the upgrade.

Default value: **running_mode**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this parameter is set to **upgrade_system_object_mode**, the database name cannot be renamed.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

upgrade_mode

Parameter description: Specifies the upgrade mode.

Parameter type: integer.

Unit: none

Value range: 0 to 2147483647

- **0**: No upgrade is ongoing.
- **1**: A local upgrade is ongoing.
- **2**: A grayscale upgrade is ongoing.

Default value: **0**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: This parameter is used for upgrade. You are advised not to modify it. You are advised to use the default value.

Risks and impacts of improper settings: Do not modify this parameter during the upgrade. Otherwise, the upgrade may fail and rollback cannot be performed. In non-upgrade scenarios, modifying this parameter may cause database usage errors or other unpredictable consequences.

NOTE

Special case: When the gray upgrade is used, if the major version upgrade policy is selected, that is, the upgrade script needs to be executed and the binary package needs to be replaced, the value of **upgrade_mode** is set to **2**; if the minor version upgrade policy is selected, that is, only the binary package needs to be replaced, the value of **upgrade_mode** is not set to **2**.

6.3.26 Miscellaneous Parameters

enable_default_ustore_table

Parameter description: Specifies whether the Ustore is used by default. This parameter is valid only when **enable_ustore** is enabled. If this parameter is set to **on**, all created tables are Ustore tables by default. If this parameter is set to **off**, all created tables are Astore tables by default. In upgrade scenarios, the default value of this parameter ensures compatibility. That is, the default value after the upgrade is the original default value.

Parameter type: Boolean

Unit: none

Value range:

- **on**: The Ustore is used by default.
- **off**: The Ustore is not used by default.

Default value: **on**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: When using Ustore tables, you must enable the **track_counts** and **track_activities** parameters. Otherwise, space bloat may occur.

enable_ustore

Parameter description: Specifies whether to enable Ustore. If this parameter is set to **on**, Ustore tables can be created.

Parameter type: Boolean

Unit: none

Value range:

- **on**: The Ustore is enabled.
- **off**: The Ustore is disabled.

Default value: **on**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: This parameter is used for Ustore version control. You are advised not to change the value.

Risks and impacts of improper settings: When using Ustore tables, you must enable the **track_counts** and **track_activities** parameters. Otherwise, space bloat may occur.

enable_segment_datafile_preallocate

Parameter description: Specifies whether to allocate disk space immediately during segment-page file name extension.

Parameter type: Boolean

Unit: none

Value range:

- **on**: The immediate disk space allocation mode is enabled. During file expansion, fallocate is preferentially used to allocate disk space immediately. If the system does not support fallocate, the byte-by-byte zero write mode is used to apply for disk space.
- **off**: The immediate disk space allocation mode is disabled. In this mode, disk space is not allocated immediately when a file is expanded, and the file increases in hole mode.

Default value: **on**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

consistency_check_module

Parameter description: Specifies the module that requires consistency check.

Parameter type: string.

Unit: none

Value range: If the module is enabled (**on**), consistency check is performed. If the module is disabled (**off**), consistency check is not performed. You can use SHOW consistency_check_module to view the status.

```
ALL,on(),off(INDEX)
```

Currently, only the INDEX module supports the verification. The INDEX module verifies the consistency between index tuples and heap table tuples during the B-tree index scan of the Astore table.

Default value: **'off(ALL)'**. That is, the verification of all modules is disabled by default.

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

1. First, you can use SHOW consistency_check_module to check which modules support verification. The output of the verification module is as follows:
   ```
   gaussdb=# SHOW consistency_check_module;
    consistency_check_module
   --------------------------
    ALL,on(),off(INDEX)
   (1 row)
   ```
2. Modules that can be verified are identified by uppercase letters, and the special ID **ALL** is used for setting all modules. You can use **on** or **off** to specify whether to perform verification. For example, to verify the consistency between indexes and heap tables, run the following commands:
   ```
   gaussdb=# SET consistency_check_module='on(INDEX)';
   SET
   gaussdb=# SHOW consistency_check_module;
    consistency_check_module
   --------------------------
    ALL,on(INDEX),off()
   (1 row)
   ```
   The command output shows that the INDEX check is enabled.
3. The **ALL** identifier can be used to quickly enable or disable the verification of all modules.
   ```
   gaussdb=# SET consistency_check_module='off(ALL)';
   SET
   gaussdb=# SHOW consistency_check_module;
    consistency_check_module
   --------------------------
    ALL,on(),off(INDEX)
   (1 row)

   gaussdb=# SET consistency_check_module='on(ALL)';
   SET
   gaussdb=# SHOW consistency_check_module;
    consistency_check_module
   --------------------------
   ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
 ALL,on(INDEX),off()
(1 row)
```

Setting suggestion: Enable the verification of the corresponding module as required.

Risks and impacts of improper settings: If this function is enabled, consistency check is performed during SQL execution, which takes extra time or affects performance. Exercise caution when enabling this function.

reserve_space_for_nullable_atts

Parameter description: Specifies whether to reserve space for the nullable attribute of an Ustore table.

Parameter type: Boolean

Unit: none

Value range:

- **on**: Space is reserved for the nullable attribute of an Ustore table.
- **off**: Space is not reserved for the nullable attribute of an Ustore table.

Default value: **on**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

server_version

Parameter description: Specifies the server version number in the character string format.

Parameter type: string.

Unit: none

Value range: **"9.2.4"**

Default value: **"9.2.4"**

Setting method: This is a fixed INTERNAL parameter. It can be viewed but cannot be modified. This parameter is used only by internal database tools. You are advised not to use it.

Setting suggestion: This parameter is not recommended. If you need to query the kernel version, you can obtain it by using the opengauss_version() function.

Risks and impacts of improper settings: none

server_version_num

Parameter description: Specifies the server version number in the integer format.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter type: integer.

Unit: none

Value range: **90204**

Default value: **90204**

Setting method: This is a fixed INTERNAL parameter. It can be viewed but cannot be modified. This parameter is used only by internal database tools. You are advised not to use it.

Setting suggestion: This parameter is not recommended. If you need to query the kernel version, you can obtain it by using the opengauss_version() function.

Risks and impacts of improper settings: none

block_size

Parameter description: Specifies the block size of the current database.

Parameter type: integer.

Unit: none

Value range: **8192**

Default value: **8192**

Setting method: This is a fixed INTERNAL parameter. It can be viewed but cannot be modified.

Setting suggestion: This parameter can only be viewed.

Risks and impacts of improper settings: none

segment_size

Parameter description: Specifies the segment file size of the current database.

Parameter type: integer.

Unit: 8 KB

Value range: **131072**

Default value: **131072**, that is, 1 GB.

Setting method: This is a fixed INTERNAL parameter. It can be viewed but cannot be modified.

Setting suggestion: This parameter can only be viewed.

Risks and impacts of improper settings: none

max_index_keys

Parameter description: Specifies the maximum number of index keys supported by the current database.

Parameter type: integer.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Unit: none

Value range: **32**

Default value: **32**

Setting method: This is a fixed INTERNAL parameter. It can be viewed but cannot be modified.

Setting suggestion: This parameter can only be viewed.

Risks and impacts of improper settings: none

integer_datetimes

Parameter description: Specifies whether the date and time are in the 64-bit integer format.

Parameter type: Boolean

Unit: none

Value range:

- **on**: The date and time format in 64-bit integer format is supported.
- **off**: The date and time format in 64-bit integer format is not supported.

Default value: **on**

Setting method: This is a fixed INTERNAL parameter. It can be viewed but cannot be modified.

Setting suggestion: This parameter can only be viewed.

Risks and impacts of improper settings: none

lc_collate

Parameter description: Specifies the string collation locale of the current database.

Parameter type: string.

Unit: none

Value range: a string.

Default value: Determined by the configuration during the cluster installation and deployment.

Setting method: This is a fixed INTERNAL parameter. It can be viewed but cannot be modified.

Setting suggestion: This parameter can only be viewed.

Risks and impacts of improper settings: none

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

lc_ctype

Parameter description: Specifies the locale settings for character types and case conversion in the current database. For example, it specifies what a letter and its upper-case equivalent are.

Parameter type: string.

Unit: none

Value range: a string.

Default value: Determined by the configuration during the cluster installation and deployment.

Setting method: This is a fixed INTERNAL parameter. It can be viewed but cannot be modified.

Setting suggestion: This parameter can only be viewed.

Risks and impacts of improper settings: none

max_identifier_length

Parameter description: Specifies the maximum identifier length.

Parameter type: integer.

Unit: none

Value range: **63**

Default value: **63**

Setting method: This is a fixed INTERNAL parameter. It can be viewed but cannot be modified.

Setting suggestion: This parameter can only be viewed.

Risks and impacts of improper settings: none

server_encoding

Parameter description: Specifies the server-side encoding (character set) of the current database.

By default, gs_initdb will initialize the setting of this parameter based on the system environment during database creation. You can also run the **locale** command to check the current configuration environment.

Parameter type: string.

Unit: none

Value range: a string.

Default value: Determined by the system environment when the database is created.

Setting method: This is a fixed INTERNAL parameter. It can be viewed but cannot be modified.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Setting suggestion: This parameter can only be viewed.

Risks and impacts of improper settings: none

datanode_heartbeat_interval

Parameter description: Specifies the interval for sending heartbeat messages between heartbeat threads.

Parameter type: integer.

Unit: milliseconds

Value range: 1000 to 60000

Default value: **1000** (that is, 1s)

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**. For example, if the value is **1000** without a unit, **datanode_heartbeat_interval** indicates 1000 ms. If the value is **1s**, **datanode_heartbeat_interval** indicates 1s. The unit must be **ms**, **s**, **min**, **h**, or **d** if required.

Setting suggestion: Set this parameter to a value less than or equal to **wal_receiver_timeout**/2.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

dfs_partition_directory_length

Parameter description: Specifies the maximum directory name length for the partition directory of a table partitioned by VALUE in the HDFS.

Parameter type: integer.

Unit: none

Value range: 92 to 7999

Default value: **512**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

max_concurrent_autonomous_transactions

Parameter description: Specifies the maximum number of autonomous transaction connections, that is, the maximum number of concurrent autonomous transactions executed at the same time. If this parameter is set to **0**, autonomous transactions cannot be executed.

Parameter type: integer.

Unit: none

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Value range: 0 to 10000. The theoretical maximum value is **10000**, and the actual maximum value is a dynamic value. The calculation formula is 262143 – **job_queue_processes** – **autovacuum_max_workers** – **max_inner_tool_connections** – **max_connections** – **AUXILIARY_BACKENDS** – **AV_LAUNCHER_PROCS**. The values of **job_queue_processes**, **autovacuum_max_workers**, **max_inner_tool_connections**, and **max_connections** depend on the settings of the corresponding GUC parameters. **AUXILIARY_BACKENDS** indicates the number of reserved auxiliary threads and is fixed at **20**. **AV_LAUNCHER_PROCS** indicates the number of launcher threads reserved for autovacuum and is fixed at **2**.

Default value:

- Independent deployment: **160** (128-core CPU/1024 GB memory); **80** (60-core CPU/480 GB memory); **40** (32-core CPU/256 GB memory); **20** (16-core CPU/128 GB memory); **10** (8-core CPU/64 GB memory, 4-core CPU/32 GB memory, 4-core CPU/16 GB memory)

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Suggestion: Set this parameter based on actual service requirements and hardware configurations. It is recommended that this parameter be set to a value less than or equal to 1/10 of **max_connections**. If you only increase the value of this parameter but do not adjust the memory parameters in the same proportion, the memory may be insufficient and the error message "memory is temporarily unavailable" is displayed when the service load is heavy.

Risks and impacts of improper settings: If the value range of this parameter is changed during the upgrade and the value is changed before the commit operation, you need to change the value range to the value allowed before the upgrade if you roll back the upgrade. Otherwise, the database may fail to be started.

cluster_run_mode

Parameter description: Specifies whether a CN or DN belongs to the primary or standby cluster in a dual-cluster DR scenario. The default value is used for a single cluster.

Parameter type: enumerated type

Unit: none

Value range:

- **cluster_primary**: The node is in the primary cluster.
- **cluster_standby**: The node is in the standby cluster.

Default value: **cluster_primary**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Mark the parameter used by the standby cluster for DR. You are advised not to set the parameter.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Risks and impacts of improper settings: After the modification, the standby cluster for DR may be abnormal.

max_resource_package

Parameter description: Specifies the maximum number of threads that each DN can run concurrently on an acceleration database instance.

Parameter type: integer.

Unit: none

Value range: 0 to 2147483647

Default value: **0**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

enable_gpi_auto_update

Parameter description: Determines whether global indexes are updated by default in partition DDL commands.

Parameter type: Boolean

Unit: none

Value range:

- **on**: Global indexes are updated regardless of whether the partition DDL commands contain the UPDATE GLOBAL INDEX clause.
- **off**: Global indexes are not updated by default. They are updated during the DROP/TRUNCATE PARTITION operation only when the partition-level DDL commands specify the UPDATE GLOBAL INDEX clause, or when the **enable_drop_truncate_partition_keep_gpi** parameter is enabled.

Default value: **off**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Set this parameter based on service requirements.

Risks and impacts of improper settings: If this parameter is set to **off** and the partition DDL does not contain the UPDATE GLOBAL INDEX clause, the global index is unavailable. This parameter must be set to the same value on CNs and DNs. Otherwise, the global index function may be abnormal.

enable_drop_truncate_partition_keep_gpi

Parameter description: Specifies whether the global index remains valid upon the DROP/TRUNCATE PARTITION operation on a partitioned table.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter type: Boolean

Unit: none

Value range:

- **on**: The global index remains valid. In this case, the global index is always valid, regardless of whether the DROP/TRUNCATE PARTITION statement contains the UPDATE GLOBAL INDEX clause. This priority is higher than that of the **enable_gpi_auto_update** parameter and the UPDATE GLOBAL INDEX clause explicitly specified by the user.
- **off**: The global index is not always valid. In this case, the global index is always valid only when the DROP/TRUNCATE PARTITION statement contains the UPDATE GLOBAL INDEX clause or the **enable_gpi_auto_update** parameter is enabled.

Default value:

- For a newly installed database, the default value is **on**.
- For an upgraded database, the default value is **off**.

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Set this parameter based on service requirements.

Risks and impacts of improper settings: If this parameter is set to **off**, the global index becomes invalid when the DROP/TRUNCATE PARTITION statement does not contain the UPDATE GLOBAL INDEX clause and the **enable_gpi_auto_update** parameter is disabled. This parameter must be set to the same value on CNs and DNs. Otherwise, the global index function may be abnormal.

enable_gpi_fast_prune

Parameter description: Specifies whether to vacuum dead tuples generated by previous DDL operations during DML operations on the global partitioned index (GPI) of a Ustore table.

Parameter type: Boolean

Unit: none

Value range:

- **on**: The vacuum mechanism is enabled. Dead tuples generated by DDL operations are vacuumed not only using the autovacuum thread but also when the index page space is insufficient during DML operations.
- **off**: The vacuum mechanism is disabled. Dead tuples generated by DDL operations are vacuumed only using the autovacuum thread.

Default value: **on**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Set this parameter based on service requirements. You are advised to enable this parameter in service scenarios where high-frequency DDL/DML operations exist and GPIs are used. You are advised to disable this

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

parameter in service scenarios where GPIs are not used or partitioned table DDL operations are not performed.

Risks and impacts of improper settings: If this parameter is set to **off**, dead tuples generated by DDL operations are only vacuumed using the autovacuum thread. As a result, the GPI space may expand due to accumulation of invalid tuples, affecting query performance.

enable_cluster_resize

Parameter description: Specifies the unique identifier of the scale-out tool in the kernel. If this parameter is enabled, the current session is connected to the scale-out tool.

Parameter type: Boolean

Unit: none

Value range:

- **on**: The current session is connected to the scale-out tool.
- **off**: The current session is not connected to the scale-out tool.

Default value: **off**

Setting method: This is a SUSET parameter. Set it based on instructions provided in **Table 6-1**. Only the redistribution user and initial user can set this parameter in a session.

Setting suggestion: This parameter is used for internal O&M. Do not set it to **on** unless absolutely necessary.

Risks and impacts of improper settings: If this parameter is forcibly set to **on**, the kernel considers that the current session is a scale-out tool and can execute scale-out-related system functions or DDL APIs, which may cause misuse.

change_cluster_mode

Parameter description: Specifies whether the cluster is in the mode switchover process. Mode switchover refers to: A cluster with one primary and two standby nodes is switched to a cluster with one primary node, one standby node, and one log; a cluster with one primary node, one standby node, and one log is switched to a cluster with one primary and two standby nodes; standby DNs and log DNs in a cluster with one primary node, one standby node, and one log are switched to each other.

Parameter type: integer.

Unit: none

Value range: 0 to 2147483647

- The value **0** indicates that the cluster mode is not being switched.
- The value **1** indicates that the cluster mode is being switched.
- Other values are meaningless and have the same effect as the value **0**.

Default value: **0**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: This parameter specifies whether the read function of the standby node in a distributed system is available. If this parameter is set to **1**, the read function of the standby node in a distributed system cannot be used. Exercise caution when setting this parameter.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

enable_partrouting_optimization

Parameter description: Specifies whether to optimize the insertion of partitioned tables.

Parameter type: Boolean

Unit: none

Value range:

- **on**: The insertion of partitioned tables is optimized. For the INSERT SELECT statement, if the SELECT statement contains a constant partition key, partition routing needs to be performed only once for the INSERT statement, improving performance.
- **off**: The insertion of partitioned tables is not optimized. Before inserting each piece of data, you need to perform partition routing to determine the partitioned table to be inserted.

Default value: **on**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this parameter is disabled, the performance optimization effect brought by this parameter is not affected in some scenarios where data is inserted into partitioned tables.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

Constraints for optimizing the insertion of partitioned tables:

- Only the INSERT SELECT statement is supported.
- In INSERT INTO ta SELECT FROM tb, the column values in the SELECT result set must be constants for all partition key values inserted into table **a**.
  - INSERT INTO ta SELECT c,d FROM b WHERE tb.c='1' or SELECT '1' as c, d FROM tb: The result column **tb.c** is a constant.
  - INSERT INTO ta SELECT c,d FROM b WHERE tb.c=func('1');: If func() is neither a volatile function nor a stable/immutable function that contains non-constant parameters, **tb.c** can be determined as a constant.
  - If the column value is the return value of an aggregate function, for example, INSERT INTO ta SELECT count(c),d FROM b WHERE tb.c='1' group by c, d;, the count(c) cannot be determined as a constant.
- This optimization is not supported when the partition key is an auto-increment column, a generated column, or a column with a default value.
- The UPSERT clause is not supported.
- Tables that contain BEFORE and INSTEAD triggers are not supported because the data to be inserted may be changed.

enable_cross_partition_dead_row_cache

Parameter description: Specifies whether to enable cross-partition dead row vacuuming. This feature is mainly used for large Astore partitioned tables. It combines and vacuums dead tuple TIDs in different partitions to reduce the GPI access frequency and decouple the vacuum duration from the number of partitions. The vacuum duration is related only to the data volume. That is, when the data volume is the same, the time required for vacuuming a partitioned table is close to or the same as that for vacuuming an ordinary table. This feature is optimized in scenarios where there are a large number of partitions and GPIs.

Parameter type: Boolean

Unit: none

Value range:

- **on**: Cross-partition dead row vacuuming is enabled.
- **off**: Cross-partition dead row vacuuming is disabled.

Default value: **on**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this function is disabled, the VACUUM/AUTOVACUUM operation of the Astore table with GPI may be slow.

enable_art_tid_cache

Parameter description: Specifies whether to enable the ART cache for dead row TIDs. The Adaptive Radix Tree structure can be used to store TIDs to reduce the memory consumption of VACUUM. In this way, more TIDs can be cached with the same memory overhead, reducing the number of index scans on large tables. In

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

addition, the time complexity of searching for TIDs is reduced, improving the index vacuum efficiency.

Parameter type: Boolean

Unit: none

Value range:

- **on**: The TID of the dead row cached in the ART is enabled.
- **off**: The TID of the dead row cached in the ART is disabled.

Default value: **on**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this function is disabled, the VACUUM/AUTOVACUUM operation of the Astore table may be slow.

storage_debug_parameter

Parameter description: Specifies the debugging parameters of the storage module. This parameter is used only in the debug version.

Parameter type: string.

Unit: none

Value range: a string of storage configuration parameters separated by semicolons (;), for example, **"oid_threshold=100000;xid_stepsize=10"**.

- **oid_threshold**: maximum number of OIDs that can be applied for. The value ranges from 100000 to 4200000000. The default value is **4200000000**.
- **oid_stepsize**: step size for applying for OIDs. The value ranges from 1 to 4200000000. The default value is **1**.
- **xid_stepsize**: step size for applying for transaction XIDs. The value ranges from 1 to 100000. The default value is **1**.
- **toast_tuple_threshold**: tuple width required for creating a TOAST table. The value ranges from 100 to 7000. The default value is **2000**.

Default value: **""**.

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

enable_unique_checking_of_unusable_index

Parameter description: Specifies whether to block the insert and update operations when there is an unusable unique index in the table.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter type: Boolean

Unit: none

Value range:

- **on**: If a table contains an UNUSABLE unique index, an INSERT statement and an UPDATE statement that involves the index will report an error, prompting you to process the UNUSABLE unique index first.
- **off**: If a table contains an UNUSABLE unique index, INSERT and UPDATE statements that involve the index will not report errors.

Default value: **off**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Set this parameter based on service requirements. You are advised to set it to **on**.

Risks and impacts of improper settings: If this parameter is enabled, a large number of errors may be reported to ensure the UNIQUE constraint. If this parameter is disabled, duplicate data in the unique index column is inserted into the table. As a result, the index cannot be rebuilt.

NOTE

If this parameter is enabled:

- For an Astore table, an error is reported when an index column of a non-UNUSABLE index is updated because a new tuple is generated.
- For a Ustore non-partitioned table, no error is reported when the index column of a non-UNUSABLE index is updated. If the update is not performed in place, an error is reported when the index column of a non-UNUSABLE index is updated.
- For a Ustore partitioned table, when the UNUSABLE unique index is a global index, an error is reported if the new data and old data are not in the same partition after the partition key is updated because a new tuple is generated.
- For a Ustore partitioned table, if the UNUSABLE unique index is a local index that contains the partition key, an error is reported when the partition key is updated.

enable_verify_datafiles

Parameter description: Specifies whether to enable the verification function for data file mis-deletion. This function can only be used to detect mis-deletion of data files (files in the **base**, **global**, **pg_tblspc**, and **undo** directories) when the cluster is running properly. Mis-deletion detection includes only two scenarios: files are deleted by mistake (**rm**) or renamed (**mv**). There is a time difference between the mis-deletion of data files and the detection. If the database is shut down during this period, the mis-deleted files cannot be detected.

Parameter type: Boolean

Unit: none

Value range:

- **on**: The verification function for data file mis-deletion is enabled.
- **off**: The verification function for data file mis-deletion is disabled.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Default value: **off**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Set the value based on service requirements. After this function is enabled, the list of properly deleted files needs to be maintained and traversed for verification, which may affect the performance. In addition, the detection capability depends on the inotify capability of the system kernel. The maximum number of monitored directories (including subdirectories at each level) is specified by **fs.inotify.max_user_watches**, and the maximum number of messages that can be concurrently processed is specified by **fs.inotify.max_queued_events**. If the number of files to be deleted at the same time exceeds the value of **max_queued_events**, the message queue may overflow and the file deletion alarm may be lost.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

disable_indirect_table_updates

Parameter description: Specifies whether to prohibit multiple DML operations on the same table within a single query, including modifications performed by the main statement, CTEs, subqueries, and triggers.

This parameter is mainly used to mitigate risks associated with modifying the same table multiple times within a single query, such as execution sequence dependencies, trigger-based recursive modifications, non-deterministic results, and data consistency issues.

Parameter type: Boolean

Unit: none

Value range:

- **on**: Multiple DML operations cannot be performed on the same table within a single query.
- **off**: Multiple DML operations can be performed on the same table within a single query.

Default value: **off**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Set the value based on service requirements.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

NOTE

- When this parameter is enabled, DML operations cannot be performed again in a row trigger for the same table. However, if the outer DML operation is INSERT and the DML operation in the trigger for the same table is also INSERT, the DML operation is allowed in this scenario.
- In the scenario where a trigger is nested for self-update, if two triggers are called on the CN and DN respectively, the verification does not take effect.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

enable_hashbucket

Parameter description: Specifies whether to create a hash bucket table by default when CREATE TABLE is executed.

Parameter type: Boolean

Unit: none

Value range:

- **on**: A hash bucket table is created by default.
- **off**: A hash bucket table is not created by default.

Default value: **off**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value. Set this parameter to **on** only when hash bucket tables are required by default.

Risks and impacts of improper settings: After this parameter is set to **on**, the CREATE TABLE statement is used to create a segment-page hash bucket table instead of an ordinary page table by default. Hash bucket tables and ordinary page tables have different specifications and restrictions in terms of data storage mode, space usage, buffer usage, and other feature support. For details, see "Feature Usage Guidelines > Bucket Distributed Tables" in *Developer Guide*. Before using hash bucket tables, make sure you understand its meaning and fully verify the change in a test environment.

NOTE

- The **enable_hashbucket** parameter takes effect only on CREATE TABLE and CREATE TABLE AS statements.
- The **enable_hashbucket** parameter does not take effect in the following scenarios:
  - A table is created in the PG_CATALOG schema.
  - The initial user of the cluster executes the related table creation statement.
  - The CREATE TABLE LIKE statement is executed and **INCLUDING RELOPTIONS** or **INCLUDING ALL** is specified. (In this case, whether the new table is a hash bucket table is the same as that of the source table.)
  - The table to be created is not a persistent table (for example, a temporary table, global temporary table, or unlogged table).
  - The table to be created is not a hash distributed table (for example, a replication table or range distributed table).
  - The WITH clause in the table creation statement specifies that **segment** is **off** or **hashbucket** is **off**.
- When you set the **enable_hashbucket** parameter using method 1 or 2 in **Table 6-1**, you are advised to set the same value for all nodes in the cluster. If the parameter values on different nodes are different, whether the parameter takes effect is determined by the parameter value on the CN that delivers the table creation statement.
- Do not set this parameter to **on** during the upgrade observation period.

vacuum_truncate

Parameter description: Specifies whether to truncate consecutive idle tail pages during table vacuuming.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter type: Boolean

Unit: none

Value range:

- **on**: Consecutive idle tail pages are truncated during table vacuuming.
- **off**: Consecutive idle tail pages are not truncated during table vacuuming.

Default value: **on**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this parameter is set to **off**, the vacuum process does not truncate idle tail pages, which may cause space expansion of Astore tables.

NOTE

- This parameter is valid only for Astore tables and is invalid for hash bucket tables and segment tables.
- If this parameter conflicts with the table-level option **vacuum_truncate**, the table-level option takes precedence.
  - If the table-level **vacuum_truncate** is set to **on** and the global parameter is set to **off**, the VACUUM TRUNCATE function is enabled for the table.
  - If the table-level **vacuum_truncate** is set to **off** and the global parameter is set to **on**, the VACUUM TRUNCATE function is disabled for the table.
  - If the table-level parameter is not set, the global parameter determines whether to enable the VACUUM TRUNCATE function.

6.3.27 Wait Event

enable_instr_track_wait

Parameter description: Specifies whether to enable real-time collection of wait event information.

Parameter type: Boolean

Unit: none

Value range:

- **on** indicates that the function of collecting wait event information is enabled.
- **off** indicates that the function of collecting wait event information is disabled.

Default value: **on**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: You are advised to set it to **on**.

Risks and impacts of improper settings: If this parameter is disabled, wait events cannot be collected in real time, which makes it difficult to locate faults in a timely manner.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

enable_instr_track_wait is restricted by **track_activities**. If **track_activities** is disabled, wait events are not recorded.

6.3.28 Query

instr_unique_sql_count

Parameter description: Specifies the maximum number of unique SQL statements that can be collected in real time.

If the value decreases, the system clears the original data and collects statistics again. If the value increases, the system does not collect statistics again.

When the number of unique SQL records generated in the system (to view the statistics, query **dbe_perf.statement** or **dbe_perf.summary_statement**) is greater than the value of **instr_unique_sql_count**, the extra unique SQL records are not collected.

Parameter type: integer.

Unit: none

Value range: 0 to 2147483647. The value **0** indicates that the function of collecting unique SQL information is disabled.

Default value: **200000**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If the value is too large, the upper limit of the memory occupied by the dbe_perf.statement view increases. If the value is too small, the number of statements recorded in the view may be too small. As a result, no fault locating method is available, affecting the diagnosis of slow SQL statements.

instr_unique_sql_size

Parameter description: Specifies the maximum length of query information recorded by the unique SQL statements, full SQL statements, and ASP functions. If the actual length of a statement exceeds the value of this parameter, the statement will be truncated. The byte length is calculated based on the character set of the database where the query is executed.

Parameter type: integer.

Unit: bytes

Value range: 100 to 102400

Default value: **1024**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Setting suggestion: Retain the default value.

Risks and impact of improper configuration: If the value is too large, the upper limit of the memory occupied by the dbe_perf.statement view increases. If the value is too small, the statements recorded in the view may be incomplete. As a result, no fault locating method is available, affecting the diagnosis of slow SQL statements.

instr_unique_sql_combination_options

Parameter description: Specifies the configuration items of combining unique SQL statements of the same type. The value of this parameter consists of multiple configuration items separated by commas (,).

If this feature is enabled, the IDs of unique SQL statements of the same type are normalized, and the generated unique SQL strings are normalized.

Parameter type: string.

Unit: none

Value range: See **Table 6-52**.

NOTE

- When configuring the combination function, set the character string based on **Table 6-52**. Use commas (,) to separate multiple configuration items, for example, **SET instr_unique_sql_combination_options='in_clause';**.
- If this parameter is left blank, this function is disabled, for example, **SET instr_unique_sql_combination_options='';**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 6-52 Configuration items of the combination function

Configuration Item	Behavior Control
in_clause	Combines only fixed parameters and prepared binding parameters in the IN clause of the SELECT IN() statement. Example 1: **select * from example_table where column in (1,2,3);** Unique SQL string after combination: **select * from example_table where column in (1…n);** Example 2: **select * from example_table where column in ($1,$2,$3);** Unique SQL string after combination: **select * from example_table where column in ($1…$n);** Example 3: **select * from example_table where column in (1,2,$1,3,$2);** Unique SQL string after combination: **select * from example_table where column in (1…n,$1…$n);** Example 4: **select * from example_table where (column1, column2) in ((1, 'a'), (2, 'b'), (3, 'c'));** Unique SQL string after combination: **select * from example_table where (column1, column2) in ((1…n));**
forbid_select_for_update	Specifies whether the FOR UPDATE clause in the SELECT statement is involved in normalization calculation. If this option is enabled, **for update**, **for share**, **for update wait n**, **for update nowait**, **for update skip locks** are displayed in the normalized view and different values of **unique_sql_id** are generated. If this option is disabled, all the preceding clauses and statements without the for update clause are normalized into the same sentence and share the same **unique_sql_id**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Configuration Item	Behavior Control
temp_table	Specifies the calculation method of **unique_sql_id** for local temporary tables. If this option is disabled, the table OID is used as the table ID when the DML statement of the local temporary table calculates **unique_sql_id**. When the same operation is performed on the temporary tables with the same name created in different sessions, different **unique_sql_id** values are generated and displayed separately in the unique SQL-related views and functions. If the number of temporary tables created by service statements is controllable or the execution status of temporary table-related operations needs to be analyzed at the session level, you are advised to disable this option. If this option is enabled, the hash value of the table name string is used as the table ID when the DML statement of the local temporary table calculates **unique_sql_id**. In this case, tables with the same name but different table structures cannot be distinguished. When the same operation is performed on temporary tables with the same name created in different sessions, the same **unique_sql_id** is generated and can be displayed in the unique SQL-related views and functions. If there are a large number of same operations on local temporary tables with the same name in service statements, you are advised to enable this option to avoid generating too many records.

Default value: **"in_clause,forbid_select_for_update,temp_table"**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this parameter is modified, the Unique SQL ID of the merged query statement will be changed, affecting the SQL statements for which SQL patch has been created.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- During the upgrade, the parameter value before the upgrade is retained by default. When a new instance is delivered, the default value is **"in_clause, forbid_select_for_update,temp_table"**.
- For values of the bigint, real, float4, blob, numeric, decimal, number, dec, or integer type, if **in()** contains a single parameter or multiple parameters, two different **unique_sql_id** values are generated.
- After the **forbid_select_for_update** option is enabled, the constant *n* in the **for update wait** *n* clause is not normalized. Different constants are recorded as different statements. (The **for update wait 0** and **for update nowait** clauses have the same semantics and are normalized to the same clause. The statement columns in the dbe_perf.statement, gs_asp, and statement_history views record the statement whose execution time is earlier.)
- After **instr_unique_sql_combination_options** is modified, **unique_sql_id** generated by the statements related to the modification is different from the original **unique_sql_id**. The original SQL patch may become invalid. You need to install the SQL patch again based on the new **unique_sql_id**.

instr_unique_sql_track_type

Parameter description: Specifies how unique SQL statements are recorded.

Parameter type: enumerated type.

Unit: none

Value range:

- **top**: Only top-level SQL statements are recorded.
- **all**: All SQL statements are recorded.

Default value: **all**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

NOTE

- The default value of this parameter is **all**. Compared with **top**, the value **all** additionally records statistics about statements in the stored procedure, which causes performance loss for the execution of the stored procedure and more severe impact on the performance of statements that are executed quickly, such as simple expressions in the stored procedure.
- If this parameter is set to **top**, the OPEN CURSOR statement in the stored procedure is recorded.

unique_sql_retention_time

Parameter description: Specifies the interval for cleaning the unique SQL hash table. The default value is 30 minutes.

Parameter type: integer.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Unit: minutes

Value range: 1 to 3650

Default value: **30**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**. The value cannot contain a unit.

Setting suggestion: You are advised not to modify this parameter because this parameter has no function control point in the current version.

Risks and impacts of improper settings: Changing the value of this parameter may cause unexpected results in the cluster. Retain the default value.

enable_instr_rt_percentile

Parameter description: Specifies whether to enable the function of calculating the response time of 80% and 95% SQL statements in the system.

Parameter type: Boolean.

Unit: none

Value range:

- **on** indicates that the function is enabled.
- **off** indicates that the function is disabled.

Default value: **on**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: You are advised to enable the parameter.

Risks and impacts of improper settings: If this parameter is disabled, 80% and 95% SQL response time cannot be recorded. As a result, system performance cannot be directly monitored.

percentile

Parameter description: Specifies the percentage of SQL statements whose response time is to be calculated by the backend calculation thread.

Parameter type: string.

Unit: none

Value range: **"80,95"**

Default value: **"80,95"**

Setting method: This is a fixed INTERNAL parameter. It can be viewed but cannot be modified.

Setting suggestion: This parameter can only be viewed.

Risks and impacts of improper settings: none

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

instr_rt_percentile_interval

Parameter description: Specifies the interval at which the background calculation thread calculates the SQL response time.

Parameter type: integer

Unit: seconds

Value range: 0 to 3600

Default value: **10**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**. For example, if the value is **60** without a unit, **instr_rt_percentile_interval** indicates 60s. If the value is **1min**, **instr_rt_percentile_interval** indicates 1 minute. The unit must be **s**, **min**, or **h**, if required.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

enable_instr_cpu_timer

Parameter description: Specifies whether to capture the CPU time consumed during SQL statement execution.

Parameter type: Boolean.

Unit: none

Value range:

- **on** indicates that the CPU time consumed during SQL statement execution is captured.
- **off** indicates that the CPU time consumed during SQL statement execution is not captured.

Default value: **on**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: You are advised to enable the parameter.

Risks and impacts of improper settings: If this parameter is disabled, the CPU time consumed by SQL execution in the system may not be recorded, which affects slow SQL analysis.

perf_directory

Parameter description: Specifies the directory of the output file of the performance view dotting task. Only the SYSADMIN user can access this parameter. The value can be an absolute path, or relative to the data directory.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- Valid path: Users have read and write permissions on the path.
- Invalid path: Users do not have read or write permission on the path.

Parameter type: string.

Unit: none

Value range: valid path of a directory.

Default value: specified during installation.

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If **perf_directory** in the configuration file is set to an invalid path, the cluster cannot be restarted.

enable_stmt_track

Parameter description: Specifies whether to enable Full/Slow SQL capture.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: Full/Slow SQL capture is enabled.
- **off**: Full /Slow SQL capture is disabled.

Default value: **on**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

track_stmt_parameter

Parameter description: After **track_stmt_parameter** is enabled, the executed statements recorded in **statement_history** are not normalized. The complete SQL statement information can be displayed to help the database administrator locate faults. For a simple query, the complete statement information is displayed. For a PBE statement, the complete statement information and information about each variable value are displayed. The format is **"query string; parameters: *$1=value1,$2=value2,...*"** This parameter is used to display full SQL information. You can set the GUC parameter to control the memory, preventing the **query** parameter from occupying too much memory when it is a long string or a large object. The memory control of full SQL information is divided into two parts. The SQL statement part is controlled by the **instr_unique_sql_size** parameter, and the SQL parameter part is controlled by the **track_stmt_mem_ctl** parameter. After this

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

parameter is enabled, the P packets in statement_history may not record query information. Changing the value of this parameter does not affect the SQL statements that are being executed. When the SQL bypass logic is executed in PBE statements, the parameters are directly delivered to DNs. Therefore, you cannot obtain complete statement information by querying statement_history on CNs. In addition, because DNs do not have the query string information, you cannot obtain complete statement information by querying statement_history on DNs.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The function of displaying complete SQL statement information is enabled.
- **off**: The function of displaying complete SQL statement information is disabled.

Default value: **off**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If most SQL statements are long, more memory and disk space are occupied.

track_stmt_session_slot

Parameter description: Specifies the maximum number of full/slow SQL statements that can be cached in a session. If the number of full/slow SQL statements exceeds this value, new statements will not be traced until the flush thread flushes the cached statements to the disk to reserve idle space.

Parameter type: integer.

Unit: none

Value range: 0 to 2147483647

Default value: **1000**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: The memory of each occupied slot is about 800 bits. The specific value depends on the statement complexity. In scenarios with heavy service pressure, if the value is too large, the memory usage will increase rapidly. If the value is too small, some statements to be analyzed may be missed.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

track_stmt_details_size

Parameter description: Specifies the maximum size of execution events that can be collected by a single statement. The value of this parameter affects the lock information of the **details** column in the **statement_history** table.

Parameter type: integer.

Unit: byte

Value range: 0 to 100000000

Default value: **4096**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**. The value cannot contain a unit.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

track_stmt_retention_time

Parameter description: Specifies the retention period of full SQL statements and slow SQL statements in the **statement_history** table and the retention period of files that have been flushed to disks on the standby node. This is a combination of parameters. This parameter is read every 60 seconds and records exceeding the retention period are deleted. Only the SYSADMIN user can access this parameter.

Parameter type: string.

Unit: none

Value range:

This parameter consists of two parts in the format of **'full sql retention time, slow sql retention time'**. The meanings of the two parts are as follows:

- **full sql retention time**: The retention period of full SQL statements. The value ranges from 0 to 86400. The unit is second.
- **slow sql retention time**: The retention period of slow SQL statements. The value ranges from 0 to 604800. The unit is second.

Default value: **"3600,604800"**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If the retention period is too long, a large amount of space may be occupied. If the retention period is too short, the data retention period may be too short. As a result, no fault locating method is available, affecting diagnosis.

track_stmt_stat_level

Parameter description: Determines the level of statement execution tracing.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter type: string.

Unit: none

Value range:

This parameter consists of two parts in the format of **'full sql stat level, slow sql stat level'**. The meanings of the two parts are as follows:

- The first part indicates the tracing level of full SQL statements. The value can be **OFF**, **L0**, **L1**, or **L2**.
- The second part indicates the tracing level of slow SQL statements. The value can be **OFF**, **L0**, **L1**, or **L2**.

NOTE

If the tracing level of full SQL statements is not OFF, the current SQL tracing level is the higher level (L2 > L1 >L0) of full SQL statements and slow SQL statements. (The **query_plan** column is still subject to the original trace level.) For details about the levels, see **Table 7-153**.

Default value: **"OFF,L0"**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If the full SQL tracing function is enabled, the performance is affected and a large amount of disk space may be occupied.

track_stmt_standby_chain_size

Parameter description: Specifies the maximum memory and disk space occupied by fast/slow SQL statement records on the standby node. This is a combination of parameters. Only the SYSADMIN user can access the database.

Parameter type: string.

Unit: none

Value range:

This parameter consists of four parts in the format of **'Full SQL memory size, Full SQL disk size, Slow SQL memory size, Slow SQL disk size'**. The meanings of the four parts are as follows:

Full SQL and slow SQL statements are stored in different locations. Therefore, four values are used for control.

- **Full SQL memory size**: The maximum memory space reserved for fast SQL statements. The value range is [16,1024], in MB.
- **Full SQL disk size**: The maximum disk space occupied by reserved fast SQL statements. The value range is [512,1048576], in MB.
- **Slow SQL memory size**: The maximum memory space reserved for slow SQL statements. The value range is [16,1024], in MB.
- **Slow SQL disk size**: The maximum disk space reserved for slow SQL statements. The value range is [512,1048576], in MB.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

The memory size cannot be greater than the disk size.

Default value: **"32, 1024, 16, 512"**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If the value is too large, a large amount of memory or disk space may be occupied. If the value is too small, some statements to be analyzed may be missed.

track_stmt_flush_mode

Parameter description: Specifies the storage mode of full SQL statements.

Parameter type: string.

Unit: none

Value range:

This parameter consists of two parts in the format of **'full sql flush mode, slow sql flush mode'**. The meanings of the two parts are as follows:

- The first part indicates the full SQL tracing mode. The value can be **MEMORY** or **FILE**. If this parameter is set to **MEMORY**, full SQL statements are recorded in the memory. If this parameter is set to **FILE**, full SQL statements are recorded in disk files.
- The second part indicates the slow SQL tracing mode. In the current version, the value can only be **FILE**. If this parameter is set to **FILE**, slow SQL statements are recorded in disk files.

Default value: **"FILE,FILE"**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this parameter is set to **"MEMORY,FILE"**, the kernel supports full SQL statements, which occupies certain shared memory. The memory size is specified by the **track_stmt_shm_size** parameter.

track_stmt_shm_size

Parameter description: Specifies the size of the full SQL shared memory.

Parameter type: integer

Unit: byte

Value range: 134217728 to 1073741824

Default value: **134217728**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

track_stmt_mem_ctl

Parameter description: Specifies the memory upper limit of each O&M sub-function.

Parameter type: string.

Unit: none

Value range: This parameter consists of three parts, that is, **'MESSAGE_MEM,GSTRACE_MEM,SQL_PARAM_MEM'**. The meanings are as follows:

- **MESSAGE_MEM**: When a statement is executed on the JDBC side, each time point is collected and sent to the database. This key is used to control the maximum number of bytes that can be received in the database. The received information is stored in the **driver_info** column in the **DBE_PERF.statement_history** table. The value ranges from 256 to 4096, in bytes.
- **GSTRACE_MEM**: The function dotting information is recorded in the memory. This key is used to control the memory size of the function dotting record of each SQL statement. The information is stored in the **details** column of the **DBE_PERF.statement_history** table. The value ranges from 0 to 104857600, in bytes.
- **SQL_PARAM_MEM**: The memory size of the SQL statement parameter part is controlled. That is, this parameter is valid only after **track_stmt_parameter** is enabled. For PBE statements, the complete statement information is displayed, and the value of each variable is added in the format of "query string;parameters:$1=value1,$2=value2..." In this case, the memory occupied by the parameters part is controlled. The value can be **0** or a number ranging from 100 to 102400, in bytes. The value **0** indicates that the length of the added parameters is not controlled and all parameter content is recorded.

Default value:
"MESSAGE_MEM=256,GSTRACE_MEM=2048,SQL_PARAM_MEM=1024"

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If the value is too large, too much memory may be occupied. If the value is too small, the number of statements recorded in the view may be too small. As a result, no fault locating method is available, affecting the diagnosis of slow SQL statements.

driver_traceid_level

Parameter description: Specifies the generation mode of the trace ID in the **DBE_PERF.statement_history** table.

Parameter type: string.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Unit: none

Value range: "none" and **"transaction"**

- **"none"**: The user-defined trace ID of the service is enabled to ensure compatibility with earlier versions.
- **"transaction"**: Statements in the same transaction use the same trace ID.

Default value: **"none"**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Adjust the value based on service requirements.

Risks and impacts of improper settings: none

track_stmt_wait_driver_threshold

Parameter description: Collects statistics about statement execution time in the JDBC. When the statistics are transmitted to the database within the time range specified by this parameter, the statistics are processed in the database and flushed to disks. The statistics are recorded in the **driver_info** column of the **DBE_PERF.statement_history** table. If timeout occurs, the information is discarded.

Parameter type: integer.

Unit: milliseconds

Value range: 0 to 60000. The value **0** indicates that the function of collecting unique SQL information is disabled.

Default value: **5000**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**. For example, if the value is **60000** without a unit, **track_stmt_wait_driver_threshold** indicates 60000 ms. If the value is **1min**, **track_stmt_wait_driver_threshold** indicates 1 minute. The unit must be **ms**, **s**, or **min** if required.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this parameter is set to a large value, SQL statements that fail to be executed occupy memory for a long time. As a result, statistics about newly executed SQL statements cannot be collected, and a large amount of memory is occupied.

enable_gstrace

Parameter description: Specifies whether to enable full-link GSTrace to trace kernel code execution.

Parameter type: Boolean.

Unit: none

Value range:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **on**: enabled.
- **off**: disabled.

Default value: **on**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: none

concurrent_dml_mode

Parameter description: Specifies how to handle concurrent DML execution conflicts (lock conflicts) in a table where the function of updating distribution keys is enabled (that is, the table attribute **enable_update_distkey** is set to **on**).

This parameter takes effect only on DNs.

Parameter type: integer

Unit: none

Value range: 0 to 1

- **0**: loose mode. That is, after a conflict occurs, the DML statement that obtains the lock later does not report an error.
- **1**: strict mode. If a conflict occurs, the DML statement that obtains the lock later terminates and reports an error.

Default value: **1**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Set this parameter based on the value range. If the DML statement that obtains the lock later does not report an error after a conflict is expected, set this parameter to **0**. If the DML statement that obtains the lock later terminates and reports an error after a conflict is expected, set this parameter to **1**.

Risks and impacts of improper settings: If this parameter is set to **0**, the DML statement that obtains the lock later may fail to obtain the data to be updated. Unexpected operations may occur during concurrent updates. For example, the later statement is successfully executed but does not take effect, or an extra data record is inserted using the MERGE INTO syntax. Therefore, change the parameter value after you fully understand the parameter meaning and test the parameter.

sql_hash_abort_list

Parameter description: Specifies the SQL exception blocking patch created based on the GUC parameter.

Parameter type: string.

Unit: none

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Value range: a single SQL hash value or multiple SQL hash values separated by commas (,).

Default value: ''

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: The performance may be affected, but the performance does not decrease by more than 5%.

NOTE

- Whether to block SQL statements is checked only on CNs and does not take effect on DNs.
- The valid range of SQL hash value is [1,4294967295].
- A maximum of 1,000 SQL hash values can be configured, and only the first 1,000 SQL hash values take effect.
- There is a low probability (1/4294967295) that hash conflicts occur in the exception blocking patch configured based on SQL hash values. As a result, irrelevant statements are blocked. You are advised to evaluate the risks.
- The configured SQL hash values do not distinguish databases and schemas. The same SQL statements in different databases and schemas are blocked.
- If multiple SQL execution paths contain the same internally executed SQL statement and the internally executed SQL statement is blocked, all external SQL statements that depend on the internally executed SQL statement are blocked. Exercise caution when performing this operation.

6.3.29 System Performance Snapshot

enable_perf_trigger

Parameter description: Specifies whether to enable the flame graph function for high seconds-level CPU usage.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The flame graph function is enabled for high seconds-level CPU usage.
- **off**: The flame graph function is disabled for high seconds-level CPU usage.

Default value: **on**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

perf_trigger_limit

Parameter description: Specifies the threshold for triggering flame graph collection due to high CPU usage. When the CPU usage exceeds the value of this parameter, a flame graph of high CPU usage is generated.

Parameter type: integer

Unit: %

Value range: 0 to 100

Default value: **90**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

perf_trigger_increase

Parameter description: Specifies the threshold for triggering flame graph collection due to high seconds-level CPU usage. When the increase rate of the system CPU usage compared with that in the previous second exceeds the value of this parameter, a flame graph of high seconds-level CPU usage is generated.

Parameter type: integer

Unit: %

Value range: 0 to 100

Default value: **30**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

enable_wdr_snapshot

Parameter description: Specifies whether to enable the database monitoring snapshot function.

Parameter type: Boolean.

Unit: none

Value range:

- **on** indicates that the database monitoring snapshot function is enabled.
- **off** indicates that the database monitoring snapshot function is disabled.

Default value: **on**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: You are advised not to enable this function in the following scenarios:

- In multi-table and multi-database scenarios, WDR snapshots are recorded in each database in serial mode, which takes a long time. Therefore, you are advised not to enable it.
- In the multi-table scenario, the query speed of the pg_stat_all_tables is slow due to the performance problems of some internal tables. In this case, the generation speed of WDR snapshot function is slow. Therefore, you are advised not to enable it.
- If WDR snapshots are generated during a large number of DDL operations, the generation may fail. Therefore, you are advised not to enable it.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

enable_wdr_snapshot_standby

Parameter description: Specifies whether the WDR function is supported on a distributed standby node. If this parameter is enabled, WDR snapshots obtain the performance data of the standby node and store the data on the primary node. This parameter takes effect only in GTM-free mode, that is, **enable_gtm_free** is set to **on**.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The distributed standby node supports the WDR function.
- **off**: The distributed standby node does not support the WDR function.

Default value: **off**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value. If you want to adjust the value, make sure you understand the parameter meaning and adjust the value with caution to avoid risks caused by misoperations.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

NOTE

To set **enable_wdr_snapshot_standby** to **on**, the following conditions must be met:

- The value of **wal_level** is **logical** or **hot_standby**.
- The value of **hot_standby** is **on**.
- In distributed standby node read mode, **gtm_option** is set to **2** or **enable_gtm_free** is set to **on**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

enable_show_standby_name

Parameter description: Specifies whether to display the names of the primary and standby nodes in the same shard. The names are used to distinguish the primary and standby nodes. This parameter is used to distinguish primary and standby DNs by **node_name** in the performance view that is queried. If this parameter is enabled, different names are returned when pgxc_node_str() is queried on different nodes of the same shard.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The function of distinguishing primary and standby node names is enabled.
- **off**: The function of distinguishing primary and standby node names is disabled.

Default value: **off**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

enable_wdr_cache

Parameter description: This parameter is used to adjust the status of the GUC parameter **enable_gsstat_cache** for WDR background threads. If **enable_wdr_cache** is set to **on**, **enable_gsstat_cache** is set to **on** for WDR backup threads. Otherwise, **enable_gsstat_cache** is set to **off**.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: Set **enable_gsstat_cache** to **on**.
- **off**: Set **enable_gsstat_cache** to **off**.

Default value: **on**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

wdr_snapshot_retention_days

Parameter description: Specifies the number of days database monitoring snapshots are retained. If the number of snapshots generated during database

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

running exceeds the maximum number of snapshots that can be generated within the retention period (24 x 8 = 192 by default), the system deletes the snapshots with the smallest ID at an interval specified by the value of **wdr_snapshot_interval**.

NOTE

This parameter is valid only when **enable_wdr_snapshot** is set to **on**.

Parameter type: integer

Unit: day

Value range: 1 to 30

Default value: **8**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**. The value cannot contain a unit.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: A larger value of this parameter indicates the higher disk usage.

wdr_snapshot_query_timeout

Parameter description: Specifies the execution timeout for the SQL statements associated with database monitoring snapshot operations. If the execution of a statement is not complete within the specified time and the result is returned, the snapshot operation fails, but some snapshots that have been generated are retained.

Parameter type: integer

Unit: seconds

Value range: 0 to 2147483647

Default value: **100**

Setting method: This parameter is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**. The value **0** indicates that there is no timeout limit. For example, if the value is **60** without a unit, **wdr_snapshot_query_timeout** indicates 60s. If the value is **1min**, **wdr_snapshot_query_timeout** indicates 1 minute. The unit must be **s**, **min**, **h**, or **d** if required.

Setting suggestion: Set this parameter based on the actual scenario. If you do not care about the data in the snapshot and want to quickly generate a snapshot, set this parameter to a smaller value. If you want to ensure that the data in the snapshot is complete, set this parameter to a larger value.

Risks and impacts of improper settings: If snapshot generation times out, a larger value of this parameter results in a longer timeout period. As a result, the snapshot generation time is prolonged, but the data in the snapshot is more complete.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

wdr_snapshot_interval

Parameter description: Specifies the interval at which the background thread snapshot automatically takes snapshots of the database monitoring data.

NOTE

This parameter is valid only when **enable_wdr_snapshot** is set to **on**.

Parameter type: integer

Unit: minute

Value range: 10 to 60

Default value: **60**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**. For example, if the value is **60** without a unit, **wdr_snapshot_interval** indicates 60 minutes. If the value is **1h**, **wdr_snapshot_interval** indicates 1 hour. The unit must be **min**, **h**, or **d** if required.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: A smaller value of this parameter indicates the larger disk usage.

wdr_snapshot_space_threshold

Parameter description: Specifies the threshold at which the space used by snapshots is controlled. When the space used by snapshots reaches 50% of the value of this parameter, the control logic of the database is enabled to stabilize the space used by the snapshots.

NOTE

- This parameter is valid only when **enable_wdr_snapshot** is set to **on**.
- If this parameter is set to a value smaller than the space used by the snapshots, the space usage does not shrink. Instead, the control logic is enabled to control the snapshot growth and stabilize the space used by the snapshots.

Parameter type: integer

Unit: KB

Value range: 0 to 107374182400

Default value: **0**, indicating that the function of controlling the space used by snapshots based on the space threshold is disabled.

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**. For example, if the value is **1024** without a unit, **wdr_snapshot_space_threshold** indicates 1024 KB. If the value is **1MB**, **wdr_snapshot_space_threshold** indicates 1 MB. The unit must be KB, MB, or GB if required.

Setting suggestion: Set this parameter based on the actual scenario.

Risks and impacts of improper settings: If this parameter is incorrectly set, only the latest group of snapshots is available.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

wdr_snapshot_full_backup_interval

Parameter description: Specifies the interval at which a full WDR snapshot is created. The interval specified by this parameter is about a number instead of time. For example, if the parameter is set to **12**, a full snapshot and then 11 incremental snapshots are generated for each group. If the parameter is set to **1**, all snapshots generated are full snapshots.

NOTE

- This parameter is valid only when **enable_wdr_snapshot** is set to **on**.
- If you change the value of this parameter after multiple snapshots have been generated, the next snapshot will be a full snapshot. For example, after five WDR incremental snapshots have been generated, if the parameter value is changed to **10**, a full snapshot will be generated before a new interval starts.
- When a snapshot is deleted, other snapshots in the same group are deleted. The number of snapshots to be deleted depends on the value of this parameter when the earliest group of snapshots is generated and is irrelevant to the current value.

Parameter type: integer

Unit: none

Value range: 1 to 24

Default value: **12**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Set this parameter based on the actual scenario.

Risks and impacts of improper settings: A smaller value of this parameter indicates more full snapshots and fewer snapshots that can be retained with the same space usage.

enable_asp

Parameter description: Specifies whether to enable the active session profile (ASP) function.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The ASP function is enabled.
- **off**: The ASP function is disabled.

Default value: **on**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

enable_asp_standby

Parameter description: Specifies whether the standby node is enabled for ASP. After this function is enabled, the collected data of the standby node is obtained synchronously when the ASP is sampled.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The standby node function is enabled for ASP. ASP obtains the data collected from all standby nodes.
- **off**: The standby node function is disabled for ASP.

Default value: **on**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

asp_flush_mode

Parameter description: Specifies the mode for the ASP to update data to the disk. The value can be **"file"** (default value), **"table"** (system catalog), or **"all"** (system catalog and file). Only the SYSADMIN user can access this parameter.

Parameter type: string.

Unit: none

Value range: **"table"**, **"file"**, and **"all"**

Default value: **"table"**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

asp_flush_rate

Parameter description: When the number of samples reaches the value of **asp_sample_num**, the samples in the memory are updated to the disk based on a certain proportion. **asp_flush_rate** indicates the update proportion. If this parameter is set to **10**, it indicates that the update ratio is 10:1.

Parameter type: integer

Unit: none

Value range: 1 to 10

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Default value: **10**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If the value is too small, the amount of data flushed to disks increases.

asp_flush_interval

Parameter description: Specifies the interval at which ASP flushes data.

Parameter type: integer

Unit: seconds

Value range: 300 to 3600

Default value: **300**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**. For example, if the value is **60** without a unit, **asp_flush_interval** indicates 60s. If the value is **1min**, **asp_flush_interval** indicates 1 minute. The unit must be **s**, **min**, or **h**, if required.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

asp_log_filename

Parameter description: Generates the file name format when writing files using ASP. Only the SYSADMIN user can access this parameter.

Parameter type: string.

Unit: none

Value range: valid character string in the file name format.

Default value: **"asp-***%Y-%m-%d_%H%M%S***.log"**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

asp_retention_days

Parameter description: Specifies the maximum number of days for reserving ASP samples when they are written to the system catalog.

Parameter type: integer

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Unit: day

Value range: 1 to 7

Default value: **2**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**. The value cannot contain a unit.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If the value is too large, the disk space occupied by the gs_asp system catalog increases.

asp_sample_interval

Parameter description: Specifies the sampling interval.

Parameter type: integer

Unit: seconds

Value range: 1 to 10

Default value: **1**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**. For example, if the value is **10** without a unit, **asp_sample_interval** indicates 10s. If the value is **10s**, **asp_sample_interval** indicates 10s. The unit must be **s** if required.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

asp_sample_num

Parameter description: Specifies the maximum number of samples allowed in the LOCAL_ACTIVE_SESSION view. Only the SYSADMIN user can access this parameter.

Parameter type: integer

Unit: none

Value range: 10000 to 100000

Default value: **100000**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

asp_log_directory

Parameter description: Specifies the directory for storing ASP log files on the server when **asp_flush_mode** is set to **all** or **file**. It can be an absolute path or a

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

relative path (relative to the data directory). Only the SYSADMIN user can access the path.

NOTE

- Valid path: Users have read and write permissions on the path.
- Invalid path: Users do not have read or write permission on the path.

Parameter type: string.

Unit: none

Value range: valid path of a directory.

Default value: specified during installation.

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Set this parameter after thorough tests and verification.

Risks and impacts of improper settings: If **asp_log_directory** in the configuration file is set to an invalid path, the cluster cannot be restarted.

gs_perf_interval

Parameter description: Specifies the interval at which the stacks are collected automatically.

Parameter type: floating-point number

Unit: minute

Value Range: 0 to 60. **0** indicates that the function of automatically collecting stack information is disabled.

NOTE

The valid value ranges from 0.2 to 60. If you attempt to set this parameter to a non-zero value less than 0.2, the value will be automatically adjusted to the default value **5**.

Default value: **5**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**. For example, if the value is **60** without a unit, **gs_perf_interval** indicates 60 minutes. If the value is **1h**, **gs_perf_interval** indicates 1 hour. The unit must be **min**, **h**, or **d** if required.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If the value is too small, the collection frequency is high, which may affect the system performance. In addition, a large number of logs are generated, occupying a large amount of storage space. Before modifying this parameter, make sure you understand its meaning and fully verify the change in a test environment.

gs_perf_deploy_mode

Parameter description: Specifies the deployment status of the **gs_perf_service** collection process.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter type: string.

Unit: none

Value range: **"ROOT"**, **"DBUSER"**, and **"DISABLE"**

- **"ROOT"**: The collection process is deployed in the **ROOT** state and supports all flame graph collection functions.
- **"DBUSER"**: The collection process is deployed in the **DBUSER** state and supports only on-CPU flame graph collection functions.
- **"DISABLE"**: The collection process is deployed in the **DISABLE** state and does not provide the flame graph function.

Default value: **"ROOT"**

Setting method: This is a fixed INTERNAL parameter. It can be viewed but cannot be modified.

Setting suggestion: This parameter can only be viewed.

Risks and impacts of improper settings: none

gs_perf_freq

Parameter description: Specifies the frequency of automatically collecting stack information.

Parameter type: integer

Unit: Hz

Value range: 10 to 1000

Default value: **999**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**. The value cannot contain a unit.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

gs_perf_retention_days

Parameter description: Specifies the retention period of flame graph files.

Parameter type: integer

Unit: day

Value range: 1 to 8

Default value: **3**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**. The value cannot contain a unit.

Setting suggestion: Retain the default value.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

6.3.30 Black Box Parameters

blackbox_number

Parameter description: Specifies the maximum number of black box files that can be retained in the *$GAUSSLOG*/**gs_blackbox/***{nodename}* directory.

Parameter type: integer.

Unit: none

Value range: 0 to 10. **0** indicates that the black box function is disabled.

Default value: **5** (256-core CPU/2048 GB memory, 192-core CPU/1536 GB memory, 128-core CPU/1024 GB memory, 104-core CPU/1024 GB memory, 96-core CPU/1024 GB memory, 96-core CPU/768 GB memory, 80-core CPU/640 GB memory, 64-core CPU/512 GB memory, 60-core CPU/480 GB memory, 32-core CPU/256 GB memory, 16-core CPU/128 GB memory, 8-core CPU/64 GB memory, 4-core CPU/32 GB memory); **0** (4-core CPU/16 GB memory)

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this parameter is set to **0**, the black box function is disabled, and files in the *$GAUSSLOG*/**gs_blackbox/***{nodename}* directory are not managed or controlled. The gs_blackbox tool function is not affected.

blackbox_directory

Parameter description: Specifies the directory for storing black box temporary files.

Parameter type: string.

Unit: none

Value range: a string in the format of a valid directory. The file system type of the directory must be tmpfs.

Default value: **"/dev/shm"**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing. You can run the **df -TH** *[path]* command to query the file system type. The current user must have the read and write permissions on the newly specified directory. After the parameter is set and the node is restarted, you need to manually clear the files in the original directory.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

6.3.31 Security Configuration

enable_security_policy

Parameter description: Specifies whether the unified audit and dynamic data masking policies take effect.

NOTE

- Unified audit: The unified audit mechanism is a technology that implements efficient security audit management by customizing audit policies. After the administrator defines the audit object and audit behaviors, if the task executed by a user is associated with an audit policy, the corresponding audit behavior is generated and the audit log is recorded.
- Dynamic data masking: The dynamic data masking mechanism is a technology that protects privacy data by customizing masking policies. It can effectively prevent unauthorized users from accessing sensitive information while retaining original data.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The security policy is enabled.
- **off**: The security policy is disabled.

Default value: **off**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this parameter is set to **on**, system resources will be occupied and system performance will be affected.

unified_audit_location

Parameter description: Specifies the location where unified audit logs are recorded.

Parameter type: integer.

Unit: none

Value range: **0** and **1**

- **0**: Unified audit logs are recorded in the location configured for rsyslog.
- **1**: Unified audit logs are recorded in the traditional audit log file.

Default value: **0**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**. Before using unified audit logs to record audit logs, ensure that the GUC parameter **audit_enabled** is enabled.

Setting suggestion: Retain the default value.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Risks and impacts of improper settings: If unified audit logs are required to record audit logs, set this parameter to **1**. This setting will occupy the resources used by the traditional audit function.

use_elastic_search

Parameter description: Specifies whether to send unified audit logs to Elasticsearch. If **enable_security_policy** and this parameter are enabled, unified audit logs are sent to Elasticsearch through HTTP or HTTPS (used by default).

Parameter type: Boolean.

Unit: none

Value range:

- **on**: Unified audit logs are sent to Elasticsearch.
- **off**: Unified audit logs are not sent to Elasticsearch.

Default value: **off**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value. This parameter is enabled when unified audit logs need to be sent to the Elasticsearch system.

Risks and impacts of improper settings: If this parameter enabled, you need to ensure that Elasticsearch specified by **elastic_search_ip_addr** can be properly connected. Otherwise, the setting of **use_elastic_search** does not take effect.

elastic_search_ip_addr

Parameter description: Specifies the IP address of the Elasticsearch system. If HTTPS is used, the format is **https://***ip*:*port*:*username*. If HTTP is used, the format is **http://***ip*:*port*. In the preceding command, *ip* indicates the IP address of the Elasticsearch server. *port* indicates the listening port for Elasticsearch HTTP communication, and the value ranges from 9200 to 9299. *username* indicates the username used for registering an Elasticsearch account. The initial user is **elastic**. If the HTTPS protocol is used, you need to configure related certificates.

Parameter type: string.

Unit: none

Value range: valid IP address string or empty string.

Default value: **""**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value. This parameter is set when unified audit logs need to be sent to the Elasticsearch system and **use_elastic_search** is set to **on**.

Risks and impacts of improper settings: You need to ensure that the specified Elasticsearch can be properly connected. Otherwise, the setting of **use_elastic_search** does not take effect.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

is_sysadmin

Parameter description: Specifies whether the current user is an initial user.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The user is an initial user.
- **off**: The user is not an initial user.

Default value: **off**

Setting method: This is a fixed INTERNAL parameter. It can be viewed but cannot be modified.

Setting suggestion: This parameter can only be viewed.

Risks and impacts of improper settings: none

enable_tde

Parameter description: Specifies whether to enable the TDE function. Before creating an encrypted table, set this parameter to **on** and set **tde_key_info** for key information.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The TDE function is enabled.
- **off**: The TDE function is disabled.

Default value: **off**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: If this parameter is set to **on**, ensure that the key information in the **tde_key_info** parameter is correctly configured and the key service can be accessed properly. Otherwise, the TDE function cannot be used.

Risks and impacts of improper settings: If encrypted data exists, exercise caution when disabling this function. After this function is disabled, encrypted table data cannot be read and encrypted logs cannot be replayed. As a result, the node may be faulty (**FATAL**/**PANIC**), the database may fail to be restarted, or the database may be unavailable.

tde_key_info

Parameter description: If TDE is enabled, transparent data needs to access the external key service to implement key management. This parameter is used to configure information about the key service, such as the service address, identity authentication information, and project information.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter type: string.

Unit: none

Value range: Contact technical support.

Default value: **""**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Set this parameter based on the key service in use.

Risks and impacts of improper settings: If encrypted data exists, exercise caution when changing the value of this parameter. Incorrect configuration means that the key is lost. As a result, encrypted table data cannot be read and encrypted logs cannot be replayed. As a result, the node may be faulty (**FATAL**/**PANIC**), the database may fail to be restarted, or the database may be unavailable.

tde_request_kms_count

Parameter description: Specifies the number of attempts to access the key management service after the TDE function is enabled.

Parameter type: integer.

Unit: none

Value range: 1 to 10

Default value: **3**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this parameter is set to **1**, the key management service is requested only once, which cannot defend against intermittent network disconnection or jitter.

tde_index_default_encrypt

Parameter description: After this parameter is enabled, if you create an index whose base table is an encrypted table, the database automatically sets the index as an encrypted index, copies encryption parameters such as the algorithms and keys of the base table for the index, and encrypts the data of the index before storing it.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: Encryption parameters are automatically set for indexes of encrypted tables.
- **off**: Encryption parameters are not automatically set for indexes in encrypted tables.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Default value: **off**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: If indexes of all encrypted tables need to be encrypted, enable this parameter. You do not need to manually set indexes to encrypted indexes.

Risks and impacts of improper settings: If this parameter is set to **on**, indexes created in encrypted tables are automatically encrypted, affecting index query performance.

tde_encrypt_config

Parameter description: Specifies whether TDE supports Xlogs and undo logs.

Parameter type: string.

Unit: none

Value range: The value is in the format of **"key=value, key=value, ..."**, in which valid values of **key** and **value** are as follows.

key	value	Default Value	Function
log_encrypt	**on** or **off**	on	Specifies whether to encrypt Xlogs and undo logs.
log_algorithm	**aes_128_ctr** or **sm4_ctr**	aes_128_ctr	Specifies the algorithm for encrypting Xlogs and undo logs.
table_algorithm	**aes_128_ctr**, **sm4_ctr**, **aes_128_ctr_sha256_hmac**, **sm4_ctr_sm3_hmac**, or **aes_128_gcm**	aes_128_ctr	In the syntax CREATE .. SET (enable_tde=on, encrypt_algo=aes_128_ctr), if the **encrypt_algo** parameter is not set, the parameter set in **table_algorithm** is used by default.

Default value: **""**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value or adjust the value based on service requirements.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

block_encryption_mode

Parameter description: Specifies the block encryption mode used by the aes_encrypt and aes_decrypt functions for encryption and decryption.

Value type: enumerated type

Unit: none

Value range: **aes-128-cbc**, **aes-192-cbc**, **aes-256-cbc**, **aes-128-cfb1**, **aes-192-cfb1**, **aes-256-cfb1**, **aes-128-cfb8**, **aes-192-cfb8**, **aes-256-cfb8**, **aes-128-cfb128**, **aes-192-cfb128**, **aes-256-cfb128**, **aes-128-ofb**, **aes-192-ofb**, and **aes-256-ofb**. **aes** indicates the encryption or decryption algorithm. **128**, **192**, and **256** indicate the key length (unit: bit). **cbc**, **cfb1**, **cfb8**, **cfb128**, and **ofb** indicate the block encryption or decryption mode.

Default value: **aes-128-cbc**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value or adjust the value based on service requirements.

Risks and impacts of improper settings: The use of the aes_encrypt and aes_decrypt functions is affected.

enable_mac_check

Parameter description: Specifies whether label-based mandatory access control takes effect.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: Label-based mandatory access control takes effect.
- **off**: Label-based mandatory access control does not take effect.

Default value: **off**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value or adjust the value based on service requirements.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

allow_initialuser_exec_others_udf

Parameter description: Specifies whether the initial user is allowed to execute functions or stored procedures defined by other users.

Parameter type: Boolean.

Unit: none

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Value range:

- **on**: The initial user is allowed to execute functions or stored procedures defined by other users.
- **off**: The initial user is not allowed to execute functions or stored procedures defined by other users.

Default value:

- If a new version is directly installed, the default value is **off**.
- For a database upgraded from an earlier version, if the source version does not support this GUC parameter, the default value is **on**. If the source version supports this parameter, the current value of this parameter is retained after the upgrade.

Setting method: This is a SUSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Set this parameter to **off** to reduce the risk of unauthorized operations.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

allow_sysadmin_exec_others_udf

Parameter description: Specifies whether the SYSADMIN user is allowed to execute functions or stored procedures defined by other users.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The SYSADMIN user is allowed to execute functions or stored procedures defined by other users.
- **off**: The SYSADMIN user is not allowed to execute functions or stored procedures defined by other users.

Default value: **on**

Setting method: This is a SUSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Set this parameter to **off** to reduce the risk of unauthorized operations. The SYSADMIN user can set this parameter to **on** in sessions as required.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

enable_rls_match_index

Parameter description: Specifies whether indexes of a base table can be scanned based on target predicate conditions in row-level security scenarios. Target scenario: The row level security (RLS) policies are set and enabled in the base

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

table, and the query predicate contains the unleakproof system function or like operator.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: Base table indexes can be scanned in the target scenario.
- **off**: Base table indexes cannot be scanned in the target scenario.

Default value: **off**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value. If hotspot query statements belong to the target scenario and there are few row-level access policies in the base table, enabling this function significantly improves query performance.

Risks and impacts of improper settings: If this parameter is set to **on**, the bitmap scanning operator is switched to the lossy mode, and there are a large number of RLS policies, filtering predicates will be executed repeatedly, affecting performance.

NOTE

- The modification of this parameter affects the generation of the execution plan in the target scenario. You can manually invalidate the cache plan by reconnecting to the system or creating operators.
- If this parameter is enabled, the generation of the bitmap scanning operator is affected, and the RLS policy predicate is inserted into the Recheck filter condition. Therefore, when the operator is switched to the lossy mode and there are many RLS policies, the performance is affected.

restrict_nonsystem_relation_kind

Parameter description: Specifies whether the relationship object types created by users can be accessed.

Parameter type: string.

Unit: none

Value range:

- **""**: There is no restriction.
- **"view"**: The access to views created by the user is disabled.
- **"foreign-table"**: The access to foreign tables created by the user is disabled.

Default value: **""**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

When gs_dump is used to export data, access to views and foreign tables created by users must be disabled to prevent malicious attacks. The tool sets this parameter to **'view, foreign-table'** at the session level. You do not need to manually configure this parameter.

enable_tde_async_encryption

Parameter description: Specifies whether to enable the asynchronous TDE function.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The asynchronous TDE function is enabled.
- **off**: The asynchronous TDE function is disabled.

Default value: **off**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: If the service performance significantly deteriorates after the TDE function is enabled and all new data tables use the same asynchronous encryption data key, you are advised to enable this parameter to improve the performance.

Risks and impacts of improper settings: none

tde_async_dek

Parameter description: Stores the information about the asynchronous encryption key of transparent data, including the master key ID and data key ciphertext.

Parameter type: string.

Unit: none

Value range: a string.

Default value: **""**

Setting method: This is a SIGHUP parameter and cannot be set.

Setting suggestion: This parameter is automatically set by the database.

Risks and impacts of improper settings: none

tde_dkcache_remain_time

Parameter description: Specifies the validity period of the TDE key cache.

Parameter type: integer.

Unit: hour

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Value range: 0 to 1440

Default value: **1**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this parameter is set to **0** or a large value, the TDE key cache that is not used may remain in the database memory for a long time.

NOTE

- If this parameter is set to **0**, the TDE key cache takes effect permanently and is not cleared from the memory.
- If this parameter is set to a non-zero value, the TDE key cache is cleared from the memory only when it is not used for more than **tde_dkcache_remain_time** hours. (The cache is cleared every hour.)

enable_fips

Parameter description: Specifies whether to enable the FIPS mode. To enable the FIPS mode, set this parameter to **on** and ensure that the FIPS mode has been enabled in the operating environment.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The FIPS mode is enabled.
- **off**: The FIPS mode is disabled.

Default value: **off**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: If this parameter is set to **on**, ensure that the existing data does not use the algorithms that are not supported by FIPS. Otherwise, unexpected exceptions may occur.

Risks and impacts of improper settings: After this parameter is set to **on**, the existing data that uses the algorithms that are not supported by FIPS cannot be used (including but not limited to data import, export, backup, and restoration). As a result, unexpected exceptions may occur. You are advised not to enable the FIPS mode in an environment with data. If you need to enable the FIPS mode, ensure that the existing data does not use the algorithms that are not supported by FIPS.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- If this parameter is set to **on**, the GUC parameter **password_encryption_type** becomes invalid when it is set to **0**, **1**, or **3**. The SHA-256 algorithm is forcibly used to encrypt user passwords. Users whose historical passwords are encrypted using MD5 or SM3 cannot log in to the system.
- If this GUC parameter is set to **on**, errors can be intercepted and reported only for encryption and decryption functions, user creation, login, and TLS communication algorithms based on FIPS standards. To enter the FIPS mode, you need to configure OpenSSL to enter the FIPS mode. Otherwise, unexpected behavior may occur.

enable_thread_permission_down

Parameter description: Specifies whether to enable the background thread permission control. If this parameter is enabled, the background thread uses permissions of the gs_role_signal_backend role. If this parameter is disabled, the background thread uses the initial user permission.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The low permission mode is enabled.
- **off**: The low permission mode is disabled.

Default value:

- **on**: default value for a newly installed database.
- **off**: default value after an upgrade from a version earlier than 507.0.0 to the current version.

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Set this parameter to **on** to prevent background threads from exceeding their permissions.

Risks and impacts of improper settings: none

enableSeparationOfDuty

Parameter description: Specifies whether the separation of duties is enabled.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The separation of duties is enabled.
- **off**: The separation of duties is disabled.

Default value: **off**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this parameter is set to **on**, the permissions of a system administrator are restricted, and some operations that can be performed before may fail.

enable_nonsysadmin_execute_direct

Parameter description: Specifies whether non-SYSADMIN and non-MONADMIN users are allowed to execute the EXECUTE DIRECT ON statement.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: Any user is allowed to execute the EXECUTE DIRECT ON statement.
- **off**: Only users with the SYSADMIN or MONADMIN permission are allowed to execute the EXECUTE DIRECT ON statement.

Default value: **off**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

enable_access_server_directory

Parameter description: Specifies whether to allow non-initial users to create, modify, and delete directories.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: Non-initial users are allowed to create, modify, and delete directories.
- **off**: Non-initial users are not allowed to create, modify, or delete directories.

Default value: **off**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTICE

- To use the advanced package UTL_FILE to access files on the server, you must have the permissions on the specified directory.
- For security purposes, only the initial user can create, modify, and delete directories by default.
- If **enable_access_server_directory** is enabled, users with the SYSADMIN permission and users who inherit the permissions of the built-in role gs_role_directory_create can create directories. A user with the SYSADMIN permission, the owner of a directory, a user who is granted the DROP permission on the directory, or a user who inherits the permissions of the built-in role gs_role_directory_drop can delete the directory. A user with the SYSADMIN permission and the owner of a directory object can change the owner of the directory, and the user must be a member of the new owner.

6.3.32 HyperLogLog

hll_default_log2m

Parameter description: Specifies the number of buckets for HLL data. The number of buckets affects the precision of distinct values calculated by HLL. More buckets indicate a smaller deviation. The deviation range is as follows: $[-1.04/2^{hll_default_log2m \times 1/2}, +1.04/2^{hll_default_log2m \times 1/2}]$

Parameter type: integer.

Unit: none

Value range: 10 to 16

Default value: **14**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value or adjust the value based on service requirements.

Risks and impacts of improper settings: If the value is too small, the required precision cannot be met. If the value is too large, resources may be wasted.

hll_default_log2explicit

Parameter description: Specifies the default threshold for switching from the explicit mode to the sparse mode.

Parameter type: integer.

Unit: none

Value range: 0 to 12

- **0**: The explicit mode is skipped.
- 1 to 12: The mode is switched when the base value reaches $2^{hll_default_log2explicit}$.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Default value: **10**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value or adjust the value based on service requirements.

Risks and impacts of improper settings: If the value is too small, the required precision cannot be met. If the value is too large, resources may be wasted.

hll_default_log2sparse

Parameter description: Specifies the default threshold for switching from the **sparse** mode to the **full** mode.

Parameter type: integer.

Unit: none

Value range: 0 to 14

- **0**: The sparse mode is skipped.
- 1 to 14: The mode is switched when the base value reaches $2^{hll_default_log2sparse}$.

Default value: **12**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value or adjust the value based on service requirements.

Risks and impacts of improper settings: If the value is too small, the required precision cannot be met. If the value is too large, resources may be wasted.

hll_duplicate_check

Parameter description: Specifies whether the duplicate check is enabled by default.

Parameter type: integer.

Unit: none

Value range: 0 to 1

- **0**: The function is disabled by default.
- **1**: The function is enabled by default.

Default value: **0**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value or adjust the value based on service requirements.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Risks and impacts of improper settings: If this parameter is enabled, more resources may be consumed for duplicate check, but the accuracy of distinct value calculation is improved.

6.3.33 User-defined Functions

udf_memory_limit

Parameter description: Specifies the maximum physical memory that can be used when CNs and DNs execute UDFs. This parameter does not take effect in the current version.

Parameter type: integer

Unit: KB

Value range: 200 x 1024 to 2147483647

Default value: **204800** (that is, 200 MB)

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**. For example, if this parameter is set to **204800** without a unit, it indicates 204800 KB. If this parameter is set to **300MB**, it indicates 300 MB. The unit must be KB, MB, or GB if required.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

FencedUDFMemoryLimit

Parameter description: Specifies the virtual memory used by each fenced udf worker process.

Parameter type: integer

Unit: KB

Value range: 0 to 2147483647

Default value: **0**, indicating that the memory is not controlled.

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**. The value of this parameter can be specified without a unit, for example, **200** (indicating 200 KB), or with a unit, for example, **3MB**, (indicating 3 MB). The unit must be KB, MB, or GB if required.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

UDFWorkerMemHardLimit

Parameter description: Specifies the maximum value of **FencedUDFMemoryLimit**.

Parameter type: integer

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Unit: KB

Value range: 0 to 2147483647

Default value: **1048576**, that is, 1 GB.

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**. The value of this parameter can be specified without a unit, for example, **200** (indicating 200 KB), or with a unit, for example, **3MB**, (indicating 3 MB). The unit must be KB, MB, or GB if required.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

enable_udf_execute_direct

Parameter description: Specifies whether the EXECUTE DIRECT ON statement is allowed to execute user-defined functions, functions in the advanced packages DBE_SQL, PKG_SERVICE, and DBE_XMLGE, as well as DBE_UTILITY.EXEC_DDL_STATEMENT.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The EXECUTE DIRECT ON statement is allowed to execute user-defined functions, functions in the advanced packages DBE_SQL, PKG_SERVICE, and DBE_XMLGE, as well as DBE_UTILITY.EXEC_DDL_STATEMENT.
- **off**: The EXECUTE DIRECT ON statement is not allowed to execute user-defined functions, functions in the advanced packages DBE_SQL, PKG_SERVICE, and DBE_XMLGE, as well as DBE_UTILITY.EXEC_DDL_STATEMENT.

Default value: **off**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after you fully understand the parameter meaning and test the parameter to avoid unexpected results.

6.3.34 Scheduled Jobs

job_queue_processes

Parameter description: Specifies the number of jobs that can be concurrently executed.

Parameter type: integer.

Unit: none

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Value range: 0 to 1000

- Setting **job_queue_processes** to **0** indicates that the scheduled job function is disabled and that no job will be executed. (Enabling scheduled jobs may affect the system performance. At sites where this function is not required, you are advised to disable it.)
- Setting **job_queue_processes** to a value that is greater than **0** indicates that the scheduled job function is enabled and this value is the maximum number of jobs that can be concurrently processed.

After the scheduled job function is enabled, the job_scheduler thread polls the **pg_job** system catalog at a scheduled interval. The scheduled job check is performed every second by default.

Too many concurrent jobs consume many system resources, so you need to set the number of concurrent jobs to be processed. If the current number of concurrent jobs reaches the value of **job_queue_processes** and some of them expire, these jobs will be postponed to the next polling period. Therefore, you are advised to set the polling interval (the **Interval** parameter of the submit API) based on the execution duration of each job to avoid the problem that jobs in the next polling period cannot be properly processed because of overlong job execution time.

Default value: **10**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: If there are a large number of concurrent jobs at the same time, a small parameter value will cause job waiting, and a large parameter value will consume more system resources. Therefore, you are advised to set this parameter to **100**. You can adjust the parameter value based on system resource usage.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

enable_prevent_job_task_startup

Parameter description: Specifies whether to start the job thread.

Parameter type: Boolean

Unit: none

Value range:

- **on** indicates that the job thread is not started.
- **off** indicates that the job thread is started.

Default value: **off**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

6.3.35 Thread Pool

enable_thread_pool

Parameter description: Specifies whether to enable the thread pool function.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The thread pool function is enabled.
- **off**: The thread pool function is disabled.

Default value: **on**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: In low-concurrency persistent connection performance-sensitive scenarios, you are advised to disable this parameter. In other scenarios, you are advised to enable this parameter.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

enable_connect_thread_pool

Parameter description: Specifies whether to enable the thread pool authentication. This thread pool authentication is optimization for the thread pool connection mode and depends on the thread pool connection function. To use this function, you need to enable the thread pool parameter **enable_thread_pool**. The thread pool authentication function is enabled only when both **enable_connect_thread_pool** and **enable_thread_pool** are set to **true**. If **enable_connect_thread_pool** is set to **true** and **enable_thread_pool** is set to **false**, the thread pool authentication function is disabled.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The thread pool authentication is enabled.
- **off**: The thread pool authentication is disabled.

Default value:

- **on**: default value of the newly installed database.
- **off**: default value of the database after upgrade from versions earlier than 505.2.1.SPC0800.

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Enable this parameter in common scenarios.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Risks and impacts of improper settings: After this function is enabled, the jitter caused by high-concurrency connection setup on SQL services can be alleviated, but the connection access performance is reduced. If there are high requirements on the connection performance, you should properly configure the **connect_thread_pool_attr** parameter and the client timeout interval.

thread_pool_attr

Parameter description: Specifies the detailed attributes of the thread pool function. This parameter is valid only when **enable_thread_pool** is set to **on**. Only the SYSADMIN user can access this parameter.

Parameter type: string.

Unit: none

Value range:

This parameter is in the format of **'thread_num, group_num, cpubind_info, enable_thread_pool_auto_scaling'**. The meanings of each part are as follows:

- **thread_num** is the total number of initial threads in the thread pool, which can be dynamically expanded. The value ranges from 0 to 4096. The value **0** indicates that the database automatically configures the number of threads in the thread pool based on the number of CPU cores. If the value is greater than **0**, the number of threads in the thread pool is the same as the value of **thread_num**. You are advised to set the thread pool size based on the hardware configuration. The formula is as follows: Value of **thread_num** = Number of CPU cores x 3 to 5. The maximum value of **thread_num** is **4096**.
- **group_num** indicates the number of thread groups in the thread pool. The value ranges from 0 to 64. The value **0** indicates that the database automatically configures the number of thread groups in the thread pool based on the number of NUMA groups. If the value is greater than **0**, the number of thread groups in the thread pool is the same as the value of **group_num**.
- **cpubind_info** specifies whether the thread pool is bound to a core. The available configuration modes are as follows: 1. **'(nobind)'** indicates that no core is bound to threads. 2. **'(allbind)'** indicates that all queried CPU cores in the current system are bound to threads. 3. **'(nodebind: 1, 2)'** indicates that CPU cores in NUMA groups 1 and 2 are bound to threads. 4. **'(cpubind: 0-30)'** indicates that CPU cores 0 to 30 are bound to threads. 5. **'(numabind: 0-30)'**: CPU cores 0 to 30 in the NUMA group are bound to threads. When CPU core binding is specified, ensure that the number of NUMA groups is the same as the value of **group_num**. This parameter is case-insensitive.
- **enable_thread_pool_auto_scaling**: specifies whether to enable automatic scaling of the thread pool. This parameter is optional. The value **1** indicates that the function is enabled, and the value **0** indicates that the function is disabled. By default, this parameter is not set, indicating that the automatic scaling function of the thread pool is enabled.

Default value:

- Independent deployment: **'2048,2,(nobind)'** (128-core CPU/1024 GB memory); **'1024,2,(nobind)'** (60-core CPU/480 GB memory and 32-core CPU/256 GB memory); **'512,2,(nobind)'** (16-core CPU/128 GB memory);

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

'256,2,(nobind)' (8-core CPU/64 GB memory); **'128,2,(nobind)'** (4-core CPU/32 GB memory); **'64,2,(nobind)'** (4-core CPU/16 GB memory)

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: When the memory is sufficient and the CPU performance is good, increase the value of this parameter if the service requires more connections. Before changing the value, verify the change in the test environment.

Risks and impacts of improper settings: If the value of **thread_pool_attr** is greater than or equal to that of **max_connections**, all proc resources are occupied by the thread pool, causing proc resource insufficiency. You are advised to retain the default value. Before changing the values, check the specifications of the parameters and ensure that the hardware resources are sufficient. Otherwise, the cluster may be abnormal.

NOTE

Ensure that the sum of the number of threads specified by **thread_pool_attr** and the number of threads specified by **static_thread_pool_num** does not exceed min(4096, **max_connections**), and the value of **static_thread_pool_num** must be greater than the number of DN shards multiplied by the value of **group_num**. Otherwise, the static pool cannot be created.

connect_thread_pool_attr

Parameter description: Specifies the detailed attributes of the thread pool connection function. This parameter is valid only when **enable_thread_pool** and **enable_connect_thread_pool** are both set to **on**. Only the SYSADMIN user can access this parameter.

Parameter type: string.

Unit: none

Value range: **'auto'** or a character string in the format of '*thread_num, group_num, cpubind_info, enable_adjust_connect_pool*'.

- If the value is **'auto'**, the connection thread pool parameters are automatically calculated and set by the database based on the specifications of the deployed host. In the 4-core CPU scenario, the value is **'8,1,(cpubind:** *Two any bound valid CPUs***)'**. In other scenarios, the value is **'8,1,(nobind)'**.
- If the value is a character string consisting of configuration items, the format is '*thread_num, group_num, cpubind_info, enable_adjust_connect_pool*'. The configuration items are described as follows:
  - *thread_num*: total number of initial threads in the connection setup thread pool, which can be dynamically expanded. The value range is [1,Max(8,*Number of CPU cores*)] (that is, the lower limit is **1**, and the upper limit is the larger value between 8 and the number of CPU cores of the current deployment host). For example, if the total number of CPU cores of the current deployment host is 4, the upper limit of the number of threads in the connection setup thread pool is 4, which is less than 8. In this case, the upper limit is 8, and the value range of **thread_num** is [1,8]. If the total number of CPU cores of the current deployment host is 64, the upper limit of the number of threads in the connection setup

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

thread pool is 64, which is greater than 8. In this case, the upper limit is 64, and the value range of **thread_num** is [1,64]. The maximum number of threads is 500. If the value of **thread_num** is greater than the upper limit, scale-out is automatically disabled, and the number of threads in the connection thread pool does not change. If the value of **thread_num** is less than the upper limit, the value of the **enable_adjust_connect_pool** column is used to specify whether to enable scale-out.

- **group_num**: number of thread groups in the connection thread pool. The value is fixed to **1** and cannot be changed.
- **cpubind_info**: specifies whether the connection thread pool is bound to cores. The available configuration modes are as follows:
  - **'(nobind)'**: The connection thread pool is not bound to cores.
  - **'(allbind)'**: All CPUs that can be queried in the current system are used to bind threads to cores.
  - **'(nodebind: 1, 2)'**: CPUs in NUMA groups 1 and 2 are used to bind threads to cores.
  - **'(cpubind: 0-30)'**: CPUs 0 to 30 are used to bind threads to cores.
  - **'(numabind: 0-30)'**: CPUs 0 to 30 in the NUMA group are used to bind threads to cores. This parameter is case-insensitive.
- **enable_adjust_connect_pool**: specifies whether to disable the scale-out function of the connection thread pool. This parameter can be left empty. The default value is **0**, indicating that the scale-out function of the thread pool is enabled. If this parameter is set to **1**, the scale-out function is disabled. If the connection thread pool is overloaded, the emergency scale-out during the overload is not controlled by this parameter.

Default value: **'auto'**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: When the memory is sufficient and the CPU performance is good, increase the value of this parameter if the service requires more connections.

Risks and impacts of improper settings: Change the value after you fully understand the parameter meaning and test the parameter. If the value exceeds the value range, the GaussDB process cannot be started properly.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- The value of **thread_num** in this parameter affects the system as follows: If the value of **thread_num** is small, the connection thread pool occupies fewer resources. In the scenario of a large number of concurrent connections, the connection performance deteriorates and the overload resistance capability of the system is improved. If the value of **thread_num** is large, the connection thread pool occupies more system resources. In the scenario of a large number of concurrent connections, the connection performance improves, but the overload resistance capability of the system is affected. Set this parameter within the allowed range based on service requirements.
- If the connection setup thread pool cannot allocate threads to process connection setup sessions for 2 seconds, the thread pool is overloaded. In the overload state, the system preferentially responds to the latest connection setup session and forcibly closes the connection setup session that has been waiting for more than 2 seconds.

static_thread_pool_num

Parameter description: Specifies the number of threads used to create a static thread pool (static pool). This parameter takes effect only on distributed CNs after **enable_thread_pool** is enabled.

Parameter type: integer.

Unit: none

Value range: 0 to 1024

Default value: 10% x **group_num** x **thread_num**. For details about **group_num** and **thread_num**, see **thread_pool_attr**.

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- A static thread pool is created to prevent DNs from exhausting threads of the CN thread pool and ensure that available threads are connected to DNs to execute services.
- Ensure that the sum of the number of threads specified by **thread_pool_attr** and the number of threads specified by **static_thread_pool_num** does not exceed min(4096, **max_connections**), and the value of **static_thread_pool_num** must be greater than the number of DN shards multiplied by the value of **group_num**. Otherwise, the static pool cannot be created.
- **static_thread_pool_num** is a virtual value and does not take effect immediately after being set. When the CN thread pool is fully loaded or exhausted, the CN creates a number of threads specified by **static_thread_pool_num**. These threads make up a static pool.
- The static thread pool is included in the entire thread pool. After the static thread pool is configured, the maximum number of available worker threads decreases accordingly. For example, if the size of the static thread pool is set to **100** and the upper limit of the thread pool is set to **500**, the upper limit of the actual available normal threads is 400.
- The static thread pool occupies the number of connections. Therefore, the number of connections may not reach the value of **max_connections** due to the static thread pool. In this case, you can disable the static thread pool to avoid this problem.
- The CN static pool is used for single-DN connection services and evenly allocates threads to each DN shard in the cluster. The calculation formula is as follows: **static_thread_pool_num**/*n* (*n* indicates the number of DN shards). If the number of threads used exceeds the calculated fixed quota, an error is reported.
- If the static pool thread is held by the multi-DN connection service, an error is reported and the threads are returned.
- Non-default thread groups cannot be created in a static pool in multi-tenant mode.
- If **static_thread_pool_num** is set to **0**, the static pool function is disabled. If you do not want the static pool to control multiple DN connections, disable this function.
- Restrictions on creating a static thread pool: The prerequisite is that the thread pool is enabled on the distributed CN. The current function resolves DN shard faults and ensures that the CN has available threads for services to ensure continuous services. If the design does not include the solution for the fully occupied thread pool due to single-CN query, querying services only on a single CN at the same time are not controlled or counted in statistics.

thread_pool_stream_attr

Parameter description: Specifies the detailed attributes of the stream thread pool function. This parameter is valid only when **enable_thread_pool** is set to **on** and only takes effect on DNs. Only the SYSADMIN user can access this parameter.

Parameter type: string.

Unit: none

Value range:

This parameter consists of the four parts **'stream_thread_num'**, **'stream_proc_ratio'**, **'group_num'**, and **'cpubind_info'**, whose meanings are as follows:

- **stream_thread_num** indicates the total number of threads in the stream thread pool. The value ranges from 0 to 4096. The value **0** indicates that the database automatically configures the number of threads in the thread pool based on the number of CPU cores. If the value is greater than **0**, the number of threads in the thread pool is the same as the value of

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

stream_thread_num. You are advised to set the thread pool size based on the hardware configuration. The formula is as follows: Value of **stream_thread_num** = Number of CPU cores x 3 to 5. The maximum value of **stream_thread_num** is **4096**.

- **stream_proc_ratio** indicates the ratio of proc resources reserved for stream threads. The value is a floating-point number. The default value is **0.2**. The reserved proc resources are calculated as follows: Value of **stream_proc_ratio** x Value of **stream_thread_num**.
- **group_num** indicates the number of thread groups in the thread pool. The value ranges from 0 to 64. The value **0** indicates that the database automatically configures the number of thread groups in the thread pool based on the number of NUMA groups. If the value is greater than **0**, the number of thread groups in the thread pool is the same as the value of **group_num**. The value of **group_num** in **thread_pool_stream_attr** must be the same as that in **thread_pool_attr**. If they are set to different values, the value of **group_num** in **thread_pool_attr** is used.
- **cpubind_info** specifies whether the thread pool is bound to a core. The available configuration modes are as follows: 1. **'(nobind)'** indicates that no core is bound to threads. 2. **'(allbind)'** indicates that all queried CPU cores in the current system are bound to threads. 3. **'(nodebind: 1, 2)'** indicates that CPU cores in NUMA groups 1 and 2 are bound to threads. 4. **'(cpubind: 0-30)'** indicates that CPU cores 0 to 30 are bound to threads. 5. **'(numabind: 0-30)'** indicates that CPU cores 0 to 30 in the NUMA group are bound to threads. This parameter is case-insensitive. The value of **cpubind_info** in **thread_pool_stream_attr** must be the same as that in **thread_pool_attr**. If they are set to different values, the value of **cpubind_info** in **thread_pool_attr** is used.

Default value:

- **stream_thread_num**: **16**
- **stream_proc_ratio**: **0.2**
- **group_num** and **cpubind_info**: For details, see **thread_pool_attr**.

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: When the memory is sufficient and the CPU performance is good, increase the value of this parameter if the service requires more concurrent performance.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

max_stream_threads

Parameter description: When the number of active stream threads (excluding those in the **sync quit** state) exceeds the value of **max_stream_threads**, the system waits until the number of active stream threads falls within the range specified by **max_stream_threads** before reusing or starting new stream threads.

When the number of stream threads exceeds the value of **max_stream_threads**, idle stream threads exit in batches by default until the number of stream threads

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

is less than or equal to the value of **max_stream_threads** or no idle stream thread exists.

This parameter takes effect only when **enable_thread_pool** is enabled.

Parameter type: integer.

Unit: none

Value range: 0 to 4096

Default value:

Independent deployment:

4096 (192-core CPU/1536 GB memory, 128-core CPU/1024 GB memory, 104-core CPU/1024 GB memory, and 96-core CPU/1024 GB memory); **2048** (96-core CPU/768 GB memory and 80-core CPU/640 GB memory); **1024** (64-core CPU/512 GB memory, 60-core CPU/480 GB memory, and 32-core CPU/256 GB memory); **128** (16-core CPU/128 GB memory); **64** (8-core CPU/64 GB memory); **32** (4-core CPU/32 GB memory); **16** (4-core CPU/16 GB memory)

Hybrid deployment

2048 (192-core CPU/1536 GB memory, 128-core CPU/1024 GB memory, 104-core CPU/1024 GB memory, 96-core CPU/1024 GB memory); **1024** (96-core CPU/768 GB memory, 80-core CPU/640 GB memory); **512** (80-core CPU/512 GB memory, 72-core CPU/576 GB memory, 64-core CPU/512 GB memory, 60-core CPU/480 GB memory, 32-core CPU/256 GB memory); **64** (16-core CPU/128 GB memory); **32** (8-core CPU/64 GB memory); **16** (4-core CPU/32 GB memory); **16** (4-core CPU/16 GB memory)

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: If the memory is sufficient and the CPU performance is good, increase the value of this parameter if the service requires higher parallel execution performance. Otherwise, decrease the value.

Risks and impacts of improper settings:

- If this parameter is set to a small value, the parallel execution plan cannot be generated, or the plan is queued while waiting for available stream threads, increasing the query delay.
- If this parameter is set to a large value and the number of CPU cores is small, the stream thread may occupy a large number of CPU resources, affecting the performance of other services.

NOTE

max_stream_threads is used to control the upper limit of stream threads on a single DN. If this parameter is set to **0**, the control is disabled.

stream_resource_control_attr

Parameter description: This parameter consists of three parts: **cpu_control_threshold**, **stop_stream_create_threshold**, and **os_run_queue_threshold**. They are used to control the CPU upper limit, the default error reporting threshold for new stream services, and the threshold for

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

the total number of running threads in the OS to exceed the number of CPU cores, respectively.

This parameter takes effect only when **enable_thread_pool** is enabled.

Parameter type: string.

Unit: none

Value range:

This parameter consists of three parts: **cpu_control_threshold**, **stop_stream_create_threshold**, and **os_run_queue_threshold**. The meanings of the three parts are as follows:

- **cpu_control_threshold**: threshold for controlling the CPU upper limit. The value ranges from 0 to 100.
- **stop_stream_create_threshold**: default error reporting threshold for new stream services. The value ranges from 0 to 100.
- **os_run_queue_threshold**: threshold for the total number of threads in the running state in the OS to exceed the multiple of the number of CPU cores. The value ranges from 0 to 100.

If the values of **cpu_control_threshold**, **stop_stream_create_threshold**, and **run_queue_threshold** are all **0**, this function is disabled.

When both **cpu_control_threshold** and **stop_stream_create_threshold** take effect, **cpu_control_threshold** must be smaller than or equal to **stop_stream_create_threshold**.

Default value:

- **cpu_control_threshold**: **0**
- **stop_stream_create_threshold**: **0**
- **os_run_queue_threshold**: **0**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

NOTE

When the CPU usage exceeds the value of **stop_stream_create_threshold**, the error message "Stream worker is temporarily unavailable. Try later..." is displayed when you attempt to start a new stream service.

thread_pool_idle_time

Parameter description: Specifies the idle time of a thread in the thread pool. When the idle time of a thread in the thread pool exceeds the value of this parameter, the thread exits and releases related memory resources. This parameter is valid only when **enable_thread_pool** is enabled. Only the SYSADMIN user can access this parameter. This parameter does not apply to threads in the authentication thread pool or static thread pool.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter type: integer.

Unit: seconds

Value range: 0 to 2147483647

Default value: **300**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: This parameter affects the number of threads in the thread pool. You are advised not to set this parameter to a small value. If this parameter is set to a small value, threads in the thread pool may be started and stopped more frequently, affecting the performance.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

resilience_threadpool_reject_cond

Parameter description: Specifies the percentage of thread pool usage for escape from overload. This parameter takes effect only when the GUC parameters **enable_thread_pool** and **use_workload_manager** are enabled.

Parameter type: string.

Unit: none

Value range:

This parameter consists of the two parts **recover_threadpool_percent** and **overload_threadpool_percent**, whose meanings are as follows:

- **recover_threadpool_percent**: specifies the thread pool usage when the thread pool recovers to the normal state. When the thread pool usage is less than the value of this parameter, the escape from overload function is disabled and new connections are allowed. The value ranges from 0 to *INT_MAX*. The value indicates a percentage.
- **overload_threadpool_percent**: specifies thread pool usage when the thread pool is overloaded. If the thread pool usage is greater than the value of this parameter, the current thread pool is overloaded. In this case, the escape from overload function is enabled to kill sessions and forbid new connections. The value ranges from 0 to *INT_MAX*. The value indicates a percentage.

Example:

```
resilience_threadpool_reject_cond = '50,90'
```

When the thread pool usage exceeds 90%, new connections are forbidden and stacked sessions are killed. When the thread pool usage decreases to 50%, session killing is stopped and new connections are allowed. The kill policy is as follows: idle sessions are killed first and then sessions are killed in sequence based on the session status (sessions with the same status are killed in ascending order of start time).

Default value: **'0,0'**, indicating that the thread pool escape function is disabled.

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

NOTE

- The thread pool usage can be queried in the DBE_PERF.local_threadpool_status view. The initial number of threads in the thread pool can be obtained by querying the **thread_pool_attr** parameter.
- If this parameter is set to a small value, the thread pool escape from overload process is frequently triggered. As a result, ongoing sessions are forcibly logged out, and new connections fail to be connected for a short period of time. Therefore, exercise caution when setting this parameter based on the actual thread pool usage.
- The values of **recover_threadpool_percent** and **overload_threadpool_percent** can be **0** at the same time. In addition, the value of **recover_threadpool_percent** must be smaller than that of **overload_threadpool_percent**. Otherwise, the setting does not take effect.
- If the **use_workload_manager** parameter is disabled and the **bypass_workload_manager** parameter is enabled, this parameter also takes effect. The **bypass_workload_manager** parameter is of the SIGHUP type; therefore, after the reload mode is set, you need to restart the database for the setting to take effect.
- After the parameter is dynamically set to **"0,0"**, if session killing has been started, the killing action will not be terminated. You can wait for more than 10 seconds and then connect to the database to prevent new connections from being killed.

6.3.36 Full-Text Search

ngram_gram_size

Parameter description: Specifies the tokenization length of the N-gram parser.

Parameter type: integer.

Unit: none

Value range: 1 to 4

Default value: **2**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: none

NOTE

This parameter cannot affect the parsing behaviors of pg_catalog.ngram and other text search configurations that explicitly specify **gram_size**. You need to use ALTER TEXT SEARCH CONFIGURATION to modify options of created configurations.

ngram_grapsymbol_ignore

Parameter description: Specifies whether the N-gram parser ignores graphical characters.

Parameter type: Boolean.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Unit: none

Value range:

- **on**: Ignore graphical characters.
- **off**: Do not ignore graphical characters.

Default value: **off**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: none

ngram_punctuation_ignore

Parameter description: Specifies whether the N-gram parser ignores punctuations.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: Ignore punctuations.
- **off**: Do not ignore punctuations.

Default value: **on**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: none

default_text_search_config

Parameter description: Specifies a full-text search configuration. The text search configuration is used by text search functions that do not have an explicit argument specifying the configuration.

Parameter type: string.

Unit: none

Value range: **"pg_catalog.english"**, **"pg_catalog.simple"**, **"pg_catalog.ngram"**, and **"pg_catalog.pound"**.

- **pg_catalog.english** and **pg_catalog.simple**: apply to English word tokenization scenarios.
- **pg_catalog.ngram**: applies to non-semantic Chinese word tokenization scenarios.
- **pg_catalog.pound**: applies to the non-semantic scenarios where the text to be parsed is separated by fixed separators.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

When a configuration file matching the environment is determined, gs_initdb will initialize the configuration file with a setting that corresponds to the environment.

Default value: **pg_catalog.english**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: none

Risks and impacts of improper settings: If the text search configuration does not exist, an error is reported. If the specified text search configuration is deleted, set **default_text_search_config** again. Otherwise, an error will be reported, indicating incorrect configuration.

tsearch_options

Parameter description: Specifies whether to enable full-text search.

Parameter type: string.

Unit: none

Value range: **configuration**, **dictionary**, and **debug_function**. If multiple options are configured, separate them with commas (,).

- **configuration**: allows full-text search for text configuration items, including CREATE/ALTER/DROP TEXT SEARCH CONFIGURATION syntax.
- **dictionary**: allows full-text search for dictionary syntax, including CREATE/ALTER/DROP TEXT SEARCH DICTIONARY.
- **debug_function**: allows full-text search for debugging functions, including the ts_debug, ts_parse, ts_token_type, ts_lexize, and ts_stat functions.

Default value:

- The default value for a newly installed cluster is **""**.
- After the database upgrade in a version earlier than 506.0.0, the default value is **"configuration,dictionary,debug_function"**.

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: none

6.3.37 Backup and Restoration

operation_mode

Parameter description: Specifies whether the system enters the backup and restoration mode.

Parameter type: Boolean.

Unit: none

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Value range:

- **on**: The backup and restoration mode is entered.
- **off**: The backup and restoration mode is not entered.

Default value: **off**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Changing the value of this parameter may cause unexpected results in the cluster. Retain the default value.

enable_cbm_tracking

Parameter description: Specifies whether to enable the CBM tracing function.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The cbm tracking is enabled.
- **off**: The cbm tracking is disabled.

Default value: **off**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Enable this parameter to perform full or incremental backup for the cluster by using Roach. Otherwise, the backup will fail.

Risks and impacts of improper settings: If this parameter is disabled, incremental backup will fail.

max_size_for_xlog_retention

Parameter description: Specifies when to forcibly update the backup replication slot or logical replication slot to prevent the disk from being full and the cluster from being read-only because logs cannot be recycled during backup or logical decoding.

Parameter type: integer.

Unit: none

Value range: –100 to 2147483647

- The value **0** indicates that this function is disabled.
- A negative value indicates that the backup replication slot or logic replication slot is forcibly updated when the disk usage exceeds the threshold and logs are recycled due to blocked backup operation or logical decoding. For example, **-80** indicates that the disk usage exceeds 80% of the threshold.
- A positive value indicates that the backup replication slot or logic replication slot is forcibly updated when the size of stacked logs exceeds the threshold

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

and logs are recycled due to blocked backup operation or logical decoding. For example, **32** indicates that the backup replication slot lags behind the redo location of the current checkpoint by more than 32 log segments. (The size of each log segment is 16 MB.)

Default value: **-80**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Set this parameter to a value slightly smaller than that of **datastorage_threshold_value_check** of the CM Server component to prevent the cluster from entering the read-only state.

Risks and impacts of improper settings: If the value is too small, backup may fail frequently.

max_cbm_retention_time

Parameter description: Specifies the interval at which CBM backup files are forcibly recycled. If CBM files cannot be recycled during backup, the disk will be full and the cluster will be read-only.

Parameter type: integer.

Unit: second

Value range: 86400 to 2147483647

Default value: **1209600** (that is, 14 days)

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**. For example, if this parameter is set to **86400** without a unit, it indicates 86400s. If this parameter is set to **1d**, it indicates 1 day. The unit must be **s**, **min**, **h**, or **d** if required.

Setting suggestion: Set this parameter based on the full backup interval.

Risks and impacts of improper settings: If the value is too small, backup may fail frequently.

enable_standby_move_buckets

Parameter description: Specifies whether a CN is allowed to connect to a standby node to move buckets. This parameter is used only for cluster-level restoration. When restoring the backup set generated during hash bucket redistribution, this parameter is used to establish a connection with the standby DN when the CN sends the buckets migration command to the DN. This parameter takes effect only in this connection. In other cases, the value is **off**.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The standby node can receive connections.
- **off**: The standby node cannot receive connections.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Default value: **off**

Setting method: This is a BACKEND parameter and cannot be set or reloaded using gs_guc. This parameter does not take effect when written into the configuration file. It is used only as an O&M parameter for data restoration.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Changing the value of this parameter may cause unexpected results in the cluster. Retain the default value.

hadr_max_size_for_xlog_receiver

Parameter description: Specifies the synchronization progress difference threshold between archive log download and log replay. When the progress difference exceeds the threshold, the system automatically suspends archive log download to avoid log accumulation and resource overload.

Parameter type: integer.

Unit: KB

Value range: 0 to 2147483647

Default value: **268435456**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If the value is too small, the download of archive logs may be frequently suspended.

6.3.38 Undo

The GUC parameter of undo is valid only for the Ustore.

undo_space_limit_size

Parameter description: Specifies the threshold for forcibly recycling undo space. When the undo space usage reaches 80% of the threshold, forcible recycling starts. You are advised to set **undo_space_limit_size** to a value greater than or equal to that of **undo_limit_size_per_transaction**.

Parameter type: integer.

Unit: page (8 KB)

Value range: 102400 to 2147483647. The default unit is page.

Default value: **33554432** (that is, 256 GB)

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**. For example, the value **1000000** indicates 1,000,000 pages, and the value **1000000kB** indicates 1,000,000 KB. If the value contains a unit, the value can be KB, MB, or GB, but cannot be TB.

Setting suggestion: Retain the default value. If the disk space is small and cannot meet the requirement of the default value, you can decrease the value of this

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

parameter as required. If long transactions or large transactions exist in the service, you need to increase the value of **undo_space_limit_size** based on the disk space. For details about the adjustment value, refer to the **info** column of the gs_stat_undo system function (see **Table 1-149**).

Risks and impacts of improper settings: If this parameter is set to a small value when undo records cannot be reclaimed in a timely manner, undo records may be forcibly reclaimed. As a result, there is an extremely low probability that the error message "snapshot too old! the undo record has been forcibly discard" is displayed. If this parameter is set to a large value when the disk space is insufficient and undo records cannot be reclaimed in a timely manner, a large number of undo records may be retained in the database system. As a result, the undo records occupy the physical disk space with other data, and services may be affected when the disk space is insufficient.

undo_limit_size_per_transaction

Parameter description: Specifies the undo space threshold of a single transaction. If the threshold is reached, the transaction is rolled back due to an error. You are advised to set **undo_limit_size_per_transaction** to a value less than or equal to that of **undo_space_limit_size**. If the value of **undo_limit_size_per_transaction** is greater than that of **undo_space_limit_size**, the displayed value is the same as the configured value when you run the **show undo_limit_size_per_transaction** command to query the parameter value. The only difference is that the smaller value between **undo_space_limit_size** and **undo_limit_size_per_transaction** is used as the actual undo space threshold of a single transaction.

Parameter type: integer.

Unit: page (8 KB)

Value range: 256 to 2147483647. The default unit is page. If this parameter is set to a value greater than 134217728 (that is, 1 TB), the value **134217728** takes effect.

Default value: **4194304** (32 GB)

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**. For example, the value **10000** indicates 10000 pages, and the value **10000KB** indicates 10000 KB. If the value contains a unit, the value can be KB, MB, or GB, but cannot be TB.

Setting suggestion: Retain the default value. If the disk space or memory space is small and cannot meet the requirement of the default value, you can decrease the value of this parameter as required. If a long transaction or a large transaction exists in the service and the number of undo records generated in a single transaction is greater than the value of this parameter, you need to increase the value of **undo_limit_size_per_transaction** based on the disk space. For details about the adjustment value, refer to the **info** column in the gs_stat_undo system function (**Table 1-149**). If **undo_limit_size_per_transaction** is set to a value greater than 1 TB, the system performance and stability may be affected. Therefore, if the parameter is set to a value greater than 134217728 (that is, 1 TB), the configured value is displayed when you run the **show undo_limit_size_per_transaction** command to query the parameter value, but the value **134217728** takes effect.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Risks and impacts of improper settings: If the parameter is set to small value, the number of undo records generated in a single transaction may exceed the threshold. As a result, the error message "undo size of the transaction exceeds the threshold" is displayed and the transaction is rolled back.

6.3.39 DCF Parameters Settings

enable_dcf

Parameter description: Specifies whether to enable the DCF mode. You are advised not to manually modify this parameter.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The current log replication mode is DCF.
- **off**: The current log replication mode is not DCF.

Default value: **off**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: To use the DCF log replication mode, run the mode switching command. Do not manually modify the **enable_dcf** parameter. This parameter takes effect only on DNs and does not take effect on CNs.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

dcf_ssl

Parameter description: This parameter is no longer used. The DCF reuses the GUC parameter **ssl**. For details, see **Security and Authentication**.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: SSL is used.
- **off**: SSL is not used.

Default value: **on**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

dcf_config

Parameter description: Specifies the DCF cluster configuration information, which is configured by the OM during installation and cannot be modified after installation.

Parameter type: string.

Unit: none

Value range: a string.

Default value: configured by the OM during installation.

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: This parameter can only be viewed.

Risks and impacts of improper settings: none

dcf_data_path

Parameter description: Specifies the DCF data path, which is configured by the OM during installation and cannot be modified after installation.

Parameter type: string.

Unit: none

Value range: valid path of a directory.

Default value: **dcf_data** in the DN data directory

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: This parameter can only be viewed.

Risks and impacts of improper settings: none

dcf_log_path

Parameter description: Specifies the DCF log path, which is configured by the OM during installation and cannot be modified after installation.

Parameter type: string.

Unit: none

Value range: valid path of a directory.

Default value: **dcf_log** in the DN data directory

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: This parameter can only be viewed.

Risks and impacts of improper settings: none

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

dcf_node_id

Parameter description: Specifies the ID of the DN where the DCF is located. This parameter is defined by the user during installation and mode switching.

Parameter type: integer.

Unit: none

Value range: 1 to 2147483647

Default value: specified by users during installation.

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

dcf_max_workers

Parameter description: Specifies the largest number of DCF callback function threads. The DCF needs to apply for the shared memory and semaphore before it calls the function registered by the DN with the DCF through the callback function.

Parameter type: integer.

Unit: none

Value range: 0 to 262143

Default value: **40**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this parameter is set to a large value, resources may be insufficient and the cluster installation may fail.

dcf_truncate_threshold

Parameter description: Specifies the threshold for a DN to truncate DCF logs.

Parameter type: integer.

Unit: none

Value range: 1 to 2147483647

Default value: **100000**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Risks and impacts of improper settings: If the threshold is too large, logs may not be truncated for a long time, occupying memory.

dcf_election_timeout

Parameter description: Specifies the timeout interval for selecting the DCF leader and follower. The election timeout interval depends on the status of the network between DNs. If the timeout interval is short and the network quality is poor, timeout occurs. After the network recovers, the election becomes normal. You are advised to set a proper timeout interval based on the current network status. Restriction on the DCF node clock: The maximum clock difference between DCF nodes is less than half of the election timeout interval. In DCF manual election mode, to ensure timely CM election, do not modify this parameter. Instead, use the default election timeout interval.

Parameter type: integer.

Unit: second

Value range: 1 to 600

Default value: **3**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**. For example, if the value is **60** without a unit, **dcf_election_timeout** indicates 60s. If the value is **1min**, **dcf_election_timeout** indicates 1 minute. The unit must be second or minute if required.

Setting suggestion: Set a proper timeout interval based on the current network status.

Risks and impacts of improper settings: If the network environment is poor and the timeout period is short, timeout election may occur.

dcf_enable_auto_election_priority

Parameter description: Specifies whether the DCF priority is allowed to be automatically adjusted.

Parameter type: integer.

Unit: none

Value range:

- **0**: not allowed.
- **1**: allowed.

Default value: **1**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

dcf_election_switch_threshold

Parameter description: Specifies the DCF threshold for preventing frequent switchover to primary. It is recommended that this parameter be set based on the maximum fault duration acceptable for user services.

Parameter type: integer.

Unit: second

Value range: 0 to 2147483647

Default value: **0**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**. The value cannot contain a unit.

Setting suggestion: Set this parameter based on the maximum fault duration acceptable to services.

Risks and impacts of improper settings: If this parameter is set to a large value, services may be unavailable for a long time.

dcf_run_mode

Parameter description: Specifies the DCF election mode, including the automatic election mode, manual election mode, and disabling the election mode. Currently, the election mode can be disabled only in minority restoration scenarios. If the election mode is disabled, the database instance will become unavailable.

NOTE

The working mode of a cluster can be switched only when the cluster is running properly. Otherwise, the cluster is still abnormal after the switching. The DCF working mode configured in GUC parameters must be the same as that configured by using cm_ctl. That is, both DCF working modes must be set to manual or automatic at the same time.

For example, to set the DCF manual mode, run the following command:

```
cm_ctl set --param --server -k dn_arbitrate_mode=quorum
cm_ctl reload --param --server
gs_guc reload -Z datanode -I all -N all  -c "dcf_run_mode=1"
```

To set the DCF automatic mode, run the following command:

```
cm_ctl set --param --server -k dn_arbitrate_mode=paxos
cm_ctl reload --param --server
gs_guc reload -Z datanode -I all -N all  -c "dcf_run_mode=0"
```

Parameter type: enumerated type

Unit: none

Value range: **0**, **1**, and **2**

- **0**: automatic election mode.
- **1**: manual election mode.
- **2**: disabling the election mode.

Default value: **1**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Currently, disabling the election mode applies only to minority recovery scenarios. If the election mode is disabled, the database instance will be unavailable.

dcf_log_level

Parameter description: Specifies the DCF log level.

Parameter type: string.

Unit: none

Value range:

- To disable the log function, set this parameter to **"NONE"**, which cannot be used together with the following log levels:
- To enable the log function, set this parameter to one or a combination of the following log levels: **"RUN_ERR|RUN_WAR|RUN_INF|DEBUG_ERR|DEBUG_WAR|DEBUG_INF|TRACE|PROFILE|OPER"**.

  If two or more log levels are used together, separate them with vertical bars (|). The log level cannot be set to an empty character string.

Default value: **"RUN_ERR|RUN_WAR|DEBUG_ERR|OPER|RUN_INF|PROFILE"**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If the log level is too low, logs may be missing.

dcf_log_backup_file_count

Parameter description: Specifies the number of DCF run log backups.

Parameter type: integer.

Unit: none

Value range: 1 to 1000

Default value: **100**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If the value is too small, the number of backup files is small and logs are lost.

dcf_max_log_file_size

Parameter description: Specifies the maximum size of a DCF run log file.

Parameter type: integer.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Unit: MB

Value range: 1 to 1000.

Default value: **10**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**. For example, if the value is **10** without a unit, **dcf_max_log_file_size** indicates 10 MB. If the value is **10MB**, **dcf_max_log_file_size** indicates 10 MB. The unit must be MB if required.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If the value is too large, a single log file may be opened and the query efficiency may decrease.

dcf_socket_timeout

Parameter description: Specifies the timeout interval for the DCF communication module to connect to the socket. This parameter takes effect upon the system restart. In an environment where the network quality is poor, if the timeout interval is set to a small value, a connection may fail to be set up. In this case, you need to increase the value.

Parameter type: integer.

Unit: ms

Value range: 10 to 600000 (10 minutes)

Default value: **5000**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**. For example, if the value is **5000** without a unit, **dcf_socket_timeout** indicates 5000 ms. If the value is **1min**, **dcf_socket_timeout** indicates 1 minute (that is, 60000 ms). The unit must be millisecond, second, or minute if required.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: When the network environment is poor, a small timeout period may cause a connection setup failure.

dcf_connect_timeout

Parameter description: Specifies the timeout interval for the DCF communication module to set up a connection. This parameter takes effect upon the system restart. In an environment where the network quality is poor, if the timeout interval is set to a small value, a connection may fail to be set up. In this case, you need to increase the value.

Parameter type: integer.

Unit: ms

Value range: 10 to 600000 (10 minutes)

Default value: 60000

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**. For example, if the value is **5000** without a unit, **dcf_connect_timeout** indicates 5000 ms. If the value is **1min**, **dcf_connect_timeout** indicates 1 minute (that is, 60000 ms). The unit must be millisecond, second, or minute if required.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: When the network environment is poor, a small timeout period may cause a connection setup failure.

dcf_mec_fragment_size

Parameter description: Specifies the fragment size of the DCF communication module. This parameter takes effect upon the system restart.

Parameter type: integer.

Unit: KB

Value range: 32 to 10240

Default value: **64**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**. The value cannot contain a unit.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

dcf_stg_pool_max_size

Parameter description: Specifies the maximum size of the memory pool of the DCF storage module. This parameter takes effect upon the system restart.

Parameter type: integer.

Unit: MB

Value range: 32 to 2147483647

Default value: **2048**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**. For example, if the value is **2048** without a unit, **dcf_stg_pool_max_size** indicates 2048 MB. If the value is **5GB**, **dcf_stg_pool_max_size** indicates 5 GB (that is, 5120 MB). The unit must be MB or GB if required.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If the value is too large, memory resources may be insufficient. If the value is too small, storage module resources may be insufficient.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

dcf_stg_pool_init_size

Parameter description: Specifies the minimum size of the memory pool of the DCF storage module. This parameter takes effect upon the system restart.

Parameter type: integer.

Unit: MB

Value range: 32 to 2147483647

Default value: **32**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**. For example, if the value is **2048** without a unit, **dcf_stg_pool_init_size** indicates 2048 MB. If the value is **5GB**, **dcf_stg_pool_init_size** indicates 5 GB (that is, 5120 MB). The unit must be MB or GB if required.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If the value is too large, memory resources may be insufficient. If the value is too small, storage module resources may be insufficient.

dcf_mec_pool_max_size

Parameter description: Specifies the maximum size of the memory pool of the DCF communication module. This parameter takes effect upon the system restart.

Parameter type: integer.

Unit: MB

Value range: 32 to 2147483647

Default value: **200**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**. For example, if the value is **2048** without a unit, **dcf_mec_pool_max_size** indicates 2048 MB. If the value is **5GB**, **dcf_mec_pool_max_size** indicates 5 GB (that is, 5120 MB). The unit must be MB or GB if required.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If the value is too large, memory resources may be insufficient. If the value is too small, communications module resources may be insufficient.

dcf_flow_control_disk_rawait_threshold

Parameter description: Specifies the disk waiting threshold for DCF flow control.

Parameter type: integer.

Unit: μs

Value range: 0 to 2147483647

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Default value: **100000**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**. The value cannot contain a unit.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this parameter is set to a large value, the performance may deteriorate and the memory usage may increase.

dcf_flow_control_net_queue_message_num_threshold

Parameter description: Specifies the threshold for the number of messages in a network queue for DCF flow control.

Parameter type: integer.

Unit: none

Value range: 0 to 2147483647

Default value: **1024**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this parameter is set to a small value, the performance may deteriorate severely.

dcf_flow_control_cpu_threshold

Parameter description: Specifies the threshold for DCF CPU flow control.

Parameter type: integer.

Unit: none

Value range: 0 to 2147483647

Default value: **100**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this parameter is set to a small value, the performance may deteriorate severely.

dcf_mec_batch_size

Parameter description: Specifies the number of batch messages for DCF communication. When the value is **0**, the DCF automatically adjusts the value based on the network and the amount of data to be written. This parameter takes effect upon the system restart.

Parameter type: integer.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Unit: none

Value range: 0 to 1024

Default value: **0**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this parameter is set to a small value, the communications efficiency between nodes decreases.

dcf_mem_pool_max_size

Parameter description: Specifies the maximum DCF memory. This parameter takes effect upon the system restart.

Parameter type: integer.

Unit: MB

Value range: 32 to 2147483647

Default value: **2048**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**. For example, if the value is **2048** without a unit, **dcf_mem_pool_max_size** indicates 2048 MB. If the value is **5GB**, **dcf_mem_pool_max_size** indicates 5 GB (that is, 5120 MB). The unit must be MB or GB if required.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this parameter is set to a small value, the cluster installation will fail.

dcf_mem_pool_init_size

Parameter description: Specifies the initial size of the DCF memory. This parameter takes effect upon the system restart.

Parameter type: integer.

Unit: MB

Value range: 32 to 2147483647

Default value: **32**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**. For example, if the value is **2048** without a unit, **dcf_mem_pool_init_size** indicates 2048 MB. If the value is **5GB**, **dcf_mem_pool_init_size** indicates 5 GB (that is, 5120 MB). The unit must be MB or GB if required.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this parameter is set to a small value, the cluster installation will fail.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

dcf_compress_algorithm

Parameter description: Specifies the compression algorithm for DCF run log transmission.

Parameter type: integer.

Unit: none

Value range:

- **0**: no compression.
- **1**: LZ4 compression algorithm.

Default value: **0**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: To enable the LZ4 compression algorithm, set **dcf_compress_algorithm** to **1**.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

dcf_compress_level

Parameter description: Specifies the compression level for DCF log transmission. Before this parameter takes effect, a valid compression algorithm must be configured, that is, the **dcf_compress_algorithm** parameter is set.

Parameter type: integer.

Unit: none

Value range: 1 to 22. If compression is disabled, the configured compression level does not take effect.

Default value: **1**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

dcf_mec_channel_num

Parameter description: Specifies the number of DCF communication channels. This parameter takes effect upon the system restart.

Parameter type: integer.

Unit: none

Value range: 1 to 64

Default value: **1**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this parameter is set to a small value, the communications efficiency between nodes may decrease.

dcf_rep_append_thread_num

Parameter description: Specifies the number of DCF log replication threads. This parameter takes effect upon the system restart.

Parameter type: integer.

Unit: none

Value range: 1 to 1000

Default value: number of DN copies in each shard.

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this parameter is set to a large value, threads may be idle and the resource usage may decrease.

dcf_mec_agent_thread_num

Parameter description: Specifies the number of DCF communication working threads. This parameter takes effect upon the system restart.

Parameter type: integer.

Unit: none

Value range: 1 to 1000

Default value: **10**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: It is recommended that the value be greater than or equal to 2 x Number of nodes x **dcf_mec_channel_num**.

Risks and impacts of improper settings: If this parameter is set to a large value, threads may be idle and the resource usage may decrease.

dcf_mec_reactor_thread_num

Parameter description: Specifies the number of reactor threads used by the DCF. This parameter takes effect upon the system restart.

Parameter type: integer.

Unit: none

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Value range: 1 to 100

Default value: **1**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: It is recommended that the ratio of the value of **dcf_mec_reactor_thread_num** to the value of **dcf_mec_agent_thread_num** be 1:40.

Risks and impacts of improper settings: If this parameter is set to a large value, threads may be idle and the resource usage may decrease.

dcf_log_file_permission

Parameter description: Specifies the attribute of the DCF run log file. The parameter setting takes effect after the system is restarted. This parameter is configured during installation and cannot be modified. To allow other users in the same group to access logs, ensure that all parent directories can be accessed by other users in the same group. That is, if **dcf_log_path_permission** is set to **750**, **dcf_log_file_permission** can only be set to **600** or **640**. If **dcf_log_path_permission** is set to **700**, **dcf_log_file_permission** must be set to **600**.

Parameter type: enumerated type.

Unit: none

Value range: **600** and **640**

Default value: **600**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: The permission of **dcf_log_path_permission** must be higher than that of **dcf_log_file_permission**.

Risks and impacts of improper settings: Improper settings may cause user access failures.

dcf_log_path_permission

Parameter description: Specifies the attribute of the DCF run log directory. The parameter setting takes effect after the system is restarted. This parameter is configured during installation and cannot be modified. To allow other users in the same group to access the log path, set this parameter to **750**. Otherwise, set this parameter to **700**.

Parameter type: enumerated type.

Unit: none

Value range: **700** and **750**

Default value: **700**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Setting suggestion: To allow other users in the same group to access the log path, set this parameter to **750**. Otherwise, set this parameter to **700**.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

dcf_majority_groups

Parameter description: Sets the DCF policy-based majority function. For a group that requires this parameter, at least one standby node in the group receives logs. That is, there is a synchronous standby node in the group. If nodes are added to or deleted from the DCF instance or the group value of a node in the instance is changed, you need to modify the configuration accordingly. When modifying this parameter, ensure that the value of **group** exists and is valid.

Parameter type: string.

Unit: none

Value range:

- To disable the policy-based majority function, enter an empty string **""**.
- To enable the function, configure valid group values separated by commas (,). The group values must exist in **dcf_config**. For example, if the group values 1 and 2 are added to the DCF policy-based majority configuration, you can set this parameter to **"1,2"**. If the group value does not exist in **dcf_config** or other characters are configured, the DCF considers the configured group invalid.

Default value: **""**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

NOTICE

If all nodes in a group are faulty after the parameter is configured, you need to remove the group from the parameter list when performing node build operations (node recovery or node replacement without changing the IP address) on a node. After the node recovers, you can configure the group again.

dcf_node_id_map

Parameter description: Specifies the dictionary mapping between standby DN names and DCF node IDs. The parameter setting takes effect after the system is restarted. This parameter is configured during installation and cannot be modified. This parameter is used in DCF cluster installation, upgrade, and node replacement scenarios. The value of **standby_name** configured in the GUC parameter **synchronous_standby_names** must be included in this dictionary.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter type: string.

Unit: none

Value range: The setting format is **'standby_name1:dcf_node_id1,standby_name2:dcf_node_id2'**. The values of standby DN names and the corresponding DCF node IDs are separated by commas (,).

Default value: **""**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Improper settings may cause cluster installation and upgrade failures.

dcf_candidate_names

Parameter description: Specifies the DCF candidate list. That is, names of DNs that may be selected as the primary node. In DCF automatic mode, the election policy is controlled by this parameter. DNs not in the list cannot be elected as a primary node.

Parameter type: string.

Unit: none

Value range: a value in the format of **'dn_name1,dn_name2,dn_name3'**. The parameter depends on **dcf_node_id_map**. DN names must be in **dcf_node_id_map** and separated by commas (,).

Default value: **""**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

dcf_thread_effective_time

Parameter description: Specifies the effective time of the DCF flushing thread. This parameter is used to determine whether the disk I/O hangs. If the DCF control log cannot update and I/O resources cannot be accessed within the period specified by this parameter, the DCF considers that the thread I/O hangs and the switchover is triggered. If this parameter is set to **0**, the I/O hang detection is disabled.

Parameter type: integer.

Unit: second

Value range: 0 to 1000

Default value: 160

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**. The value cannot contain a unit.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

dcf_pri_leader_timeout

Parameter description: Specifies the timeout interval for priority-based leader election. In DCF automatic mode, after priority-based leader election is enabled, the backup node triggers priority-based leader election. If the backup node is not elected as the leader within the timeout interval, the election is canceled. If this parameter is set to **0**, the priority-based selection of the primary node waits until the election is successful.

Parameter type: integer.

Unit: second

Value range: 0 to 3600

Default value: **60**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**. The value cannot contain a unit.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this parameter is set to a large value, the cluster may be in the no-primary state for a long time.

dcf_static_leader_timeout

Parameter description: Specifies the timeout interval for preferentially electing the old leader. In DCF automatic mode, after the cluster is restarted, the old leader is preferentially elected. If the election fails within the timeout interval, the election is canceled.

Parameter type: integer.

Unit: second

Value range: 0 to 600

Default value: **60**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**. The value cannot contain a unit.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this parameter is set to a large value, the cluster may be in the no-primary state for a long time.

6.3.40 Flashback

This section describes parameters related to the flashback function.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

enable_recyclebin

Parameter description: Specifies whether the recycle bin is enabled or disabled in real time.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The recycle bin is enabled in real time.
- **off**: The recycle bin is disabled in real time.

Default value: **off**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: To use the flashback table function, set **enable_recyclebin** to **on**.

Risks and impacts of improper settings: When this parameter is disabled, the flashback function cannot be used.

NOTICE

After the recycle bin function is enabled, when a table or index is dropped from the database, a hidden object starting with **BIN** is automatically generated. These objects are used to locate the original data during subsequent restoration. All bin objects are created in the schema where the original service table is located.

recyclebin_retention_time

Parameter description: Specifies the retention period of objects in the recycle bin. The objects will be automatically deleted after the retention period expires.

Parameter type: integer.

Unit: second

Value range: 1 to 2147483647

Default value: **900** (that is, 15 minutes)

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**. For example, if the value is **900** without a unit, **recyclebin_retention_time** indicates 900s. If the value is **15min**, **recyclebin_retention_time** indicates 15 minutes. The unit must be **s**, **min**, **h**, or **d** if required.

Setting suggestion: Set the retention period of objects in the recycle bin as required.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

undo_retention_time

Parameter description: Specifies the period for retaining undo logs of earlier versions.

Parameter type: integer.

Unit: second

Value range: 0 to 259200. **0** indicates that the flashback point snapshot information is not retained.

Default value: **0**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**. For example, if the value is **900** without a unit, **undo_retention_time** indicates 900s. If the value is **15min**, **undo_retention_time** indicates 15 minutes. The unit must be **s**, **min**, **h**, or **d** if required.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If the value is out of the range or the value contains a unit other than **s**, **min**, **h**, and **d**, an error message is displayed.

NOTICE

- If this parameter is set to **0** during the Ustore flashback query, the snapshot information at the flashback point will be cleared. In earlier versions, no flashback query can be performed. When a flashback query is performed, the error message "cannot find the restore point" is displayed.
- If the time within which the undo logs of earlier versions need to be retained is time1 and the SQL statement execution time for the flashback query is time2, you need to set **undo_retention_time** to a value greater than time1 + time2. That is, set **undo_retention_time** to a value greater than time1 + time2 + 3s. You are advised to set **undo_retention_time** to a value equal to time1 + 1.5 x time2. For example, if you want to retain the logs of earlier versions within the latest 3 hours, and the SQL statement execution time for the flashback query is 1 hour, set **undo_retention_time** to a value equal to 3 hours + 1.5 x 1 hour, that is, 4.5 hours.

6.3.41 Rollback Parameters

max_undo_workers

Parameter description: Specifies the number of undo worker threads called during asynchronous rollback. The parameter setting takes effect after the system is restarted.

Parameter type: integer.

Unit: none

Value range: 1 to 100

Default value: **5**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Only the maximum number of threads that can concurrently perform asynchronous rollback is affected. If the value is too small, the asynchronous rollback speed may be slow. When a large number of transactions that require asynchronous rollback exist in the system, there is an extremely low probability that the undo reclamation speed is affected. If the host configuration is not high and a large number of transactions that require asynchronous rollback exist in the system, a large number of asynchronous rollback threads will be started at the same time, occupying certain system resources.

6.3.42 AI Features

enable_hypo_index

Parameter description: Specifies whether the database optimizer considers the created virtual index when executing **EXPLAIN**. By executing **EXPLAIN** on a specific query statement, you can evaluate whether the index can improve the execution efficiency of the query statement based on the execution plan provided by the optimizer. This parameter can be set at the PDB level.

Parameter type: Boolean

Unit: none

Value range:

- **on**: A virtual index is created when the **EXPLAIN** command is executed.
- **off**: No virtual index is created when the **EXPLAIN** command is executed.

Default value: **off**. In the PDB scenario, if this parameter is not set, the global setting is inherited.

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-2**.

Setting suggestion: Set the value based on service requirements.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

enable_ai_stats

Parameter description: Specifies whether to create or use intelligent statistics.

Parameter type: Boolean

Unit: none

Value range:

- **on**: Intelligent statistics are created and used.
- **off**: Intelligent statistics are not created or used.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Default value: **off**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If you modify the settings during database running, the plan may deteriorate.

multi_stats_type

Parameter description: Specifies the type of statistics to be created when **enable_ai_stats** is set to **on**.

Parameter type: enumerated type

Unit: none

Value range: **"BAYESNET"**, **"MCV"**, and **"ALL"**

- **"BAYESNET"**: Only intelligent statistics are created.
- **"MCV"**: Only traditional statistics are created.
- **"ALL"**: Both traditional statistics and intelligent statistics are created.

Default value: **"BAYESNET"**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

ai_stats_cache_limit

Parameter description: Specifies the maximum number of models that can be cached when **enable_ai_stats** is set to **on**.

Parameter type: integer.

Unit: none

Value range: 30 to 1000

Default value: **100**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Set this parameter based on the number of multi-column statistics models.

Risks and impacts of improper settings: If the value is too large, unnecessary memory is occupied. If the value is too small, models are frequently read from hard disks, deteriorating system performance.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

enable_operator_prefer

Parameter description: Specifies whether to enable the operator preference rule. If the estimated costs are similar, the parameterized path is preferred for table join.

Parameter type: Boolean

Unit: none

Value range:

- **on**: Parameterized path preference is enabled.
- **off**: Parameterized path preference is disabled.

Default value: **off**

NOTE

There are two prerequisites for this parameter to take effect:

- The parameterized path is generated.
- The estimated cost of the parameterized path is similar to that of other index scan operators.

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value. You are advised to specify this parameter only in sessions or hints.

Risks and impacts of improper settings: If this parameter is modified, the plan may deteriorate.

enable_adaptive_cost

Parameter description: Specifies whether to enable the feedback-based optimizer cardinality and cost correction functions. If this parameter is enabled, the processes of collecting operator information and estimating cardinality are enabled, and the thread for starting backend model maintenance is enabled; otherwise, the thread exits.

Parameter type: Boolean

Unit: none

Value range:

- **on**: The operator information and cardinality estimation processes are enabled.
- **off**: The operator information and cardinality estimation processes are disabled.

Default value:

- **on**: default value of the newly installed database.
- **off**: default value of the database in versions earlier than 506.0.0 after the database is upgraded.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value. Enable or disable this parameter based on whether automatic optimization is required for query statements.

Risks and impacts of improper settings: If this function is not required, for example, no complex statement that needs to be optimized exists in the service, enabling this function occupies more system resources.

enable_feedback_cardest

Parameter description: Specifies whether to enable the feedback-based optimizer cardinality and cost correction functions. This parameter is used by developers to diagnose model-related problems. If **enable_adaptive_cost** is set to **off**, and this parameter is set to **on**, the operator information is still collected and the API of cardinality estimation feedback is still called. However, in this case, the thread for backend automatic model maintenance is not enabled. Developers can use the gs_acm_analyze_workload_manual() function to manually train models for diagnosing problems.

Parameter type: Boolean

Unit: none

Value range:

- **on**: The operator information is collected, and the API of cardinality estimation feedback is still called. However, the backend automatic model maintenance thread is not enabled.
- **off**: The **enable_adaptive_cost** parameter takes full control.

Default value:

- **on**: default value of the newly installed database.
- **off**: default value of the database in versions earlier than 506.0.0 after the database is upgraded.

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

adaptive_cardest_strategy

Parameter description: Specifies the preference of the selection cardinality estimation model.

Parameter type: enumerated type

Unit: none

Value range: **"auto"**, **"use_statistics"**, and **"use_feedback"**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **"auto"**: adaptive mode. In this mode, the system automatically determines whether to use the statistical method or feedback method based on the estimation accuracy in the history.
- **"use_statistics"**: Statistics are preferentially used for cardinality estimation.
- **"use_feedback"**: The feedback model is preferentially used for cardinality estimation.

Default value: **"auto"**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this parameter is modified during system running, the plan may deteriorate.

maximal_feedback_model_num

Parameter description: Specifies the maximum number of cardinality feedback models. If the actual number exceeds the value of this parameter, no new models will be trained.

Parameter type: integer.

Unit: none

Value range: –1 to 1000000. **-1** indicates no limit.

Default value: **10000**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If the value is too small, the feedback cardinality estimation function may become invalid because new models cannot be trained. If the value is too large, too much disk space may be occupied, causing performance deterioration.

feedback_model_cache_limit

Parameter description: Specifies the maximum number of cardinality feedback models that can be cached in the global memory.

Parameter type: integer.

Unit: none

Value range: 10 to 100000

Default value: **500**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Risks and impacts of improper settings: If the value is too large, unnecessary memory is occupied. If the value is too small, models are frequently read from hard disks, deteriorating system performance.

feedback_model_expired_time

Parameter description: Specifies the timeout interval for cardinality feedback models (check using gs_abo_model_statistic), which is used to clear expired models periodically.

Parameter type: integer.

Unit: milliseconds

Value range: 500 to 2147483647

Default value: **86400000** (that is, 1 day)

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**. For example, if the value is **6000** without a unit, **feedback_model_expired_time** indicates 6000 ms. If the value is **1min**, **feedback_model_expired_time** indicates 1 minute (that is, 60000 ms). The unit must be **ms**, **s**, **min**, **h**, or **d** if required.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If the timeout interval is too long, the system performance deteriorates. If the timeout interval is too short, the model is cleared frequently, affecting functions.

feedback_collection_expired_time

Parameter description: Specifies the timeout interval for feeding back information about untrained operators. You can view the operator feedback information by using gs_stat_get_acm_feedback_operator_info(). Expired operator information is periodically deleted.

Parameter type: integer.

Unit: milliseconds

Value range: 50 to 2147483647

Default value: **3600000** (that is, 1 hour)

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**. For example, if the value is **6000** without a unit, **feedback_collection_expired_time** indicates 6000 ms. If the value is **1min**, **feedback_collection_expired_time** indicates 1 minute (that is, 60000 ms). The unit must be **ms**, **s**, **min**, **h**, or **d** if required.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If the timeout interval is too long, the system performance deteriorates. If the timeout interval is too short, the feedback data is cleared frequently, affecting functions.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

adaptive_cost_min_time

Parameter description: Specifies the execution duration threshold of SQL statements for cardinality feedback collection. Only the feedback of statements whose execution duration is greater than the value of this parameter is collected.

Parameter type: integer.

Unit: milliseconds

Value range: 0 to 2147483647

Default value: **1000**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**. For example, if the value is **6000** without a unit, **adaptive_cost_min_time** indicates 6000 ms. If the value is **1min**, **adaptive_cost_min_time** indicates 1 minute (that is, 60000 ms). The unit must be **ms**, **s**, **min**, **h**, or **d** if required.

Setting suggestion: You are advised to set this parameter to 20% of the execution duration of slow queries to be tuned.

Risks and impacts of improper settings: If the value is too small, the system performance deteriorates by 1% to 2%. If the value is too large, the query that can be automatically optimized does not take effect.

cost_update_window_size

Parameter description: Specifies the size of the sliding window for collecting regression data.

Parameter type: integer.

Unit: none

Value range: 1 to 20

Default value: **5**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If the parameter value is less than 3, the estimated cost parameter may be overfitting and the actual situation may be incorrect. As a result, the optimizer generates an incorrect execution plan.

adaptive_costest_strategy

Parameter description: Specifies whether the new or old cost model is used for cost evaluation.

Parameter type: enumerated type

Unit: none

Value range:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **l0**: The new cost model is triggered only when the cardinality estimation is correct (for example, using the cardinality estimation feedback).
- **l1**: The new cost model is preferentially used for calculation.

Default value: **l0**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value. You are advised to modify this parameter only in sessions or hints.

Risks and impacts of improper settings: If this parameter is set to **l1**, there is a serious risk of plan deterioration.

adaptive_costmodel_calibration_interval

Parameter description: Specifies the interval at which the cost model correction logic is triggered.

Parameter type: integer.

Unit: milliseconds

Value range: 0 to 2147483647. The value **0** indicates that the cost models are not automatically corrected.

Default value: **3600000** (that is, 1 hour)

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**. For example, if the value is **6000** without a unit, **adaptive_costmodel_calibration_interval** indicates 6000 ms. If the value is **1min**, **adaptive_costmodel_calibration_interval** indicates 1 minute (that is, 60000 ms). The unit must be **ms**, **s**, **min**, **h**, or **d** if required.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If the value is too small, the cost model frequently triggers the correction function, deteriorating the system performance. If the value is too large, the model cannot be corrected in a timely manner, affecting the function optimization effect.

adaptcost_extended_feature

Parameter description: Specifies whether to enable the adaptive cost extension function.

Parameter type: string.

Unit: none

Value range:

- **none**: No adaptive cost extension function is used.
- **support_or**: Operators that contain the OR and IN conditions are supported.
- **support_left_join**: Operators that contain the leftjoin or rightjoin condition are supported.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **support_stream_cost**: Adaptive cost estimation of the stream operator is supported.
- **use_knn_support**: The KNN model is preferentially used to support the IN/OR and leftjoin/rightjoin operators.

Default value:
"support_or,support_left_join,support_stream_cost,use_knn_support"

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Some operators may fail to use the adaptive cost and the plan cannot be optimized.

enable_collect_abo_history

Parameter description: Specifies whether to enable the persistence of feedback cardinality/cost estimation information.

Parameter type: Boolean

Unit: none

Value range:

- **on**: The feedback cardinality/cost estimation information is collected.
- **off**: The feedback cardinality/cost estimation information is not collected.

Default value: **on**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this function is not required, for example, no complex statement that needs to be optimized exists in the service, enabling this function occupies more system resources.

feedback_record_expired_time

Parameter description: Specifies the timeout interval of records in the gs_abo_history system catalog. Records that exceed the timeout interval are periodically deleted.

Parameter type: integer.

Unit: milliseconds

Value range: 500 to 2147483647

Default value: **86400000** (that is, 1 day)

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**. For example, if the value is **6000** without a unit, **feedback_record_expired_time** indicates 6000 ms. If the value is **1min**,

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

feedback_record_expired_time indicates 1 minute (that is, 60000 ms). The unit must be **ms**, **s**, **min**, **h**, or **d** if required.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If the timeout interval is too long, the system performance deteriorates. If the timeout interval is too short, the record is cleared frequently, affecting functions.

enable_ai_watchdog

Parameter description: Enables or disables the AI watchdog function.

Parameter type: Boolean

Unit: none

Value range:

- **on**: enabled.
- **off**: disabled.

Default value: **on**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Enabling this function occupies system resources.

enable_ai_watchdog_forcible_oom_detection

Parameter description: Forcibly enables or disables the OOM detection function of the AI watchdog. If this parameter is disabled, the system automatically determines whether to enable the OOM detection function based on the current database specifications. In automatic determination mode, the OOM detection function is enabled only when **max_process_memory** is set to **64GB** or a larger value. The OOM detection function depends on the information obtained by the memory management module. Therefore, if the memory management module is disabled or invalid, the OOM detection function is not enabled.

Parameter type: Boolean

Unit: none

Value range:

- **on**: enabled.
- **off**: disabled.

Default value: **off**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Risks and impacts of improper settings: Enabling this function occupies system resources.

enable_ai_watchdog_healing

Parameter description: Enables or disables the self-healing function of the AI watchdog.

Parameter type: Boolean

Unit: none

Value range:

- **on**: enabled.
- **off**: disabled.

Default value: **on**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

ai_watchdog_max_cpu_usage

Parameter description: Specifies the expected upper limit of the database CPU usage. The value is normalized based on the multi-core situation. If this parameter is set to **0**, the system does not check the CPU usage.

Parameter type: floating-point number

Unit: none

Value range: 0 to 1

Default value: **0.8**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If the value is too large, exceptions may not be detected in a timely manner.

ai_watchdog_oom_dynamic_used_threshold

Parameter description: Specifies the expected upper limit of the dynamic memory usage of the database.

Parameter type: floating-point number

Unit: none

Value range: 0 to 1

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Default value: 0.95

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If the value is too large, exceptions may not be detected in a timely manner.

ai_watchdog_oom_growth_confidence

Parameter description: Specifies the confidence level of the OOM detection algorithm.

Parameter type: floating-point number

Unit: none

Value range: 0.1 to 1

Default value: 0.95

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

ai_watchdog_oom_malloc_failures

Parameter description: Specifies the maximum number of consecutive memory allocation failures tolerated. If the number of consecutive memory allocation failures exceeds this value, the OOM detection function may be triggered.

Parameter type: integer.

Unit: none

Value range: 1 to 32000

Default value: **50**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If the value is too small, alarms are frequently generated. If this value is too large, exceptions cannot be detected in a timely manner.

ai_watchdog_oom_other_used_memory_threshold

Parameter description: Specifies the expected upper limit of memory usage of other parts of the database.

Parameter type: integer.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Unit: MB

Value range: –1 to 1048576

Default value: The value varies according to the following situations:

1. If this parameter is set through the OM installation, the default value is **-1**.

   NOTE

   When the value is **-1**, the upper limit of the other parts of the memory usage is specified based on the following rules:

   1. If the value of **max_process_memory** is less than 300 GB, the upper limit of the other parts of the memory usage is 20 GB.
   2. If the value of **max_process_memory** is greater than or equal to 300 GB and less than 600 GB, the upper limit of the other parts of the memory usage is 40 GB.
   3. If the value of **max_process_memory** is greater than or equal to 600 GB, the upper limit of the other parts of the memory usage is 60 GB.

   If the default value **-1** is not used, the upper limit of the other parts of the memory usage is the value set by the user.

2. If this parameter is not set through the OM installation, the default value is **20480**.

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If the value is too small, alarms are frequently generated. If this value is too large, exceptions cannot be detected in a timely manner.

ai_watchdog_oom_process_threshold

Parameter description: Specifies the expected percentage of the database process usage to the value of **max_process_memory**. When the threshold is reached, memory leakage determination is triggered.

Parameter type: floating-point number

Unit: none

Value range: 0 to 10

Default value: The value varies according to the following situations:

1. If this parameter is set through the OM installation, the default value is **1**.
2. If this parameter is not set through the OM installation, the default value is **1.1**.

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

ai_watchdog_oom_shared_threshold

Parameter description: Specifies the expected upper limit of the shared memory usage of the database.

Parameter type: floating-point number

Unit: none

Value range: 0 to 1

Default value: 0.4

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

ai_watchdog_rto_restriction_time

Parameter description: Specifies the RTO threshold of the AI watchdog self-healing function. If the RTO threshold is exceeded, self-healing is not performed.

Parameter type: integer.

Unit: seconds

Value range: 0 to 36000

Default value: **600**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**. The value cannot contain a unit.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

ai_watchdog_tolerance_times

Parameter description: Specifies the maximum number of consecutive abnormal events that can be tolerated by the AI watchdog before self-healing is started. This parameter can be used to avoid incorrect operations.

Parameter type: integer.

Unit: none

Value range: 0 to 100

Default value: **4**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

ai_watchdog_tps_threshold

Parameter description: Specifies the lower limit of the expected TPS usage of the database instance. If the TPS usage is lower than the value of this parameter, the exception determination logic is triggered.

Parameter type: integer.

Unit: none

Value range: 0 to 32000

Default value: **2**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

ai_watchdog_wait_time

Parameter description: Adjusts the waiting time. To prevent the database from frequently performing self-healing operations, the database waits for a period of time after startup.

Parameter type: integer.

Unit: seconds

Value range: 0 to 36000

Default value: **1800**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**. The value cannot contain a unit.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If the value is too small, false alarms may be reported when the database is just started. If the value is too large, exceptions within the waiting time may not be detected.

ai_watchdog_warning_retention

Parameter description: Specifies the maximum number of alarm records that the AI watchdog can retain in the dbe_perf.ai_watchdog_detection_warnings view.

Parameter type: integer.

Unit: none

Value range: 0 to 32000

Default value: 20

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

6.3.43 Global SysCache Parameters

enable_global_syscache

Parameter description: Specifies whether to enable the global system cache function.

Parameter type: Boolean

Unit: none

Value range:

- **on** indicates that the global system cache function is enabled.
- **off** indicates that the global system cache function is disabled.

Default value: **on**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value. Enabling the global system cache function can reduce the system cache memory usage and improve the concurrent expansion capability. If this parameter is enabled, **global_syscache_threshold** must be used together. In this case, the thread pool mode is recommended. After this parameter is enabled, you are advised to set **wal_level** of the standby node to **hot_standby** or higher level if you need to access the standby node.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

global_syscache_threshold

Parameter description: Specifies the maximum memory usage of the global system cache. To use this parameter, you need to enable the **enable_global_syscache** parameter.

Parameter type: integer.

Unit: KB

Value range: 16384 to 1073741824

Default value: **163840** (160 MB)

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**. For example, if this parameter is set to **163840** without a unit, it indicates 163840 KB. If this parameter is set to **160MB**, it indicates 160 MB. The unit must be KB, MB, or GB if required.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Setting suggestion: Set it to the smaller value of the number of hot databases and the number of threads multiplied by the memory size allocated to each database, that is, **global_syscache_threshold** = **min(count(hot dbs),count(threads))** x **memofdb**.

The number of hot databases is the number of databases that are frequently accessed. In thread pool mode, the number of threads is the sum of the number of threads in the thread pool and the number of background threads. In non-thread pool mode, the number of hot databases is used.

memofdb indicates the average memory allocated to each database. The background noise memory of each database is 2 MB. Each time a table or index is added, 11 KB memory is added.

Risks and impacts of improper settings: If the value is too small, memory is frequently evicted, and a large number of memory fragments cannot be recycled. As a result, memory control fails.

6.3.44 Read Parameters of the Standby Node in a Distributed System

enable_standby_read

Parameter description: Specifies whether to enable the read function of the standby node for a session.

NOTICE

This function can be enabled only in GTM-free, GTM-lite, non-standby cluster for DR, non-transaction block, and hot-standby modes.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The read function of the standby node in a distributed system is enabled for the session.
- **off**: The read function of the standby node in a distributed system is disabled for the session.

Default value: **off**

Setting method: This parameter is a USERSET parameter and can be set only at the session level (**enable_standby_read** is set to **on**). It cannot be set using gs_guc set/reload.

Setting suggestion: This parameter cannot be set using gs_guc. If you need to query the standby node, enable it in the session.

Risks and impacts of improper settings: If this parameter is set at a non-session level (for example, enabling this parameter in the configuration file), the cluster cannot be started when a parameter conflict occurs. If no parameter conflict

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

occurs, the read function of the standby node in a distributed system is also enabled for background threads such as autovacuum and WorkloadMonitor. As a result, DDL and DML operations are affected and errors are reported.

enable_direct_standby_datanodes

Parameter description: Specifies whether to enable the EXECUTE DIRECT ON extension capability for a session. After this parameter is enabled, the EXECUTE DIRECT ON statement can be connected to any standby DN or all standby DNs of a shard to execute queries. For details about the EXECUTE DIRECT ON syntax, see **EXECUTE DIRECT**.

NOTICE

- This function can be enabled only in GTM-free mode, non-transaction block, and hot-standby mode.
- In the same session, an error is reported if **enable_direct_standby_datanodes** is set to **on** after **enable_standby_read** is set to **on**. An error is also reported if **enable_standby_read** is set to **on** after **enable_direct_standby_datanodes** is set to **on**.
- After this parameter is enabled, the current session is read-only, and DDL and DML jobs are affected and errors are reported.
- After this parameter is enabled, you can use EXECUTE DIRECT ON to query only system DFX information such as system views, system functions, and system catalogs. Common user tables cannot be queried.
- After the **enable_direct_standby_datanodes** parameter is enabled, EXECUTE DIRECT ON supports distributed standby node query. Before using this function during the upgrade, ensure that the CN and DN instance processes have been replaced with the latest binary files. Otherwise, packet verification fails and an error is reported.
- After this parameter is enabled, the data queried from system views such as dbe_perf.statement and dbe_perf.summary_statement is the data on independent CNs and does not include the data on the primary DN. You are advised not to enable this parameter for data query.
- To query data on DNs, use EXECUTE DIRECT ON DATANODES.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The EXECUTE DIRECT ON extension capability is enabled for the session.
- **off**: The EXECUTE DIRECT ON extension capability is disabled for the session.

Default value: **off**

Setting method: This parameter is a USERSET parameter and can be set only at the session level (**enable_direct_standby_datanodes** is set to **on**). It cannot be set using gs_guc set/reload.

Setting suggestion: This parameter is used to specify whether to enable EXECUTE DIRECT ON to perform the connection behavior in the distributed standby node

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

read scenario. This function is mainly used for WDR, database test, and O&M. You are advised not to enable this function in other scenarios. This parameter cannot be set using gs_guc. If you need to query the standby node, enable it in the session.

Risks and impacts of improper settings: If this parameter is enabled in the configuration file, the database node cannot be started.

standby_read_delay

Parameter description: Specifies the maximum difference between the primary and standby nodes when data is read from the standby node. If the difference exceeds the value of this parameter, data cannot be read from the standby node.

Parameter type: integer.

Unit: ms

Value range: –1 to 2147483647

- **-1**: The difference between the primary and standby nodes does not need to be verified when data is read from the standby node.
- **0**: Data can be read from the standby node only when there is no difference between the primary and standby nodes.

Default value: **10000000**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**. For example, if this parameter is set to **86400** without a unit, it indicates 86400 ms. If this parameter is set to **1d**, it indicates 1 day. The unit must be **ms**, **s**, **min**, **h**, or **d** if required.

Setting suggestion: Set this parameter based on service requirements.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

standby_read_rto

Parameter description: Specifies the maximum RTO of the system when data is read from the standby node. If the RTO exceeds the value of this parameter, data cannot be read from the standby node.

Parameter type: integer.

Unit: ms

Value range: –1 to 2147483647

- **-1**: The system RTO does not need to be verified when data is read from the standby node.
- **0**: Data can be read from the standby node only when the RTO of at least one standby node is 0.

Default value: **60000**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**. For example, if this parameter is set to **86400** without a unit, it

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

indicates 86400 ms. If this parameter is set to **1d**, it indicates 1 day. The unit must be **ms**, **s**, **min**, **h**, or **d** if required.

Setting suggestion: Set this parameter based on service requirements.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

6.3.45 Restoring Data on the Standby Node

standby_page_repair

Parameter description: Specifies whether to automatically repair the page after a fault is detected on the replay target page during replay on the standby node. The current version supports three types of rectification: CRC failure, uninitialized page, and page LSN verification error. Bad blocks of VM, Xlog, Clog, MOT, and undo metadata cannot be repaired, and LSN errors of FSM cannot be repaired. Undo records can be repaired only when CRC fails. Temporary tables, global temporary tables, and unlogged tables do not involve primary and standby restoration. The page file-level loss cannot be repaired.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The standby node automatically detects and repairs pages during replay.
- **off**: The standby node does not automatically detect and repair pages during replay.

Default value: **on**

NOTICE

- If a large number of bad blocks exist due to a standby node exception, the replay performance of the standby node is affected, and Xlogs may be stacked on the standby node. In addition, an exception log is printed each time an Xlog is replayed to a bad block.
- To ensure the consistency between the primary and standby nodes, if the standby node has unrepaired bad blocks, the checkpoint needs to be stopped. As a result, Xlogs may be stacked, and the replay on the bad blocks will be suspended, which may cause inconsistency between the primary and standby nodes. If bad blocks exist when the standby node is restarted or promoted to primary, the instance will exit abnormally. Before the exit, the Xlog chain on the bad blocks will be collected, which may prolong the RTO.

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If automatic repair is disabled, bad blocks will be stored in the bad block table once bad blocks are detected, causing the adverse impact described in NOTICE.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

6.3.46 Ledger Database

enable_ledger

Parameter description: Specifies whether to enable the ledger database. If this parameter is set to **on**, the ledger database is enabled, and a new tamper-proof mode can be created and the common mode can be changed to the tamper-proof mode.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The ledger database is enabled.
- **off**: The ledger database is disabled.

Default value: **off**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: The ledger database is disabled by default. To enable it, set **enable_ledger** to **on**.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

ledger_hist_level

Parameter description: Specifies whether to record SQL statements in the global blockchain table.

Parameter type: integer

Unit: none

Value range:

- **0**: SQL statements are not recorded in the global blockchain table.
- **1**: SQL statements are recorded in the global blockchain table.

Default value: **1**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

6.3.47 Creating an Index Online

delete_cctmp_table

Parameter description: Specifies whether to delete temporary tables generated during Ustore online index creation or rebuilding.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: indicates that the temporary tables are deleted.
- **off**: indicates that the temporary tables are retained.

Default value: **on**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: This parameter is enabled by default. Set this parameter to **off** if you want to retain temporary tables generated during online index creation or rebuilding.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

enable_bypass_insert_sequence

Parameter description: Specifies whether SQL Bypass is supported when an INSERT statement of a table that contains auto-increment columns.

NOTE

- This parameter takes effect only when the GUC parameter **enable_opfusion** is enabled.
- The types of auto-increment columns are smallint, int, and bigint.
- The constraints of the SQL Bypass insert statement are inherited.
- Auto-increment sequence is supported only for INSERT statements.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: SQL Bypass optimization is supported.
- **off**: SQL Bypass optimization is not supported.

Default value: **on**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **18.2-Table 1 GUC parameter types**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this parameter is disabled, INSERT statements containing auto-increment lists cannot be optimized using SQL Bypass, which reduces the execution efficiency of INSERT statements.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

6.3.48 Online DDL Operations

enable_online_ddl

Parameter description: Specifies whether to enable online DDL or online VACUUM. This parameter is used together with the ONLINE/OFFLINE keyword. (For details about the keyword, see **ALTER TABLE** and **VACUUM**.)

Parameter type: Boolean.

Unit: none

Value range:

- **on**: Online DDL is enabled and does not take effect in the current version.
- **off**: Online DDL is disabled and does not take effect in the current version.

Default value: **off**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: You are advised to disable this parameter. This parameter does not take effect in the current version. If you need to use the new online DDL features, add the keyword ONLINE to the syntax.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

6.3.49 Data Lifecycle Management: OLTP Table Compression

enable_ilm

Parameter description: Specifies whether to enable the OLTP table compression of data lifecycle management.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: enabled.
- **off**: disabled.

Default value: **off**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: The default value is **off**. To enable this feature, contact Huawei technical support to purchase a license and then set this parameter to **on**.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

ilm_instance_compress

Parameter description: Sets a specified ILM compression policy to an instance-level compression policy. Currently, only the cross-page transparent compression (that is, TURBO) policy can be specified as an instance-level policy. When **ilm_instance_compress** is set to **turbo**, the TURBO compression policy is automatically added to all objects that support cross-page transparent compression in the instance.

Parameter type: enumerated type

Unit: none

Value range:

- **off**: disabled.
- **turbo**: enabled. The instance-level compression policy type is **turbo**.

Default value: **off**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: This parameter is disabled by default. To enable instance-level compression, set it to **turbo**.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

ilm_instance_compress_configuration

Parameter description: Specifies the default configuration of an instance-level compression policy, which consists of the compression level and compression cold and hot management time. For example, the default value indicates that the data that is not modified within one day in the compressed object is compressed at the low level. The time range cannot exceed 3 years.

Parameter type: string.

Unit: none

Value range:

- Compression level: **low**, **medium**, or **high**
- Hot and cold management time: an integer
- Cold and hot management time unit: **hour**, **day**, **month**, or **year**

Default value: **low,1,day**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value **low,1,day**.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

turbo_compress_shared_buffers

Parameter description: Specifies the size of the metadata buffer dedicated for cross-page transparent compression.

Parameter type: integer.

Unit: 8 KB (per page)

Value range: 0 to 1073741823

Default value: **0**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**. For example, if the value is **1024** without a unit, the value of **turbo_compress_shared_buffers** is 1024 x 8 KB, that is, 8192 KB. If the value is **8MB** with a unit, the value of **turbo_compress_shared_buffers** is 8 MB. If the value contains a unit, the value must be KB, MB, or GB and must be an integer multiple of 8 KB.

Setting suggestion: The default value is **0**, indicating that cross-page transparent compression is disabled. If this function is required, set this parameter to 1/128 of **shared_buffers**. If a transparently compressed table already exists, this parameter cannot be set to **0**.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

turbo_compress_default_configuration

Parameter description: Specifies the default configuration of cross-page transparent compression. A semicolon (;) is used to separate different levels, which are **low**, **medium**, and **high** in sequence. Commas (,) are used to separate compression configurations at different levels. The configurations are the encoder size, compressor size, and compression unit size in sequence.

Parameter type: string.

Unit: none

Value range:

- Encoder: **tiling**, **smartdiff**, and **pattern**
- Compressor: **zstd** and **lz4**
- Compression unit size: **1**, **2**, **4**, **8**, **16**, **32**, and **64**

Default value: **tiling,zstd,4;tiling,zstd,16;pattern,zstd,16**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value **tiling,zstd,4;tiling,zstd,16;pattern,zstd,16**.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

turbo_compress_pattern_encoder

Parameter description: Specifies the mode encoder for cross-page transparent compression. When the encoder in **turbo_compress_default_configuration** is set to **pattern**, you can set this parameter to specify the mode encoding algorithm to be used. Multiple mode encoding algorithms can be combined and separated by vertical bars (|).

Parameter type: string.

Unit: none

Value range:

- **none**: no encoding.
- **transpose**: row and column transpose.
- **transpose|column_encode**: row and column transpose and column encoding.
- **transpose|dedup|column_encode**: row and column transpose, column encoding, and deduplication.

Default value: **transpose**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value **transpose**.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

NOTICE

- Whether the pattern code has positive benefits depends on the data feature. If the evaluation does not generate positive benefits, the pattern code is automatically closed.
- Mode encoding requires extra memory. When the memory resources are insufficient, mode encoding is automatically disabled.

turbo_compress_enable_double_write

Parameter description: Specifies whether to enable cross-page transparent compression doublewrite. After this function is disabled, compressed data may be damaged in abnormal breakdown scenarios.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: enabled.
- **off**: disabled.

Default value: **on**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- A complete cross-page transparent compression doublewrite requires recording both metadata and actual data.
- If both **turbo_compress_enable_double_write** and **enable_double_write** are set to **on**, doublewrite is recorded for both parts. If both parameters are set to **off**, doublewrite is not recorded for both parts. If only one parameter is set to **on**, doublewrite is recorded only for metadata.
- If the doublewrite operation is not recorded, the damaged metadata cannot be restored. If only the doublewrite operation is recorded, the damaged data can be restored using HA.

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value **on**.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

turbo_compress_preload_workers_num

Parameter description: Specifies the number of threads for prefetching compressed pages in parallel replay or ultimate RTO mode.

Parameter type: integer.

Unit: none

Value range: 0 to 16

Default value: **0**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value **0**.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

turbo_compress_force_fast_allocate

Parameter description: Specifies whether to use fast preemption to allocate space during table compression. By default, **0** is used for allocation.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: enabled.
- **off**: disabled.

Default value: **off**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Setting suggestion: Set this parameter to **on** for file systems, such as ext4, that support fast preemption to improve the expansion speed of compressed tables.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

6.3.50 Session-level Transaction Pushdown and Related Parameters

session_type

Parameter description: Specifies the type of the current session. The value is case-insensitive. An execution plan is generated based on the actual value.

Parameter type: enumerated type

Unit: none

Value range:

- **single_node**: single-node session. Read and write operations can be pushed down. Nodes to be pushed down are determined and an execution plan is generated based on the GUC parameter **exec_target_node**.
- **global_read_only**: cross-node read-only session. A distributed plan is generated normally, but distributed write operations are forbidden.
- **normal**: default session, which is the same as the original behavior. The plan is executed based on the original logic of the database.

Default value: **normal**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-2**. Note that this parameter cannot be set globally using gs_guc.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: When data is inserted in single-node session mode (**session_type** is set to **single_node**), correct data distribution is ensured by the application layer. If an incorrect node is specified, data may be inconsistent.

exec_target_node

Parameter description: Specifies the name of the DN where DML statements and some DDL statements (TRUNCATE and ALTER TABLE...TRUNCATE PARTITION...) of the current session are executed. The name is case-sensitive. If the DN name is invalid, an error is reported during the setting.

NOTE

This parameter is valid only when the GUC parameter **session_type** is set to **single_node**.

Parameter type: string.

Unit: none

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Value range: names of all DNs in the current cluster. You can obtain the names of all DNs by querying the PGXC_NODE system catalog.

Default value: ""

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-2**. Note that this parameter cannot be set globally using gs_guc.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: In single-node session mode, if the parameters are not used according to the restrictions, data inconsistency may occur.

NOTE

The single-node session mode has the following restrictions:

- The router function does not take effect in this scenario.
- The DN specified by **node_name hint** does not take effect and is delivered by **exec_target_node**.
- Statements involving row-level security are not supported.
- Reading on the distributed standby node is not supported.
- Advanced package statements are not supported.
- GPC is not supported.
- In single-node session mode, when the PBE statement is used, the plan type is directly set to **GPlan**. If the single-node session mode is specified after a plan is generated, the original plan type remains unchanged.

Examples

```
gaussdb=# SET log_min_messages = debug2;
gaussdb=# SET logging_module = 'on(opt_choice)';
gaussdb=# CREATE TABLE t1(a int ,b int);
gaussdb=# PREPARE x(int) AS SELECT * FROM t1;
gaussdb=# EXPLAIN EXECUTE x(10);
NOTICE:  [Choosing C/G/A Plan]: GPlan, reason: Using pbe optimization.
NOTICE:  [Choosing C/G/A Plan]: CPlan, reason: First 5 times using CPlan.
                QUERY PLAN
--------------------------------------------------
 Data Node Scan  (cost=0.00..0.00 rows=0 width=0)
   Node/s: All datanodes
(2 rows)
gaussdb=# DEALLOCATE x;

gaussdb=# PREPARE x(int) AS SELECT * FROM t1;
gaussdb=# SET session_type=single_node;
gaussdb=# SET exec_target_node=datanode1;
gaussdb=# EXPLAIN EXECUTE x(10);
NOTICE:  [Choosing C/G/A Plan]: GPlan, reason: Using pbe optimization.
NOTICE:  [Choosing C/G/A Plan]: GPlan, reason: Using pbe optimization.
                QUERY PLAN
--------------------------------------------------
 Data Node Scan  (cost=0.00..0.00 rows=0 width=0)
   Node/s: datanode1
(2 rows)
gaussdb=# DEALLOCATE x;
gaussdb=# DROP TABLE t1;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

6.3.51 Enhanced TOAST

enable_enhance_toast_table

Parameter description: Specifies whether the enhanced TOAST out-of-line storage table is used.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: enabled.
- **off**: disabled.

Default value: **on**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: The default value of this parameter is **on**. To disable the enhanced TOAST out-of-line storage function, set this parameter to **off**.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

6.3.52 Global Temporary Table

max_active_global_temporary_table

Parameter description: Specifies whether global temporary tables can be created. The value of this parameter determines the memory reserved in the shared cache for hash tables required by global temporary tables. The total number of active global temporary tables in all sessions is not forcibly limited.

Parameter type: integer.

Unit: none

Value range: 0 to 1000000

- **0**: The global temporary table function is disabled.
- > 0: The global temporary table function is enabled.

Default value: **1000**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

vacuum_gtt_defer_check_age

Parameter description: Specifies the difference between the minimum value of **relfrozenxid** of all global temporary tables and that of all ordinary tables in the

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

current database after VACUUM is executed. If the minimum value of **relfrozenxid** of all global temporary tables is greater than the specified value, the alarm "global temp table oldest relfrozenxid %lu is the oldest in the entire db" is generated to remind users to manually execute VACUUM. Otherwise, Clogs may not be recycled.

Parameter type: integer.

Unit: none

Value range: 0 to 1000000

Default value: **10000**.

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

enable_gtt_concurrent_truncate

Parameter description: Specifies whether to support concurrent execution of TRUNCATE TABLE and DML operations on global temporary tables and concurrent execution of TRUNCATE TABLE on global temporary tables.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The preceding operations can be performed concurrently.
- **off**: The preceding operations cannot be performed concurrently.

Default value: **on**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

global_gtt_cn_session_key

Parameter description: Specifies the ID of the current session, that is, the global unique session ID of a distributed global temporary table.

Parameter type: string.

Unit: none

Value range: a string.

Default value: none

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Setting method: This is an internal parameter and cannot be set by users. No query result is returned.

Setting suggestion: No setting is allowed.

Risks and impacts of improper settings: none

gtt_reuse_wait_timeout

Parameter description: Specifies the maximum timeout interval for the current session to wait for the previous session to release related resources when the current session reuses the GTT session mapping entry during the REUSE operation on a distributed global temporary table.

Parameter type: integer

Unit: milliseconds

Value range: 0 to 1200000

Default value: **5000** (5s)

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value. If the network latency is high or errors are frequently reported when long transactions frequently use global temporary tables, you can increase the value of this parameter to prevent REUSE failures caused by waiting timeout.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing. If the value is too small, REUSE timeout errors may occur within the normal cleanup period, affecting service continuity. If the value is too large, DN threads may be blocked in REUSE waiting for a long time, affecting the response of the threads to other requests.

6.3.53 Single-Node Table

default_nodegroup

Parameter description: Specifies whether to enable the function of setting single-node attributes by default when a schema is created.

Parameter type: string.

Unit: none

Value range:

- **NONE**: The function of setting single-node attributes is disabled by default when a schema is created.
- **SCHEMA**: The function of setting single-node attributes is enabled by default when a schema is created.

Default value: **NONE**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

NOTE

If **default_nodegroup** is set to **SCHEMA**, only common users are allowed to set single-node attributes by default. Administrators, O&M personnel, and initial user are not allowed to set single-node attributes by default.

single_node_table_strategy

Parameter description: Specifies the behavior of creating single-node tables.

Parameter type: string.

Unit: none

Value range: **FORBID**, **ALLOW_STRICT**, **ALLOW_DEFAULT_NON_PART**, and **ALLOW_DEFAULT_ALL**

- **FORBID**: Disables the function of creating single-node tables, including the capability of converting other tables into single-node tables.
- **ALLOW_STRICT**: Enables the function of explicitly creating single-node tables, including partitioned and non-partitioned tables.
- **ALLOW_DEFAULT_NON_PART**: Enables the function of creating a new single-node table by default based on the single-node attribute of the schema when no distribution policy is specified and the TO GROUP clause is not specified for non-partitioned tables. This function is enabled on the basis of the function of explicitly creating single-node tables.
- **ALLOW_DEFAULT_ALL**: Enables the function of creating a single-node table by default based on the single-node attribute of the schema when no distribution policy is specified and the TO GROUP clause is not specified for partitioned tables and non-partitioned tables. This function is enabled on the basis of the function of explicitly creating single-node tables.

Default value: **ALLOW_STRICT**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

NOTE

Single-node tables support backup and restoration. If the GUC parameter **single_node_table_strategy** is enabled in the source database and a single-node table exists, but the GUC parameter **single_node_table_strategy** is disabled in the target database, the following situations may occur during backup and restoration:

- For database-level backup and restoration: The restoration can be performed properly, and the table has the single-node attribute.
- For table-level backup and restoration: An error is reported. You need to modify the parameter (enable the GUC parameter **single_node_table_strategy**) before performing the restoration.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

6.3.54 HTAP

This section describes the parameters related to the hybrid transactional/analytical processing (HTAP) feature.

enable_htap

Parameter description: Specifies whether to enable the HTAP feature. After the HTAP feature is enabled, the inventory row-store data of the column specified by the COLVIEW keyword is loaded to the in-memory column view (IMCV). It is used to improve the query efficiency of the analytical processing (AP).

Parameter type: Boolean

Unit: none

Value range:

- **on**: The HTAP feature is enabled.
- **off**: The HTAP feature is disabled.

Default value: **off**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: This parameter is disabled by default. If you need to enable this parameter, consider the database application scenario. When a large number of APs need to be queried, enable this parameter to improve the query efficiency. You are advised not to enable this parameter in only TP query scenarios.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

htap_max_mem_size

Parameter description: Specifies the upper limit of the available memory for the HTAP feature. This parameter takes effect only when the HTAP feature is enabled. After the dynamic memory usage of GaussDB reaches the upper limit, no more memory can be allocated even if the HTAP memory usage does not reach the upper limit.

Parameter type: integer.

Unit: KB

Value range: 102400 to 1073741824

Default value: **1048576**, that is, 1 GB.

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**. The value can be specified without a unit, for example, **1000000** (indicating 1000000 KB), or with a unit, for example, **1GB** (indicating 1 GB). The unit must be KB, MB, or GB if required. You can increase the value of this parameter without restarting the system. If you decrease the value of this parameter, no error is reported, but the change takes effect only after the system is restarted. That is, the value before the restart is the original value, and the value after the restart is the new value.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Setting suggestion: The value of this parameter cannot exceed the value of **max_process_memory** and the maximum shared memory. Allocate idle memory as the value of this parameter based on the actual application scenario. If **htap_memctl_policy** is set to **swap** or **escape**, the value of **htap_used_memory** may be slightly greater than that of **htap_max_mem_size** during loading and rebuilding. After the loading or rebuilding is complete, the value of **htap_used_memory** automatically falls below that of **htap_max_mem_size**.

In extreme cases, the memory overflow during manual loading or rebuilding is calculated as follows: Number of tables loaded at the same time x **htap_rowgroup_pagenum** x 8 KB x Degree of parallelism (for details, see **gs_imcv_flush**).

The overflow caused by automatic rebuilding in extreme cases during service running is calculated as follows: **htap_flush_workers** (number of background threads) x **htap_rowgroup_pagenum** x 8 KB.

Risks and impacts of improper settings: The **htap_max_mem_size** setting is based on the dynamic memory and memory management mechanism of GaussDB. If **max_process_memory** is set improperly, **htap_max_mem_size** is set to a large value, or logical memory management is disabled, the system memory may be insufficient. If **htap_max_mem_size** is set to a small value, an insufficient memory exception may be frequently triggered or the IMCV table may be flushed to disks during IMCV creation based on the value of **htap_memctl_policy**.

NOTE

- The maximum available memory of this parameter refers to the memory occupied by user data in column-store format in HTAP. In addition, the memory of metadata such as IMCU descriptors is not counted in this range. Therefore, the actual memory used by HTAP is greater than this value.
- A row group in HTAP column-store format is mapped to a certain number of pages in row-store format, that is, the parameter **htap_rowgroup_pagenum**. The number of IMCUs contained in a row group corresponds to the number of columns in a table. Therefore, the metadata background noise is affected by the data volume, number of columns, and number of row-store page mappings of the table. In the large data volume scenario where the number of page mappings is 8192, the number of columns in a single table is 100, and the data volume loaded in the column-store format is 1 TB, the HTAP metadata background noise is within 1.5 GB.
- You can query the **max_dynamic_memory** (maximum dynamic memory) and **dynamic_used_memory** (used dynamic memory) in the gs_total_memory_detail view.

htap_rowgroup_pagenum

Parameter description: Specifies the relationship between the number of row groups and the number of row-store page mappings of the HTAP feature. This parameter takes effect only when the HTAP feature is enabled.

Parameter type: integer.

Unit: none

Value range: **1000**, **2048**, **4096**, and **8192**

Default value: **1000**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Setting suggestion: Retain the default value for small data volume scenarios where the column-store data is less than 100 GB. Use the maximum value 8192 for column-store data scenarios where the column-store data is more than 1 TB.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

htap_eviction_threshold

Parameter description: Specifies the threshold for swapping in and out the HTAP feature buffer. This parameter takes effect only when the HTAP feature is enabled.

Parameter type: integer.

Unit: %

Value range: 0 to 100

- **0**: No IMCU is loaded to the shared buffer.
- **100**: The buffer evicts only when the memory usage exceeds the upper limit. No eviction or loading is performed in other time.
- Other values: The buffer starts the eviction task only when the HTAP memory usage reaches **htap_max_mem_size** x **htap_eviction_threshold**/100.

Default value: **90**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value. If you set this parameter to **0** or **100**, you need to fully understand the parameter meaning and evaluate the impact.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

htap_memctl_policy

Parameter description: Specifies the memory management policy mode of the HTAP feature. This parameter takes effect only when the HTAP feature is enabled.

Parameter type: enumerated type

Unit: none

Value range:

- **delete**: This value is deprecated. After the value is forcibly changed, the value that takes effect is **escape**.
- **swap**: When the HTAP memory is insufficient, data exchange occurs. The Anti-Cache and lazy loading policies are used. Infrequently used data is asynchronously flushed to the local disk. If a table is loaded in the column-store format by using DDL statements, the excess data is flushed to disks when the memory is insufficient.
- **escape**: When the HTAP memory is insufficient, only the metadata of new column-store data is stored. During data query, the data is read back from

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

rows instead of being stored in the column-store format, which is similar to the row group where all pages are dirty pages.

Default value: **swap**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

This policy takes effect in the following two memory insufficiency scenarios:

1. The HTAP memory usage reaches the upper limit specified by **htap_max_mem_size**.
2. The global dynamic memory usage reaches the upper limit of dynamic memory management.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

enable_imcvscan

Parameter description: Specifies whether to enable the HTAP memory column scanning operator IMCVScan. This parameter takes effect only when the HTAP feature is enabled.

Parameter type: Boolean

Unit: none

Value range:

- **on**: The HTAP memory column scanning operator IMCVScan is enabled.
- **off**: The HTAP memory column scanning operator IMCVScan is disabled.

Default value: **on**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

enable_hybrid_imcvscan

Parameter description: Specifies whether to enable the HTAP column-to-row hybrid scan feature. This parameter takes effect only when the HTAP feature is enabled and depends on the value of **enable_imcvscan**.

Parameter type: Boolean

Unit: none

Value range:

- **on**: The HTAP column-row hybrid scan feature is enabled. This feature is enabled only when **enable_imcvscan** is set to **on**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **off**: The HTAP column-row hybrid scan feature is disabled, regardless of the value of **enable_imcvscan**.

Default value: **on**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

imcvscan_consistency

Parameter description: Specifies the consistency semantics of column-store scanning. This parameter takes effect only when the HTAP feature is enabled and depends on the value of **enable_imcvscan**.

In strong consistency semantics, column-store scanning always keeps consistent with the row-store result regardless of whether there are unsynchronized row-store changes in the column-store data.

In weak consistency semantics, only column-store data is scanned. If there are unsynchronized row-store changes in the column-store data, consistency with the row-store result is not guaranteed. Column-to-row conversion and standby node IMCV scan are not supported.

Parameter type: enumerated type

Unit: none

Value range:

- **strong**: strong consistency, which ensures strong consistency with the row-store scan result.
- **weak**: weak consistency. Only column-store data is scanned. If column-store data has unsynchronized row-store changes, the consistency with the row-store result is not guaranteed.

Default value: **strong**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value. You are advised to use weak consistency semantics only when there is no strong consistency requirement between column-store scan results and row-store data. Weak consistency semantics does not support column-to-row conversion. When **enable_hybrid_imcvscan** is set to **on**, the setting of **imcvscan_consistency** to **weak** is ignored and strong consistency semantics is used.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing. In weak consistency semantics, do not use the column-store scan result as the basis for service operations to avoid data problems.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

htap_router_mode

Parameter description: Specifies the HTAP transparent routing mode. This parameter takes effect only when the HTAP feature is enabled.

Parameter type: enumerated type

Unit: none

Value range:

- **row**: The query is forcibly loaded to select a row-store plan.
- **column**: When columns in a query request are loaded to IMCV, the column-store plan IMCVScan is forcibly executed regardless of the cost. If some columns are not loaded to IMCV, the row-store plan is executed.
- **auto**: The system automatically selects a hybrid plan based on whether the columns in the query request are loaded to IMCV and the cost of the row-column plan.

Default value: **row**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: If there are hybrid loads, you are advised to set this parameter to **auto**.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

htap_flush_workers

Parameter description: Specifies the maximum number of background threads for HTAP. This parameter takes effect only when the HTAP feature is enabled. The background threads are used to synchronize incremental row-store data to IMCV row groups, asynchronously load data, and swap data in and out of the buffer.

Parameter type: integer.

Unit: none

Value range: 1 to 256

Default value: **3**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: If multiple tables need to be loaded, increase the value of this parameter. After the loading is complete, decrease the value to the default one.

Risks and impacts of improper settings: If the value is too large, the TP performance may be affected. If the value is too small, the AP performance may be affected.

htap_flush_pagenum

Parameter description: Specifies the dirty page threshold for synchronizing incremental row-store data to the IMCV row group. If the number of dirty pages is

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

greater than the threshold, synchronization is triggered. This parameter takes effect only when the HTAP feature is enabled.

Parameter type: integer.

Unit: none

Value range: -1 or 1 to 8192. The value **-1** indicates that the threshold is infinite and synchronization is not performed based on the number of dirty pages.

Default value: **512**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value. Decreasing the value of this parameter improves AP performance, but may affect TP performance. Increasing the value of this parameter affects AP performance. The value of this parameter is associated with that of **htap_rowgroup_pagenum**. If the value is greater than the number of page mappings, the value **htap_rowgroup_pagenum** is used.

Risks and impacts of improper settings: If the value is too small, the TP performance may be affected. If the value is too large, the AP performance may be affected. The default value is recommended.

htap_flush_interval

Parameter description: Specifies the maximum time interval for synchronizing incremental row-store data to the IMCV row group. This parameter takes effect only when the HTAP feature is enabled.

Parameter type: integer.

Unit: seconds

Value range: -1 or 1 to 36000. The value **-1** indicates that the threshold is infinite and synchronization is not performed based on the interval.

Default value: **300**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value. Decreasing the value of this parameter improves AP performance, but may affect TP performance. Increasing the value of this parameter affects AP performance.

Risks and impacts of improper settings: If the value is too small, the TP performance may be affected. If the value is too large, the AP performance may be affected. The default value is recommended.

enable_async_populate

Parameter description: Specifies whether the **ALTER ... COLVIEW** command waits for column-store data to be loaded before returning a result. This parameter depends on whether the HTAP feature is enabled. In distributed mode, column-store data cannot be synchronously loaded. The value **on** takes effect regardless of the setting.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The **ALTER ... COLVIEW** command returns a result immediately after creating metadata. The actual data loading to IMCV is performed in the background.
- **off**: After the **ALTER ... COLVIEW** command creates metadata, the command returns a result only after the background thread loads data to IMCV.

Default value: **on**

Setting method: This is a USERSET parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

htap_deploy_mode

Parameter description: Specifies the HTAP deployment mode. This parameter takes effect only when the HTAP feature is enabled. In distributed mode, HTAP can be deployed only on the primary node. In distributed mode, the value **primary** takes effect regardless of the setting.

Parameter type: enumerated type

Unit: none

Value range:

- **primary**: deployed on the primary node. Only the HTAP function is enabled on the primary node. IMCV DDL logs are not replayed on the standby node. During a switchover, IMCV is unloaded when the primary node is demoted to the standby node, and IMCV is reloaded when the standby node is promoted to the primary node.
- **all**: deployed on both the primary and standby nodes. IMCV data on the primary and standby nodes is retained during a switchover.
- **standby**: deployed on the standby node. Only the HTAP function is enabled on the standby node. When IMCV is created on the primary node, only metadata is created, and data is not loaded. During a switchover, IMCV is loaded when the primary node is demoted to the standby node, and IMCV is unloaded when the standby node is promoted to the primary node. Only metadata is created.

Default value: **primary**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Retain the default value. In a primary/standby cluster, set this parameter to the same value on both nodes.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

htap_compression_methods

Parameter description: Specifies whether to enable the IMCV column-store compression feature and the list of enabled compression algorithms. This parameter takes effect only when the HTAP feature is enabled.

Parameter type: enumerated type

Unit: none

Value range:

- **none**: The IMCV column-store compression feature is disabled.
- **delta_plus_rle**: The IMCV column-store compression feature is enabled, and the delta_plus_rle algorithm is used.
- **dict**: The IMCV column-store compression feature is enabled, and the dict algorithm is used.
- **lz4**: The IMCV column-store compression feature is enabled, and the LZ4 algorithm is used.
- **all**: The IMCV column-store compression feature is enabled, and the delta_plus_rle, dict, and LZ4 algorithms are used.

Default value: **none**

Setting method: This is a POSTMASTER parameter. Set it based on instructions provided in **Table 6-1**.

Setting suggestion: Use the default value when the memory is sufficient. In an environment with small memory and large data volume, enable IMCV column-store compression to keep as much data as possible in the memory.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

6.3.56 Vector Database Parameters

diskann_probe_ncandidates

Parameter description: Specifies the size of the candidate set when the GsDiskANN index is used to retrieve vectors.

Parameter type: integer

Unit: none

Value range: 1 to 32768

Default value: **128**

Setting method: This is a USERSET parameter. Set it based on instructions provided in "Database GUC Parameters > Setting Parameters" in *Reference*.

Setting suggestion:

- Retain the default value. Obtain the optimal parameter settings through experiments.
- The **diskann_probe_ncandidates** parameter can be set and take effect for some queries that use the GsDiskANN index. You are advised to set the parameter only in a session using SET. You are advised not to use gs_guc to set the parameter globally.

Risks and impacts of improper settings: If the value is too large, the query performance deteriorates. If the value is small, the retrieval rate is insufficient.

diskann_hybrid_search_type

Parameter description: Specifies the query policy for vector-scalar hybrid searches. This parameter can be set and take effect for queries in the vector-scalar hybrid search.

NOTE

This parameter takes effect at the session level. You are advised to set the GUC parameter using method 2 in "Database GUC Parameters > Setting Parameters" in *Reference*. Otherwise, the specified policy cannot be selected on DNs.

Parameter type: string

Unit: none

Value range:

- **"AUTO"** (default): The policy is selected based on the values of **diskann_hybrid_pre_filter_selectivity** and **diskann_hybrid_flat_upper_bound**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **"PRE_FILTER_FLAT"**: The policy is to perform filtering and then flat search.
- **"PRE_FILTER_ANN"**: The policy is to perform filtering and then graph search.
- **"POST_FILTER_ANN"**: The policy is to perform graph search and then filtering.

Default value: **"AUTO"**

Setting method: This is a USERSET parameter. Set it based on instructions provided in "Database GUC Parameters > Setting Parameters" in *Reference*.

Setting suggestion: Retain the default value. Obtain the optimal parameter settings through experiments.

Risks and impacts of improper settings: If this parameter is set to an improper value in different data set scenarios, the retrieval rate may be insufficient or the query performance may deteriorate.

diskann_hybrid_pre_filter_selectivity

Parameter description: Specifies the selectivity threshold of the pre-filter policy in the vector-scalar hybrid search. If the selectivity is less than the threshold, pre-filter is performed. If the selectivity is greater than or equal to the threshold, post-filter is performed.

NOTE

- If the value of **diskann_hybrid_search_type** is not the default value, this parameter does not take effect.
- This parameter takes effect at the session level. You are advised to set the GUC parameter using method 2 in "Database GUC Parameters > Setting Parameters" in *Reference*. Otherwise, the specified policy cannot be selected on DNs.

Parameter type: floating-point

Unit: none

Value range: 0 to 1

Default value: **0.15**

Setting method: This is a USERSET parameter. Set it based on instructions provided in "Database GUC Parameters > Setting Parameters" in *Reference*.

Setting suggestion: Retain the default value. Obtain the optimal parameter settings through experiments.

Risks and impacts of improper settings: If this parameter is set to an improper value, the retrieval rate may be insufficient or the query performance may deteriorate.

diskann_hybrid_pullup_selectivity

Parameter description: Specifies the selectivity threshold for moving pre-filter conditions to post-filter when vector-scalar hybrid search is performed in the pre-filter scenario. A smaller value indicates that more pre-filter conditions are moved to post-filter. The default value is **1.0**, indicating that no pre-filter conditions are moved to post-filter.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- When conditions are moved to post-filter, each sub-condition connected by AND at the outermost layer is considered as a whole to determine whether to move it. For example, in **A > 5 AND (B > 3 OR C > 3)**, **A > 5** is a whole, and **(B > 3 OR C > 3)** is a whole. **(B > 3 OR C > 3)** is either placed in pre-filter or post-filter, and will not be split.
- The priority of this parameter is lower than that of the **diskann_hybrid_search_type** and **diskann_hybrid_pre_filter_selectivity** parameters. Pre-filter can be moved to post-filter only when **diskann_hybrid_search_type** is set to the default value and the overall selectivity of the filter conditions is less than the value of **diskann_hybrid_pre_filter_selectivity**.
- The algorithm moves as many conditions as possible from pre-filter to post-filter in descending order of selectivity until the following limitations are no longer met: post-filter selectivity > **diskann_hybrid_pullup_selectivity**; post-filter selectivity ≥ **diskann_hybrid_pre_filter_selectivity**.
- This parameter does not take effect when the overall filter selectivity is **0**.
- The behavior of **diskann_hybrid_pullup_selectivity < diskann_hybrid_pre_filter_selectivity** is equivalent to that of **diskann_hybrid_pullup_selectivity = diskann_hybrid_pre_filter_selectivity**.
- The algorithm ensures that not all pre-filter conditions are moved to post-filter.

Parameter type: floating-point

Unit: none

Value range: 0 to 1

Default value: **1**

Setting method: This is a USERSET parameter. Set it based on instructions provided in "Database GUC Parameters > Setting Parameters" in *Reference*.

Setting suggestion: In the pre-filter flat or graph search policy, the overhead of generating a bitmap based on the filter conditions is directly proportional to the sum of the data set size multiplied by the selectivity of each filter condition. Therefore, if the sum of the data set size multiplied by the selectivity is too large, causing the query delay of the pre-filter policy to be excessively high, you can decrease the value of this parameter to move some pre-filter conditions to post-filter, reducing the overhead of bitmap generation.

Risks and impacts of improper settings: This parameter setting will cause the execution plan to change. If it is set improperly, the query may not use the optimal execution plan.

diskann_hybrid_flat_upper_bound

Parameter description: Specifies the maximum data volume threshold of the flat search policy before performing the vector-scalar hybrid search in pre-filter scenarios. If the data volume is less than the threshold, flat search is performed. If the data volume is greater than the threshold, vector search is performed.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- If this parameter is set to **0**, the value **8000** takes effect in the Arm64 architecture, and the value **11000** takes effect in other architectures.
- If the value of **diskann_hybrid_search_type** is not the default value, this parameter does not take effect.
- This parameter takes effect at the session level. You are advised to set the GUC parameter using method 2 in "Database GUC Parameters > Setting Parameters" in *Reference*. Otherwise, the specified policy cannot be selected on DNs.

Parameter type: integer

Unit: none

Value range: 0 to 1000000

Default value: **0**

Setting method: This is a USERSET parameter. Set it based on instructions provided in "Database GUC Parameters > Setting Parameters" in *Reference*.

Setting suggestion: Retain the default value. Obtain the optimal parameter settings through experiments.

Risks and impacts of improper settings: If this parameter is set to an improper value, the retrieval rate may be insufficient or the query performance may deteriorate.

diskann_hybrid_neighbor_search_prune_factor

Parameter description: Specifies the pruning factor for neighbors that do not meet the query conditions during the search process in the scenario where the filtering-before-ANN policy is used for vector-scalar hybrid indexing. The value **0** indicates no pruning, and the value **1** indicates full pruning. A larger value indicates a higher pruning ratio.

Parameter type: floating-point

Unit: none

Value range: 0 to 1

Default value: **0**.

Setting method: This is a USERSET parameter. Set it based on instructions provided in "Database GUC Parameters > Setting Parameters" in *Reference*.

Setting suggestion:

- The value **0.3** is recommended. In most scenarios, a larger pruning factor improves query performance but reduces the retrieval rate. Conversely, a smaller pruning factor improves the retrieval rate but reduces query performance. It is recommended that you obtain the optimal parameter configuration through experiments.
- This parameter takes effect at the session level. You are advised to set GUC parameters using method 2 in "Database GUC Parameters > Setting Parameters" in *Reference*. Otherwise, the specified filtering policy cannot be used on DNs.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Risks and impacts of improper settings: If this parameter is set to a large value, the retrieval rate may be insufficient.

diskann_hybrid_enable_lazy_flip_bitmap

Parameter description: Specifies whether to enable the lazy flip bitmap feature. In the case of a scalar query or IS NOT NULL query condition with a selectivity greater than 50% under the pre-filter flat or graph search policy, the lazy flip bitmap calculates the complement of the query to reduce the overhead of inserting data into the bitmap.

Parameter type: Boolean

Unit: none

Value range:

- **on**: enabled.
- **off**: disabled.

Default value: **on**

Setting method: This is a USERSET parameter. Set it based on instructions provided in "Database GUC Parameters > Setting Parameters" in *Reference*.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

gsivfflat_probes

Parameter description: Specifies the number of inverted tables to be searched when the GsIVFFLAT index is used to retrieve vectors. If this value exceeds the total number of inverted tables of the GsIVFFLAT index, the entire table is searched. The total number of inverted tables of the GsIVFFLAT index is specified by the **ivf_nlist** parameter during index build.

Parameter type: integer

Unit: none

Value range: 1 to 32768

Default value: **5**

Setting method: This is a USERSET parameter. Set it based on instructions provided in "Database GUC Parameters > Setting Parameters" in *Reference*.

Setting suggestion: Set this parameter to 3% of the value of **ivf_nlist** during index build. You are advised to obtain the optimal parameter configuration through experiments.

Risks and impacts of improper settings: If this parameter is set to a larger value, the search takes a longer time but the search result is more accurate.

gsivfflat_secondary_probes

Parameter description: Specifies the number of secondary inverted tables to be searched when the GsIVFFLAT index is used to retrieve vectors. If this value

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

exceeds the total number of secondary inverted tables, the entire table is searched. The total number of secondary inverted tables is specified by the **ivf_nlist2** parameter during index build.

Parameter type: integer

Unit: none

Value range: 1 to 32768

Default value: **5**

Setting method: This is a USERSET parameter. Set it based on instructions provided in "Database GUC Parameters > Setting Parameters" in *Reference*.

Setting suggestion: You are advised to set this parameter to a value between 1/4 and 1/2 of the value of **ivf_nlist2** during index build. You are advised to obtain the optimal parameter configuration through experiments.

Risks and impacts of improper settings: If this parameter is set to a larger value, the search takes a longer time but the search result is more accurate.

NOTE

gsivfflat_secondary_probes has the same effect as **gsivfflat_probes**. It takes effect only when the vector index is a double-layer index, which effectively accelerates the query speed. You are advised to obtain the optimal parameter configuration through experiments.

enable_vectordb

Parameter description: Specifies whether vector indexes can be created and whether vector indexes can be added, modified, and queried.

Parameter type: Boolean

Unit: none

Value range:

- **on**: allowed.
- **off**: not allowed.

Default value: **off**

Setting method: This is a SIGHUP parameter. Set it based on instructions provided in "Database GUC Parameters > Setting Parameters" in *Reference*.

Setting suggestion: If users are not allowed to use vector database features such as vector index, set this parameter to **off**. Otherwise, set this parameter to **on**.

Risks and impacts of improper settings: The parameter value determines whether users can use the vector database features. If the parameter value is incorrect, users may be unable to use the intended database features.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 6-53 GUC parameters related to the vector database

GUC Parameter	Level	Value Range (Default Value)	Description
maintenance_work_mem	Session	[1024,2147483647]/[1MB,2048GB) (65536/64MB)	Maximum amount of memory used in maintenance operations. The default unit is KB.
diskann_probe_ncandidates	Session	[1, 32768](128)	Size of the candidate set when the GsDiskANN index is used to retrieve vectors.
gsivfflat_probes	Session	[1, 32768](5)	Number of inverted tables to be searched. If it exceeds the total number of inverted tables, the entire table is searched.
gsivfflat_secondary_probes	Session	[1, 32768](5)	Number of secondary inverted tables to be searched. If it exceeds the total number of secondary inverted tables, the entire table is searched.
enable_vectordb	SIGHUP	[off,on](off)	An advanced feature that specifies whether vector indexes can be created and whether vector indexes can be added, modified, and queried.

6.4 CM Parameters

Modifying CM parameters affects the running mechanism of GaussDB. You are advised to ask GaussDB engineers to do it for you. For details about how to modify CM parameters, see method 1 in **Table 6-2** or the corresponding method in **Table 6-3**. All CM parameters can be set using methods in **Table 6-3**. You are advised to use the cm_ctl tool.

You can view CM Agent parameters in the **cm_agent.conf** file in the CM Agent data directory and CM Server parameters in the **cm_server.conf** file in the CM Server data directory.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

6.4.1 CM Agent Parameters

log_dir

Parameter description: Specifies the directory where CM Agent logs are stored. The value can be an absolute path, or a path relative to the CM Agent data directory.

Parameter type: string

Unit: none

Value range: a valid directory.

Default value: "*$GAUSSLOG*/cm/cm_agent", indicating that the CM Agent logs are generated in the CM directory in *$GAUSSLOG*.

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 1 in **Table 6-2**. The modification takes effect only after the cluster is restarted.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

log_file_size

Parameter description: Specifies the size of a log file. If a log file exceeds the specified size, a new one is created to record logs.

Parameter type: integer

Unit: MB

Value range: 0 to 2047

Default value: **16**

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 1 and method 2 in **Table 6-2**. For example, if this parameter is set to **16** without a unit, it indicates 16 MB. If this parameter is set to **16MB**, it indicates 16 MB. The unit must be MB if required.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

log_min_messages

Parameter description: Specifies which message levels are written to the CM Agent log. A higher level covers the messages of all the lower levels. The lower the level is, the fewer messages will be written into the log.

Value type: enumerated

Unit: none

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Value range: **debug5**, **debug1**, **log**, **warning**, **error**, and **fatal**.

Default value: **warning**

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 1 and method 2 in **Table 6-2**.

Setting suggestion: Set this parameter based on the hard disk size.

Risks and impacts of improper settings: If a low level is set, debugging information may be lost.

log_threshold_check_interval

Parameter description: Specifies the interval for compressing and clearing logs.

Parameter type: integer

Unit: seconds (s)

Value range: 0 to 2147483647

Default value: **1800**

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 1 and method 2 in **Table 6-2**.

Setting suggestion: Retain the default value. You can adjust the value based on the disk space and scenario requirements.

Risks and impacts of improper settings: If this parameter is set to a large value, too much disk space may be occupied.

log_max_size

Parameter description: Specifies the maximum size of a log file.

Parameter type: integer

Unit: MB

Value range: 0 to 2147483647

Default value: **10240**

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 1 and method 2 in **Table 6-2**.

Setting suggestion: Retain the default value. You can adjust the value based on the disk space and scenario requirements.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

log_max_count

Parameter description: Specifies the maximum number of logs that can be stored on hard disks.

Parameter type: integer

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Unit: none

Value range: 0 to 2147483647

Default value: **10000**

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 1 and method 2 in **Table 6-2**.

Setting suggestion: Retain the default value. You can adjust the value based on the disk space and scenario requirements.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

log_saved_days

Parameter description: Specifies the number of days for storing logs.

Parameter type: integer

Unit: day

Value range: 0 to 1000

Default value: **90**

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 1 and method 2 in **Table 6-2**.

Setting suggestion: Retain the default value. You can adjust the value based on the disk space and scenario requirements.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

enable_log_compress

Parameter description: Specifies whether to enable the log compression function.

Parameter type: Boolean

Unit: none

Value range:

- **on**: The log compression function is enabled.
- **off**: The log compression function is disabled.

Default value: **on**

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 1 and method 2 in **Table 6-2**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

incremental_build

Parameter description: Specifies whether a standby DN is incrementally built.

Parameter type: Boolean

Unit: none

Value range:

- **on**: Standby DNs are incrementally rebuilt.
- **off**: Standby DNs are fully rebuilt.

Default value: **on**

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 1 and method 2 in **Table 6-2**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

alarm_component

Parameter description: Specifies the location of the alarm component that processes alarms.

Parameter type: string

Unit: none

Value range: a valid file path.

- If **--alarm-type** in the gs_preinstall script is set to **5**, no third-party component is connected and alarms are written into system_alarm logs. In this case, the value of **alarm_component** is **/opt/huawei/snas/bin/snas_cm_cmd**.
- If **--alarm-type** in the gs_preinstall script is set to **1**, a third-party component is connected. In this case, the value of **alarm_component** is the absolute path of the executable program of the third-party component.

Default value: **"/opt/huawei/snas/bin/snas_cm_cmd"**

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 1 and method 2 in **Table 6-2**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

alarm_report_interval

Parameter description: Specifies the interval at which an alarm is reported.

Parameter type: integer

Unit: seconds

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Value range: 1 to 2147483647

Default value: **1**

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 1 and method 2 in **Table 6-2**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If the value is too large, alarms may not be reported in a timely manner. If the value is too small, the CPU load may increase.

alarm_report_max_count

Parameter description: Specifies the maximum number of times an alarm is reported.

Parameter type: integer

Unit: none

Value range: 1 to 2592000

Default value: **1**

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 1 and method 2 in **Table 6-2**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If the value is too large, the CPU load may increase.

agent_report_interval

Parameter description: Specifies the interval at which CM Agent reports the instance status.

Parameter type: integer

Unit: seconds

Value range: 1 to 2147483647

Default value: **1**

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 1 and method 2 in **Table 6-2**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If the value is too large, CM fault detection and recovery cannot be performed in a timely manner.

agent_phony_dead_check_interval

Parameter description: Specifies the interval at which CM Agent checks whether the CN, DN, or GTM process is suspended.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter type: integer

Unit: seconds

Value range: 0 to 2147483647

Default value: **10**

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 1 and method 2 in **Table 6-2**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If the value is too large, CM fault detection and recovery cannot be performed in a timely manner. If the value is too small, the CPU load increases.

agent_check_interval

Parameter description: Specifies the interval at which the CM Agent queries the status of instances, such as the DNs, CN, and GTM.

Parameter type: integer

Unit: seconds

Value range: 1 to 2147483647

Default value: 2

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 1 and method 2 in **Table 6-2**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If the value is too large, CM fault detection and recovery cannot be performed in a timely manner. If the value is too small, the CPU load increases.

agent_heartbeat_timeout

Parameter description: Specifies the timeout interval for CM Agent to detect the CM Server heartbeat. If CM Agent does not receive the heartbeat message from CM Server within the timeout interval, the CM Agent terminates the connection with CM Server.

Parameter type: integer

Unit: seconds

Value range: 2 to 2147483647

Default value: **8**

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 1 and method 2 in **Table 6-2**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If the value is too large or too small, false negative and false positive may occur during fault detection.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

agent_connect_timeout

Parameter description: Specifies the time to wait before the attempt of CM Agent to connect to CM Server times out.

Parameter type: integer

Unit: seconds

Value range: 0 to 2147483647

Default value: **1**

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 1 and method 2 in **Table 6-2**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If the value is too large or too small, false negative and false positive may occur during fault detection.

agent_connect_retries

Parameter description: Specifies the number of times CM Agent retries to connect to the CM Server.

Parameter type: integer

Unit: none

Value range: 0 to 2147483647

Default value: **15**

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 1 and method 2 in **Table 6-2**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If the value is too large or too small, false negative and false positive may occur during fault detection.

agent_conn_db_timeout

Parameter description: Specifies the connection timeout interval for checking instance status. The CM Agent monitors the status of CN and DN instances; if no connection is established within this timeframe, it is considered a connection failure.

Parameter type: integer

Unit: seconds

Value range: 1 to 2147483647

Default value: 2

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 2 in **Table 6-3**.

Setting suggestion: Retain the default value.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

agent_conn_db_phony_dead_timeout

Parameter description: Specifies the connection timeout interval for checking zombie instances. The CM Agent checks for zombie CN and DN instances; if no connection is established within this timeframe, it is considered a connection failure.

Parameter type: integer

Unit: seconds

Value range: 1 to 2147483647

Default value: **5**

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 2 in **Table 6-3**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

agent_status_check_connection_type

Parameter description: Specifies the type of the connection used for the CM Agent to check node status.

Parameter type: integer

Unit: none

Value range:

- **0**: libpq by default and UDS in case of communication failure through libpq in high load state. When UDS connections are used for communication, the reserved memory status is queried.
- **1**: libpq only. The logic is the same as that in 506.0.0 and earlier versions.
- **2**: UDS only.

Default value: **0**

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 2 in **Table 6-3**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

agent_kill_instance_timeout

Parameter description: Specifies the interval from the time when CM Agent fails to connect to the primary CM Server to the time when CM Agent terminates all instances on the node.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter type: integer

Unit: seconds

Value range: 0 to 2147483647

Default value: **0**, indicating that the operation of stopping all instances on the node is not initiated.

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 1 and method 2 in **Table 6-2**.

Setting suggestion: If you want to set this parameter to a value other than 0, ensure that the value is greater than the time required for promoting the CM Server to primary.

Risks and impacts of improper settings: If the value is too large, CM faults may not be rectified in a timely manner.

agent_backup_open

Parameter description: Specifies whether the CM runs in the standby cluster for DR.

Parameter type: integer

Unit: none

Value range: 0 to 3

- **0**: No DR relationship is established.
- **1**: The OceanStor Dorado-based DR relationship is established.
- **2**: The streaming replication-based DR relationship is established.
- **3**: The logical DR relationship is established.

Default value: **0**

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 1 in **Table 6-2**. The modification takes effect only after the cluster is restarted.

Setting suggestion: This parameter is internally called. You are advised not to modify it.

Risks and impacts of improper settings: Changing the value of this parameter may cause unexpected results in the cluster. Retain the default value.

enable_gtm_phony_dead_check

Parameter description: Specifies whether to enable the GTM zombie check function.

Parameter type: integer

Unit: none

Value range: 0 to 1

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **0**: The GTM zombie check function is disabled.
- **1**: The GTM zombie check function is enabled.

Default value: **1**

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 1 and method 2 in **Table 6-2**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

security_mode

Parameter description: Specifies whether CNs and DNs are started in secure mode.

Parameter type: Boolean

Unit: none

Value range:

- **on**: CNs and DNs are started in secure mode.
- **off**: CNs and DNs are started in non-secure mode.

Default value: **off**

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 1 and method 2 in **Table 6-2**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

upgrade_from

Parameter description: Specifies the internal version number of the cluster before an in-place upgrade. Do not modify the value of this parameter.

Parameter type: integer

Unit: none

Value range: 0 to 4294967295

Default value: **0**

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 1 and method 2 in **Table 6-2**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Manual modification may cause in-place upgrade failures.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

process_cpu_affinity

Parameter description: Specifies whether to bind a primary DN process to a CPU core before starting the process. Only Arm is supported.

Parameter type: integer

Unit: none

Value range: 0 to 2

- If the value is **0**, core binding is not optimized.
- If the value is greater than 0, core binding is optimized and the number of physical CPU slices is 2^n.

Default value: **0**

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 1 in **Table 6-2**. The modification takes effect only after the cluster and CM Agent are restarted.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

dilatation_shard_count_for_disk_capacity_alarm

Parameter description: Specifies the number of shards to be added in the scale-out scenario. This parameter is used to calculate the threshold for reporting a disk capacity alarm.

Parameter type: integer

Unit: none

Value range: 0 to 2147483647

- If the value is **0**, the disk scale-out alarm reporting is disabled.
- If the value is greater than 0, disk scale-out alarm reporting is enabled, and the alarm reporting threshold is calculated based on the number of shards specified by this parameter.

Default value: **1**

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 1 and method 2 in **Table 6-2**.

Setting suggestion: Set the number of shards to be the same as the actual number of shards to be added.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

enable_cn_auto_repair

Parameter description: Specifies whether to enable the automatic CN repair function.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter type: Boolean

Unit: none

Value range:

- **on**: The automatic CN recovery is enabled. That is, after a CN is removed, the agent automatically attempts to recover the CN and resume the CN.
- **off**: The automatic CN recovery is disabled.

Default value: **on**

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 1 and method 2 in **Table 6-2**.

Setting suggestion: Automatic CN recovery is enabled by default. If it is disabled, CNs will not be automatically resumed. If you want to adjust the value, make sure you understand the parameter meaning and adjust the value with caution to avoid risks caused by misoperations.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

enable_xc_maintenance_mode

Parameter description: Specifies whether the pgxc_node system catalog can be modified when the cluster is in read-only mode.

Parameter type: Boolean

Unit: none

Value range:

- **on**: The pgxc_node system catalog can be modified.
- **off**: The pgxc_node system catalog cannot be modified.

Default value: **on**

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 1 in **Table 6-2**. The modification takes effect only after the cluster is restarted.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

unix_socket_directory

Parameter description: Specifies the directory location of the Unix socket.

Parameter type: string.

Unit: none

Value range: a valid directory.

Default value: ""

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 1 and method 2 in **Table 6-2**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

enable_dcf

Parameter description: Specifies the status of the DCF mode.

Parameter type: Boolean

Unit: none

Value range:

- **on**: The DCF mode is enabled.
- **off**: The DCF mode is disabled.

Default value: **off**

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 1 and method 2 in **Table 6-2**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

enable_e2e_rto

Parameter description: Specifies whether to enable the E2E RTO function. After this function is enabled, the zombie detection period and network detection timeout interval are shortened. The CM can reach the E2E RTO value (RTO for a single instance: ≤ 10s; RTO for overlay faults: ≤ 30s).

Parameter type: integer

Unit: none

Value range: 0 to 1

- **0**: The E2E RTO function is disabled.
- **1**: The E2E RTO function is enabled.

Default value: **0**

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 1 and method 2 in **Table 6-2**.

Setting suggestion: Retain the default value. You can adjust the value as required.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

environment_threshold

Parameter description: Specifies the thresholds for the physical environment and node status monitored by the agent. If the thresholds are exceeded, logs will be printed. The thresholds include the memory usage threshold, CPU usage threshold, disk usage threshold, instance memory usage threshold, and instance thread pool usage threshold.

Parameter type: string

Unit: none

Value range: This parameter consists of five parts: memory usage threshold, CPU usage threshold, disk usage threshold, instance memory usage threshold, and instance thread pool usage threshold. The value range of each threshold is 0 to 100, in percentage (%). The value **0** indicates that the detection is disabled. Different thresholds are separated by commas (,). The value must be enclosed with parentheses. For example, **"(0,0,0,0,0)"** indicates that none of the five thresholds is detected.

Default value: **"(0,0,0,0,0)"**

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 1 and method 2 in **Table 6-2**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

thread_effective_time

Parameter description: Specifies the timeout interval for a round of thread running. If the timeout occurs, the thread is suspended and automatically exits.

Parameter type: integer

Unit: seconds

Value range: 0 to 1200. The value **0** indicates that the thread monitoring capability is disabled.

Default value: **60**

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 2 in **Table 6-3**.

Setting suggestion: You are advised not to change the parameter value. If you need to change the parameter value, contact Huawei technical support.

Risks and impacts of improper settings: If the value is too large or too small, false negative and false positive may occur during fault detection.

ping_fault_kill_inst_timeout

Parameter description: Specifies the timeout interval for restarting a primary DN after the primary DN cannot ping all standby DNs.

Parameter type: integer

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Unit: seconds

Value range: 0 to 1000. The value **0** indicates that the ping fault processing capability is disabled.

Default value: **30**

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 2 in **Table 6-3**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If the value is too large or too small, false negative and false positive may occur during fault detection.

high_cpu_threshold

Parameter description: Specifies the CPU usage threshold. When the CPU usage exceeds the threshold, the CM Agent prints CPU usage information in logs at a specified check interval (1s by default).

Parameter type: integer

Unit: %

Value range: 0 to 100

Default value: **95**

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 2 in **Table 6-3**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

high_mem_threshold

Parameter description: Specifies the memory usage threshold. When the memory usage exceeds the threshold, the CM Agent prints memory usage information in logs at a specified check interval (1s by default).

Parameter type: integer

Unit: %

Value range: 0 to 100

Default value: **95**

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 2 in **Table 6-3**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

high_disk_threshold

Parameter description: Specifies the disk I/O threshold. When the I/O exceeds the threshold, the CM Agent prints I/O information in logs at a specified check interval (1s by default). The iostat -xm information is recorded in the **system_stat** log file for 10 consecutive times at an interval of 1s.

Parameter type: integer

Unit: %

Value range: 0 to 100

Default value: **95**

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 2 in **Table 6-3**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

high_load_io_rw_times

Parameter description: Determines the number of I/O read and write times in high load state. When the number of database I/O read and write times reaches the threshold, the database is considered to be in the high load state and does not rectify issues like disk hang or D-state.

Parameter type: integer

Unit: times/second

Value range: 0 to 2147483647. The value **0** indicates that no judgment is made on the number of I/O read/write times.

Default value: **10**

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 2 in **Table 6-3**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

high_load_io_traffic

Parameter description: Determines the I/O traffic in high load state. When the database I/O traffic volume reaches the threshold, the database is considered to be in the high-load state and does not rectify issues like disk hang or D-state.

Parameter type: integer

Unit: KB/s

Value range: 0 to 2147483647. The value **0** indicates that no judgment is made on the I/O read and write traffic.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Default value: **256**

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 2 in **Table 6-3**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

sys_check_interval

Parameter description: Specifies the system resource check period, that is, the interval for checking the CPU, memory, and disk I/O usage. The value **0** indicates that the check is disabled.

Parameter type: integer

Unit: seconds

Value range: 0 to 10

Default value: **1**

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 2 in **Table 6-3**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If the value is too large, alarms may not be reported in a timely manner.

network_check_concurrency

Parameter description: Specifies the number of concurrent network checks, that is, the number of network links to be checked at the same time. The value **0** indicates that the check is disabled.

Parameter type: integer

Unit: none

Value range: 0 to 1000

Default value: **10**

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 2 in **Table 6-3**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If the value is too small, CM fault detection and recovery cannot be performed in a timely manner. If the value is too large, the CPU load increases.

network_check_interval

Parameter description: Specifies the network check interval. The value **0** indicates that the check is disabled.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter type: integer

Unit: seconds

Value range: 0 to 1000

Default value: **5**

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 2 in **Table 6-3**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If the value is too large, CM fault detection and recovery cannot be performed in a timely manner. If the value is too small, the CPU load increases.

asyn_log_enable

Parameter description: Specifies whether to enable asynchronous logging. After this parameter is enabled, the CM Agent starts asynchronous logging.

Parameter type: Boolean

Unit: none

Value range:

- **on**: The CM Agent starts asynchronous logging.
- **off**: The CM Agent does not start asynchronous logging but uses serial logging.

Default value: **on**

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 2 in **Table 6-3**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this parameter is disabled, logs may be lost.

asyn_log_max_buf_size

Parameter description: Specifies the size of the asynchronous log buffer. When asynchronous logs are stacked and the stacked logs exceed the buffer size, subsequent logs cannot be recorded.

Parameter type: integer

Unit: KB

Value range: 1 to 1048576

Default value: **1024**

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 2 in **Table 6-3**.

Setting suggestion: Adjust the value based on the memory and hard disk size.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

asyn_log_fault_solution

Parameter description: Specifies the asynchronous log processing solution after a log disk fault is identified. When the CM detects that a log disk is faulty or the asynchronous log buffer overflows, the CM processes asynchronous logs based on the configuration.

Parameter type: integer

Unit: none

Value range: 0 to 2

- **0**: No extra processing is performed on logs. All logs are retained in the buffer until the buffer size reaches the upper limit. After the buffer size reaches the upper limit, no more logs are recorded.
- **1**: Logs are filtered. After a log disk fault is identified, only key logs, alarms, and logs at the ERROR level or higher are saved to the buffer until the buffer size reaches the upper limit. After the buffer size reaches the upper limit, no more logs are recorded.
- **2**: Logs are discarded. After a log disk fault is identified, only key logs and alarms are saved to the buffer until the buffer size reaches the upper limit. After the buffer size reaches the upper limit, no more logs are recorded.

Default value: **0**

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 2 in **Table 6-3**.

Setting suggestion: Adjust the value based on the memory and hard disk size.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

disk_check_hung_timeout

Parameter description: Specifies the timeout interval for a disk I/O hang. When a single disk I/O check exceeds the timeout interval, the disk I/O hang occurs. The value **0** indicates that the disk hang check is disabled.

Parameter type: integer

Unit: seconds

Value range: 0 to 1000

Default value: **20**. If you cannot determine whether the detected disk is striped during installation, the default value is **60**.

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 2 in **Table 6-3**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If the value is too large or too small, false negative and false positive may occur during fault detection.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

disk_check_block_timeout

Parameter description: If file operations such as open are blocked due to certain reasons in the file system and the blocking duration exceeds the value of this parameter, the system determines that the disk is faulty. If this parameter is set to **0**, the determination is disabled.

Parameter type: integer

Unit: seconds

Value range: 0 to 1000

Default value: **40**

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 2 in **Table 6-3**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If the value is too large or too small, false negative and false positive may occur during fault detection.

disk_check_interval

Parameter description: Specifies the traffic of disk I/O hang check, that is, the minimum duration within which specified data needs to be written. The default check interval is 5 seconds. The value **0** indicates that the disk check is disabled.

Parameter type: integer

Unit: seconds

Value range: 0 to 1000

Default value: **5**

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 2 in **Table 6-3**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Improper settings may cause inaccurate fault detection and delayed fault rectification.

disk_check_io_size

Parameter description: Specifies the disk I/O hang check traffic, that is, the size of data written to the disk within the check duration. This is an I/O operation directly performed on the disk. By default, 512-byte data is written. If the detected disk is striped, the default value is changed to 262144 bytes (256 KB) during installation. A maximum of 1 GB data can be written. The value **0** indicates that the disk hang check is disabled. Disk detection has a whitelist, including the CM/CN/DN/GTM data directory, disk where the log directory resides, and disk where the user-defined tablespace directory resides.

Parameter type: integer

Unit: byte

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Value range: 0 to 1073741824

Default value: **512**

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 2 in **Table 6-3**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Improper settings may cause inaccurate fault detection and delayed fault rectification.

disk_check_shared_storage_hung_timeout

Parameter description: Specifies the timeout interval for detecting I/O hang of the OceanStor Dorado shared disk. If the I/O hang detection time of the OceanStor Dorado shared disk exceeds the value of this parameter, the system determines that the OceanStor Dorado shared disk has I/O hang.

Parameter type: integer

Unit: seconds

Value range: 0 to 1000. The value **0** indicates that the I/O hang detection function of the OceanStor Dorado shared disk is disabled.

Default value: **30**

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 2 in **Table 6-3**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this parameter is incorrectly set, the system may incorrectly determine that the OceanStor Dorado shared disk has I/O hang.

process_unhealthy_alarm_time

Parameter description: Specifies the detection timeout interval for triggering the process status alarm. When a process is in an abnormal state (**D**, **T**, or **Z**) for a long time exceeding the value of this parameter, a process status alarm is triggered.

Parameter type: integer

Unit: seconds

Value range: 0 to 2147483647. The value **0** indicates that this function is disabled.

Default value: **50**

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 2 in **Table 6-3**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If the value is too large or too small, false negative and false positive may occur during fault detection.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

enable_tblspc_disk_check

Parameter description: Specifies whether to enable the tablespace disk check function.

Parameter type: Boolean

Unit: none

Value range:

- **on**: The tablespace disk check is enabled. That is, the disk where the tablespace is located is hung and the corresponding DN is stopped.
- **off**: The tablespace disk check function is disabled.

Default value: **on**

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 1 in **Table 6-3**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

max_network_package_loss

Parameter description: Checks the packet loss rate between the primary and standby DNs on the data plane. If the packet loss rate of the primary DN exceeds the threshold, a restart is triggered.

Parameter type: integer

Unit: %

Value range: 0 to 99. The value **0** indicates that this function is disabled.

Default value: **30**

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 2 in **Table 6-3**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If the value is too large, faults may not be rectified in a timely manner.

enable_auto_start

Parameter description: Specifies whether CM Agent automatically starts DNs and CNs.

Parameter type: integer

Unit: none

Value range: 0 to 1

- **0**: The automatic startup function is disabled.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **1**: The automatic startup function is enabled.

Default value: **1**

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 2 in **Table 6-3**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

enable_check_az_network

Parameter description: Specifies whether to enable AZ-level data plane network detection.

Parameter type: Boolean

Unit: none

Value range:

- **on**: AZ-level data plane network detection is enabled.
- **off**: AZ-level data plane network detection is disabled.

Default value: **on**

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 2 in **Table 6-3**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this parameter is disabled, the fault detection function deteriorates.

expect_stop_az_name

Parameter description: Specifies the name of the AZ to be stopped by the AZ-level network detection function.

Parameter type: string

Unit: none

Value range: name of an existing AZ in the environment. If this parameter is left empty, instances in the AZ opposite to the primary CM Server are stopped.

Default value: **""**

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 2 in **Table 6-3**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

check_az_network_concurrency

Parameter description: Specifies the number of concurrent AZ-level network detection tasks.

Parameter type: integer

Unit: none

Value range: 1 to 10

Default value: **2**

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 2 in **Table 6-3**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If the value is too small, CM fault detection and recovery cannot be performed in a timely manner. If the value is too large, the CPU load increases.

cm_hadr_process_type

Parameter description: Specifies the DR process ID.

Value type: enumerated

Unit: none

Value range:

- **none**: There is no process.
- **failover**: A standby cluster for DR is promoted to primary.
- **switchover_promote**: A standby cluster for DR is promoted to primary during the cluster switchover.
- **switchover_demote**: A primary cluster is demoted to a standby cluster for DR during the cluster switchover.

Default value: **none**

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 2 in **Table 6-3**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

emergence_sql_check_max_cn_count

Parameter description: Specifies the maximum number of CNs in a cluster allowed in a first aid. If the number of CNs exceeds the value of this parameter, no SQL statement detection is performed. If this parameter is set to **0**, the CN detection is disabled.

Parameter type: integer

Unit: none

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Value range: 0 to 256

Default value: **16**

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 2 in **Table 6-3**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

enable_topology_network_gtm_gtm_collect

Parameter description: Controls whether to enable network topology detection between GTMs.

Parameter type: Boolean

Unit: none

Value range:

- **on**: Network detection is enabled.
- **off**: Network detection is disabled.

Default value: **off**

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 1 or method 2 in **Table 6-3**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

topology_network_collecting_group_size

Parameter description: Specifies the number of DN shards collected by each collector thread on the data plane network topology. This parameter can be used only in quorum mode.

Parameter type: integer

Unit: none

Value range: 8 to 32

Default value: **16**

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 1 in **Table 6-3**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

topology_network_collecting_failed_times

Parameter description: Specifies the number of consecutive network disconnections on the data plane. If the number of disconnections exceeds the value of this parameter, the data plane network topology is abnormal. This parameter can be used only in quorum mode.

The value must be the same as that of **topology_network_collecting_failed_times** in the CM Server parameters.

Parameter type: integer

Unit: none

Value range: 3 to 50

Default value: **5**

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 2 in **Table 6-3**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

topology_network_collecting_interval

Parameter description: Specifies the data plane network topology detection period. If this parameter is set to **0**, network topology detection is disabled. This parameter can be used only in quorum mode.

Parameter type: integer

Unit: seconds

Value range: 0 to 600

Default value: 2

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 2 in **Table 6-3**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

topology_network_check_max_cn_count

Parameter description: Specifies the maximum number of CNs in a cluster supported by data plane network topology detection. If the number of CNs exceeds the value of this parameter, the data plane network topology detection is not performed. If this parameter is set to **0**, network topology detection is disabled. This parameter can be used only in quorum mode.

Parameter type: integer

Unit: none

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Value range: 0 to 256

Default value: **16**

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 2 in **Table 6-3**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

max_cma_check_inst_timeout

Parameter description: Specifies the timeout interval for the CM Agent to check instances each round. When the timeout interval expires, the AIM_AI_CheckInstanceTooLong alarm is reported. If this parameter is set to **0**, the alarm is not reported.

Parameter type: integer

Unit: seconds

Value range: 0 to 1000

Default value: **20**

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 2 in **Table 6-3**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If the value is too small, alarms might be frequently reported.

enable_gsmonitor

Parameter description: Specifies whether to enable the GSMonitor system resource statistics tool.

Parameter type: Boolean

Unit: none

Value range:

- **on**: GSMonitor is enabled.
- **off**: GSMonitor is disabled.

Default value: **on**

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 2 in **Table 6-3**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

gsmonitor_max_store_duration

Parameter description: Specifies the maximum number of days for storing GSMonitor logs.

Parameter type: integer

Unit: day

Value range: 2 to 30

Default value: **14**

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 2 in **Table 6-3**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

gsmonitor_max_store_space

Parameter description: Specifies the maximum space for storing GSMonitor logs.

Parameter type: integer

Unit: MB

Value range: 512 to 10240

Default value: **2048**

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 2 in **Table 6-3**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

gsmonitor_interval

Parameter description: Specifies the GSMonitor profiling interval.

Parameter type: string

Unit: none

Value range:

- "interval1,interval2,interval3,interval4"

  This parameter is divided into four parts, formatted as "*interval1*,*interval2*,*interval3*,*interval4*".

  interval1 indicates the collection interval when the CPU usage ranges from 0% to 49%. The value ranges from 2 to 2147483647, in seconds.

  interval2 indicates the collection interval when the CPU usage ranges from 50% to 69%. The value ranges from 2 to 2147483647, in seconds.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

interval3 indicates the collection interval when the CPU usage ranges from 70% to 89%. The value ranges from 2 to 2147483647, in seconds.

interval4 indicates the collection interval when the CPU usage ranges from 90% to 100%. The value ranges from 2 to 2147483647, in seconds.

- **"auto"**: equivalent to **"30,10,5,2"**

Default value: **"30,10,5,2"**

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 2 in **Table 6-3**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

hadr_replconninfo_config_mode

Parameter description: Specifies the DR type of the current database instance.

Parameter type: string.

Unit: none

Value range: **"local_file"** or **"cluster_manager"**

Default value: **"local_file"**

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 2 in **Table 6-3**.

Setting suggestion: This parameter is internally called. You are advised not to modify it.

Risks and impacts of improper settings: Changing the value of this parameter may cause unexpected results in the cluster. Retain the default value.

default_build_mode

Parameter description: Specifies the mode used by CM Agent to automatically initiate primary/standby instance rebuild.

Value type: enumerated

Unit: none

Value range:

- **auto**: indicates that incremental rebuild is performed three times during the rebuild of the primary and standby nodes. If all the three incremental rebuild attempts fail and the failure is not caused by the primary node searching failure, the full rebuild mode is used.
- **incremental**: indicates that the incremental rebuild mode is used to rebuild the primary and standby nodes.
- **full**: indicates that the full rebuild mode is used to rebuild the primary and standby nodes.

Default value: **auto**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 2 in **Table 6-3**.

Setting suggestion: Retain the default value. If you need to change the value, contact Huawei technical support.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

enable_preparse

Parameter description: Specifies whether to check DN pre-parsing. After this function is enabled, the DN pre-parsing result is checked and used as the basis for DN arbitration.

Parameter type: integer.

Unit: none

Value range:

- **0**: disabled.
- **1**: enabled.

Default value: **1**

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 2 in **Table 6-3**.

Setting suggestion: Retain the default value. If you need to change the value, contact Huawei technical support.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

6.4.2 CM Server Parameters

log_dir

Parameter description: Specifies the directory where CM Server logs are stored. The value can be an absolute path, or a path relative to the CM Server data directory.

Parameter type: string.

Unit: none

Value range: valid path of a directory.

Default value: "*$GAUSSLOG*/cm/cm_server", indicating that the CM Server logs are generated in the CM directory in *$GAUSSLOG*.

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 1 in **Table 6-2**. The modification takes effect only after the cluster is restarted.

Setting suggestion: Retain the default value.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

log_file_size

Parameter description: Specifies the size of a log file. If a log file exceeds the specified size, a new one is created to record logs.

Parameter type: integer.

Unit: MB

Value range: 0 to 2047

Default value: **16**

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 1 and method 2 in **Table 6-2**. For example, if this parameter is set to **16** without a unit, it indicates 16 MB. If this parameter is set to **16MB**, it indicates 16 MB. The unit must be MB if required.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

log_min_messages

Parameter description: Specifies the level of messages to be written to the CM Server log. Each level covers all the levels following it. The lower the level is, the fewer messages will be written into the log.

Parameter type: enumerated type

Unit: none

Value range: **debug5**, **debug1**, **log**, **warning**, **error**, and **fatal**.

Default value: **warning**

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 1 and method 2 in **Table 6-2**.

Setting suggestion: Set this parameter based on the hard disk size.

Risks and impacts of improper settings: If a low level is set, debugging information may be lost.

thread_count

Parameter description: Specifies the number of threads in the agent thread pool.

Parameter type: string.

Unit: none

Value range: This parameter consists of two parts: '**worker_thread_count** and **io_ratio**. The meanings of the two parts are as follows:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **worker_thread_count**: specifies the number of AgentWorker threads. The value ranges from 2 to 1000.
- **io_ratio**: specifies the ratio of I/O threads to worker threads. The value *n* indicates that one AgentIO thread corresponds to *n* AgentWorker threads. The value ranges from 1 to 100. At least one AgentIO thread is required.

NOTE

If the value of **worker_thread_count**, namely the number of AgentWorker threads, is greater than the sum of the number of cluster nodes and the number of threads for processing cm_ctl requests (if the number of cluster nodes is less than 32, one thread is used by default; otherwise, four threads are used), the value that takes effect is the sum of the number of cluster nodes and the number of threads for processing cm_ctl requests.

Default value: **"(1000,1)"**

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 1 in **Table 6-2**. The modification takes effect only after the cluster is restarted.

Setting suggestion: Retain the default value. If you want to adjust the value, make sure you understand the parameter meaning and adjust the value with caution to avoid risks caused by misoperations.

Risks and impacts of improper settings: If this parameter is incorrectly set, CM faults may not be detected and rectified in a timely manner, and the CPU load may increase.

thread_effective_time

Parameter description: Specifies the timeout interval for a round of thread running. If the timeout occurs, the thread is suspended and the process automatically exits.

Parameter type: integer.

Unit: seconds

Value range: 0 to 1200. The value **0** indicates that the thread monitoring capability is disabled.

Default value: **20**

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 1 and method 2 in **Table 6-3**.

Setting suggestion: You are advised not to change the parameter value. If you need to change the parameter value, contact Huawei technical support.

Risks and impacts of improper settings: Improper settings may cause inaccurate fault detection and delayed fault rectification.

ctl_thread_count

Parameter description: Specifies the number of threads in the ctl thread pool.

Parameter type: string.

Unit: none

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Value range:

The value is a string of more than 0 characters. This parameter consists of two parts: **worker_thread_count** and **io_ratio**. The meanings of the two parts are as follows:

- **worker_thread_count**: specifies the number of CtlWorker threads. The value ranges from 0 to 1000. If the value is **0**, the number of CtlWorker threads is equal to the number of nodes in the cluster.
- **io_ratio**: specifies the ratio of I/O threads to worker threads. The value *n* indicates that one CtlIO thread corresponds to *n* CtlWorker threads. The value ranges from 1 to 100. At least one CtlIO thread is required.

Default value: **"(0,1)"**

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 1 in **Table 6-3**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: CM performance may deteriorate.

alarm_component

Parameter description: Specifies the location of the alarm component that processes alarms.

Parameter type: string.

Unit: none

Value range: valid file path.

- If **--alarm-type** in the gs_preinstall script is set to **5**, no third-party component is connected and alarms are written into system_alarm logs. In this case, the value of **alarm_component** is **/opt/huawei/snas/bin/snas_cm_cmd**.
- If **--alarm-type** in the gs_preinstall script is set to **1**, a third-party component is connected. In this case, the value of the GUC parameter **alarm_component** is the absolute path of the executable program of the third-party component.

Default value: **"/opt/huawei/snas/bin/snas_cm_cmd"**

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 1 and method 2 in **Table 6-2**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

alarm_report_interval

Parameter description: Specifies the interval at which an alarm is reported.

Parameter type: integer.

Unit: seconds

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Value range: 0 to 2147483647

Default value: **3**

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 1 and method 2 in **Table 6-2**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If the value is too large, alarms may not be reported in a timely manner. If the value is too small, the CPU load may increase.

alarm_report_max_count

Parameter description: Specifies the maximum number of times an alarm is reported.

Parameter type: integer.

Unit: none

Value range: 1 to 2592000

Default value: **1**

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 1 and method 2 in **Table 6-2**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If the value is too large, the CPU load may increase.

instance_failover_delay_timeout

Parameter description: Specifies the delay in CM Server failover after the primary CM Server breakdown is detected. It takes effect for GTM arbitration.

Parameter type: integer.

Unit: seconds

Value range: 0 to 2147483647

Default value: **0**

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 1 and method 2 in **Table 6-2**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If the value is too large, database faults may not be rectified in a timely manner.

instance_heartbeat_timeout

Parameter description: Specifies the timeout interval for CM Server to detect the instance heartbeat.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter type: integer.

Unit: seconds

Value range: 1 to 2147483647

Default value: **6**

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 1 and method 2 in **Table 6-2**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If the value is too large or too small, false negative and false positive may occur during fault detection.

instance_keep_heartbeat_timeout

Parameter description: The CM Agent periodically checks the instance status and reports the status to the CM Server. If the instance status cannot be detected for a long time and the accumulated time exceeds the value of this parameter, the CM Server delivers a command to the CM Agent to restart the instance.

Parameter type: integer.

Unit: seconds

Value range: 0 to 2147483647

Default value: **40**

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 1 and method 2 in **Table 6-2**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If the value is too large or too small, false negative and false positive may occur during fault detection.

instance_phony_dead_restart_interval

Parameter description: Specifies the interval at which the CM Agent process restarts and kills a zombie CN, DN, or GTM instance. The interval between two consecutive kill operations cannot be less than the value of this parameter. Otherwise, the CM Agent process does not deliver commands.

Parameter type: integer.

Unit: seconds

Value range: 0 to 2147483647

Default value: **0**

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 1 and method 2 in **Table 6-2**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If the value is too large or too small, false negative and false positive may occur during fault detection.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

coordinator_heartbeat_timeout

Parameter description: Specifies the heartbeat timeout that triggers the automatic removal of faulty CNs. The setting of this parameter takes effect immediately, and you do not need to restart the cluster.

Parameter type: integer.

Unit: seconds

Value range: 0 to 2592000. **0** indicates that a faulty CN will not be automatically removed.

Default value: 25

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 1 and method 2 in **Table 6-2**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If the value is too large, the CN may fail to be removed for a long time. If the value is too small, the CN may fail to be removed.

phony_dead_effective_time

Parameter description: Specifies the maximum number of times CN, DN, or GTM processes are detected as zombie. If the number of times a process is detected as zombie is greater than the specified value, the process is considered as a zombie process and will be restarted.

Parameter type: integer.

Unit: none

Value range: 1 to 2147483647

Default value: **5**

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 1 and method 2 in **Table 6-2**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If the value is too large or too small, false negative and false positive may occur during fault detection.

enable_transaction_read_only

Parameter description: Specifies whether to enable the threshold detection function of the CM Server disk. After this function is enabled, CM Server automatically sets the database to read-only when the disk usage is greater than the value of **datastorage_threshold_value_check**.

Parameter type: Boolean

Unit: none

Value range:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **on**: The threshold detection function is enabled.
- **off**: The threshold detection function is disabled.

Default value: **on**

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 1 and method 2 in **Table 6-2**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Disabling this function may cause high disk usage.

enable_disk_full_check

Parameter description: Specifies whether to enable the check for full disks. (If the disk usage exceeds the value of **disk_full_threshold**, instance processes on the faulty node will be stopped.)

Parameter type: Boolean

Unit: none

Value range:

- **on**: The disk full check is enabled.
- **off**: The disk full check is disabled.

Default value: **on**

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 1 in **Table 6-3**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

disk_full_threshold

Parameter description: Specifies the disk usage threshold in a database. When the disk usage of the data directory exceeds the specified value, the disk is full and the database is automatically stopped. When the disk usage is less than the value specified by **datastorage_threshold_value_check**, the database is automatically started. The value of **disk_full_threshold** takes effect only when it is greater than that of **datastorage_threshold_value_check**.

Parameter type: integer.

Unit: %

Value range: 1 to 99

Default value: **98**

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 2 in **Table 6-3**.

Setting suggestion: Retain the default value.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Risks and impacts of improper settings: If the value is too large, other processes may be unavailable.

datastorage_threshold_check_interval

Parameter description: Specifies the interval for checking the disk usage. The system checks the disk usage at the interval specified by the user.

Parameter type: integer.

Unit: seconds

Value range: 1 to 2592000

Default value: **10**

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 1 and method 2 in **Table 6-2**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If the value is too large, CM fault detection and recovery cannot be performed in a timely manner. If the value is too small, the CPU load increases.

datastorage_threshold_value_check

Parameter description: Specifies the usage threshold of a read-only disk in a database. When the disk usage of the data directory exceeds the specified value, the database is automatically set to read-only mode. In the read-only mode, log replay cannot be restricted and the disk usage increases. Therefore, you need to pay attention to the cluster disk capacity and handle read-only alarms in a timely manner to prevent the disk space from being used up; otherwise, the database cannot be restored quickly.

Parameter type: integer.

Unit: %

Value range: 1 to 99

Default value: **85**

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 1 and method 2 in **Table 6-2**.

Setting suggestion: Retain the default value. You can adjust this parameter based on the disk space. When adjusting this parameter, you are advised to adjust the **max_size_for_xlog_retention** parameter of the DN at the same time to prevent the cluster read-only threshold from being triggered by backup operations.

This parameter is default to 85% considering the following factors:

- GaussDB is usually used to carry core services featuring large storage capacity and high concurrency requirements. Therefore, reserving 15% of the space ensures that there is enough space to allow for data increase during the period before storage scale-up when the disk space is insufficient.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- Disk space is reserved for O&M operations after the database enters the read-only mode, such as log processing, space recycling, and backup, to ensure sufficient space for O&M operations when a problem occurs.
- Most customers prefer the default setting of 85%.

Risks and impacts of improper settings: If the value is too large, the disk space usage is too high and the restoration cannot be achieved quickly.

datastorage_threshold_recover

Parameter description: Specifies the buffer threshold for canceling the database read-only mode. If the disk usage of the data directory exceeds the value of **datastorage_threshold_value_check**, the data directory is set to read-only. The read-only mode is disabled only when the disk usage is less than the value of **datastorage_threshold_value_check** minus **datastorage_threshold_recover**. For a removed CN, to prevent repeated removal and addition, the CN can be added only when the disk usage is less than the value of **datastorage_threshold_value_check** minus **datastorage_threshold_recover**. If the disk usage exceeds the value, the CN cannot be added back. After the primary database becomes read-only, a switchover can be performed only when the disk usage of the standby database is less than the value of **datastorage_threshold_value_check** minus **datastorage_threshold_recover**.

Parameter type: integer.

Unit: %

Value range: 0 to 99

Default value: **5**

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 2 in **Table 6-3**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

max_datastorage_threshold_check

Parameter description: Specifies the maximum interval for checking the disk usage. After you modify the read-only mode parameter, the system automatically checks whether the disk usage reaches the threshold at the specified interval.

Parameter type: integer.

Unit: seconds

Value range: 1 to 2592000

Default value: **43200**

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 1 and method 2 in **Table 6-2**.

Setting suggestion: Retain the default value.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Risks and impacts of improper settings: If the value is too large, CM fault detection and recovery cannot be performed in a timely manner.

enable_az_auto_switchover

Parameter description: Specifies whether to enable the automatic copy reduction function.

Parameter type: integer.

Unit: none

Value range: 0 to 1

- **0**: disabled.
- **1**: enabled.

Default value: **1**

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 1 and method 2 in **Table 6-2**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this function is disabled, the CM cannot restore the cluster by reducing copies when a majority of nodes are faulty.

enable_az_conn_check

Parameter description: Specifies whether to enable AZ network arbitration. The CM Server will shut down the isolated AZ.

Parameter type: integer.

Unit: none

Value range: 0 to 1

- **0**: disabled.
- **1**: enabled. After this function is enabled, the CM Server performs AZ network arbitration.

Default value: **1**

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 2 in **Table 6-3**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

cm_auth_method

Parameter description: Specifies the port authentication mode of the CM module.

Parameter type: enumerated type

Unit: none

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Value range:

- **trust**: Port authentication is not configured.
- **gss**: Kerberos port authentication is used.

Default value: **trust**

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 1 and method 2 in **Table 6-2**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: You can change the value to **"gss"** only after the Kerberos server and client are successfully installed. Otherwise, the CM cannot communicate properly, affecting the cluster status.

cm_krb_server_keyfile

Parameter description: Specifies the location of the key file on the Kerberos server. The value must be an absolute path. The file is usually stored in the *${GAUSSHOME}***/kerberos** directory and ends with keytab. The file name is the same as the name of the user who runs the cluster.

Parameter type: string.

Unit: none

Value range: absolute path of the key file of the Kerberos server.

Default value: *${GAUSSHOME}***/kerberos/***{UserName}***.keytab**. The default value cannot take effect and is used only as a prompt.

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 1 and method 2 in **Table 6-2**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: This parameter is paired with the preceding parameter **cm_auth_method**. When **cm_auth_method** is set to **"gss"**, this parameter must be set to a correct path. Otherwise, the cluster status will be affected.

cm_hadr_process_type

Parameter description: Specifies the DR process ID.

Parameter type: enumerated type

Unit: none

Value range:

- **none**: There is no process.
- **failover**: A standby cluster for DR is promoted to primary.
- **switchover_promote**: A standby cluster for DR is promoted to primary during the cluster switchover.
- **switchover_demote**: A primary cluster is demoted to a standby cluster for DR during the cluster switchover.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Default value: **none**

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 2 in **Table 6-3**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

cma_fault_kill_instance_timeout

Parameter description: Specifies timeout interval for waiting for a DN to be reported after the internal status of the primary CM Server is set to **unknown**. The CM Server runs the **pssh** command to remotely kill the DN that fails to be reported and restart the DN process. This parameter is not added to the CM Server configuration file by default. You need to manually add it.

Parameter type: integer.

Unit: seconds

Value range: 0 to 21474836. **0**: disabled.

Default value: This parameter is enabled by default. The default value is (**cm_server_num** x **agent_connect_timeout** x **agent_connect_retries** + **agent_heartbeat_timeout** + 10).

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 2 in **Table 6-3**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Faults may not be rectified in a timely manner.

cma_disconnect_to_cms_alarm_timeout

Parameter description: Specifies the timeout period for the CM Agent to disconnect from the primary CM Server. After the timeout, the cluster reports the ALM_AI_AbnormalConn alarm. When the duration of consecutive disconnections doubles the threshold, the ALM_AI_LongTimeAbnormalConn alarm is continuously reported.

Parameter type: integer.

Unit: seconds

Value range: 0 to 1000

- **0**: None of ALM_AI_AbnormalConn or ALM_AI_LongTimeAbnormalConn is reported.
- 1 to 1000: indicates the duration when the CM Agent is disconnected from the primary CM Server.

Default value: **40**

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 2 in **Table 6-3**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: none

cm_server_arbitrate_delay_base_time_out

Parameter description: Specifies the basic delay duration for CM Server arbitration. If the primary CM Server is disconnected, the arbitration starts to be timed. If the disconnection duration exceeds the arbitration delay duration, a new primary CM Server will be selected. The arbitration delay duration is determined by the basic delay duration, the node index (server ID), and the incremental delay duration. The formula is as follows: Arbitration delay duration = Basic delay duration + Node index x Incremental delay duration.

Parameter type: integer.

Unit: seconds

Value range: 0 to 2147483647

Default value: 10

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 1 and method 2 in **Table 6-2**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If the value is too small, the CM Server disconnection fault is false positive. If the value is too large, the CM fault cannot be rectified in a timely manner.

cm_server_arbitrate_delay_incrememtal_time_out

Parameter description: Specifies the incremental delay duration for CM Server arbitration. If the primary CM Server is disconnected, the arbitration starts to be timed. If the disconnection duration exceeds the arbitration delay duration, a new primary CM Server will be selected. The arbitration delay duration is determined by the basic delay duration, the node index (server ID), and the incremental delay duration. The formula is as follows: Arbitration delay duration = Basic delay duration + Node index x Incremental delay duration.

Parameter type: integer.

Unit: seconds

Value range: 0 to 2147483647

Default value: **3**

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 1 and method 2 in **Table 6-2**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If the value is too small, the CM Server disconnection fault is false positive. If the value is too large, the CM fault cannot be rectified in a timely manner.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

cmserver_ha_connect_timeout

Parameter description: Specifies the time to wait before the attempt of CM Server to connect to other CM Servers times out.

Parameter type: integer.

Unit: seconds

Value range: 1 to 2147483647

Default value: **2**

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 1 and method 2 in **Table 6-2**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If the value is too large or too small, false negative and false positive may occur during fault detection.

cmserver_ha_heartbeat_timeout

Parameter description: Specifies the timeout interval for a CM Server to receive heartbeat signals from other CM Servers.

Parameter type: integer.

Unit: seconds

Value range: 1 to 2147483647

Default value: **6**

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 1 and method 2 in **Table 6-2**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If the value is too large or too small, false negative and false positive may occur during fault detection.

cmserver_ha_status_interval

Parameter description: Specifies the interval between synchronizations of primary and standby CM Server status.

Parameter type: integer.

Unit: seconds

Value range: 1 to 2147483647

Default value: **1**

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 1 and method 2 in **Table 6-2**.

Setting suggestion: Retain the default value.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Risks and impacts of improper settings: If the value is too large, CM fault detection and recovery cannot be performed in a timely manner. If the value is too small, the CPU load increases.

cmserver_demote_delay_on_etcd_fault

Parameter description: Specifies the delay within which CM Server switches from the primary state to the standby state due to unhealthy ETCD.

Parameter type: integer.

Unit: seconds

Value range: 1 to 2147483647

Default value: **8**

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 1 and method 2 in **Table 6-2**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If the value is too small, the ETCD fault detection result is false positive. If the value is too large, the CM fault cannot be rectified in a timely manner.

force_promote

Parameter description: Specifies whether CM Server enables forcible switchover (that is, when the cluster status is unknown, the basic functions of the cluster are available at the cost of data loss). This parameter applies to both CNs and DNs.

Parameter type: integer.

Unit: none

Value range: 0 to 1

- **0**: The forced switching logic function is disabled.
- **1**: The forcible switchover logic function is enabled.

Default value: **0**

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 1 and method 2 in **Table 6-2**.

Setting suggestion: If you can accept the loss of some data caused by forcible service (system) switchover, enable this parameter when the service recovery has the highest priority.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

switch_rto

Parameter description: Specifies the delay for the forcible switchover of CM Server. When **force_promote** is set to **1** and a shard in the cluster does not have primary node, the system starts timing. After the delay, forcible switchover is executed.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter type: integer.

Unit: seconds

Value range: 60 to 2147483647

Default value: **600**

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 1 and method 2 in **Table 6-2**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If the value is too small, the database fault is false positive. If the value is too large, the fault cannot be rectified in a timely manner.

enable_finishredo_retrieve

Parameter description: Specifies whether to retrieve data of Xlogs that are cut off by redo logs after a forcible CM Server switchover. If this parameter is set to **on**, data is automatically retrieved after a forcible switchover.

Parameter type: Boolean

Unit: none

Value range:

- **on**: Data is retrieved.
- **off**: Data is not retrieved.

Default value: **off**

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 1 and method 2 in **Table 6-2**.

Setting suggestion: Adjust the value according to the actual situation.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

backup_open

Parameter description: Specifies whether the CM runs in the standby cluster for DR.

Parameter type: integer

Unit: none

Value range: 0 to 3

- **0**: No DR relationship is established.
- **1**: The OceanStor Dorado-based DR relationship is established.
- **2**: The streaming replication-based DR relationship is established.
- **3**: The logical DR relationship is established.

Default value: **0**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 1 in **Table 6-2**. The modification takes effect only after the cluster is restarted.

Setting suggestion: Do not enable this parameter for clusters that are not standby clusters for DR. This parameter is internally called. You are advised not to modify it.

Risks and impacts of improper settings: Changing the value of this parameter may cause unexpected results in the cluster. Retain the default value.

install_type

Parameter description: Specifies the settings related to the standby cluster for DR to distinguish the cluster type.

Parameter type: integer

Unit: none

Value range: 0 to 2

- **0**: a cluster for which no DR relationship is established.
- **1**: an OceanStor Dorado-based cluster.
- **2**: a streaming-based cluster.

Default value: **0**

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 1 in **Table 6-2**. The modification takes effect only after the cluster is restarted.

Setting suggestion: Do not enable this parameter for clusters that are not standby clusters for DR.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

enable_ssl

Parameter description: Specifies whether to enable SSL.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The SSL certificate is enabled.
- **off**: The SSL certificate is disabled.

Default value: **off**

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 1 in **Table 6-2**. The modification takes effect only after the cluster is restarted.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Setting suggestion: Disable this function by default. The CM component stores only the control information about clusters and does not involve user data. Therefore, disabling this function by default does not affect user data security.

Risks and impacts of improper settings: none

ssl_cert_expire_alert_threshold

Parameter description: Specifies the SSL certificate expiration alarm time. If the certificate expiration time is less than the value of this parameter, an alarm indicating that the certificate is about to expire is reported.

Parameter type: integer

Unit: day

Value range: 7–180

Default value: **90**

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 1 in **Table 6-2**. The modification takes effect only after the cluster is restarted.

Setting suggestion: Adjust the value according to the actual situation.

Risks and impacts of improper settings: If the value is too small, alarms may not be rectified in a timely manner.

ssl_cert_expire_check_interval

Parameter description: Specifies the period for checking whether the SSL certificate expires.

Parameter type: integer

Unit: seconds

Value range: 0 to 2147483647

Default value: **86400** (that is, one day)

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 1 in **Table 6-2**. The modification takes effect only after the cluster is restarted.

Setting suggestion: Adjust the value according to the actual situation.

Risks and impacts of improper settings: If the value is too small, the CPU load increases. If the value is too large, alarms cannot be reported in a timely manner.

delay_arbitrate_timeout

Parameter description: Specifies the waiting time for a node in the same AZ as the primary DN to be promoted to primary after redo replay.

Parameter type: integer

Unit: seconds

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Value range: 0 to 2147483647

Default value: **0**

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 1 and method 2 in **Table 6-2**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If the value is too large, DN faults may not be rectified in a timely manner.

dcf_heartbeat_timeout

Parameter description: Specifies the time to wait before the DCF instance heartbeat times out in the CM&DCF joint arbitration. If the primary DCF instance heartbeat times out, the DCF instance is unreachable by the CM and the CM will automatically trigger a DCF switchover. It takes effect only in DCF self-arbitration mode.

Parameter type: integer.

Unit: seconds

Value range: 0 to 2147483647. If this parameter is set to **0**, heartbeat timeout detection is disabled for DCF instances in joint arbitration.

Default value: **0**

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 2 in **Table 6-3**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: After this function is disabled, the CM does not process the unreachable DCF instances. If a DCF instance is unreachable and abnormal, the CM cannot assist the arbitration. Before modifying this parameter, make sure you understand its meaning and fully verify the change in a test environment.

enable_dcf

Parameter description: Specifies the status of the DCF mode.

Parameter type: Boolean.

Unit: none

Value range:

- **on**: The DCF mode is enabled.
- **off**: The DCF mode is disabled.

Default value: **off**

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 1 and method 2 in **Table 6-2**.

Setting suggestion: Retain the default value.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

ddb_type

Parameter description: Specifies whether to switch between ETCD and DCC modes.

Parameter type: integer

Unit: none

Value range: 0 to 1

- **0**: The ETCD mode is enabled.
- **1**: The DCC mode is enabled.

Default value: **0**

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 1 in **Table 6-2**. The modification takes effect only after the cluster is restarted.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

ddb_log_level

Parameter description: Specifies the DDB log level.

Parameter type: string.

Unit: none

Value range:

- **"NONE"**: The log function is disabled. It cannot be used together with the following log levels.
- **"RUN_ERR|RUN_WAR|RUN_INF|DEBUG_ERR|DEBUG_WAR|DEBUG_INF|TRACE|PROFILE|OPER"**: Enable the log function. You can set this parameter to one or a combination of the preceding log levels. If two or more log levels are used together, separate them with vertical bars (|). The log level cannot be set to an empty character string.

Default value: **"RUN_ERR|RUN_WAR|DEBUG_ERR|OPER|RUN_INF|PROFILE"**

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 1 and method 2 in **Table 6-2**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

ddb_log_backup_file_count

Parameter description: Specifies the maximum number of log files that can be saved.

Parameter type: integer

Unit: none

Value range: 1 to 100

Default value: **10**

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 1 and method 2 in **Table 6-2**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

ddb_max_log_file_size

Parameter description: Specifies the maximum number of bytes in a log.

Parameter type: string.

Unit: none

Value range: The value of this parameter consists of digits and a unit. The value ranges from 1 to 1000, in MB.

Default value: **"10M"**

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 1 and method 2 in **Table 6-2**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

ddb_log_suppress_enable

Parameter description: Specifies whether to enable the log suppression function.

Parameter type: integer

Unit: none

Value range: 0 to 1

- **0**: The log suppression function is disabled.
- **1**: The log suppression function is enabled.

Default value: **0**

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 1 and method 2 in **Table 6-2**.

Setting suggestion: Retain the default value.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

ddb_election_timeout

Parameter description: Specifies the DCC election timeout period.

Parameter type: integer

Unit: seconds

Value range: 1–600

Default value: **3**

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 1 and method 2 in **Table 6-2**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

ddb_dcf_sync_nodes

Parameter description: Specifies the standby node list for DCC synchronous replication.

Parameter type: string.

Unit: none

Value range: a valid standby node list. The value can be in the following format:

ANY *num_sync:node_id*[, ...]

NOTE

num_sync indicates the number of standby nodes to be synchronized and *node_id* indicates the sequence number of each standby node. Example: ddb_dcf_sync_nodes='ANY 1:2,3'.

Default value: **""**

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 2 in **Table 6-3**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

ddb_dcf_extreme_mode

Parameter description: Specifies the DCC log commit policy.

Parameter type: integer

Unit: none

Value range: 0 to 2

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **0**: maximum protection, that is, majority commit.
- **1**: maximum availability. When the standby node is faulty, the primary node can choose direct commit. When the standby node is normal, the primary node can choose majority commit.
- **2**: maximum performance, that is, local commit.

Default value: **0**

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 2 in **Table 6-3**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

alarm_ddb_unhealth_threshold

Parameter description: Specifies the threshold for reporting an alarm for an unhealthy DDB.

Parameter type: integer.

Unit: none

Value range: 0 to 2592000

Default value: **5**

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 2 in **Table 6-3**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

enable_e2e_rto

Parameter description: Specifies whether to enable the E2E RTO function. After this function is enabled, the zombie detection period and network detection timeout time are shortened. The CM can reach the E2E RTO value (RTO for a single instance: ≤ 10s; RTO for overlay faults: ≤ 30s).

Parameter type: integer.

Unit: none

Value range: 0 to 1

- **0**: The E2E RTO function is disabled.
- **1**: The E2E RTO function is enabled.

Default value: **0**

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 1 and method 2 in **Table 6-2**.

Setting suggestion: Retain the default value. You can adjust the value as required.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

enable_synclist_single_inst

Parameter description: Specifies whether to reduce copies to one primary and zero standby. After this function is enabled, the number of copies will be reduced to one primary and zero standby. If the parameter is incorrectly set, the default value is used.

Parameter type: Boolean

Unit: none

Value range:

- **on**: This function is enabled.
- **off**: This function is disabled.

Default value: **off**

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 1 and method 2 in **Table 6-2**.

Setting suggestion: Retain the default value. If you need to change the value, contact Huawei technical support.

Risks and impacts of improper settings: If this parameter is enabled and all standby nodes are faulty, the primary node automatically switches to the local commit mode. In this case, if the primary node is faulty again, unrecoverable impacts may occur.

asyn_log_enable

Parameter description: Specifies whether to enable asynchronous logging. After this parameter is enabled, the CM Server starts asynchronous logging.

Parameter type: Boolean

Unit: none

Value range:

- **on**: The CM Server starts asynchronous logging.
- **off**: The CM Server does not start asynchronous logging but uses serial logging.

Default value: **on**

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 2 in **Table 6-3**.

Setting suggestion: Retain the default value.

Risks and impacts of improper settings: If this parameter is disabled, logs may be lost.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

asyn_log_max_buf_size

Parameter description: Specifies the size of the asynchronous log buffer. When asynchronous logs are stacked and the stacked logs exceed the buffer size, subsequent logs cannot be recorded.

Parameter type: integer.

Unit: KB

Value range: 1 to 1048576

Default value: **1024**

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 2 in **Table 6-3**.

Setting suggestion: Adjust the value based on the memory and hard disk size.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

asyn_log_fault_solution

Parameter description: Specifies the asynchronous log processing solution after a log disk fault is identified. When the CM detects that a log disk is faulty or the asynchronous log buffer overflows, the CM processes asynchronous logs based on the configuration.

Parameter type: integer.

Unit: none

Value range: 0 to 2

- **0**: No extra processing is performed on logs. All logs are retained in the buffer until the buffer size reaches the upper limit. After the buffer size reaches the upper limit, no more logs are recorded.
- **1**: Logs are filtered. After a log disk fault is identified, only key logs, alarms, and logs at the ERROR level or higher are saved to the buffer until the buffer size reaches the upper limit. After the buffer size reaches the upper limit, no more logs are recorded.
- **2**: Logs are discarded. After a log disk fault is identified, only key logs and alarms are saved to the buffer until the buffer size reaches the upper limit. After the buffer size reaches the upper limit, no more logs are recorded.

Default value: **0**

Setting method: This parameter is a CM parameter. For details about how to modify this parameter, see method 2 in **Table 6-3**.

Setting suggestion: Adjust the value based on the memory and hard disk size.

Risks and impacts of improper settings: Change the parameter value after fully understanding the parameter meaning and verifying it through testing.

enable_isolate

Parameter description: Specifies whether to isolate instances.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter type: integer.

Unit: none

Value range: 0 to 1

- **0**: This function is disabled.
