  Page number of the damaged file. Set this parameter based on the **block_num** column in local_bad_block_info. If you want to verify the undo pages of the Ustore table, enter the block number of the undo pages to be verified.

  Value range: OID ranging from 0 to 4294967295. Note: A negative value will be forcibly converted to a non-negative integer.

- verify_mem

  Specifies whether to verify a specified page in the memory. If this parameter is set to **false**, only pages on the disk are verified. If this parameter is set to **true**, pages in the memory and on the disk are verified. If a page on the disk is damaged, the system verifies the basic information of the page in the memory and flushes the page to the disk to restore the page. If a page is not found in the memory during memory page verification, the page on the disk is read through the memory API. During this process, if the disk page is faulty, the remote read automatic repair function is triggered.

  Value range: The value is of a Boolean type and can be **true** or **false**.

- is_segment

  Determines whether the table is a segment-page table. Set this parameter based on the value of **bucket_node** in local_bad_block_info. If the value of **bucket_node** is **-1**, the table is not a segment-page table. In this case, set **is_segment** to **false**. If the value of **bucket_node** is not -1, set **is_segment** to **true**. Segment-page storage is supported.

  Value range: The value is of a Boolean type and can be **true** or **false**.

Return type: record

Examples (Set parameters based on the output of local_bad_block_info. Otherwise, an error is reported.):

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Page-based storage:

```
gaussdb=# SELECT * FROM gs_verify_and_tryrepair_page('base/16552/24745',0,false,false);
node_name        |       path       |  blocknum  |         disk_page_res         | mem_page_res | is_repair
-----------------+------------------+------------+-------------------------------+--------------+----------
dn_6001_6002_6003 | base/16552/24745 |     0      | page verification succeeded.|              | f
```

Segment-page storage:

```
gaussdb=# SELECT * FROM gs_verify_and_tryrepair_page('base/14365/1',4494,false,true);
node_name        |     path      | blocknum |         disk_page_res         | mem_page_res | is_repair
-----------------+---------------+----------+-------------------------------+--------------+-----------
dn_6001_6002_6003 | base/14365/1 |     4494 | page verification succeeded. |              | f
```

- gs_repair_page(path text, blocknum oid, is_segment bool, timeout int)

  Description: Restores the specified page of the instance. This function can be used only by the primary DN that is properly connected to the primary and standby DNs. By default, only the initial user, users with the SYSADMIN permission, and users with the OPRADMIN permission in the O&M mode on the primary DN can view the information. Other users can view the information only after being granted permissions.

  Note: If a page on a DN is damaged, a verification error at the PANIC level is reported when the DN is promoted to primary. The DN cannot be promoted to primary, which is normal.

  Parameters

  – path

    Path of the damaged page. Set this parameter based on the **file_path** column in local_bad_block_info or the **path** column in the gs_verify_and_tryrepair_page function.

    Value range: a string

  – blocknum

    Number of the damaged page. Set this parameter based on the **block_num** column in local_bad_block_info or the **blocknum** column in the gs_verify_and_tryrepair_page function.

    Value range: OID ranging from 0 to 4294967295. Note: A negative value will be forcibly converted to a non-negative integer.

  – is_segment

    Determines whether the table is a segment-page table. The value of this parameter is determined by the value of **bucket_node** in local_bad_block_info. If the value of **bucket_node** is **–1**, the table is not a segment-page table and **is_segment** is set to **false**. If the value of **bucket_node** is not **–1**, **is_segment** is set to **true**. Segment-page storage is supported.

    Value range: The value is of a Boolean type and can be **true** or **false**.

  – timeout

    Duration of waiting for standby DN replay. The page to be repaired needs to wait for the standby DN to be played back to the location of the current primary DN. Set this parameter based on the replay duration of the standby DN.

    Value range: 60s to 3600s.

  Return type: Boolean

  Examples (Set parameters based on the output of local_bad_block_info. Otherwise, an error is reported.):

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Page-based storage:

```
gaussdb=# SELECT * FROM gs_repair_page('base/16552/24745',0,false,60);
result
--------
t
```

Segment-page storage:

```
gaussdb=# SELECT * FROM gs_repair_page('base/16552/1',4494,true,60);
result
--------
t
```

- gs_seg_verify_datafile(IN tablespace_name name, IN database_name name, IN file_id integer, IN bucketnode integer, IN start_block_id bigint default 0, IN end_block_id bigint default UINT32MAX)

  Description: Verifies segment-page files 1 to 5, checks whether the main fork has page damage, and records the verification result in the local_bad_block_info() function. Only users with the SYSADMIN attribute and users with the OPRADMIN attribute in O&M mode can execute this function.

  Parameters

Name	Type	Description
tablespace_name	name	Tablespace name.
database_name	name	Database name.
file_id	integer	File name. The value ranges from 1 to 5.
bucketnode	integer	Bucket node of the table. • **0** to **1023** indicate the bucket nodes of a hash bucket table. • **1024** indicates the bucket node of a segment-page ordinary table. Currently, only hash bucket tables and segment-page ordinary tables are supported.
start_block_id	bigint	Start value of the verification page range. The default value is **0**.
end_block_id	bigint	End value of the verification page range. The default value is **4294967295**.

  Return value: none

  Example:

```
gaussdb=# SELECT * FROM gs_seg_verify_datafile('seg_tblspc', 'postgres', 2, 1024);
WARNING:  page verification failed, calculated checksum 60994 but expected 11565, the block num is 4157
 gs_seg_verify_datafile
------------------------

(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- gs_edit_page_bypath(path text, blocknum int64, offset int, data text, data_size int, read_backup bool, storage_type text)

  Description: Transfers the path, block number, offset, target data to be modified, and length of the target table file, modifies the target data to the corresponding fields on the page, and returns the path of the modified file to be flushed to the disk. The **read_backup** column determines the file reading mode, and the **storage_type** column indicates the file storage mode (for example, segment-page storage). To prevent incorrect modification, this function does not directly modify the original page but modifies the copied page and flushes the modified page to the specified path. Only the SYSADMIN or OPRADMIN in O&M mode can execute this function, and the function applies only to the primary node. In a distributed environment, this function must be executed on DNs.

  Return type: text.

  Table 1-262 gs_edit_page_bypath parameters

Category	Parameter	Type	Description
Input parameter	path	text	Physical file path of the file to be modified, which is related to the **read_backup** field. The value can be the relative path of the file in the database directory or the absolute path of files such as the backup file. If the target file does not exist or fails to be read, an error message is displayed. • If **read_backup** is **false**, the path format is *tablespace name*/*database oid*/*table relfilenode* (*physical file name*). For example, **base/16603/16394**. • If **read_backup** is **true**, **path** is a valid path. In this case, because other information about the input file cannot be obtained, you need to ensure that the input data is correct.
Input parameter	blocknum	bigint	Block number of the page to be repaired. Value range: 0 to *MaxBlockNumber*. Reads the page corresponding to the specified physical or logical block number based on the **read_backup** field. If the specified block number is out of range, an error message is returned.
Input parameter	offset	int	In-page offset of the field to be modified. Value range: 0 ≤ **offset** < *BLCKSZ*. If the specified value is less than **0** or greater than or equal to that of **BLCKSZ**, the system view is used to return the corresponding error information.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Category	Parameter	Type	Description
Input parameter	data	text	Type of the target value to be modified. Type: ● **'0x'**: hexadecimal. ● **'0b'**: binary. ● **'0s'**: character string. Others: If the value of the **data** parameter is not one of the preceding types, the value can only be a decimal numeric string.
Input parameter	data_size	int	Length of the written data, in bytes. Value range: 1 to 8. If the specified write length is less than 1 byte or greater than 8 bytes, or the sum of offset and data_size is greater than the value of **BLCKSZ**, the system view is used to return the corresponding error information.
Input parameter	read_backup	bool	Specifies whether to read pages from the backup directory. If this parameter is set to **false**, the target page is read based on the logical block number. Otherwise, the page is read based on the physical block number.
Input parameter	storage_type	text	Specifies the file storage mode. This parameter is optional. ● **'page'**: page mode. ● **'segment'**: segment-page mode. In page-based mode, only U-page and UB-tree data pages can be edited and modified. In segment-page mode, Astore data pages can be edited and modified. Tables with tablespaces are not supported. Other information about the input file cannot be obtained. Therefore, you need to ensure that the input data type is correct.
Output parameter	output_msg	text	If the modification is successful, the absolute path of the modified file is returned. The modified file is stored in the **gs_log/dump** directory. If the modification fails, a failure message is returned.

In the example, set parameters based on the parameter description and use the actual physical path.

Example 1: Overwrite the data whose value is **0X1FFF** at the offset of 16 bytes on page 0 in the **base/15808/25075** table.

```
gaussdb=# SELECT gs_edit_page_bypath('base/15808/25075',0,16,'0x1FFF', 2, false, 'page');
                gs_edit_page_bypath
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
-----------------------------------------------------------------------
 /gs_log_dir/dump/1663_15808_25075_0.editpage
(1 rows)
```

Example 2: If the input parameter does not comply with the specifications, an error message is returned.

```
gaussdb=# SELECT gs_edit_page_bypath('base/15808/25075', 0,16,'@1231!', 8, false, 'page');
           gs_edit_page_bypath
-----------------------------------------
 Error: the parameter 'data' decode failed.
(1 row)
```

Example 3: When the data to be written is the same as the original value, an alarm is returned.

```
gaussdb=# SELECT gs_edit_page_bypath('/gs_log_dir/dump/1663_15808_25075_0.editpage',
0,16,'0x1FFF', 2, true, 'page');
                  gs_edit_page_bypath
-------------------------------------------------------------
 Warning: source buffer is consistent with target buffer.
(1 row)
```

- gs_repair_page_bypath(src_path text, src_blkno int64, dest_path text, dest_blkno int64, storage_type text)

  Description: Transfers the path and page number of the source file, and writes the page to the specified page number of the target file. You can repair pages of the standby node through the primary node or repair the pages of the primary node through the standby node. In addition, you can initialize bad blocks using this function. In a distributed environment, this function must be executed on DNs.

  a. Target pages are overwritten and synchronized to the standby node. In page storage mode, U-heap and UB-tree pages can be modified. The Undo Record page, Undo Slot page, compressed table, and Astore page will be supported later. In segment-page storage mode, Astore pages and hash bucket tables can be modified. System catalog files and data sections cannot be modified.
  b. With this function, you can overwrite target pages during the write operation. Before overwriting, the target page is backed up and flushed to a specified directory. The backup page can be rewritten back to the target page. If an ordinary table is modified on the primary node, a new WAL is generated and synchronized to the standby node. If an ordinary table is modified on the standby node, no WAL is recorded.
  c. The repair view applies only to the primary node or the standby node when the read on standby function is enabled. Only the SYSADMIN or OPRADMIN in O&M mode can use this function. All modifications will be recorded in database logs. In addition, you are advised to enable the audit logging function of system functions before using this function to record audit information.
  d. When the repair view is called on the standby node, the standby node can be repaired only by reading pages from the primary node.
  e. During the repair, the LSNs of the source and target pages must be the same, and the CRC check of the page must be passed. Otherwise, the repair fails. During this process, other repair methods may be triggered.
  f. The target page is verified. If the target page is correct, it cannot be overwritten. Currently, the U-heap and UB-tree pages can be verified.

  Return type: text.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

CAUTION

Calling this system function is a high-risk operation. Exercise caution when performing this operation.

Category	Parameter	Type	Description
Input parameter	src_path	text	Path of the source file. The following types of paths are supported: • Data files and index files: **gs_log/dump/1663_15808_25075_0.editpage**. • **src_path** is set to **'standby'** on the primary node. That is, pages are read from the standby node to repair the primary node. • **src_path** is set to **'primary'** on the standby node. That is, pages are read from the primary node to repair the standby node. On the standby node, **src_path** can only be set to **'primary'** and the read function must be enabled on the standby node before the repair. • **src_path** is set to **init_block** on the primary node to allow skipping bad blocks in extreme scenarios.
Input parameter	src_blkno	bigint	Physical block number of the source page. Value range: 0 to *MaxBlockNumber*.
Input parameter	dest_path	text	Relative path of the target file. For example, **base/15808/25075**.
Input parameter	dest_blkno	bigint	Logical block number of the target page. Value range: 0 to *MaxBlockNumber*.
Input parameter	storage_type	text	Specifies the target file storage mode. This parameter is optional. • **'page'**: page mode. • **'segment'**: segment-page mode.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Category	Parameter	Type	Description
Output parameter	output_msg	text	If the overwrite operation is successful, the backup path of the target page is returned. If the overwrite operation fails, an error message is returned. The format of the flushed file name is *relfilepath_blocknum_timestamp.repairpage*.

Set parameters based on the preceding table and ensure that the physical file exists. If the input parameter is abnormal or the restoration fails, an error is reported.

Example 1: Enter a file in a specified path to overwrite the target file.

```
gaussdb=# SELECT * FROM gs_repair_page_bypath('gs_log/dump/1663_15991_16767_0.editpage', 0, 'base/15991/16767', 0, 'page');
                                        output_msg
-------------------------------------------------------------------------------------------------
/gs_log_dir/dump/1663_15991_16767_0_738039702421788.repairpage
(1 row)
```

Example 2: Read pages from the standby node to repair the primary node.

```
gaussdb=# SELECT * FROM gs_repair_page_bypath('standby', 0, 'base/15990/16768', 0, 'page');
                                        output_msg
-------------------------------------------------------------------------------------------------
/gs_log_dir/dump/1663_15990_16768_0_738040397197907.repairpage
(1 row)
```

Example 3: Read pages from the primary node to repair the standby node.

```
gaussdb=# SELECT * FROM gs_repair_page_bypath('primary', 0, 'base/15990/16768', 0, 'page');
                                        output_msg
-------------------------------------------------------------------------------------------------
 /gs_log_dir/dump/1663_15990_16768_0_738040506157799.repairpage
(1 row)
```

Example 4: Initialize the target page and skip bad blocks.

```
gaussdb=# SELECT * FROM gs_repair_page_bypath('init_block', 0, 'base/15990/16768', 0, 'page');
                                        output_msg
-------------------------------------------------------------------------------------------------
 /gs_log_dir/dump/1663_15990_16768_0_738040768010281.repairpage
(1 row)
```

- gs_edit_repair_page(path text, blocknum int64, area text, index int, name text, value uint64)

  Description: Modifies the XID-related columns on a page based on the input source file path and page number, and directly updates the page in the database. Calling this function to modify a page generates the corresponding Xlogs. Before the modification, the source page and parsed page of the original page are dumped to the log path, and the function returns the path of the dump file.

  The limitations on this function are as follows:

  – It can be called only on the primary DN.

  – Compressed pages cannot be repaired.

  – Segment-page pages cannot be repaired.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- Only the initial user, users with the SYSADMIN attribute, and users with the OPRADMIN attribute in O&M mode can call this function.
- Only pages that pass the CRC can be repaired.

Return type: text.

NOTE

This system function is used to handle XID damage and is a high-risk operation. Exercise caution when using this function and do not call it frequently.

Table 1-263 gs_edit_repair_page parameters

Category	Parameter	Category	Description
Input parameter	path	text	Path of the source file. To obtain the relative path of a table file, call pg_relation_filepath(table_name text). To obtain the path of a partitioned table, query the pg_partition system catalog and call pg_partition_filepath(partition_oid). For example, **base/16603/16394**.
Input parameter	blocknum	bigint	Physical block number of the source page. The value ranges from 0 to *MaxBlockNumber*.
Input parameter	area	text	Target area of a page. The options are as follows: • **header**: page header. • **td**: td or ted part of the U-heap page. • **tuple**: page tuple.
Input parameter	index	integer	Index of the target area in the same type of area. The value starts from 0. The header area supports only the index 0.
Input parameter	name	text	Target columns to be repaired. • **header**: **pd_prune_xid**, **pd_xid_base**, and **pd_multi_base** • **td**: **xid** • **tuple(uheap)**: **xid** • **tuple(heap)**: **xmin** and **xmax** • **tuple(ubtree)**: **xmin** and **xmax**
Input parameter	value	bigint	Target value to be repaired.
Output parameter	output_msg	text	If the repair is successful, the dump file path is returned. If the repair fails, an error message is returned.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Pass the parameters based on the preceding table and ensure that the physical file exists. If the parameter is abnormal or the repair fails, the function reports an error.

Example 1: Modify **pd_prune_xid** in the header on page 0 in the **base/14816/16404** file.

```
gaussdb=# select * from gs_edit_repair_page('base/14816/16404', 0, 'header', 0, 'pd_prune_xid', 0);
                        output_msg
-------------------------------------------------------------------
/gs_log_dir/dump/1663_14816_16404_0_824366317606633.originpage+
/gs_log_dir/dump/1663_14816_16404_0.dump
(1 row)
```

Example 2: Modify **xid** of ted 0 in the **td** part on page 3 in the **base/14816/16404** file.

```
gaussdb=# select * from gs_edit_repair_page('base/14816/16404', 3, 'td', 0, 'xid', 196218);
                        output_msg
-------------------------------------------------------------------
/gs_log_dir/dump/1663_14816_16404_3_824368882816559.originpage+
/gs_log_dir/dump/1663_14816_16404_3.dump
(1 row)
```

Example 3: Modify **xmax** of tuple 16 in the **tuple** part on page 5 in the **base/14816/16387** file.

```
gaussdb=# select * from gs_edit_repair_page('base/14816/16387', 5, 'tuple', 16, 'xmax', 0);
                        output_msg
-------------------------------------------------------------------
/gs_log_dir/dump/1663_14816_16387_5_824368882816559.originpage+
/gs_log_dir/dump/1663_14816_16387_5.dump
(1 row)
```

- gs_repair_undo_byzone(zone_id int)

  Description: Transfers the ID of the undo zone to be repaired, repairs the metadata of the target undo zone, and returns the repair result details. If the undo zone is not repaired, no information is output.

  Return type: record

  Note: Currently, the function can be called only on the primary node. After the repair is successful, the repair will be synchronized to the standby node by recording Xlogs. The caller must be a SYSADMIN or an OPRADMIN in O&M mode. You are advised to enable the audit logging function before using the function to record audit information.

  CAUTION

  Calling this system function is a high-risk operation. Exercise caution when performing this operation.

  Table 1-264 gs_repair_undo_byzone parameters

Category	Parameter	Type	Description
Input parameter	zone_id	int	Undo zone ID. • **-1**: repairs the metadata of all undo zones. • **0** to **1048575**: repairs the metadata of the undo zone corresponding to the zone ID.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Category	Parameter	Type	Description
Output parameter	zone_id	int	Undo zone ID.
Output parameter	repair_detail	text	Repair result of the undo zone metadata corresponding to the zone ID. If the repair is successful, "rebuild undo meta succeed." is displayed. If the repair fails, "rebuild undo meta failed." as well as the failure cause is displayed.

Example 1: If the undo zone meta information corresponding to the entered **zone_id** is not damaged, no output is expected.

```
gaussdb=# SELECT * FROM gs_repair_undo_byzone(4);
 zone_id | repair_detail
---------+---------------
(0 rows)
```

Example 2: If the undo zone metadata corresponding to the entered **zone_id** is successfully restored, the system displays a message indicating that the restoration is successful.

```
gaussdb=# SELECT * FROM gs_repair_undo_byzone(78);
 zone_id | repair_detail
---------+---------------
      78 | rebuild undo meta succeed.
(1 row)
```

Example 3: If the undo zone metadata corresponding to the entered zone ID fails to be repaired, the detailed information about the repair failure is displayed.

```
gaussdb=# SELECT * FROM gs_repair_undo_byzone(0);
 zone_id | repair_detail
---------+---------------
       0 | rebuild undo meta failed. try lock undo zone_id failed.
(1 row)
```

NOTE

If the undo zone to be repaired is damaged and the zone ID is occupied by another active thread, calling this repair function will end the thread that occupies the zone ID and forcibly repair the damaged undo zone metadata.

- gs_verify_urq(index_oid oid, partindex_oid oid, blocknum bigint, queue_type text)

  Description: Verifies the correctness of the index recycling queue (potential queue/available queue/single page).

  Parameters: See **Table 1-265**.

  Return type: record

Table 1-265 gs_verify_urq parameters

Category	Parameter	Type	Description
Input parameter	index_oid	oid	UB-tree index OID. • Ordinary index: index OID. • Global index: GPI OID. • Local index: OID of the primary index.
Input parameter	partindex_oid	oid	UB-tree partitioned index OID. • Ordinary index: 0. • Global index: 0. • Local index: OID of the partitioned index (primary or secondary).
Input parameter	blocknum	bigint	Specifies the page number: • If the queue type is single page, the correctness of all tuples of **blocknum** on a single page is verified. The value range is [0,*Queue file size*/8192). • If the queue is empty or free, **blocknum** is an invalid value.
Input parameter	queue_type	text	Specifies the queue type: • **empty queue**: potential queue • **free queue**: available queue • **single page**: single-page queue
Output parameter	error_code	text	Error code
Output parameter	detail	text	Detailed error information and other key information.

When using the example, set parameters based on the parameter description and use the actual OID and **blocknum**. Otherwise, an error is reported.

Example 1:

```
gaussdb=# SELECT * FROM gs_verify_urq(16387, 0, 1, 'free queue');
 error_code | detail
------------+--------
(0 rows)
```

Example 2:

```
gaussdb=# SELECT * FROMgs_verify_urq(16387, 0, 1, 'empty queue');
     error_code       |
detail
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
----------------------
+-------------------------------------------------------------------------------------------------------------------
 VERIFY_URQ_PAGE_ERROR | invalid urq meta: oid 16387, blkno 1, head_blkno = 1, tail_blkno = 3,
nblocks_upper = 4294967295, nblocks_lower = 1; urq_blocks = 6, index_blocks = 12
(1 row)
```

NOTE

Currently, this API supports only Ustore index tables. If the verification of the index recycling queue is normal, the view does not display the error code and error details. Otherwise, the view displays the error code and error details. The error codes include "VERIFY_URQ_PAGE_ERROR", "VERIFY_URQ_LINK_ERROR", "VERIFY_URQ_HEAD_MISSED_ERROR", and "VERIFY_URQ_TAIL_MISSED_ERROR". If any of the preceding error codes is displayed, contact Huawei technical support to locate the fault.

- gs_urq_dump_stat(index_oid oid, partindex_oid oid)

  Description: Queries information about a specified index recycling queue.

  In the return result, **recentGlobalDataXmin** and **globalFrozenXid** are two oldestxmins used by the recycling queue to determine whether the index page can be recycled, **next_xid** is the XID of the next latest transaction, **urq_blocks** indicates the total number of pages in the recycling queue and information about valid pages in the free queue (available queue) and empty queue (potential queue). For PCR indexes, the output recentGlobalDataXmin is replaced by globalRecycleXid that affects the recycling of the PCR index pages.

  Parameters: See **Table 1-266**.

  Table 1-266 gs_urq_dump_stat parameters

Category	Parameter	Type	Description
Input parameter	index_oid	oid	UB-tree index OID. • Ordinary index: index OID. • Global index: GPI OID. • Local index: OID of the primary index.
Input parameter	partindex_oid	oid	UB-tree partitioned index OID. • Ordinary index: 0. • Global index: 0. • Local index: OID of the partitioned index (primary or secondary).
Output parameter	result	text	Detailed statistics about the index recycling queue.

  When using the example, set parameters based on the parameter description and use the actual OID. Otherwise, an error is reported.

  Example (RCR):

```
gaussdb=# SELECT * FROM gs_urq_dump_stat(16387, 0);
                                                result
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

(1 row)
```

NOTE

Currently, this API supports only Ustore index tables.

- gs_repair_urq(index_oid oid, partindex_oid oid)

  Description: Repairs (with loss) index recycling queues (potential and available queues). The recycling queue file of the current index is deleted and an empty recycling queue file is created. If the repair is successful, "reinitial the recycle queue of index relation successfully" is displayed.

  Parameters: See **Table 1-267**.

  Note: The current function can be called only on the primary node.

Table 1-267 gs_repair_urq parameters

Category	Parameter	Type	Description
Input parameter	index_oid	oid	UB-tree index OID. • Ordinary index: index OID. • Global index: GPI OID. • Local index: OID of the primary index.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Category	Parameter	Type	Description
Input parameter	partindex_oid	oid	UB-tree partitioned index OID. • Ordinary index: 0. • Global index: 0. • Local index: OID of the partitioned index (primary or secondary).
Output parameter	result	text	When the rebuilding is successful, "reinitial the recycle queue of index relation successfully" is displayed. Otherwise, the rebuilding fails.

When using the example, set parameters based on the parameter description and use the actual OID. Otherwise, an error is reported.

Example:

```
gaussdb=# SELECT * FROM gs_repair_urq(16387, 0);
                            result
-------------------------------------------------------------
 reinitial the recycle queue of index relation successfully.
(1 row)
```

NOTE

Currently, this API supports only Ustore index tables.

- gs_check_table(table_oid oid, partition_oid oid, index_oid oid, partindex_oid oid, start_blk bigint, end_blk bigint, duration text, need_repair bool, mode text)

  Description: Verifies reverse data consistency between heap tables and indexes.

  Constraints: The Astore and Ustore are supported. MOT storage engines are not supported. The verification of standby nodes is supported, but the verification of the logger node is not supported. The verification of common row-store tables, ILM compressed tables, TDE tables, and hash bucket tables is supported by heap tables. The verification of temporary tables, global temporary tables, and unlogged tables is not supported by heap tables. Indexes support B-tree and UB-tree index verification and are compatible with segment-page storage.

  Parameters: For details, see **Table 1-268**.

  Return type: record

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 1-268 gs_check_table parameters

Category	Parameter	Type	Description
Input parameter	table_oid	oid	Heap table OID. • Ordinary table: heap table OID. • Partitioned table: main table OID.
Input parameter	partition_oid	oid	Partition OID. • Ordinary table: **0**. • Partitioned table: partition OID. • All partitions scanned in the partitioned table: **0**.
Input parameter	index_oid	oid	Index OID. • Ordinary index: index OID. • Global index: GPI OID. • Local index: OID of the primary index. • All scanned indexes: **0**.
Input parameter	partindex_oid	oid	Partitioned index OID. • Ordinary index: 0. • Global index: 0. • Local index: OID of the partitioned index (primary or secondary). • Local index of all scanned partitions: **0**.
Input parameter	start_blk	bigint	Number of the verification start page. If this parameter and **end_blk** are set to **-1**, the verification starts from the beginning by default. When all partitions in a partitioned table are scanned, only the verification from the beginning is supported. The values of **start_blk** and **end_blk** must be **-1**.
Input parameter	end_blk	bigint	Number of the verification end page.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Category	Parameter	Type	Description
Input parameter	duration	text	Verification duration. The value can be in millisecond, second, minute, hour, or day, for example, **500ms**, **60s**, **10min**, **2h**, or **1d**. The maximum value is **24h**. There may be a millisecond-level, seconds-level, or minute-level error. If this parameter is set to **0**, the verification is complete by default. The verification duration is the minimum value of the actual execution time and the configured time. If the execution time exceeds the configured time, the verification stops and the current verification position is recorded. The next scanning can be resumed from the recorded position.
Input parameter	need_repair	bool	Specifies whether to automatically repair inconsistency. That is, add or delete index tuples based on heap tables. Currently, this parameter can only be set to **false**. This parameter is a pre-embedded parameter. This version does not support automatic repair.
Input parameter	mode	text	Pre-embedded parameter of the validation mode. The value can be **increment** or **full**. Resumable verification, increment verification, and full verification are supported.
Output parameter	error_code	int	Error code.
Output parameter	output_filepath	text	Relative path for flushing parsed data to disks. The path is the **gs_log/dump** dictionary. The flushed file name is **dbverify**_*Error code_Heap table OID_Timestamp*.**log**. The following is an example: /*$GAUSSLOG*/**gs_log/dump/dbverify_0_16384_123456.log**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

When using the example, set parameters based on the parameter description and use the actual and matching OID and **blocknum**. Otherwise, an error is reported.

Example 1:

```
gaussdb=# select * from gs_check_table((select oid from pg_class where relname='t2'),0,0,0,-1,-1, '1h',
false, 'full');
 verify_code |                                output_filepath
-------------+-------------------------------------------------------------------------------------
           0 | /$GAUSSLOG/gs_log/dump/dbverify_0_17279_766073191583799.log
(1 row)
```

Example 2:

```
gaussdb=# select * from gs_check_table((select oid from pg_class where relname='t1'),0,(select oid
from pg_class where relname='index_t1'),0,2,10, '2s', false, 'full');
 verify_code |                                output_filepath
-------------+-------------------------------------------------------------------------------------
           0 | /$GAUSSLOG/gs_log/dump/dbverify_0_17168_766073338594117.log
(1 row)
```

NOTE

Calling this system function is a high-risk operation. Exercise caution when performing this operation.

Currently, this API supports consistency check between Astore and Ustore tables and between B-tree and UB-tree indexes. If no consistency problem is found after the verification, the error code is **0**. If an error code other than **0** is displayed, contact Huawei technical support to locate the fault.

Resumable verification and increment verification:

The information related to resumable verification and incremental verification is not persisted. After the database process is restarted, the previous verification is lost. When the verification is performed again, the full verification is performed from the beginning.

If the verification mode is **increment** and the last verification on the table and index is not complete, resumable verification is triggered and the verification starts from the position where the last verification is interrupted.

If the verification mode is **increment** and the last verification on the table and index is complete, increment verification is triggered to verify the incremental modification page.

If the verification mode is **full**, full verification is performed from the beginning.

I/O flow control:

By default, **io_priority** is set to a low priority for I/O flow control.

Use permission:

Only the initial user, users with the SYSADMIN, OPRADMIN, or MONADMIN permission can execute verification system functions. Only data tables or indexes in the current database can be verified.

Recommended application scenario:

You are advised to perform the verification during off-peak hours to ensure that most data is static data during the verification and ensure the integrity and accuracy of the verification.

- gs_check_index(index_oid oid, partindex_oid oid, duration text, need_repair bool, mode text)

  Description: Verifies forward data consistency between heap tables and indexes.

  Constraints: The Astore and Ustore are supported. MOT storage engines are not supported. The verification of standby nodes is supported, but the verification of the logger node is not supported. The verification of common

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

row-store tables, ILM compressed tables, TDE tables, and hash bucket tables is supported by heap tables. The verification of temporary tables, global temporary tables, and unlogged tables is not supported by heap tables. Indexes support B-tree and UB-tree index verification and are compatible with segment-page storage.

Parameters: For details, see **Table 1-269**.

Return type: record

Table 1-269 gs_check_index parameters

Category	Parameter	Type	Description
Input parameter	index_oid	oid	Index OID. • Ordinary index: index OID. • Global index: GPI OID. • Local index: OID of the primary index.
Input parameter	partindex_oid	oid	Partitioned index OID. • Ordinary index: 0. • Global index: 0. • Local index: OID of the partitioned index (primary or secondary). • Local index of all scanned partitions: **0**.
Input parameter	duration	text	Verification duration. The value can be in millisecond, second, minute, hour, or day, for example, **500ms**, **60s**, **10min**, **2h**, or **1d**. The maximum value is **24h**. There may be a millisecond-level, seconds-level, or minute-level error. If this parameter is set to **0**, the verification is complete by default. The verification duration is the minimum value of the actual execution time and the configured time. If the execution time exceeds the configured time, the verification stops and the current verification position is recorded. The next scanning can be resumed from the recorded position.

Category	Parameter	Type	Description
Input parameter	need_repair	bool	Specifies whether to automatically repair inconsistency. That is, add or delete index tuples based on heap tables. Currently, this parameter can only be set to **false**. This parameter is a pre-embedded parameter. This version does not support automatic repair.
Input parameter	mode	text	Pre-embedded parameter of the validation mode. The value can be **increment** or **full**. Resumable verification, increment verification, and full verification are supported.
Output parameter	error_code	int	Error code.
Output parameter	output_filepath	text	Relative path for flushing parsed data to disks. The path is the **gs_log/dump** dictionary. The flushed file name is **dbverify**_*Error code_Heap table OID_Timestamp*.**log**. The following is an example: /*$GAUSSLOG*/**gs_log/dump/dbverify_0_16384_123456.log**

When using the example, set parameters based on the parameter description and use the actual and matching OID. Otherwise, an error is reported.

Example 1:

```
gaussdb=# select * from gs_check_index((select oid from pg_class where relname='index_t1'),0, '1h',
false, 'full');
 verify_code |                                output_filepath
-------------+-------------------------------------------------------------------------------------
           0 | /$GAUSSLOG/gaussdb/single_node/gs_log/dump/dbverify_0_17302_766074761373434.log
(1 row)
```

Example 2:

```
gaussdb=# select * from gs_check_index((select oid from pg_class where relname='index_range_2'),
(select oid from pg_partition where parentid=(select oid from pg_class where
relname='index_range_2')and relname='p1_a_idx'), '10s', false, 'full');
 verify_code |                                output_filepath
-------------+-------------------------------------------------------------------------------------
           0 | /$GAUSSLOG/gaussdb/single_node/gs_log/dump/dbverify_0_17306_766074834795344.log
(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

Currently, this API supports consistency check between Astore and Ustore tables and between B-tree and UB-tree indexes. If no consistency problem is found after the verification, the error code is **0**. If an error code other than **0** is displayed, contact Huawei technical support to locate the fault.

Resumable verification and increment verification:

The information related to resumable verification and incremental verification is not persisted. After the database process is restarted, the previous verification is lost. When the verification is performed again, the full verification is performed from the beginning.

If the verification mode is **increment** and the last verification on the table and index is not complete, resumable verification is triggered and the verification starts from the position where the last verification is interrupted.

If the verification mode is **increment** and the last verification on the table and index is complete, increment verification is triggered to verify the incremental modification page.

If the verification mode is **full**, full verification is performed from the beginning.

I/O flow control:

By default, **io_priority** is set to a low priority for I/O flow control.

Use permission:

Only the initial user, users with the SYSADMIN, OPRADMIN, or MONADMIN permission can execute verification system functions. Only data tables or indexes in the current database can be verified.

Recommended application scenario:

You are advised to perform the verification during off-peak hours to ensure that most data is static data during the verification and ensure the integrity and accuracy of the verification.

CAUTION

Calling this system function is a high-risk operation. Exercise caution when performing this operation.

- gs_get_standby_bad_block_info()

  Description: Displays the pages that have been detected on the standby node but have not been repaired. By default, only the initial user, users with the SYSADMIN permission, users with the OPRADMIN permission in the O&M mode, and users with the MONADMIN permission on the standby DN can view the information. Other users can view the information only after being granted permissions. There are four return values in the **invalid_type** column: **NOT_PRESENT** (the page does not exist), **NOT_INITIALIZED** (the page initialization fails), **LSN_CHECK_ERROR** (the LSN check fails), and **CRC_CHECK_ERROR** (the CRC verification fails).

  Return type: record

  Example (If no page is detected but not repaired, no line is displayed.)

```
gaussdb=# SELECT * FROM gs_get_standby_bad_block_info();
 spc_node | db_node | rel_node | bucket_node | fork_num | block_num |  invalid_type   |
master_page_lsn
----------+---------+----------+-------------+----------+-----------+-----------------+-----------------
   1663   |   16552 |   24745  |      -1     |    0     |     0     | CRC_CHECK_ERROR | 0/B2009E8
(1 rows)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

1.6.43 Multixact Recycling Function

- gs_vacuum_multixact()

  Description: Recycles data files in **offsets** and **members** in the **pg_multixact** directory.

  Return type: Boolean

  - If a file is successfully recycled, **true** is returned.
  - If no file can be recycled, **false** is returned.

  The limitations on this function are as follows:

  - This function can be executed only on the primary DN or on the corresponding primary DN using EXECUTE DIRECT.
  - Only the initial user or users with the SYSADMIN attribute can call this function.
  - Manual recycling cannot be performed on CNs.

  Example 1: If no file can be recycled, **false** is returned.

```
gaussdb=# SELECT gs_vacuum_multixact();
 gs_vacuum_multixact
---------------------
 f
(1 row)
```

  Example 2: If the file is successfully recycled, **true** is returned.

```
gaussdb=# SELECT gs_vacuum_multixact();
 gs_vacuum_multixact
---------------------
 t
(1 row)
```

  NOTE

  The logic for determining whether a file can be recycled is calculated based on **datminmxid** in the PG_DATABASE system catalog. In some scenarios, **datminmxid** may not be updated. For example, a global temporary table exists in the current database. The data in a global temporary table is isolated at the session level. Therefore, the VACUUM background thread cannot access the information about the global temporary table. As a result, the **relminmxid** column of the global temporary table cannot be automatically updated, and **datminmxid** cannot be updated. Therefore, you need to run the **VACUUM FREEZE** *Table name***;** command on all global temporary tables in the session of the global temporary table to update **relminmxid** of the current global temporary table.

1.6.44 Functions of the XML Type

NOTE

- In all the following XML functions, when the GUC parameter **xmloption** is set to **content**, the value of **encoding** in the XML declaration can be **ZHS16GBK**. When the GUC parameter **xmloption** is set to **document**, the value of **encoding** in the XML declaration cannot be **ZHS16GBK**. If **encoding** is set to **ZHS16GBK**, an error is reported.
- XML functions support a maximum of 256 nested layers in XML files.

- xmlparse ({ DOCUMENT | CONTENT } value [wellformed])

  Description: Generates XML values from character data.

  Parameter: data of the TEXT type

  Return type: XML

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Example:

```
gaussdb=# SELECT XMLPARSE (DOCUMENT '<?xml version="1.0"?><book><title>Manual</
title><chapter>...</chapter></book>');
                  xmlparse
-----------------------------------------------------------
 <book><title>Manual</title><chapter>...</chapter></book>
(1 row)
gaussdb=# SELECT XMLPARSE (CONTENT 'abc<foo>bar</foo><bar>foo</bar>');
         xmlparse
---------------------------------
 abc<foo>bar</foo><bar>foo</bar>
(1 row)
gaussdb=# SELECT XMLPARSE (CONTENT 'abc<foo>bar</foo' wellformed);
    xmlparse
------------------
 abc<foo>bar</foo
(1 row)
```

- xmlserialize({ DOCUMENT | CONTENT } value AS type)

  Description: Generates a string from an XML file.

  Parameter: data of the XML type

  Return type: The data type can be character, character varying, text, or any variant of them.

  Example:

  ```
  gaussdb=# SELECT xmlserialize(CONTENT 'good' AS CHAR(10));
   xmlserialize
  --------------
   good
  (1 row)
  gaussdb=# SELECT xmlserialize(DOCUMENT '<head>bad</head>' as text);
    xmlserialize
  ------------------
   <head>bad</head>
  (1 row)
  ```

  NOTE

  If a string value is converted to XML without using the xmlparse or xmlserialize function, the **XML OPTION** session parameter determines the value, **DOCUMENT** or **CONTENT**. The **XML OPTION** session parameter can be set by the standard command.

  ```
  SET XML OPTION { DOCUMENT | CONTENT };
  ```

  Or use similar syntax to set this parameter.

  ```
  SET xmloption TO { DOCUMENT | CONTENT };
  ```

- xmlcomment(text)

  Description: Creates an XML value that contains an XML comment with the specified text as the content. The text does not contain the "--" character and does not end with a "-" character. Besides, the text should meet the format requirements of XML comments. If the parameter is empty, the result is also empty.

  Parameter: data of the TEXT type

  Return type: XML

  Example:

  ```
  gaussdb=# SELECT xmlcomment('hello');
    xmlcomment
  --------------
   <!--hello-->
  ```

- xmlconcat(xml[, ...])

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description: Concatenates a list of single XML values into a single value that contains an XML content fragment. Null values are ignored, and the result is null only when all parameters are null. In ORA-compatible mode, you can set **a_format_version** to **10c** and **a_format_dev_version** to **s2** to check whether the input segment is well-formed XML text.

Parameter: data of the XML type.

Return type: XML

Example 1:

```
gaussdb=# SET xmloption=content;
SET
gaussdb=# SELECT XMLCONCAT(('<?xml version="1.0" encoding="GB2312" standalone="no"?
><bar>foo</bar>'),('<?xml version="1.0" encoding="GB2312" standalone="no" ?><bar>foo</bar>')) ;
                        xmlconcat
----------------------------------------------------------------------
<?xml version="1.0" standalone="no"?><bar>foo</bar><bar>foo</bar>
(1 row)
gaussdb=# SELECT XMLCONCAT('abc>');
 xmlconcat
-----------
 abc>
(1 row)
```

Example 2: Syntax of the ORA-compatible database

```
gaussdb=# CREATE DATABASE gaussdb_ora DBCOMPATIBILITY='ORA';
CREATE DATABASE
gaussdb=# \c gaussdb_ora
gaussdb_ora=# SET a_format_version='10c';
SET
gaussdb_ora=# SET a_format_dev_version=s2;
SET
gaussdb_ora=# SET xmloption=content;
SET
gaussdb_ora=# SELECT XMLCONCAT(('<?xml version="1.0" encoding="GB2312" standalone="no"?
><bar>foo</bar>'),('<?xml version="1.0" encoding="GB2312" standalone="no" ?><bar>foo</bar>')) ;
                        xmlconcat
----------------------------------------------------------------------
 <?xml version="1.0" standalone="no"?><bar>foo</bar><bar>foo</bar>
(1 row)

gaussdb_ora=# SELECT XMLCONCAT('abc>');
ERROR:  invalid XML document
DETAIL:  line 1: Start tag expected, '<' not found
abc>
^
CONTEXT:  referenced column: xmlconcat
gaussdb_ora=# \c postgres
gaussdb=# DROP DATABASE gaussdb_ora;
DROP DATABASE
```

NOTE

In ORA-compatible database, if **a_format_version** is set to **10c** and **a_format_dev_version** is set to **s2**, and the **encoding** attribute in the XML declaration is set to **ZHS16GBK**, the XMLCONCAT function reports an error.

- xmlagg(xml [order_by_clause])

  Description: Concatenates the input values called by the aggregate function. Cross-line concatenation is supported. For details about **order_by_clause**, see **SELECT**. In ORA-compatible database mode, you can set **a_format_version** to **10c** and **a_format_dev_version** to **s2**. The **xmloption** parameter of the database is set to **content** by default. When **xmloption** is set to **document**, newline characters are used to concatenate multiple XML lines. If the

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

encoding attribute value in the XML declaration is not the default UTF-8, the aggregation result contains the XML declaration.

Parameter: XML

Return type: XML

Example 1:

```
gaussdb=# CREATE TABLE xmltest (
           id int,
           data xml
          );
NOTICE:  The 'DISTRIBUTE BY' clause is not specified. Using 'id' as the distribution column by default.
HINT:  Please use 'DISTRIBUTE BY' clause to specify suitable data distribution column.
gaussdb=# INSERT INTO xmltest VALUES (1, '<value>one</value>');
INSERT 0 1
gaussdb=# INSERT INTO xmltest VALUES (2, '<value>two</value>');
INSERT 0 1
gaussdb=# SELECT xmlagg(data) FROM xmltest;
              xmlagg
--------------------------------------
 <value>one</value><value>two</value>
(1 row)
```

Example 2: Syntax of the ORA-compatible database

```
gaussdb=# SET xmloption=document;
SET
gaussdb=# SELECT xmlagg(data) FROM xmltest;
      xmlagg
--------------------
 <value>one</value>+
 <value>two</value>
(1 row)
gaussdb=# DELETE FROM XMLTEST;
DELETE 2
gaussdb=# INSERT INTO xmltest VALUES (1, '<?xml version="1.0" encoding="GBK"?><value>one</
value>');
INSERT 0 1
gaussdb=# INSERT INTO xmltest VALUES (2, '<?xml version="1.0" encoding="GBK"?><value>two</
value>');
INSERT 0 1
gaussdb=# SELECT xmlagg(data) FROM xmltest;
                       xmlagg
------------------------------------------------------------
 <?xml version="1.0" encoding="GBK"?><value>one</value>+
 <value>two</value>
(1 row)
gaussdb=# SELECT xmlagg(data order by id desc) FROM xmltest;
                       xmlagg
------------------------------------------------------------
 <?xml version="1.0" encoding="GBK"?><value>two</value>+
 <value>one</value>
(1 row)

gaussdb=# DROP TABLE xmltest;
```

NOTE

Both the input and return types of the xmlagg function are XML. The maximum size of a single XML data type is 1 GB. Therefore, xmlagg does not support scenarios where the aggregation result exceeds 1 GB.

- xmlelement([ENTITYESCAPING | NOENTITYESCAPING] { [NAME] element_name | EVALNAME element_name } [, xmlattributes([ENTITYESCAPING | NOENTITYESCAPING] value [[AS] attname | AS EVALNAME attname] [, ...])] [, content [[AS] alias] [, ...]])

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description: Generates an XML element with the given name, attribute, and content.

Return type: XML

Example:

```
gaussdb=# SELECT xmlelement(name foo);
 xmlelement
------------
 <foo/>

-- In ORA-compatible mode:

gaussdb_ora=# \c postgres
gaussdb=# DROP DATABASE gaussdb_ora;
DROP DATABASE
```

NOTE

- For **xmlelement** and **xmlattributes**, when the value of **name** is **NULL**, the database behavior is different from that of the O database. When the **name** field of **xmlelement** is set to **NULL**, the name information is empty and the attribute information is not displayed. When the **name** field of **xmlattributes** is set to **NULL**, the attribute information is not displayed.
- After the following two parameters are set, the content escape rule of **xmlelement** is ORA compatible. If the two parameters are not set, the content escape rule of **xmlelement** is PG compatible.

  ```
  SET a_format_version='10c';
  SET a_format_dev_version=s2;
  ```

- xmlforest(content [AS name] [, ...])

  Description: Generates an XML sequence of elements using the given name and content.

  Return type: XML

  Example:

  ```
  gaussdb=# SELECT xmlforest('abc' AS foo, 123 AS bar);
          xmlforest
  ------------------------------
   <foo>abc</foo><bar>123</bar>
  ```

- xmlpi(name target [, content])

  Description: Creates an XML processing instruction. If the content is not empty, the content cannot contain character collations.

  Return type: XML

  Example:

  ```
  gaussdb=# SELECT xmlpi(name php, 'echo "hello world";');
            xmlpi
  -----------------------------
   <?php echo "hello world";?>
  ```

- xmlroot(xml, version text | no value [, standalone yes|no|no value])

  Description: Modifies the attributes of the root node of an XML value. If a version is specified, it replaces the value in the version declaration of the root

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

node. If a standalone property is specified, it replaces the value of standalone declaration in the root node.

Example:

```
gaussdb=# SELECT xmlroot('<?xml version="1.1"?><content>abc</content>',version '1.0', standalone
yes);
                        xmlroot
-------------------------------------------------------------
 <?xml version="1.0" standalone="yes"?><content>abc</content>
(1 row)
```

- xmlexists(text passing [BY REF] xml [BY REF])

  Description: Evaluates an XPath 1.0 expression (the first parameter) with the passed XML value as its context item. If the evaluation result generates an empty set of nodes, the function returns **false**. If any other value is generated, the function returns **true**. If the value of any parameter is null, the function returns **Null**. The non-null value passed as a context item must be an XML document, not a content fragment or any non-XML value.

  Parameter: XML

  Return type: Boolean

  Example:

  ```
  gaussdb=# SELECT xmlexists('//town[text() = ''Toronto'']' PASSING BY REF '<towns><town>Toronto</
  town><town>Ottawa</town></towns>');
   xmlexists
  ------------
   t
  (1 row)
  ```

- xml_is_well_formed(text)

  Description: Checks whether the text is in the correct XML format and returns a Boolean value.

  Parameter: text

  Return type: Boolean

  Example:

  ```
  gaussdb=# SELECT xml_is_well_formed('<>');
   xml_is_well_formed
  --------------------
   f
  (1 row)
  ```

- xml_is_well_formed_document(text)

  Description: Checks whether the text is a well-formed XML document and returns a Boolean value.

  Parameter: text

  Return type: Boolean

  Example:

  ```
  gaussdb=# SELECT xml_is_well_formed_document('<pg:foo xmlns:pg="http://postgresql.org/
  stuff">bar</pg:foo>');
   xml_is_well_formed_document
  -----------------------------
   t
  (1 row)
  ```

- xml_is_well_formed_content(text)

  Description: Checks whether the text is well-formed XML content and returns a Boolean value.

  Parameter: text

  Return type: Boolean

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Example:

```
gaussdb=# SELECT xml_is_well_formed_content('k');
 xml_is_well_formed_content
----------------------------
 t
(1 row)
```

- xpath(xpath, xml [, nsarray])

  Description: Calculates an XPath 1.0 expression, for example, xpath (a text value), on XML data. It returns an array of XML values corresponding to the node set generated by the XPath expression. If the XPath expression returns a scalar value rather than a node set, a single-element array is returned.

  The second parameter must be a well-formed XML document. It must have a single root node element.

  The optional third parameter of the function is an array of namespace mappings. This array should be a two-dimensional text array with the length of the second axis being equal to 2 (that is, it should be an array of arrays, each of which consists of exactly 2 elements). The first element of each array entry is the namespace name (alias), and the second element is the namespace URI. It is not required that aliases provided in this array be the same as those being used in the XML document itself (that is, both in the XML document and in the XPath function context, aliases are local).

  Return type: xml[].

  Example:

  ```
  gaussdb=# SELECT xpath('/my:a/text()', '<my:a xmlns:my="http://example.com">test</
  my:a>',ARRAY[ARRAY['my', 'http://example.com']]);
   xpath
  --------
   {test}
  (1 row)
  ```

- xpath_exists(xpath, xml [, nsarray])

  Description: This function is a special form of the xpath function. It returns a Boolean indicating whether the query is satisfied or not (that is, whether it produces any value other than an empty node set), instead of returning the individual XML values that satisfy the XPath 1.0 expression. This function is equivalent to the standard XMLEXISTS predicate, but it also provides support for a namespace mapping parameter.

  Return type: Boolean

  Example:

  ```
  gaussdb=# SELECT xpath_exists('/my:a/text()', '<my:a xmlns:my="http://example.com">test</
  my:a>',ARRAY[ARRAY['my', 'http://example.com']]);
   xpath_exists
  --------------
   t
  (1 row)
  ```

NOTE

The following XML function examples show the data you need to prepare:

```
gaussdb=# CREATE SCHEMA testxmlschema;
CREATE SCHEMA
gaussdb=# CREATE TABLE testxmlschema.test1 (a int, b text);
CREATE TABLE
gaussdb=# INSERT INTO testxmlschema.test1 VALUES (1, 'one'), (2, 'two'), (-1, null);
INSERT 0 3
gaussdb=# CREATE DATABASE test;
CREATE DATABASE

-- After the example is executed, run the following commands to delete the preceding data:
gaussdb=# DROP DATABASE test;
DROP DATABASE
gaussdb=# DROP TABLE testxmlschema.test1;
DROP TABLE
gaussdb=# DROP SCHEMA testxmlschema;
DROP SCHEMA
```

- query_to_xml(query text, nulls boolean, tableforest boolean, targetns text)

  Description: This function maps the contents of a query to an XML schema document.

  Return type: XML

  Example:

```
gaussdb=# SELECT query_to_xml('SELECT * FROM testxmlschema.test1', false, false, '');
                    query_to_xml
------------------------------------------------------------
 <table xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">+
                                                            +
 <row>                                                      +
   <a>1</a>                                                 +
   <b>one</b>                                               +
 </row>                                                     +
                                                            +
 <row>                                                      +
   <a>2</a>                                                 +
   <b>two</b>                                               +
 </row>                                                     +
                                                            +
 <row>                                                      +
   <a>-1</a>                                                +
 </row>                                                     +
                                                            +
 </table>                                                   +
(1 row)
```

- query_to_xmlschema(query text, nulls boolean, tableforest boolean, targetns text)

  Description: This function maps the contents of a query to an XML document and an XML schema document, and joins the two documents together.

  Return type: XML

  Example:

```
gaussdb=# SELECT query_to_xmlschema('SELECT * FROM testxmlschema.test1', false, false, '');
                                query_to_xmlschema
-----------------------------------------------------------------------------------------------
 <xsd:schema                                                                  +
     xmlns:xsd="http://www.w3.org/2001/XMLSchema">                                    +

```

- table_to_xmlschema(tbl regclass, nulls boolean, tableforest boolean, targetns text)

  Description: This function maps the contents of a relational table to an XML schema document.

  Return type: XML

  Example:

```
gaussdb=# SELECT table_to_xmlschema('testxmlschema.test1', false, false, '');
                                        table_to_xmlschema

(1 row)
```

NOTE

- For XPath-related functions, only XPath() and XPath_exists() are supported. These functions use the XPath language to query XML files and depend on the Libxml2 library, which is provided only in XPath1.0. Therefore, only XPath 1.0 is supported.
- The XQuery, XML extension, and XSLT functions are not supported.

- getclobval(xml)

  Description: Converts an XML type to a CLOB type. This function is valid only when parameters **a_format_version** is set to **10c** and **a_format_dev_version** is set to **s4**.

  Parameter: The input parameter is of the XML type.

  Return type: CLOB

  Example:

```
gaussdb=# CREATE DATABASE gaussdb_ora DBCOMPATIBILITY='ORA';
CREATE DATABASE
gaussdb=# \c gaussdb_ora
gaussdb_ora=# SET a_format_version='10c';
SET
gaussdb_ora=# SET a_format_dev_version='s4';
SET
gaussdb_ora=# declare
 xmldata xml;
 result clob;
begin
 xmldata := '<a>123</a>';
 result := getclobval(xmldata);
 RAISE NOTICE 'result is : %',result;
END;
/
NOTICE:  result is : <a>123</a>
gaussdb_ora=# SELECT getclobval(xmlparse(document '<a>123</a>'));
 getclobval
------------
 <a>123</a>
(1 row)

gaussdb_ora=# \c postgres
gaussdb=# DROP DATABASE gaussdb_ora;
DROP DATABASE
```

- getstringval(xml)

  Description: Converts an XML type to a string. This function is valid only when **a_format_version** is set to **10c** and **a_format_dev_version** is set to **s4**.

  Parameter: The input parameter is of the XML type.

  Return type: VARCHAR2

  Example:

```
gaussdb=# CREATE DATABASE gaussdb_ora DBCOMPATIBILITY='ORA';
CREATE DATABASE
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gaussdb=# \c gaussdb_ora
gaussdb_ora=# SET a_format_version='10c';
SET
gaussdb_ora=# SET a_format_dev_version='s4';
SET
gaussdb_ora=# declare
 xmldata xml;
 result varchar2;
begin
 xmldata := '<a>123<b>456</b></a>';
 result := getstringval(xmldata);
 RAISE NOTICE 'result is : %',result;
END;
/
NOTICE:  result is : <a>123<b>456</b></a>
gaussdb_ora=# select getstringval(xmlparse(document '<a>123<b>456</b></a>'));
    getstringval
----------------------
 <a>123<b>456</b></a>
(1 row)

gaussdb_ora=# \c postgres
gaussdb=# DROP DATABASE gaussdb_ora;
DROP DATABASE
```

- xmlsequence(xml)

  Description: Converts an XML parameter into an array of the XMLTYPE type. Each array element is an XMLTYPE object. The input parameter of this function cannot be null and must be a valid XML document. If the input parameter does not meet the requirements, the function returns a null value or throws an exception. This function can be used to process multiple child nodes in an XML document or split an XML document into multiple fragments.

  Parameter: XML

  Return type: array of the XMLType type.

  Example: If you want to convert this document into an array containing three elements, each of which is a book node, use the following statement:

```
gaussdb=# SELECT xmlsequence(xml('<books><book><title>The Catcher in the Rye</
title><author>J.D. Salinger</author><year>1951</year></book><book><title>1984</
title><author>George Orwell</author><year>1949</year></book><book><title>The Hitchhiker''s
Guide to the Galaxy</title><author>Douglas Adams</author><year>1979</year></book></books>'));
                      xmlsequence
------------------------------------------------------------
 {"<books>                                          +
    <book>                                         +
      <title>The Catcher in the Rye</title>           +
      <author>J.D. Salinger</author>                  +
      <year>1951</year>                               +
    </book>                                        +
    <book>                                         +
      <title>1984</title>                             +
      <author>George Orwell</author>                    +
      <year>1949</year>                               +
    </book>                                        +
    <book>                                         +
      <title>The Hitchhiker's Guide to the Galaxy</title>+
      <author>Douglas Adams</author>                    +
      <year>1979</year>                               +
    </book>                                        +
  </books>"}
(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

If an XML file contains double quotation marks, the result of the xmlsequence function contains escape characters of double quotation marks when you query the result of the xmlsequence function independently. The use of the xmlsequence function is not affected.

- xmlcast(value_expression as datatype)

  Description: Converts the input data of the XML type to the specified target data type after extracting the text content from the document.

  Parameter: **value_expression** indicates the document content of the XML type.

  Return type: specified target data type.

  Example:

```
-- Convert data of the XML type to data of the NUMBER type.
gaussdb=# CREATE DATABASE ora_db DBCOMPATIBILITY = 'ORA';
CREATE DATABASE
gaussdb=# \c ora_db
ora_db=# SELECT XMLCAST(XML('<number_value>123.45</number_value>') AS NUMBER) AS
number_value FROM dual;
 number_value
--------------
       123.45
(1 row)
ora_db=# \c postgres
gaussdb=# DROP DATABASE ora_db;
DROP DATABASE
```

NOTE

- This function can be used only in Oracle-compatible mode.
- The malformed XML files support only the XML files with multiple root nodes returned by the value_expression expression.
- The following target data types cannot be converted: BYTEAWITHOUTORDERWITHEQUALCOL, BYTEAWITHOUTORDERCOL, _BYTEAWITHOUTORDERWITHEQUALCOL, _BYTEAWITHOUTORDERCOL, and some pseudo types.
- This function cannot be used during the upgrade observation period.

1.6.45 Functions of the XMLType Type

NOTE

XMLType functions support a maximum of 256 nested layers in XML files.

- createxml(varchar2[,varchar2,numeric,numeric])

  Description: Statically creates the XMLType type. The input parameters are of the varchar2 type.

  Parameters: The first parameter is the character string to be converted to XMLType (required column). The second parameter is the optional schema URL used to make the input comply with the specified schema (optional column, which is empty by default and does not take effect currently). The third parameter is the flag indicating whether the instance is valid according to the given XML schema (optional column, which is **0** by default and does not take effect currently). The fourth parameter is the flag indicating whether the instance is well-formed (optional column, which is **0** by default and does not take effect currently).

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Return type: XMLType

Example:

```
gaussdb=# SELECT createxml('<a>123</a>');
 createxml
--------------
 <a>123</a>
(1 row)
```

NOTE

- Different from that in the Oracle Database, in PL/SQL, createxml allows input parameters to be empty strings and returns **NULL**.
- For character encoding, only UTF-8, GBK, ZHS16GBK, and LATIN1 to LATIN10 are supported, and the **version** column can only be set to **1.x**.
- The createxml function can be called using the xmltype.createxml() syntax.

  Example:

  ```
  gaussdb=# SELECT xmltype.createxml('<a>123</a>');
   createxml
  ------------
   <a>123</a>
  (1 row)
  ```

- In this chapter, the function whose input parameter is xmltype() can be called in xmltype().func() mode. The XMLType type returned by a function is passed to the next function as the input parameter. This syntax supports multi-layer nesting. (If the input parameter is defined as XMLType by a user, this syntax is not supported.)

  Example:

  ```
  gaussdb=# SELECT xmltype('<a>123<b>456</b></a>').extract('/a/b').getstringval();
   xmltypefunc
  -------------
   <b>456</b>
  (1 row)
  ```

  The actual effect of the preceding example is the same as that of the following function nesting:

  ```
  gaussdb=# SELECT getstringval(extractxml(xmltype('<a>123<b>456</b></a>'),'/a/b'));
   getstringval
  --------------
   <b>456</b>
  (1 row)
  ```

- In a stored procedure, variables of the XMLType type can call functions in a.func() mode. This syntax supports one-layer nesting.

  Example:

  ```
  gaussdb=# declare
          a xmltype;
          b varchar2;
  begin
          a:=xmltype('<a>123<b>456</b></a>');
          b:=a.getstringval();
          RAISE NOTICE 'xmltype_str is : %',b;
  end;
  /
  NOTICE:  xmltype_str is : <a>123<b>456</b></a>
  ```

- createxml(clob [,varchar2,numeric ,numeric])

  Description: Statically creates the XMLType type. The input parameters are of the CLOB type.

  Parameters: The first parameter is the CLOB to be converted to XMLType (required column). The second parameter is the optional schema URL used to make the input comply with the specified schema (optional column, which is empty by default and does not take effect currently). The third parameter is the flag indicating whether the instance is valid according to the given XML

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

schema (optional column, which is **0** by default and does not take effect currently). The fourth parameter is the flag indicating whether the instance is well-formed (optional column, which is **0** by default and does not take effect currently).

Return type: XMLType

Example:

```
gaussdb=# declare
 xmltype_clob clob;
 xmltype_obj xmltype;
 xmltype_str varchar2(1000);
begin
 xmltype_clob := '<a>123</a>';
 xmltype_obj := createxml(xmltype_clob);
 xmltype_str := xmltype_obj.getstringval();
 RAISE NOTICE 'xmltype_str is : %',xmltype_str;
end;
/
NOTICE:  xmltype_str is : <a>123</a>
```

NOTE

The maximum size of the input parameter of the CLOB type is 1 GB minus 1 byte.

- createxml(blob,numeric[,varchar2,numeric,numeric])

  Description: Statically creates the XMLType type. The input parameters are of the BLOB type.

  Parameters: The first parameter is the BLOB to be converted to XMLType (required column). The second parameter is the character set ID of the input XML data (required column). The third parameter is the optional schema URL used to make the input comply with the specified schema (optional column, which is empty by default and does not take effect currently). The fourth parameter is the flag indicating whether the instance is valid according to the given XML schema (optional column, which is **0** by default and does not take effect currently). The fifth parameter is the flag indicating whether the instance is well-formed (optional column, which is **0** by default and does not take effect currently).

  Return type: XMLType

  Example:

```
gaussdb=# declare
 xmltype_blob blob;
 xmltype_obj xmltype;
 xmltype_str varchar2(1000);
begin
 xmltype_blob := xmltype('<a>123</a>').getblobval(7);
 xmltype_obj := createxml(xmltype_blob,7);
 xmltype_str := xmltype_obj.getstringval();
 RAISE NOTICE 'xmltype_str is : %',xmltype_str;
end;
/
NOTICE:  xmltype_str is : <?xml version="1.0" encoding="UTF8"?>
<a>123</a>
```

NOTE

  - The maximum size of input parameters of the BLOB type is 256 MB minus 1 byte.
  - The character set ID ranges from 1 to 43.

- getblobval(xmltype,numeric)

  Description: Converts the XMLType type to the BLOB type. The xmltype().func() method can be called.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameters: The first parameter is of the XMLType type, and the second parameter is the ID of the target character set to be converted.

Return type: BLOB

Example:

```
gaussdb=# SELECT getblobval(xmltype('<asd/>'),7);
                                 getblobval
----------------------------------------------------------------------------------------------------

3C3F786D6C2076657273696F6E3D22312E302220656E636F64696E673D2255544638223F3E0A3C6173
642F3E
(1 row)
```

xmltype ().func ():

```
gaussdb=# SELECT xmltype('<asd/>').getblobVal(7);
                                 xmltypefunc
----------------------------------------------------------------------------------------------------

3C3F786D6C2076657273696F6E3D22312E302220656E636F64696E673D2255544638223F3E0A3C6173
642F3E
(1 row)
```

NOTE

The maximum length of the input parameter of the XMLType type is 256 MB minus 1 byte.

- getclobval(xmltype)

  Description: Converts the XMLType type to the CLOB type. The xmltype().func() method can be called.

  Parameter: The input parameter is of the XMLType type.

  Return type: CLOB

  Example:

  ```
  gaussdb=# SELECT getclobval(xmltype('<a>123</a>'));
   getclobval
  --------------
   <a>123</a>
  (1 row)
  ```

  xmltype ().func ():

  ```
  gaussdb=# SELECT xmltype('<a>123</a>').getclobval();
   xmltypefunc
  --------------
   <a>123</a>
  (1 row)
  ```

- getnumberval(xmltype)

  Description: Converts the XMLType type to the numeric type. The xmltype().func() method can be called.

  Parameter: The input parameter is of the XMLType type.

  Return type: numeric

  Example:

  ```
  gaussdb=# SELECT getnumberval(xmltype('<a>123</a>').extract('/a/text()'));
   getnumberval
  --------------
            123
  (1 row)
  ```

  xmltype ().func ():

  ```
  gaussdb=# SELECT xmltype('<a>123</a>').extract('/a/text()').getnumberval();
   xmltypefunc
  --------------
            123
  (1 row)
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- isfragment(xmltype)

  Description: Returns a result indicating whether the XMLType type is fragment (1) or document (0). The xmltype().func() method can be called.

  Parameter: The input parameter is of the XMLType type.

  Return type: numeric

  Example:

```
gaussdb=# SELECT isfragment(xmltype('<a>123</a>'));
 isfragment
--------------
            0
(1 row)
```

  xmltype ().func ():

```
gaussdb=# SELECT xmltype('<a>123</a>').isfragment();
 xmltypefunc
--------------
            0
(1 row)
```

- xmltype(varchar2[,varchar2,numeric,numeric])

  Description: Creates the XMLType type from the varchar2 type.

  Parameters: The first parameter is the character string to be converted to XMLType (required column). The second parameter is the optional schema URL used to make the input comply with the specified schema (optional column, which is empty by default and does not take effect currently). The third parameter is the flag indicating whether the instance is valid according to the given XML schema (optional column, which is **0** by default and does not take effect currently). The fourth parameter is the flag indicating whether the instance is well-formed (optional column, which is **0** by default and does not take effect currently).

  Return type: XMLType

  Example:

```
gaussdb=# SELECT xmltype('<a>123</a>');
 xmltype
--------------
 <a>123</a>
(1 row)
```

  NOTE

  - Different from that in the Oracle Database, in PL/SQL, XMLType allows input parameters to be empty strings and returns **NULL**.
  - For character encoding, only UTF-8, GBK, ZHS16GBK, and LATIN1 to LATIN10 are supported, and the **version** column can only be set to **1.x**.

- xmltype(clob[,varchar2,numeric,numeric])

  Description: Creates the XMLType type from the CLOB type.

  Parameters: The first parameter is the CLOB to be converted to XMLType (required column). The second parameter is the optional schema URL used to make the input comply with the specified schema (optional column, which is empty by default and does not take effect currently). The third parameter is the flag indicating whether the instance is valid according to the given XML schema (optional column, which is **0** by default and does not take effect currently). The fourth parameter is the flag indicating whether the instance is well-formed (optional column, which is **0** by default and does not take effect currently).

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Return type: XMLType

Example:

```
gaussdb=# declare
 xmltype_clob clob;
 xmltype_obj xmltype;
 xmltype_str varchar2(1000);
begin
 xmltype_clob := '<a>123</a>';
 xmltype_obj := xmltype(xmltype_clob);
 xmltype_str := xmltype_obj.getstringval();
 RAISE NOTICE 'xmltype_str is : %',xmltype_str;
end;
/
NOTICE:  xmltype_str is : <a>123</a>
```

NOTE

The maximum size of the input parameter of the CLOB type is 1 GB minus 1 byte.

- xmltype(blob, numeric [,varchar2,numeric ,numeric])

  Description: Creates the XMLType type from the BLOB type.

  Parameters: The first parameter is the BLOB to be converted to XMLType (required column). The second parameter is the character set ID of the input XML data. The third parameter is the optional schema URL used to make the input comply with the specified schema (optional column, which is empty by default and does not take effect currently). The fourth parameter is the flag indicating whether the instance is valid according to the given XML schema (optional column, which is **0** by default and does not take effect currently). The fifth parameter is the flag indicating whether the instance is well-formed (optional column, which is **0** by default and does not take effect currently).

  Return type: XMLType

  Example:

```
gaussdb=# declare
 xmltype_blob blob;
 xmltype_obj xmltype;
 xmltype_str varchar2(1000);
begin
 xmltype_blob := getblobval(createxml('<a>123</a>'),7);
 xmltype_obj := xmltype(xmltype_blob,7);
 xmltype_str := xmltype_obj.getstringval();
 RAISE NOTICE 'xmltype_str is : %',xmltype_str;
end;
/
NOTICE:  xmltype_str is : <?xml version="1.0" encoding="UTF8"?>
<a>123</a>
```

NOTE

- The maximum size of input parameters of the BLOB type is 256 MB minus 1 byte.
- The character set ID ranges from 1 to 42.

- getstringval(xmltype)

  Description: Converts the XMLType to a string.

  Parameter: XMLType to be converted.

  Return type: varchar2

  The getstringval function can be called in either of the following ways:

  Example 1:

```
gaussdb=# SELECT getstringval('<a>123<b>456</b></a>');
    getstringval
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
----------------------
 <a>123<b>456</b></a>
(1 row)
```

Example 2: The calling mode is compatible with the ORA syntax.

```
gaussdb=# SELECT xmltype('<a>123<b>456</b></a>').getstringval();
    xmltypefunc
----------------------
 <a>123<b>456</b></a>
(1 row)
```

- getrootelement(xmltype)

  Description: Gets the root element of the XMLType type.

  Parameter: XMLType whose root element is to be obtained.

  Return type: varchar2

  The getrootelement function can be called in either of the following ways:

  Example 1:

```
gaussdb=# SELECT getrootelement('<a>123<b>456</b></a>');
 getrootelement
----------------
 a
(1 row)
```

  Example 2: The calling mode is compatible with the ORA syntax.

```
gaussdb=# SELECT xmltype('<a>123<b>456</b></a>').getrootelement();
 xmltypefunc
-------------
 a
(1 row)
```

- getnamespace(xmltype)

  Description: Gets the namespace of the XMLType top-level element.

  Parameter: XMLType whose namespace is to be obtained.

  Return type: varchar2

  The getnamespace function can be called in either of the following ways:

  Example 1:

```
gaussdb=# SELECT getnamespace('<c:a xmlns:c="asd">123<d:b xmlns:d="qwe">456</d:b></c:a>');
 getnamespace
--------------
 asd
(1 row)
```

  Example 2: The calling mode is compatible with the ORA syntax.

```
gaussdb=# SELECT xmltype('<c:a xmlns:c="asd">123<d:b xmlns:d="qwe">456</d:b></
c:a>').getnamespace();
 xmltypefunc
-------------
 asd
(1 row)
```

- existsnode(xmltype, varchar2[, varchar2])

  Description: Determines whether the XML node exists in XMLType based on the XPath expression. If the XML node exists, **1** is returned. Otherwise, **0** is returned.

  Parameters: XMLType to be queried, path of the XPath node to be queried, and namespace of the XPath path (If the input parameter has a namespace, aliases must be defined for both the XPath and namespace, as shown in example 3.)

  Return type: numeric

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

The existsnode function can be called in either of the following ways:

Example 1:

```
gaussdb=# SELECT existsnode('<a>123<b>456</b></a>','/a/b');
 existsnode
------------
          1
(1 row)
```

Example 2: The calling mode is compatible with the ORA syntax.

```
gaussdb=# SELECT xmltype('<a>123<b>456</b></a>').existsnode('/a/b');
 xmltypefunc
-------------
           1
(1 row)
```

Example 3:

```
gaussdb=# SELECT existsnode('<a:b xmlns:a="asd">123<c>456</c></a:b>','/a:b/c','xmlns:a="asd"');
 existsnode
------------
          1
(1 row)
```

Example 4: The calling mode is compatible with the ORA syntax.

```
gaussdb=# SELECT xmltype('<a:b xmlns:a="asd">123<c>456</c></a:b>').existsnode('/a:b/
c','xmlns:a="asd"');
 xmltypefunc
-------------
           1
(1 row)
```

- extractxml(xmltype, varchar2[, varchar2])

  Description: Checks whether an XML node exists in the given XMLType based on the XPath expression. If so, the XMLType containing the node is returned. If not, **NULL** is returned. The return value can be inserted into a table of the XMLType type.

  Parameters: XMLType to be queried, path of the XPath node to be queried, and namespace of the XPath path (If the input parameter has a namespace, aliases must be defined for both the XPath and namespace, as shown in example 3.)

  Return type: XMLType

  The extractxml function can be called in either of the following ways:

  Example 1:

  ```
  gaussdb=# SELECT extractxml('<a>123<b>456</b></a>','/a/b');
   extractxml
  ------------
   <b>456</b>
  (1 row)
  ```

  Example 2: The calling mode is compatible with the ORA syntax.

  ```
  gaussdb=# SELECT xmltype('<a>123<b>456</b></a>').extract('/a/b');
   xmltypefunc
  -------------
   <b>456</b>
  (1 row)

  gaussdb=# SELECT xmltype('<a>123<b>456</b></a>').extractxml('/a/b');
   xmltypefunc
  -------------
   <b>456</b>
  (1 row)
  ```

  Example 3:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gaussdb=# SELECT extractxml('<a:b xmlns:a="asd">123<c>456</c></a:b>','/a:b','xmlns:a="asd"');
              extractxml
----------------------------------------
 <a:b xmlns:a="asd">123<c>456</c></a:b>
(1 row)
```

Example 4: The calling mode is compatible with the ORA syntax.

```
gaussdb=# SELECT xmltype('<a:b xmlns:a="asd">123<c>456</c></a:b>').extract('/a:b','xmlns:a="asd"');
             xmltypefunc
----------------------------------------
 <a:b xmlns:a="asd">123<c>456</c></a:b>
(1 row)

gaussdb=# SELECT xmltype('<a:b xmlns:a="asd">123<c>456</c></a:b>').extractxml('/
a:b','xmlns:a="asd"');
             xmltypefunc
----------------------------------------
 <a:b xmlns:a="asd">123<c>456</c></a:b>
(1 row)
```

- extractvalue(xmltype | xml, varchar2[, varchar2])

  Description: Extracts the value of an XPath expression from an XML file based on the XPath expression (only XPath 1.0 is supported). The result of the XPath expression must be a single node and must be a text node, attribute, or element. If the XPath expression contains an element expression, the element must have a text node as a child node. The function returns the text. If the result is an attribute, the function returns the value of the attribute.

  Parameters: **xmltype | xml**: XML text to be queried; **varchar2**: XPath expression to be queried (XPath node path); **[, varchar2]** (optional): Namespace of the XPath node path. (If the input parameter contains a namespace with an alias, you need to define an alias for both the XPath expression and namespace. If the default namespace is used, you do not need to define an alias, as shown in example 3.)

  Return type: varchar2

  The extractvalue function can be called in two ways: input without namespace and input with namespace.

  Example 1: The input does not contain a namespace.

```
gaussdb=# set a_format_version='10c';
SET
gaussdb=# set a_format_dev_version='s5';
SET
gaussdb=# SELECT EXTRACTVALUE(xmltype('<book><title>Harry Potter</title><author>J.K. Rowling</
author></book>'), '/book/title') AS book_title;
  book_title
--------------
 Harry Potter
(1 row)
```

  Example 2: The input contains a namespace.

```
gaussdb=# SELECT EXTRACTVALUE(xmltype('<ns:book xmlns:ns="http://
www.example.com"><ns:title>Harry Potter</ns:title><ns:author>J.K. Rowling</ns:author></ns:book>'),
'/ns:book/ns:title', 'xmlns:ns="http://www.example.com"') AS book_title;
  book_title
--------------
 Harry Potter
(1 row)
```

  Example 3: The input contains multiple namespaces.

```
gaussdb=# SELECT EXTRACTVALUE(xmltype('<ns:book xmlns:ns="http://www.example.com"
xmlns:ff="http://www.ff.com"><ff:title>Harry Potter</ff:title><ns:author>J.K. Rowling</ns:author></
ns:book>'), '/ns:book/ff:title', 'xmlns:ns="http://www.example.com" xmlns:ff="http://www.ff.com"') AS
book_title;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
 book_title
--------------
 Harry Potter
(1 row)
gaussdb=# SELECT EXTRACTVALUE(xmltype('<store><book xmlns="abc"><root xmlns="abcd">mike</
root><root>mikeab</root></book><root xmlns="abcd">mikedwsa</root></store>'),
'//root', 'xmlns="abc" xmlns:ns2="abc1" xmlns="abcd"') FROM dual;
 extractvalue
--------------
 mikeab
(1 row)
```

NOTE

- If the input contains multiple namespaces, they can be separated by one or more spaces (or newline characters). However, the namespace expression is in the **xmlns:***Name*="*Namespace*" format and the default namespace rule is in the **xmlns='***URL*' format.
- This function is compatible with the xmltype expression function, but the node value returned by the xmltype text must be unique.
- The XPath expression supports only XPath 1.0.
- Currently, the namespace URL in the XML text cannot be a space, and the namespace URL in the namespace expression cannot be a space.
- In the default namespace scenario, the default namespace declared first in the namespace expression is the default namespace of the current XML text.
- This function can be used only in Oracle-compatible mode after setting **a_format_version** to **'10c'** and **a_format_dev_version** to **'s5'**.

- xmlsequence(xmltype)

  Description: Converts an XMLTYPE parameter into an array of the XMLTYPE type. Each array element is an XMLTYPE object. The input parameter of this function cannot be null and must be a valid XML document. If the input parameter does not meet the requirements, the function returns a null value or throws an exception. This function can be used to process multiple child nodes in an XML document or split an XML document into multiple fragments.

  Parameter: The input parameter is of the XMLType type.

  Return type: array of the XMLType type.

  Example 1: If you want to convert this document into an array containing three elements, each of which is a book node, use the following statement:

```
gaussdb=# SELECT xmlsequence(xmltype('<books><book><title>The Catcher in the Rye</
title><author>J.D. Salinger</author><year>1951</year></book><book><title>1984</
title><author>George Orwell</author><year>1949</year></book><book><title>The Hitchhiker''s
Guide to the Galaxy</title><author>Douglas Adams</author><year>1979</year></book></books>'));
                    xmlsequence
------------------------------------------------------------
{"<books>                                    +
   <book>                                   +
     <title>The Catcher in the Rye</title>          +
     <author>J.D. Salinger</author>                 +
     <year>1951</year>                          +
   </book>                                  +
   <book>                                   +
     <title>1984</title>                        +
     <author>George Orwell</author>                 +
     <year>1949</year>                          +
   </book>                                  +
   <book>                                   +
     <title>The Hitchhiker's Guide to the Galaxy</title>+
     <author>Douglas Adams</author>                 +
     <year>1979</year>                          +
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
    </book>                                    +
  </books>"}
(1 row)
```

Example 2: If you want to extract the title and author of each book from this array, use the following statement:

```
gaussdb=# SELECT unnest(xmlsequence(xmltype('<books><book><title>The Catcher in the Rye</
title><author>J.D. Salinger</author><year>1951</year></book><book><title>1984</
title><author>George Orwell</author><year>1949</year></book><book><title>The Hitchhiker''s
Guide to the Galaxy</title><author>Douglas Adams</author><year>1979</year></book></
books>').extract('//title/text()'))) AS title
 , unnest(xmlsequence(xmltype('<books><book><title>The Catcher in the Rye</title><author>J.D.
Salinger</author><year>1951</year></book><book><title>1984</title><author>George Orwell</
author><year>1949</year></book><book><title>The Hitchhiker''s Guide to the Galaxy</
title><author>Douglas Adams</author><year>1979</year></book></books>').extract('//author/
text()'))) AS author;
                          title                           |               author
----------------------------------------------------------+----------------------------------------
 The Catcher in the Rye1984The Hitchhiker's Guide to the Galaxy | J.D. SalingerGeorge OrwellDouglas
Adams
(1 row)
```

Example 3: If you want to convert the array into a JSON string, use the following statement:

```
gaussdb=# SELECT array_to_json(array_agg(row_to_json(t)))
FROM (
 SELECT unnest(xmlsequence(xmltype('<books><book><title>The Catcher in the Rye</
title><author>J.D. Salinger</author><year>1951</year></book><book><title>1984</
title><author>George Orwell</author><year>1949</year></book><book><title>The Hitchhiker''s
Guide to the Galaxy</title><author>Douglas Adams</author><year>1979</year></book></
books>').extract('//title/text()'))) AS title
  , unnest(xmlsequence(xmltype('<books><book><title>The Catcher in the Rye</title><author>J.D.
Salinger</author><year>1951</year></book><book><title>1984</title><author>George Orwell</
author><year>1949</year></book><book><title>The Hitchhiker''s Guide to the Galaxy</
title><author>Douglas Adams</author><year>1979</year></book></books>').extract('//author/
text()'))) AS author
) t;
                                array_to_json
-------------------------------------------------------------------------------------------------------------
 [{"title":"The Catcher in the Rye1984The Hitchhiker's Guide to the Galaxy","author":"J.D.
SalingerGeorge OrwellDouglas Adams"}]
(1 row)
```

NOTE

If an XML file contains double quotation marks, the result of the xmlsequence function contains escape characters of double quotation marks when you query the xmlsequence function independently. The use of the xmlsequence function is not affected.

- xmlcast(value_expression as datatype)

  Description: Converts the input data of XMLType to the specified target data type after extracting the text content from the document.

  Parameter: **value_expression** indicates the document content of XMLType.

  Return type: specified target data type.

  Example:

```
-- Convert the data of XMLType to the data of the VARCHAR2 type.
gaussdb=# CREATE DATABASE ora_db DBCOMPATIBILITY = 'ORA';
CREATE DATABASE
gaussdb=# \c ora_db
ora_db=# SELECT XMLCAST(XMLTYPE('<varchar2_value>Hello, GaussDB!</varchar2_value>') AS
VARCHAR2(50)) AS varchar2_value FROM dual;
 varchar2_value
-----------------
 Hello, GaussDB!
(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
ora_db=# \c postgres
gaussdb=# DROP DATABASE ora_db;
DROP DATABASE
```

NOTE

- This function can be used only in Oracle-compatible mode.
- The malformed XML files support only the XML files with multiple root nodes returned by the value_expression expression.
- The following target data types cannot be converted: BYTEAWITHOUTORDERWITHEQUALCOL, BYTEAWITHOUTORDERCOL, _BYTEAWITHOUTORDERWITHEQUALCOL, _BYTEAWITHOUTORDERCOL, and some pseudo types.
- This function cannot be used during the upgrade observation period.

- xmlquery(sequence_string RETURNING SEQUENCE)

  Description: Generates a sequence from the specified **sequence_string** when XMLTABLE is used in SQL queries (that is, **xmltable_clause** is specified in SELECT queries).

  Parameter: **sequence_string**, which is a string in the format of "a to b", indicates that a sequence from number a to number b is generated.

  Return type: numeric sequence of the XMLType.

  Example:

```
-- Generate a sequence.
gaussdb=# SELECT * FROM XMLTABLE ( '/' PASSING XMLQUERY ( '1 to 10' RETURNING SEQUENCE )
COLUMNS N NUMBER PATH '.' );
 n
----
 1
 2
 3
 4
 5
 6
 7
 8
 9
10
(10 rows)
```

  NOTE

  - This function can be used only in Oracle-compatible mode.
  - Only character strings in the format of "a to b" are supported. In this scenario, this function can be used only in XMLTABLE. For details about XMLTABLE, see **xmltable_clause specified in from_item**.
  - The generated sequence is an int64 number ranging from –9223372036854775808 to 9223372036854775807. The maximum number of generated sequences is 2147483647.
  - This function cannot be used during the upgrade observation period.

- xmlquery(xpath_string PASSING document_expression RETURNING CONTENT)

  Description: Parses the XPath expression to locate and return the specified node set or atomic value in the document content of XMLType.

  The following lists related parameters.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Description
xpath_string	XPath expression used for search. • Only the XPath 1.0 syntax is supported. XPath expressions such as **namespace::*** are not supported. • The XQuery expressions are not supported.
document_expression	Document content of XMLType. Currently, only single-root data is supported. The root node of the XML text is fixed in XMLQUERY as the context space where text search is started.

Return type: query result of the XMLType.

Example:

```
-- Calculate the XPath expression query result of the XMLType.
gaussdb=# CREATE DATABASE ora_db DBCOMPATIBILITY = 'ORA';
CREATE DATABASE
gaussdb=# \c ora_db
ora_db=#
SELECT xmlquery( '/' PASSING XMLTYPE( '<PDRecord> <PDName>Leo</PDName> </PDRecord>')
RETURNING CONTENT);
                xmlquery
-------------------------------------------
 <PDRecord> <PDName>Leo</PDName> </PDRecord>+

(1 row)
ora_db=# \c postgres
gaussdb=# DROP DATABASE ora_db;
DROP DATABASE
```

NOTE

- This function can be used only in Oracle-compatible mode.
- This function cannot be used during the upgrade observation period.

1.6.46 Pivot Table Functions

- tablefunc()

  Description: Extended API for processing table data, including pivot table functions. Only system administrators can install extensions.

  NOTE

  By default, the extension is installed in the public schema. You are advised to install the extension in the user schema by running **create extension tablefunc [schema {user_schema}]**.

- crosstab(source_sql text [, N int])

  Description: Uses the result of **source_sql** as the source data to generate a pivot table.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Return type: SETOF record

Example:

```
gaussdb=# CREATE extension tablefunc;
CREATE EXTENSION
gaussdb=# CREATE TABLE cross_test(group_id text, id int, var text);
CREATE TABLE
gaussdb=# SELECT * FROM cross_test;
 group_id | id | var
----------+----+-----
(0 rows)

gaussdb=# SELECT * FROM crosstab('SELECT group_id, var FROM cross_test order by 1, 2;') AS
c(group_ text, cat1 text, cat2 text, cat3 text);
 group_ | cat1 | cat2 | cat3
--------+------+------+------
(0 rows)
```

NOTE

N is an invalid parameter and has no impact on the result of the function.

- crosstabN(source_sql text)

  Description: Uses the result of **source_sql** as the source data to generate a pivot table with "*N*+1" columns. crosstabN is a group of functions, including crosstab2, crosstab3, and crosstab4.

  Return type: setof tablefunc_crosstab_N. tablefunc_crosstab_N includes tablefunc_crosstab_2, tablefunc_crosstab_3, and tablefunc_crosstab_4.

  Example:

  ```
  -- If N in crossbatN(source_sql text) is set to 2, a pivot table with three columns is generated.
  gaussdb=# SELECT * FROM crosstab2('SELECT group_id, var FROM cross_test ORDER BY 1, 2;');
   row_name | category_1 | category_2
  ----------+------------+------------
  (0 rows)
  ```

- crosstab(source_sql text, category_sql text)

  Description: Uses the result of **source_sql** as the source data to generate a pivot table based on the result category of **category_sql**.

  Return type: SETOF record

  Example:

  ```
  gaussdb=# SELECT * FROM crosstab('SELECT group_id, var FROM cross_test order by 1, 2;', 'SELECT
  generate_series(1, 4)') AS c(group_ text, cat1 text, cat2 text, cat3 text, cat4 text);
   group_ | cat1 | cat2 | cat3 | cat4
  --------+------+------+------+------
  (0 rows)

  gaussdb=# DROP TABLE cross_test;
  gaussdb=# DROP EXTENSION tablefunc;
  ```

1.6.47 Global PL/SQL Cache Functions

- invalidate_plsql_object(), invalidate_plsql_object(schema, objname, objtype)

  Description: Invalidates objects in the global PL/SQL cache. This function is available only when **enable_global_plsqlcache** is set to **on**. The current distributed version does not support this function. The user who calls this function must have the SYSADMIN permission.

  Parameters: This function is an overloaded function. If there is no input parameter, all global cache objects in all databases are invalidated.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

If the parameters **schema**, **objname**, and **objtype** are specified, the specified global cache object in the current database becomes invalid. **schema** indicates the name of the schema to which the object belongs. **objname** indicates the object name. **objtype** indicates the object type. If the object type is a package, the value is **package**. If the object type is a function or stored procedure, the value is **function**.

- gs_plsql_memory_object_detail(db_oid, obj_oid, obj_type)

  Description: Obtains the valid memory usage of packages and functions created during stored procedures. When **enable_global_plsqlcache** is set to **off**, this function displays the memory usage of stored procedures in the current session. Cross-session query is not supported. The current distributed version does not support this function. The user who calls this function must have the SYSADMIN permission.

  Parameters: This function requires the **db_oid**, **obj_oid**, and **obj_type** input parameters. If the input parameters do not match, an empty line is returned. For details about the parameters, see **Table 1-270**. If the **db_oid** and **obj_oid** input parameters are set to **0**, the valid memory usage of all packages and functions in the cache is queried by default.

  Return type: tuple

Table 1-270 gs_plsql_memory_object_detail parameters

Parameter	Type	Description	Value Range
db_oid	uint32	The valid memory usage of the stored procedure in the database whose OID is **db_oid**. The default value **0** indicates all database instances in the current cache.	0 to 2^32 – 1.
obj_oid	uint32	OID of the queried object. The default value **0** indicates all packages and functions in the current cache.	0 to 2^32 – 1.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Type	Description	Value Range
obj_type	text	Type of the queried object. The target object is a package or function.	**all**: queries all object types by default. **pkg**: queries the valid memory usage of packages that meet the conditions. **func**: queries the valid memory usage of functions that meet the conditions. **func_in_pkg**: queries the valid memory usage of functions in the package that meets the conditions.

The gs_plsql_memory_object_detail function displays the valid memory usage that meets the query conditions in the database, as described in **Table 1-271**.

Table 1-271 gs_plsql_memory_object_detail return values

Name	Type	Description
object_oid	uint32	OID of the queried memory object.
context_name	text	Name of a memory object.
item	text	Name of the queried memory object item.
searchpath	text	Schema and other environment variables of the compilation product accessed by the memory object.
guc	uint64	Environment parameter when an object is created, that is, the value of **behavior_compat_flags**.
file	text	File where the memory object is created.
line	uint32	Number of lines in the file where the memory object is created.
size	uint32	Size of a memory object.
db_oid	uint32	OID of the database where the queried memory object is located.

- dump_plsql_compiled_object(object_id, object_type)

  Description: Prints the package and function compilation product information of a stored procedure. If the GUC parameter **enable_global_plsqlcache** is set

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

to **off**, this function can only search for compilation product information in the current session. Cross-session or cross-database query is not supported. The user who calls this function must have the SYSADMIN permission.

Parameters: This function requires the input parameters **object_oid** and **object_type**. If the number or type of the input parameters does not match, an error is reported. **Table 1-272** lists the parameters and their descriptions.

Return type: text.

Table 1-272 dump_plsql_compiled_object parameters

Parameter	Type	Description	Value Range
object_oid	uint32	OID of the queried object.	0 to 2^32 – 1.
object_type	text	Type of the queried object (case-insensitive).	• **"package"**: The object type is package. • **"function"**: The object type is function. (The query effect is equivalent to that of procedure.) • **"procedure"**: The object type is procedure. (The query effect is equivalent to that of function.)

Example:

```
-- When the GUC parameter enable_global_plsqlcache is set to off, create a stored procedure and call dump_plsql_compiled_object to print the compilation product information of the stored procedure.
gaussdb=# \x
Expanded display is on.
gaussdb=# CREATE OR REPLACE PROCEDURE test_proc(a out int, b out int) AS
gaussdb$# BEGIN
gaussdb$# a := 1;
gaussdb$# b := 1;
gaussdb$# END;
gaussdb$# /
CREATE PROCEDURE
gaussdb=# SELECT test_proc();
-[ RECORD 1 ]----
test_proc | (1,1)

gaussdb=# SELECT oid FROM pg_proc WHERE proname = 'test_proc';
-[ RECORD 1 ]
oid | 16388

gaussdb=# SELECT * FROM dump_plsql_compiled_object(16388, 'function');

1.6.48 UUID Functions

- sys_guid()

  Description: Generates and returns a 16-byte universally unique identifier (UUID). The generated UUID contains the IP address of the current node, generation timestamp, and random number.

  Parameter: none

  Return type: raw

  Example:

```
gaussdb=# SET a_format_version='10c';
SET
gaussdb=# SET a_format_dev_version='s5';
SET
gaussdb=# SELECT sys_guid();
             sys_guid
----------------------------------
 9010675E560CB33C1BDAFA163E378F87
 (1 row)
```

- uuid()

  Description: Returns a UUID defined in RFC 4122, ISO/IEF 9834-8:2005, and related standards. The identifier is a string of lowercase hexadecimal digits, which are divided into several groups: a group of 8 digits, three groups of 4 digits, and a group of 12 digits. A total of 32 digits represent 128 bits.

  Parameter: none

  Return type: varchar

  Example:

```
gaussdb=# SELECT uuid();
                 uuid
--------------------------------------
 dd8cbe92-1a25-013c-a514-e435c87e9182
(1 row)
```

- uuid_short()

  Description: Returns a short UUID under certain conditions. This identifier is a 64-bit unsigned integer.

  The returned value is unique when the following conditions are met:

  – The number of service nodes in the current cluster cannot exceed 256.

  – You cannot set the system time of the server host between node restarts.

  – The average number of uuid_short() calls per second between node restarts is less than 16 million.

  Parameter: none

  Return type: uint64

  Example:

```
gaussdb=# SELECT uuid_short();
    uuid_short
--------------------
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
100440026956955649
(1 row)
```

NOTE

For upgrade from a version to GaussDB Kernel 505.0.0, the uuid_short() function cannot be used if the upgrade is not committed.

1.6.49 SQL Statement Concurrency Control Functions

- gs_add_workload_rule(rule_type, rule_name, databases, start_time, end_time, max_workload, option_val)

  Description: Creates an SQL statement concurrency control rule. Users must have the SYSADMIN permission. This function can be executed only on the CN.

  Parameters: For details, see **Table 1-273**.

  Return type: int8

  Table 1-273 gs_add_workload_rule parameters

Parameter	Type	Description	Value Range
rule_type	text	Type of the concurrency control rule, which is case-insensitive.	**"sqlid"**: Concurrency control is based on the unique SQL ID. **"select"**, **"insert"**, **"update"**, **"delete"**, and **"merge"**: Concurrency control is based on the query type and keyword. **"resource"**: CN process–level concurrency control is based on the system resource usage. **"client"**: Concurrency control is based on client information, including IP addresses and application names. **NOTE** The priorities of concurrency control rules are as follows: client > resource > sqlid > select = insert = update = delete = merge
rule_name	name	Name of a concurrency control rule, which is used to search for the concurrency control rule.	Any character string or **NULL**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Type	Description	Value Range
databases	name[]	Array of database names for which the concurrency control rule takes effect. The value is case-sensitive.	List of names of created databases. The value can be **NULL**, indicating that the configuration takes effect in all databases. The relationship between multiple databases is OR. Currently, the database list takes effect only when **rule_type** is set to a query type or client type because a unique SQL ID is bound to a database and belongs to only one database. The database is specified when a client is connected. The concurrency control rules based on resource usage take effect for the entire CN process, that is, all databases.
start_time	timestamptz	Start time of a concurrency control rule.	The value can be **NULL**, indicating that it takes effect from now on. **NOTE** When creating a concurrency control rule, you are advised not to use **sysdate** as the start time and end time of the rule in the SQL statement. The precision of **sysdate** is only accurate to seconds, and the fractional part of the second is rounded off. As a result, the concurrency control rule may not take effect in a very short period of time. You are advised to use **now()** instead of **sysdate**.
end_time	timestamptz	End time of a concurrency control rule.	The value can be **NULL** or **''**, indicating that the rule is always effective.
max_workload	int8	Maximum number of concurrent requests set in a concurrency control rule.	-

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Type	Description	Value Range
option_val	text[]	Supplementary information about the concurrency control rule.	It matches **rule_type**. The matching relationship is as follows: • **"sqlid"**: specifies the unique ID of the SQL statement whose concurrency is to be controlled and slow SQL control rule. The format is '{id=1234, time_limit=100, max_execute_time=500, max_iops=1}', in which **id** indicates the unique SQL ID and is required. You can obtain it from the dbe_perf.statement or pg_stat_activity view. Other options are optional. For details about their meanings, see "Hint-based Optimization > Hints for Setting Slow SQL Control Rules" in *SQL Optimization Guide*. • **"select"**, **"insert"**, **"update"**, **"delete"**, and **"merge"**: keyword sequence for concurrency control, which is case-insensitive and can be **NULL**. The relationship between multiple keywords is AND. • **"resource"**: resource threshold for traffic limiting. The format is '{cpu-80, memory-70}'. Note that the values of cpu and memory are considered as **0** regardless of the current values. That is, this concurrency control rule is triggered regardless of the actual CPU and memory usage. • **"client"**: information about the client whose concurrency is to be controlled, including the IP address and application name. The format is '{ip=*192.168.1.1*, appname=*app1*}'. At least one of **ip** and **appname** must be specified.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Example:

```
gaussdb=#  SELECT gs_add_workload_rule('sqlid', 'rule for one query', '{}', now(), NULL, 20,
'{id=32413214}');
 gs_add_workload_rule
----------------------
                    1
(1 row)

gaussdb=#  CREATE DATABASE db1;
gaussdb=#  CREATE DATABASE db2;
gaussdb=#  SELECT gs_add_workload_rule('select', 'rule for select', '{db1, db2}', NULL, NULL, 100,
'{tb1, tb2}');
 gs_add_workload_rule
----------------------
                    2
(1 row)

gaussdb=#  SELECT gs_add_workload_rule('resource', 'rule for resource', '{}', NULL, NULL, 20,
'{cpu-80}');
 gs_add_workload_rule
----------------------
                    3
(1 row)

gaussdb=# SELECT gs_add_workload_rule('client', 'rule for client', '{}', NULL, NULL, 20,
'{appname=app1}');
 gs_add_workload_rule
----------------------
                    4
(1 row)

gaussdb=#  SELECT gs_delete_workload_rule(rule_id) FROM gs_workload_rule; -- Delete all
concurrency control rules.
 gs_delete_workload_rule
-------------------------
 t
 t
 t
 t
(4 rows)

gaussdb=#  DROP DATABASE db1;
gaussdb=#  DROP DATABASE db2;
```

- gs_update_workload_rule(rule_id, rule_name, databases, start_time, end_time, max_workload, option_val)

  Description: To update an SQL statement concurrency control rule, users need to reset all parameters instead of only some parameters. Users must have the SYSADMIN permission. This function can be executed only on the CN.

  Parameters: For details, see **Table 1-274**.

  Return type: Boolean

  Table 1-274 gs_update_workload_rule parameters

Parameter	Type	Description	Value Range
rule_id	int8	ID of the concurrency control rule to be updated.	-

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Type	Description	Value Range
rule_name	name	Name of a concurrency control rule, which is used to search for the concurrency control rule.	Any character string or **NULL**.
databases	name[]	Array of database names for which the concurrency control rule takes effect. The value is case-sensitive.	List of names of created databases. The value can be **NULL**, indicating that the configuration takes effect in all databases. The relationship between multiple databases is OR. Currently, the database list takes effect only when **rule_type** is set to a query type or the client type because a unique SQL ID is bound to a database and belongs to only one database. The database is specified when a client is connected. The concurrency control rules based on resource usage take effect for the entire CN process, that is, all databases.
start_time	timestamptz	Start time of a concurrency control rule.  Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Example:

```
gaussdb=#  CREATE DATABASE db1;
gaussdb=#  SELECT gs_add_workload_rule('select', 'rule for select', '{db1}', NULL, NULL, 100, '{tb1,
tb2}');
 gs_add_workload_rule
----------------------
                   5
(1 row)

gaussdb=#  SELECT gs_update_workload_rule(5, 'rule for select 2', '{db1}', now(), NULL, 50, '{tb1}');
 gs_update_workload_rule
-------------------------
 t
(1 row)

gaussdb=#  SELECT gs_delete_workload_rule(rule_id) FROM gs_workload_rule; -- Delete all
concurrency control rules.
 gs_delete_workload_rule
-------------------------
 t
(1 row)

gaussdb=#  DROP DATABASE db1;
```

- gs_delete_workload_rule(rule_id)

  Description: Deletes an SQL statement concurrency control rule. Users must have the SYSADMIN permission. This function can be executed only on the CN.

  Parameter: **rule_id** indicates the ID of the concurrency control rule to be deleted. The type is int8.

  Return type: Boolean

  Example:

  ```
  gaussdb=#  SELECT gs_add_workload_rule('sqlid', 'rule for one query', '{}', NULL, NULL, 20,
  '{id=32413214}');
   gs_add_workload_rule
  ----------------------
                     6
  (1 row)

  gaussdb=#  SELECT gs_delete_workload_rule(6);
   gs_delete_workload_rule
  -------------------------
   t
  (1 row)
  ```

- gs_get_workload_rule_stat(rule_id)

  Description: Queries the number of times that SQL statements are blocked by SQL statement concurrency control rules. Users must have the SYSADMIN permission. This function can be executed only on the CN.

  Parameter: **rule_id** indicates the ID of the concurrency control rule to be queried. The type is int8. You can set **rule_id** to **-1**, indicating that all SQL statement concurrency control rules are queried.

  Table 3 Return value types

Name	Type	Description
rule_id	int8	ID of the SQL statement concurrency control rule.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Name	Type	Description
validate_count	int8	Number of SQL statements intercepted by the SQL statement concurrency control rule.

Example:

```
gaussdb=#  SELECT gs_add_workload_rule('sqlid', 'rule for one query', '{}', now(), NULL, 20,
'{id=32413214}');
 gs_add_workload_rule
----------------------
                    7
(1 row)

gaussdb=#  SELECT gs_add_workload_rule('resource', 'rule for resource', '{}', NULL, NULL, 20,
'{cpu-80}');
 gs_add_workload_rule
----------------------
                    8
(1 row)

gaussdb=#  SELECT * FROM gs_get_workload_rule_stat(7);
 rule_id | validate_count
---------+----------------
       7 |              0
(1 row)

gaussdb=#  SELECT * FROM gs_get_workload_rule_stat(-1);
 rule_id | validate_count
---------+----------------
       7 |              0
       8 |              0
(2 rows)

gaussdb=#  SELECT gs_delete_workload_rule(rule_id) FROM gs_workload_rule;
 gs_delete_workload_rule
-------------------------
 t
 t
(2 rows)
```

- gs_refresh_workload_rule_cache()

  Description: Updates the cache of the concurrency control rule to keep it consistent with the data in the concurrency control rule system catalog. It cannot be executed in a transaction. Users must have the SYSADMIN permission.

  Return type: Boolean

  NOTE

  If a concurrency control rule is added, deleted, or modified in a transaction and the transaction is rolled back, the system catalog is restored to the status before the transaction starts, but the concurrency control rule cache still retains the changed content. As a result, the system catalog is inconsistent with the concurrency control rule cache. In this case, you need to call this function to manually synchronize the data.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

1.6.50 SQL Tool Functions

The tools are used to manage SQL patches, including creating, deleting, enabling, and disabling SQL patches. Common users have only the USAGE permission and do not have the CREATE, ALTER, DROP, or COMMENT permission.

For details, see "Performing Optimization with SQL Patches" in *SQL Optimization Guide*.

- DBE_SQL_UTIL.create_hint_sql_patch(patch_name, unique_sql_id, hint_string, description, enabled, query_string, is_sql_hash)

  Description: create_hint_sql_patch creates hint SQL patches on the connected CN and returns whether the execution is successful.

  Parameters: For details, see **Table 1-275**.

  Return type: Boolean

  Only the initial user, SYSADMIN, OPRADMIN, and MONADMIN have the permission to call it.

  NOTE

  - SQL patches are not shared among CNs and need to be created on each CN.
  - If load balancing is enabled or a CN needs to be specified, you are advised to use the **DBE_SQL_UTIL.create_remote_hint_sql_patch** API to create a CN.
  - When **query_string** is passed to an EXECUTE statement, the system obtains the PREPARE statement corresponding to the current session and creates an SQL patch. If there is no corresponding prepared statement, the operation is invalid.

  Table 1-275 DBE_SQL_UTIL.create_hint_sql_patch input parameters and return values

Parameter	Type	Description
patch_name	IN name	Patch name.
unique_sql_id	IN bigint	Globally unique ID.
hint_string	IN text	Hint text.
description	IN text	Patch description. The default value is **NULL**.
enabled	IN bool	Specifies whether the patch takes effect. The default value is **true**.
query_string	IN text	Original SQL statement corresponding to the SQL hash. The default value is **NULL**.
is_sql_hash	IN bool	Specifies whether the patch is created based on the SQL hash value. The default value is **false**.
result	OUT bool	Specifies whether the execution is successful.

- DBE_SQL_UTIL.create_hint_sql_patch(patch_name, unique_sql_id, parent_unique_sql_id, hint_string, description, enabled)

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description: create_hint_sql_patch creates hint SQL patches on the connected CN and returns whether the execution is successful. This function is an overloaded function of the original function. It allows you to restrict the scope of the hint patch by specifying the value of **parent_unique_sql_id**.

Parameters: For details, see **Table 1-276**.

Return type: Boolean

Only the initial user, SYSADMIN, OPRADMIN, and MONADMIN have the permission to call it.

Table 1-276 Input parameters and return values of the overloaded function of DBE_SQL_UTIL.create_hint_sql_patch

Parameter	Type	Description
patch_name	IN name	Patch name.
unique_sql_id	IN bigint	Globally unique ID.
parent_unique_sql_id	IN bigint	Globally unique ID of the outer SQL statement, indicating the scope where the SQL patch takes effect. • **0**: The SQL patch takes effect only in the outer SQL statement. • Non-zero value: The SQL patch takes effect only in a specific stored procedure.
hint_string	IN text	Hint text.
description	IN text	Patch description. The default value is **NULL**.
enabled	IN bool	Specifies whether the patch takes effect. The default value is **true**.
result	OUT bool	Specifies whether the execution is successful.

- DBE_SQL_UTIL.create_remote_hint_sql_patch(node_name, patch_name, unique_sql_id, hint_string, description, enabled, query_string, is_sql_hash)

  Description: create_remote_hint_sql_patch creates hint SQL patches on a specified CN and returns whether the execution is successful.

  Parameters: For details, see **Table 1-277**.

  Return type: Boolean

  Only the initial user, SYSADMIN, OPRADMIN, and MONADMIN have the permission to call it.

  NOTE

  When **query_string** is passed to an EXECUTE statement, the system obtains the PREPARE statement corresponding to the current session and creates an SQL patch. If there is no corresponding prepared statement, the operation is invalid.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 1-277 DBE_SQL_UTIL.create_remote_hint_sql_patch input parameters and return values

Parameter	Type	Description
node_name	IN text	Name of the target node. If the value is **ALL**, SQL patches are created for all CNs.
patch_name	IN name	Patch name.
unique_sql_id	IN bigint	Globally unique ID.
hint_string	IN text	Hint text.
description	IN text	Patch description. The default value is **NULL**.
enabled	IN bool	Specifies whether the patch takes effect. The default value is **true**.
query_string	IN text	Original SQL statement corresponding to the SQL hash. The default value is **NULL**.
is_sql_hash	IN bool	Specifies whether the patch is created based on the SQL hash value. The default value is **false**.
result	OUT bool	Specifies whether the execution is successful.

- DBE_SQL_UTIL.create_abort_sql_patch(patch_name, unique_sql_id, description, enabled, query_string, is_sql_hash)

  Description: create_abort_sql_patch creates abort SQL patches on the connected CN and returns whether the execution is successful.

  Parameters: For details, see **Table 1-278**.

  Return type: Boolean

  Only the initial user, SYSADMIN, OPRADMIN, and MONADMIN have the permission to call it.

  NOTE

  - SQL patches are not shared among CNs and need to be created on each CN.
  - If load balancing is enabled or a CN needs to be specified, you are advised to use the **DBE_SQL_UTIL.create_remote_abort_sql_patch** API to create a CN.
  - When **query_string** is passed to an EXECUTE statement, the system obtains the PREPARE statement corresponding to the current session and creates an SQL patch. If there is no corresponding prepared statement, the operation is invalid.

Table 1-278 DBE_SQL_UTIL.create_abort_sql_patch input parameters and return values

Parameter	Type	Description
patch_name	IN name	Patch name.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Type	Description
unique_sql_id	IN bigint	Globally unique ID.
description	IN text	Patch description. The default value is **NULL**.
enabled	IN bool	Specifies whether the patch takes effect. The default value is **true**.
query_string	IN text	Original SQL statement corresponding to the SQL hash. The default value is **NULL**.
is_sql_hash	IN bool	Specifies whether the patch is created based on the SQL hash value. The default value is **false**.
result	OUT bool	Specifies whether the execution is successful.

- DBE_SQL_UTIL.create_abort_sql_patch(patch_name, unique_sql_id, parent_unique_sql_id, description, enabled)

  Description: create_abort_sql_patch creates abort SQL patches on the connected CN and returns whether the execution is successful. This function is an overloaded function of the original function. It allows you to restrict the scope of the abort SQL patch by specifying the value of **parent_unique_sql_id**.

  Parameters: For details, see **Table 1-279**.

  Return type: Boolean

  Only the initial user, SYSADMIN, OPRADMIN, and MONADMIN have the permission to call it.

  Table 1-279 Input parameters and return values of the overloaded function of DBE_SQL_UTIL.create_abort_sql_patch

Parameter	Type	Description
patch_name	IN name	Patch name.
unique_sql_id	IN bigint	Globally unique ID.
parent_unique_sql_id	IN bigint	Globally unique ID of the outer SQL statement, indicating the scope where the SQL patch takes effect. • **0**: The SQL patch takes effect only in the outer SQL statement. • Non-zero value: The SQL patch takes effect only in a specific stored procedure.
description	IN text	Patch description. The default value is **NULL**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Type	Description
enabled	IN bool	Specifies whether the patch takes effect. The default value is **true**.
result	OUT bool	Specifies whether the execution is successful.

- DBE_SQL_UTIL.create_remote_abort_sql_patch(node_name, patch_name, unique_sql_id, description, enabled, query_string, is_sql_hash)

  Description: create_remote_abort_sql_patch creates abort SQL patches on the connected CN and returns whether the execution is successful.

  Parameters: For details, see **Table 1-280**.

  Return type: Boolean

  Only the initial user, SYSADMIN, OPRADMIN, and MONADMIN have the permission to call it.

  NOTE

  When **query_string** is passed to an EXECUTE statement, the system obtains the PREPARE statement corresponding to the current session and creates an SQL patch. If there is no corresponding prepared statement, the operation is invalid.

  Table 1-280 DBE_SQL_UTIL.create_remote_abort_sql_patch input parameters and return values

Parameter	Type	Description
node_name	IN text	Name of the target node. If the value is **ALL**, SQL patches are created for all CNs.
patch_name	IN name	Patch name.
unique_sql_id	IN bigint	Globally unique ID.
description	IN text	Patch description. The default value is **NULL**.
enabled	IN bool	Specifies whether the patch takes effect. The default value is **true**.
query_string	IN text	Original SQL statement corresponding to the SQL hash. The default value is **NULL**.
is_sql_hash	IN bool	Specifies whether the patch is created based on the SQL hash value. The default value is **false**.
result	OUT bool	Specifies whether the execution is successful.

- DBE_SQL_UTIL.drop_sql_patch(patch_name)

  Description: drop_sql_patch deletes SQL patches on the connected CN and returns whether the execution is successful.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameters: For details, see **Table 1-281**.

Return type: Boolean

Only the initial user, SYSADMIN, OPRADMIN, and MONADMIN have the permission to call it.

NOTE

- SQL patches are not shared among CNs and need to be executed on each CN.
- If load balancing is enabled or a CN needs to be specified, you are advised to use the **DBE_SQL_UTIL.drop_remote_sql_patch** API to delete a CN.

Table 1-281 DBE_SQL_UTIL.drop_sql_patch input parameters and return values

Parameter	Type	Description
patch_name	IN name	Patch name.
result	OUT bool	Specifies whether the execution is successful.

- DBE_SQL_UTIL.drop_remote_sql_patch(node_name, patch_name)

  Description: drop_remote_sql_patch deletes SQL patches from a specified CN and returns whether the execution is successful.

  Parameters: For details, see **Table 1-282**.

  Return type: Boolean

  Only the initial user, SYSADMIN, OPRADMIN, and MONADMIN have the permission to call it.

  Table 1-282 DBE_SQL_UTIL.drop_remote_sql_patch input parameters and return values

Parameter	Type	Description
node_name	IN text	Target node name.
patch_name	IN name	Patch name.
result	OUT bool	Specifies whether the execution is successful.

- DBE_SQL_UTIL.enable_sql_patch(patch_name)

  Description: enable_sql_patch enables SQL patches on the connected CN and returns whether the execution is successful.

  Parameters: For details, see **Table 1-283**.

  Return type: Boolean

  Only the initial user, SYSADMIN, OPRADMIN, and MONADMIN have the permission to call it.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- SQL patches are not shared among CNs and need to be executed on each CN.
- If load balancing is enabled or a CN needs to be specified, you are advised to use the **DBE_SQL_UTIL.enable_remote_sql_patch** API to enable SQL patches.

Table 1-283 DBE_SQL_UTIL.enable_sql_patch input parameters and return values

Parameter	Type	Description
patch_name	IN name	Patch name.
result	OUT bool	Specifies whether the execution is successful.

- DBE_SQL_UTIL.enable_remote_sql_patch(node_name, patch_name)

  Description: enable_remote_sql_patch enables SQL patches on a specified CN and returns whether the execution is successful.

  Parameters: For details, see **Table 1-284**.

  Return type: Boolean

  Only the initial user, SYSADMIN, OPRADMIN, and MONADMIN have the permission to call it.

  Table 1-284 DBE_SQL_UTIL.enable_remote_sql_patch input parameters and return values

Parameter	Type	Description
node_name	IN text	Target node name.
patch_name	IN name	Patch name.
result	OUT bool	Specifies whether the execution is successful.

- DBE_SQL_UTIL.disable_sql_patch(patch_name)

  Description: disable_sql_patch disables SQL patches on the connected CN and returns whether the execution is successful.

  Parameters: For details, see **Table 1-285**.

  Return type: Boolean

  Only the initial user, SYSADMIN, OPRADMIN, and MONADMIN have the permission to call it.

  NOTE

  - SQL patches are not shared among CNs and need to be executed on each CN.
  - If load balancing is enabled or a CN needs to be specified, you are advised to use the **DBE_SQL_UTIL.disable_remote_sql_patch** API to disable SQL patches.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 1-285 DBE_SQL_UTIL.disable_sql_patch input parameters and return values

Parameter	Type	Description
patch_name	IN name	Patch name.
result	OUT bool	Specifies whether the execution is successful.

- DBE_SQL_UTIL.disable_remote_sql_patch(node_name, patch_name)

  Description: disable_remote_sql_patch disables SQL patches on a specified CN and returns whether the execution is successful.

  Parameters: For details, see **Table 1-286**.

  Return type: Boolean

  Only the initial user, SYSADMIN, OPRADMIN, and MONADMIN have the permission to call it.

  Table 1-286 DBE_SQL_UTIL.disable_remote_sql_patch input parameters and return values

Parameter	Type	Description
node_name	IN text	Target node name.
patch_name	IN name	Patch name.
result	OUT bool	Specifies whether the execution is successful.

- DBE_SQL_UTIL.show_sql_patch(patch_name, unique_sql_id, status, enabled, abort)

  Description: show_sql_patch displays the SQL patch corresponding to a specified patch name and returns the running result.

  Parameters: For details, see **Table 1-287**.

  Return type: record.

  Only the initial user, SYSADMIN, OPRADMIN, and MONADMIN have the permission to call it.

  Table 1-287 DBE_SQL_UTIL.show_sql_patch input parameters and return values

Parameter	Type	Description
patch_name	IN name	Patch name.
unique_sql_id	OUT bigint	Globally unique ID.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Type	Description
status	OUT char	Specifies whether the patch is created based on a unique SQL ID or SQL hash value. • **'d'**: unique SQL ID. • **'h'**: SQL hash value.
enabled	OUT bool	Specifies whether the patch takes effect.
abort	OUT bool	Specifies whether the patch is an abort hint.
hint_str	OUT text	Hint text.

- DBE_SQL_UTIL.sqlpatch_query_hash(query_string, need_validate)

  Description: sqlpatch_query_hash obtains the SQL hash value of a specified SQL statement.

  Parameters: For details, see **Table 1-288**.

  Return type: int8

  Only the initial user, SYSADMIN, OPRADMIN, and MONADMIN have the permission to call it.

  NOTE

  When the **cursor_sharing** parameter is set to **force**, the SQL hash value is calculated based on the parameterized SQL text. In this case, you need to pass the parameterized SQL text and set **need_validate** to **false** to obtain the SQL hash value after automatic parameterization. For example: SELECT DBE_SQL_UTIL.sqlpatch_query_hash('SELECT * FROM t WHERE a =?', false);

  Table 1-288 DBE_SQL_UTIL.sqlpatch_query_hash input parameters and return values

Parameter	Type	Description
query_string	IN text	SQL text.
need_validate	IN boolean	Specifies whether to perform syntax check.
result	OUT bigint	Hash value corresponding to the SQL text.

- DBE_SQL_UTIL.gs_show_plan_by_hash(sql_hash, plan_hash)

  Description: In this version, if the gs_show_plan_by_hash function is used, a message is returned indicating that the function is not supported in the current form.

  Parameters: For details, see **Table 1-289**.

  Return type: text.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 1-289 DBE_SQL_UTIL.gs_show_plan_by_hash input parameters and return values

Parameter	Type	Description
sql_hash	IN bigint	Hash value of SQL text.
plan_hash	IN bigint	Hash value of the SQL plan.
gs_show_plan_by_hash	OUT text	The returned result is a message indicating that the function is not supported in the current form.

1.6.51 Multi-Tenant Database Functions

The following functions are used for the multi-tenant database feature and are not supported in the distributed system: The following functions are not supported in the distributed system:

- gs_reload_pdb_conf(name pdbname)
- gs_resplan_cgroup_info()
- gs_resplan_stat_info(view_type integer)
- gs_get_pdb_tablespace_location(pdb_id oid in, tablespace_oid oid in)
- get_instr_db_rt_percentile()
- get_instr_user_login_info()
- gs_resplan_shared_memory_info()

The following functions are used in internal system views and are not recommended in the distributed system:

- get_mtd_user()
- get_instr_sql_count_info()

1.6.52 Global Temporary Table Functions

- pg_get_gtt_relstats(relOid)

  Description: Displays basic information about a global temporary table specified by the current session. The query result of the distributed global temporary table on a CN is not meaningful, and the query result on a DN is empty. Therefore, it is not recommended in distributed mode.

  Parameter: OID of the global temporary table

  Return type: record

  Example:

```
gaussdb=# SELECT * FROM pg_get_gtt_relstats(24576);
 relfilenode | relpages | reltuples | relallvisible | relfrozenxid | relminmxid
-------------+----------+-----------+---------------+--------------+------------
       24576 |        0 |         0 |             0 |        53969 |          0
(1 row)
```

- pg_get_gtt_statistics(relOid, attnum, ''::text)

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description: Displays statistics about a single column in a global temporary table specified by the current session. Before using this function, perform ANALYZE on the table.

Parameter: OID and the **attnum** attribute of the global temporary table

Return type: record

Example:

```
gaussdb=# SELECT * FROM  pg_get_gtt_statistics(24576, 1,''::text);
 starelid | starelkind | staattnum | stainherit | stanullfrac | stawidth | stadistinct | stakind1 | stakind2 |
stakind3 | stakind4 | stakind5 | staop1 | staop2 | staop3 | staop4 | staop5 | stanumbers1 | stanumbers2
| stanumbers3 | stanumbers
4 | stanumbers5
|
                                  stavalues1

          | stavalues2 | stavalues3 | stavalues4 | stavalues5 | stadndistinct | staextinfo

----------+------------+-----------+------------+-------------+----------+-------------+----------+----------
+----------+----------+----------+--------+--------+--------+--------+--------+-------------+-------------
+-------------+-----------
--+-------------
+-----------------------------------------------------------------------------------------------------------------
-------------------------------------------------------------------------------------------------------
-----------------------------------------------------------------------------------------------------------------
-----------------------------------------+------------+------------+------------+------------+---------------

25,430,435,440,445,450,455,460,465,470,475,480,485,490,495,500} |             |             |             |
|             1 |
(1 row)
```

- pg_list_gtt_relfrozenxids()

  Description: Displays the frozen XID of each session. If the value of **pid** is **0**, the earliest frozen XID of all sessions is displayed. In distributed mode, gs_global_list_gtt_relfrozenxids() is recommended.

  Parameter: none

  Return type: record

  Example:

  ```
  gaussdb=# SELECT * FROM pg_list_gtt_relfrozenxids();
        pid        | relfrozenxid
  -----------------+--------------
   139988750038784 |        53969
                 0 |        53969
  (2 rows)
  ```

- pg_gtt_attached_pid(relOid)

  Description: Displays PIDs and session IDs of all threads that are using the specified global temporary table. If the thread pool is enabled and the session that is using the global temporary table is in the detach state, the PID is **0** and **sessionid** indicates the session ID. In distributed mode, gs_gtt_attached_pid(relOid) is recommended.

  Parameter: OID of the global temporary table

  Return type: record

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Example:

```
gaussdb=# SELECT * FROM pg_gtt_attached_pid(24576);
 relid |       pid       | sessionid
-------+-----------------+-----------
 24576 | 139988750038784 |         1
(1 row)
```

- gs_gtt_attached_pid(relOid)

  Description: Displays the IDs of all sessions that are using a specified distributed global temporary table. This is executed on DNs, but not supported on CNs.

  Parameter: OID of the global temporary table

  Return type: record

  Example:

  ```
  gaussdb=# SELECT * FROM gs_gtt_attached_pid(16384);
   relid |       pid       |   cn_name    | cn_timeline | cn_sequence | cn_session_id
  -------+-----------------+--------------+-------------+-------------+---------------
   16384 | 140648560719616 | coordinator1 |           2 |           1 |             1
  (1 row)
  ```

- gs_global_list_gtt_relfrozenxids()

  Description: Displays XIDs of frozen transactions on each DN. This is executed on CNs. PID is **–1** when the current session is not joined with a global temporary table. This cannot be executed on DNs.

  Parameter: none

  Return type: record

  Example:

  ```
  gaussdb=# SELECT * FROM gs_global_list_gtt_relfrozenxids();
   node_name |       pid       | relfrozenxid
  -----------+-----------------+--------------
   datanode1 | 140648560719616 |        53959
   datanode1 |               0 |        53959
   datanode2 | 140539996403456 |        53959
   datanode2 |               0 |        53959
  (4 rows)
  ```

- gs_local_gtt_clean_session(clean_type, clean_obj, clean_table)

  Description: Clears global temporary tables joined with global sessions on CNs. This is executed on DNs, but not supported on CNs.

  The following lists related parameters.

Name	Type	Description
clean_type	Enumeration	• **0**: All session mappings whose timeline is earlier than the current timeline are cleared. • **1**: The session mapping joined with a specified CN session is cleared. • **2**: Data of a specified table in all sessions is cleared. (This is for internal use only and cannot be executed by users.)

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

clean_obj	string	Constructor: • coorname_timeline_seq_sess (when **clean_type** is set to **1**) • coorname_timeline (when **clean_type** is set to **0**) • schema name (when **clean_type** is set to **2**)
clean_table	string	If **clean_type** is set to **2**, the value is a table name. If **clean_type** is set to other values, the value is null.

Return type: void

Example:

Use gs_local_get_cn_session_key on a CN to obtain the latest **cn_session_key**.

```
gaussdb=# SELECT * FROM gs_local_get_cn_session_key();
   cn_name    | cn_timeline | cn_sequence | cn_session_id
--------------+-------------+-------------+---------------
 coordinator1 |           2 |           1 |             1
(1 row)
```

Use gs_local_dump_gtt_sess_map to obtain the residual **cn_session_key** on a DN that needs to be manually cleared.

```
gaussdb=# SELECT * FROM gs_local_dump_gtt_sess_map();
   cn_name    | cn_timeline | cn_sequence | cn_session_id | uniq_sess_id | refcnt | database_id |
current_database_id
--------------+-------------+-------------+---------------+--------------+--------+-------------
+----------------------
 coordinator1 |           1 |           1 |             1 |            1 |      0 |       13771 |              13771
(1 row)
```

Clear the residual **cn_session_key** that meets the following conditions:

– timeline < CN timeline

– refcnt = 0

```
gaussdb=# SELECT * FROM gs_local_gtt_clean_session(0, 'coordinator1_2', '');
 gs_local_gtt_clean_session
----------------------------

(1 row)
```

- gs_global_dist_gtt_clean_remain_sessions()

  Description: Clears all residual session information in a global temporary table. This is executed on CNs, but not supported on DNs.

  Parameter: none

  Return type: void

  Example:

  ```
  gaussdb=# SELECT * FROM gs_global_dist_gtt_clean_remain_sessions();
   gs_global_dist_gtt_clean_remain_sessions
  ------------------------------------------

  (1 row)
  ```

- gs_local_get_cn_session_key()

  Description: Displays the session key of the current session. This is executed on CNs. This cannot be executed on DNs.

  Parameter: none

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Return type: record

Example:

```
gaussdb=# SELECT * FROM gs_local_get_cn_session_key();
   cn_name    | cn_timeline | cn_sequence | cn_session_id
--------------+-------------+-------------+---------------
 coordinator1 |           2 |           1 |             1
(1 row)
```

- gs_local_dump_gtt_sess_map()

  Description: Displays the unique session ID **cn_session_key** of a distributed global temporary table stored on a DN. The ID consists of the following columns: **cn_name**, **cn_timeline**, **cn_sequence**, **cn_session_id**, **uniq_sess_id**, **refcnt**, **database_id**, and **current_database_id**. This is executed on DNs, but not supported on CNs.

  Parameter: none

  Return type: record

  Example:

```
gaussdb=# SELECT * FROM gs_local_dump_gtt_sess_map();
   cn_name    | cn_timeline | cn_sequence | cn_session_id | uniq_sess_id | refcnt | database_id |
current_database_id
--------------+-------------+-------------+---------------+--------------+--------+-------------
+---------------------
 coordinator1 |           1 |           1 |             1 |            1 |      0 |       13771 |             13771
(1 row)
```

- gs_global_gtt_clean_data(schema_name, table_name)

  Description: Clears the data files of the specified global temporary table in all sessions. This is for internal use only and cannot be executed by users.

  The following lists related parameters.

Name	Type	Description
schema_name	string	Name of a schema to be cleared.
table_name	string	Name of a table to be cleared.

  Return type: void

  Example:

```
gaussdb=# SELECT gs_global_gtt_clean_data('public', 'gtt');
ERROR:  The input parameter is invalid.
CONTEXT:  referenced column: gs_local_gtt_clean_session
SQL statement "EXECUTE DIRECT ON DATANODES 'SELECT pg_catalog.gs_local_gtt_clean_session(2,
''public'', ''gtt'')'"
PL/pgSQL function gs_global_gtt_clean_data(text,text) line 6 at EXECUTE statement
referenced column: gs_global_gtt_clean_data
```

- gs_gtt_local_clean_cn_remain_session_keys()

  Description: Clears residual data in global temporary tables on other DNs when a DN is faulty. This is executed on CNs, not supported on DNs.

  Return type: void

```
gaussdb=# select * from gs_gtt_local_clean_cn_remain_session_keys();
 gs_gtt_local_clean_cn_remain_session_keys
-------------------------------------------
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
(1 row)
```

1.6.53 Database Link Functions

- close_database_link(dblink_name name)

  Description: Closes a database link in the current session based on the database link name. A database link with active transactions cannot be closed.

  Table 1-290 close_database_link(dblink_name name) parameters

Name	Type	Input/ Output	Description
dblink_name	name	Input	Name of a database link.
close_database_link	boolean	Output	Result of closing the DATABASE LINK (**t**: success; **f**: failure).

  Example:

```
gaussdb=# SELECT close_database_link('xxx');
 close_database_link
---------------------
 t
(1 row)

gaussdb=# BEGIN;
BEGIN
gaussdb=# SELECT * FROM t1@dblink;
c1 | c2 | c3
----+----+----
1 | |
(1 row)
gaussdb=# INSERT INTO t1@dblink VALUES (2,0,0);
INSERT 0 1
gaussdb=# SELECT * FROM t1@dblink;
c1 | c2 | c3
----+----+----
1 | |
2 | 0 | 0
(2 rows)
gaussdb=# SELECT close_database_link('dblink');
ERROR: Dblink dblink is in use.
CONTEXT: referenced column: close_database_link
gaussdb=# END;
ROLLBACK
```

- gs_ora_diag(dblink_name name DEFAULT NULL::name)

  Description: Obtains information about the database link that connects to the Oracle Database. The following information is obtained based on the database link name: gs_ora_fdw version, GaussDB version, Oracle Database's client version, and Oracle Database's server version. If the parameter is set to **NULL** and the query user is an administrator, information such as ORACLE_HOME, ORACLE_SID, TNS_ADMIN, TWO_TASK, and LDAP_ADMIN is also returned.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 1-291 gs_ora_diag(dblink_name name DEFAULT NULL::name) parameters

Name	Type	Input/ Output	Description
dblink_name	name	Input	Name of a database link.
gs_ora_diag	text	Output	Diag information of a database link.

Example:

```
-- Administrator.
gaussdb=# SELECT gs_ora_diag('xxx');
                                  gs_ora_diag
-------------------------------------------------------------------------------
 gs_ora_fdw 1.0.0, GaussDB 9.2.4, Oracle client 19.24.0.0.0, Oracle server 19.0.0.0.0
(1 row)
gaussdb=# SELECT gs_ora_diag();

gs_ora_diag
-------------------------------------------------------------------------------------------------------------------------------
-----------------------------
 gs_ora_fdw 1.0.0, GaussDB 9.2.4, Oracle client 19.24.0.0.0, ORACLE_HOME=/xxx/instantclient_19_24,
TNS_ADMIN=/xxx/instantclient_19_24/network/admin
(1 row)

-- Common user.
gaussdb=# SELECT gs_ora_diag('xxx');
                                  gs_ora_diag
-------------------------------------------------------------------------------
 gs_ora_fdw 1.0.0, GaussDB 9.2.4, Oracle client 19.24.0.0.0, Oracle server 19.0.0.0.0
(1 row)

gaussdb=# SELECT gs_ora_diag();
                      gs_ora_diag
-------------------------------------------------------------
 gs_ora_fdw 1.0.0, GaussDB 9.2.4, Oracle client 19.24.0.0.0
(1 row)
```

- gs_ora_get_handle_alloc(dblink_oid oid)

  Description: Obtains the size (in bytes) of the memory used by the database link through the OCI based on the OID of the database link.

Table 1-292 gs_ora_get_handle_alloc(dblink_oid oid) parameters

Name	Type	Input/ Output	Description
dblink_oid	oid	Input	OID of the specified database link.
gs_ora_get_handle_alloc	numeric	Output	Size of the memory used by the database link through the OCI, in bytes.

Example:

```
gaussdb=# SELECT gs_ora_get_handle_alloc(xxx);
 gs_ora_get_handle_alloc
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
--------------------------
                151224
(1 row)
```

- gs_ora_get_handle_alloc_all()

  Description: Obtains the environment handle of each node and calculates the total memory size used by all database links through OCI, in bytes.

  Table 1-293 gs_ora_get_handle_alloc_all() parameters

Name	Type	Input/ Output	Description
gs_ora_get_handle_alloc_all	numeric	Output	Total size of memory used by all database links through OCI, in bytes.

  Example:

```
gaussdb=# SELECT gs_ora_get_handle_alloc_all();
 gs_ora_get_handle_alloc_all
-----------------------------
                      429000
(1 row)
```

- gs_ora_connection_status(dblink_oid oid)

  Description: Obtains the connection status of a database link in the current session based on the OID of the database link.

  Table 1-294 gs_ora_connection_status(dblink_oid oid) parameters

Name	Type	Input/ Output	Description
dblink_oid	oid	Input	OID of the specified database link.
gs_ora_connection_status	text	Output	Connection status of the database link in the current session (**CONNECTED**: connected; **LOST**: disconnected).

  Example:

```
gaussdb=# SELECT gs_ora_connection_status(xxx);
 gs_ora_connection_status
--------------------------
 CONNECTED
(1 row)
```

- gs_ora_fdw_handler()

  Description: The processing function of the foreign data wrapper oracle_fdw, which returns an fdw_handler structure containing a pointer to the callback function.

  Input parameter: none

  Return type: fdw_handler

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- gs_ora_fdw_validator(option text[], dblink_oid oid)

  Description: The check function of the foreign data wrapper gs_ora_fdw, which inspects the common options provided for gs_ora_fdw. If the option or option value is invalid or missing, an error is reported.

  Table 1-295 gs_ora_fdw_validator(option text[], dblink_oid oid) parameters

Name	Type	Input/ Output	Description
dblink_oid	oid	Input	OID of the specified database link.
option	text[]	Input	Option of a database link.

  Return type: void

- is_dblink_in_use(dblink_oid oid)

  Description: Obtains whether a database link is used based on the OID of the database link.

  Table 1-296 is_dblink_in_use(dblink_oid oid) parameters

Name	Type	Input/Output	Description
dblink_oid	oid	Input	OID of the specified database link.
is_dblink_in_use	bool	Output	Usage status of the database link.

  Example:

```
gaussdb=# SELECT is_dblink_in_use(xxx);
 is_dblink_in_use
------------------------------
 f
(1 row)
```

- dblink_has_updatasent (dblink_oid oid)

  Description: Checks whether a DML statement has been sent through the database link corresponding to an OID in the current transaction but has not been committed yet.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 1-297 dblink_has_updatasent (dblink_oid oid) parameters

Name	Type	Input/Output	Description
dblink_oid	oid	Input	OID of the specified database link.
dblink_has_updatasent	bool	Output	Specifies whether the database link has sent DML statements and is in the uncommitted phase.

Example:

```
gaussdb=# SELECT dblink_has_updatasent(xxx);
 dblink_has_updatasent
-----------------------------
 f
(1 row)
```

- is_dblink_in_transaction(dblink_oid oid)

  Description: Obtains whether a database link is in a transaction based on the OID of the database link.

  Table 1-298 is_dblink_in_transaction(dblink_oid oid) parameters

Name	Type	Input/Output	Description
dblink_oid	oid	Input	OID of the specified database link.
is_dblink_in_transaction	bool	Output	Specifies whether the database link is in a transaction.

  Example:

```
gaussdb=# SELECT is_dblink_in_transaction(xxx);
 is_dblink_in_transaction
-----------------------------
 f
(1 row)
```

1.6.54 GSMonitor System Resource Statistics Functions

- gs_get_cpustat(start_time timestamptz, end_time timestamptz)

  Description: Queries CPU resource information within a period of time. To call this function, you must have the MONADMIN or SYSADMIN permission.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

The following describes the parameters.

Parameter	Description	Value Range
start_time	Required. Start time of the query.	Timestamptz type.
end_time	Required. End time of the query.	Timestamptz type.

Return type: SETOF record

The following describes the return columns.

Column	Type	Description
collection_time	timestamptz	Collection time.
cpu_name	text	Name.
%total	float8	Total: CPU usage (user + kernel).
%user	float8	User mode: CPU usage (user space).
%system	float8	System mode: CPU usage (kernel space).
%idle	float8	CPU usage in the idle state.
%iowait	float8	Percentage of CPU resources waiting for I/Os.
lavg_1	float8	One-minute load (unit: count).
lavg_5	float8	Five-minute load (unit: count).
lavg_15	float8	15-minute load (unit: count).

- gs_get_procstat(start_time timestamptz, end_time timestamptz, sort_order text[, display_type text])

  Description: Queries process information within a period of time. To call this function, you must have the MONADMIN or SYSADMIN permission.

  The following describes the parameters.

Parameter	Description	Value Range
start_time	Required. Start time of the query.	Timestamptz type.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Description	Value Range
end_time	Required. End time of the query.	Timestamptz type.
sort_order	Required. Sorting rules.	Text type. The value can be **'IO_R'**, **'IO_W'**, **'CPU'** or **'MEM'** (case-insensitive). • **'IO_R'**: sorts data by I/O read rate in descending order. • **'IO_W'**: sorts data by I/O write rate in descending order. • **'CPU'**: sorts data by CPU usage in descending order. • **'MEM'**: sorts data by used memory size in descending order.
display_type	Optional. Display mode.	Text type. Currently, only **'pretty'** (case-insensitive) is supported, indicating that the affiliation relationship is displayed.

Return type: SETOF record

The following describes the return columns.

Column	Type	Description
collection_time	timestamptz	Collection time.
pid	int8	Process name.
tid	int8	Thread name.
state	text	Status.
ppid	int8	Parent process ID.
priority	int8	Priority (dynamic).
nice	int8	Priority (static).
num_threads	int8	Number of threads.
utime	float8	User-mode runtime (unit: jiffies).
stime	float8	Kernel-mode runtime (unit: jiffies).
ssize	int8	Size of the shared memory (unit: byte).
vsize	int8	Virtual memory size of a process (unit: byte).
io_r	float8	I/O read rate (unit: operations/s).

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Column	Type	Description
io_w	float8	I/O write rate (unit: operations/s).
io	float8	Total I/O rate (unit: operations/s).
rss	int8	Size of the resident set used by a process (unit: page).
%cpu_usage	float8	CPU usage.
comm	text	Command name of a process.

- gs_get_iostat(start_time timestamptz, end_time timestamptz[, display_type text])

  Description: Queries I/O resource information within a period of time. To call this function, you must have the MONADMIN or SYSADMIN permission.

  The following describes the parameters.

Parameter	Description	Value Range
start_time	Required. Start time of the query.	Timestamptz type.
end_time	Required. End time of the query.	Timestamptz type.
display_type	Optional. Display mode.	Text type. Currently, only **'pretty'** (case-insensitive) is supported, indicating that the affiliation relationship is displayed.

  Return type: SETOF record

  The following describes the return columns.

Column	Type	Description
collection_time	timestamptz	Collection time.
devname	text	Device name.
rkB/s	float8	I/O read rate (unit: KB/s).
wkB/s	float8	I/O write rate (unit: KB/s).
r/s	float8	I/O read operations per second (unit: operations/s).

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Column	Type	Description
w/s	float8	I/O write operations per second (unit: operations/s).
rawait	float8	Average wait time of read operations (unit: ms).
wawait	float8	Average wait time of write operations (unit: ms).
svctm	float8	Average I/O service time (unit: ms).
avgqu-sz	int8	Number of current I/O waiting queues.
%util	float8	Disk usage: Percentage of time a device spends on I/O operations.

- gs_get_memstat(start_time timestamptz, end_time timestamptz)

  Description: Queries memory resource information within a period of time. To call this function, you must have the MONADMIN or SYSADMIN permission.

  The following describes the parameters.

Parameter	Description	Value Range
start_time	Required. Start time of the query.	Timestamptz type.
end_time	Required. End time of the query.	Timestamptz type.

  Return type: SETOF record

  The following describes the return columns.

Column	Type	Description
collection_time	timestamptz	Collection time.
mem_total	int8	Total memory size (unit: byte).
mem_used	int8	Size of the used memory (unit: byte).
mem_free	int8	Size of the idle memory (unit: byte).
mem_usage	float8	Memory usage.
buffer	int8	Size of the buffer memory (unit: byte).

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Column	Type	Description
cache	int8	Size of the cache stack memory (unit: byte).
mem_available	int8	Size of the memory available for starting a new application (unit: byte).
active	int8	Size of actively cached memory (unit: byte).
inactive	int8	Size of inactively cached memory (unit: byte).
swap_total	int8	Total size of the swap space (unit: byte).
swap_free	int8	Size of the idle swap space (unit: byte).

- gs_get_netstat(start_time timestamptz, end_time timestamptz)

  Description: Queries network resource information within a period of time. To call this function, you must have the MONADMIN or SYSADMIN permission.

  The following describes the parameters.

Parameter	Description	Value Range
start_time	Required. Start time of the query.	Timestamptz type.
end_time	Required. End time of the query.	Timestamptz type.

  Return type: SETOF record

  The following describes the return columns.

Column	Type	Description
collection_time	timestamptz	Collection time.
interface	text	API name.
tag	text	Tag.
rkb/s	float8	Rx rate (kbit/s).
tkb/s	float8	Tx rate (kbit/s).
kb/s	float8	Total rate (kbit/s).
rp/s	float8	Rx packet rate (packets/s).
tp/s	float8	Tx packet rate (packets/s).
p/s	float8	Total data packet rate (packets/s).

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Column	Type	Description
rerr/s	float8	Rx packet error rate (packets/s).
terr/s	float8	Tx packet error rate (packets/s).
%err	float8	Total error rate.

1.6.55 Sorting Calculation Functions

The sorting calculation functions provide basic calculation capabilities for sorting scenarios.

Table 1-299 Sorting calculation functions

Description	Functions
Sorts a given column by time sequence and returns the first value.	**first(value_array anyarray, time_array timearray)**
Sorts a given column by time sequence and returns the last value.	**last(value_array anyarray, time_array timearray)**
Sorts a given column by sequence and returns a percentile value.	**percentile_cont(percentile float)**
Sorts a given column in ascending order and returns a percentile value.	**value_of_percentile(column float, percentile float, compression float)**
Sorts a given column in ascending order and calculates the percentile based on the percentile value.	**percentile_of_value(column float, percentilevalue float, compression float)**
Sorts a given column and returns the minimum *K* tuples.	**top_k(array real[],k int)**
Sorts a given column and returns the maximum *K* tuples.	**bottom_k(array real[],k int)**

first(value_array anyarray, time_array timearray)

Description: Sorts a given column by time sequence and returns the first value.

Parameters: See **Table 1-300**.

Return type: anyelement

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 1-300 Parameters of the first function

Parameter	Type	Description
value_array	anyarray	Array of the queried column.
time_array	timearray	Array of time values.

NOTE

- The function uses the INTEGER type as an array index internally and does not support data volumes exceeding the value range supported by the INTEGER type.

Example:

```
gaussdb=# SELECT
gaussdb-#     first(array_agg(value), array_agg(time))
gaussdb-# FROM
gaussdb-#     (VALUES ('2019-07-12 00:00:00'::timestamptz,'c','a'),
gaussdb(#             ('2019-07-12 00:01:00'::timestamptz,'b','a'),
gaussdb(#             ('2019-07-12 00:02:01'::timestamptz,'a','b')) v(time, value, tag)
gaussdb-# GROUP BY tag;
 first
-------
 c
 a
(2 rows)
```

last(value_array anyarray, time_array timearray)

Description: Sorts a given column by time sequence and returns the last value.

Parameters: See **Table 1-301**.

Return type: anyelement

Table 1-301 Parameters of the last function

Parameter	Type	Description
value_array	anyarray	Array of the queried column.
time_array	timearray	Array of time values.

NOTE

- The function uses the INTEGER type as an array index internally and does not support data volumes exceeding the value range supported by the INTEGER type.

Example:

```
gaussdb=# SELECT
gaussdb-#     last(array_agg(value), array_agg(time))
gaussdb-# FROM
gaussdb-#     (VALUES ('2019-07-12 00:00:00'::timestamptz,'c','a'),
gaussdb(#             ('2019-07-12 00:01:00'::timestamptz,'b','a'),
gaussdb(#             ('2019-07-12 00:02:01'::timestamptz,'a','b')) v(time, value, tag)
gaussdb-# GROUP BY tag;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
 last
------
 b
 a
(2 rows)
```

percentile_cont(percentile float)

Description: Sorts a given column by sequence and returns a percentile value. It must be used together with WITHIN GROUP (ORDER BY) to specify the column to be calculated. The column must be of the numeric or interval type.

Parameters: See **Table 1-302**.

Return type: float or interval, depending on whether the value of the column specified by WITHIN GROUP (ORDER BY) is of the numeric or interval type.

Table 1-302 Parameters of the percentile_cont function

Parameter	Type	Description
percentile	float	Specifies the percentile. The value range is [0,1]. The precision value is of the floating-point type. For example, 0.95 means the 95th percentile value.

NOTE

- **percentile** is a decimal in the range [0,1]. The value is of the floating-point type and does not support the percent sign (%), for example, 95%.

Example:

```
gaussdb=# SELECT
gaussdb-#      percentile_cont(0.5) WITHIN GROUP (ORDER BY value)
gaussdb-# FROM
gaussdb-#     (VALUES ('2019-07-12 00:00:01'::timestamptz,'red',1),
gaussdb(#     ('2019-07-12 00:00:01'::timestamptz,'blue',2)) v(time,color,value);
 percentile_cont
-----------------
             1.5
(1 row)
```

value_of_percentile(column float, percentile float, compression float)

Description: Sorts a given column in ascending order and returns a percentile value.

Parameters: See **Table 1-303**.

Return type: float

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 1-303 Parameters of the value_of_percentile function

Parameter	Type	Description
column	float	Specifies the column name.
percentile	float	Specifies the percentile. The value range is [0,1]. For example, **0.95** means the 95th percentile value.
compression	float	Specifies the compression coefficient. The value range is [0,500]. The default value is **300**. If you want to use the default value, set this parameter to **0**. Otherwise, set this parameter based on the value range. For example, if the value is **300**, the total data volume is compressed based on 300. The larger the data volume, the larger the memory usage.

NOTE

- You need to specify the column name.
- **percentile** is a decimal in the range [0,1]. The value is of the floating-point type and does not support the percent sign (%), for example, 95%.
- **compression** is a number in the range [0,500]. The default value is **300**. If the input value is greater than 500 or less than 0, the default value is used.
- You are advised to use this function in scenarios that meet the following conditions. Under the premise of satisfying these conditions, the accuracy exceeds 75% in most cases.

  (1) The overall data follows a normal distribution.

  (2) The data is evenly distributed on each DN, following a normal distribution as well.

  (3) The data volume must be greater than 10,000.

  (4) It is only suitable for extreme data, specifically data with percentiles less than 1% and greater than 99%.

Example:

```
gaussdb=#DROP TABLE IF EXISTS partition_scan2;
gaussdb=#CREATE TABLE partition_scan2(a int);
gaussdb=#insert into partition_scan2 values(generate_series(1,100,1));
gaussdb=# SELECT value_of_percentile(a,0.8,0) from partition_scan2;
 value_of_percentile
---------------------
                80.5
(1 row)
```

percentile_of_value(column float, percentilevalue float, compression float)

Description: Sorts a given column in ascending order and returns a percentile.

Parameters: See **Table 1-304**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Return type: float

Table 1-304 Parameters of the percentile_of_value function

Parameter	Type	Description
column	float	Specifies the column name.
percentilevalue	float	Specifies the percentile value. The percentile is calculated based on the percentile value. The precision is a floating-point value.
compression	float	Specifies the compression coefficient. The value range is [0,500]. The precision is a floating-point value. The default value is **300**. If the default value is used, set this parameter to **0**. Otherwise, set this parameter based on the value range. For example, if the value is **300**, the total data volume is compressed based on 300. The larger the data volume, the larger the memory usage.

NOTE

- You need to specify the column name.
- **percentilevalue**: any value. The precision is a floating-point value.
- **compression** is a number in the range [0,500]. The default value is **300**. If the input value is greater than 500 or less than 0, the default value is used.
- You are advised to use this function in scenarios that meet the following conditions. Under the premise of satisfying these conditions, the accuracy exceeds 75% in most cases.

  (1) The overall data follows a normal distribution.

  (2) The data is evenly distributed on each DN, following a normal distribution as well.

  (3) The data volume must be greater than 10,000.

  (4) It is only suitable for extreme data, specifically data with percentiles less than 1% and greater than 99%.

Example:

```
gaussdb=#DROP TABLE IF EXISTS partition_scan2;
gaussdb=#CREATE TABLE partition_scan2(a int);
gaussdb=#insert into partition_scan2 values(generate_series(1,100,1));
gaussdb=# SELECT percentile_of_value(a,80,0) from partition_scan2;
 percentile_of_value
---------------------
               .795
(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

top_k(array real[],k int)

Description: Sorts a given column in ascending order and returns the minimum *K* tuples.

Parameters: See **Table 1-305**.

Return type: real[]

Table 1-305 Parameters of the top_k function

Parameter	Type	Description
array	real[]	Array to be input.
k	int	Specifies the minimum *K* tuples.

NOTE

- *K* should be a non-negative number. If it is negative, a null value is returned.
- *K* should be less than the array size. If it is greater than the current array length, an error is reported.
- array_sort is used for internal sorting, supporting only one-dimensional arrays. For details, see **Array Functions and Operators**.
- The **array** parameter cannot be empty. If it is empty, the function returns null directly.
- Arrays with data volumes exceeding the value range of the int type cannot be used.

Example:

```
gaussdb=# SELECT
gaussdb-#       top_k(array_agg(v), 0.5),v2
gaussdb-# FROM
gaussdb-#       (VALUES (1,'a'),(2,'a'),(3,'a'),(4,'a'),(5,'a'),(6,'a')) v(v,v2)
gaussdb-# GROUP BY v2;
 top_k | v2
-------+----
 {1}   | a
(1 row)
```

bottom_k(array real[],k int)

Description: Sorts a given column in ascending order and returns the maximum *K* tuples.

Parameters: See **Table 1-306**.

Return type: real[]

Table 1-306 Parameters of the bottom_k function

Parameter	Type	Description
k	int	Specifies the maximum *K* tuples.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- *K* should be a non-negative number. If it is negative, a null value is returned.
- *K* should be less than the array size. If it is greater than the current array length, an error is reported.
- array_sort is used for internal sorting, supporting only one-dimensional arrays. For details, see **Array Functions and Operators**.
- The **array** parameter cannot be empty. If it is empty, the function returns null directly.
- Arrays with data volumes exceeding the value range of the int type cannot be used.

Example:

```
gaussdb=# SELECT
gaussdb-#       bottom_k(array_agg(v), 0.5),v2
gaussdb-# FROM
gaussdb-#       (VALUES (1,'a'),(2,'a'),(3,'a'),(4,'a'),(5,'a'),(6,'a')) v(v,v2)
gaussdb-# GROUP BY v2;
 bottom_k | v2
----------+----
 {6}      | a
(1 row)
```

1.6.56 Autonomous Transaction Feature Functions

- gs_autonomous_transaction_detail()

  Description: Displays the autonomous transaction sessions to which the user belongs and the relationships of parent transactions and sub-transactions on the current CN. Users with the MONADMIN or SYSADMIN permission can view all autonomous transaction sessions and the relationships of parent transactions and sub-transactions on the current CN. Calling on DNs is not allowed.

  Parameter: none.

  Return type: SETOF record

  Return values: Refer to **Table 1-307**.

  Table 1-307 Return values of the gs_autonomous_transaction_detail function

Name	Type	Description
autonomous_transaction_session_id	bigint	Session ID of an autonomous transaction.
autonomous_transaction_thread_id	bigint	Thread ID of an autonomous transaction.
parent_autonomous_transaction_session_id	bigint	Parent session ID of an autonomous transaction.

  Example:

```
gaussdb=#
CREATE OR REPLACE PROCEDURE proc_test()  AS
DECLARE
PRAGMA AUTONOMOUS_TRANSACTION;
BEGIN
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
pg_sleep(60);
END;
/
gaussdb=# CALL proc_test();

-- A new session needs to be created for query. --
gaussdb=# SELECT * FROM pg_catalog.gs_autonomous_transaction_detail() AS
gaussdb-#     (autonomous_transaction_session_id bigint, autonomous_transaction_thread_id bigint,
parent_autonomous_transaction_session_id bigint);
 autonomous_transaction_session_id | autonomous_transaction_thread_id |
parent_autonomous_transaction_session_id
-----------------------------------+-----------------------------------+-----------------------------------------
                  139778155607808 |                  139778155607808 |                      139777830549248
(1 row)
```

- gs_get_autonomous_transaction_count()

  Description: Queries the autonomous transaction count on the current CN. Calling on DNs is not allowed.

  Parameter: none.

  Return type: integer

  Return values: See **Table 1-308**.

  Table 1-308 Return values of the gs_get_autonomous_transaction_count function

Name	Type	Description
gs_get_autonomous_transaction_count	integer	Current autonomous transaction count.

  Example:

  ```
  gaussdb=#
  CREATE OR REPLACE PROCEDURE proc_test()  AS
  DECLARE
  PRAGMA AUTONOMOUS_TRANSACTION;
  BEGIN
  pg_sleep(60);
  END;
  /
  gaussdb=# CALL proc_test();

  -- A new session needs to be created for query. --
  gaussdb=# SELECT gs_get_autonomous_transaction_count();
   gs_get_autonomous_transaction_count
  -------------------------------------
                                     1
  (1 row)
  ```

- gs_reset_autonomous_transaction_count()

  Description: Restores the autonomous transaction count on the current CN to the correct value and returns the correct autonomous transaction count. To call this function, you must have the MONADMIN or SYSADMIN permission. Calling on DNs is not allowed.

  Parameter: none.

  Return type: integer

  Return values: See **Table 1-309**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 1-309 Return values of the gs_reset_autonomous_transaction_count function

Name	Type	Description
gs_reset_autonomous_transaction_count	integer	Correct autonomous transaction count after restoration.

Example:

```
gaussdb=# SELECT gs_reset_autonomous_transaction_count();
 gs_reset_autonomous_transaction_count
---------------------------------------
                                     0
(1 row)

gaussdb=#
CREATE OR REPLACE PROCEDURE proc_test()  AS
DECLARE
PRAGMA AUTONOMOUS_TRANSACTION;
BEGIN
pg_sleep(60);
END;
/
gaussdb=# CALL proc_test();

-- A new session needs to be created for query. --
gaussdb=# SELECT gs_reset_autonomous_transaction_count();
 gs_reset_autonomous_transaction_count
---------------------------------------
                                     1
(1 row)
```

- gs_global_autonomous_transaction_detail()

  Description: Displays the autonomous transaction sessions to which the user belongs and the relationships of parent transactions and sub-transactions on each CN. Users with the MONADMIN or SYSADMIN permission can view all autonomous transaction sessions and the relationships of parent transactions and sub-transactions on each CN. Calling on DNs is not allowed.

  Parameter: none.

  Return type: SETOF record

  Return values: Refer to **Table 1-310**.

  NOTE

  When the GUC parameter **enable_nonsysadmin_execute_direct** is set to **off**, this function can be called only by users with the MONADMIN or SYSADMIN permission.

Table 1-310 Return values of the gs_global_autonomous_transaction_detail function

Name	Type	Description
node_name	text	CN name.
autonomous_transaction_session_id	bigint	Session ID of an autonomous transaction.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Name	Type	Description
autonomous_transaction_thread_id	bigint	Thread ID of an autonomous transaction.
parent_autonomous_transaction_session_id	bigint	Parent session ID of an autonomous transaction.

Example:

```
gaussdb=#
CREATE OR REPLACE PROCEDURE proc_test()  AS
DECLARE
PRAGMA AUTONOMOUS_TRANSACTION;
BEGIN
pg_sleep(60);
END;
/
gaussdb=# CALL proc_test();

-- A new session needs to be created for query. --
gaussdb=# SELECT * FROM gs_global_autonomous_transaction_detail();
  node_name   | autonomous_transaction_session_id | autonomous_transaction_thread_id |
parent_autonomous_transaction_session_id
--------------+-----------------------------------+----------------------------------
+-----------------------------------------
 coordinator1 |                140477506516736 |                140477506516736 |
140477683726080
(1 row)
```

- gs_global_get_autonomous_transaction_count()

  Description: Queries the current autonomous transaction count on each CN. Calling on DNs is not allowed.

  Parameter: none.

  Return type: SETOF record

  Return values: Refer to **Table 1-311**.

  NOTE

  When the GUC parameter **enable_nonsysadmin_execute_direct** is set to **off**, this function can be called only by users with the MONADMIN or SYSADMIN permission.

Table 1-311 Return values of the gs_global_get_autonomous_transaction_count function

Name	Type	Description
node_name	text	CN name.
gs_get_autonomous_transaction_count	integer	Current autonomous transaction count.

Example:

```
gaussdb=#
CREATE OR REPLACE PROCEDURE proc_test()  AS
```

```
DECLARE
PRAGMA AUTONOMOUS_TRANSACTION;
BEGIN
pg_sleep(60);
END;
/
gaussdb=# CALL proc_test();

-- A new session needs to be created for query. --
gaussdb=# SELECT * FROM gs_global_get_autonomous_transaction_count();
  node_name   | gs_get_autonomous_transaction_count
--------------+-------------------------------------
 coordinator1 |                                   1
(1 row)
```

- gs_global_reset_autonomous_transaction_count([exec_node_name text])

  Description: Restores the autonomous transaction count on each CN to the correct value and returns the correct autonomous transaction count on each CN after the restoration. If the **exec_node_name** parameter is specified, the autonomous transaction count on the specified node is restored to the correct value. To call this function, you must have the MONADMIN or SYSADMIN permission. Calling on DNs is not allowed.

  Parameter: **exec_node_name**, specifying the name of a CN. This parameter is optional.

  Return type: SETOF record

  Return values: Refer to **Table 1-312**.

  Table 1-312 Return values of the gs_global_reset_autonomous_transaction_count function

Name	Type	Description
node_name	text	CN name.
gs_reset_autonomous_transaction_count	integer	Correct autonomous transaction count after restoration.

  Example:

```
gaussdb=#
CREATE OR REPLACE PROCEDURE proc_test()  AS
DECLARE
PRAGMA AUTONOMOUS_TRANSACTION;
BEGIN
pg_sleep(60);
END;
/
gaussdb=# CALL proc_test();

-- A new session needs to be created for query. --
gaussdb=# SELECT * FROM gs_global_reset_autonomous_transaction_count();
  node_name   | gs_reset_autonomous_transaction_count
--------------+---------------------------------------
 coordinator1 |                                     1
(1 row)

gaussdb=# SELECT * FROM gs_global_reset_autonomous_transaction_count('coordinator1');
  node_name   | gs_reset_autonomous_transaction_count
--------------+---------------------------------------
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
 coordinator1 |                      1
(1 row)
```

1.6.57 DSL Rule Management Functions

- dsl_add_rule()

  Description: Adds a DSL rule. Only the initial user can call this function.

  Parameters: See **Table 1-313**.

  Return type: text.

  Return value: DSL rule name.

  Table 1-313 Parameters of the dsl_add_rule function

Input Parameter	Type	Required	Description
rulename	name	Y	Name of a DSL rule. The name must start with a letter and can have up to 64 bytes, containing a mix of letters, digits, underscores (_), and hyphens (-). Chinese characters and other special characters are not allowed.
ruletext	text	Y	Text content of the DSL rule.
priority	integer	Y	Priority of the DSL rule. The priority must be globally unique and fall within the range of 1 to 9999. A larger value indicates a lower priority.
enabled	boolean	N	Specifies whether to enable the rule. The default value is **FALSE**.
ruledesc	name	N	Description of the DSL rule. The description can be left blank or contain a maximum of 64 bytes.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Input Parameter	Type	Required	Description
ruledbcompatibility	text	N	Compatibility mode of the database that houses the DSL rule. Values: **ORA**, **MYSQL**, **TD**, **PG**, **M**, and **ANY**. They represent O-, MY-, TD-, PG-, M-, and all-compatible modes, respectively. You can set multiple compatibility modes, separated by vertical bars (|). For example, **A|PG** indicates compatibility with both Oracle Database and PG. Default value: **ANY**.
planmode	text	N	Plan type supported by the rule. The options are **Stream**, **RemoteQuery**, and **ANY**, with **ANY** being the default value.

Example:

```
gaussdb=# SELECT dsl_add_rule(
'compute_const',
'Filter<> {args: $expr: *}
=>
Filter<> {args: (expr_compute $expr)
}',
3,
true);
 dsl_add_rule
---------------
 compute_const
(1 row)
```

- dsl_del_rule()

  Description: Deletes a DSL rule. Only the initial user and system administrators can call this function.

  Parameters: See **Table 1-314**.

  Return type: integer.

  Return value: number of DSL rules deleted.

  Table 1-314 Parameters of the dsl_del_rule function

Input Parameter	Type	Description
rulename	name	Name of a DSL rule.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Example:

```
gaussdb=# SELECT dsl_del_rule('compute_const');
 dsl_del_rule
--------------
            1
(1 row)
```

- dsl_set_rule()

  Description: Modifies a DSL rule (or rather, a specific attribute of the rule). The content of the rule cannot be modified. Only the initial user and system administrators can call this function.

  Parameters: See **Table 1-315**.

  Return type: integer.

  Return value: number of DSL rules modified.

  Table 1-315 Parameters of the dsl_set_rule function

Input Parameter	Type	Description
rulename	name	Name of a DSL rule.
attrname	text	Attribute name. The supported attributes are **enabled**, **priority**, **ruledesc**, **dbcompatibility**, and **planmode**.
attrval	text	Attribute value.

  Example:

```
gaussdb=# SELECT dsl_set_rule('compute_const', 'priority', '8');
 dsl_set_rule
--------------
            1
(1 row)

gaussdb=# \x
Expanded display is on.

gaussdb=# SELECT * FROM GS_DSL_REWRITERULE WHERE rulename = 'compute_const';
-[ RECORD 1 ]---+-----------------------------------
enabled         | t
externalrule    | t
costbased       | f
priority        | 8  -- The priority of the rule is set to 8.
dbcompatibility | 31
planmode        | 3
createtime      | xxxx-xx-xx 16:43:18.766029+08
lastupdatetime  | Parameters of the xxdsl_reload_rule function xx-xx-xx 16:44:55.785637+08
rulename        | compute_const
rulehash        | 8576886722021209825
ruletext        | Filter<> {args: $expr: *}
                | =>
                | Filter<> {args: (expr_compute $expr)
                | }
ruledesc        |
```

- dsl_reload_rule()

  Description: Loads a DSL rule to the cache.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameters: See **Table 1-316**.

Return type: text.

Return value: **success** or **failed**.

Table 1-316 Parameters of the dsl_reload_rule function

Input Parameter	Type	Description
nodename	text	Node name. An empty value indicates that the rule will be executed on all nodes.

Example:

```
gaussdb=# SELECT dsl_reload_rule();
 dsl_reload_rule
-----------------
 success
(1 row)
```

1.6.58 ROWID Functions

- rowid_tableoid(rowid)

  Description: Obtains the **table_oid** value of the ROWID type.

  Parameter: rowid

  Return type: OID

  Examples:

  ```
  gaussdb=# CREATE DATABASE ora_test DBCOMPATIBILITY='ORA';
  CREATE DATABASE
  gaussdb=# \c ora_test
  Non-SSL connection (SSL connection is recommended when requiring high-security)
  You are now connected to database "ora" as user "$user".
  ora_test=# SELECT rowid_tableoid('AAAAAAAAAP//BBBBBAAAAAAAAAAAC');
   rowid_tableoid
  ----------------
      1090785344
  (1 row)
  ora_test=# \c postgres
  Non-SSL connection (SSL connection is recommended when requiring high-security)
  You are now connected to database "postgres" as user "$user".
  gaussdb=# DROP DATABASE ora_test;
  DROP DATABASE
  ```

- rowid_sequence(rowid)

  Description: Obtains the **row_no** value of the ROWID type.

  Parameter: rowid

  Return type: int8

  Examples:

  ```
  gaussdb=# CREATE DATABASE ora_test DBCOMPATIBILITY='ORA';
  CREATE DATABASE
  gaussdb=# \c ora_test
  Non-SSL connection (SSL connection is recommended when requiring high-security)
  You are now connected to database "ora" as user "$user".
  ora_test=# SELECT rowid_sequence('AAAAAAAAAP//BBBBBAAAAAAAAAAAC');
   rowid_sequence
  ----------------
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
           2
(1 row)
ora_test=# \c postgres
Non-SSL connection (SSL connection is recommended when requiring high-security)
You are now connected to database "postgres" as user "$user".
gaussdb=# DROP DATABASE ora_test;
DROP DATABASE
```

- rowid_nodeid(rowid)

  Description: Obtains the **node_slice** value of the ROWID type.

  Parameter: rowid

  Return type: int2

  Examples:

```
gaussdb=# CREATE DATABASE ora_test DBCOMPATIBILITY='ORA';
CREATE DATABASE
gaussdb=# \c ora_test
Non-SSL connection (SSL connection is recommended when requiring high-security)
You are now connected to database "ora" as user "$user".
ora_test=# SELECT rowid_nodeid('AAAAAAAAAP//BBBBBAAAAAAAAAAAAC');
 rowid_nodeid
--------------
           0
(1 row)
ora_test=# \c postgres
Non-SSL connection (SSL connection is recommended when requiring high-security)
You are now connected to database "postgres" as user "$user".
gaussdb=# DROP DATABASE ora_test;
DROP DATABASE
```

- rowid_hashbucketid(rowid)

  Description: Obtains the **bucket_id** value of the ROWID type.

  Parameter: rowid

  Return type: int2

  Examples:

```
gaussdb=# CREATE DATABASE ora_test DBCOMPATIBILITY='ORA';
CREATE DATABASE
gaussdb=# \c ora_test
Non-SSL connection (SSL connection is recommended when requiring high-security)
You are now connected to database "ora" as user "$user".
ora_test=# SELECT rowid_hashbucketid('AAAAAAAAAP//BBBBBAAAAAAAAAAAAC');
 rowid_hashbucketid
--------------------
                 -1
(1 row)
ora_test=# \c postgres
Non-SSL connection (SSL connection is recommended when requiring high-security)
You are now connected to database "postgres" as user "$user".
gaussdb=# DROP DATABASE ora_test;
DROP DATABASE
```

1.6.59 Functions for Recompilation upon Invalidation

- transform_view_dep_source()

  Description: Updates the **source** column in the **GS_DEP_SOURCE** system catalog. Specifically, it extends the asterisk (*) in "SELECT *" within the view definition statement, appends the schema used by objects at the time of view creation, and updates view dependencies. This function can be only called by administrators.

  Parameter: none.

  Return type: void.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- gs_compile_schema(schema_name in varchar2 default null, compile_all in boolean default false, retry_times in int default 10)

  Description: Recompiles packages, functions, stored procedures, and views in the specified namespace.

  Parameters: Refer to **Table 1-317**.

  Return type: Boolean, specifically **true** (successful) and **false** (failed).

  Table 1-317 gs_compile_schema parameters

Parameter	Type	IN/OUT	Can Be Empty	Description
schema_name	VARCHAR2	IN	Yes	Specifies the namespace name.
compile_all	Boolean	IN	Yes	Specifies whether to recompile all objects, including the views that are currently valid. • **false**: The invalid views in the PG_OBJECT table is compiled. • **true**: All views in the PG_OBJECT table are compiled.
retry_times	INT	IN	Yes	Specifies the number of retry times when recompilation fails.

  Example:

```
-- Enable recompilation upon invalidation.
gaussdb=# SET enable_view_invalidation='on';

-- Create a schema, a table, a view that depends on the table, and another view that depends on this view.
gaussdb=# DROP SCHEMA IF EXISTS tesch2 CASCADE;
gaussdb=# CREATE SCHEMA tesch2;
gaussdb=# SET current_schema = tesch2;
gaussdb=# CREATE TABLE tab1 (c1 INT, c2 INT);
NOTICE:  The 'DISTRIBUTE BY' clause is not specified. Using 'c1' as the distribution column by default.
HINT:  Please use 'DISTRIBUTE BY' clause to specify suitable data distribution column.
CREATE TABLE
gaussdb=# CREATE VIEW v_tab1 AS SELECT * FROM tab1;
gaussdb=# CREATE VIEW v_tab2 AS SELECT * FROM v_tab1;
gaussdb=# CREATE VIEW v_tab3 AS SELECT * FROM tab1;

-- Drop the table.
gaussdb=# DROP TABLE tab1;

-- Check the object's validity.
gaussdb=# SELECT c.relname, o.valid FROM pg_catalog.pg_object o JOIN pg_catalog.pg_class c ON c.oid = o.object_oid WHERE c.relname = 'v_tab1' or c.relname = 'v_tab2' or c.relname = 'v_tab3';
 relname | valid
---------+-------
 v_tab1  | f
 v_tab2  | f
 v_tab3  | f
(3 rows)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
-- Restore the dropped table.
gaussdb=# CREATE TABLE tab1 (c1 INT, c2 INT);
NOTICE:  The 'DISTRIBUTE BY' clause is not specified. Using 'c1' as the distribution column by default.
HINT:  Please use 'DISTRIBUTE BY' clause to specify suitable data distribution column.
CREATE TABLE

-- Recompile view objects in the tesch2 namespace.
gaussdb=# CALL pg_catalog.gs_compile_schema('tesch2', true, 1);

-- Drop the schema.
gaussdb=# DROP SCHEMA tesch2 CASCADE;
```

1.6.60 Other System Functions

Other system functions are classified into PG-compatible functions and internal functions. These functions are not recommended. If you need to use them, contact Huawei technical support.

PG-compatible Functions and Operators

- The following table lists the built-in functions and operators of GaussDB that are compatible with PostgreSQL. For details about the functions, see the PostgreSQL official documentation.

_pg_char_max_length	_pg_char_octet_length	_pg_datetime_precision	_pg_expandarray	_pg_index_position	_pg_interval_type	_pg_numeric_precision

Internal Functions

The following lists the functions used by GaussDB to implement internal system functions. You are advised not to use these functions. If you need to use them, contact Huawei technical support.

- spread_collect()

  Description: Calculates the difference between the maximum and minimum values in a certain period of time. This function is used for data collection of aggregate functions.

  Parameters: s real[], v real[]

  Return type: real[]

- spread_final()

  Description: Calculates the difference between the maximum and minimum values in a certain period of time. This function is used for the final data processing of the aggregate function.

  Parameter: s real[]

  Return type: real

- spread_internal()

  Description: Calculates the difference between the maximum and minimum values in a certain period of time. This function is used for the intermediate data processing of aggregate functions.

  Parameters: s real[], v real

  Return type: real[]

- xidin4()

  Description: Inputs a 4-byte xid.

  Parameter: cstring

  Return type: xid32

- gap_fill_internal()

  Description: Returns the first non-NULL value in the parameter list.

  Parameter: s anyelement, v anyelement

  Return type: anyelement

- int1send()

  Description: Packs unsigned 1-byte integers into the internal data buffer stream.

  Parameter: tinyint

  Return type: bytea

- is_contain_namespace()

  Description: Searches for the table name and namespace split location. If no namespace exists, 0 is returned.

  Parameter: relationname name

  Return type: integer

- is_oid_in_group_members()

  Description: Not supported

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter: node_oid oid, group_members oidvector_extend

Return type: Boolean

- isubmit_on_nodes_internal()

  Description: Not supported

  Parameter: job bigint, node_name name, database name, what text, next_date timestamp without time zone, job_interval text

  Return type: integer

- listagg()

  Description: Specifies aggregate functions of the list type.

  Parameters: smallint, text

  Return type: text

- log_fdw_validator()

  Description: Specifies validation functions.

  Parameters: text[], oid

  Return type: void

- nvarchar2typmodin()

  Description: Obtains the typmod information of the varchar type.

  Parameter: cstring[]

  Return type: integer

- nvarchar2typmodout()

  Description: Obtains the typmod information of the varchar type, constructs a character string, and returns the character string.

  Parameter: integer

  Return type: cstring

- pg_nodes_memmon()

  Description: Not supported.

  Parameter: nan

  Return type: innernname text, innerusedmem bigint, innertopctxt bigint, nname text, usedmem text, sharedbuffercache text, topcontext text

- read_disable_conn_file()

  Description: Reads forbidden connection files.

  Parameter: nan

  Return type: disconn_mode text, disconn_host text, disconn_port text, local_host text, local_port text, redo_finished text

- regex_like_m()

  Description: Specifies the regular expression match, which is used to determine whether a character string complies with a specified regular expression.

  Parameters: text, text

  Return type: Boolean

- update_pgjob()

  Description: Updates a job.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameters: bigint, "char", bigint, timestamp without time zone, timestamp without time zone, timestamp without time zone, timestamp without time zone, timestamp without time zone, smallint, text

Return type: void

- enum_cmp()

  Description: Specifies the enumeration comparison function, which is used to determine whether two enumeration classes are equal and determine their relative sizes.

  Parameters: anyenum, anyenum

  Return type: integer

- enum_eq()

  Description: Specifies the enumeration comparison function, which is used to implement the equal sign (=).

  Parameters: anyenum, anyenum

  Return type: Boolean

- enum_first()

  Description: Returns the first element in the enumeration class.

  Parameter: anyenum

  Return type: anyenum

- enum_ge()

  Description: Specifies the enumeration comparison function, which is used to implement the greater-than sign (>) and equal sign (=).

  Parameters: anyenum, anyenum

  Return type: Boolean

- enum_gt()

  Description: Specifies the enumeration comparison function, which is used to implement the greater-than sign (>).

  Parameters: anyenum, anyenum

  Return type: Boolean

- enum_in()

  Description: Specifies the enumeration comparison function, which is used to determine whether an element is in an enumeration class.

  Parameters: cstring, OID

  Return type: anyenum

- enum_larger()

  Description: Specifies the enumeration comparison function, which is used to implement the greater-than sign (>).

  Parameters: anyenum, anyenum

  Return type: anyenum

- enum_last()

  Description: Returns the last element in the enumeration class.

  Parameter: anyenum

  Return type: anyenum

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- enum_le()

  Description: Specifies the enumeration comparison function, which is used to implement the less-than sign (<) and equal sign (=).

  Parameters: anyenum, anyenum

  Return type: Boolean

- enum_lt()

  Description: Specifies the enumeration comparison function, which is used to implement the less-than sign (<).

  Parameters: anyenum, anyenum

  Return type: Boolean

- enum_smaller()

  Description: Specifies the enumeration comparison function, which is used to implement the less-than sign (<).

  Parameters: anyenum, anyenum

  Return type: Boolean

- node_oid_name()

  Description: Not supported

  Parameter: oid

  Return type: cstring

- pg_buffercache_pages()

  Description: Reads data from the shared buffer.

  Parameter: nan

  Return type: bufferid integer, relfilenode oid, bucketid smallint, storage_type oid, reltablespace oid, reldatabase oid, relforknumber smallint, relblocknumber bigint, isdirty Boolean, usage_count smallint

- pg_check_xidlimit()

  Description: Checks whether nextxid is greater than or equal to xidwarnlimit.

  Parameter: nan

  Return type: Boolean

- pg_comm_delay()

  Description: Displays the delay status of the communications library of a single DN.

  Parameter: nan

  Return type: text, text, integer, integer, integer, integer

- pg_comm_recv_stream()

  Description: Displays the receiving stream status of all communication libraries on a single DN.

  Parameter: nan

  Return type: text, bigint, text, bigint, integer, integer, integer, text, bigint, integer, integer, integer, bigint, bigint, bigint, bigint, bigint

- pg_comm_send_stream()

  Description: Displays the sending stream status of all communication libraries on a single DN.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter: nan

Return type: text, bigint, text, bigint, integer, integer, integer, text, bigint, integer, integer, integer, bigint, bigint, bigint, bigint, bigint

- pg_comm_status()

  Description: Displays the communication status of a single DN.

  Parameter: nan

  Return type: text, integer, integer, bigint, bigint, bigint, bigint, bigint, integer, integer, integer, integer, integer

- pg_log_comm_status()

  Description: Prints some logs on the DN.

  Parameter: nan

  Return type: Boolean

- pg_parse_clog()

  Description: Parses Clog to obtain the XID status of an ordinary table.

  Parameter: nan

  Return type: xid xid, status text

- pg_parse_clog(bucketid)

  Description: Parses Clog to obtain the XID status of a specified bucket ID.

  Parameter: **bucketid** indicates the physical bucket ID of the hash bucket table. The value **–1** indicates an ordinary table.

  Return type: xid xid, status text

- pg_pool_ping()

  Description: Sets PoolerPing.

  Parameter: Boolean

  Return type: SETOF Boolean

- pg_pool_validate()

  Description: Compares fields in the **pgxc_node** system catalog to check whether a connection is available.

  Parameter: clear Boolean, co_node_name cstring

  Return type: pid bigint, node_name text

- pg_resume_bkp_flag()

  Description: Obtains the delay Xlog flag for backup and restoration.

  Parameter: slot_name name

  Return type: start_backup_flag Boolean, to_delay Boolean, ddl_delay_recycle_ptr text, rewind_time text

  NOTE

  To call this function, users must possess the SYSADMIN or OPRADMIN permission. In the case of OPRADMIN, **operation_mode** must be enabled.

- gs_static_threadpool_ctrl_status()

  Description: Queries statistics about the static pool threads in the thread pool. When a CN thread pool is enabled, a distributed CN supports the query of related static pool information, and a DN returns a blank line. When the

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

thread pool is disabled, a blank line is returned. If **static_thread_pool_num** is set to **0** or less than the number of groups in the thread pool, the default value of the static thread pool is **0**.

Parameter: nan

Return value: text node_name, int group_id, and text worker_info. For details about the return value, see **Table 1-318**.

Table 1-318 GS_STATIC_THREADPOOL_CTRL_STATUS columns

Name	Type	Description
node_name	OUT text	Instance name.
group_id	OUT int	Group ID of the thread pool.
worker_info	OUT text	Dynamic statistics about the running thread pool of the current group. The information includes: **default** and **default_s**: number of threads, including default value of the dynamic thread pool and default value of the static thread pool. **expect** and **expect_s**: number of threads, including the expected value of the dynamic thread pool and expected value of the static thread pool. **actual**: actual number of running threads, including dynamic pool threads and static pool threads. **static threads limit**: number of static pool threads configured for the current group. **has static threads**: specifies whether a static pool is created for the current group. The default value is **0**, indicating no creation. **idle static threads**: number of idle static pool threads. **wait session num**: number of waiting sessions.

- gs_thrdstream_worker_info()

  Description: Queries statistics about the stream thread pool. The query can be performed only on DNs running in thread pool mode.

  Parameter: nan

  Return values: **text node_name**, **int group_id**, **text db_info**, and **text stream_info**. For details about the returned columns, see **Table 1-319**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 1-319 GS_THRDSTREAM_WORKER_INFO columns

Name	Type	Description
node_name	OUT text	Instance name.
group_id	OUT integer	Group ID of the thread pool.
db_info	OUT text	Dynamic database statistics about the running stream thread pool of the current group. The information includes: • **total stream reusing db**: number of databases that are being used or reused in the stream thread pool. • **free session db**: number of databases that do not have running sessions in the stream thread pool.
stream_info	OUT text	Dynamic stream thread statistics about the running stream thread pool of the current group. The information includes: • **actual**: number of actually started stream threads. • **idle**: number of idle stream threads. • **using**: number of stream threads in use. • **init session threads**: number of stream threads for initializing a session. • **reuse session threads**: number of stream threads that reuse sessions.

- pg_stat_get_pooler_status()

  Description: Queries the cache connection status in the pooler.

  Parameter: nan

  Return type: See **Table 1-320**.

  Table 1-320 Return values of pg_stat_get_pooler_status

Name	Type	Description
database_name	OUT text	Database name.
user_name	OUT text	Username.
tid	OUT bigint	In non-thread pool logic, this parameter indicates the ID of the thread connected to the CN. In thread pool logic, this parameter indicates the ID of the session connected to the CN.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Name	Type	Description
pgoptions	OUT text	Database connection options. For details, see the **options** column in "Application Development Guide > Appendix > libpq > Connection Parameters" in *Developer Guide*.
node_oid	OUT bigint	OID of the node connected.
in_use	OUT boolean	Specifies whether the connection is currently used. • **t** (true): The connection is in use. • **f** (false): The connection is not in use.
session_params	OUT text	GUC session parameter delivered by the connection.
fdsock	OUT bigint	Local socket.
local_host	OUT text	Local IP address.
local_port	OUT bigint	Local port number.
remote_host	OUT text	Peer IP address.
remote_port	OUT bigint	Peer port number.
remote_pid	OUT bigint	If the peer site is not in the thread pool logic, the value is the thread ID of the peer site. If the peer site is in the thread pool logic, the value is the session ID of the peer site.
used_count	OUT bigint	Number of reuse times of a connection.
idx	OUT bigint	Peer DN ID in the local CN.
streamid	OUT bigint	Stream ID in the physical connection.

- gs_stat_get_pooler_agent()

  Description: Queries information about the pooler agent on the connected CN to help locate connection pool problems. Only system administrators can access this function. If a DN is connected for query, an empty table is returned.

  Parameter: nan

  Return type: See **Table 1-321**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 1-321 Return values of gs_stat_get_pooler_agent()

Name	Type	Description
index	OUT bigint	Index of the current agent in the global agents.
database_name	OUT text	Name of the database in the current session.
user_name	OUT text	Username of the current session.
session_id	OUT bigint	• ID of the thread connected to the CN for non-thread pool logic. • Session ID for connecting to the CN for thread pool logic.
dn_oids	OUT oid[]	List of recorded DN OIDs.
cn_oids	OUT oid[]	List of recorded CN OIDs.
agent_init	OUT timestamp with time zone	Time when the agent is initialized. The agent is initialized when a session is created or the pgxc catalog information is reloaded.

- get_node_modulo()
  Description: Computes indexes of a node in a group.
  Parameters: See **Table 1-322**.

  Table 1-322 get_node_modulo input parameters

Parameter	Type	Description	Value Range
node_oid	IN oid	Node OID.	[0, 2^32-1]
group_oid	IN oid	OID of a node group.	[0, 2^32-1]

  Return type: uint4
- check_murmurhash_route_node()
  Description: Checks whether the node where the key is distributed is correct.
  Parameters: See **Table 1-323**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 1-323 check_murmurhash_route_node input parameters

Parameter	Type	Description	Value Range
key	IN text	Character string of the hash key.	-
node_modulo	IN uint4	Index of a node in a node group.	[0, 2^32-1]
node_num	IN uint4	Number of nodes in a node group.	[0, 2^32-1]

Return type: uint4

- gs_libcomm_fd_info()

  Description: Queries the socket persistent connection information of the libcomm communications library.

  Parameter: nan

  Return value: See **Table 1-324**.

Table 1-324 Return values of gs_libcomm_fd_info

Name	Type	Description
node_name	OUT text	DN name.
ip	OUT text	IP address of the DN.
ctrl_port	OUT bigint	Control channel port.
data_port	OUT bigint	Data channel port.
remote_name	OUT text	Name of the peer DN.
remote_ip	OUT text	Peer IP address.
remote_port	OUT bigint	Peer port number.
local_ip	OUT text	Local IP address.
local_port	OUT bigint	Local port number.
fd	OUT bigint	Socket connection.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Name	Type	Description
type	OUT text	Type of the TCP connection channel. The options are as follows: • **DATA_SEND_FD**: socket of the sender of the data channel • **DATA_RECV_FD**: socket of the receiver of the data channel. • **CTL_SEND_FD**: socket of the sender of the control channel. • **CTL_RECV_FD**: socket of the receiver of the control channel.

NOTE

This function can be used only on the DN. If no information is returned, the libcomm persistent connection is not established for the current DN instance.

- gs_libcomm_memory_info()

  Description: Queries the basic configuration information used by the internal memory of the current libcomm communications library.

  Parameter: nan

  Return value: See **Table 1-325**.

  Table 1-325 Return values of gs_libcomm_memory_info

Name	Type	Description
node_name	OUT text	Instance name of the DN.
current_used_memory	OUT bigint	Memory used by the libcomm communications library, in bytes.
current_data_item_num	OUT bigint	Number of data blocks in the libcomm lock-free queue.
init_mailbox_memory	OUT bigint	Memory used by libcomm to initialize the mailbox, in bytes.
max_datanode	OUT bigint	Maximum number of DNs supported by the libcomm communications library.
max_stream	OUT bigint	Maximum number of data streams supported by a single TCP connection of the libcomm.
max_quota_size	OUT bigint	Total buffer size of the libcomm logical connection, in bytes.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Name	Type	Description
max_usable_memory	OUT bigint	Maximum memory that can be used by the libcomm communications library cache, in bytes.
max_memory_pool	OUT bigint	Total size of the memory resource pool that can be used by the libcomm communications library on each DN. The unit is byte.

- gs_validate_ext_listen_ip()

  Description: Connects to DNs, queries invalid worker threads on DNs connected to the original extended IP address, and clears the threads.

  Parameters: See **Table 1-326**.

  Return value: bigint pid, text node_name

  Note: This function is used only when old connections still exist on the original extended IP address after the extended IP address is reloaded. This function clears the threads where the original IP connections are located. Executing this function will clear communication listening on the extended IP address. Exercise caution when performing O&M operations. Currently, this command can be executed only by connecting to DNs and delivered by the administrator.

  Table 1-326 GS_VALIDATE_EXT_LISTEN_IP columns

Name	Type	Description
clear	IN cstring	Specifies whether to clear data. The options are as follows: **on**: clear; **off**: not clear.
validate_node_name	IN cstring	Name of the DN where the extended IP address connections to be cleared are located.
validate_ip	IN cstring	Extended IP address whose connections are to be cleared.
pid	OUT bigint	ID of the worker thread where the extended IP address connections to be cleared are located.
node_name	OUT text	Name of the instance to which the extended IP address connections to be cleared belong.

- gs_comm_listen_address_ext_info()

  Description: Displays the DFX information about the extended IP address configured for **listen_address_ext** connected to the current instance.

  Parameter: nan

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Return type: text node_name, text app, bigint tid, integer lwtid, bigint query_id, integer socket, text remote_ip, text remote_port, text local_ip or text local_port For details about the returned columns, see **Table 1-327**.

Table 1-327 GS_COMM_LISTEN_ADDRESS_EXT_INFO columns

Name	Type	Description
node_name	OUT text	Name of the current instance.
app	OUT text	Client connected to the DN.
tid	OUT bigint	Thread ID of the current thread.
lwtid	OUT integer	Lightweight thread ID of the current thread.
query_id	OUT bigint	Query ID of the current thread.
socket	OUT integer	Socket FD of the current physical connection.
remote_ip	OUT text	Peer IP address of the current connection.
remote_port	OUT text	Peer port of the current connection.
local_ip	OUT text	Local IP address of the current connection.
local_port	OUT text	Local port of the current connection.

- gs_get_global_listen_address_ext_info

  Description: Queries the global extended IP address configuration on the CN.

  Parameters: See **Table 1-328**.

  Return type: text node_name, text host, text port, text ext_listen_ip

  Note: If the input parameter of the function is **all**, the function depends on the **ext_ip_info** static configuration file. If the file is abnormal, use the CM/OM tool to rectify the fault. In this case, the configuration cannot be updated in real time. You can set the input parameter to **primary** to obtain the configuration information about all primary DNs.

  Table 1-328 GS_GET_GLOBAL_LISTEN_ADDRESS_EXT_INFO columns

Name	Type	Description
dn_mode	IN cstring	Specifies the range of DNs to be displayed. If this parameter is set to **null**, all DNs are queried by default.
node_name	OUT text	DN name.
host	OUT text	Listening IP address of the DN.
port	OUT text	Listening port of the DN.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Name	Type	Description
ext_listen_ip	OUT text	Extended listening IP address of the DN.

- gs_get_listen_address_ext_info()

  Description: Queries the extended IP address configuration of the current instance.

  Parameter: nan

  Return type: text node_name, text host, bigint port, text ext_listen_ip For details about the returned columns, see **Table 1-329**.

  Table 1-329 GS_GET_LISTEN_ADDRESS_EXT_INFO

Name	Type	Description
node_name	OUT text	DN name.
host	OUT text	Listening IP address of the DN.
port	OUT bigint	Listening port of the DN.
ext_listen_ip	OUT text	Extended listening IP address of the DN.

- psortoptions()

  Description: Returns the psort attribute.

  Parameters: text[], Boolean

  Return type: bytea
- remove_job_class_depend()

  Description: Removes the job dependency.

  Parameter: oid

  Return type: void
- xideq4()

  Description: Compares two xids to check whether they are the same.

  Parameters: xid32, xid32

  Return type: Boolean
- xideqint8()

  Description: Compares two xids to check whether they are the same.

  Parameters: xid, bigint

  Return type: Boolean
- xidlt()

  Description: Returns whether xid1 < xid2 is true.

  Parameters: xid, xid

  Return type: Boolean

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- xidlt4()

  Description: Returns whether xid1 < xid2 is true.

  Parameters: xid32, xid32

  Return type: Boolean

- get_local_cont_query_stat()

  Description: Obtains the statistics of a specified continuous computing view on the local node.

  Parameter: cq_id oid

  Return type: cq oid, w_in_rows int8, w_in_bytes int8, w_out_rows int8, w_out_bytes int8, w_pendings int8, w_errors int8, r_in_rows int8, r_in_bytes int8, r_out_rows int8, r_out_bytes int8, r_errors int8, c_in_rows int8, c_in_bytes int8, c_out_rows int8, c_out_bytes int8, c_pendings int8, c_errors int8

- get_local_cont_query_stats()

  Description: Obtains all continuous computing view statistics of the local node.

  Parameter: nan

  Return type: cq oid, w_in_rows int8, w_in_bytes int8, w_out_rows int8, w_out_bytes int8, w_pendings int8, w_errors int8, r_in_rows int8, r_in_bytes int8, r_out_rows int8, r_out_bytes int8, r_errors int8, c_in_rows int8, c_in_bytes int8, c_out_rows int8, c_out_bytes int8, c_pendings int8, c_errors int8

- get_cont_query_stats()

  Description: Obtains statistics about all continuous computing views on each DN.

  Parameter: nan

  Return type: node name, cq oid, w_in_rows int8, w_in_bytes int8, w_out_rows int8, w_out_bytes int8, w_pendings int8, w_errors int8, r_in_rows int8, r_in_bytes int8, r_out_rows int8, r_out_bytes int8, r_errors int8, c_in_rows int8, c_in_bytes int8, c_out_rows int8, c_out_bytes int8, c_pendings int8, c_errors int8

- reset_local_cont_query_stat()

  Description: Resets the statistics of a specified continuous computation view on the local node.

  Parameter: cq_id oid

  Return type: Boolean

- reset_local_cont_query_stats()

  Description: Resets association statistics on the specified continuous computation view of the local node.

  Parameter: cq_id oid

  Return type: Boolean

- reset_cont_query_stats()

  Description: Resets the continuous computation view statistics corresponding to the STREAM object on each DN.

  Parameter: stream_id oid

  Return type: Boolean

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- check_cont_query_schema_changed()

  Description: Determines the schema change status of a specified continuous computation view.

  Parameter: cq_id oid

  Return type: Boolean

- gs_get_standby_cluster_barrier_status()

  Description: Queries the barrier log replay information of the standby CN or DN, including the latest received barrier, LSN of the latest received barrier, barrier replayed last time, and target barrier to be replayed.

  Parameter: nan

  Return type: barrier_id text, barrier_lsn text, recovery_id text, target_id text

  Note: To call this function, the user must have the SYSADMIN or OPRADMIN permission. For the O&M administrator role, **operate_mode** must be enabled.

- gs_set_standby_cluster_target_barrier_id()

  Description: Set the target barrier to be replayed.

  Parameter: barrier_id

  Return type: target_id text

  Note: To call this function, the user must have the SYSADMIN or OPRADMIN permission. For the O&M administrator role, **operate_mode** must be enabled.

- gs_query_standby_cluster_barrier_id_exist()

  Description: Queries whether the specified barrier is received by the standby node.

  Parameter: barrier_id

  Return type: Boolean

  Note: To call this function, the user must have the SYSADMIN or OPRADMIN permission. For the O&M administrator role, **operate_mode** must be enabled.

- standby_read_status()

  Description: Obtains the CSN-based snapshot information of all DNs in a cluster, the difference between the primary and standby DNs, and the CSN-based snapshot information used for the last read on standby. This is used for read on standby in the distributed GTM-free scenario.

  Parameter: nan

  Return type: text, text, text, integer, bigint, bigint, bigint For details about the returned columns, see **Table 1-330**.

  Table 1-330 standby_read_status columns

Name	Type	Description
name	text	DN name.
type	text	DN type (**primary** for the primary node and **standby** for the standby node).
host	text	IP address used by the DN.
port	integer	Port used by the DN.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Name	Type	Description
collected_csn	bigint	CSN-based snapshot information of the DN (For the primary node, the value is **0**. For the standby node, the value is the collected CSN.)
delay	bigint	Difference between the primary and standby DNs. The unit is ms.
visited_csn	bigint	CSN information used for the last read query on the standby node. (This parameter is valid only for the standby node where the last query is executed.)

- gs_shutdown_cross_region_walsenders()

  Description: Interrupts cross-cluster streaming replication.

  Parameter: nan

  Return type: void

  Note: To call this function, the user must have the SYSADMIN or OPRADMIN permission. For the O&M administrator role, **operate_mode** must be enabled.

  The following stream functions exist but are not supported. You are advised not to use them.

  streaming_int8_avg_gather, streaming_numeric_avg_gather, streaming_float8_avg_gather, streaming_interval_avg_gather, streaming_int8_sum_gather, streaming_int2_int4_sum_gather
- is_dblink_in_transaction()

  Description: Checks whether a database link corresponding to an OID is used in the current transaction.

  Parameter: oid

  Return type: Boolean
- dblink_has_updatasent()

  Description: Checks whether DML statements are sent using a database link corresponding to an OID in the current transaction and are not committed.

  Parameter: oid

  Return type: Boolean
- get_last_xmin_by_oid()

  Description: Obtains the maximum **xmin** value of all columns in a table based on the table OID.

  Parameter: oid

  Return type: xid
- get_relid_by_relname()

  Description: Obtains the OID of a table based on the table name and relnamespace.

  Parameters: cstring, OID

  Return type: OID

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- btint12cmp()

  Description: Compares the values of two parameters. If the value is greater than another one, a positive number is returned. If the value is equal to another one, **0** is returned. If the value is less than another one, a negative number is returned.

  Parameters: int1, int2

  Return type: integer

- btint14cmp()

  Description: Compares the values of two parameters. If the value is greater than another one, a positive number is returned. If the value is equal to another one, **0** is returned. If the value is less than another one, a negative number is returned.

  Parameters: int1, int4

  Return type: integer

- btint18cmp()

  Description: Compares the values of two parameters. If the value is greater than another one, a positive number is returned. If the value is equal to another one, **0** is returned. If the value is less than another one, a negative number is returned.

  Parameters: int1, int8

  Return type: integer

- btint116cmp()

  Description: Compares the values of two parameters. If the value is greater than another one, a positive number is returned. If the value is equal to another one, **0** is returned. If the value is less than another one, a negative number is returned.

  Parameters: int1, int16

  Return type: integer

- btint1numericcmp()

  Description: Compares the values of two parameters. If the value is greater than another one, a positive number is returned. If the value is equal to another one, **0** is returned. If the value is less than another one, a negative number is returned.

  Parameters: int1, numeric

  Return type: integer

- btint21cmp()

  Description: Compares the values of two parameters. If the value is greater than another one, a positive number is returned. If the value is equal to another one, **0** is returned. If the value is less than another one, a negative number is returned.

  Parameters: int2, int1

  Return type: integer

- btint216cmp()

  Description: Compares the values of two parameters. If the value is greater than another one, a positive number is returned. If the value is equal to

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

another one, **0** is returned. If the value is less than another one, a negative number is returned.

Parameters: int2, int16

Return type: integer

- btint2numericcmp()

  Description: Compares the values of two parameters. If the value is greater than another one, a positive number is returned. If the value is equal to another one, **0** is returned. If the value is less than another one, a negative number is returned.

  Parameters: int2, numeric

  Return type: integer

- btint41cmp()

  Description: Compares the values of two parameters. If the value is greater than another one, a positive number is returned. If the value is equal to another one, **0** is returned. If the value is less than another one, a negative number is returned.

  Parameters: int4, int1

  Return type: integer

- btint416cmp()

  Description: Compares the values of two parameters. If the value is greater than another one, a positive number is returned. If the value is equal to another one, **0** is returned. If the value is less than another one, a negative number is returned.

  Parameters: int4, int16

  Return type: integer

- btint4numericcmp()

  Description: Compares the values of two parameters. If the value is greater than another one, a positive number is returned. If the value is equal to another one, **0** is returned. If the value is less than another one, a negative number is returned.

  Parameters: int4, numeric

  Return type: integer

- btint81cmp()

  Description: Compares the values of two parameters. If the value is greater than another one, a positive number is returned. If the value is equal to another one, **0** is returned. If the value is less than another one, a negative number is returned.

  Parameters: int8, int1

  Return type: integer

- btint816cmp()

  Description: Compares the values of two parameters. If the value is greater than another one, a positive number is returned. If the value is equal to another one, **0** is returned. If the value is less than another one, a negative number is returned.

  Parameters: int8, int16

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Return type: integer

- btint8numericcmp()

  Description: Compares the values of two parameters. If the value is greater than another one, a positive number is returned. If the value is equal to another one, **0** is returned. If the value is less than another one, a negative number is returned.

  Parameters: int8, numeric

  Return type: integer

- btint161cmp()

  Description: Compares the values of two parameters. If the value is greater than another one, a positive number is returned. If the value is equal to another one, **0** is returned. If the value is less than another one, a negative number is returned.

  Parameters: int16, int1

  Return type: integer

- btint162cmp()

  Description: Compares the values of two parameters. If the value is greater than another one, a positive number is returned. If the value is equal to another one, **0** is returned. If the value is less than another one, a negative number is returned.

  Parameters: int16, int2

  Return type: integer

- btint164cmp()

  Description: Compares the values of two parameters. If the value is greater than another one, a positive number is returned. If the value is equal to another one, **0** is returned. If the value is less than another one, a negative number is returned.

  Parameters: int16, int4

  Return type: integer

- btint168cmp()

  Description: Compares the values of two parameters. If the value is greater than another one, a positive number is returned. If the value is equal to another one, **0** is returned. If the value is less than another one, a negative number is returned.

  Parameters: int16, int8

  Return type: integer

- btnumericint1cmp()

  Description: Compares the values of two parameters. If the value is greater than another one, a positive number is returned. If the value is equal to another one, **0** is returned. If the value is less than another one, a negative number is returned.

  Parameters: numeric, int1

  Return type: integer

- btnumericint2cmp()

  Description: Compares the values of two parameters. If the value is greater than another one, a positive number is returned. If the value is equal to

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

another one, **0** is returned. If the value is less than another one, a negative number is returned.

Parameters: numeric, int2

Return type: integer

- btnumericint4cmp()

  Description: Compares the values of two parameters. If the value is greater than another one, a positive number is returned. If the value is equal to another one, **0** is returned. If the value is less than another one, a negative number is returned.

  Parameters: numeric, int4

  Return type: integer

- btnumericint8cmp()

  Description: Compares the values of two parameters. If the value is greater than another one, a positive number is returned. If the value is equal to another one, **0** is returned. If the value is less than another one, a negative number is returned.

  Parameters: numeric, int8

  Return type: integer

- btint16cmp()

  Description: Compares the values of two parameters. If the value is greater than another one, a positive number is returned. If the value is equal to another one, **0** is returned. If the value is less than another one, a negative number is returned.

  Parameters: int16, int16

  Return type: integer

- hashint16()

  Description: Calculates the hash value of an input parameter.

  Parameter: int16

  Return type: integer

- hashint1_numeric()

  Description: Calculates the hash value of an input parameter.

  Parameter: int1

  Return type: integer

- hashint2_numeric()

  Description: Calculates the hash value of an input parameter.

  Parameter: int2

  Return type: integer

- hashint4_numeric()

  Description: Calculates the hash value of an input parameter.

  Parameter: int4

  Return type: integer

- hashint8_numeric()

  Description: Calculates the hash value of an input parameter.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter: int8

Return type: integer

- int12eq()

  Description: Compares whether two parameter values are equal. If they are equal, **true** is returned. Otherwise, **false** is returned.

  Parameters: int1, int2

  Return type: Boolean

- int14eq()

  Description: Compares whether two parameter values are equal. If they are equal, **true** is returned. Otherwise, **false** is returned.

  Parameters: int1, int4

  Return type: Boolean

- int18eq()

  Description: Compares whether two parameter values are equal. If they are equal, **true** is returned. Otherwise, **false** is returned.

  Parameters: int1, int8

  Return type: Boolean

- int116eq()

  Description: Compares whether two parameter values are equal. If they are equal, **true** is returned. Otherwise, **false** is returned.

  Parameters: int1, int16

  Return type: Boolean

- int1numericeq()

  Description: Compares whether two parameter values are equal. If they are equal, **true** is returned. Otherwise, **false** is returned.

  Parameters: int1, numeric

  Return type: Boolean

- int21eq()

  Description: Compares whether two parameter values are equal. If they are equal, **true** is returned. Otherwise, **false** is returned.

  Parameters: int2, int1

  Return type: Boolean

- int216eq()

  Description: Compares whether two parameter values are equal. If they are equal, **true** is returned. Otherwise, **false** is returned.

  Parameters: int2, int16

  Return type: Boolean

- int2numericeq()

  Description: Compares whether two parameter values are equal. If they are equal, **true** is returned. Otherwise, **false** is returned.

  Parameters: int2, numeric

  Return type: Boolean

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- int41eq()

  Description: Compares whether two parameter values are equal. If they are equal, **true** is returned. Otherwise, **false** is returned.

  Parameters: int4, int1

  Return type: Boolean

- int416eq()

  Description: Compares whether two parameter values are equal. If they are equal, **true** is returned. Otherwise, **false** is returned.

  Parameters: int4, int16

  Return type: Boolean

- int4numericeq()

  Description: Compares whether two parameter values are equal. If they are equal, **true** is returned. Otherwise, **false** is returned.

  Parameters: int4, numeric

  Return type: Boolean

- int81eq()

  Description: Compares whether two parameter values are equal. If they are equal, **true** is returned. Otherwise, **false** is returned.

  Parameters: int8, int1

  Return type: Boolean

- int816eq()

  Description: Compares whether two parameter values are equal. If they are equal, **true** is returned. Otherwise, **false** is returned.

  Parameters: int8, int16

  Return type: Boolean

- int8numericeq()

  Description: Compares whether two parameter values are equal. If they are equal, **true** is returned. Otherwise, **false** is returned.

  Parameters: int8, numeric

  Return type: Boolean

- int161eq()

  Description: Compares whether two parameter values are equal. If they are equal, **true** is returned. Otherwise, **false** is returned.

  Parameters: int16, int1

  Return type: Boolean

- int162eq()

  Description: Compares whether two parameter values are equal. If they are equal, **true** is returned. Otherwise, **false** is returned.

  Parameters: int16, int2

  Return type: Boolean

- int164eq()

  Description: Compares whether two parameter values are equal. If they are equal, **true** is returned. Otherwise, **false** is returned.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameters: int16, int4

Return type: Boolean

- int168eq()

  Description: Compares whether two parameter values are equal. If they are equal, **true** is returned. Otherwise, **false** is returned.

  Parameters: int16, int8

  Return type: Boolean

- numericint1eq()

  Description: Compares whether two parameter values are equal. If they are equal, **true** is returned. Otherwise, **false** is returned.

  Parameters: numeric, int1

  Return type: Boolean

- numericint2eq()

  Description: Compares whether two parameter values are equal. If they are equal, **true** is returned. Otherwise, **false** is returned.

  Parameters: numeric, int2

  Return type: Boolean

- numericint4eq()

  Description: Compares whether two parameter values are equal. If they are equal, **true** is returned. Otherwise, **false** is returned.

  Parameters: numeric, int4

  Return type: Boolean

- numericint8eq()

  Description: Compares whether two parameter values are equal. If they are equal, **true** is returned. Otherwise, **false** is returned.

  Parameters: numeric, int8

  Return type: Boolean

- int12ne()

  Description: Compares whether two parameter values are equal. If they are not equal, **true** is returned. Otherwise, **false** is returned.

  Parameters: int1, int2

  Return type: Boolean

- int14ne()

  Description: Compares whether two parameter values are equal. If they are not equal, **true** is returned. Otherwise, **false** is returned.

  Parameters: int1, int4

  Return type: Boolean

- int18ne()

  Description: Compares whether two parameter values are equal. If they are not equal, **true** is returned. Otherwise, **false** is returned.

  Parameters: int1, int8

  Return type: Boolean

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- int116ne()

  Description: Compares whether two parameter values are equal. If they are not equal, **true** is returned. Otherwise, **false** is returned.

  Parameters: int1, int16

  Return type: Boolean

- int1numericne()

  Description: Compares whether two parameter values are equal. If they are not equal, **true** is returned. Otherwise, **false** is returned.

  Parameters: int1, numeric

  Return type: Boolean

- int21ne()

  Description: Compares whether two parameter values are equal. If they are not equal, **true** is returned. Otherwise, **false** is returned.

  Parameters: int2, int1

  Return type: Boolean

- int216ne()

  Description: Compares whether two parameter values are equal. If they are not equal, **true** is returned. Otherwise, **false** is returned.

  Parameters: int2, int16

  Return type: Boolean

- int2numericne()

  Description: Compares whether two parameter values are equal. If they are not equal, **true** is returned. Otherwise, **false** is returned.

  Parameters: int2, numeric

  Return type: Boolean

- int41ne()

  Description: Compares whether two parameter values are equal. If they are not equal, **true** is returned. Otherwise, **false** is returned.

  Parameters: int4, int1

  Return type: Boolean

- int416ne()

  Description: Compares whether two parameter values are equal. If they are not equal, **true** is returned. Otherwise, **false** is returned.

  Parameters: int4, int16

  Return type: Boolean

- int4numericne()

  Description: Compares whether two parameter values are equal. If they are not equal, **true** is returned. Otherwise, **false** is returned.

  Parameters: int4, numeric

  Return type: Boolean

- int81ne()

  Description: Compares whether two parameter values are equal. If they are not equal, **true** is returned. Otherwise, **false** is returned.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameters: int8, int1

Return type: Boolean

- int816ne()

  Description: Compares whether two parameter values are equal. If they are not equal, **true** is returned. Otherwise, **false** is returned.

  Parameters: int8, int16

  Return type: Boolean

- int8numericne()

  Description: Compares whether two parameter values are equal. If they are not equal, **true** is returned. Otherwise, **false** is returned.

  Parameters: int8, numeric

  Return type: Boolean

- int161ne()

  Description: Compares whether two parameter values are equal. If they are not equal, **true** is returned. Otherwise, **false** is returned.

  Parameters: int16, int1

  Return type: Boolean

- int162ne()

  Description: Compares whether two parameter values are equal. If they are not equal, **true** is returned. Otherwise, **false** is returned.

  Parameters: int16, int2

  Return type: Boolean

- int164ne()

  Description: Compares whether two parameter values are equal. If they are not equal, **true** is returned. Otherwise, **false** is returned.

  Parameters: int16, int4

  Return type: Boolean

- int168ne()

  Description: Compares whether two parameter values are equal. If they are not equal, **true** is returned. Otherwise, **false** is returned.

  Parameters: int16, int8

  Return type: Boolean

- numericint1ne()

  Description: Compares whether two parameter values are equal. If they are not equal, **true** is returned. Otherwise, **false** is returned.

  Parameters: numeric, int1

  Return type: Boolean

- numericint2ne()

  Description: Compares whether two parameter values are equal. If they are not equal, **true** is returned. Otherwise, **false** is returned.

  Parameters: numeric, int2

  Return type: Boolean

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- numericint4ne()

  Description: Compares whether two parameter values are equal. If they are not equal, **true** is returned. Otherwise, **false** is returned.

  Parameters: numeric, int4

  Return type: Boolean

- numericint8ne()

  Description: Compares whether two parameter values are equal. If they are not equal, **true** is returned. Otherwise, **false** is returned.

  Parameters: numeric, int8

  Return type: Boolean

- int12lt()

  Description: Compares whether a parameter is less than another one. If the parameter is less than another one, **true** is returned. Otherwise, **false** is returned.

  Parameters: int1, int2

  Return type: Boolean

- int14lt()

  Description: Compares whether a parameter is less than another one. If the parameter is less than another one, **true** is returned. Otherwise, **false** is returned.

  Parameters: int1, int4

  Return type: Boolean

- int18lt()

  Description: Compares whether a parameter is less than another one. If the parameter is less than another one, **true** is returned. Otherwise, **false** is returned.

  Parameters: int1, int8

  Return type: Boolean

- int116lt()

  Description: Compares whether a parameter is less than another one. If the parameter is less than another one, **true** is returned. Otherwise, **false** is returned.

  Parameters: int1, int16

  Return type: Boolean

- int1numericlt()

  Description: Compares whether a parameter is less than another one. If the parameter is less than another one, **true** is returned. Otherwise, **false** is returned.

  Parameters: int1, numeric

  Return type: Boolean

- int21lt()

  Description: Compares whether a parameter is less than another one. If the parameter is less than another one, **true** is returned. Otherwise, **false** is returned.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameters: int2, int1

Return type: Boolean

- int216lt()

  Description: Compares whether a parameter is less than another one. If the parameter is less than another one, **true** is returned. Otherwise, **false** is returned.

  Parameters: int2, int16

  Return type: Boolean

- int2numericlt()

  Description: Compares whether a parameter is less than another one. If the parameter is less than another one, **true** is returned. Otherwise, **false** is returned.

  Parameters: int2, numeric

  Return type: Boolean

- int41lt()

  Description: Compares whether a parameter is less than another one. If the parameter is less than another one, **true** is returned. Otherwise, **false** is returned.

  Parameters: int4, int1

  Return type: Boolean

- int416lt()

  Description: Compares whether a parameter is less than another one. If the parameter is less than another one, **true** is returned. Otherwise, **false** is returned.

  Parameters: int4, int16

  Return type: Boolean

- int4numericlt()

  Description: Compares whether a parameter is less than another one. If the parameter is less than another one, **true** is returned. Otherwise, **false** is returned.

  Parameters: int4, numeric

  Return type: Boolean

- int81lt()

  Description: Compares whether a parameter is less than another one. If the parameter is less than another one, **true** is returned. Otherwise, **false** is returned.

  Parameters: int8, int1

  Return type: Boolean

- int816lt()

  Description: Compares whether a parameter is less than another one. If the parameter is less than another one, **true** is returned. Otherwise, **false** is returned.

  Parameters: int8, int16

  Return type: Boolean

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- int8numericlt()

  Description: Compares whether a parameter is less than another one. If the parameter is less than another one, **true** is returned. Otherwise, **false** is returned.

  Parameters: int8, numeric

  Return type: Boolean

- int161lt()

  Description: Compares whether a parameter is less than another one. If the parameter is less than another one, **true** is returned. Otherwise, **false** is returned.

  Parameters: int16, int1

  Return type: Boolean

- int162lt()

  Description: Compares whether a parameter is less than another one. If the parameter is less than another one, **true** is returned. Otherwise, **false** is returned.

  Parameters: int16, int2

  Return type: Boolean

- int164lt()

  Description: Compares whether a parameter is less than another one. If the parameter is less than another one, **true** is returned. Otherwise, **false** is returned.

  Parameters: int16, int4

  Return type: Boolean

- int168lt()

  Description: Compares whether a parameter is less than another one. If the parameter is less than another one, **true** is returned. Otherwise, **false** is returned.

  Parameters: int16, int8

  Return type: Boolean

- numericint1lt()

  Description: Compares whether a parameter is less than another one. If the parameter is less than another one, **true** is returned. Otherwise, **false** is returned.

  Parameters: numeric, int1

  Return type: Boolean

- numericint2lt()

  Description: Compares whether a parameter is less than another one. If the parameter is less than another one, **true** is returned. Otherwise, **false** is returned.

  Parameters: numeric, int2

  Return type: Boolean

- numericint4lt()

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description: Compares whether a parameter is less than another one. If the parameter is less than another one, **true** is returned. Otherwise, **false** is returned.

Parameters: numeric, int4

Return type: Boolean

- numericint8lt()

  Description: Compares whether a parameter is less than another one. If the parameter is less than another one, **true** is returned. Otherwise, **false** is returned.

  Parameters: numeric, int8

  Return type: Boolean

- int12gt()

  Description: Compares whether a parameter is greater than another one. If the parameter is greater than another one, **true** is returned. Otherwise, **false** is returned.

  Parameters: int1, int2

  Return type: Boolean

- int14gt()

  Description: Compares whether a parameter is greater than another one. If the parameter is greater than another one, **true** is returned. Otherwise, **false** is returned.

  Parameters: int1, int4

  Return type: Boolean

- int18gt()

  Description: Compares whether a parameter is greater than another one. If the parameter is greater than another one, **true** is returned. Otherwise, **false** is returned.

  Parameters: int1, int8

  Return type: Boolean

- int116gt()

  Description: Compares whether a parameter is greater than another one. If the parameter is greater than another one, **true** is returned. Otherwise, **false** is returned.

  Parameters: int1, int16

  Return type: Boolean

- int1numericgt()

  Description: Compares whether a parameter is greater than another one. If the parameter is greater than another one, **true** is returned. Otherwise, **false** is returned.

  Parameters: int1, numeric

  Return type: Boolean

- int21gt()

  Description: Compares whether a parameter is greater than another one. If the parameter is greater than another one, **true** is returned. Otherwise, **false** is returned.

Parameters: int2, int1

Return type: Boolean

- int216gt()

  Description: Compares whether a parameter is greater than another one. If the parameter is greater than another one, **true** is returned. Otherwise, **false** is returned.

  Parameters: int2, int16

  Return type: Boolean

- int2numericgt()

  Description: Compares whether a parameter is greater than another one. If the parameter is greater than another one, **true** is returned. Otherwise, **false** is returned.

  Parameters: int2, numeric

  Return type: Boolean

- int41gt()

  Description: Compares whether a parameter is greater than another one. If the parameter is greater than another one, **true** is returned. Otherwise, **false** is returned.

  Parameters: int4, int1

  Return type: Boolean

- int416gt()

  Description: Compares whether a parameter is greater than another one. If the parameter is greater than another one, **true** is returned. Otherwise, **false** is returned.

  Parameters: int4, int16

  Return type: Boolean

- int4numericgt()

  Description: Compares whether a parameter is greater than another one. If the parameter is greater than another one, **true** is returned. Otherwise, **false** is returned.

  Parameters: int4, numeric

  Return type: Boolean

- int81gt()

  Description: Compares whether a parameter is greater than another one. If the parameter is greater than another one, **true** is returned. Otherwise, **false** is returned.

  Parameters: int8, int1

  Return type: Boolean

- int816gt()

  Description: Compares whether a parameter is greater than another one. If the parameter is greater than another one, **true** is returned. Otherwise, **false** is returned.

  Parameters: int8, int16

  Return type: Boolean

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- int8numericgt()

  Description: Compares whether a parameter is greater than another one. If the parameter is greater than another one, **true** is returned. Otherwise, **false** is returned.

  Parameters: int8, numeric

  Return type: Boolean

- int161gt()

  Description: Compares whether a parameter is greater than another one. If the parameter is greater than another one, **true** is returned. Otherwise, **false** is returned.

  Parameters: int16, int1

  Return type: Boolean

- int162gt()

  Description: Compares whether a parameter is greater than another one. If the parameter is greater than another one, **true** is returned. Otherwise, **false** is returned.

  Parameters: int16, int2

  Return type: Boolean

- int164gt()

  Description: Compares whether a parameter is greater than another one. If the parameter is greater than another one, **true** is returned. Otherwise, **false** is returned.

  Parameters: int16, int4

  Return type: Boolean

- int168gt()

  Description: Compares whether a parameter is greater than another one. If the parameter is greater than another one, **true** is returned. Otherwise, **false** is returned.

  Parameters: int16, int8

  Return type: Boolean

- numericint1gt()

  Description: Compares whether a parameter is greater than another one. If the parameter is greater than another one, **true** is returned. Otherwise, **false** is returned.

  Parameters: numeric, int1

  Return type: Boolean

- numericint2gt()

  Description: Compares whether a parameter is greater than another one. If the parameter is greater than another one, **true** is returned. Otherwise, **false** is returned.

  Parameters: numeric, int2

  Return type: Boolean

- numericint4gt()

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description: Compares whether a parameter is greater than another one. If the parameter is greater than another one, **true** is returned. Otherwise, **false** is returned.

Parameters: numeric, int4

Return type: Boolean

- numericint8gt()

  Description: Compares whether a parameter is greater than another one. If the parameter is greater than another one, **true** is returned. Otherwise, **false** is returned.

  Parameters: numeric, int8

  Return type: Boolean

- int12le()

  Description: Compares whether a parameter is less than or equal to another one. If the parameter is less than or equal to another one, **true** is returned. Otherwise, **false** is returned.

  Parameters: int1, int2

  Return type: Boolean

- int14le()

  Description: Compares whether a parameter is less than or equal to another one. If the parameter is less than or equal to another one, **true** is returned. Otherwise, **false** is returned.

  Parameters: int1, int4

  Return type: Boolean

- int18le()

  Description: Compares whether a parameter is less than or equal to another one. If the parameter is less than or equal to another one, **true** is returned. Otherwise, **false** is returned.

  Parameters: int1, int8

  Return type: Boolean

- int116le()

  Description: Compares whether a parameter is less than or equal to another one. If the parameter is less than or equal to another one, **true** is returned. Otherwise, **false** is returned.

  Parameters: int1, int16

  Return type: Boolean

- int1numericle()

  Description: Compares whether a parameter is less than or equal to another one. If the parameter is less than or equal to another one, **true** is returned. Otherwise, **false** is returned.

  Parameters: int1, numeric

  Return type: Boolean

- int21le()

  Description: Compares whether a parameter is less than or equal to another one. If the parameter is less than or equal to another one, **true** is returned. Otherwise, **false** is returned.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameters: int2, int1

Return type: Boolean

- int216le()

  Description: Compares whether a parameter is less than or equal to another one. If the parameter is less than or equal to another one, **true** is returned. Otherwise, **false** is returned.

  Parameters: int2, int16

  Return type: Boolean

- int2numericle()

  Description: Compares whether a parameter is less than or equal to another one. If the parameter is less than or equal to another one, **true** is returned. Otherwise, **false** is returned.

  Parameters: int2, numeric

  Return type: Boolean

- int41le()

  Description: Compares whether a parameter is less than or equal to another one. If the parameter is less than or equal to another one, **true** is returned. Otherwise, **false** is returned.

  Parameters: int4, int1

  Return type: Boolean

- int416le()

  Description: Compares whether a parameter is less than or equal to another one. If the parameter is less than or equal to another one, **true** is returned. Otherwise, **false** is returned.

  Parameters: int4, int16

  Return type: Boolean

- int4numericle()

  Description: Compares whether a parameter is less than or equal to another one. If the parameter is less than or equal to another one, **true** is returned. Otherwise, **false** is returned.

  Parameters: int4, numeric

  Return type: Boolean

- int81le()

  Description: Compares whether a parameter is less than or equal to another one. If the parameter is less than or equal to another one, **true** is returned. Otherwise, **false** is returned.

  Parameters: int8, int1

  Return type: Boolean

- int816le()

  Description: Compares whether a parameter is less than or equal to another one. If the parameter is less than or equal to another one, **true** is returned. Otherwise, **false** is returned.

  Parameters: int8, int16

  Return type: Boolean

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- int8numericle()

  Description: Compares whether a parameter is less than or equal to another one. If the parameter is less than or equal to another one, **true** is returned. Otherwise, **false** is returned.

  Parameters: int8, numeric

  Return type: Boolean

- int161le()

  Description: Compares whether a parameter is less than or equal to another one. If the parameter is less than or equal to another one, **true** is returned. Otherwise, **false** is returned.

  Parameters: int16, int1

  Return type: Boolean

- int162le()

  Description: Compares whether a parameter is less than or equal to another one. If the parameter is less than or equal to another one, **true** is returned. Otherwise, **false** is returned.

  Parameters: int16, int2

  Return type: Boolean

- int164le()

  Description: Compares whether a parameter is less than or equal to another one. If the parameter is less than or equal to another one, **true** is returned. Otherwise, **false** is returned.

  Parameters: int16, int4

  Return type: Boolean

- int168le()

  Description: Compares whether a parameter is less than or equal to another one. If the parameter is less than or equal to another one, **true** is returned. Otherwise, **false** is returned.

  Parameters: int16, int8

  Return type: Boolean

- numericint1le()

  Description: Compares whether a parameter is less than or equal to another one. If the parameter is less than or equal to another one, **true** is returned. Otherwise, **false** is returned.

  Parameters: numeric, int1

  Return type: Boolean

- numericint2le()

  Description: Compares whether a parameter is less than or equal to another one. If the parameter is less than or equal to another one, **true** is returned. Otherwise, **false** is returned.

  Parameters: numeric, int2

  Return type: Boolean

- numericint4le()

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description: Compares whether a parameter is less than or equal to another one. If the parameter is less than or equal to another one, **true** is returned. Otherwise, **false** is returned.

Parameters: numeric, int4

Return type: Boolean

- numericint8le()

  Description: Compares whether a parameter is less than or equal to another one. If the parameter is less than or equal to another one, **true** is returned. Otherwise, **false** is returned.

  Parameters: numeric, int8

  Return type: Boolean

- int12ge()

  Description: Compares whether a parameter is greater than or equal to another one. If the parameter is greater than or equal to another one, **true** is returned. Otherwise, **false** is returned.

  Parameters: int1, int2

  Return type: Boolean

- int14ge()

  Description: Compares whether a parameter is greater than or equal to another one. If the parameter is greater than or equal to another one, **true** is returned. Otherwise, **false** is returned.

  Parameters: int1, int4

  Return type: Boolean

- int18ge()

  Description: Compares whether a parameter is greater than or equal to another one. If the parameter is greater than or equal to another one, **true** is returned. Otherwise, **false** is returned.

  Parameters: int1, int8

  Return type: Boolean

- int116ge()

  Description: Compares whether a parameter is greater than or equal to another one. If the parameter is greater than or equal to another one, **true** is returned. Otherwise, **false** is returned.

  Parameters: int1, int16

  Return type: Boolean

- int1numericge()

  Description: Compares whether a parameter is greater than or equal to another one. If the parameter is greater than or equal to another one, **true** is returned. Otherwise, **false** is returned.

  Parameters: int1, numeric

  Return type: Boolean

- int21ge()

  Description: Compares whether a parameter is greater than or equal to another one. If the parameter is greater than or equal to another one, **true** is returned. Otherwise, **false** is returned.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameters: int2, int1

Return type: Boolean

- int216ge()

  Description: Compares whether a parameter is greater than or equal to another one. If the parameter is greater than or equal to another one, **true** is returned. Otherwise, **false** is returned.

  Parameters: int2, int16

  Return type: Boolean

- int2numericge()

  Description: Compares whether a parameter is greater than or equal to another one. If the parameter is greater than or equal to another one, **true** is returned. Otherwise, **false** is returned.

  Parameters: int2, numeric

  Return type: Boolean

- int41ge()

  Description: Compares whether a parameter is greater than or equal to another one. If the parameter is greater than or equal to another one, **true** is returned. Otherwise, **false** is returned.

  Parameters: int4, int1

  Return type: Boolean

- int416ge()

  Description: Compares whether a parameter is greater than or equal to another one. If the parameter is greater than or equal to another one, **true** is returned. Otherwise, **false** is returned.

  Parameters: int4, int16

  Return type: Boolean

- int4numericge()

  Description: Compares whether a parameter is greater than or equal to another one. If the parameter is greater than or equal to another one, **true** is returned. Otherwise, **false** is returned.

  Parameters: int4, numeric

  Return type: Boolean

- int81ge()

  Description: Compares whether a parameter is greater than or equal to another one. If the parameter is greater than or equal to another one, **true** is returned. Otherwise, **false** is returned.

  Parameters: int8, int1

  Return type: Boolean

- int816ge()

  Description: Compares whether a parameter is greater than or equal to another one. If the parameter is greater than or equal to another one, **true** is returned. Otherwise, **false** is returned.

  Parameters: int8, int16

  Return type: Boolean

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- int8numericge()

  Description: Compares whether a parameter is greater than or equal to another one. If the parameter is greater than or equal to another one, **true** is returned. Otherwise, **false** is returned.

  Parameters: int8, numeric

  Return type: Boolean

- int161ge()

  Description: Compares whether a parameter is greater than or equal to another one. If the parameter is greater than or equal to another one, **true** is returned. Otherwise, **false** is returned.

  Parameters: int16, int1

  Return type: Boolean

- int162ge()

  Description: Compares whether a parameter is greater than or equal to another one. If the parameter is greater than or equal to another one, **true** is returned. Otherwise, **false** is returned.

  Parameters: int16, int2

  Return type: Boolean

- int164ge()

  Description: Compares whether a parameter is greater than or equal to another one. If the parameter is greater than or equal to another one, **true** is returned. Otherwise, **false** is returned.

  Parameters: int16, int4

  Return type: Boolean

- int168ge()

  Description: Compares whether a parameter is greater than or equal to another one. If the parameter is greater than or equal to another one, **true** is returned. Otherwise, **false** is returned.

  Parameters: int16, int8

  Return type: Boolean

- numericint1ge()

  Description: Compares whether a parameter is greater than or equal to another one. If the parameter is greater than or equal to another one, **true** is returned. Otherwise, **false** is returned.

  Parameters: numeric, int1

  Return type: Boolean

- numericint2ge()

  Description: Compares whether a parameter is greater than or equal to another one. If the parameter is greater than or equal to another one, **true** is returned. Otherwise, **false** is returned.

  Parameters: numeric, int2

  Return type: Boolean

- numericint4ge()

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description: Compares whether a parameter is greater than or equal to another one. If the parameter is greater than or equal to another one, **true** is returned. Otherwise, **false** is returned.

Parameters: numeric, int4

Return type: Boolean

- numericint8ge()

  Description: Compares whether a parameter is greater than or equal to another one. If the parameter is greater than or equal to another one, **true** is returned. Otherwise, **false** is returned.

  Parameters: numeric, int8

  Return type: Boolean

- timestamp_in

  Description: Converts the input cstring type to the timestamp type.

  Parameter: cstring

  Return type: timestamp

- timestamp_out

  Description: Converts the timestamp type to the cstring type.

  Parameter: timestamp

  Return type: cstring

- datea_cmp

  Description: Compares two parameters. If the first parameter is greater than the second parameter, **1** is returned. If the first parameter is less than the second parameter, **–1** is returned. If the two parameters are equal, **0** is returned.

  Parameters: datea, datea

  Return type: int4

- datea_eq

  Description: Compares whether two parameter values are equal. If they are equal, **true** is returned. Otherwise, **false** is returned.

  Parameters: datea, datea

  Return type: Boolean

- datea_ge

  Description: Returns **true** if the first parameter is greater than or equal to the second parameter; otherwise, returns **false**.

  Parameters: datea, datea

  Return type: Boolean

- datea_gt

  Description: Returns **true** if the first parameter is greater than the second parameter; otherwise, returns **false**.

  Parameters: datea, datea

  Return type: Boolean

- datea_le

  Description: Returns **true** if the first parameter is less than or equal to the second parameter; otherwise, returns **false**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameters: datea, datea

Return type: Boolean

- datea_lt

  Description: Returns **true** if the first parameter is less than the second parameter; otherwise, returns **false**.

  Parameters: datea, datea

  Return type: Boolean

- datea_neq

  Description: Compares whether two parameter values are equal. If they are not equal, **true** is returned. Otherwise, **false** is returned.

  Parameters: datea, datea

  Return type: Boolean

- datea_pl_interval

  Description: Returns the result of adding the datea type to the interval type.

  Parameters: datea, interval

  Return type: datea

- interval_pl_datea

  Description: Returns the result of adding the interval type to the datea type.

  Parameters: interval, datea

  Return type: datea

- datea_pl_float4

  Description: Adds a float4 type value to a datea type value and returns the result.

  Parameters: **datea** and **float4**.

  Return type: datea

- float4_pl_datea

  Description: Adds a datea type value to a float4 type value and returns the result.

  Parameters: **float4** and **datea**.

  Return type: datea

- datea_pl_float8

  Description: Adds a float8 type value to a datea type value and returns the result.

  Parameters: **datea** and **float8**.

  Return type: datea

- float8_pl_datea

  Description: Adds a datea type value to a float8 type value and returns the result.

  Parameters: **float8** and **datea**.

  Return type: datea

- datea_pl_int8

  Description: Adds an int8 type value to a datea type value and returns the result.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameters: **datea** and **int8**.

Return type: datea

- int8_pl_datea

  Description: Adds a datea type value to an int8 type value and returns the result.

  Parameters: **int8** and **datea**.

  Return type: datea

- datea_pl_text

  Description: Subtracts a text type value from a datea type value and returns the result.

  Parameters: **datea** and **text**.

  Return type: datea

- text_pl_datea

  Description: Adds a datea type value to a text type value and returns the result.

  Parameters: **text** and **datea**.

  Return type: datea

- numeric_pl_datea

  Description: Adds a datea type value to a numeric type value and returns the result.

  Parameters: **numeric** and **datea**.

  Return type: datea

- datea_mi_interval

  Description: Returns the result of subtracting the datea type from the interval type.

  Parameters: datea, interval

  Return type: datea

- datea_mi

  Description: Returns the subtraction result of two datea types.

  Parameters: datea, datea

  Return type: numeric

- datea_mi_timestamp

  Description: Returns the result of subtracting the datea type from the timestamp type.

  Parameters: datea, timestamp

  Return type: interval

- timestamp_mi_datea

  Description: Returns the result of subtracting the timestamp type from the datea type.

  Parameters: timestamp, datea

  Return type: interval

- datea_mi_float4

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description: Subtracts a float4 type value from a datea type value and returns the result.

Parameters: **datea** and **float4**.

Return type: datea

- datea_mi_float8

  Description: Subtracts a float8 type value from a datea type value and returns the result.

  Parameters: **datea** and **float8**.

  Return type: datea

- datea_mi_int8

  Description: Subtracts an int8 type value from a datea type value and returns the result.

  Parameters: **datea** and **int8**.

  Return type: datea

- datea_mi_numeric

  Description: Subtracts a numeric type value from a datea type value and returns the result.

  Parameters: **datea** and **numeric**.

  Return type: datea

- datea_mi_text

  Description: Subtracts a text type value from a datea type value and returns the result.

  Parameters: **datea** and **text**.

  Return type: datea

- datea_larger

  Description: Returns the larger value of two datea types.

  Parameters: datea, datea

  Return type: datea

- datea_smaller

  Description: Returns the smaller value of two datea types.

  Parameters: datea, datea

  Return type: datea

- datea_in

  Description: Converts the input cstring type to the datea type.

  Parameter: cstring

  Return type: datea

- datea_out

  Description: Converts the datea type to the cstring type.

  Parameter: datea

  Return type: cstring

- datea_recv

  Description: Converts binary data to the datea type.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter: internal

Return type: datea

- datea_send

  Description: Converts the datea type to binary data.

  Parameter: datea

  Return type: bytea

- rowid_cmp(rowid, rowid)

  Description: Compares two parameters. If the first parameter is greater than the second parameter, **1** is returned. If the first parameter is less than the second parameter, **–1** is returned. If the two parameters are equal, **0** is returned.

  Parameters: rowid and rowid.

  Return type: int4

- rowid_eq(rowid, rowid)

  Description: Compares whether two parameter values are equal. If they are equal, **true** is returned. Otherwise, **false** is returned.

  Parameters: rowid and rowid.

  Return type: Boolean

- rowid_ge(rowid, rowid)

  Description: Returns **true** if the first parameter is greater than or equal to the second parameter; otherwise, returns **false**.

  Parameters: rowid and rowid.

  Return type: Boolean

- rowid_gt(rowid, rowid)

  Description: Returns **true** if the first parameter is greater than the second parameter; otherwise, returns **false**.

  Parameters: rowid and rowid.

  Return type: Boolean

- rowid_le(rowid, rowid)

  Description: Returns **true** if the first parameter is less than or equal to the second parameter; otherwise, returns **false**.

  Parameters: rowid and rowid.

  Return type: Boolean

- rowid_lt(rowid, rowid)

  Description: Returns **true** if the first parameter is less than the second parameter; otherwise, returns **false**.

  Parameters: rowid and rowid.

  Return type: Boolean

- rowid_ne(rowid, rowid)

  Description: Compares whether two parameter values are equal. If they are not equal, **true** is returned. Otherwise, **false** is returned.

  Parameters: rowid and rowid.

  Return type: Boolean

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- rowid_larger(rowid, rowid)

  Description: Returns the larger value of two rowid types.

  Parameters: rowid and rowid.

  Return type: rowid.
- rowid_smaller(rowid, rowid)

  Description: Returns the smaller value of two rowid types.

  Parameters: rowid and rowid.

  Return type: rowid.
- rowid_in(cstring)

  Description: Converts the input cstring type to the rowid type.

  Parameter: cstring

  Return type: rowid.
- rowid_out(rowid)

  Description: Converts the rowid type to the cstring type.

  Parameter: rowid

  Return type: cstring
- rowid_recv(internal)

  Description: Converts binary data to the rowid type.

  Parameter: internal

  Return type: rowid.
- rowid_send(rowid)

  Description: Converts the rowid type to binary data.

  Parameter: rowid

  Return type: bytea
- gs_relation_is_updatable()

  Description: Returns whether a relationship can be inserted, updated, or deleted. If the value can be updated, **4** is returned. If the value can be inserted, **8** is returned. If the value can be deleted, **16** is returned. If the value meets the requirements, the value obtained by adding the corresponding values is returned.

  Parameters: OID, Boolean

  Return type: int32
- gs_column_is_updatable()

  Description: Returns whether a column can be updated. If the column can be updated, **t** is returned. Otherwise, **f** is returned.

  Parameters: OID, int16, Boolean

  Return type: Boolean
- hash_meet_partition(partition_num, hash_key_name1, hash_key_name2)

  Description: Calculates the hash partition where a tuple is located when an online DDL statement is used to exchange partitions. Returns the index of the partition where the tuple is located.

  Parameter: int32, text

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Return type: int32

Parameter	Type	Description	Value Range
partition_num	int32	Total number of partitions in a partitioned table.	-
hash_key_name	text	Partition key name of the hash partitioned table. The number of variable parameters is the same as the number of partition keys.	-

Example:

```
-- Create a table.
gaussdb=# CREATE TABLE t1(c1 INT,c2 INT) PARTITION BY HASH(c2)
(
    PARTITION P1,
    PARTITION P2,
    PARTITION P3
);

gaussdb=# INSERT INTO t1 VALUES(generate_series(1,10), generate_series(1,10));

gaussdb=# SELECT * FROM t1 WHERE hash_meet_partition(3, c2) = 0;
 c1 | c2
----+----
  1 |  1
  4 |  4
  8 |  8
  9 |  9
 10 | 10
(5 rows)

gaussdb=# SELECT * FROM t1 partition (p1);
 c1 | c2
----+----
  1 |  1
  4 |  4
  8 |  8
  9 |  9
 10 | 10
(5 rows)
```

- online_ddl_cleanup(relschema, relname)

  Description: Clears and restores temporary tools when a fault occurs during online DDL or online VACUUM FULL execution.

  Parameters: text, text

  Return type: text

Parameter	Type	Description	Value Range
relschema	text	Schema of a table.	-
relname	text	Name of a table.	-

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- **online_ddl_cleanup** is not supported on the standby node.
- After a fault occurs, the temporary status of the table is automatically cleared when the online DDL or online VACUUM FULL is executed next time.

Example:

```
-- Create a table.
gaussdb=# CREATE TABLE t1(c1 int, c2 int);
-- Execute the online DDL.
gaussdb=# ALTER TABLE ONLINE t1 ALTER c2 type BIGINT;

-- Clear a fault after it occurs.
gaussdb=# SELECT online_ddl_cleanup('public','t1');
 online_ddl_cleanup
--------------------
 cleanup success
(1 row)
```

- gs_stat_progress_online_ddl(relschema, relname)

  Description: Queries the status and progress of the ongoing online VACUUM FULL operation in the system.

  Parameters: Both parameters can be left empty, set to **NULL**, or not set to **NULL** at the same time.

  Return type: table. Each row represents a phase of a DDL operation.

Parameter	Type	Description	Value Range
relschema	cstring	Schema where online VACUUM FULL is executed.	-
relname	cstring	Name of the table where online VACUUM FULL is executed.	-

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

1. In the current version, only the progress of online VACUUM FULL can be monitored. The progress of other online DDL operations cannot be monitored.
2. If the **relschema** and **relname** parameters are not empty, you can query the residual online DDL information of the table. If both **relschema** and **relname** are null or left empty, you can query information about all online VACUUM FULL operations that are being executed.
3. The temporary table of online DDL operations is located in the **online$$ddl$$ [***Hash value of (Schema name of the table + Table name)***]** schema.
4. If the GUC parameter **delete_cctmp_table** is set to **on**, the schema of the temporary table will be deleted after the online DDL operation is complete. If this parameter is set to **off**, the schema will be renamed to **online$$ddl$$[***Hash value of (Schema name of the table + Table name)***]_[***Date and time***]**.
5. If the current user is the initial user or a system administrator, the user can query the progress of all online VACUUM FULL operations that are being executed. If the current user is a common user, the user can only query the progress of the tasks executed by themselves.
6. The progress monitoring information is quasi-real-time. That is, the monitoring function returns the latest phase in real time, but the progress information in each phase is not updated in real time.

Example:

```
-- Session 1: Execute online VACUUM FULL.
gaussdb=# VACUUM FULL t1 online;
-- Session 2: Execute the progress monitoring function.
gaussdb=# \x -- Modify the output formatting.
gaussdb=# select * from gs_stat_progress_online_ddl('public', 't1') ;

| }
```

The meaning of each field is as follows.

Parameter	Description
pid	Process ID.
node_name	Name of the node where the statement is executed.
phase_id	Phase number, which increases in ascending order.
rel_schema	Schema of a table.
rel_name	Table name.
sql_command	Executed SQL statement.
started_time	Time when the SQL statement starts to be executed.
elapsed_time	End time of the query.
phase_name	Name of the online DDL execution phase, including **Initialization**, **Base data copy**, **Reindexing**, **Catchup** *<N>*, and **Last catchup**.
phase_started_time	Start time of the phase.
phase_elapsed_time	Actual execution time of the phase.
lock_level	Lock level.
lock_try_times	Number of attempts to obtain the lock. Value range: • Greater than or equal to 1: The lock has been obtained. • **0**: The lock has not been obtained, or the lock has been obtained but the progress information is not updated in real time.
lock_hold_time	Duration of holding the lock.
phase_detail	Detailed information about the current phase. The information displayed in each phase is in JSON format and may vary.

- The **phase_detail** information in the **Initialization** phase is empty.
- The **phase_detail** information in the **Base data copy** phase contains the following fields:

Parameter	Description
total_pages	Estimated number of pages to be inserted.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Description
inserted_rows	Number of rows that have been inserted. This value is updated after the phase ends.
insert_speed	Actual insertion rate. This value is updated after the phase ends.
parallel_threads	Value of the **parallel_threads** parameter to be used or actually used in this phase. If a table contains an expression index, indexes cannot be built in parallel, and the value of **parallel_threads** is always **1**.

- The **phase_detail** column in the **Reindexing** phase contains the following fields:

Parameter	Description
total_indexes	Total number of indexes to be rebuilt.
indexes_rebuilt	Number of indexes that have been rebuilt.
parallel_threads	Value of **parallel_threads** to be used or actually used in this phase. If a table contains an expression index, indexes cannot be built in parallel, and the value of **parallel_threads** is always **1**.
parallel_workers	**parallel_workers** option of the source table. For details, see the description of **parallel_workers** in **ALTER TABLE**.

NOTE

During online DDL execution, two additional indexes are created for the generated temporary table. (The temporary table is located in the **online$$ddl$$[***Hash value of (Schema of the table + Table name)***]** schema. Therefore, the value of **total_index** is equal to the number of indexes created by users plus 2.

When indexes are built in parallel, the value of **indexes_rebuilt** may not be updated in real time.

- The **phase_detail** information in the **Catchup** *<N>* phase contains the following fields:

Parameter	Description
short_lock_level	Level of the strong lock that is held for a short period of time when the catchup phase starts.
short_lock_try_times	Number of retries to obtain a strong lock when the catchup phase starts.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Description
short_lock_hold_time	Duration of holding a strong lock for a short period of time when the catchup phase starts.
total_delete_pages	Estimated number of pages to be deleted.
total_insert_pages	Estimated number of pages to be inserted.
deleted_rows	Number of rows that are actually deleted. The value is updated after the phase ends.
delete_speed	Actual deletion speed. The value is updated after the phase ends.
inserted_rows	Number of rows that have been inserted. This value is updated after the phase ends.
insert_speed	Actual insertion speed. The value is updated after the phase ends.
last_catchup_threshold	Value of **last_catchup_threshold** to be used or actually used when this phase is executed.
max_catchup_times	Value of **max_catchup_times** to be used or actually used when this phase is executed.

- The **phase_detail** information in the **Last catchup** phase contains the following fields:

Parameter	Description
total_delete_pages	Estimated number of pages to be deleted.
total_insert_pages	Estimated number of pages to be inserted.
deleted_rows	Number of rows that are actually deleted. The value is updated after the phase ends.
delete_speed	Actual deletion speed. The value is updated after the phase ends.
inserted_rows	Number of rows that have been inserted. This value is updated after the phase ends.
insert_speed	Actual insertion speed. The value is updated after the phase ends.
last_catchup_threshold	Value of **last_catchup_threshold** to be used or actually used when this phase is executed.
max_catchup_times	Value of **max_catchup_times** to be used or actually used when this phase is executed.
total_gpis	Number of GPIs to be rebuilt. This parameter is displayed only when the DDL operation is partition-level VACUUM FULL.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Description
gpis_rebuilt	Number of GPIs that have been rebuilt. In the current version, the value of this parameter is not updated in real time. It is updated to the value of **total_GPIs** only after all GPIs are rebuilt. This field is displayed only when the online VACUUM FULL operation is performed at the partition level.
parallel_workers	**parallel_workers** option of the source table. For details, see the description of **parallel_workers** in **ALTER TABLE**.

NOTE

In the index rebuild phase, the number of parallel workers is affected by both the online DDL parameter **parallel_threads** and the table size. However, in the last catchup process, the number of parallel workers is not affected by the online DDL parameter **parallel_threads**.

- gs_online_ddl_set_parameters(relschema, relname, params)

  Description: Dynamically modifies parameters during the execution of online DDL operations or online VACUUM FULL.

  Parameters:

  - **relschema**: schema name of the table. The type is cstring and the value cannot be empty.
  - **relname**: table name. The type is cstring and the value cannot be empty.
  - **params**: optional parameters. The type is variable-length text[]. It indicates the key-value pairs of the parameters to be modified. The format is 'key', 'value'. Multiple parameters can be updated at a time.
    - If **params** is specified, the parameters are modified based on the key-value pairs. A maximum of seven key-value pairs are supported. The key must be a parameter supported by the system, and the value must be a valid value within the supported range of the parameter.
    - If **params** is not specified, the query is executed and all parameter values supported by the function are returned.
    - If a parameter is entered for multiple times, the parameter value is not within the supported range, or the number of key-value pairs exceeds seven, an error is reported.

  NOTE

  - Parameter verification rule: Only the parameters in the whitelist and their valid values are processed. Otherwise, an error is reported.
  - Permission control rule: Only the system administrators, initial user, and users who have the VACUUM FULL permission can modify and query parameter information.

  Return type: multiple columns of text in one row. All parameter values of the online DDL operation being executed on the specified table are returned.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Example:

```
gaussdb=# CREATE TABLE t1(c1 int, c2 int);

-- Session 1: Perform online VACUUM FULL.
gaussdb=# VACUUM FULL t1 online;
-- Session 2:
gaussdb=# SELECT * from gs_online_ddl_set_parameters('public', 't1', 'last_catchup_threshold', '10000',
'max_catchup_times', '30','parallel_threads', '2','online_ddl_lockwait_timeout', '10', 'lockwait_interval',
'10', 'trylock_threshold', '1', 'enable_cancel', 'true');
 parallel_threads | last_catchup_threshold | max_catchup_times | online_ddl_lockwait_timeout |
lockwait_interval | trylock_threshold | enable_cancel
------------------+------------------------+-------------------+-----------------------------+-------------------
+-------------------+---------------
 2                | 10000                  | 30                | 10                          | 10                | 1                 | true
(1 row)
```

The supported parameters are as follows:

- **parallel_threads**: controls multi-thread parallel operations to achieve higher performance when resources are sufficient. The value is an integer ranging from 1 to 32. The default value is **1**.
  - When resource control is enabled (for example, **io_limits** set to a value greater than 0 or **io_priority** set to **high**, **medium**, or **low**), setting **parallel_threads** will forcibly enable multi-threading, ignoring the current user- or session-level resource control and displaying a message indicating invalid resource control. The online VACUUM FULL operation in multi-thread mode complies with the resource control of the initial user.
  - This parameter can be set together with the **parallel_workers** parameter that controls the degree of parallelism for index build during VACUUM FULL. The **parallel_threads** parameter controls the degree of parallelism for the catchup phase during VACUUM FULL.
- **max_catchup_times**: controls the maximum number of catchups. This parameter is used to prevent the execution of VACUUM FULL from taking a long time. The value is an integer ranging from 1 to *INT_MAX*. The default value is **50**.
  - Online VACUUM FULL execution records the IUD incremental data generated during data rebuild to a temporary table and rebuilds the incremental data in multiple rounds of catchups. To prevent VACUUM FULL catchup failures due to a large number of concurrent IUD operations, you can set this parameter to limit the number of catchups.
- **last_catchup_threshold**: specifies the upper limit of the time for triggering the last catchup. After a catchup round is complete, if the duration of this round is less than the threshold, the last round of catchup and switchover is triggered. Value range: [1000,1200000] (unit: ms). The default value is **5000**.
- **online_ddl_lockwait_timeout**: specifies the lock wait timeout interval for online DDL operations. If the thread waiting for the lock fails to obtain the lock within the specified time, a lock timeout error is reported. When the **CANCEL** mode is triggered to obtain a lock, the actual timeout interval is twice the value of this parameter. Value range: [1,1200000] (unit: ms). The default value is **10000**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

  - **lockwait_interval**: specifies the lock wait increment. That is, the retry interval when the lock wait times out consecutively. If the lock wait times out in the current round, the system waits for the period specified by this parameter and then attempts to obtain the lock in the next round. Value range: [0,300] (unit: seconds). The default value is **5**.
  - **trylock_threshold**: indicates the maximum number of lock wait attempts. It must be used together with **enable_cancel**. If the lock cannot be obtained due to lock wait timeout after the maximum number of attempts is reached, the **CANCEL** mode will be used for the next attempt. If **enable_cancel** is not enabled, the lock fails to be obtained and an error is reported after the maximum number of attempts is reached. Value range: [1,*INT_MAX*] or **-1** (indicating no upper limit). The default value is **-1**.
  - **enable_cancel**: specifies whether services can be canceled. That is, when the number of lock attempts reaches the upper limit or the level-8 lock of the user table is obtained during the table switching transaction, user services are quickly terminated to ensure that the online DDL operation can successfully obtain the lock. The value can be **false** or **true**. The default value is **false**.

- anynesttable_out(anynesttable)

  Description: Converts anynesttable into cstring.

  Parameter: **anynesttable**.

  Return type: cstring.

- nesttable_count(a nesttable)

  Description: Returns the number of elements in **nesttable**.

  Parameter: **nesttable**.

  Return type: int.

- nesttable_delete(a nesttable)

  Description: Deletes all elements from **nesttable**.

  Parameter: **nesttable**.

  Return type: nesttable.

- nesttable_delete(a nesttable, index int)

  Description: Deletes the element at the specified index from **nesttable** if the index falls within the range of **nesttable**.

  Parameters: **nesttable** and **int**.

  Return type: nesttable.

- nesttable_delete(a nesttable, lower int, upper int)

  Description: Deletes elements within the specified index range *[lower,upper]* from **nesttable** if the indexes from *lower* to *upper* fall within the range of **nesttable**.

  Parameters: **nesttable**, **int**, and **int**.

  Return type: nesttable.

- nesttable_eq(a nesttable, b nesttable)

  Description: Checks whether two **nesttable** parameters are equal.

  Parameters: **nesttable** and **nesttable**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Return type: Boolean.

- nesttable_except(a nesttable, b nesttable)

  Description: Obtains the difference set of two **nesttable** parameters.

  Parameters: **nesttable** and **nesttable**.

  Return type: nesttable.

- nesttable_except_distinct(a nesttable, b nesttable)

  Description: Obtains the deduplicated difference set of two **nesttable** parameters.

  Parameters: **nesttable** and **nesttable**.

  Return type: nesttable.

- nesttable_exists(a nesttable, index int)

  Description: Checks whether an element exists at the specified index in **nesttable**.

  Parameters: **nesttable** and **int**.

  Return type: nesttable.

- nesttable_extend(a nesttable, cnt int)

  Description: Extends **nesttable** by appending *cnt* elements to it.

  Parameters: **nesttable** and **int**.

  Return type: nesttable.

- nesttable_extend(a nesttable, cnt int, index int)

  Description: Extends **nesttable** by appending *cnt* elements to it and assigning the element value at the specified index to these new elements.

  Parameters: **nesttable**, **int**, and **int**.

  Return type: nesttable.

- nesttable_first(a nesttable)

  Description: Returns the index of the first valid element in **nesttable**, or returns NULL if none is found.

  Parameter: **nesttable**.

  Return type: int.

- nesttable_in(str cstring, oid Oid, typmod int)

  Description: Converts a character string into nesttable with the specified OID.

  Parameters: **cstring**, **Oid**, and **int**.

  Return type: nesttable.

- nesttable_intersect(a nesttable, b nesttable)

  Description: Obtains the intersection of two **nesttable** parameters.

  Parameters: **nesttable** and **nesttable**.

  Return type: nesttable.

- nesttable_intersect_distinct(a nesttable, b nesttable)

  Description: Obtains the deduplicated intersection of two **nesttable** parameters.

  Parameters: **nesttable** and **nesttable**.

  Return type: nesttable.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- nesttable_last(a nesttable)

  Description: Returns the index of the last valid element in **nesttable**, or returns NULL if none is found.

  Parameter: **nesttable**.

  Return type: int.
- nesttable_ne(a nesttable, b nesttable)

  Description: Checks whether two **nesttable** parameters are unequal.

  Parameters: **nesttable** and **nesttable**.

  Return type: Boolean.
- nesttable_next(a nesttable, index int)

  Description: Returns the index of the next valid element following the specified index in **nesttable**, or returns NULL if none is found.

  Parameters: **nesttable** and **int**.

  Return type: int.
- nesttable_out(a nesttable)

  Description: Converts nesttable into cstring.

  Parameter: **nesttable**.

  Return type: cstring.
- nesttable_prior(a nesttable, index int)

  Description: Returns the index of the previous valid element before the specified index in **nesttable**, or returns NULL if none is found.

  Parameters: **nesttable** and **int**.

  Return type: int.
- nesttable_trim(a nesttable, cnt int)

  Description: Deletes *cnt* elements from the end of **nesttable** to free up storage space.

  Parameters: **nesttable** and **int**.

  Return type: int.
- nesttable_union(a nesttable, b nesttable)

  Description: Obtains the union of two **nesttable** parameters.

  Parameters: **nesttable** and **nesttable**.

  Return type: nesttable.
- nesttable_union_distinct(a nesttable, b nesttable)

  Description: Obtains the deduplicated union of two **nesttable** parameters.

  Parameters: **nesttable** and **nesttable**.

  Return type: nesttable.
- anyindexbytable_out(anyindexbytable)

  Description: Converts anyindexbytable into cstring.

  Parameter: **anyindexbytable**.

  Return type: cstring.
- indexbytable_count(a indexbytable)

  Description: Returns the number of elements in **indexbytable**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter: **indexbytable**.

Return type: int.

- indexbytable_in(str cstring, oid Oid)

  Description: Converts a character string into indexbytable with the specified OID.

  Parameters: **cstring** and **Oid**.

  Return type: indexbytable.

- indexbytable_out(a indexbytable)

  Description: Converts indexbytable into cstring.

  Parameter: **indexbytable**.

  Return type: cstring.

- indexbytableint_delete(a indexbytable)

  Description: Deletes all elements from **indexbytable**.

  Parameter: **indexbytable**.

  Return type: indexbytable.

- indexbytableint_delete(a indexbytable, index int)

  Description: Deletes the element at the specified index from **indexbytable** if the index falls within the range of **indexbytable**.

  Parameters: **indexbytable** and **int**.

  Return type: indexbytable.

- indexbytableint_delete(a indexbytable, lower int, upper int)

  Description: Deletes elements within the specified index range *[lower,upper]* from **indexbytable**.

  Parameters: **indexbytable**, **int**, and **int**.

  Return type: indexbytable.

- indexbytableint_exists(a indexbytable, index int)

  Description: Checks whether an element exists at the specified index in **indexbytable**.

  Parameters: **indexbytable** and **int**.

  Return type: indexbytable.

- indexbytableint_first(a indexbytable)

  Description: Returns the index of the first valid element in **indexbytable**, or returns NULL if none is found.

  Parameter: **indexbytable**.

  Return type: int.

- indexbytableint_last(a indexbytable)

  Description: Returns the index of the last valid element in **indexbytable**, or returns NULL if none is found.

  Parameter: **indexbytable**.

  Return type: int.

- indexbytableint_next(a indexbytable, index int)

  Description: Returns the index of the next valid element following the specified index in **indexbytable**, or returns NULL if none is found.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameters: **indexbytable** and **int**.

Return type: int.

- indexbytableint_prior(a indexbytable, index int)

  Description: Returns the index of the previous valid element before the specified index in **indexbytable**, or returns NULL if none is found.

  Parameters: **indexbytable** and **int**.

  Return type: int.

- indexbytablevarchar_delete(a indexbytable)

  Description: Deletes all elements from **indexbytable**.

  Parameter: **indexbytable**.

  Return type: indexbytable.

- indexbytablevarchar_delete(a indexbytable, index varchar)

  Description: Deletes the element at the specified index from **indexbytable** if the index falls within the range of **indexbytable**.

  Parameters: **indexbytable** and **varchar**.

  Return type: indexbytable.

- indexbytablevarchar_delete(a indexbytable, lower varchar, upper varchar)

  Description: Deletes elements within the specified index range *[lower,upper]* from **indexbytable**.

  Parameters: **indexbytable**, **varchar**, and **varchar**.

  Return type: indexbytable.

- indexbytablevarchar_exists(a indexbytable, index varchar)

  Description: Checks whether an element exists at the specified index in **indexbytable**.

  Parameters: **indexbytable** and **varchar**.

  Return type: indexbytable.

- indexbytablevarchar_first(a indexbytable)

  Description: Returns the index of the first valid element in **indexbytable**, or returns NULL if none is found.

  Parameter: **indexbytable**.

  Return type: varchar.

- indexbytablevarchar_last(a indexbytable)

  Description: Returns the index of the last valid element in **indexbytable**, or returns NULL if none is found.

  Parameter: **indexbytable**.

  Return type: varchar.

- indexbytablevarchar_next(a indexbytable, index varchar)

  Description: Returns the index of the next valid element following the specified index in **indexbytable**, or returns NULL if none is found.

  Parameters: **indexbytable** and **varchar**.

  Return type: varchar.

- indexbytablevarchar_prior(a indexbytable, index varchar)

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description: Returns the index of the previous valid element before the specified index in **indexbytable**, or returns NULL if none is found.

Parameters: **indexbytable** and **varchar**.

Return type: varchar.

- gs_partitioned_temp_fix_filenode()

  Description: Creates physical files for the partitioned tables and local indexes present on the source version during a version upgrade. If the creation is successful, the function will return **true**. If the physical files for the original objects (partitioned tables and local indexes on the source version) already exist, the function will return **false**. This function can be executed only during upgrades and by system administrators.

  Parameter: regclass

  Return type: Boolean

- double_backslash(input)

  Description: Double writes the backslash character in the LIKE matching logic of a single backslash character. The input can be of the text, bpchar, bytea, raw, or byteawithoutorderwithequalcol type.

  Parameters: text | bpchar | bytea | raw | byteawithoutorderwithequalcol

  Return type: same as the input parameter type.

1.6.61 Deprecated Functions

The following GaussDB functions have been deprecated in the current version:

- gs_wlm_get_session_info
- gs_wlm_get_user_session_info

1.6.62 Vector Data Functions and Operators

1.6.62.1 Vector Distance Calculation APIs

l2_distance

Description: Calculates the Euclidean distance between two vectors.

Type of input parameter 1: floatvector

Type of input parameter 2: floatvector

Output parameter type: float8

Code example:

```
gaussdb=# SELECT l2_distance(floatvector('[1,2,3]'), floatvector('[5,-1,3.5]'));
gaussdb=# SELECT l2_distance('[1,2,3]',  '[5,-1,3.5]');
```

vector_l2_squared_distance

Description: Calculates the square of the Euclidean distance between two vectors.

Type of input parameter 1: floatvector

Type of input parameter 2: floatvector

Output parameter type: float8

Code example:

```
gaussdb=# SELECT vector_l2_squared_distance(floatvector('[1,2,3]'), floatvector('[5,-1,3.5]'));
gaussdb=# SELECT vector_l2_squared_distance('[1,2,3]',  '[5,-1,3.5]');
```

cosine_distance

Description: Calculates the cosine distance between two vectors.

Type of input parameter 1: floatvector

Type of input parameter 2: floatvector

Output parameter type: float8

Code example:

```
gaussdb=# select cosine_distance(floatvector('[1,2,3]'), floatvector('[5,-1,3.5]'));
gaussdb=# select cosine_distance('[1,2,3]', '[5,-1,3.5]');
```

vector_spherical_distance

Description: Calculates the spherical distance between two normalized vectors (represented by the radian system of the cosine angle).

Type of input parameter 1: floatvector

Type of input parameter 2: floatvector

Output parameter type: float8

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Code example:

```
gaussdb=#  select vector_spherical_distance('[1,0,0,0]', '[0,0,0,1]');
```

NOTE

If the input vector is not normalized, the correct calculation result cannot be obtained.

1.6.62.2 Vector Operation Functions

The vector operation functions include: vector size comparison, vector addition, vector subtraction, and vector bitwise multiplication.

inner_product

Description: Calculates the inner product of two vectors.

Type of input parameter 1: floatvector

Type of input parameter 2: floatvector

Output parameter type: float8

Code example:

```
gaussdb=# SELECT inner_product(floatvector('[1,2,3]'), floatvector('[5,-1,3.5]'));
gaussdb=# SELECT inner_product('[1,2,3]', '[5,-1,3.5]');
```

vector_negative_inner_product

Description: Calculates the negative inner product of two vectors.

Type of input parameter 1: floatvector

Type of input parameter 2: floatvector

Output parameter type: float8

Code example:

```
gaussdb=# SELECT vector_negative_inner_product(floatvector('[1,2,3]'), floatvector('[5,-1,3.5]'));
gaussdb=# SELECT vector_negative_inner_product('[1,2,3]', '[5,-1,3.5]');
```

vector_dims

Description: Returns the dimension value of the floatvector vector.

Input parameter type: floatvector

Output parameter type: int4

Code example:

```
gaussdb=# SELECT vector_dims(floatvector('[1,2,3]'));
gaussdb=# SELECT vector_dims('[1,2,3]');
```

vector_norm

Description: Returns the L2 norm of a vector.

Input parameter type: floatvector

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Output parameter type: float8

Code example:

```
gaussdb=# SELECT vector_norm(floatvector('[1,2,3]'));
gaussdb=# SELECT vector_norm('[1,2,3]');
```

vector_add

Description: Calculates the sum of two vectors.

Type of input parameter 1: floatvector

Type of input parameter 2: floatvector

Output parameter type: floatvector

Code example:

```
gaussdb=# SELECT vector_add(floatvector('[1,2,3]'), floatvector('[5,-1,3.5]'));
gaussdb=# SELECT vector_add('[1,2,3]', '[5,-1,3.5]');
```

vector_sub

Description: Calculates the subtraction between two vectors.

Type of input parameter 1: floatvector

Type of input parameter 2: floatvector

Output parameter type: floatvector

Code example:

```
gaussdb=# SELECT vector_sub(floatvector('[1,2,3]'), floatvector('[5,-1,3.5]'));
gaussdb=# SELECT vector_sub('[1,2,3]', '[5,-1,3.5]');
```

vector_lt

Description: Compares vector sizes and checks whether vector 1 is less than vector 2.

Type of input parameter 1: floatvector

Type of input parameter 2: floatvector

Output parameter type: Boolean

Code example:

```
gaussdb=# SELECT vector_lt(floatvector('[1,2,3]'), floatvector('[5,-1,3.5]'));
gaussdb=# SELECT vector_lt('[1,2,3]', '[5,-1,3.5]');
```

vector_le

Description: Compares vector sizes and checks whether vector 1 is less than or equal to vector 2.

Type of input parameter 1: floatvector

Type of input parameter 2: floatvector

Output parameter type: Boolean

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Code example:

```
gaussdb=# SELECT vector_le(floatvector('[1,2,3]'), floatvector('[5,-1,3.5]'));
gaussdb=# SELECT vector_le('[1,2,3]', '[5,-1,3.5]');
```

vector_eq

Description: Compares vectors and checks whether they are equal.

Type of input parameter 1: floatvector

Type of input parameter 2: floatvector

Output parameter type: Boolean

Code example:

```
gaussdb=# SELECT vector_eq(floatvector('[1,2,3]'), floatvector('[5,-1,3.5]'));
gaussdb=# SELECT vector_eq('[1,2,3]', '[5,-1,3.5]');
```

vector_ne

Description: Compares whether two vectors are not equal.

Type of input parameter 1: floatvector

Type of input parameter 2: floatvector

Output parameter type: Boolean

Code example:

```
gaussdb=# SELECT vector_ne(floatvector('[1,2,3]'), floatvector('[5,-1,3.5]'));
gaussdb=# SELECT vector_ne('[1,2,3]', '[5,-1,3.5]');
```

vector_ge

Description: Compares vector sizes and checks whether vector 1 is greater than or equal to vector 2.

Type of input parameter 1: floatvector

Type of input parameter 2: floatvector

Output parameter type: Boolean

Code example:

```
gaussdb=# SELECT vector_ge(floatvector('[1,2,3]'), floatvector('[5,-1,3.5]'));
gaussdb=# SELECT vector_ge('[1,2,3]', '[5,-1,3.5]');
```

vector_gt

Description: Compares vector sizes and checks whether vector 1 is greater than vector 2.

Type of input parameter 1: floatvector

Type of input parameter 2: floatvector

Output parameter type: Boolean

Code example:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gaussdb=# SELECT vector_gt(floatvector('[1,2,3]'), floatvector('[5,-1,3.5]'));
gaussdb=# SELECT vector_gt('[1,2,3]', '[5,-1,3.5]');
```

vector_cmp

Description: Compares vector sizes.

Type of input parameter 1: floatvector

Type of input parameter 2: floatvector

Output parameter type: int4

Code example:

```
gaussdb=# SELECT vector_cmp(floatvector('[1,2,3]'), floatvector('[5,-1,3.5]'));
gaussdb=# SELECT vector_cmp('[1,2,3]', '[5,-1,3.5]');
```

vector_accum

Description: Returns the vector accumulation.

Type of input parameter 1: anyarray

Type of input parameter 2: floatvector

Output parameter type: anyarray

Code example:

```
-- This is a system function and is not recommended. If this function is required, the array element type must be float8.
gaussdb=# SELECT vector_accum(array[cast(3 as float8),1,2,3],  floatvector('[5,-1,3.5]'));
```

vector_combine

Description: Combines vectors.

Type of input parameter 1: anyarray

Type of input parameter 2: anyarray

Output parameter type: anyarray

Code example:

```
-- This is a system function and is not recommended. If this function is required, the array element type must be float8.
gaussdb=# SELECT vector_combine(array[cast(1 as float8),2,3], array[cast(1 as float8),2,3]);
```

vector_avg

Description: Averages vectors.

Input parameter type: anyarray

Output parameter type: floatvector

Code example:

```
-- This is a system function and is not recommended. If this function is required, the array element type must be float8.
gaussdb=# SELECT vector_avg(array[cast(1 as float8),2,3]);
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

bool_vector_dims

Description: Returns the dimension value of the boolvector vector.

Input parameter type: boolvector

Output parameter type: int4

Code example:

```
gaussdb=# SELECT bool_vector_dims(boolvector('[1,1,1]'));
```

bool_vector_cmp

Description: Compares the sizes of Boolean vectors.

Type of input parameter 1: boolvector

Type of input parameter 2: boolvector

Output parameter type: int4

Code example:

```
gaussdb=# SELECT bool_vector_cmp('[1,0,0]','[1,1,0]');
gaussdb=# SELECT bool_vector_cmp('[1,1,0]','[1,1,0]');
```

bool_vector_eq

Description: Compares Boolean vectors and checks whether they are equal.

Type of input parameter 1: boolvector

Type of input parameter 2: boolvector

Output parameter type: Boolean

Code example:

```
gaussdb=# SELECT bool_vector_eq(boolvector('[1,1,1]'), boolvector('[1,1,1]'));
gaussdb=# SELECT bool_vector_eq('[1,1,1]', '[1,1,1]');
```

1.6.62.3 Vector Functions and Operators

The floatvector supports data conversion between vector and array types, as well as conversion of strings in specific formats into the vector type.

array<->floatvector: The vector data type can be freely converted to the corresponding array type. The member data type of the floatvector vector is floating point.

string ->floatvector: You need to pay attention to the character string format. You need to contain arrays using square brackets ([]) or braces ({}) and separate elements using commas (,).

floatvector

Description:

Scenario 1: Convert array data into vector data.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Input parameter type: anyarray

Output parameter type: floatvector

Code example:

```
gaussdb=# SELECT floatvector(ARRAY[1,2,9.3]);
```

Scenario 2: Convert floatvector and check the dimensions.

Type of input parameter 1: floatvector

Type of input parameter 2: integer

Output parameter type: floatvector

Code example:

```
gaussdb=# SELECT floatvector(floatvector('[1,2,9.3]'),3);
```

vector_to_array

Description: Converts vector data to array data.

Input parameter type: floatvector

Output parameter type: real[]

Code example:

```
gaussdb=# SELECT vector_to_array(floatvector('[1,2,3]'));
```

text_to_vector

Description: Converts character data to vector data.

Input parameter type: cstring

Output parameter type: floatvector

Code example:

```
gaussdb=# SELECT text_to_vector('[1,2,9.3]');
```

vector_in

Description: Converts data in text format to the internal floatvector type.

Type of input parameter 1: cstring

Type of input parameter 2: OID

Type of input parameter 3: int4

Output parameter type: floatvector

Code example:

```
gaussdb=# SELECT vector_in('[1,2,3]',701,3);
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

vector_out

Description: Converts vector data of the internal floatvector type to the text format.

Input parameter type: floatvector

Output parameter type: cstring

Code example:

```
gaussdb=# SELECT vector_out(floatvector('[1,2,3]'));
```

vector_send

Description: Converts vector data of the internal floatvector type to the bytea type.

Input parameter type: floatvector

Output parameter type: bytea

Code example:

```
gaussdb=# SELECT vector_send(floatvector('[1,2,3]'));
```

vector_recv

Description: Converts data in binary format to the internal floatvector type.

Type of input parameter 1: integer

Type of input parameter 2: OID

Type of input parameter 3: int4

Output parameter type: floatvector

Code example:

```
-- This is a system function and cannot be called by SQL statements.
```

vector_typmod_in

Description: Specifies the floatvector input type modifier function.

Input parameter type: cstring[]

Output parameter type: integer

Code example:

```
gaussdb=# SELECT vector_typmod_in( '{1}' );
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- Vector data type members support only single precision.
- Inter-vector calculation supports only the same dimension. If the dimensions are different, an error is reported.
- The floatvector supports vector addition and subtraction. The dot product operation is performed by the inner_product function.
- When creating a table, you must specify the dimension for the vector type. If the dimension of the inserted data is inconsistent with the specified dimension, the system reports an error.
- Note that if data has been inserted into the data table, the data in the table must comply with the dimension setting when the vector dimension is changed. Otherwise, the database reports an error. If a vector index has been created for a vector attribute, you cannot change the data type of the attribute. Otherwise, the database reports an error.

boolvector

Scenario 1:

Description: Converts array data to vector data.

Input parameter type: anyarray

Output parameter type: boolvector

Code example:

```
gaussdb=# SELECT boolvector(ARRAY[1,0,1]);
```

Scenario 2:

Description: Converts data to boolvector and detects dimensions.

Type of input parameter 1: boolvector

Type of input parameter 2: integer

Output parameter type: boolvector

Code example:

```
gaussdb=# SELECT boolvector(boolvector('[1,0,1]'),3);
```

boolvector_to_array

Description: Converts vector data to array data.

Input parameter type: boolvector

Output parameter type: anyarray

Code example:

```
gaussdb=# SELECT boolvector_to_array(boolvector('[1,0,1]'));
```

text_to_boolvector

Description: Converts character data to vector data.

Input parameter type: cstring

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Output parameter type: boolvector

Code example:

```
gaussdb=# SELECT text_to_boolvector('[1,1,1]');
```

bool_vector_in

Description: Converts data in text format to the internal boolvector type.

Type of input parameter 1: cstring

Type of input parameter 2: OID

Type of input parameter 3: int4

Output parameter type: boolvector

Code example:

```
gaussdb=# SELECT bool_vector_in('[1,1,1]',701,3);
```

bool_vector_out

Description: Converts vector data of the internal boolvector type to the text format.

Input parameter type: boolvector

Output parameter type: cstring

Code example:

```
gaussdb=# SELECT bool_vector_out(boolvector('[1,1,1]'));
```

bool_vector_send

Description: Converts vector data of the internal boolvector type to the bytea type.

Input parameter type: boolvector

Output parameter type: bytea

Code example:

```
gaussdb=# SELECT bool_vector_send(boolvector('[1,1,1]'));
```

bool_vector_recv

Description: Converts data in binary format to the internal boolvector type.

Type of input parameter 1: internal

Type of input parameter 2: OID

Type of input parameter 3: int4

Output parameter type: boolvector

Code example:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
-- This is a system function and cannot be called by SQL statements.
```

bool_vector_typmod_in

Description: Specifies the boolvector input type modifier function.

Input parameter type: cstring[]

Output parameter type: integer

Code example:

```
gaussdb=# SELECT bool_vector_typmod_in( '{1}' );
```

NOTE

- The vector data type does not support NULL, NaN, or Inf as elements. If a vector contains NULL values, the database reports an error.
- When a vector data type is inserted, NULL cannot be used as the inserted value. If NULL is inserted as vector data, the database reports an error.
- Elements of the boolvector type can express Boolean data using **t(T)**/**f(F)**, **y(Y)**/**n(N)**, **1**/**0**, **true**/**false**, **yes**/**no**, or **on**/**off**.
- The boolvector type supports only the equal-to operation and does not support comparison.

gs_vector_index_options

Description: Displays the hyperparameter values of related vector indexes.

Input parameter type: text

Output parameter type: text

Code example:

```
-- Create a table.
gaussdb=# CREATE TABLE t1 (id int unique,repr floatvector(960));
Insert data.
gaussdb=# CREATE OR REPLACE FUNCTION float_random_array(dims int,range int) RETURNS float[] AS $
$BEGIN RETURN ARRAY(SELECT (random() * range)::int FROM generate_series(1, dims));END;$$
LANGUAGE plpgsql;
gaussdb=# INSERT INTO t1 SELECT i,floatvector(float_random_array(960,100)) FROM
generate_series(1,1000) as i;
Create an index.
gaussdb=# CREATE INDEX test1v on t1 using gsdiskann (repr l2) with
(pq_nseg=120,pq_nclus=64,queue_size=120,num_parallels=30,enable_pq=true,using_clustering_for_parallel=f
alse);

gaussdb=# SELECT gs_vector_index_options('test1v');
```

gs_diskann_inspect

Description: Queries the index health status, including the index disk usage, PQ compression accuracy, index graph connection health, and vacuum status.

Scenario 1:

Input parameter type: text

Output parameter type: record

Code example:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
-- Create a table.
gaussdb=# CREATE TABLE t1 (id int unique,repr floatvector(960));
-- Insert data.
gaussdb=# CREATE OR REPLACE FUNCTION float_random_array(dims int,range int) RETURNS float[] AS $
$BEGIN RETURN ARRAY(SELECT (random() * range)::int FROM generate_series(1, dims));END;$$
LANGUAGE plpgsql;
gaussdb=# INSERT INTO t1 SELECT i,floatvector(float_random_array(960,100)) FROM
generate_series(1,1000) as i;
-- Create a vector index.
gaussdb=# CREATE INDEX test1v on t1 using gsdiskann (repr l2) with
(pq_nseg=120,pq_nclus=64,queue_size=120,num_parallels=30,enable_pq=true,using_clustering_for_parallel=f
alse);
-- Display the index status on a specified DN.
gaussdb=# EXECUTE DIRECT ON (datanode1) 'SELECT * FROM gs_diskann_inspect(''test1v'');';
-- Display the index status on all DNs.
gaussdb=# SELECT * FROM gs_diskann_inspect('test1v');
```

Scenario 2:

Type of input parameter 1: text

Type of input parameter 2: text

Output parameter type: record

Code example:

```
-- Create a partitioned table.
gaussdb=# CREATE TABLE t1 (id int unique,repr floatvector(960)) partition by hash(id) (partition p1,
partition p2, partition p3);
-- Insert data.
gaussdb=# CREATE OR REPLACE FUNCTION float_random_array(dims int,range int) RETURNS float[] AS $
$BEGIN RETURN ARRAY(SELECT (random() * range)::int FROM generate_series(1, dims));END;$$
LANGUAGE plpgsql;
gaussdb=# INSERT INTO t1 SELECT i,floatvector(float_random_array(960,100)) FROM
generate_series(1,1000) as i;
-- Create a partitioned vector index.
gaussdb=# CREATE INDEX test1v on t1 using gsdiskann (repr l2) local with
(pq_nseg=120,pq_nclus=64,queue_size=120,num_parallels=30,enable_pq=true,using_clustering_for_parallel=f
alse);
-- Query a partition name and a partitioned index name.
SELECT oid,relname,parttype,parentid,boundaries FROM pg_partition WHERE parentid = 't1'::regclass::oid;
SELECT oid,relname,parttype,parentid,boundaries,indextblid FROM pg_partition WHERE parentid =
'test1v'::regclass::oid;
-- Display the index status of a specified partition on a specified DN.
gaussdb=# EXECUTE DIRECT ON (datanode1) 'SELECT * FROM gs_diskann_inspect(''test1v'', ''p1_repr_idx'');';
-- Display the index status of a specified partition on all DNs.
gaussdb=# SELECT * FROM gs_diskann_inspect('test1v', 'p1_repr_idx');
```

Scenario 3:

Type of input parameter 1: text

Type of input parameter 2: text

Type of input parameter 3: text

Output parameter type: record

Code example:

```
-- Create a partitioned table.
gaussdb=# CREATE TABLE t1 (id int unique,repr floatvector(960)) partition by hash(id) (partition p1,
partition p2, partition p3);
-- Insert data.
gaussdb=# CREATE OR REPLACE FUNCTION float_random_array(dims int,range int) RETURNS float[] AS $
$BEGIN RETURN ARRAY(SELECT (random() * range)::int FROM generate_series(1, dims));END;$$
LANGUAGE plpgsql;
gaussdb=# INSERT INTO t1 SELECT i,floatvector(float_random_array(960,100)) FROM
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
generate_series(1,1000) as i;
-- Create a partitioned vector index.
gaussdb=# CREATE INDEX test1v on t1 using gsdiskann (repr l2) local with
(pq_nseg=120,pq_nclus=64,queue_size=120,num_parallels=30,enable_pq=true,using_clustering_for_parallel=f
alse);
-- Query a partition name, partitioned index name, and DN name.
SELECT oid,relname,parttype,parentid,boundaries FROM pg_partition WHERE parentid = 't1'::regclass::oid;
SELECT oid,relname,parttype,parentid,boundaries,indextblid FROM pg_partition WHERE parentid =
'test1v'::regclass::oid;
SELECT oid,node_name, nodeis_preferred FROM pgxc_node WHERE node_type = 'D' ORDER BY 1;
-- Display the index status of a specified partition on a specified DN.
gaussdb=# SELECT * FROM gs_diskann_inspect('test1v', 'p1_repr_idx', 'datanode1');
```

gs_ivfflat_inspect

Description: Queries the GsIvfflat index status, including the fixed page number, index disk usage, and vector data distribution in the cluster. You need to connect to a DN or use the EXECUTE DIRECT ON syntax.

Scenario 1:

Input parameter type: text

Output parameter type: record

Code example:

```
-- Create a table.
gaussdb=# CREATE TABLE t1 (id int unique,repr floatvector(960));
-- Insert data.
gaussdb=# CREATE OR REPLACE FUNCTION float_random_array(dims int,range int) RETURNS float[] AS $
$BEGIN RETURN ARRAY(SELECT (random() * range)::int FROM generate_series(1, dims));END;$$
LANGUAGE plpgsql;
gaussdb=# INSERT INTO t1 SELECT i,floatvector(float_random_array(960,100)) FROM
generate_series(1,1000) as i;
-- Create a vector index.
gaussdb=# SET maintenance_work_mem='128MB';
gaussdb=# CREATE INDEX test1v on t1 using gsivfflat (repr l2) with (ivf_nlist=10);
-- Display the index status on a specified DN.
gaussdb=# EXECUTE DIRECT ON (datanode1) 'SELECT * FROM gs_ivfflat_inspect(''test1v'');';
```

Scenario 2:

Type of input parameter 1: text

Type of input parameter 2: text

Output parameter type: record

Code example:

```
-- Create a partitioned table.
gaussdb=# CREATE TABLE t1 (id int unique,repr floatvector(960)) partition by hash(id) (partition p1,
partition p2, partition p3);
-- Insert data.
gaussdb=# CREATE OR REPLACE FUNCTION float_random_array(dims int,range int) RETURNS float[] AS $
$BEGIN RETURN ARRAY(SELECT (random() * range)::int FROM generate_series(1, dims));END;$$
LANGUAGE plpgsql;
gaussdb=# INSERT INTO t1 SELECT i,floatvector(float_random_array(960,100)) FROM
generate_series(1,1000) as i;
-- Create a partitioned vector index.
gaussdb=# SET maintenance_work_mem='128MB';
gaussdb=# CREATE INDEX test1v on t1 using gsivfflat (repr l2) LOCAL with (ivf_nlist=10);
-- Query a partition name and a partitioned index name.
gaussdb=# SELECT oid,relname,parttype,parentid,boundaries FROM pg_partition WHERE parentid =
't1'::regclass::oid;
gaussdb=# SELECT oid,relname,parttype,parentid,boundaries,indextblid FROM pg_partition WHERE parentid
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
= 'test1v'::regclass::oid;
-- Display the index status of a specified partition on a specified DN.
gaussdb=# EXECUTE DIRECT ON (datanode1) 'SELECT * FROM gs_ivfflat_inspect(''test1v'', ''p1_repr_idx'');';
```

Operators for vector calculation focus on measuring similarity between vectors and binary operators of vectors.

<->

Description: Calculates the Euclidean distance (L2) between two floatvectors.

Left parameter type: floatvector

Right parameter type: floatvector

Return type: double precision

Code example:

```
gaussdb=# SELECT floatvector('[1,1,3,2]') <->  floatvector('[1,1,3,2]');
gaussdb=# SELECT '[1,2,3,2]'<-> floatvector('[1,1,3,2]');
```

<+>

Description: Calculates the cosine distance between two floatvectors.

Left parameter type: floatvector

Right parameter type: floatvector

Return type: double precision

Code example:

```
gaussdb=# SELECT floatvector('[1,1,3,2]') <+>  floatvector('[1,1,3,2]');
gaussdb=# SELECT '[1,2,3,2]'<+> floatvector('[1,1,3,2]');
```

<#>

Description: Calculates the Hamming distance between two boolvectors.

Left parameter type: boolvector

Right parameter type: boolvector

Return type: double precision

Code example:

```
gaussdb=# SELECT boolvector('[1,0,1,0]') <#>  boolvector('[1,1,1,0]');
gaussdb=# SELECT '[1,0,1,0]'<#> boolvector('[1,1,1,0]');
```

+

Description: Calculates the bitwise addition of two vectors with the same dimension.

Left parameter type: floatvector

Right parameter type: floatvector

Return type: floatvector

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Code example:

```
gaussdb=# SELECT floatvector('[1,1,3,2]') + floatvector('[1,1,3,2]');
gaussdb=# SELECT '[1,2,3,2]'+ floatvector('[1,1,3,2]');
```

-

Description: Calculates the bitwise subtraction of two vectors with the same dimension.

Left parameter type: floatvector

Right parameter type: floatvector

Return type: floatvector

Code example:

```
gaussdb=# SELECT floatvector('[1,1,3,2]') - floatvector('[1,1,3,2]');
gaussdb=# SELECT '[1,2,3,2]'- floatvector('[1,1,3,2]');
```

<

Description: Compares the lexicographical order of two vectors with the same dimension.

Left parameter type: floatvector

Right parameter type: floatvector

Return type: Boolean

Code example:

```
gaussdb=# SELECT floatvector('[1,1,3,2]') < floatvector('[1,1,3,2]');
gaussdb=# SELECT '[1,2,3,2]'< floatvector('[1,1,3,2]');
```

<=

Description: Compares the lexicographical order of two vectors with the same dimension.

Left parameter type: floatvector

Right parameter type: floatvector

Return type: Boolean

Code example:

```
gaussdb=# SELECT floatvector('[1,1,3,2]') <= floatvector('[1,1,3,2]');
gaussdb=# SELECT '[1,2,3,2]'<= floatvector('[1,1,3,2]');
```

>

Description: Compares the lexicographical order of two vectors with the same dimension.

Left parameter type: floatvector

Right parameter type: floatvector

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Return type: Boolean

Code example:

```
gaussdb=# SELECT floatvector('[1,1,3,2]') > floatvector('[1,1,3,2]');
gaussdb=# SELECT '[1,2,3,2]'> floatvector('[1,1,3,2]');
```

>=

Description: Compares the lexicographical order of two vectors with the same dimension.

Left parameter type: floatvector

Right parameter type: floatvector

Return type: Boolean

Code example:

```
gaussdb=# SELECT floatvector('[1,1,3,2]') >= floatvector('[1,1,3,2]');
gaussdb=# SELECT '[1,2,3,2]'>= floatvector('[1,1,3,2]');
```

=

Scenario 1:

Description: Determines whether two vectors with the same dimension are equal.

Left parameter type: floatvector

Right parameter type: floatvector

Return type: Boolean

Code example:

```
gaussdb=# SELECT floatvector('[1,1,3,2]') = floatvector('[1,1,3,2]');
gaussdb=# SELECT '[1,2,3,2]'= floatvector('[1,1,3,2]');
```

Scenario 2:

Description: Determines whether two boolvectors with the same dimension are consistent.

Left parameter type: boolvector

Right parameter type: boolvector

Return type: Boolean

Code example:

```
gaussdb=# SELECT boolvector('[1,0,1,0]') =  boolvector('[1,1,1,0]');
gaussdb=# SELECT '[1,0,1,0]' =  boolvector('[1,1,1,0]');
```

<>

Description: Determines whether two vectors with the same dimension are not equal.

Left parameter type: floatvector

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Right parameter type: floatvector

Return type: Boolean

Code example:

```
gaussdb=# SELECT floatvector('[1,1,3,2]') <> floatvector('[1,1,3,2]');
gaussdb=# SELECT '[1,2,3,2]'<> floatvector('[1,1,3,2]');
```

NOTE

If the vector element value is too large, the intermediate calculation result may overflow the single-precision range during distance calculation. As a result, the distance result is NaN or INF.

1.6.62.4 Functions and Operators for Similar Document Retrieval and Ranking

###

Scenario 1:

Description: Calculates the similarity between two texts based on the BM25 algorithm family. This is valid only for queries that use the BM25 index.

Left parameter type: text

Right parameter type: text

Return type: double precision

Note: This function is unavailable in the current version.

Scenario 2:

Description: Calculates the similarity between two tokenized text arrays based on the BM25 algorithm family. This is valid only for queries that use the BM25 index.

Left parameter type: text[]

Right parameter type: text[]

Return type: double precision

Note: This function is unavailable in the current version.

gs_ts_add_definition

Description: Incrementally adds dictionary content.

Input parameter type: regdictionary, "char", text[]

Output parameter type: Boolean

Note: This function is unavailable in the current version.

gs_bm25_tokenize

Description: Uses a specified dictionary to tokenize the input text and returns tokenized text arrays.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Input parameter type: text, cstring (default value: **"pg_catalog.simple_cn_segmentation"**)

Output parameter type: text[]

Note: This function is unavailable in the current version.

gs_bm25_score

Description: Returns the similarity score of the BM25 document. This parameter is valid only when the BM25 index is used for retrieval.

Input parameter type: ctid

Output parameter type: double precision

Note: This function is unavailable in the current version.

gs_bm25_distance_text

Description: Returns the similarity score of the BM25 document. This parameter is valid only when the BM25 index is used for retrieval.

Input parameter type: text, text

Output parameter type: double precision

Note: This function is unavailable in the current version.

gs_bm25_distance_textarr

Description: Returns the similarity score of the BM25 document. This parameter is valid only when the BM25 index is used for retrieval.

Input parameter type: text[], text[]

Output parameter type: double precision

Note: This function is unavailable in the current version.

gs_bm25_docid_info

Description: Returns the **docid** information corresponding to a specified CTID in a specified BM25 index.

Input parameter type: oid, uint4, uint2

Output parameter type: record

Note: This function is unavailable in the current version.

gs_bm25_document_info

Description: Returns the forward index information corresponding to a specified **docid** in a specified BM25 index.

Input parameter type: oid, uint4

Output parameter type: record

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Note: This function is unavailable in the current version.

gs_bm25_tokenhash_info

Description: Returns the hash container information of a specified BM25 index.

Input parameter type: OID

Output parameter type: record

Note: This function is unavailable in the current version.

gs_bm25_token_info

Description: Returns the token information of a specified document in a specified BM25 index.

Input parameter type: OID, text

Output parameter type: record

Note: This function is unavailable in the current version.

gs_bm25_posting_info

Description: Returns the inverted index information corresponding to a specified **tokenid** in a specified BM25 index.

Input parameter type: OID, text

Output parameter type: record

Note: This function is unavailable in the current version.

1.7 Expressions

1.7.1 Simple Expressions

Logical Expressions

Logical Operators lists the operators and calculation rules of logical expressions.

Comparative Expressions

Comparison Operators lists the common comparative operators.

In addition to comparative operators, you can also use the following sentence structure:

- BETWEEN operators:
  a BETWEEN x AND y is equivalent to **a >= x AND a <= y**.
  a NOT BETWEEN x AND y is equivalent to **a < x OR a > y**.
- To check whether a value is null, use:
  expression IS NULL

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

expression IS NOT NULL

or an equivalent (non-standard) sentence structure:

expression ISNULL

expression NOTNULL

NOTICE

- Do not write **expression=NULL** or **expression<>(!=)NULL** because **NULL** represents an unknown value, and these expressions cannot determine whether two unknown values are equal.
- Only the comparative expressions IS NULL and IS NOT NULL support data of XML type.

- is distinct from/is not distinct from
  - is distinct from

    If the data types and values of A and B are different, the value is **true**.

    If the data types and values of A and B are the same, the value is **false**.

    Empty values are considered the same.
  - is not distinct from

    If the data types and values of A and B are different, the value is **false**.

    If the data types and values of A and B are the same, the value is **true**.

    Empty values are considered the same.
- <=> NULL-safe equal operator

  The comparison of NULL values is added on the basis of the comparison of '='. If neither the left nor right value of the operator is NULL, the result is the same as that of '='.

  If the data types and values of A and B are different, the value is **false**.

  If the data types and values of A and B are the same, the value is **true**.

  Empty values are considered the same.

  NOTE

  - The usage of the <=> operator is the same as that of IS NOT DISTINCT FROM.
  - This operator is valid only when the database is compatible with the MySQL type (that is, **sql_compatibility** is set to **'MYSQL'**). Other types do not support this operator.

Examples

```
gaussdb=# SELECT 2 BETWEEN 1 AND 3 AS RESULT;
 result
----------
 t
(1 row)

1.7.2 Condition Expressions

Data that meets the requirements specified by conditional expressions are filtered during SQL statement execution.

Conditional expressions include the following types:

- CASE

  CASE expressions are similar to the **CASE** statements in other coding languages.

  Figure 1-3 shows the syntax of a CASE expression.

  Figure 1-3 case::=

  
  A CASE clause can be used in a valid expression. The condition is an expression that returns a value of Boolean type.

  - If the result is **true**, the result of the CASE expression is the required result.
  - If the result is false, the following WHEN or ELSE clauses are processed in the same way.
  - If every WHEN condition is not true, the result of the expression is the result of the ELSE clause. If the ELSE clause is omitted and has no match condition, the result is NULL.
  - Operations on XML data are supported.
  - When the GUC parameter **enable_case_intervaltonumeric** is set to **true**, INTERVAL can be converted to NUMERIC without reporting an error.

  Example:

```
gaussdb=# CREATE TABLE case_when_t1(CW_COL1 INT) DISTRIBUTE BY HASH (CW_COL1);

gaussdb=# INSERT INTO case_when_t1 VALUES (1), (2), (3);

gaussdb=# SELECT * FROM case_when_t1;
 cw_col1
---
 1
 2
 3
(3 rows)

gaussdb=# SELECT CW_COL1, CASE WHEN CW_COL1=1 THEN 'one' WHEN CW_COL1=2 THEN 'two'
ELSE 'other' END FROM case_when_t1 ORDER BY 1;
 cw_col1 | case
---------+-------
       1 | one
       2 | two
       3 | other
(3 rows)

gaussdb=# DROP TABLE case_when_t1;

-- The default value of the GUC parameter is false. In this case, an error is reported.
gaussdb=# SHOW enable_case_intervaltonumeric;
 enable_case_intervaltonumeric
-------------------------------
 off
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
(1 row)

gaussdb=# SELECT CASE
gaussdb-#     WHEN 1=1 THEN
gaussdb-#         to_date('20240118','yyyymmdd')-to_date('20240116','yyyymmdd')
gaussdb-#     ELSE
gaussdb-#         1
gaussdb-# end;
ERROR:  CASE types integer and interval cannot be matched
LINE 3:         to_date('20240118','yyyymmdd')-to_date('20240116','y...
                ^
CONTEXT:  referenced column: case

-- Enable the GUC parameter. The result can be correctly returned.
gaussdb=# SET enable_case_intervaltonumeric=true;
SET
gaussdb=# SELECT CASE
gaussdb-#     WHEN 1=1 THEN
gaussdb-#         to_date('20240118','yyyymmdd')-to_date('20240116','yyyymmdd')
gaussdb-#     ELSE
gaussdb-#         1::int1
gaussdb-# END;
 case
------
    2
(1 row)
```

- DECODE

  Figure 1-4 shows the syntax of DECODE.

  Figure 1-4 decode::=

  
  Compare each following compare(n) with base_expr, **value(n)** is returned if a compare(n) matches the base_expr expression. If base_expr does not match each compare(n), the default value is returned.

  Operations on XML data are supported.

  Conditional Expression Functions describes the examples.

```
gaussdb=# SELECT DECODE('A','A',1,'B',2,0);
 case
------
    1
(1 row)
```

- COALESCE

  Figure 1-5 shows the syntax of COALESCE.

  Figure 1-5 coalesce::=

  
  COALESCE returns its first not-NULL value. If all the parameters are **NULL**, **NULL** is returned. This value is replaced by the default value when data is

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

displayed. Like a CASE expression, COALESCE only evaluates the parameters that are needed to determine the result. That is, parameters to the right of the first not-NULL parameter are not evaluated.

Operations on XML data are supported.

Example:

```
gaussdb=# CREATE TABLE c_tabl(description varchar(10), short_description varchar(10), last_value
varchar(10))
DISTRIBUTE BY HASH (last_value);

gaussdb=# INSERT INTO c_tabl VALUES('abc', 'efg', '123');
gaussdb=# INSERT INTO c_tabl VALUES(NULL, 'efg', '123');

gaussdb=# INSERT INTO c_tabl VALUES(NULL, NULL, '123');

gaussdb=# SELECT description, short_description, last_value, COALESCE(description, short_description,
last_value) FROM c_tabl ORDER BY 1, 2, 3, 4;
 description | short_description | last_value | coalesce
-------------+-------------------+------------+----------
 abc         | efg               | 123        | abc
             | efg               | 123        | efg
             |                   | 123        | 123
(3 rows)

gaussdb=# DROP TABLE c_tabl;
```

If **description** is not **NULL**, the value of **description** is returned. Otherwise, **short_description** is calculated. If **short_description** is not **NULL**, the value of **short_description** is returned. Otherwise, **last_value** is calculated. If **last_value** is not **NULL**, the value of **last_value** is returned. Otherwise, **none** is returned.

```
gaussdb=# SELECT COALESCE(NULL,'Hello World');
   coalesce
---------------
 Hello World
(1 row)
```

- NULLIF

  Figure 1-6 shows the syntax of NULLIF.

  Figure 1-6 nullif::=

  
  Only if **value1** is equal to **value2** can **NULLIF** return the **NULL** value. Otherwise, **value1** is returned. Operations on XML data are supported.

  Example:

```
gaussdb=# CREATE TABLE null_if_t1 (
    NI_VALUE1 VARCHAR(10),
    NI_VALUE2 VARCHAR(10)
)DISTRIBUTE BY HASH (NI_VALUE1);

gaussdb=# INSERT INTO null_if_t1 VALUES('abc', 'abc');
gaussdb=# INSERT INTO null_if_t1 VALUES('abc', 'efg');

gaussdb=# SELECT NI_VALUE1, NI_VALUE2, NULLIF(NI_VALUE1, NI_VALUE2) FROM null_if_t1 ORDER
BY 1, 2, 3;

 ni_value1 | ni_value2 | nullif
-----------+-----------+--------
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
 abc      | abc      |
 abc      | efg      | abc
(2 rows)
gaussdb=# DROP TABLE null_if_t1;
```

If **value1** is equal to **value2**, **NULL** is returned. Otherwise, **value1** is returned.

```
gaussdb=# SELECT NULLIF('Hello','Hello World');
 nullif
--------
 Hello
(1 row)
```

- GREATEST (maximum value) and LEAST (minimum value)

  Figure 1-7 shows the syntax of GREATEST.

  Figure 1-7 greatest::=

  
  You can select the maximum value from any numerical expression list. Operations on XML data are supported.

```
gaussdb=# SELECT greatest(9000,155555,2.01);
 greatest
----------
   155555
(1 row)
```

  Figure 1-8 shows the syntax of LEAST.

  Figure 1-8 least::=

  
  You can select the minimum value from any numerical expression list.

  Each of the preceding numeric expressions can be converted into a common data type, which will be the data type of the result.

  The NULL values in the list will be ignored. The result is **NULL** only if the results of all expressions are **NULL**.

  Operations on XML data are supported.

```
gaussdb=# SELECT least(9000,2);
 least
-------
     2
(1 row)
```

  Conditional Expression Functions describes the examples.

- NVL

  Figure 1-9 shows the syntax of NVL.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Figure 1-9 nvl::=

If the value of **value1** is **NULL**, **value2** is returned. Otherwise, **value1** is returned. Operations on XML data are supported.

Example:

```
gaussdb=# SELECT nvl(null,1);
nvl
-----
 1
(1 row)

gaussdb=# SELECT nvl('Hello World',1);
      nvl
---------------
 Hello World
(1 row)
```

1.7.3 Subquery Expressions

Subquery expressions include the following types:

- EXISTS/NOT EXISTS

  Figure 1-10 shows the syntax of EXISTS/NOT EXISTS.

  Figure 1-10 EXISTS/NOT EXISTS::=

  
  The parameter of an EXISTS expression is an arbitrary SELECT statement, that is, subquery. The subquery is evaluated to determine whether it returns any rows. If it returns at least one row, the result of EXISTS is true. If the subquery returns no rows, the result of EXISTS is false.

  The subquery will generally only be executed long enough to determine whether at least one row is returned, not all the way to completion.

  Operations on XML data are not supported.

  Example:

```
gaussdb=# CREATE TABLE exists_t1(a int, b int);
gaussdb=# INSERT INTO exists_t1 VALUES(1, 2),(2, 3),(3, 4),(4, 5);

gaussdb=# CREATE TABLE exists_t2(a int, c int);
gaussdb=# INSERT INTO exists_t2 VALUES(3, 4),(4, 5),(5, 6),(6, 7);

gaussdb=# SELECT * FROM exists_t1 t1 WHERE EXISTS (SELECT * FROM exists_t2 t2 WHERE t2.a =
t1.a);
 a | b
---+---
 3 | 4
 4 | 5
(2 rows)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gaussdb=# DROP TABLE exists_t1, exists_t2;
```

- IN/NOT IN

  Figure 1-11 shows the syntax of IN/NOT IN.

  Figure 1-11 IN/NOT IN::=

  
  The right-hand side is a parenthesized subquery, which must return exactly one column. The left-hand expression is evaluated and compared to each row of the subquery result. The result of IN is true if any equal subquery row is found. The result is false if no equal row is found (including the case where the subquery returns no rows).

  This is in accordance with SQL normal rules for Boolean combinations of null values. If the columns corresponding to two rows equal and are not empty, the two rows are equal to each other. If any columns corresponding to the two rows do not equal and are not empty, the two rows are not equal to each other. Otherwise, the result is **NULL**. If the results in each row are either unequal or NULL, with at least one NULL, the result of IN is null.

  Operations on XML data are not supported.

  Example:

  ```
  gaussdb=# CREATE TABLE in_t1(a int, b int);
  gaussdb=# INSERT INTO in_t1 VALUES(1, 2),(2, 3),(3, 4),(4, 5);

  gaussdb=# CREATE TABLE in_t2(a int, c int);
  gaussdb=# INSERT INTO in_t2 VALUES(3, 4),(4, 5),(5, 6),(6, 7);

  gaussdb=# SELECT * FROM in_t1 t1 WHERE t1.a IN (SELECT t2.a FROM in_t2 t2);
   a | b
  ---+---
   3 | 4
   4 | 5
  (2 rows)

  gaussdb=# DROP TABLE in_t1, in_t2;
  ```

- ANY/SOME

  Figure 1-12 shows the syntax of ANY/SOME.

  Figure 1-12 any/some::=

  
  The right-hand side is a parenthesized subquery, which must return exactly one column. The left-hand expression is evaluated and compared to each row of the subquery result using the given operator, which must yield a Boolean

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

result. The result of ANY is true if any true result is obtained. The result is false if no true result is found (including the case where the subquery returns no rows). SOME is a synonym of ANY. IN can be equivalently replaced with ANY.

Operations on XML data are not supported.

Example:

```
gaussdb=# CREATE TABLE any_t1(a int, b int);
gaussdb=# INSERT INTO any_t1 VALUES(1, 2),(2, 3),(3, 4),(4, 5);

gaussdb=# CREATE TABLE any_t2(a int, c int);
gaussdb=# INSERT INTO any_t2 VALUES(3, 4),(4, 5),(5, 6),(6, 7);

gaussdb=# SELECT * FROM any_t1 t1 WHERE t1.a < ANY(SELECT t2.a FROM any_t2 t2 where t2.a = 3
or t2.a = 4);
 a | b
---+---
 1 | 2
 2 | 3
 3 | 4
(3 rows)

gaussdb=# DROP TABLE any_t1, any_t2;
```

- ALL

  Figure 1-13 shows the syntax of ALL.

  Figure 1-13 all::=

  
  The right-hand side is a parenthesized subquery, which must return exactly one column. The left-hand expression is evaluated and compared to each row of the subquery result using the given operator, which must yield a Boolean result. The result of ALL is true if all values are true (including the case where the subquery returns no rows). The result is false if any false result is found.

  Operations on XML data are not supported.

  Example:

```
gaussdb=# CREATE TABLE all_t1(a int, b int);
gaussdb=# INSERT INTO all_t1 VALUES(1, 2),(2, 3),(3, 4),(4, 5);

gaussdb=# CREATE TABLE all_t2(a int, c int);
gaussdb=# INSERT INTO all_t2 VALUES(3, 4),(4, 5),(5, 6),(6, 7);

gaussdb=# SELECT * FROM all_t1 t1 WHERE t1.a < ALL(SELECT t2.a FROM all_t2 t2 where t2.a = 3 or
t2.a = 4);
 a | b
---+---
 1 | 2
 2 | 3
(2 rows)

gaussdb=# DROP TABLE all_t1, all_t2;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

1.7.4 Array Expressions

IN

expression **IN** *(value [, ...])*

The parentheses on the right contain an expression list. The expression result on the left is compared with the content in the expression list. If the content in the list meets the expression result on the left, the result of IN is true. If no result meets the requirements, the result of IN is false.

Example:

```
gaussdb=# SELECT 8000+500 IN (10000, 9000) AS RESULT;
 result
----------
 f
(1 row)
```

NOTE

- If the expression result is null or the expression list does not meet the expression conditions and at least one empty value is returned for the expression list on the right, the result of IN is null rather than false. This method is consistent with the Boolean rules used when SQL statements return empty values.
- Operations on XML data are not supported.

NOT IN

expression **NOT IN** *(value [, ...])*

The parentheses on the right contain an expression list. The expression result on the left is compared with the content in the expression list. If the content in the list does not meet the expression result on the left, the result of NOT IN is true. If any content meets the expression result, the result of NOT IN is false.

Example:

```
gaussdb=# SELECT 8000+500 NOT IN (10000, 9000) AS RESULT;
 result
----------
 t
(1 row)
```

NOTE

- If the query statement result is null or the expression list does not meet the expression conditions and at least one empty value is returned for the expression list on the right, the result of NOT IN is null rather than false. This method is consistent with the Boolean rules used when SQL statements return empty values.
- In all situations, X NOT IN Y equals to NOT(X IN Y).
- Operations on XML data are not supported.

ANY/SOME (array)

expression operator **ANY** *(array expression)*

expression operator **SOME** *(array expression)*

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

The right side is a parenthesized expression, which must yield an array value. The result of the expression on the left uses operators to compute and compare the results in each row of the array expression. The comparison result must be a Boolean value.

Example:

```
gaussdb=# SELECT 8000+500 < SOME (array[10000,9000]) AS RESULT;
 result
----------
 t
(1 row)

gaussdb=# SELECT 8000+500 < ANY (array[10000,9000]) AS RESULT;
 result
----------
 t
(1 row)
```

NOTE

- If at least one comparison result is true, the result of ANY is true.
- If no comparison result is true, the result of ANY is false.
- If no comparison result is true and the array expression generates at least one null value, the value of **ANY** is **NULL** rather than **false**. This method is consistent with the Boolean rules used when SQL statements return empty values.
- SOME is a synonym of ANY.
- Operations on XML data are not supported.

ALL (array)

expression operator **ALL** *(array expression)*

The right-hand side is a parenthesized expression, which must yield an array value. The result of the expression on the left uses operators to compute and compare the results in each row of the array expression. The comparison result must be a Boolean value.

- The result of ALL is true if all comparisons yield true (including the case where the array has zero elements).
- If one or more comparison results are false, the result of ALL is false.
- If the array expression yields a null array, the result of ALL will be NULL. If the expression on the left yields NULL, the result of ALL is generally NULL (though a non-strict comparison operator could possibly yield a different result). If the array on the right contains any null elements and no false comparison result is found, the result of ALL is NULL, not true (again, assuming a strict comparison operator). This method is consistent with the Boolean rules used when SQL statements return empty values.
- Operations on XML data are not supported.

Example:

```
gaussdb=# SELECT 8000+500 < ALL (array[10000,9000]) AS RESULT;
 result
----------
 t
(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

1.7.5 Row Expressions

The syntax is as follows:

```
row_constructor operator row_constructor
```

Both sides of the row expression are row constructors. The values of both rows must have the same number of fields and they are compared with each other. The row comparison allows operators including =, <>, <, <=, and >= or a similar operator.

For operators <, <=, >, and >=, the columns in rows are compared from left to right until a pair of columns that are not equal or are empty are detected. If the pair of columns contains at least one null value, the comparison result is null. Otherwise, the comparison result of this pair of columns is the final result. If no unequal or empty column is found, the values in the two rows are equal. The final result is determined based on the operator meaning.

Operations on XML data are not supported.

Example:

```
gaussdb=# SELECT ROW(1,2,NULL) < ROW(1,3,0) AS RESULT;
 result
----------
 t
(1 row)

gaussdb=# SELECT (4,5,6) > (3,2,1) AS result;
 result
--------
 t
(1 row)

gaussdb=# SELECT (4,1,1) > (3,2,1) AS result;
 result
--------
 t
(1 row)

gaussdb=# SELECT ('test','data') > ('data','data') AS result;
 result
--------
 t
(1 row)

gaussdb=# SELECT (4,1,1) > (3,2,null) AS result;
 result
--------
 t
(1 row)

gaussdb=# SELECT (null,1,1) > (3,2,1) AS result;
 result
--------

(1 row)

gaussdb=# SELECT (null,5,6) > (null,5,6) AS result;
 result
--------

(1 row)

gaussdb=# SELECT (4,5,6) > (4,5,6) AS result;
 result
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
--------
 f
(1 row)

gaussdb=# SELECT (2,2,5) >= (2,2,3) AS result;
 result
--------
 t
(1 row)

gaussdb=# SELECT (2,2,1) <= (2,2,3) AS result;
 result
--------
 t
(1 row)
```

The use of operators = and <> is slightly different from other operators. If all columns in the two rows are not empty and meet the operator condition, the two rows meet the operator condition. If any column in the two rows is not empty and does not meet the operator condition, the two rows do not meet the operator condition. If any column in the two rows is empty, the comparison result is null.

Example:

```
gaussdb=# SELECT (1,2,3) = (1,2,3) AS result;
 result
--------
 t
(1 row)

gaussdb=# SELECT (1,2,3) <> (2,2,3) AS result;
 result
--------
 t
(1 row)

gaussdb=# SELECT (2,2,3) <> (2,2,null) AS result;
 result
--------

(1 row)

gaussdb=# SELECT (null,5,6) <> (null,5,6) AS result;
 result
--------

(1 row)
```

1.7.6 Time Interval Expressions

Syntax: INTERVAL EXPR UNIT

Description: **EXPR** indicates a value, and the **UNIT** specifier indicates a unit of the value, such as HOUR, DAY, and WEEK. The keyword INTERVAL and specifier are case-insensitive.

Table 1-331 describes the value range of **UNIT** in a time interval expression. Any punctuation-separated EXPR format is allowed. The recommended separators are displayed in **Table 1-331**.

NOTE

The INTERVAL expression supports the preceding functions only when **sql_compatibility** is set to **'MYSQL'**, **b_format_version** is set to **5.7**, and **b_format_dev_version** is set to **s1**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 1-331 Value range of UNIT in a time interval expression

UNIT Value Range	Expected EXPR Format
MICROSECOND	MICROSECONDS
SECOND	SECONDS
MINUTE	MINUTES
HOUR	HOURS
DAY	DAYS
WEEK	WEEKS
MONTH	MONTHS
QUARTER	QUARTERS
YEAR	YEARS
SECOND_MICROSECOND	'SECOND_MICROSECOND'
MINUTE_MICROSECOND	'MINUTES:SECONDS.MICROSECONDS'
MINUTE_SECOND	'MINUTES:SECONDS'
HOUR_MICROSECOND	'HOURS:MINUTES:SECONDS.MICROSECONDS'
HOUR_SECOND	'HOURS:MINUTES:SECONDS'
HOUR_MINUTE	'HOURS:MINUTES'
DAY_MICROSECOND	'DAYS HOURS:MINUTES:SECONDS.MICROSECONDS'
DAY_SECOND	'DAYS HOURS:MINUTES:SECONDS'
DAY_MINUTE	'DAYS HOURS:MINUTES'
DAY_HOUR	'DAYS HOURS'
YEAR_MONTH	'YEAR_MONTH'

Example:

```
gaussdb=# SELECT DATE_ADD('2018-05-01', INTERVAL 1 DAY);
  date_add
------------
 2018-05-02
(1 row)

gaussdb=# SELECT DATE_SUB('2018-05-01', INTERVAL 1 YEAR);
  date_sub
------------
 2017-05-01
(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gaussdb=# SELECT DATE'2023-01-10' - INTERVAL 1 DAY;
     ?column?
---------------------
 2023-01-09 00:00:00
(1 row)

gaussdb=# SELECT DATE'2023-01-10' + INTERVAL 1 MONTH;
     ?column?
---------------------
 2023-02-10 00:00:00
(1 row)
```

1.8 Pseudocolumn

ROWNUM is a pseudocolumn that returns a number indicating the row number of the obtained query result. The value of **ROWNUM** in the first row is **1**, the value of **ROWNUM** in the second row is **2**, and so forth. **ROWNUM** is used to limit the number of rows returned by a query.

Here is a breakdown of the ROWNUM mechanism:

- Timing of value assignment: **ROWNUM** is dynamically assigned during the generation of the query result set. It is a pseudocolumn added to the result set of every query. This means that sequence numbers are determined after the data is filtered by the WHERE clause but before any ORDER BY.
- Comparison operator: The **ROWNUM** <= *n* (*n* > 1) operator is valid and commonly used to limit the number of returned rows, such as retrieving the first *N* records. For example:

  ```
  gaussdb=# CREATE TABLE Students (name varchar(20), id int) with (STORAGE_TYPE = USTORE);
  gaussdb=# INSERT INTO Students VALUES ('Jack', 35);
  gaussdb=# INSERT INTO Students VALUES ('Leon', 15);
  gaussdb=# INSERT INTO Students VALUES ('James', 24);
  gaussdb=# INSERT INTO Students VALUES ('Taker', 81);
  gaussdb=# INSERT INTO Students VALUES ('Mary', 25);
  gaussdb=# INSERT INTO Students VALUES ('Rose', 64);
  gaussdb=# INSERT INTO Students VALUES ('Perl', 18);
  gaussdb=# INSERT INTO Students VALUES ('Under', 57);
  gaussdb=# INSERT INTO Students VALUES ('Angel', 101);
  gaussdb=# INSERT INTO Students VALUES ('Frank', 20);
  gaussdb=# INSERT INTO Students VALUES ('Charlie', 40);

  -- Output the first 10 rows of data records in the Students table.
  gaussdb=# SELECT * FROM Students WHERE rownum <= 10;
   name  | id
  -------+-----
   Jack  |  35
   Leon  |  15
   James |  24
   Taker |  81
   Mary  |  25
   Rose  |  64
   Perl  |  18
   Under |  57
   Angel | 101
   Frank |  20
  (10 rows)
  ```

- **ROWNUM = 1** is valid and can be used to retrieve the first record.

  ```
  gaussdb=# SELECT * FROM Students WHERE rownum = 1;
   name | id
  ------+----
   Jack | 35
  (1 row)
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

The conditions **ROWNUM** = *n* (*n* > 1), **ROWNUM** > *n* (*n* >= 1), and **ROWNUM** >= *n* (*n* > 1) always yield a FALSE result, leading to no rows being returned. This is because the first row retrieved is assigned **ROWNUM=1**. If it fails to meet the specified condition (such as **ROWNUM > 1**), it will be discarded. The next record is then processed, becoming the new "first" record, and **ROWNUM** is reset to **1**. This cycle continues, with none of the rows meeting the specified condition.

```
gaussdb=# SELECT * FROM Students WHERE rownum > 1;
 name | id
------+----
(0 rows)
```

[Basic Usage of **ROWNUM**]

- Limiting the number of returned rows

```
gaussdb=# SELECT * FROM Students WHERE rownum <= 2;
 name | id
------+----
 Jack | 35
 Leon | 15
(2 rows)
```

- Implementing paginated queries: Since **ROWNUM** > *n* cannot be used directly, paginated queries need to be implemented by creating an alias (such as **rn**) for **ROWNUM** through a subquery. This turns **ROWNUM** into a "fixed" column, allowing outer queries to filter ranges accordingly.

```
gaussdb=# SELECT *
FROM (SELECT a.*, ROWNUM AS rn
      FROM
      (SELECT * FROM Students ORDER BY id DESC) a -- The inner subquery sorts data first.
      WHERE ROWNUM <= 10) -- The intermediate subquery defines the upper limit and generates an
alias for ROWNUM.
WHERE rn >= 5;
  name   | id | rn
---------+----+----
 Charlie | 40 |  5
 Jack    | 35 |  6
 Mary    | 25 |  7
 James   | 24 |  8
 Frank   | 20 |  9
 Perl    | 18 | 10
(6 rows)
```

- Obtaining the first *N* rows after sorting: When WHERE ROWNUM <= *N* and ORDER BY are simultaneously used at the same level of query, incorrect results may occur because **ROWNUM** is assigned before sorting takes place. The correct method is to use a subquery to sort rows and then assign **ROWNUM**.

```
gaussdb=# SELECT rownum, * FROM (SELECT * FROM Students ORDER BY 1) WHERE rownum <= 2;
 rownum |  name   | id
--------+---------+-----
      1 | Angel   | 101
      2 | Charlie |  40
(2 rows)
```

- Using **ROWNUM** to assign a value to each row within a specific range of the table

```
gaussdb=# SELECT * FROM Students;
  name   | id
---------+-----
 Jack    |  35
 Leon    |  15
 James   |  24
 Taker   |  81
 Mary    |  25
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
 Rose    | 64
 Perl    | 18
 Under   | 57
 Angel   | 101
 Frank   | 20
 Charlie | 40
(11 rows)

gaussdb=# UPDATE Students SET id = id + 5 WHERE rownum < 4;
UPDATE 3
gaussdb=# SELECT * FROM Students;
  name   | id
---------+-----
 Jack    | 40
 Leon    | 20
 James   | 29
 Taker   | 81
 Mary    | 25
 Rose    | 64
 Perl    | 18
 Under   | 57
 Angel   | 101
 Frank   | 20
 Charlie | 40
(11 rows)

gaussdb=# DROP TABLE Students;
DROP TABLE
```

The restrictions on using **ROWNUM** are as follows:

- Do not use ROWNUM as an alias to avoid ambiguity in SQL statements.
- Do not use ROWNUM when creating an index.
- Do not use ROWNUM as the default value when creating a table.
- Do not use ROWNUM as an alias in the WHERE clause.
- Do not use ROWNUM when inserting data.
- Do not use ROWNUM in a tableless query.
- Do not use ROWNUM in the LIMIT clause.
- **ROWNUM** cannot be used as a parameter of the EXECUTE statement.
- Do not use ROWNUM to update a clause in the UPSERT statement.
- Do not use ROWNUM as a projection column or WHERE condition in the SELECT ... FOR UPDATE statement.
- If the HAVING clause contains **ROWNUM** (not in an aggregate function), the GROUP BY clause must also contain **ROWNUM** (not in an aggregate function), unless the GROUP BY clause contains an expression, such as **SELECT a + a FROM t group by a + a having rownum < 5**.
- If the **ROWNUM** condition exists in the HAVING clause, the HAVING clause cannot be pushed down to any scan node.

```
gaussdb=# CREATE TABLE test (a int, b int);
NOTICE:  The 'DISTRIBUTE BY' clause is not specified. Using 'a' as the distribution column by default.
HINT:  Please use 'DISTRIBUTE BY' clause to specify suitable data distribution column.
CREATE TABLE
gaussdb=# INSERT INTO test SELECT generate_series, generate_series FROM generate_series(1, 10);
INSERT 0 10

-- The rownum condition cannot be pushed down to seqscan.
gaussdb=# EXPLAIN SELECT a,rownum FROM test group by a,rownum having rownum < 5;
                            QUERY PLAN
------------------------------------------------------------------------------
 HashAggregate  (cost=3.45..3.49 rows=3 width=4)
   Group By Key: a, ROWNUM
```

```
  Filter: ((ROWNUM) < 5::numeric)
  ->  Rownum  (cost=0.19..3.40 rows=10 width=4)
        ->  Streaming (type: GATHER)  (cost=0.19..3.40 rows=10 width=4)
              Node/s: All datanodes
              ->  Seq Scan on test  (cost=0.00..3.03 rows=10 width=4)
(7 rows)
```

- If a subquery contains the ROWNUM condition, the predicate cannot be pushed down to any scan node.

```
-- b<5 cannot be pushed down to seqscan.
gaussdb=# EXPLAIN SELECT * FROM (SELECT * FROM test WHERE rownum < 5) WHERE b < 5;
                                QUERY PLAN
-------------------------------------------------------------------------------------
 Streaming (type: GATHER)  (cost=0.06..0.63 rows=2 width=8)
   Node/s: All datanodes
   ->  Subquery Scan on __unnamed_subquery__  (cost=0.00..0.50 rows=2 width=8)
         Filter: (__unnamed_subquery__.b < 5)
         ->  Rownum  (cost=0.00..0.45 rows=4 width=8)
               StopKey: (ROWNUM < 5::numeric)
               ->  Streaming(type: BROADCAST)  (cost=0.00..1.36 rows=12 width=8)
                     Spawn on: All datanodes
                     ->  Rownum  (cost=0.00..1.35 rows=4 width=8)
                           StopKey: (ROWNUM < 5::numeric)
                           ->  Seq Scan on test  (cost=0.00..3.03 rows=10 width=8)
(11 rows)

gaussdb=# DROP TABLE test;
DROP TABLE
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- The query result of **ROWNUM** may be unstable due to the sequence in which the CN receives DN data.

```
gaussdb=# CREATE TABLE test(a int, b int);
gaussdb=# INSERT INTO test VALUES(generate_series(1,10),generate_series(1,10));

-- The CN receives data from DN1 and then from DN2.
gaussdb=# SELECT rownum,* FROM test;
 rownum | a  | b
--------+----+----
      1 |  1 |  1
      2 |  2 |  2
      3 |  5 |  5
      4 |  6 |  6
      5 |  8 |  8
      6 |  9 |  9
      7 |  3 |  3
      8 |  4 |  4
      9 |  7 |  7
     10 | 10 | 10
(10 rows)

-- The CN receives data from DN2 and then from DN1.
gaussdb=# SELECT rownum,* FROM test;
 rownum | a  | b
--------+----+----
      1 |  3 |  3
      2 |  4 |  4
      3 |  7 |  7
      4 | 10 | 10
      5 |  1 |  1
      6 |  2 |  2
      7 |  5 |  5
      8 |  6 |  6
      9 |  8 |  8
     10 |  9 |  9
(10 rows)
```

- It is not recommended that the ROWNUM condition be used in the JOIN ON clause. In GaussDB, when the ROWNUM condition is used in the JOIN ON clause, the behavior in the LEFT JOIN, RIGHT JOIN, FULL JOIN, and MERGE INTO scenarios is different from that in other databases, causing risks in service migration.

If the parent query contains the **rownum** restriction and the projection column of the subquery contains **rownum**, the restriction is pushed down to the subquery. The constraints are as follows:

- The parent query can be pushed down only when the **rownum** restriction condition is <, <=, or = and the subquery directly uses **rownum** as the pseudocolumn.
- If the parent query has multiple filter criteria for **rownum** in the subquery and the pushdown requirements are met, only the first filter criterion is pushed down.
- If a subquery contains volatile functions and stored procedures, the pushdown is not supported.

1.9 Type Conversion

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

1.9.1 Overview

Context

SQL is a typed language. That is, every data item has an associated data type which determines its behavior and allowed usage. GaussDB has an extensible type system that is more general and flexible than other SQL implementations. Hence, most type conversion behaviors in GaussDB are governed by general rules. This allows the use of mixed-type expressions.

The GaussDB scanner/parser divides lexical elements into five fundamental categories: integers, floating-point numbers, strings, identifiers, and keywords. Constants of most non-numeric types are first classified as strings. The SQL language definition allows specifying type names with constant strings. Example:

```
gaussdb=# SELECT text 'Origin' AS "label", point '(0,0)' AS "value";
 label  | value
--------+-------
 Origin | (0,0)
(1 row)
```

In this example, there are two literal constants of the text and point types, respectively. If a type is not specified for a string literal, then the placeholder type unknown is assigned initially.

There are four fundamental SQL constructs requiring distinct type conversion rules in GaussDB parser:

- Function calls

  Much of the SQL type system is built around a rich set of functions. Functions can have one or more arguments. Since SQL permits function overloading, the function name alone does not uniquely identify the function to be called. The parser must select the right function based on the data types of the supplied arguments.

- Operators

  SQL allows expressions with prefix and postfix unary (one-argument) operators, as well as binary (two-argument) operators. Like functions, operators can be overloaded, so the same problem of selecting the right operator exists.

- Value storage

  The INSERT and UPDATE statements place the results of expressions into a table. The expressions in the statement must be matched up with, and perhaps converted to, the types of the target columns.

- UNION, CASE, and Related Constructs

  Since all query results from a unionized SELECT statement must appear in a single set of columns, the types of the results of each SELECT clause must be matched up and converted to a uniform set. Similarly, the result expressions of a CASE construct must be converted to a common type so that the **CASE** expression as a whole has a known output type. The same holds for ARRAY constructs, and for the GREATEST and LEAST functions.

The system catalog pg_cast stores information about which conversions, or casts, exist between which data types, and how to perform those conversions. For details, see **PG_CAST**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

The return type and conversion behavior of an expression are determined during semantic analysis. Data types are divided into several basic type categories, including Boolean, numeric, string, bitstring, datetime, timespan, geometric, and network. Within each category there can be one or more preferred types, which are preferred when there is a choice of possible types. With careful selection of preferred types and available implicit casts, it is possible to ensure that ambiguous expressions (those with multiple candidate parsing solutions) can be resolved in a useful way.

All type conversion rules are designed based on the following principles:

- Implicit conversions should never have surprising or unpredictable outcomes.
- There should be no extra overhead in the parser or executor if a query does not need implicit type conversion. That is, if a query is well-formed and the types already match, then the query should execute without spending extra time in the parser and without introducing unnecessary implicit conversion calls in the query.
- Additionally, if a query usually requires an implicit conversion for a function, and if then the user defines a new function with the correct argument types, the parser should use this new function.
- XML data does not support implicit type conversion, including implicit conversion between strings and XML types.
- In ORA-compatible mode, the DATEA type can be converted only to the text, bpchar, varchar, clob, nvarchar2, timestamp, and timestamp with time zone types.

1.9.2 Operators

Operator Type Resolution

1. Select the operators to be considered from the pg_operator system catalog. Considered operators are those with the matching name and argument count. If the search path finds multiple available operators, only the most suitable one is considered.
2. Look for the best match.
   a. Discard candidate operators for which the input types do not match and cannot be converted (using an implicit conversion) to match. Unknown text can be converted to anything for this purpose. If only one candidate remains, use it; else continue to the next step.
   b. Run through all candidates and keep those with the most exact matches on input types. In this case, the domain type is considered to be the same as its base type. Keep all candidates if none survives these tests. If only one candidate remains, use it; else continue to the next step.
   c. Run through all candidates and keep those that accept preferred types (of the input data type's type category) at the most positions where type conversion will be required. Keep all candidates if none accepts preferred types. If only one candidate remains, use it; else continue to the next step.
   d. If any input arguments are of unknown types, check the type categories accepted at those argument positions by the remaining candidates. At each position, select the string category if any candidate accepts that

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

category. (This bias towards string is appropriate since an unknown-type literal looks like a string.) Otherwise, if all the remaining candidates accept the same type category, select that category; otherwise fail because the correct choice cannot be deduced without more clues. Discard candidates that do not accept the selected type category. Furthermore, if any candidate accepts a preferred type in that category, discard candidates that accept non-preferred types for that argument. Keep all candidates if none survives these tests. If only one candidate remains, use it; else continue to the next step.

e. If there are both unknown and known arguments, and all the known arguments have the same type, assume that the unknown arguments are also of that type, and check which candidates can accept that type at the unknown-argument positions. If exactly one candidate passes this test, use it. Otherwise, an error occurs.

> NOTE
>
> After an operator is found, if the type of the input parameter is different from that of the operator, implicit type conversion may occur. After the conversion, unpredictable behavior may occur. If the behavior is incorrect after implicit conversion, you can use explicit type conversion to avoid this problem. For example, after the fixed-length bpchar type is converted to the variable-length text type, spaces at the end of the character string are deleted. If the character string is compared with other character strings, errors may occur.

Examples

Example 1: Use factorial operator type resolution. There is only one factorial operator (postfix !) defined in the system catalog, and it takes an argument of bigint type. The scanner assigns bigint as an initial type to the argument in this query expression:

```
gaussdb=# SELECT 40 ! AS "40 factorial";

                  40 factorial
-------------------------------------------------
 815915283247897734345611269596115894272000000000
(1 row)
```

The parser converts the parameter type. The query is equivalent to:

```
gaussdb=# SELECT CAST(40 AS bigint) ! AS "40 factorial";
```

Example 2: String concatenation operator type resolution. A string-like syntax is used for working with string types and for working with complex extension types. Strings with unspecified type are matched with likely operator candidates. An example with one unspecified argument:

```
gaussdb=# SELECT text 'abc' || 'def' AS "text and unknown";
 text and unknown
------------------
 abcdef
(1 row)
```

In this example, the parser looks for an operator whose parameters are of the text type. Such an operator is found.

Here is a concatenation of two values of unspecified types:

```
gaussdb=# SELECT 'abc' || 'def' AS "unspecified";
 unspecified
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
-------------
 abcdef
(1 row)
```

NOTE

In this case there is no initial hint for which type to use, since no types are specified in the query. So, the parser looks for all candidate operators and finds that there are candidates accepting both string-category and bit-string-category inputs. Since string category is preferred when available, that category is selected, and then the preferred type for strings, text, is used as the specific type to resolve the unknown-type literals as.

Example 3: Absolute-value and negation operator type resolution. The GaussDB operator catalog has several entries for the prefix operator @. All the entries implement absolute-value operations for various numeric data types. One of these entries is for the float8 type, which is the preferred type in the numeric category. Therefore, GaussDB will use that entry when faced with an unknown input:

```
gaussdb=# SELECT @ '-4.5' AS "abs";
 abs
-----
 4.5
(1 row)
```

Here the system has implicitly resolved the unknown-type literal as the float8 type before applying the chosen operator.

Example 4: Use the array inclusion operator type resolution as an example. Here is another example of resolving an operator with one known and one unknown input:

```
gaussdb=# SELECT array[1,2] <@ '{1,2,3}' as "is subset";
 is subset
-----------
 t
(1 row)
```

NOTE

The GaussDB operator catalog has several entries for the infix operator <@, but the only two that could possibly accept an integer array on the left side are array inclusion (anyarray <@ anyarray) and range inclusion (anyelement <@ anyrange). Since none of these polymorphic pseudo-types (see **Pseudo-Types**) is considered preferred, the parser cannot resolve the ambiguity on that basis. However, the last resolution rule tells it to assume that the unknown-type literal is of the same type as the other input, that is, integer array. Now only one of the two operators can match, so array inclusion is selected. (Had range inclusion been selected, we would have gotten an error because the string does not have the right format to be a range literal.)

1.9.3 Functions

Function Type Resolution

- Select the functions to be considered from the pg_proc system catalog. If a non-schema-qualified function name was used, the functions in the current search path are considered. If a qualified function name was given, only functions in the specified schema are considered.

  If the search path finds multiple functions of different argument types, a proper function in the path is considered.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- Check for a function accepting exactly the input argument types. If the function exists, use it. Cases involving unknown types will never find a match at this step.
- If no exact match is found, see if the function call appears to be a special type conversion request.
- Look for the best match.
  - Discard candidate functions for which the input types do not match and cannot be converted (using an implicit conversion) to match. Unknown text can be converted to anything for this purpose. If only one candidate remains, use it; else continue to the next step.
  - Run through all candidates and keep those with the most exact matches on input types. Domains are considered the same as their base type for this purpose. Keep all candidates if none has exact matches. If only one candidate remains, use it; else continue to the next step.
  - Run through all candidates and keep those that accept preferred types at the most positions where type conversion will be required. Keep all candidates if none accepts preferred types. If only one candidate remains, use it; else continue to the next step.
  - If any input arguments are of unknown types, check the type categories accepted at those argument positions by the remaining candidates. At each position, select the string category if any candidate accepts that category. (This bias towards string is appropriate since an unknown-type literal looks like a string.) Otherwise, if all the remaining candidates accept the same type category, select that category; otherwise fail because the correct choice cannot be deduced without more clues. Now discard candidates that do not accept the selected type category. Furthermore, if any candidate accepts a preferred type in that category, discard candidates that accept non-preferred types for that argument. Keep all candidates if none survives these tests. If only one candidate remains, use it; else continue to the next step.
  - If there are both unknown and known arguments, and all the known arguments have the same type, assume that the unknown arguments are also of that type, and check which candidates can accept that type at the unknown-argument positions. If exactly one candidate passes this test, use it. Otherwise, an error occurs.

Examples

Example 1: Use the rounding function argument type resolution as the first example. There is only one round function that takes two arguments; it takes a first argument of type numeric and a second argument of type integer. In this case, the following query automatically converts the first argument of type integer to numeric:

```
gaussdb=# SELECT round(4, 4);
 round
--------
 4.0000
(1 row)
```

That query is actually transformed by the parser to:

```
gaussdb=# SELECT round(CAST (4 AS numeric), 4);
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Since numeric constants with decimal points are initially assigned the type numeric, the following query will require no type conversion and therefore might be slightly more efficient:

```
gaussdb=# SELECT round(4.0, 4);
```

Example 2: Use the substring function type resolution as the second example. There are several substr functions, one of which takes types text and integer. If the function is called with a string constant of unspecified type, the system chooses the candidate function that accepts an argument of the preferred category string (namely of type text).

```
gaussdb=# SELECT substr('1234', 3);
 substr
--------
    34
(1 row)
```

If the string is declared to be of type varchar, as might be the case if it comes from a table, then the parser will try to convert it to text:

```
gaussdb=# SELECT substr(varchar '1234', 3);
 substr
--------
    34
(1 row)
```

This is transformed by the parser to effectively become:

```
gaussdb=# SELECT substr(CAST (varchar '1234' AS text), 3);
```

NOTE

The parser learns from the pg_cast catalog that text and varchar are binary-compatible, meaning that one can be passed to a function that accepts the other without doing any physical conversion. Therefore, no type conversion is really inserted in this case.

And, if the function is called with an argument of type integer, the parser will try to convert that to text:

```
gaussdb=# SELECT substr(1234, 3);
substr
--------
 34
(1 row)
```

This is transformed by the parser to effectively become:

```
gaussdb=# SELECT substr(CAST (1234 AS text), 3);
 substr
--------
    34
(1 row)
```

1.9.4 Value Storage

Value Storage Type Resolution

1. Search for an exact match with the target column.
2. Try to directly convert the expression to the target type. If a registered conversion function exists between the two types, call the conversion function directly. If the expression is a text string of an unknown or unspecified type, the content of the text string is converted to the target type.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

3. Check whether the target type supports length conversion (a conversion from a type to itself). If a corresponding length conversion rule is found in the pg_cast catalog, apply it to the expression before storing into the destination column. This type of conversion functions receive a required parameter of the integer type to identify the **atttypmod** value of the target column (that is, the declared length of the column; the interpretation of **atttypmod** varies depending on the data type). In addition, this type of conversion function can also receive an optional parameter of the Boolean type to identify whether the conversion is explicit or implicit. The conversion function is responsible for implementing length-related semantic logic, such as length checks and content truncation.

Type Conversion Supported by Common Types in ORA-compatible Mode

Table 1-332 Common type conversion support

Source Type	Supported Target Type
int1	int2, int4, int8, float4, float8, numeric, bpchar, varchar, nvarchar2, clob
int2	int1, int4, int8, float4, float8, numeric, bpchar, varchar, nvarchar2, clob
int4	int1, int2, int8, float4, float8, numeric, bpchar, varchar, nvarchar2, clob
int8	int1, int2, int4, float4, float8, numeric, bpchar, varchar, nvarchar2, clob
float4	int1, int2, int4, int8, float8, numeric, bpchar, varchar, nvarchar2, clob
float8	int1, int2, int4, int8, float4, numeric, bpchar, varchar, nvarchar2, clob
numeric	int1, int2, int4, int8, float4, float8, bpchar, varchar, nvarchar2, clob
date	timestamp, timestamptz, bpchar, varchar
datea	timestamp, timestamptz, bpchar, varchar, nvarchar2, clob
timestamp	datea, timestamptz, varchar, nvarchar2, clob
timestamptz	timestamp, datea, clob
bpchar	int4, int8, float4, float8, numeric, date, datea, timestamp, varchar, nvarchar2, clob

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Source Type	Supported Target Type
varchar	int4, int8, float4, float8, numeric, date, datea, timestamp, bpchar, nvarchar2, clob, raw, blob
nvarchar2	int4, numeric, datea, timestamp, bpchar, varchar, clob
clob	int1, int2, int4, int8, float4, float8, numeric, datea, timestamp, bpchar, varchar, nvarchar2
raw	varchar, blob
blob	raw
xml	bpchar, varchar, nvarchar2, clob
xmltype	-

Examples

Use the character storage type conversion as an example. For a target column declared as character(20), the following statement shows that the stored value is sized correctly:

```
gaussdb=# CREATE SCHEMA tpcds;
gaussdb=# CREATE TABLE tpcds.value_storage_t1 (
    VS_COL1 CHARACTER(20)
)DISTRIBUTE BY HASH (VS_COL1);
gaussdb=# INSERT INTO tpcds.value_storage_t1 VALUES('abcdef');
gaussdb=# SELECT VS_COL1, octet_length(VS_COL1) FROM tpcds.value_storage_t1;
       vs_col1        | octet_length
----------------------+--------------
 abcdef               |           20
(1 row)
)

gaussdb=# DROP TABLE tpcds.value_storage_t1;
gaussdb=# DROP SCHEMA tpcds;
```

NOTE

What has happened here is that the two unknown literals are resolved to text by default, allowing the **||** operator to be resolved as text concatenation. Then the text result of the operator is converted to bpchar ("blank-padded char", the internal name of the character data type) to match the target column type. Since the conversion from text to bpchar is binary-coercible, this conversion does not insert any real function call. Finally, the sizing function **bpchar(bpchar, integer, Boolean)** is found in the system catalog and used for the operator's result and the stored column length. This type-specific function performs the required length check and addition of padding spaces.

1.9.5 UNION, CASE, and Related Constructs

SQL UNION constructs must match up possibly dissimilar types to become a single result set. The resolution algorithm is applied separately to each output column of a union query. The INTERSECT and EXCEPT constructs resolve dissimilar types in the same way as UNION. The CASE, ARRAY, VALUES, GREATEST and LEAST

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

constructs use the identical algorithm to match up their component expressions and select a result data type.

Type Resolution for UNION, CASE, and Related Constructs

- If all inputs are of the same type and are not unknown, resolve them as the unknown type.
- If all inputs are of the unknown type, resolve them as the text type (the preferred type of the string category). Otherwise, unknown inputs are ignored.
- If the inputs are not all of the same type category, a failure will be resulted. (The unknown type is not included in this case.)
- If the inputs are all of the same type category, choose the top preferred type in that category. (Exception: The UNION operation regards the type of the first branch as the selected type.)

  NOTE

  typcategory in the pg_type system catalog indicates the data type category. **typispreferred** specifies whether a type is preferred in **typcategory**.
- Convert all inputs to the selected type. (Retain the original lengths of strings). Fail if there is not an implicit conversion from a given input to the selected type.
- If the input contains the xml, xmltype, json, txid_snapshot, sys_refcursor, or geometry type, UNION cannot be performed.

The following describes the derivation rules of common types UNION and CASE in ORA-compatible mode. For details about common types, see **Data Types**.

NOTE

The derivation of some UNION and CASE types is related to the parsing sequence of expressions. UNION type derivation processes the output expression of each clause from left to right. CASE type derivation starts with the ELSE clause (default result expression) and then processes the result expression of each WHEN clause from left to right.

Table 1-333 Numeric types

Type (vertical: type 1; horizontal: type 2)	int1	int2	int4	int8	float4	float8	numeric
int1	int1	int2	int4	int8	float4	float8	numeric
int2	int2	int2	int4	int8	float4	float8	numeric

Type Resolution for CASE and COALESCE in TD Compatibility Type

- If all inputs are of the same type and are not unknown, resolve them as the unknown type.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- If all inputs are of the unknown type, resolve them as the text type.
- If inputs are of the string type (including unknown which is resolved as text) and digit type, resolve them as the string type. If the inputs are not of the two types, an error will be reported.
- If the inputs are all of the same type category, choose the top preferred type in that category.
- Convert all inputs to the selected type. Fail if there is not an implicit conversion from a given input to the selected type.

Type Resolution for CASE in ORA-compatible Mode

decode(expr, search1, result1, search2, result2, ..., defresult): When **sql_beta_feature** is set to **a_style_coerce**, the final return value type of the expression is set to the data type of result1 or a higher-precision data type in the same type as result1, as that in ORA-compatible mode. For example, numeric and int are both numeric data types, but numeric has higher precision and priority than int. For CASE WHEN, the behavior is the same as the default behavior in ORA-compatible mode.

- If all inputs are of the same type and are not unknown, resolve them as the unknown type. Otherwise, proceed to the next step.
- Set the data type of result1 to the final return value type preferType, which belongs to preferCategory.
- Consider the data types of result2, result3, and defresult in sequence. If the type category is also preferCategory, which is the same as that of result1, check whether the precision (priority) is higher than that of preferType. If it is, update preferType to a data type with higher precision. If the precision is higher than that of preferCategory, check whether the category can be implicitly converted to preferType. If it cannot, an error is reported.
- Uses the data type recorded by preferType as the return value type of the expression. The expression result is implicitly converted to this data type.

Note 1:

There is a special case where the character type of a super-large number is converted to the numeric type, for example, **select decode(1, 2, 2, '53465465676465454657567678676')**, in which the large number exceeds the range of the bigint and double types. If result1 is of the numeric type and does not meet the condition that all inputs are of the same type, the type of the return value is set to numeric to be compatible with this special case.

Note 2:

Priority of the numeric types: numeric > float8 > float4 > int8 > int4 > int2 > int1

Priority of the character types: text > varchar (nvarchar2) > bpchar > char

Priority of the date type: timestamptz > timestamp > datea (valid only in ORA-compatible mode) > smalldatetime > date > abstime > timetz > time

Priority of date span types: interval > tinterval > reltime

Note 3:

In Oracle-compatible mode, when **set sql_beta_feature** is set to **'a_style_coerce'**, the supported implicit type conversions are shown in **Figure 1-14**. **** indicates that

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

conversion is not required, **yes** indicates that conversion is supported, and the blank value indicates that conversion is not supported.

Examples

Example 1: Use type resolution with underspecified types in a union. The unknown-type literal **'b'** will be resolved to the text type.

```
gaussdb=# SELECT text 'a' AS "text" UNION SELECT 'b';
 text
------
 a
 b
(2 rows)
```

Example 2: Use type resolution in a simple union. The literal **1.2** is of numeric type, and the integer value **1** can be cast implicitly to numeric type, so that type is used.

```
gaussdb=# SELECT 1.2 AS "numeric" UNION SELECT 1;
 numeric
---------
       1
     1.2
(2 rows)
```

Example 3: Use type resolution in a transposed union. The type real cannot be implicitly cast to integer, but integer can be implicitly cast to real, the union result type is resolved as real.

```
gaussdb=# SELECT 1 AS "real" UNION SELECT CAST('2.2' AS REAL);
 real
------
    1
  2.2
(2 rows)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Example 4: In TD mode, if input parameters for **COALESCE** are of int and varchar types, resolve them as the varchar type. In ORA-compatible mode, an error is reported.

```
-- Create the ORA-compatible database ora_1.
gaussdb=# CREATE DATABASE ora_1 dbcompatibility = 'ORA';

-- Switch to the ora_1 database.
gaussdb=# \c ora_1

-- Create the t1 table.
ora_1=# CREATE TABLE t1(a int, b varchar(10));

-- Show the execution plan of a statement for querying the types int and varchar of input parameters for COALESCE.
a_1=# EXPLAIN SELECT coalesce(a, b) FROM t1;
ERROR:  COALESCE types integer and character varying cannot be matched
LINE 1: EXPLAIN SELECT coalesce(a, b) FROM t1;
                               ^
CONTEXT:  referenced column: coalesce

-- Delete the table.
ora_1=# DROP TABLE t1;

-- Switch to the testdb database.
ora_1=# \c testdb

-- In TD mode, create the td_1 database compatible with Teradata.
gaussdb=# CREATE DATABASE td_1 dbcompatibility = 'TD';

-- Switch to the td_1 database.
gaussdb=# \c td_1

-- Create the t2 table.
td_1=# CREATE TABLE t2(a int, b varchar(10));

-- Show the execution plan of a statement for querying the types int and varchar of input parameters for COALESCE.
td_1=# EXPLAIN VERBOSE select coalesce(a, b) from t2;
                                  QUERY PLAN
-------------------------------------------------------------------------------------
 Data Node Scan  (cost=0.00..0.00 rows=0 width=0)
   Output: (COALESCE((t2.a)::character varying, t2.b))
   Node/s: All datanodes
   Remote query: SELECT COALESCE(a::character varying, b) AS "coalesce" FROM public.t2
(4 rows)

-- Delete the table.
td_1=# DROP TABLE t2;

-- Switch to the testdb database.
td_1=# \c testdb

-- Delete Oracle- and TD-compatible databases.
gaussdb=# DROP DATABASE ora_1;
gaussdb=# DROP DATABASE td_1;
```

Example 5: In ORA-compatible mode, set the final return value type of the expression to the data type of result1 or a higher-precision data type whose category is the same as that of the data type of result1.

```
-- In ORA-compatible mode, create the ora_1 database compatible with ORA.
gaussdb=# CREATE DATABASE ora_1 dbcompatibility = 'ORA';

-- Switch to the ora_1 database.
gaussdb=# \c ora_1

-- Enable the decode compatibility parameters.
ora_1=# SET sql_beta_feature='a_style_coerce';
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
-- Create the t1 table.
ora_1=# CREATE TABLE t1(c_int int, c_float8 float8, c_char char(10), c_text text, c_date date);

-- Insert data.
ora_1=# INSERT INTO t1 VALUES(1, 2, '3', '4', date '12-10-2010');

-- The data type of result1 is char and that of defresult is text. The precision of text is higher, and the type of the return value is changed to text from char.
ora_1=# SELECT decode(1, 2, c_char, c_text) AS result, pg_typeof(result) FROM t1;
 result | pg_typeof
--------+-----------
 4      | text
(1 row)

-- The data type of result1 is int, which is a numeric type. The type of the return value is set to numeric.
ora_1=# SELECT decode(1, 2, c_int, c_float8) AS result, pg_typeof(result) FROM t1;
 result | pg_typeof
--------+-----------
      2 | numeric
(1 row)

-- The implicit conversion from the data type of defresult to that of result1 does not exist. If it is performed, an error is reported.
ora_1=# SELECT decode(1, 2, c_int, c_date) FROM t1;
ERROR:  CASE types integer and timestamp without time zone cannot be matched
LINE 1: SELECT decode(1, 2, c_int, c_date) FROM t1;
                            ^
CONTEXT:  referenced column: c_date

-- Disable the decode compatibility parameters.
ora_1=# SET sql_beta_feature='none';

-- Delete the table.
ora_1=# DROP TABLE t1;
DROP TABLE

-- Switch to the testdb database.
ora_1=# \c testdb

-- Delete the ORA-compatible database.
gaussdb=# DROP DATABASE ora_1;
DROP DATABASE
```

1.10 System Operation

GaussDB runs SQL statements to perform different system operations, such as setting variables, displaying the execution plan, and collecting garbage data.

Setting Variables

For details about how to set various parameters for a session or transaction, see **SET**.

Displaying the Execution Plan

For details about how to display the execution plan that GaussDB makes for SQL statements, see **EXPLAIN**.

Specifying a Checkpoint in Transaction Logs

By default, WALs periodically specify checkpoints in a transaction log. CHECKPOINT performs an immediate checkpoint when the related command is

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

issued, without waiting for a regular checkpoint scheduled by the system. For details, see **CHECKPOINT**.

Collecting Unnecessary Data

For details about how to collect garbage data and analyze a database as required, For details, see **VACUUM**.

Collecting Statistics

For details about how to collect statistics on tables in databases, For details, see **ANALYZE | ANALYSE**.

Setting the Constraint Check Mode for the Current Transaction

For details about how to set the constraint check mode for the current transaction, For details, see **SET CONSTRAINTS**.

1.11 Controlling Transactions

A transaction is a user-defined sequence of database operations, which form an integral unit of work.

Starting a Transaction

GaussDB starts a transaction using **START TRANSACTION** and **BEGIN**. For details, see **START TRANSACTION** and **BEGIN**.

Setting a Transaction

GaussDB sets a transaction using **SET TRANSACTION** or **SET LOCAL TRANSACTION**. For details, see **SET TRANSACTION**.

Committing a Transaction

GaussDB commits all operations of a transaction using **COMMIT** or **END**. For details, see **COMMIT | END**.

Rolling Back a Transaction

If a fault occurs during a transaction and the transaction cannot proceed, the system performs rollback to cancel all the completed database operations related to the transaction. For details, see **ROLLBACK**.

NOTE

If an execution request (not in a transaction block) received in the database contains multiple statements, the request is packed into a transaction. If one of the statements fails, the entire request will be rolled back.

1.12 Full-Text Search

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

1.12.1 Introduction

1.12.1.1 Full-Text Search

Text search operators have been used in databases for years. GaussDB provides ~, ~*, LIKE, and ILIKE operators for text data type searching and filtering. However, they lack many essential text attributes required by modern information systems. These problems can be solved by using full-text search indexes and dictionaries.

Text search lacks the following essential properties required by information systems:

- There is no semantic support, even for English.

  Regular expressions are not sufficient because they cannot easily handle derived words. For example, when you search for **satisfy** using the regular expressions, documents that contain **satisfies** cannot be found. It is possible to use OR to search for multiple derived forms, but this is tedious and error-prone because some words can have several thousand derivatives.
- They provide no ordering (ranking) of search results, which makes them ineffective when thousands of matching documents are found.
- They tend to be slow because there is no index support, so they must process all documents for every search.

Full-text search preprocesses documents to facilitate subsequent search. The preprocessing process includes:

- Parse documents into tokens.

  It is useful to identify various classes of tokens, for example, numbers, words, compound words, and email addresses, so that they can be processed differently. In principle, token classes depend on the specific application, but for most purposes it is adequate to use a predefined set of classes.
- Convert tokens into lexemes.

  A lexeme is a string, just like a token, but it has been normalized so that different forms of the same word are made alike. Normalization almost always includes folding upper-case letters to lower-case, and often involves removal of suffixes (such as "s" or "es" in English). This allows searches to find variant forms of the same word, without entering all the possible variants. Also, this step typically eliminates stop words, which are so common and usually useless for searching. (In short, tokens are raw fragments of the document text, while lexemes are words that are believed useful for indexing and searching.) GaussDB uses dictionaries to perform this step and provides various standard dictionaries.
- Store preprocessed documents.

  Each document can be represented as a sorted array of normalized lexemes. Along with the lexemes, it is often desirable to store positional information for proximity ranking. Therefore, a document that contains a more "dense" area of search words is assigned a higher rank than the one with scattered search words.

Dictionaries allow granular control over how tokens are normalized. With appropriate dictionaries, you can define stop words that should not be indexed.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

The tsvector data type is provided for storing preprocessed documents, along with the tsquery type for storing query conditions. For details, see **Text Search Types**. For details about the functions and operators available for these data types, see **Text Search Functions and Operators**. The match operator @@, which is the most important among those functions and operators, is described in **Basic Text Matching**.

1.12.1.2 What Is a Document

A document is the unit of searching in a full-text search system; for example, a magazine article or email message. The text search engine must be able to parse documents and store associations of lexemes (keywords) with their parent document. Later, these associations are used to search for documents that contain search words.

In GaussDB, a document is normally a textual column within a row of a database table, or possibly a combination (concatenation) of such columns, perhaps stored in several tables or obtained dynamically. In other words, a document can be constructed from different parts for indexing and it might not be stored anywhere as a whole. For example:

```
gaussdb=# CREATE TABLE document_table (id int,person text,time timestamp,location text,thing
text,document text);
CREATE TABLE
gaussdb=# INSERT INTO document_table VALUES('1','Jack','2024-01-01 10:00:00','company','working','Jack
worked at the company on 2024-01-01 10:00:00.');
INSERT 0 1
gaussdb=# SELECT person || '-' || thing || '-' || location || '-' || time AS identify_serials FROM document_table
WHERE id =1;
          identify_serials
----------------------------------------
 Jack-working-company-2024-01-01 10:00:00
(1 row)
gaussdb=# DROP TABLE document_table;
```

Another possibility is to store the documents as simple text files in the file system. In this case, the database can be used to store indexes for full-text search, and some unique identifiers can be used to search the documents in the file system. However, searching documents outside the database requires system administrator permissions or special function support. Therefore, this is less convenient than keeping all the data inside the database. Also, keeping everything inside the database allows easy access to document metadata to assist in indexing and display.

For text search purposes, each document must be compacted to the preprocessed tsvector format. Searching and relevance-based ranking are performed entirely on the tsvector representation of a document. The raw text is retrieved only when the document has been selected for display to a user. Therefore, tsvector is usually referred to as a document, but it is only a compact representation of the full document.

1.12.1.3 Basic Text Matching

Full-text search in GaussDB is based on the match operator @@, which returns **true** if a tsvector (document) matches a tsquery (query). It does not matter which data type is written first:

```
gaussdb=# SELECT 'a fat cat sat on a mat and ate a fat rat'::tsvector @@ 'cat & rat'::tsquery AS RESULT;
 result
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
----------
 t
(1 row)

gaussdb=# SELECT 'fat & cow'::tsquery @@ 'a fat cat sat on a mat and ate a fat rat'::tsvector AS RESULT;
 result
----------
 f
(1 row)
```

As the above example suggests, a tsquery is not only raw text, but more than a tsvector is. A tsquery contains search words, which must be already-normalized lexemes, and may combine multiple words using AND, OR, NOT, and PHRASE operators. For details, see **Text Search Types**. The to_tsquery, plainto_tsquery, and phraseto_tsquery functions are helpful for converting user-written text into a proper tsquery, for example, normalizing words appearing in the text. Similarly, to_tsvector is used to parse and normalize a document string. The following is an example of text search matching in practice:

```
gaussdb=# SELECT to_tsvector('fat cats ate fat rats') @@ to_tsquery('fat & rat') AS RESULT;
result
----------
 t
(1 row)
```

Note that this match would not succeed if it is written as follows:

```
gaussdb=# SELECT 'fat cats ate fat rats'::tsvector @@ to_tsquery('fat & rat')AS RESULT;
result
----------
 f
(1 row)
```

In the preceding match, no normalization of the word **rats** will occur. Therefore, **rats** does not match **rat**.

The @@ operator also supports textual input, allowing explicit conversion of a text string to tsvector or tsquery to be skipped in simple cases. The variants available are:

```
tsvector @@ tsquery
tsquery  @@ tsvector
text @@ tsquery
text @@ text
```

In the preceding information, the form **text @@ tsquery** is equivalent to **to_tsvector(text) @@ tsquery**. The form **text @@ text** is equivalent to **to_tsvector(text) @@ plainto_tsquery(text)**.

1.12.1.4 Configuration

Full-text search functionality includes the ability to do many more things, for example, skipping certain words (stop words), processing synonyms, and sophisticated parsing. This functionality is controlled by text search configurations. GaussDB supports predefined text search configurations in multiple languages.

During installation, you can select an appropriate text search configuration and set **default_text_search_config** accordingly in **gaussdb.conf**. If you are using the same text search configuration for the cluster, you can use the value in **gaussdb.conf**. To use different text search configurations in the cluster, run **ALTER DATABASE ... SET** in the corresponding database. Alternatively, you can set **default_text_search_config** in each session.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Each text search function has an optional **regconfig** parameter, so the configuration to be used can be explicitly specified. **default_text_search_config** is used only when this parameter is ignored.

1.12.2 Tables and Indexes

1.12.2.1 Searching a Table

It is possible to do a full-text search without an index.

- A simple query to print each row that contains the word **america** in its **body** column is as follows:

```
gaussdb=# DROP SCHEMA IF EXISTS tsearch CASCADE;
gaussdb=# CREATE SCHEMA tsearch;
gaussdb=# CREATE TABLE tsearch.pgweb(id int, body text, title text, last_mod_date date)
with(storage_type = ASTORE);
gaussdb=# INSERT INTO tsearch.pgweb VALUES(1, 'America is a rock band, formed in England in
1970 by multi-instrumentalists Dewey Bunnell, Dan Peek, and Gerry Beckley.', 'America', '2010-1-1');
gaussdb=# INSERT INTO tsearch.pgweb VALUES(2, 'England is a country that is part of the United
Kingdom. It shares land borders with Scotland to the north and Wales to the west.', 'England',
'2010-1-1');
gaussdb=# INSERT INTO tsearch.pgweb VALUES(3, 'Australia, officially the Commonwealth of
Australia, is a country comprising the mainland of the Australian continent, the island of Tasmania,
and numerous smaller islands.', 'Australia', '2010-1-1');
gaussdb=# INSERT INTO tsearch.pgweb VALUES(4, 'Japan is an island country in East Asia.', 'Japan',
'2010-1-1');
gaussdb=# INSERT INTO tsearch.pgweb VALUES(5, 'Germany, officially the Federal Republic of
Germany, is a sovereign state and federal parliamentary republic in central-western Europe.',
'Germany', '2010-1-1');
gaussdb=# INSERT INTO tsearch.pgweb VALUES(6, 'France, is a sovereign state comprising territory in
western Europe and several overseas regions and territories.', 'France', '2010-1-1');
gaussdb=# INSERT INTO tsearch.pgweb VALUES(7, 'Italy officially the Italian Republic, is a unitary
parliamentary republic in Europe.', 'Italy', '2010-1-1');
gaussdb=# INSERT INTO tsearch.pgweb VALUES(8, 'India, officially the Republic of India, is a country
in South Asia.', 'India', '2010-1-1');
gaussdb=# INSERT INTO tsearch.pgweb VALUES(9, 'Brazil, officially the Federative Republic of Brazil,
is the largest country in both South America and Latin America.', 'Brazil', '2010-1-1');
gaussdb=# INSERT INTO tsearch.pgweb VALUES(10, 'Canada is a country in the northern half of
North America.', 'Canada', '2010-1-1');
gaussdb=# INSERT INTO tsearch.pgweb VALUES(11, 'Mexico, officially the United Mexican States, is a
federal republic in the southern part of North America.', 'Mexico', '2010-1-1');

gaussdb=# SELECT id, body, title FROM tsearch.pgweb WHERE to_tsvector('english', body) @@
to_tsquery('english', 'america');
 id |                                                 body                                                 | title
----
+--------------------------------------------------------------------------------------------------------------------------------
----+---------
  1 | America is a rock band, formed in England in 1970 by multi-instrumentalists Dewey Bunnell, Dan
Peek, and Gerry Beckley. | America
  9 | Brazil, officially the Federative Republic of Brazil, is the largest country in both South America
and Latin America.   | Brazil
 10 | Canada is a country in the northern half of North
America.                                                | Canada
 11 | Mexico, officially the United Mexican States, is a federal republic in the southern part of North
America.             | Mexico
(4 rows)
```

  This will also find related words, such as **America**, since all these are processed to the same normalized lexeme.

  The query above specifies that the **english** tokenizer is used to parse and normalize the strings. You can also skip this configuration and perform the configuration through **default_text_search_config**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gaussdb=# SHOW default_text_search_config;
 default_text_search_config
----------------------------
 pg_catalog.english
(1 row)

gaussdb=# SELECT id, body, title FROM tsearch.pgweb WHERE to_tsvector(body) @@
to_tsquery('america');
 id |                                                 body                                                 | title
----
+----------------------------------------------------------------------------------------------------------------------------------
----+---------
  1 | America is a rock band, formed in England in 1970 by multi-instrumentalists Dewey Bunnell, Dan
Peek, and Gerry Beckley. | America
  9 | Brazil, officially the Federative Republic of Brazil, is the largest country in both South America
and Latin America.   | Brazil
 10 | Canada is a country in the northern half of North
America.                                             | Canada
 11 | Mexico, officially the United Mexican States, is a federal republic in the southern part of North
America.              | Mexico
(4 rows)
```

- A more complex example to select the ten most recent documents that contain **north** and **america** in the **title** or **body** column is as follows:

  ```
  gaussdb=# SELECT title FROM tsearch.pgweb WHERE to_tsvector(title || ' ' || body) @@
  to_tsquery('north & america') ORDER BY last_mod_date DESC LIMIT 10;
   title
  --------
   Canada
   Mexico
  (2 rows)

  -- Drop the table.
  gaussdb=# DROP TABLE tsearch.pgweb;
  gaussdb=# DROP SCHEMA tsearch;
  ```

  For clarity we omitted the coalesce function calls which would be needed to find rows that contain **NULL** in one of the two columns.

  The preceding examples show queries without using indexes. Most applications will find this approach too slow. Therefore, practical use of text search usually requires creating an index, except perhaps for occasional ad-hoc searches.

1.12.2.2 Creating an Index

You can create a GIN to speed up text search.

```
gaussdb=# CREATE SCHEMA tsearch;
gaussdb=# CREATE TABLE tsearch.pgweb(id int, body text, title text, last_mod_date date) with(storage_type
= ASTORE);
gaussdb=# INSERT INTO tsearch.pgweb VALUES(1, 'America is a rock band, formed in England in 1970 by
multi-instrumentalists Dewey Bunnell, Dan Peek, and Gerry Beckley.', 'America', '2010-1-1');
gaussdb=# INSERT INTO tsearch.pgweb VALUES(2, 'England is a country that is part of the United
Kingdom. It shares land borders with Scotland to the north and Wales to the west.', 'England', '2010-1-1');
gaussdb=# INSERT INTO tsearch.pgweb VALUES(3, 'Australia, officially the Commonwealth of Australia, is a
country comprising the mainland of the Australian continent, the island of Tasmania, and numerous
smaller islands.', 'Australia', '2010-1-1');
gaussdb=# INSERT INTO tsearch.pgweb VALUES(4, 'Japan is an island country in East Asia.', 'Japan',
'2010-1-1');
gaussdb=# INSERT INTO tsearch.pgweb VALUES(5, 'Germany, officially the Federal Republic of Germany, is
a sovereign state and federal parliamentary republic in central-western Europe.', 'Germany', '2010-1-1');
gaussdb=# INSERT INTO tsearch.pgweb VALUES(6, 'France, is a sovereign state comprising territory in
western Europe and several overseas regions and territories.', 'France', '2010-1-1');
gaussdb=# INSERT INTO tsearch.pgweb VALUES(7, 'Italy officially the Italian Republic, is a unitary
parliamentary republic in Europe.', 'Italy', '2010-1-1');
gaussdb=# INSERT INTO tsearch.pgweb VALUES(8, 'India, officially the Republic of India, is a country in
South Asia.', 'India', '2010-1-1');
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gaussdb=# INSERT INTO tsearch.pgweb VALUES(9, 'Brazil, officially the Federative Republic of Brazil, is the largest country in both South America and Latin America.', 'Brazil', '2010-1-1');
gaussdb=# INSERT INTO tsearch.pgweb VALUES(10, 'Canada is a country in the northern half of North America.', 'Canada', '2010-1-1');
gaussdb=# INSERT INTO tsearch.pgweb VALUES(11, 'Mexico, officially the United Mexican States, is a federal republic in the southern part of North America.', 'Mexico', '2010-1-1');
gaussdb=# CREATE INDEX pgweb_idx_1 ON tsearch.pgweb USING gin(to_tsvector('english', body));
```

The to_tsvector() function comes in to two versions: the 1-argument version and the 2-argument version. When the 1-argument version is used, the system uses the default configuration specified by **default_text_search_config**.

Notice that the 2-argument version of to_tsvector is used for index creation. Only full-text search functions that specify text search configuration can be correctly used in expression indexes. This is because the index contents must be unaffected by **default_text_search_config**, whose value can be changed at any time. If they were affected, the index contents might be inconsistent because different entries could contain tsvectors that were created with different text search configurations, and there would be no way to guess which was which. It would be impossible to dump and restore such an index correctly.

Because the 2-argument version of to_tsvector was used in the index above, only a query reference that uses the 2-argument version of to_tsvector with the same configuration will use that index. That is, **WHERE to_tsvector('english', body) @@ 'a & b'** can use the index, but **WHERE to_tsvector(body) @@ 'a & b'** cannot. This ensures that an index will be used only with the same tokenizer used to create the index entries.

It is possible to set up more complex expression indexes wherein the tokenizer name is specified by another column. For example:

```
gaussdb=# ALTER TABLE tsearch.pgweb ADD COLUMN config_name regconfig;
gaussdb=# CREATE INDEX pgweb_idx_2 ON tsearch.pgweb USING gin(to_tsvector('ngram', body));
```

This allows for mixed configurations within the same index, while recording the specific configuration used for each index entry. For example, this may be useful when the document collection includes documents in various languages. Similarly, queries that use an index must match an expression index, for example, **WHERE to_tsvector(config_name, body) @@ 'a & b'**.

Indexes can even concatenate columns:

```
gaussdb=# CREATE INDEX pgweb_idx_3 ON tsearch.pgweb USING gin(to_tsvector('english', title || ' ' || body));
```

Another approach is to create a separate **tsvector** column to hold the output of to_tsvector. This example is a concatenation of **title** and **body**, using COALESCE to ensure that one column will still be indexed when the other is **NULL**:

```
gaussdb=# ALTER TABLE tsearch.pgweb ADD COLUMN textsearchable_index_col tsvector;
gaussdb=# UPDATE tsearch.pgweb SET textsearchable_index_col = to_tsvector('english', coalesce(title,'') || ' ' || coalesce(body,''));
```

Then, create a GIN to speed up the search:

```
gaussdb=# CREATE INDEX textsearch_idx_4 ON tsearch.pgweb USING gin(textsearchable_index_col);
```

Now you are ready to perform a fast full-text search:

```
gaussdb=# SELECT title
FROM tsearch.pgweb
WHERE textsearchable_index_col @@ to_tsquery('north & america')
ORDER BY last_mod_date DESC
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
LIMIT 10;

 title
--------
 Canada
 Mexico
(2 rows)

-- Drop the table.
gaussdb=# DROP TABLE tsearch.pgweb;
gaussdb=# DROP SCHEMA tsearch;
```

One advantage of the separate-column approach over an expression index is that it is unnecessary to explicitly specify the text search tokenizer in queries in order to use the index. As shown in the preceding example, the query can depend on **default_text_search_config**. Another advantage is that searches will be faster, since it will not be necessary to call the to_tsvector again to verify index matches. The expression-index approach is simpler to set up, however, it requires less disk space since the tsvector representation is not stored explicitly.

NOTE

- GINs are supported only under Astore.
- For details about the restrictions on other GINs, see **CREATE INDEX**.

tsvector supports the creation of UGINs in Ustore.

```
-- Create a table.
gaussdb=# CREATE TABLE ustore_tbl (id int, content text, ts tsvector) WITH (storage_type = USTORE);

-- Create indexes.
gaussdb=# CREATE INDEX textsearch_ugin_idx1 ON ustore_tbl USING ugin(ts);
gaussdb=# CREATE INDEX textsearch_ugin_idx2 ON ustore_tbl USING ugin(to_tsvector('english', content));

-- Drop the table.
gaussdb=# DROP TABLE ustore_tbl;
```

NOTE

- UGINs are supported only under Ustore. Other aspects of UGINs are basically the same as those of GINs.
- For details about the restrictions on other UGINs, see **CREATE INDEX**.

1.12.3 Controlling Text Search

To implement full-text search, there must be a function to create a tsvector from a document and a tsquery from a user query. Also, we need to return results in a useful order, so we need a function that compares documents with respect to their relevance to the query. It is also important to be able to display the results nicely. All these functions can be used in GaussDB.

1.12.3.1 Parsing Documents

GaussDB provides the to_tsvector function for converting a document to the tsvector data type.

```
to_tsvector([ config regconfig, ] document text) returns tsvector
```

The to_tsvector function parses a textual document into tokens, reduces the tokens to lexemes, and returns a tsvector. The tsvector contains each lexeme and the position of the lexeme in the document. The document is processed according to the default or specified text search tokenizer. Here is a simple example:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gaussdb=# SELECT to_tsvector('english', 'a fat  cat sat on a mat - it ate a fat rats');
                  to_tsvector
-----------------------------------------------------
 'ate':9 'cat':3 'fat':2,11 'mat':7 'rat':12 'sat':4
```

In the preceding example, the tsvector result does not contain the words **a**, **on**, or **it**, the word **rats** became **rat**, and the hyphen (-) was ignored.

The to_tsvector function internally calls a parser which breaks the document text into tokens and assigns a type to each token. For each token, a list of dictionaries is consulted. where the list can vary depending on the token type. The first dictionary that recognizes the token will produce one or more normalized lexemes to represent the token. Example:

- **rats** became **rat** because one of the dictionaries recognized that the word **rats** is a plural form of **rat**.
- Some words are recognized as stop words (see **Stop Words**), which causes them to be ignored since they occur too frequently to be useful in searching. In our example, these are **a**, **on**, and **it**.
- If no dictionary in the list recognizes the token, then it is also ignored. In this example that happened to the punctuation sign (-) because there are no dictionaries assigned for its token type (space symbols), meaning space tokens will never be indexed.

The choices of parser, dictionaries, and which types of tokens to index are determined by the selected text search configuration. It is possible to have many different configurations in the same database and predefined configurations in multiple languages. In the preceding example, **english** is used by default.

The setweight function can be used to label the entries of a tsvector with a given weight, where a weight is one of the letters A, B, C, or D, which is typically used to mark entries coming from different parts of a document, such as the title and body. Then, the search results can be sorted based on the weights of the parts of the document.

Because to_tsvector(NULL) will return **NULL**, you are advised to use COALESCE whenever a column might be null. Here is the recommended method for creating a tsvector from a structured document:

```
gaussdb=# CREATE TABLE tsearch.tt (id int, title text, keyword text, abstract text, body text, ti tsvector);

gaussdb=# INSERT INTO tsearch.tt(id, title, keyword, abstract, body) VALUES (1, 'America', 'New York',
'America','America is a rock band, formed in England in 1970 by multi-instrumentalists Dewey Bunnell, Dan
Peek, and Gerry Beckley.');

gaussdb=# UPDATE tsearch.tt SET ti =
    setweight(to_tsvector(coalesce(title,'')), 'A')    ||
    setweight(to_tsvector(coalesce(keyword,'')), 'B')  ||
    setweight(to_tsvector(coalesce(abstract,'')), 'C') ||
    setweight(to_tsvector(coalesce(body,'')), 'D');
gaussdb=# DROP TABLE tsearch.tt;
```

In this example, **setweight** is used to label the source of each lexeme in the finished tsvector, and then the labeled tsvector values are concatenated using the tsvector concatenation operator ||. For details about these operations, see **Manipulating tsvector**.

1.12.3.2 Parsing Queries

GaussDB provides functions to_tsquery, plainto_tsquery, and phraseto_tsquery for converting a query to the tsquery data type. The to_tsquery function offers access

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

to more features than plainto_tsquery and phraseto_tsquery, but is less forgiving about its input.

```
to_tsquery([ config regconfig, ] querytext text) returns tsquery
```

The to_tsquery function creates a tsquery value from querytext, which must consist of single tokens separated by the operators & (AND), | (OR), ! (NOT), and <-> or <n> (PHRASE). These operators can be grouped using parentheses. The input to to_tsquery must follow the general rules for tsquery input, as described in **Text Search Types**. The difference is that while basic tsquery input takes the tokens at face value, to_tsquery normalizes each token to a lexeme using the specified or default configuration, and discards any tokens that are stop words according to the configuration. For example:

```
gaussdb=# SELECT to_tsquery('english', 'The & Fat & Rats');
  to_tsquery
---------------
 'fat' & 'rat'
(1 row)
```

As in basic tsquery input, **weight(s)** can be attached to each lexeme to restrict it to match only tsvector lexemes of those **weight(s)**. For example:

```
gaussdb=# SELECT to_tsquery('english', 'Fat | Rats:AB');
    to_tsquery
------------------
 'fat' | 'rat':AB
(1 row)
```

Also, the asterisk (*) can be attached to a lexeme to specify prefix matching.

```
gaussdb=# SELECT to_tsquery('supern:*A & star:A*B');
        to_tsquery
--------------------------
 'supern':*A & 'star':*AB
(1 row)
```

Such a lexeme will match any word having the specified string and weight in a tsquery.

```
plainto_tsquery([ config regconfig, ] querytext text) returns tsquery
```

The plainto_tsquery function converts unformatted text querytext to tsquery. The text is parsed and normalized much as for to_tsvector, then the & (AND) Boolean operator is inserted between surviving words.

For example:

```
gaussdb=# SELECT plainto_tsquery('english', 'The Fat Rats');
 plainto_tsquery
-----------------
 'fat' & 'rat'
(1 row)
```

Note that plainto_tsquery cannot recognize operators, weight labels, or prefix-match labels in its input.

```
gaussdb=# SELECT plainto_tsquery('english', 'The Fat & Rats:C');
  plainto_tsquery
---------------------
 'fat' & 'rat' & 'c'
(1 row)
```

All the input punctuation was discarded as being space symbols.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Similar to plainto_tsquery, phraseto_tsquery converts unformatted text querytext to tsquery, with the connection operator <-> (PHRASE).

1.12.3.3 Ranking Search Results

Ranking attempts to measure how relevant documents are to a particular query, so that when there are many matches the most relevant ones can be shown first. GaussDB provides two predefined ranking functions. The functions take into account lexical, proximity, and structural information; that is, how often the search words appear in the document, how close together the words are in the document, and how important is the part of the document where the words appear. However, the concept of relevancy is vague and application-specific. Different applications might require additional information for ranking, for example, document modification time. The built-in ranking functions are only examples. You can write your own ranking functions and/or combine their results with additional factors to fit your specific needs.

The two ranking functions currently available are:

```
ts_rank([ weights float4[], ] vector tsvector, query tsquery [, normalization integer ]) returns float4
```

The ts_rank function ranks vectors based on the frequency of matching lexemes in the vector.

```
ts_rank_cd([ weights float4[], ] vector tsvector, query tsquery [, normalization integer ]) returns float4
```

The ts_rank_cd function calculates a cover density ranking for a given document vector and query. Cover density is similar to ts_rank ranking, except that it considers the proximity of matching lexemes to each other.

This function requires positional information in its input. When the matching token lacks position information, the result is **0**.

For both these functions, the optional **weights** parameter offers the ability to weigh word instances more or less heavily depending on how they are labeled. The weight arrays specify how heavily to weigh each category of words, in the order:

```
{D-weight, C-weight, B-weight, A-weight}
```

If no weights are provided, then the default is used: **{0.1, 0.2, 0.4, 1.0}**.

Typically weights are used to mark words from special areas of the document, like the title or an initial abstract, so they can be treated with more or less importance than words in the document body.

Since a longer document has a greater chance of containing a search word, it is reasonable to take into account document size. For example, a hundred-word document with five instances of a search word is probably more relevant than a thousand-word document with five instances. Both ranking functions take an integer normalization option that specifies whether and how a document's length should impact its rank. The integer option controls several behaviors, so it is a bit mask: you can specify one or more behaviors using a vertical bar (|) (for example, 2|4).

- **0** (default): ignores the document length.
- **1**: divides the rank by (1 + logarithm of the document length).

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **2**: divides the rank by the document length.
- **4**: divides the rank by the mean harmonic distance between extents. This is implemented only by ts_rank_cd.
- **8** divides the rank by the number of unique words in document.
- **16** divides the rank by (1 + logarithm of the number of unique words in document).
- **32** divides the rank by (itself + 1).

If more than one flag bit is specified, the transformations are applied in the order listed.

It is important to note that the ranking functions do not use any global information, so it is impossible to produce a fair normalization to 1% or 100% as sometimes desired. Normalization option 32 (rank/(rank + 1)) can be applied to scale all ranks into the range zero to one, but this is just a cosmetic change; it will not affect the ordering of the search results.

The following is an example that selects only the top 10 matches:

```
gaussdb=# CREATE SCHEMA tsearch;
gaussdb=# CREATE TABLE tsearch.pgweb(id int, body text, title text, last_mod_date date) with(storage_type = ASTORE);
gaussdb=# INSERT INTO tsearch.pgweb VALUES(1, 'America is a rock band, formed in England in 1970 by multi-instrumentalists Dewey Bunnell, Dan Peek, and Gerry Beckley.', 'America', '2010-1-1');
gaussdb=# INSERT INTO tsearch.pgweb VALUES(2, 'England is a country that is part of the United Kingdom. It shares land borders with Scotland to the north and Wales to the west.', 'England', '2010-1-1');
gaussdb=# INSERT INTO tsearch.pgweb VALUES(3, 'Australia, officially the Commonwealth of Australia, is a country comprising the mainland of the Australian continent, the island of Tasmania, and numerous smaller islands.', 'Australia', '2010-1-1');
gaussdb=# INSERT INTO tsearch.pgweb VALUES(4, 'Japan is an island country in East Asia.', 'Japan', '2010-1-1');
gaussdb=# INSERT INTO tsearch.pgweb VALUES(5, 'Germany, officially the Federal Republic of Germany, is a sovereign state and federal parliamentary republic in central-western Europe.', 'Germany', '2010-1-1');
gaussdb=# INSERT INTO tsearch.pgweb VALUES(6, 'France, is a sovereign state comprising territory in western Europe and several overseas regions and territories.', 'France', '2010-1-1');
gaussdb=# INSERT INTO tsearch.pgweb VALUES(7, 'Italy officially the Italian Republic, is a unitary parliamentary republic in Europe.', 'Italy', '2010-1-1');
gaussdb=# INSERT INTO tsearch.pgweb VALUES(8, 'India, officially the Republic of India, is a country in South Asia.', 'India', '2010-1-1');
gaussdb=# INSERT INTO tsearch.pgweb VALUES(9, 'Brazil, officially the Federative Republic of Brazil, is the largest country in both South America and Latin America.', 'Brazil', '2010-1-1');
gaussdb=# INSERT INTO tsearch.pgweb VALUES(10, 'Canada is a country in the northern half of North America.', 'Canada', '2010-1-1');
gaussdb=# INSERT INTO tsearch.pgweb VALUES(11, 'Mexico, officially the United Mexican States, is a federal republic in the southern part of North America.', 'Mexico', '2010-1-1');

gaussdb=# SELECT id, title, ts_rank_cd(to_tsvector(body), query) AS rank
FROM tsearch.pgweb, to_tsquery('america') query
WHERE query @@ to_tsvector(body)
ORDER BY rank DESC
LIMIT 10;
 id |  title  | rank
----+---------+------
 11 | Brazil  |   .2
  2 | America |   .1
 12 | Canada  |   .1
 13 | Mexico  |   .1
(4 rows)
```

The following is the same example using normalized ranking:

```
gaussdb=# SELECT id, title, ts_rank_cd(to_tsvector(body), query, 32 /* rank/(rank+1) */ ) AS rank
FROM tsearch.pgweb, to_tsquery('america') query
WHERE  query @@ to_tsvector(body)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
ORDER BY rank DESC
LIMIT 10;
 id |  title  |   rank
----+---------+----------
 11 | Brazil  |  .166667
  2 | America | .0909091
 12 | Canada  | .0909091
 13 | Mexico  | .0909091
(4 rows)

-- Drop the table.
gaussdb=# DROP TABLE tsearch.pgweb;
gaussdb=# DROP SCHEMA tsearch;
```

Ranking can be expensive since it requires consulting the tsvector of each matching document, which can be subject to I/O bound and therefore slow.

1.12.3.4 Highlighting Search Results

To present search results, it is ideal to show a part of each document and how it is related to the query. Typically, the search engine highlights the search words within the document snippets displayed. GaussDB provides the ts_headline function to implement this functionality.

```
ts_headline([ config regconfig, ] document text, query tsquery [, options text ]) returns text
```

ts_headline accepts a document and a query, and returns a snippet from the document where terms from the query are highlighted. The configuration used to parse the document can be specified by **config**. If **config** is omitted, the configuration specified by **default_text_search_config** is used.

options indicates optional configurations, consisting of one or more option=value pairs, which must be separated by commas. The available options are:

- **StartSel**, **StopSel**: The strings with which to delimit search words appearing in the document, to distinguish them from other excerpted words. You must double-quote these strings if they contain spaces or commas. The maximum length is 32767 bytes.
- **MaxWords**, **MinWords**: These numbers determine the longest and shortest excerpted words to output.
- **ShortWord**: Words of this length or less will be dropped at the start and end of an excerpt. The default value **3** eliminates common English articles.
- **HighlightAll**: Boolean flag. If **true** is returned, the whole document will be used as an excerpt, ignoring the preceding three parameters.
- **MaxFragments**: Maximum number of text excerpts or fragments to display. The default value **0** selects a non-fragmented excerpt generation method. A value greater than zero selects fragmented excerpt generation. This method finds text fragments with as many search words as possible and stretches those fragments around the search words. As a result, search words are close to the middle of each fragment and have words on each side. Each fragment contains a maximum of words specified by **MaxWords** and words of a length specified by **ShortWord** or less are dropped at the start and end of each fragment. If not all search words are found in the document, then a single fragment specified by **MinWords** will be displayed at the beginning of the document.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **FragmentDelimiter**: When more than one fragment is displayed, the fragments will be separated by this string. The maximum length is 32767 bytes.

Any unspecified options receive these defaults:

```
StartSel=<b>, StopSel=</b>,
MaxWords=35, MinWords=15, ShortWord=3, HighlightAll=FALSE,
MaxFragments=0, FragmentDelimiter=" ... "
```

For example:

```
gaussdb=# SELECT ts_headline('english',
'The most common type of search
is to find all documents containing given query terms
and return them in order of their similarity to the
query.',
to_tsquery('english', 'query & similarity'));
                      ts_headline
------------------------------------------------------------
 containing given <b>query</b> terms
 and return them in order of their <b>similarity</b> to the
 <b>query</b>.
(1 row)

gaussdb=# SELECT ts_headline('english',
'The most common type of search
is to find all documents containing given query terms
and return them in order of their similarity to the
query.',
to_tsquery('english', 'query & similarity'),
'StartSel = <, StopSel = >');
                      ts_headline
------------------------------------------------------------
 containing given <query> terms
 and return them in order of their <similarity> to the
 <query>.
(1 row)
```

The ts_headline function uses the original document, not a tsvector excerpt, so it may be slow and should be used with care.

1.12.4 Additional Features

1.12.4.1 Manipulating tsvector

GaussDB provides functions and operators that can be used to manipulate documents that are already in tsvector type.

- tsvector || tsvector

  The tsvector concatenation operator returns a new tsvector which combines the lexemes and positional information of the two tsvectors given as arguments. Positions and weight labels are retained during the concatenation. Positions appearing in the right-hand tsvector are offset by the largest position mentioned in the left-hand tsvector, so that the result is nearly equivalent to the result of performing to_tsvector on the concatenation of the two original document strings. (The equivalence is not exact because any stop words removed from the end of the left-hand argument will not affect the result, whereas they would have affected the positions of the lexemes in the right-hand argument if textual concatenation were used.)

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

One advantage of using concatenation in the tsvector form, rather than concatenating text before applying to_tsvector, is that you can use different tokenizers to parse different sections of the document. Also, because the setweight function marks all lexemes of the given tsvector in the same way, it is necessary to parse the text and do setweight before concatenating if you want to label different parts of the document with different weights.

- setweight(vector tsvector, weight "char") returns tsvector

  The setweight function returns a copy of the input tsvector in which every position has been labeled with the given weight, either A, B, C, or D. (D is the default for new tsvectors and as such is not displayed on output.) These labels are retained when tsvectors are concatenated, allowing words from different parts of a document to be weighted differently by ranking functions.

  NOTICE

  Note that weight labels apply to positions, not lexemes. If the input tsvector has been stripped of positions, then setweight does not take effect.

- length(vector tsvector) returns integer

  Returns the number of lexemes stored in the vector.

- strip(vector tsvector) returns tsvector

  Removes position and weight information from all lexemes in the input tsvector, leaving only the distinct lexemes, and returns a new tsvector.

1.12.4.2 Manipulating Queries

GaussDB provides functions and operators that can be used to manipulate queries that are already in tsquery type.

- tsquery && tsquery

  Returns the AND-combination of the two given queries.

- tsquery || tsquery

  Returns the OR-combination of the two given tsqueries.

- !! tsquery

  Returns the negation (NOT) of the given tsquery.

- tsquery <-> tsquery

  Returns the phrase result of the two given tsqueries.

- numnode(query tsquery) returns integer

  Returns the number of nodes (lexemes plus operators) in a tsquery. This function is useful to determine if the query is meaningful (return result > 0), or contains only stop words (returns 0). For example:

```
gaussdb=# SELECT numnode(plainto_tsquery('the any'));
NOTICE:  text-search query contains only stop words or doesn't contain lexemes, ignored
CONTEXT:  referenced column: numnode
 numnode
---------
       0

gaussdb=# SELECT numnode('foo & bar'::tsquery);
 numnode
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
---------
       3
```

- querytree(query tsquery) returns text

  Returns the portion of a tsquery that can be searched with an index. This function is useful for detecting unindexable queries, for example those containing only stop words or only negated terms. For example:

```
gaussdb=# SELECT querytree(to_tsquery('!defined'));
 querytree
-----------
 T
(1 row)
```

1.12.4.3 Rewriting Queries

Functions in the ts_rewrite family search a given tsquery for occurrences of a target subquery, and replace each occurrence with a substitute subquery. In essence, this operation is a tsquery-specific version by substring replacement. A target and substitute query combination can be considered as a query rewriting rule. A collection of such rewriting rules can be a powerful search aid. For example, you can expand the search scope using synonyms (such as, new york, big apple, nyc, and gotham) or narrow down the search scope.

- ts_rewrite (query tsquery, target tsquery, substitute tsquery) returns tsquery

  This form of ts_rewrite simply applies a single rewriting rule: the target query is replaced by the substitute query wherever it appears. For example:

```
gaussdb=# SELECT ts_rewrite('a & b'::tsquery, 'a'::tsquery, 'c'::tsquery);
 ts_rewrite
------------
 'b' & 'c'
```

- ts_rewrite (query tsquery, select text) returns tsquery

  This form of ts_rewrite accepts a starting query and an SQL **SELECT** command, which is given as a text string. The **SELECT** command must yield two columns of the tsquery type. For each row of the query result, occurrences of the first column value (the target) are replaced by the second column value (the substitute) within the current query.

  NOTE

  Note that when multiple rewriting rules are applied in this way, the order of rewriting can be important; therefore in practice, perform ORDER BY on the original query based on some columns.

  Consider a real-life astronomical example. Use table-driven rewriting rules to expand the search scope of a supernovae.

```
gaussdb=# CREATE TABLE tsearch.aliases (id int, t tsquery, s tsquery);

gaussdb=# INSERT INTO tsearch.aliases VALUES(1, to_tsquery('supernovae'), to_tsquery('supernovae|
sn'));

gaussdb=# SELECT ts_rewrite(to_tsquery('supernovae & crab'), 'SELECT t, s FROM tsearch.aliases');
          ts_rewrite
---------------------------------
 'crab' & ( 'supernova' | 'sn' )
```

  You can change the rewriting rules just by updating the table.

```
gaussdb=# UPDATE tsearch.aliases
SET s = to_tsquery('supernovae|sn & !nebulae')
WHERE t = to_tsquery('supernovae');
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gaussdb=# SELECT ts_rewrite(to_tsquery('supernovae & crab'), 'SELECT t, s FROM tsearch.aliases');
               ts_rewrite
--------------------------------------------
 'crab' & ( 'supernova' | 'sn' & !'nebula' )
```

Rewriting can be slow when there are many rewriting rules, since it checks every rule for a possible match. To filter out obvious non-candidate rules, we can use operators of the tsquery type. In the example below, only those rules which might match the original query are selected:

```
gaussdb=# SELECT ts_rewrite('a & b'::tsquery, 'SELECT t,s FROM tsearch.aliases WHERE ''a &
b''::tsquery @> t');
 ts_rewrite
------------
 'b' & 'a'
(1 row)
gaussdb=# DROP TABLE tsearch.aliases;
```

1.12.4.4 Collecting Document Statistics

The ts_stat function is useful for checking your configuration and for finding stop-word candidates.

```
ts_stat(sqlquery text, [ weights text, ]
       OUT word text, OUT ndoc integer,
       OUT nentry integer) returns setof record
```

sqlquery is a text value containing an SQL query which must return a single tsvector column. ts_stat executes the query and returns statistics about each distinct lexeme (word) contained in the tsvector data. The columns returned are:

- **word text**: a lexeme.
- **ndoc integer**: number of a lexeme in a tsvector (document).
- **nentry integer**: total number of occurrences of a lexeme.

If **weights** is specified, only occurrences having one of those weights are counted. For example, to find the ten most frequent words in a document collection:

```
gaussdb=# SET tsearch_options = 'debug_function';
gaussdb=# CREATE SCHEMA tpcds;
gaussdb=# CREATE TABLE tpcds.store_returns (
    sr_reason_sk     integer,
    sr_reason_id     character(16),
    sr_reason_desc   character(100),
    sr_customer_sk   integer);
gaussdb=# INSERT INTO tpcds.store_returns VALUES(1, 'test_001', 'test_desc_001', 5), (12, 'test_002',
'test_desc_002', 8), (23, 'test_003', 'test_desc_003', 9), (14, 'test_004', 'test_desc_004', 10), (45, 'test_005',
'test_desc_005', 12), (55, 'test_006', 'test_desc_006', 1), (43, 'test_007', 'test_desc_007', 12);
gaussdb=# SELECT * FROM ts_stat('SELECT to_tsvector(''english'', sr_reason_sk) FROM tpcds.store_returns
WHERE sr_customer_sk < 10') ORDER BY nentry DESC, ndoc DESC, word LIMIT 10;
 word | ndoc | nentry
------+------+--------
 1    |    1 |      1
 12   |    1 |      1
 23   |    1 |      1
 55   |    1 |      1
(4 rows)
```

The same, but counting only word occurrences with weight A or B:

```
gaussdb=# SELECT * FROM ts_stat('SELECT to_tsvector(''english'', sr_reason_sk) FROM tpcds.store_returns
WHERE sr_customer_sk < 10', 'a') ORDER BY nentry DESC, ndoc DESC, word LIMIT 10;
 word | ndoc | nentry
------+------+--------
(0 rows)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
-- Drop the table.
gaussdb=# DROP TABLE tpcds.store_returns;
gaussdb=# DROP SCHEMA tpcds;
gaussdb=# SET tsearch_options = '';
```

1.12.5 Parsers

A text search parser breaks raw document text into tokens and recognizes each token's type, where the set of types is defined by the parser itself. Note that a parser does not modify the text. It simply identifies plausible word boundaries. Because of this limited scope, there is less need for application-specific custom parsers than there is for custom dictionaries.

Currently, GaussDB provides the following built-in parsers: pg_catalog.default for English tokenization, and pg_catalog.ngram and pg_catalog.pound for full-text search in texts containing Chinese, or both Chinese and English.

The built-in parser pg_catalog.default can recognize 23 token types, as shown in **Table 1-337**.

Table 1-337 Default parser's token types

Token Type	Description	Example
asciiword	Word, all ASCII letters	elephant
word	Word, all letters	mañana
numword	Word, letters and digits	beta1
asciihword	Hyphenated word, all ASCII	up-to-date
hword	Hyphenated word, all letters	lógico-matemática
numhword	Hyphenated word, letters and digits	test-beta1
hword_asciipart	Hyphenated word part, all ASCII	test in the context test-beta1
hword_part	Hyphenated word part, all letters	lógico or matemática in the context lógico-matemática
hword_numpart	Hyphenated word part, letters and digits	beta1 in the context test-beta1
email	Email address	foo@example.com
protocol	Protocol head	http://
url	URL	example.com/stuff/index.html
host	Host	example.com
url_path	URL path	/stuff/index.html, in the context of a URL

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Token Type	Description	Example
file	File or path name	/usr/local/foo.txt, if not within a URL
sfloat	Scientific notation	-1.23E+56
float	Decimal notation	-1.234
int	Signed integer	-1234
uint	Unsigned integer	1234
version	Version number	8.3.0
tag	XML tag	<a href="dictionaries.html">
entity	XML entity	&
blank	Space symbols	(any whitespace or punctuation not otherwise recognized)

Note: The parser's notion of a "letter" is determined by the database's locale setting, specifically **lc_ctype**. Words containing only the basic ASCII letters are reported as a separate token type, since it is sometimes useful to distinguish them. In most European languages, token types word and asciiword should be treated alike.

The email type does not support all valid email characters as defined by RFC 5322. Specifically, the only non-alphanumeric characters supported for email usernames are period, dash, and underscore.

It is possible for the parser to recognize overlapping tokens in the same piece of text. For example, a hyphenated word will be reported both as the entire word and as each component.

```
gaussdb=# SELECT alias, description, token FROM ts_debug('english','foo-bar-beta1');
      alias      |              description               |     token
-----------------+----------------------------------------+----------------
 numhword        | Hyphenated word, letters and digits    | foo-bar-beta1
 hword_asciipart | Hyphenated word part, all ASCII        | foo
 blank           | Space symbols                          | -
 hword_asciipart | Hyphenated word part, all ASCII        | bar
 blank           | Space symbols                          | -
 hword_numpart   | Hyphenated word part, letters and digits | beta1
```

This behavior is desirable since it allows searches to work for both the whole compound word and for components. Here is another example:

```
gaussdb=# SELECT alias, description, token FROM ts_debug('english','http://example.com/stuff/index.html');
  alias   |  description  |            token
----------+---------------+------------------------------
 protocol | Protocol head | http://
 url      | URL           | example.com/stuff/index.html
 host     | Host          | example.com
 url_path | URL path      | /stuff/index.html
```

N-gram is a mechanical word segmentation method, and applies to non-semantic Chinese word segmentation scenarios. The N-gram segmentation method ensures

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

the completeness of tokens. However, to cover all the possibilities, it adds unnecessary words to the index, resulting in a large number of index items. N-gram supports Chinese encoding, including GBK and UTF-8. **Table 1-338** lists six built-in token types.

Table 1-338 Token types

Alias	Description
zh_words	chinese words
en_word	english word
numeric	numeric data
alnum	alnum string
grapsymbol	graphic symbol
multisymbol	multiple symbol

Pound segments words in a fixed format. It is used to segment to-be-parsed nonsense Chinese and English words that are separated by fixed delimiters. It supports Chinese encoding (including GBK and UTF-8) and English encoding (including ASCII). Pound has six built-in token types (as listed in **Table 1-339**) and supports five delimiters (as listed in **Table 1-340**). The default delimiter is the pound key (#). For Pound, the maximum length of a token is 256 characters.

Table 1-339 Token types

Alias	Description
zh_words	chinese words
en_word	english word
numeric	numeric data
alnum	alnum string
grapsymbol	graphic symbol
multisymbol	multiple symbol

Table 1-340 Delimiter types

1.12.6 Dictionaries

1.12.6.1 Overview

A dictionary is used to define stop words, that is, words to be ignored in full-text search.

A dictionary can also be used to normalize words so that different derived forms of the same word will match. A normalized word is called a lexeme.

In addition to improving retrieval quality, normalization and removal of stop words can reduce the size of the tsvector representation of a document, thereby improving performance. Normalization and removal of stop words do not always have linguistic meaning. Users can define normalization and removal rules in dictionary definition files based on application environments.

A dictionary is a program that receives a token as input and returns:

- An array of lexemes if the input token is known to the dictionary (note that one token can produce more than one lexeme).
- A lexeme. (The lexeme has the TSL_FILTER flag set. The TSL_FILTER flag is automatically set in a filtering dictionary and is not perceived by users.) A new token will replace the original one and is passed to the subsequent dictionary. (The current dictionary may be referred to as a filtering dictionary.)
- An empty array if the input token is known to the dictionary but is a stop word.
- **NULL** if the dictionary does not recognize the token.

GaussDB provides predefined dictionaries for many languages and also provides the predefined dictionary templates Simple and Snowball. These templates can be used to create new dictionaries with custom parameters.

When using full-text search, you are advised to:

- In the text search configuration, configure a parser together with a set of dictionaries to process the parser's output tokens. For each token type that the parser can return, a separate list of dictionaries is specified by the configuration. When a token of that type is found by the parser, each dictionary in the list is consulted in turn, until a dictionary recognizes it as a known word. If it is identified as a stop word, or no dictionary recognizes the token, it will be discarded and not indexed or searched for. Generally, the first dictionary that returns a non-**NULL** output determines the result, and any remaining dictionaries are not consulted. However, a filtering dictionary can replace the input token with a modified one, which is then passed to subsequent dictionaries.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- The general rule for configuring a list of dictionaries is to place first the most narrow, most specific dictionary, then the more general dictionaries, finishing with a very general dictionary, like the Snowball stemmer dictionary or the Simple dictionary, which recognizes everything.

1.12.6.2 Stop Words

Stop words are words that are very common, appear in almost every document, and have no discrimination value. Therefore, they can be ignored in the context of full-text search. Each type of dictionaries treats stop words in different ways. For example, Ispell dictionaries first normalize words and then check the list of stop words, while Snowball dictionaries first check the list of stop words.

Every English text contains words like "a" and "the", so it is useless to store them in an index. However, stop words affect the positions in tsvector, which in turn affect ranking.

```
gaussdb=# SELECT to_tsvector('english','in the list of stop words');
        to_tsvector
----------------------------
 'list':3 'stop':5 'word':6
```

Words in positions 1, 2, and 4 are stop words and are not displayed. Ranks calculated for documents with and without stop words are quite different:

```
gaussdb=# SELECT ts_rank_cd (to_tsvector('english','in the list of stop words'), to_tsquery('list & stop'));
 ts_rank_cd
------------
        .05

gaussdb=# SELECT ts_rank_cd (to_tsvector('english','list stop words'), to_tsquery('list & stop'));
 ts_rank_cd
------------
         .1
```

1.12.6.3 Simple Dictionary

A Simple dictionary operates by converting the input token to lower case and checking it against a list of stop words. If the token is found in the list, an empty array will be returned, causing the token to be discarded. If it is not found, the lower-cased form of the word is returned as a normalized lexeme. In addition, you can set **Accept** (default: **true**) to **false** for Simple dictionaries to report non-stop-words as unrecognized, allowing them to be passed on to the next dictionary in the list.

Precautions

- Most types of dictionaries rely on dictionary configuration files. The name of a configuration file can only be lowercase letters, digits, and underscores (_).
- A dictionary cannot be created in the pg_temp schema.
- Dictionary configuration files must be stored in UTF-8 encoding. They will be translated to the actual database encoding, if that is different, when they are read into the server.
- Generally, a session will read a dictionary configuration file only once, when it is first used within the session. To modify a configuration file, run the **ALTER TEXT SEARCH DICTIONARY** statement to update and reload the file.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Procedure

Step 1 Create a Simple dictionary.

```
gaussdb=# CREATE TEXT SEARCH DICTIONARY public.simple_dict (
    TEMPLATE = pg_catalog.simple,
    STOPWORDS = english
);
```

english.stop is the full name of the stop word file. For details about the syntax and parameters for creating a Simple dictionary, see **CREATE TEXT SEARCH DICTIONARY**.

Step 2 Use the Simple dictionary.

```
gaussdb=# SELECT ts_lexize('public.simple_dict','YeS');
 ts_lexize
-----------
 {yes}
(1 row)

gaussdb=# SELECT ts_lexize('public.simple_dict','The');
 ts_lexize
-----------
 {}
(1 row)
```

Step 3 Set **Accept** to **false** so that the Simple dictionary returns **NULL** instead of a lower-cased non-stop word.

```
gaussdb=# ALTER TEXT SEARCH DICTIONARY public.simple_dict ( Accept = false );
ALTER TEXT SEARCH DICTIONARY
gaussdb=# SELECT ts_lexize('public.simple_dict','YeS');
 ts_lexize
-----------

(1 row)

gaussdb=# SELECT ts_lexize('public.simple_dict','The');
 ts_lexize
-----------
 {}
(1 row)

gaussdb=# DROP TEXT SEARCH DICTIONARY public.simple_dict;
```

----End

1.12.6.4 Snowball Dictionary

A Snowball dictionary is based on a project by Martin Porter and is used for stem analysis, providing stemming algorithms for many languages. GaussDB provides predefined Snowball dictionaries for many languages. You can query the PG_TS_DICT system catalog to view the predefined Snowball dictionaries and supported stemming algorithms.

A Snowball dictionary recognizes everything, no matter whether it is able to simplify the word. Therefore, it should be placed at the end of the dictionary list. It is not recommended that you place it before any other dictionary because a token will never pass it through to the next dictionary.

For details about the syntax of Snowball dictionaries, see **CREATE TEXT SEARCH DICTIONARY**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

1.12.7 Configuration Examples

Text search configuration specifies the following components required for converting a document into a tsvector:

- A parser, used for breaking a text into tokens.
- A list of dictionaries, used for converting each token into a lexeme.

Each time when the to_tsvector or to_tsquery function is called, a text search configuration is required to specify a processing procedure. The GUC parameter **default_text_search_config** specifies the default text search configuration, which will be used if the text search function does not explicitly specify a text search configuration.

GaussDB provides some predefined text search configurations. You can also create user-defined text search configurations. In addition, to facilitate the management of text search objects, multiple gsql meta-commands are provided to display information about text search objects. (For details, see **Meta-Command Reference**.)

Procedure

Step 1 Set the default text search configuration used by and valid only in the current session. The current full-text search configuration can be set to **ngram**, **pound**, **simple**, or **english**.

```
gaussdb=# set default_text_search_config = 'ngram';
SET
```

----End

1.12.8 Testing and Debugging Text Search

NOTICE

This function is for internal use only. You are advised not to use it.

The behavior of a custom text search tokenizer can easily become confusing. The functions described in this section are useful for testing text search objects. You can test a complete tokenizer, or test parsers and dictionaries separately.

1.12.8.1 Testing a Tokenizer

The ts_debug function allows easy testing of a text search tokenizer.

```
ts_debug([ config regconfig, ] document text,
        OUT alias text,
        OUT description text,
        OUT token text,
        OUT dictionaries regdictionary[],
        OUT dictionary regdictionary,
        OUT lexemes text[])
        returns setof record
```

ts_debug displays information about every token of a document as produced by the parser and processed by the configured dictionaries. It uses the tokenizer specified by **config**, or **default_text_search_config** if that argument is omitted.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

ts_debug returns one row for each token identified in the text by the parser. The columns returned are:

- **alias**: short name of the token, which is of the text type.
- **description**: token description, which is of the text type.
- **token**: token text, which is of the text type.
- **dictionaries**: dictionaries selected for tokens, which are of the regdictionary type.
- **dictionary**: dictionary that recognizes tokens, which is of the regdictionary type. If this parameter is left empty, tokens will not be recognized.
- **lexemes**: lexeme produced by the dictionary that recognizes tokens, which is of the text array type. If this parameter is left empty, no lexeme will be produced. An empty array ({}) means that the token will be recognized as a stop word.

Here is a simple example:

```
gaussdb=# SELECT * FROM ts_debug('english','a fat  cat sat on a mat - it ate a fat rats');
   alias   |   description   | token |  dictionaries  |  dictionary  | lexemes
-----------+-----------------+-------+----------------+--------------+---------
 asciiword | Word, all ASCII | a     | {english_stem} | english_stem | {}
 blank     | Space symbols   |       | {}             |              |
 asciiword | Word, all ASCII | fat   | {english_stem} | english_stem | {fat}
 blank     | Space symbols   |       | {}             |              |
 asciiword | Word, all ASCII | cat   | {english_stem} | english_stem | {cat}
 blank     | Space symbols   |       | {}             |              |
 asciiword | Word, all ASCII | sat   | {english_stem} | english_stem | {sat}
 blank     | Space symbols   |       | {}             |              |
 asciiword | Word, all ASCII | on    | {english_stem} | english_stem | {}
 blank     | Space symbols   |       | {}             |              |
 asciiword | Word, all ASCII | a     | {english_stem} | english_stem | {}
 blank     | Space symbols   |       | {}             |              |
 asciiword | Word, all ASCII | mat   | {english_stem} | english_stem | {mat}
 blank     | Space symbols   |       | {}             |              |
 blank     | Space symbols   | -     | {}             |              |
 asciiword | Word, all ASCII | it    | {english_stem} | english_stem | {}
 blank     | Space symbols   |       | {}             |              |
 asciiword | Word, all ASCII | ate   | {english_stem} | english_stem | {ate}
 blank     | Space symbols   |       | {}             |              |
 asciiword | Word, all ASCII | a     | {english_stem} | english_stem | {}
 blank     | Space symbols   |       | {}             |              |
 asciiword | Word, all ASCII | fat   | {english_stem} | english_stem | {fat}
 blank     | Space symbols   |       | {}             |              |
 asciiword | Word, all ASCII | rats  | {english_stem} | english_stem | {rat}
(24 rows)
```

1.12.8.2 Testing a Parser

The ts_parse function allows direct testing of a text search parser.

```
ts_parse(parser_name text, document text,
        OUT tokid integer, OUT token text) returns setof record
```

ts_parse parses the given document and returns a series of records, one for each token produced by parsing. Each record includes a **tokid** showing the assigned token type and a **token** which is the text of the token. For example:

```
gaussdb=# SELECT * FROM ts_parse('default', '123 - a number');
 tokid | token
-------+--------
    22 | 123
    12 |
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
   12 | -
    1 | a
   12 |
    1 | number
(6 rows)
```

The ts_token_type function returns the token type and description of the specified parser.

```
ts_token_type(parser_name text, OUT tokid integer,
              OUT alias text, OUT description text) returns setof record
```

ts_token_type returns a table which describes each type of token the specified parser can recognize. For each token type, the table gives the integer **tokid** that the parser uses to label a token of that type, the **alias** that names the token type in tokenizer commands, and a short description. For example:

```
gaussdb=# SELECT * FROM ts_token_type('default');
 tokid |      alias      |                description
-------+-----------------+-------------------------------------------
     1 | asciiword       | Word, all ASCII
     2 | word            | Word, all letters
     3 | numword         | Word, letters and digits
     4 | email           | Email address
     5 | url             | URL
     6 | host            | Host
     7 | sfloat          | Scientific notation
     8 | version         | Version number
     9 | hword_numpart   | Hyphenated word part, letters and digits
    10 | hword_part      | Hyphenated word part, all letters
    11 | hword_asciipart | Hyphenated word part, all ASCII
    12 | blank           | Space symbols
    13 | tag             | XML tag
    14 | protocol        | Protocol head
    15 | numhword        | Hyphenated word, letters and digits
    16 | asciihword      | Hyphenated word, all ASCII
    17 | hword           | Hyphenated word, all letters
    18 | url_path        | URL path
    19 | file            | File or path name
    20 | float           | Decimal notation
    21 | int             | Signed integer
    22 | uint            | Unsigned integer
    23 | entity          | XML entity
(23 rows)
```

1.12.8.3 Testing a Dictionary

The ts_lexize function facilitates dictionary testing.

ts_lexize(dict regdictionary, token text) returns text[]. ts_lexize returns an array of lexemes if the input token is known to the dictionary, or an empty array if the token is known to the dictionary but it is a stop word, or **NULL** if it is an unknown word.

For example:

```
gaussdb=# SELECT ts_lexize('english_stem', 'stars');
 ts_lexize
-----------
 {star}

gaussdb=# SELECT ts_lexize('english_stem', 'a');
 ts_lexize
-----------
 {}
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTICE

The ts_lexize function expects a single token, not text.

1.12.9 Restrictions

GaussDB's full-text search feature has the following restrictions:

- The length of each tsvector lexeme must be less than 2047 bytes.
- The length of a tsvector (lexemes+positions) must be less than 1 MB.
- Position values in tsvector must be greater than 0 and less than or equal to 16383. Values greater than 16383 are forcibly set to **16383**.
- Less than or equal to 255 positions per tsvector lexeme. Excessive positions, if any, will be discarded.
- The total number of keywords and operators in a tsquery must be less than 32768.
- The accuracy of full-text search is related to the parser and dictionary list in the text search configuration. In Chinese scenarios, you are advised to use ngram or pound as the text search configuration item. In other scenarios, you are advised to use english or simple as the text search configuration item.
- ILM policies can be added or modified for data objects only in the tsvector or tsquery function of **Row Expression Function Whitelist**.
- The Tokenweight dictionary function is used internally by the BM25 index. You are advised not to use it in the full-text search feature because it may contain unknown risks. Use other dictionary functions instead.
- The distance specified by the phrase operator (PHRASE) must be greater than or equal to 0 and less than or equal to 16384. Otherwise, an error is reported.

1.13 SQL Syntax

1.13.1 SQL Syntax

Table 1-341 SQL syntax

Format	Description
[ ]	The part enclosed in brackets ([]) is optional.
...	Preceding elements can appear repeatedly.
[x | y | ...]	One item is selected from two or more options or no item is selected.
{ x | y | ... }	One item is selected from two or more options.
[x | y | ...] [...]	Multiple parameters or no parameter can be selected. If multiple parameters are selected, separate them with spaces.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Format	Description
[x | y | ...] [,...]	Multiple parameters or no parameter can be selected. If multiple parameters are selected, separate them with commas (,).
{ x | y | ... } [...]	At least one parameter can be selected. If multiple parameters are selected, separate them with spaces.
{ x | y | ... } [,...]	At least one parameter can be selected. If multiple parameters are selected, separate them with commas (,).

1.13.2 DCL Syntax Overview

Data control language (DCL) is used to define and control users' access permissions on database objects (such as tables, views, and stored procedures) and database instances.

Granting Permissions

GaussDB provides a statement for granting permissions to data objects and roles. For details, see **GRANT**.

Revoking Permissions

GaussDB provides a statement for revoking permissions. For details, see **REVOKE**.

Setting Default Permissions

GaussDB allows you to set permissions for objects that will be created in the future. For details, see **ALTER DEFAULT PRIVILEGES**.

Changing Owners

GaussDB provides a statement for changing the owner of a database object. For details, see **REASSIGN OWNED**.

Defining a Role

Roles are used to manage permissions in a database. For database security purposes, management and operation permissions should be assigned to different roles. **Table 1-342** lists the involved SQL statements.

Table 1-342 SQL statements for defining a role

Description	SQL Statement
Creating a role	**CREATE ROLE**
Altering role attributes	**ALTER ROLE**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description	SQL Statement
Dropping a role	DROP ROLE

Defining a User

In database management, a user is an identity credential for accessing the database system. By granting permissions to users, you can precisely control their access to database objects and the database instance itself, thereby implementing refined management of database access. **Table 1-343** lists the involved SQL statements.

Table 1-343 SQL statements for defining a user

Description	SQL Statement
Creating a user	CREATE USER
Altering user attributes	ALTER USER
Dropping a user	DROP USER

Modifying, Displaying, and Restoring a GUC Parameter

Table 1-344 SQL statements for modifying, displaying, and restoring a GUC parameter

Description	SQL Statement
Modifying a GUC parameter	SET
Altering a session	ALTER SESSION
Showing the current value of a GUC parameter	SHOW
Restoring a GUC parameter to the default value	RESET

1.13.3 DDL Syntax Overview

Data definition language (DDL) is a standard SQL language used to define and alter database objects. It mainly includes statements such as CREATE, ALTER, and DROP, which are used to create, alter, and drop database objects, such as tables, indexes, views, constraints, and data type definitions.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

> **NOTE**
>
> GaussDB does not support DDL operations when the CN is incomplete. For example, if a CN in cluster is faulty, creating a database or a table will fail.

Dropping Database Objects Owned by a Database Role

GaussDB provides a statement for dropping database objects owned by a database role. For details, see **DROP OWNED**.

Defining a CMK

A client master key (CMK) is mainly used to encrypt column encryption keys (CEKs) in the encrypted database feature. Defining a CMK includes creating and dropping a CMK. **Table 1-345** lists the involved SQL statements.

Table 1-345 SQL statements for defining a CMK

Description	SQL Statement
Creating a CMK	**CREATE CLIENT MASTER KEY**
Dropping a CMK	**DROP CLIENT MASTER KEY**

Defining a Column Encryption Key (CEK)

CEKs are mainly used to encrypt data in the encrypted database feature. Defining a CEK includes creating a CEK, rotating the CMK for encrypting the CEK, and dropping a CEK. **Table 1-346** lists the involved SQL statements.

Table 1-346 SQL statements for defining a CEK

Description	SQL Statement
Creating a CEK	**CREATE COLUMN ENCRYPTION KEY**
Changing the client master key specified by a CEK	**ALTER COLUMN ENCRYPTION KEY**
Dropping a CEK	**DROP COLUMN ENCRYPTION KEY**

Defining a Database

A database is the warehouse for organizing, storing, and managing data. Defining a database includes: creating a database, altering the database attributes, and dropping the database. **Table 1-347** lists the involved SQL statements.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 1-347 SQL statements for defining a database

Description	SQL Statement
Creating a database	**CREATE DATABASE**
Altering database attributes	**ALTER DATABASE**
Dropping a Database	**DROP DATABASE**

Defining a Schema

A schema is the set of a group of database objects and is used to control the access to the database objects. **Table 1-348** lists the involved SQL statements.

Table 1-348 SQL statements for defining a schema

Description	SQL Statement
Creating a schema	**CREATE SCHEMA**
Altering schema attributes	**ALTER SCHEMA**
Dropping a schema	**DROP SCHEMA**

Defining a Tablespace

A tablespace is used to manage data objects and corresponds to a catalog on a disk. **Table 1-349** lists the involved SQL statements.

Table 1-349 SQL statements for defining a tablespace

Description	SQL Statement
Creating a tablespace	**CREATE TABLESPACE**
Altering tablespace attributes	**ALTER TABLESPACE**
Dropping a tablespace	**DROP TABLESPACE**

Defining a Table

A table is a special data structure in a database and is used to store data objects and relationship between data objects. **Table 1-350** lists the involved SQL statements.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 1-350 SQL statements for defining a table

Description	SQL Statement
Creating a table	**CREATE TABLE**
Altering table attributes	**ALTER TABLE**
Modifying one or more tables to be flashed back	**RENAME TABLE**
Dropping a table	**DROP TABLE**
Creating a table from the results of a query	**CREATE TABLE AS**

Defining a Partitioned Table

Partitioned tables are a type of logical table designed to improve query performance, though data is physically stored in ordinary tables. **Table 1-351** lists the involved SQL statements.

Table 1-351 SQL statements for defining a partitioned table

Description	SQL Statement
Creating a partitioned table	**CREATE TABLE PARTITION**
Modifying a partitioned table (including adding/deleting partitions and modifying partition attributes)	**ALTER TABLE PARTITION**
Dropping a partitioned table	**DROP TABLE**
Creating a partitioned table based on the query result	**CREATE TABLE PARTITION | SUBPARTITION AS**

Defining an Index

An index indicates the sequence of values in one or more columns in a database table. It is a data structure that improves the speed of data access to specific information in a database table. **Table 1-352** lists the involved SQL statements.

Table 1-352 SQL statements for defining an index

Description	SQL Statement
Creating an index	**CREATE INDEX**
Altering index attributes	**ALTER INDEX**
Dropping an index	**DROP INDEX**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description	SQL Statement
Rebuilding an index	REINDEX
Creating a global secondary index in a specified table	CREATE GLOBAL INDEX

Defining a Stored Procedure

A stored procedure is a set of SQL statements for achieving specific functions and is stored in the database after compilation. Users can specify a name and provide parameters (if necessary) to execute the stored procedure. **Table 1-353** lists the involved SQL statements.

Table 1-353 SQL statements for defining a stored procedure

Description	SQL Statement
Creating a stored procedure	CREATE PROCEDURE
Dropping a stored procedure	DROP PROCEDURE
Altering the attributes of a user-defined stored procedure or recompiling a stored procedure	ALTER PROCEDURE

Defining a Function

In GaussDB, a function is similar to a stored procedure, which is a set of SQL statements. The function and stored procedure are used the same. **Table 1-354** lists the involved SQL statements.

Table 1-354 SQL statements for defining a function

Description	SQL Statement
Creating a function	CREATE FUNCTION
Modifying attributes of a function or recompiling the function	ALTER FUNCTION
Dropping a function	DROP FUNCTION

Defining a Package

A package consists of the package specification and package body. It is used to manage stored procedures and functions by class, which is similar to classes in languages such as Java and C++. **Table 1-355** lists the involved SQL statements.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 1-355 SQL statements for defining a package

Description	SQL Statement
Creating a package	CREATE PACKAGE
Dropping a package	DROP PACKAGE
Altering a package attribute	ALTER PACKAGE

NOTE

In the current mode, the PACKAGE syntax must be executed in an ORA-compatible database.

Defining a Resource Pool

A resource pool is a system catalog used by the workload management module to specify attributes related to resource management, such as Cgroups. **Table 1-356** lists the involved SQL statements.

Table 1-356 SQL statements for defining a resource pool

Description	SQL Statement
Creating a resource pool	CREATE RESOURCE POOL
Altering a resource pool attribute	ALTER RESOURCE POOL
Dropping a resource pool	DROP RESOURCE POOL

Defining an Aggregate Function

Table 1-357 SQL statements for defining an aggregate function

Description	SQL Statement
Creating an aggregate function	CREATE AGGREGATE
Modifying an aggregate function	ALTER AGGREGATE
Dropping an aggregate function	DROP AGGREGATE

Defining a Plug-in Extension

This feature is for internal use. Only advanced packages or extensions in the database can be operated.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 1-358 SQL statements for defining a plug-in extension

Description	SQL Statement
Creating (installing) an extension	**CREATE EXTENSION**
Dropping an extension from the database	**DROP EXTENSION**

Defining a Data Type

Table 1-359 SQL statements for defining a data type

Description	SQL Statement
Creating a data type	**CREATE TYPE**
Modifying a data type	**ALTER TYPE**
Dropping a data type	**DROP TYPE**

Defining a Database Link

A database link is an object that can be used to operate a remote database. **Table 1-360** lists the related SQL statements.

Table 1-360 DATABASE LINK-related SQL statements

Description	SQL Statement
Creating a database link	**CREATE DATABASE LINK**
Modifying a database link	**ALTER DATABASE LINK**
Dropping a database link	**DROP DATABASE LINK**

Defining an Audit Policy

Table 1-361 SQL statements for defining an audit policy

Description	SQL Statement
Creating a unified audit policy	**CREATE AUDIT POLICY**
Altering a unified audit policy	**ALTER AUDIT POLICY**
Dropping an audit policy	**DROP AUDIT POLICY**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Setting the nodeis_active Column of a Specified Node

ALTER COORDINATOR describes how to change the value of the **nodeis_active** column of a specified node in the pgxc_node system catalog.

Defining a Directory

Table 1-362 SQL statements for defining a directory

Description	SQL Statement
Creating a directory	**CREATE DIRECTORY**
Modifying attributes of a directory	**ALTER DIRECTORY**
Dropping a specified directory	**DROP DIRECTORY**

Defining a Foreign Table

Table 1-363 SQL statements for defining a foreign table

Description	SQL Statement
Creating a foreign table	**CREATE FOREIGN TABLE**
Altering attributes of a foreign table	**ALTER FOREIGN TABLE**
Dropping a foreign table	**DROP FOREIGN TABLE**

Defining a Foreign Data Wrapper

Table 1-364 SQL statements related to the foreign data wrapper

Description	SQL Statement
Creating a foreign data wrapper	**CREATE FOREIGN DATA WRAPPER**
Altering attributes of a foreign data wrapper	**ALTER FOREIGN DATA WRAPPER**
Dropping a foreign data wrapper	**DROP FOREIGN DATA WRAPPER**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

SQL Statements Related to the gs_global_config System Catalog

Table 1-365 SQL statements related to the gs_global_config system catalog

Description	SQL Statement
Adding and changing parameter values in a system catalog	ALTER GLOBAL CONFIGURATION
Dropping parameter values from a system catalog	DROP GLOBAL CONFIGURATION
Inserting one or more weak passwords into a system catalog	CREATE WEAK PASSWORD DICTIONARY
Dropping all weak passwords in a system catalog	DROP WEAK PASSWORD DICTIONARY

Defining a User Group

Table 1-366 SQL statements for defining a user group

Description	SQL Statement
Creating a user group	CREATE GROUP
Altering attributes of a user group	ALTER GROUP
Dropping a user group	DROP GROUP

Defining a Procedural Language

Table 1-367 SQL statements for defining a procedural language

Description	SQL Statement
Creating a procedural language	CREATE LANGUAGE
Altering attributes of a procedural language	ALTER LANGUAGE
Dropping a procedural language	DROP LANGUAGE

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Defining a Masking Policy

Table 1-368 SQL statements for defining a masking policy

Description	SQL Statement
Creating a masking policy	**CREATE MASKING POLICY**
Altering a masking policy	**ALTER MASKING POLICY**
Dropping a masking policy	**DROP MASKING POLICY**

Defining a Materialized View

Table 1-369 SQL statements for defining a materialized view

Description	SQL Statement
Creating a complete-refresh materialized view	**CREATE MATERIALIZED VIEW**
Creating a fast-refresh materialized view	**CREATE INCREMENTAL MATERIALIZED VIEW**
Altering multiple auxiliary attributes of an existing materialized view	**ALTER MATERIALIZED VIEW**
Forcibly deleting an existing materialized view from the database	**DROP MATERIALIZED VIEW**
Refreshing a materialized view in complete-refresh mode	**REFRESH MATERIALIZED VIEW**
Refreshing a materialized view in fast-refresh mode	**REFRESH INCREMENTAL MATERIALIZED VIEW**

Defining a Node

Table 1-370 SQL statements for defining a node

Description	SQL Statement
Creating a node	**CREATE NODE**
Altering attributes of an existing node	**ALTER NODE**
Dropping a node	**DROP NODE**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Defining a resource label

Table 1-371 SQL statements for defining a resource label

Description	SQL Statement
Creating a resource label	**CREATE RESOURCE LABEL**
Altering a resource label	**ALTER RESOURCE LABEL**
Dropping a resource label	**DROP RESOURCE LABEL**

Defining a row-level security policy

Table 1-372 SQL statements for defining a row-level security policy

Description	SQL Statement
Creating a row-level security policy for a table	**CREATE ROW LEVEL SECURITY POLICY**
Modifying an existing row-level security policy	**ALTER ROW LEVEL SECURITY POLICY**
Dropping a row-level security policy from a table	**DROP ROW LEVEL SECURITY POLICY**

Defining a Sequence

Table 1-373 SQL statements for defining a sequence

Description	SQL Statement
Adding a sequence to the current database	**CREATE SEQUENCE**
Altering parameters of a specified sequence	**ALTER SEQUENCE**
Dropping a sequence from the current database	**DROP SEQUENCE**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Defining a Foreign Server

Table 1-374 SQL statements for defining a foreign server

Description	SQL Statement
Creating a foreign server	**CREATE SERVER**
Adding, altering, and dropping parameters of a specified server	**ALTER SERVER**
Dropping a specified server	**DROP SERVER**

Defining a Synonym Object

Table 1-375 SQL statements for defining a synonym object

Description	SQL Statement
Creating a synonym object	**CREATE SYNONYM**
Modifying the owner of a synonym object	**ALTER SYNONYM**
Dropping a specified synonym object	**DROP SYNONYM**

Defining a Trigger

Table 1-376 SQL statements for defining a trigger

Description	SQL Statement
Creating a trigger	**CREATE TRIGGER**
Altering trigger attributes	**ALTER TRIGGER**
Dropping a trigger	**DROP TRIGGER**

Defining a View

Table 1-377 SQL statements for defining a view

Description	SQL Statement
Creating a view	**CREATE VIEW**
Modifying the auxiliary attributes of a view	**ALTER VIEW**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description	SQL Statement
Forcibly dropping an existing view from the database	**DROP VIEW**

Collecting Statistics

For details about how to collect statistics related to the contents of ordinary tables in the database, see **ANALYZE | ANALYSE**.

Creating a Synchronization Point

For details about how to create a synchronization point between nodes in a new cluster, see **CREATE BARRIER**.

Creating an Encoding Conversion Task

For details about how to create a new conversion between two character set encodings, see **CREATE CONVERSION**.

Defining a Model

Table 1-378 SQL statements for defining a model

Description	SQL Statement
Training a machine learning model and saving the model	**CREATE MODEL**
Dropping a model that has been trained and saved	**DROP MODEL**

Defining a Security Label

Table 1-379 SQL statements for defining a security label

Description	SQL Statement
Creating a security label	**CREATE SECURITY LABEL**
Applying, updating, or canceling a security label	**SECURITY LABEL ON**
Dropping a security label	**DROP SECURITY LABEL**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Importing a Database/Table

Table 1-380 SQL statements for data import

Description	SQL Statement
Preparation phase for importing a database	**IMPDP DATABASE CREATE**
Execution phase of importing a database	**IMPDP RECOVER**
Preparation phase for importing a table	**IMPDP TABLE PREPARE**
Execution phase of importing a table	**IMPDP TABLE**

Exporting a File

Table 1-381 SQL statements for exporting files

Description	SQL Statement
Exporting all physical files of a database	**EXPDP DATABASE**
Exporting all files related to a table	**EXPDP TABLE**

Full-Text Search

Table 1-382 SQL statements for full-text search

Description	SQL Statement
Creating a text search configuration	**CREATE TEXT SEARCH CONFIGURATION**
Creating a full-text search dictionary	**CREATE TEXT SEARCH DICTIONARY**
Altering attributes of a text search configuration	**ALTER TEXT SEARCH CONFIGURATION**
Altering attributes of a full-text search dictionary	**ALTER TEXT SEARCH DICTIONARY**
Dropping an existing text search configuration	**DROP TEXT SEARCH CONFIGURATION**
Dropping a full-text search dictionary	**DROP TEXT SEARCH DICTIONARY**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Clearing a Recycle Bin

GaussDB provides a statement for clearing a recycle bin. For details, see **PURGE**.

Clustering a Table

GaussDB provides a statement for clustering a table based on a specified index. For details, see **CLUSTER**.

Defining an Object Comment

GaussDB provides a statement for creating and modifying comments of a specified object. For details, see **COMMENT**.

Creating a Table Based on Query Results

GaussDB supports statements for creating a table based on query results and inserting queried data into the new table. For details, see **SELECT INTO**.

Restoring a Table to an Earlier State

GaussDB allows you to restore a table to an earlier state in the event of a manual operation or application error. For details, see **TIMECAPSULE TABLE**.

Truncating Table Data

GaussDB provides a statement for quickly truncating all rows from a table. For details, see **TRUNCATE**.

Recycling Storage Space

GaussDB supports statements for recycling storage space occupied by deleted rows in a table or B-tree index. For details, see **VACUUM**.

1.13.4 DML Syntax Overview

Data manipulation language (DML) is used to perform operations on data in database tables, such as inserting, updating, querying, or deleting data.

Inserting Data

Table 1-383 SQL statements for inserting data

Function	SQL Statement
Inserting one or more records to a database table	**INSERT**
Inserting one or more records to multiple tables	**INSERT ALL**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Updating Data

For details about how to modify one or more records in a database table, see **UPDATE**.

Changing or Inserting Data

GaussDB provides a statement for matching data in the target table with that in the source table based on join conditions. If the join conditions are met, the target table is updated. If the join conditions are not met, data is inserted into the target table. For details, see **MERGE INTO**.

Querying Data

The query statement SELECT is used to retrieve required data in a database. For details, see **SELECT**.

Deleting Data

GaussDB provides a statement for deleting data that meets specified conditions from a table. For details, see **DELETE**.

Copying Data

GaussDB provides a statement for copying data between tables and files. For details, see **COPY**.

Locks

Table 1-384 Lock-related SQL statements

Function	SQL Statement
Multiple lock modes (used to control concurrent access to table data)	**LOCK**
Bucket-based lock	**LOCK BUCKETS**

Calling a Function

GaussDB provides multiple statements for calling functions. These statements have the same syntax structure. For details, see **CALL** and **CREATE FUNCTION**.

Prepared Statements

Table 1-385 SQL statements related to prepared statements

Description	SQL Statement
Creating a prepared statement	**PREPARE**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description	SQL Statement
Executing a prepared statement	**EXECUTE**
Deallocating a prepared statement	**DEALLOCATE**

Killing a Session

A session is a connection established between a user and a database. GaussDB provides a statement for killing a session. For details, see **ALTER SYSTEM KILL SESSION**.

Executing an Anonymous Code Block

GaussDB provides a statement for executing an anonymous code block. For details, see **DO**.

Executing an SQL Statement on a Specified Node

GaussDB provides a statement for executing an SQL statement on a specified node. For details, see **EXECUTE DIRECT**.

Retrieving Data Using a Cursor

GaussDB provides a statement for retrieving data using a created cursor. For details, see **FETCH**.

Inserting or Replacing Data

GaussDB provides a statement for inserting or replacing data in a table. For details, see **REPLACE**.

Calculating a Value based on an Expression

GaussDB provides a statement for calculating a value of a row or a group of rows based on a given value expression. For details, see**VALUES**.

Importing Data

GaussDB provides a statement for importing data from a file to a specified table in the database. For details, see **LOAD DATA**.

Defining a Cursor

To process SQL statements, a stored procedure thread allocates memory to store context. Cursors are handles or pointers pointing to context regions. With cursors, stored procedures can control alterations in context areas. **Table 1-386** lists the involved SQL statements.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 1-386 SQL statements for defining a cursor

Description	SQL Statement
Creating a cursor	CURSOR
	DECLARE
Moving a cursor	MOVE
Closing a cursor	CLOSE

Showing an Execution Plan of an SQL Statement

GaussDB provides a statement for showing an execution plan of an SQL statement. For details, see **EXPLAIN**.

1.13.5 Other Syntax List

In addition to DCL, DDL, and DML syntax, GaussDB also provides syntax for other functions.

Shutting Down The Current Node

GaussDB allows users to run the **SHUTDOWN** command to shut down the current database node. For details, see **SHUTDOWN**.

SQL Statements Related to Bucket Scale-out

GaussDB supports statements used by the scale-out tool to notify the kernel of the buckets that have been migrated. For details, see **MARK BUCKETS**.

Clearing Database Connections

GaussDB supports statements for clearing database connections. For details, see **CLEAN CONNECTION**.

Storing Execution Plans

GaussDB provides a statement for storing query execution plan information in the **PLAN_TABLE** table. For details, see **EXPLAIN PLAN**.

Prediction

GaussDB provides a statement for using a trained model to perform prediction tasks. For details, see **PREDICT BY**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Managing a Transaction

Table 1-387 SQL statements related to transactions

Description	SQL Statement
Rolling back the current transaction and canceling the changes in the transaction	ABORT
	ROLLBACK
Starting a transaction	BEGIN
	SET TRANSACTION
	START TRANSACTION
Setting transaction log checkpoints	CHECKPOINT
Committing the current transaction	COMMIT | END
Committing a prepared two-phase transaction	COMMIT PREPARED
Preparing the current transaction for two-phase commit	PREPARE TRANSACTION
Deleting a savepoint previously defined for the current transaction	RELEASE SAVEPOINT
Canceling a transaction ready for two-phase commit	ROLLBACK PREPARED
Rolling back to a savepoint	ROLLBACK TO SAVEPOINT
Creating a savepoint in the current transaction	SAVEPOINT
Setting constraint check timing for the current transaction	SET CONSTRAINTS

Setting a User Identifier

Table 1-388 SQL statements for setting a user identifier

Description	SQL Statement
Setting the current user identifier of the current session	SET ROLE

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description	SQL Statement
Setting the session user identifier and the current user identifier of the current session to a specified user	SET SESSION AUTHORIZATION

Upgrading a Database

Table 1-389 SQL statements for upgrading a database

Description	SQL Statement
Generating an upgrade rollback script for system objects	GENERATED UPDATE SYSTEM OBJECT
Updates the version information of system objects to the system catalog GS_SYSTEM_OBJECTS_VERSION to determine the changes of system objects during the upgrade.	REFRESH SYSTEM OBJECT

1.13.6 Online DDL and Related Operations

DDL operations on table objects (definition or modification of database table objects) are classified into the following types based on the impact on data:

Instant Change DDL

Definition and feature:

- Only the metadata of the table is modified. No data operation is required.
- The execution is fast and usually completed in milliseconds.
- An exclusive lock is held for a short period of time during the execution, which has little impact on concurrent services.

Impact of concurrency:

- Normal scenario: If there is no long transaction on the target table, the impact on services is small.
- Abnormal scenario: If a long transaction exists, DDL execution may be blocked and subsequent services may be affected.

Table 1-390 lists the supported instant change DDL operations. For details about the syntax, see ALTER TABLE.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 1-390 Instant change DDL operations supported by the current version

Category	Operation	Required Time	Remarks
Column operations	The supported operations are as follows: • Add columns, that is, set default values of columns to an expression. • Drop columns. • Rename columns. • Set and drop default values of columns. • Extend the varchar size (only when the length increases). • Modify the numeric precision **numeric(*p*,*s*)**, only when *p* increases and *s* remains unchanged. • Modify the definition of an ENUM column.	When only metadata is changed, the time required is irrelevant to the data volume.	• Instant DDL operations do not require the ONLINE keyword. If the ONLINE keyword is added to an instant DDL operation, it will be ignored. • During the execution of instant DDL operations, an exclusive lock is held for a short period of time. If there is no concurrent long transaction, DDL operations are completed in milliseconds, which has little impact on concurrent transactions. Before a DDL operation is executed, if there are concurrent long transactions on the target table, the DDL operation is blocked while waiting for an exclusive lock. This further blocks subsequent concurrent transactions
Table operations	The supported operations are as follows: • Rename tables. • Specify character sets. • Drop tables.	When only metadata is changed, the time required is irrelevant to the data volume.	
Tablespace operations	The supported operations are as follows: • Rename tablespaces. • Change owners of tablespaces. • Delete tablespaces.	When only metadata is changed, the time required is irrelevant to the data volume.	
Constraint operations	The supported operations are as follows: • Set a column constraint to **NULL**.	When only metadata is changed, the time required is irrelevant to the data volume.	
Partitio	The supported	When only metadata	

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Category	Operation	Required Time	Remarks
n operations	operations are as follows: • Add, drop, and truncate partitions, enable or disable row movement, and invalidate partitioned indexes.	is changed, the time required is irrelevant to the data volume.	after the DDL operation.

Data Operation DDL

Definition and feature:

- The actual data needs to be reorganized or checked.
- The execution time is proportional to the data volume.
- In traditional mode, tables cannot provide read or write services during execution, which may cause long-term service interruption.

Online DDL

Definition and feature:

- With the ONLINE keyword, data operation DDL statements are executed online by reorganizing (checking) basic data and appending (checking) incremental data.
- ROWID tables are not supported.

Impact of concurrency:

- During the execution, users can continue to read and write the database for most of the time.
- An exclusive lock is held only for a short period of time at the beginning and end.
- The impact on normal services is significantly reduced.

Table 1-391 lists the supported online DDL operations. For details about online DDL parameter settings and behavior limitations, see **ALTER TABLE**, and **VACUUM**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 1-391 Online DDL operations supported by the current version

Category	Operation	Required Time	Remarks
Column operations	The supported operations are as follows: • Change column lengths. • Change column precisions. • Change column types.	When data needs to be reorganized, the time required depends on the data volume.	• To perform online DDL operations, you need to use the ONLINE keyword. • Online DDL operations still hold an exclusive lock for a short period of time during initialization and final metadata switching, which may be affected by concurrent long transactions on the target table. Before an online DDL operation is executed or during metadata switching, if there are concurrent long transactions on the target table, the DDL operation may be blocked while waiting for an exclusive lock. This further blocks subsequent concurrent transactions. • Online DDL operations do not support rowid tables. For details about the syntax, see **ALTER TABLE** and **VACUUM**.
Table operations	The supported operations are as follows: Move tablespaces online at the table level.	When data needs to be moved, the time required depends on the data volume.	
Constraint operations	The supported operations are as follows: Add NOT NULL, CHECK, UNIQUE, and PRIMARY KEY constraints.	When data needs to be queried, the time required depends on the data volume.	
Partition operations	The supported operations are as follows: Split, merge, and exchange partitions and move partition tablespaces.	When data needs to be moved, the time required depends on the data volume.	
Recycling storage space	VACUUM FULL	When data needs to be reorganized, the time required depends on the data volume.	
Index operations	Build, rebuild, or drop an index using CONCURRENTLY.	When data needs to be queried, the time required depends on the data volume.	For details about index operations, see **CREATE INDEX**, **REINDEX** and **DROP INDEX**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

1.13.7 A

1.13.7.1 ABORT

Description

Rolls back the current transaction and cancels the changes in the transaction.

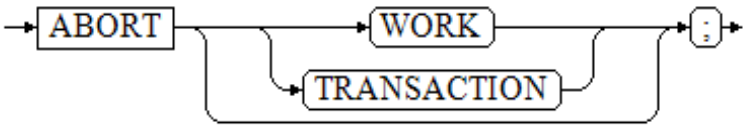
It is equivalent to **ROLLBACK**, and is present only for historical reasons. Now **ROLLBACK** is recommended.

Precautions

ABORT has no impact outside a transaction, but will return a NOTICE message.

Syntax

```
ABORT [ WORK | TRANSACTION ] ;
```



Parameters

WORK | TRANSACTION

Optional keyword, which is used only to improve readability.

Examples

```
-- Create the customer_demographics_t1 table.
gaussdb=# CREATE TABLE customer_demographics_t1
(
    CD_DEMO_SK              INTEGER              NOT NULL,
    CD_GENDER               CHAR(1)                      ,
    CD_MARITAL_STATUS       CHAR(1)                      ,
    CD_EDUCATION_STATUS     CHAR(20)                     ,
    CD_PURCHASE_ESTIMATE    INTEGER                      ,
    CD_CREDIT_RATING        CHAR(10)                     ,
    CD_DEP_COUNT            INTEGER                      ,
    CD_DEP_EMPLOYED_COUNT   INTEGER                      ,
    CD_DEP_COLLEGE_COUNT    INTEGER
)
DISTRIBUTE BY HASH (CD_DEMO_SK);

-- Insert data.
gaussdb=# INSERT INTO customer_demographics_t1 VALUES(1920801,'M', 'U', 'DOCTOR DEGREE', 200,
'GOOD', 1, 0,0);

-- Start a transaction.
gaussdb=# START TRANSACTION;

-- Update the column value. Change the value of cd_education_status to Unknown.
gaussdb=# UPDATE customer_demographics_t1 SET cd_education_status= 'Unknown';

-- Abort the transaction. All updates are rolled back.
gaussdb=# ABORT;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
-- Query data and find that the value of cd_education_status is not changed to Unknown.
gaussdb=# SELECT * FROM customer_demographics_t1 WHERE cd_demo_sk = 1920801;
cd_demo_sk | cd_gender | cd_marital_status | cd_education_status  | cd_purchase_estimate | cd_credit_rating
| cd_dep_count | cd_dep_employed_count | cd_dep_college_count
------------+-----------+-------------------+----------------------+----------------------+-----------------
+--------------+-----------------------+----------------------
   1920801 | M         | U                 | DOCTOR DEGREE        |                200 | GOOD             |           1
|                0 |                     0
(1 row)

-- Drop the table.
gaussdb=# DROP TABLE customer_demographics_t1;
```

Helpful Links

SET TRANSACTION, **COMMIT | END**, and **ROLLBACK**

1.13.7.2 ALTER AGGREGATE

Description

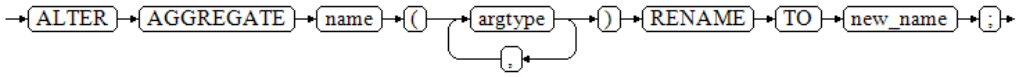
Modifies the definition of an aggregate function, including the name, owner, and schema.

Precautions

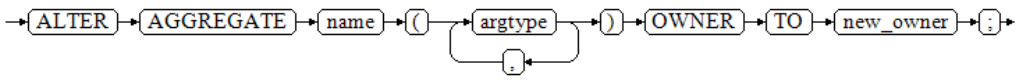
To use the ALTER AGGREGATE statement, you must be the owner of the aggregate function. To modify the schema of the aggregate function, you must have the CREATE permission on the new schema. To modify the owner of the aggregate function, you must be a direct or indirect member of the new owner and the member must have the CREATE permission on the schema of the aggregate function. The preceding rules prevent owners from performing illegal operations by deleting and rebuilding aggregate functions. However, users with the SYSADMIN permission can still alter the ownership of any aggregate function in any way.

Syntax

```
ALTER AGGREGATE name ( argtype [ , ... ] ) RENAME TO new_name;
```



```
ALTER AGGREGATE name ( argtype [ , ... ] ) OWNER TO new_owner;
```



```
ALTER AGGREGATE name ( argtype [ , ... ] ) SET SCHEMA new_schema;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameters

- **name**

  Name (optionally schema-qualified) of an existing aggregate function.

- **argtype**

  Input data type of the aggregate function. To reference a zero-parameter aggregate function, you can pass an asterisk (*) instead of the input data type list.

- **new_name**

  New name of an aggregate function.

- **new_owner**

  New owner of the aggregate function.

- **new_schema**

  New schema of the aggregate function.

Examples

- Change the name of the aggregate function.

```
-- Create a user-defined function.
gaussdb=# CREATE OR REPLACE FUNCTION int_add(int,int)
 RETURNS int AS $BODY$
DECLARE
BEGIN
 RETURN $1 + $2;
END;
$BODY$ language plpgsql;

-- Create an aggregate function.
gaussdb=# CREATE AGGREGATE myavg (int)
(
    sfunc = int_add,
    stype = int,
    initcond = '0'
);

-- Rename the aggregate function myavg that accepts int-type parameters to my_average.
gaussdb=# ALTER AGGREGATE myavg(int) RENAME TO my_average;
```

- Change the owner of the aggregate function.

```
-- Create a user joe.
gaussdb=# CREATE USER joe PASSWORD '********';

-- Change the owner of the aggregate function my_average that accepts int-type parameters to joe.
gaussdb=# ALTER AGGREGATE my_average(int) OWNER TO joe;
```

- Change the schema of the aggregate function.

```
-- Create a schema myschema.
gaussdb=# CREATE SCHEMA myschema;

-- Move the aggregate function my_average that accepts int-type parameters to myschema.
gaussdb=# ALTER AGGREGATE my_average(int) SET SCHEMA myschema;

-- Delete the schema, user, and related function.
gaussdb=# DROP SCHEMA myschema CASCADE;
gaussdb=# DROP USER joe;
gaussdb=# DROP FUNCTION int_add(int,int);
```

Helpful Links

CREATE AGGREGATE and **DROP AGGREGATE**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Compatibility

The SQL standard does not contain the ALTER AGGREGATE statement.

1.13.7.3 ALTER ASYNC ENCRYPTION KEY ROTATION

Description

Rotates the key for asynchronous TDE.

Precautions

- This statement can be executed only when **enable_tde** and **enable_tde_async_encryption** are enabled.
- Only users with the SYSADMIN permission can run this statement.
- M-compatible databases do not support this statement.
- Unified audit logging is not supported.

Syntax

```
ALTER ASYNC ENCRYPTION KEY ROTATION;
```

Examples

```
-- Enable the asynchronous TDE.
gaussdb=# show enable_tde_async_encryption;
 enable_tde_async_encryption
-----------------------------
 on
(1 row)

-- Create two TDE tables t1 and t2. Run the \d command. The output indicates that the two tables use the same data key (that is, the asynchronous encryption key).
gaussdb=# CREATE TABLE t1 (c1 INT, c2 TEXT) WITH (enable_tde = on);
CREATE TABLE
gaussdb=# CREATE TABLE t2 (c1 INT, c2 TEXT) WITH (enable_tde = on);
CREATE TABLE
gaussdb=# \d

-- Rotate the asynchronous encryption key.
gaussdb=# ALTER ASYNC ENCRYPTION KEY ROTATION;
ALTER TDE ROTATE ENCRYPTION KEY

-- Create a TDE table t3. Run the \d command. The output indicates that the data key of table t3 is different from that of tables t1 and t2, that is, the asynchronous encryption key is rotated.
gaussdb=# CREATE TABLE t3 (c1 INT, c2 TEXT) WITH (enable_tde = on);
CREATE TABLE
gaussdb=# \d

-- Drop encrypted tables.
gaussdb=# DROP TABLE t1,t2,t3;
```

1.13.7.4 ALTER AUDIT POLICY

Description

Modifies a unified audit policy.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

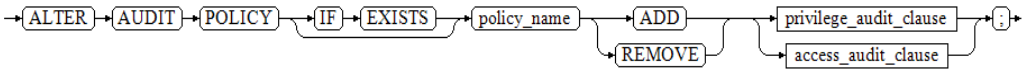
Precautions

- Only users with the POLADMIN or SYSADMIN permission, or the initial user can maintain audit policies.
- The unified audit policy takes effect only after **enable_security_policy** is enabled.

Syntax

Add or delete an operation type in the audit policy.

```
ALTER AUDIT POLICY [ IF EXISTS ] policy_name { ADD | REMOVE } { privilege_audit_clause |
access_audit_clause };
```



Change the filter criteria in the audit policy.

```
ALTER AUDIT POLICY [ IF EXISTS ] policy_name MODIFY ( filter_group_clause );
```

Delete the filter criteria from the audit policy.

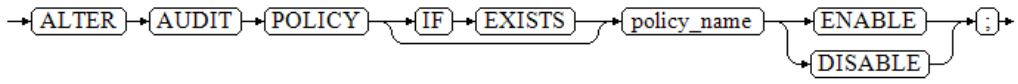
```
ALTER AUDIT POLICY [ IF EXISTS ] policy_name DROP FILTER;
```

Change the description of the audit policy.

```
ALTER AUDIT POLICY [ IF EXISTS ] policy_name COMMENTS policy_comments;
```

Enable or disable the audit policy.

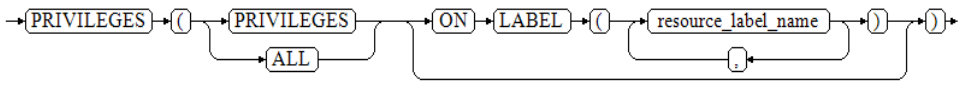
```
ALTER AUDIT POLICY [ IF EXISTS ] policy_name { ENABLE | DISABLE };
```



- privilege_audit_clause

  PRIVILEGES operation type and target resource label in the audit policy.

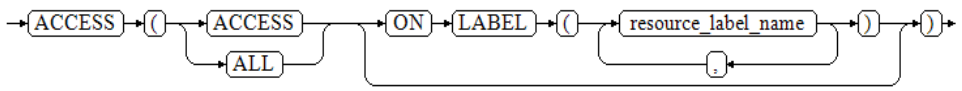
  ```
  PRIVILEGES ({ PRIVILEGES | ALL } [ ON LABEL ( resource_label_name [, ... ] ) ])
  ```

- access_audit_clause

  ACCESS operation type and target resource label in the audit policy.

  ```
  ACCESS ({ ACCESS | ALL } [ ON LABEL ( resource_label_name [, ... ] ) ])
  ```

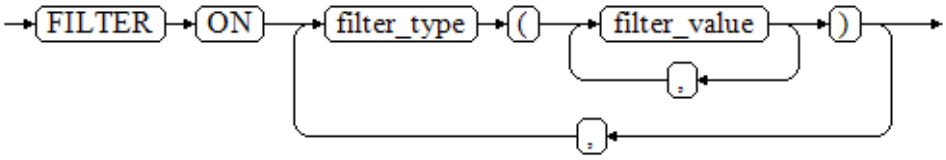
  


- filter_group_clause

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Filter criteria in the audit policy.

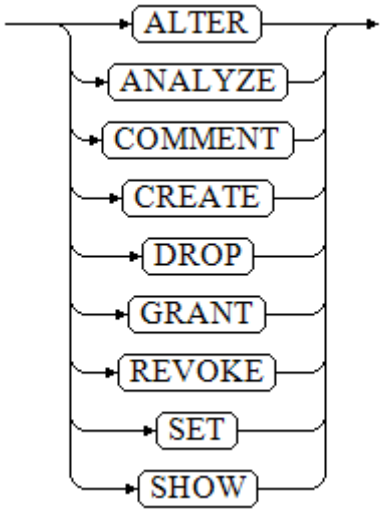
```
FILTER ON { filter_type ( filter_value [, ... ] ) } [, ... ]
```



- PRIVILEGES:

  Perform audit when the following operations are performed on the database.

  ```
  { ( ALTER | ANALYZE | COMMENT | CREATE | DROP | GRANT | REVOKE | SET | SHOW ) }
  ```

- ACCESS:

  Perform audit when the following operations are performed on the database.

  ```
  { ( COPY | DEALLOCATE | DELETE | EXECUTE | REINDEX | INSERT | PREPARE | SELECT | TRUNCATE |
  UPDATE ) }
  ```

  
 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameters

- **policy_name**

  Specifies the name of an audit policy, which must be unique.

  Value range: character strings complying with **Identifier Naming Conventions**.

- **resource_label_name**

  Specifies a resource label name.

- **PRIVILEGES**

  Specifies the database operations to be audited. Currently, the following operations can be audited: ALTER, ANALYZE, COMMENT, CREATE, DROP, GRANT, REVOKE, SET, and SHOW.

- **ACCESS**

  Specifies the database operations to be audited. Currently, the following operations can be audited: COPY, DEALLOCATE, DELETE, EXECUTE, REINDEX, INSERT, PREPARE, SELECT, TRUNCATE, and UPDATE.

- **ALL**

  Audits all database operations supported by **PRIVILEGES** or **ACCESS**. When the format is { PRIVILEGES | ALL }, **ALL** indicates all operations specified by **PRIVILEGES**. When the format is { ACCESS | ALL }, **ALL** indicates all operations specified by **ACCESS**.

- **filter_type**

  Specifies the types of information to be filtered by the policy: **IP**, **ROLES**, and **APP**.

- **filter_value**

  Specifies the detailed information to be filtered.

- **policy_comments**

  Records comments on the audit policy.

- **ENABLE | DISABLE**

  Enables or disables the unified audit policy.

Examples

- Add or delete an operation type in the audit policy.

```
-- Create audit policy adt1 for executing CREATE on the database.
gaussdb=# CREATE AUDIT POLICY adt1 PRIVILEGES CREATE;

-- Add DROP to the adt1 audit policy.
gaussdb=# ALTER AUDIT POLICY adt1 ADD PRIVILEGES (DROP);

-- Delete DROP from the adt1 audit policy.
gaussdb=# ALTER AUDIT POLICY adt1 REMOVE PRIVILEGES (DROP);
```

- Change the comments of the audit policy.

```
-- Change the comment of the adt1 audit policy to adt1_comments.
gaussdb=#  ALTER AUDIT POLICY adt1 COMMENTS 'adt1_comments';
```

- Change the filter information of the audit policy.

```
-- Create a user bob_audit.
gaussdb=#  CREATE USER bob_audit PASSWORD '********';

-- Change the filtering user of the adt1 audit policy to bob_audit.
gaussdb=#  ALTER AUDIT POLICY adt1 MODIFY (FILTER ON (ROLES(bob_audit)));
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
-- Delete user bob_audit.
gaussdb=# DROP USER bob_audit;
```

- Delete the filter criteria from the audit policy.

```
-- Delete the filter criteria in the adt1 audit policy.
gaussdb=#  ALTER AUDIT POLICY adt1  DROP FILTER;
```

- Disable the audit policy.

```
-- Disable the adt1 audit policy.
gaussdb=#  ALTER AUDIT POLICY adt1  DISABLE;

-- Delete the adt1 audit policy.
gaussdb=# DROP AUDIT POLICY adt1;
```

Helpful Links

CREATE AUDIT POLICY and DROP AUDIT POLICY

1.13.7.5 ALTER COLUMN ENCRYPTION KEY

Description

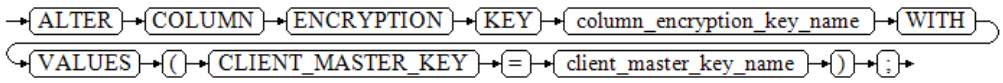
Encrypts the CMKs of CEKs in round robin (RR) mode and encrypts the plaintext of CEKs.

Precautions

- This syntax is specific to a fully-encrypted database. When connecting to the database server, enable the fully-encrypted database before using this syntax.
- This syntax takes effect on CMKs only. Encrypting the plaintext of CEKs does not change the ciphertext of the encrypted columns.

Syntax

```
ALTER COLUMN ENCRYPTION KEY column_encryption_key_name WITH VALUES ( CLIENT_MASTER_KEY = client_master_key_name );
```



Parameters

- **column_encryption_key_name**

  Specifies the key name. In the same namespace, the value of this parameter must be unique.

  Value range: character strings complying with Identifier Naming Conventions.

- **client_master_key_name**

  Specifies the new CMK used to re-encrypt the CEK.

  Value range: name of an existing CMK created using the CREATE CLIENT MASTER KEY syntax. The encrypted CMKs are different from those specified before RR encryption.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTICE

SM algorithm constraints: SM2, SM3, and SM4 are Chinese national cryptography standards. To avoid legal risks, these algorithms must be used together. If the CMK used before CEK rotation is an SM algorithm, the CMK specified for CEK rotation must also be an SM algorithm.

Helpful Links

CREATE COLUMN ENCRYPTION KEY and **DROP COLUMN ENCRYPTION KEY**

1.13.7.6 ALTER COORDINATOR

Description

Changes the CN status. You can run the statement on any normal CN in the cluster to change the value of the **nodeis_active** field of a specified node in the pgxc_node system catalog. You can also specify the nodes where the system catalog is modified.

Precautions

- ALTER COORDINATOR is a statement for modifying system catalogs. Only administrators and users in internal maintenance mode (for example, CM administrator) can execute this statement.
- This statement is dedicated for CN removal and must be used together with other operations. You are advised not to run it by yourself.
- After this statement is executed, **SELECT reload_active_coordinator()** needs to be called to update the connection pool information of the node on which the system catalog is modified.

Syntax

```
ALTER COORDINATOR nodename SET status
    WITH (other_nodename [, ... ]) (nodetype);
```

Parameters

- **nodename**

  Specifies the CN name corresponding to a row of records in the pgxc_node system catalog. After the node name is specified, the value of **nodeis_active** in the record is changed.

  Value range: character strings. Only CN names are allowed, and the names must have corresponding records in the pgxc_node system catalog.

- **status**

  Specifies the CN status, that is the updated value of **nodeis_active** in the pgxc_node system catalog.

  Value range: **FALSE** and **TRUE**

- **other_nodename**

  Specifies the range of nodes on which the SQL statement is executed. When **ALTER COORDINATOR** is executed, the SQL statement is automatically

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

delivered to all nodes in the range. The current execution node must be included.

Value range: a string. Only CNs are supported. Ensure that the node name has a corresponding record in the pgxc_node system catalog and the node is normal. Otherwise, the SQL statement fails to be executed.

- **nodetype**

  Type of the node to be changed, which is the value of **node_type** in the pgxc_node system catalog.

  Value range: **"C"** (CN)

Examples

- Remove a faulty CN.

```
-- The cluster has three CNs: cn_5001, cn_5002, and cn_5003, which are working properly. If cn_5001 is faulty and the removal time meets the requirement, cn_5001 needs to be removed from the cluster.
gaussdb=# ALTER COORDINATOR cn_5001 SET False WITH (cn_5002,cn_5003);

-- Refresh the pgxc_node system catalog. On the cn_5002 and cn_5003 nodes, run the following SQL statement to update the value of nodeis_active corresponding to the cn_5001 record in the pgxc_node system catalog to false:
gaussdb=# SELECT reload_active_coordinator();

-- Check the CN status. The value of nodeis_active changes to f (false).
gaussdb=#  SELECT nodeis_active,node_name FROM pgxc_node where node_name='cn_5001';
 nodeis_active | node_name
---------------+-----------
 f             | cn_5001
(1 row)
```

- Restore the CN whose fault has been rectified.

```
-- After the cn_5001 fault is rectified, add cn_5001 back to the cluster.
gaussdb=#  ALTER COORDINATOR cn_5001 SET True WITH (cn_5002,cn_5003);

-- Refresh the pgxc_node system catalog. On the cn_5002 and cn_5003 nodes, run the following SQL statement to update the value of nodeis_active corresponding to the cn_5001 record in the pgxc_node system catalog to true:
gaussdb=# SELECT reload_active_coordinator();

-- Check the CN status. The value of nodeis_active changes to t (true).
gaussdb=# SELECT nodeis_active,node_name FROM pgxc_node where node_name='cn_5001';
 nodeis_active | node_name
---------------+-----------
 t             | cn_5001
(1 row)
```

1.13.7.7 ALTER DATABASE

Description

Alters database attributes, including the database name, owner, connection limit, and object isolation.

Precautions

- Only the database owner or a user with the ALTER permission can run the **ALTER DATABASE** command. A system administrator has this permission by default. Here are the permission limits for the attributes you want to alter:
  - To change the database name, you must have the CREATEDB permission.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

  - To change a database owner, you must be a database owner or system administrator and a member of the new owner role, with the CREATEDB permission.
  - To change the default tablespace of the database, the user must have the CREATE permission on the tablespace. After this operation, tables and indexes in a default tablespace are physically migrated to a new tablespace. Note that tables and indexes outside the default tablespace are not affected.
- Do not directly rename the current database. If you need to rename the database, connect to another database and rename the original database.
- Do not rename other schemas as **templatem** or rename the **templatem** or **templatea** schema as another name.

Syntax

- Rename the database.

```
ALTER DATABASE database_name
   RENAME TO new_name;
```

- Modify the owner of a database.

```
ALTER DATABASE database_name
   OWNER TO new_owner;
```

- Change the maximum number of connections to the database.

```
ALTER DATABASE database_name
   [ WITH ] CONNECTION LIMIT connlimit;
```

- Change the default tablespace of the database.

```
ALTER DATABASE database_name
   SET TABLESPACE new_tablespace;
```

NOTICE

If some tables or objects in the database have been created in new_tablespace, the default tablespace of the database cannot be changed to **new_tablespace**. An error will be reported during the execution.

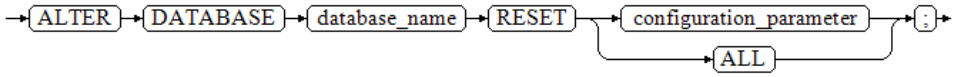
- Change the session parameter value of the database. The current version does not support setting database-level parameters.

```
ALTER DATABASE database_name
   SET configuration_parameter { { TO | = } { value | DEFAULT } | FROM CURRENT };
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

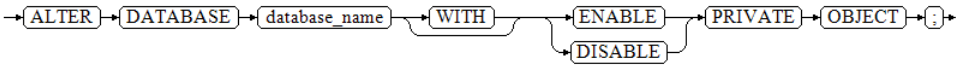
- Reset the database configuration parameter. The current version does not support setting database-level parameters.

```
ALTER DATABASE database_name RESET
  { configuration_parameter | ALL };
```



- Change the object isolation attribute of the database. To change the object isolation attribute of a database, the database must be connected. Otherwise, the change will fail.

```
ALTER DATABASE database_name [ WITH ] { ENABLE | DISABLE } PRIVATE OBJECT;
```



NOTE

For a newly created database, the object isolation attribute is disabled by default. When this attribute is enabled, the database automatically adds row-level security policies to the PG_CLASS, PG_ATTRIBUTE, PG_PROC, PG_NAMESPACE, PGXC_SLICE, PG_DATABASE, and PG_PARTITION system catalogs. Common users can view the objects (such as tables, functions, views, and columns) that they have the permission to access in the system catalogs. Administrators are not affected by this attribute. After this attribute is enabled, administrators can still view all database objects.

- Change the database time zone.

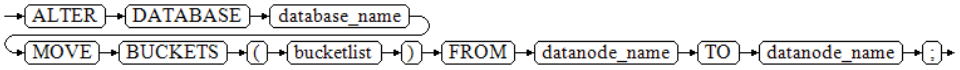
```
ALTER DATABASE database_name SET DBTIMEZONE = time_zone;
```

- Bind a node group to the hash bucket table to determine the bucket mapping.

```
ALTER DATABASE database_name
  TO GROUP group_name ;
```

- Migrate a specified bucket from one DN to another.

```
ALTER DATABASE database_name
  MOVE BUCKETS(bucketlist) FROM datanode_name TO datanode_name;
```



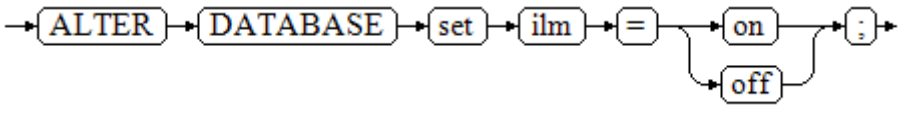
NOTE

This statement can be called only during hash bucket scale-out. It is a hash bucket database-level redistribution command. Example:

```
ALTER DATABASE testdb MOVE BUCKETS (0, 1, 2, 3) FROM datanode1 TO datanode3;
```

- Enable or disable the ILM feature of the database.

```
ALTER DATABASE set ilm = { on | off };
```



Parameters

- **database_name**

  Specifies the name of the database whose attributes are to be changed.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Value range: character strings complying with **Identifier Naming Conventions**.

- **new_name**

  Specifies the new name of a database.

  Value range: a string. It must comply with **Identifier Naming Conventions** and contain a maximum of 63 characters.

  - If the value contains more than 63 characters, the database truncates it and retains the first 63 characters as the database name.
  - If the database name contains uppercase letters, they are automatically converted to lowercase letters.
  - If you want to create a database name that contains uppercase letters, enclose the name with double quotation marks ("").

- **new_owner**

  Specifies the new owner of a database.

  Value range: a string. It must be a valid username.

- **connlimit**

  Specifies the maximum number of concurrent connections that can be made to this database (excluding administrators' connections).

  Value range: an integer in the range [–1,2^{31} – 1]. The default value is **–1**, indicating that the maximum number of concurrent database connections is not limited. You are advised to set the value to an integer ranging from 1 to 50.

- **new_tablespace**

  Specifies the new default tablespace of a database. The tablespace exists in the database.

  Value range: a string. It must be a valid tablespace name. The default tablespace is **pg_default**.

  NOTE

  If you change the default tablespace of a database, the tables and indexes in the old tablespace are moved into the new tablespace. This operation does not affect the tables or indexes in other non-default tablespaces.

- **time_zone**

  To set the time zone of the database, you must have the permission to operate the database.

  Value range: a string. Currently, the following time zones are supported:

  - Time zones supported by the system and their abbreviations.
  - [–15:59,+15:00]

  NOTE

  This parameter can be specified only when the connected database is in ORA-compatible mode and **a_format_version** is set to **'10c'** and **a_format_dev_version** is set to **'s2'**.

- **group_name**

  Specifies the name of the node group bound to a hash bucket table. Common users can only bind the table to the installation node group but cannot alter it.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **bucketlist**

  Specifies the bucketlist involved in redistribution

  Value range: a string. The value range of each bucket is [0,1023].

- **datanode_name**

  Specifies the name of the node involved in bucket migration.

  Value range: character strings complying with **Identifier Naming Conventions**.

- **configuration_parameter**

  Specifies the database session parameter whose attributes are to be altered.

  NOTICE

  The current version does not support setting database-level parameters.

  - **value**

    Sets a specified database session parameter to a given value.

    Value range: a string.

    - **DEFAULT**: The default system setting is used in the new session.
    - **OFF**: The setting is disabled.
    - **RESET**: The default system setting is used in the new session.
    - User-specified value: The value must meet the restriction of the modified parameter.

  - **FROM CURRENT**

    Uses the value of **configuration_parameter** of the current session.

- **RESET configuration_parameter**

  Resets the specified database session parameter.

  NOTICE

  The current version does not support resetting database-level parameters.

- **RESET ALL**

  Resets all database session parameters.

  NOTICE

  The current version does not support resetting database-level parameters.

Examples

- Rename the database.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
-- Create the database testdb.
gaussdb=# CREATE DATABASE testdb;

-- Rename testdb to test_db1.
gaussdb=# ALTER DATABASE testdb RENAME TO test_db1;
```

- Change the maximum number of database connections.

```
-- Change the maximum number of connections to test_db1 to 100.
gaussdb=# ALTER DATABASE test_db1 WITH CONNECTION LIMIT 100;

-- View information about test_db1.
gaussdb=# SELECT datname,datconnlimit FROM pg_database WHERE datname = 'test_db1';
 datname  | datconnlimit
----------+--------------
 test_db1 |          100
(1 row)
```

- Change the database owner.

```
-- Create user scott.
gaussdb=# CREATE USER scott PASSWORD '********';

-- Change the owner of test_db1 to scott.
gaussdb=# ALTER DATABASE test_db1 OWNER TO scott;

-- View information about test_db1.
gaussdb=# SELECT t1.datname, t2.usename
          FROM pg_database t1, gs_user t2
          WHERE t1.datname='test_db1' AND t1.datdba=t2.usesysid;
 datname  | usename
----------+---------
 test_db1 | scott
(1 row)
```

- Change the default tablespace of the database.

```
-- Create a tablespace.
gaussdb=# CREATE TABLESPACE tbs_data1 RELATIVE LOCATION 'tablespace1/tbs_data1';

-- Change the default tablespace of test_db1.
gaussdb=# ALTER DATABASE test_db1 SET TABLESPACE tbs_data1;

-- View information about test_db1.
gaussdb=# SELECT t1.datname AS database, t2.spcname AS tablespace
          FROM pg_database t1, pg_tablespace t2
          WHERE t1.dattablespace = t2.oid AND
               t1.datname = 'test_db1';
 database | tablespace
----------+------------
 test_db1 | tbs_data1
(1 row)
```

- Change the database time zone.

  Prerequisites: The currently connected database is an ORA-compatible database, **a_format_version** is set to **'10c'**, and **a_format_dev_version** is set to **'s2'**.

```
-- Create an ORA-compatible database. The PRC time zone is used by default.
gaussdb=# CREATE DATABASE testdb2 DBCOMPATIBILITY = 'ORA';

-- Check the time zone of the testdb2 database.
gaussdb=# SELECT datname,datcompatibility,dattimezone FROM pg_database WHERE datname =
'testdb2';
 datname | datcompatibility | dattimezone
---------+------------------+-------------
 testdb2 | ORA              | PRC
(1 row)

-- Switch to the testdb2 database and change the database time zone to '+08:00'.
gaussdb=# \c testdb2
testdb2=# SET a_format_version='10c';
testdb2=# SET a_format_dev_version='s2';
testdb2=# ALTER DATABASE testdb2 SET DBTIMEZONE = '+08:00';
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
-- Check the database time zone.
testdb2=# SELECT datname,datcompatibility,dattimezone FROM pg_database WHERE datname =
'testdb2';
 datname | datcompatibility | dattimezone
---------+------------------+-------------
 testdb2 | ORA              | +08:00
(1 row)
```

- Change the object isolation attribute of the database.

```
-- Create user jack.
gaussdb=# CREATE USER jack PASSWORD '********';

-- Create the test_tbl1 table in test_db1.
gaussdb=# \c test_db1
test_db1=# CREATE TABLE test_tbl1(c1 int,c2 int);

-- Switch to user jack and view pg_tables.
test_db1=# SET ROLE jack PASSWORD '********';
test_db1=> SELECT tablename FROM pg_tables WHERE tablename = 'test_tbl1';
 tablename
-----------
 test_tbl1
(1 row)

-- Change the object isolation attribute.
test_db1=> SET ROLE scott PASSWORD '********';
test_db1=> ALTER DATABASE test_db1 ENABLE PRIVATE OBJECT;

-- Switch to user jack and view pg_tables.
test_db1=> SET ROLE jack PASSWORD '********';

-- Due to the isolation attribute, 0 data records can be queried.
test_db1=> SELECT tablename FROM pg_tables WHERE tablename = 'test_tbl1';
 tablename
-----------
(0 rows)

-- Switch to the default user and perform the deletion.
test_db1=> RESET ROLE;
test_db1=# DROP TABLE public.test_tbl1;

-- Switch to the default database. Change the database name based on actual situation.
test_db1=# \c postgres
gaussdb=# DROP DATABASE test_db1;
gaussdb=# DROP DATABASE testdb2;
gaussdb=# DROP TABLESPACE tbs_data1;
gaussdb=# DROP USER jack;
gaussdb=# DROP USER scott;
```

Helpful Links

CREATE DATABASE and **DROP DATABASE**

1.13.7.8 ALTER DATABASE LINK

Description

Modifies database link objects.

Precautions

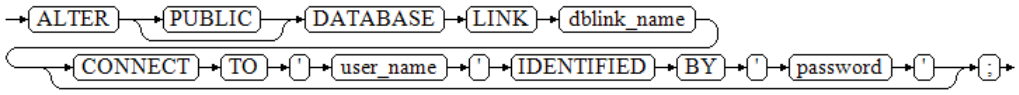
- For details about database links, see "Feature Usage Guidelines > Database Links" in *Developer Guide*.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- If the database link is connected to GaussDB, only the username and password of the database link object can be altered.

Syntax

```
ALTER [PUBLIC] DATABASE LINK dblink_name
   [CONNECT TO 'user_name' IDENTIFIED BY 'password'];
```



Parameters

- **dblink_name**

  Name of a connection.

- **user_name**

  Username for connecting to a remote database.

- **password**

  Password for connecting to a remote database.

- **PUBLIC**

  Connection type. If **PUBLIC** is not specified, the default value **PRIVATE** is used.

Examples

```
-- Create an ORA-compatible data record.
gaussdb=#  CREATE DATABASE ora_test_db DBCOMPATIBILITY 'ORA';
CREATE DATABASE

-- Switch to another database.
gaussdb=# \c ora_test_db

-- Create a user with the SYSADMIN permission.
ora_test_db=# CREATE USER local_user WITH SYSADMIN PASSWORD '********';
CREATE ROLE
ora_test_db=# SET ROLE local_user PASSWORD '********';
SET

-- Create a public database link.
ora_test_db=> CREATE PUBLIC DATABASE LINK public_dblink CONNECT TO 'local_user' IDENTIFIED BY
'********' USING (host '***.***.***.***',port '*****',dbname 'remote_db');
CREATE DATABASE LINK

-- Create a common user.
ora_test_db=> CREATE USER remote_user PASSWORD '********';
CREATE ROLE

-- Change database link object information.
ora_test_db=> ALTER PUBLIC DATABASE LINK public_dblink CONNECT TO 'remote_user' IDENTIFIED BY
'********';
ALTER DATABASE LINK

-- Drop the public database link.
ora_test_db=> DROP PUBLIC DATABASE LINK public_dblink;
DROP DATABASE LINK

-- Drop users.
ora_test_db=> RESET ROLE;
RESET
ora_test_db=# DROP USER local_user;
DROP ROLE
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
ora_test_db=# DROP USER remote_user;
DROP ROLE

-- Switch back to the initial database and drop the test database. Replace postgres with the actual database name.
ora_test_db=# \c postgres
gaussdb=# DROP DATABASE ora_test_db;
DROP DATABASE
```

CREATE DATABASE LINK and **DROP DATABASE LINK**

1.13.7.9 ALTER DEFAULT PRIVILEGES

Description

Alters the default permissions of a user on a specific object in the database. It does not affect the permissions assigned to existing objects.

Precautions

Currently, you can change only the permissions for tables (including views), sequences, functions, types, CMKs of encrypted databases, and CEKs.

Syntax

```
ALTER DEFAULT PRIVILEGES
   [ FOR { ROLE | USER } target_role [, ...] ]
   [ IN SCHEMA schema_name [, ...] ]
   abbreviated_grant_or_revoke;
```

- abbreviated_grant_or_revoke grants or revokes permissions on some objects.

  ```
  {grant_on_tables_clause
    | grant_on_sequences_clause
    | grant_on_functions_clause
    | grant_on_types_clause
    | grant_on_client_master_keys_clause
    | grant_on_column_encryption_keys_clause
    | revoke_on_tables_clause
    | revoke_on_sequences_clause
    | revoke_on_functions_clause
    | revoke_on_types_clause
    | revoke_on_client_master_keys_clause
    | revoke_on_column_encryption_keys_clause
  }
  ```

- grant_on_tables_clause grants permissions on tables.

  ```
  GRANT { { SELECT | INSERT | UPDATE | DELETE | TRUNCATE | REFERENCES | ALTER | DROP |
  COMMENT | INDEX | VACUUM }
     [, ...] | ALL [ PRIVILEGES ] }
     ON TABLES
     TO { [ GROUP ] role_name | PUBLIC } [, ...]
     [ WITH GRANT OPTION ]
  ```

- grant_on_sequences_clause grants permissions on sequences.

  ```
  GRANT { { SELECT | UPDATE | USAGE | ALTER | DROP | COMMENT }
     [, ...] | ALL [ PRIVILEGES ] }
     ON SEQUENCES
     TO { [ GROUP ] role_name | PUBLIC } [, ...]
     [ WITH GRANT OPTION ]
  ```

- grant_on_functions_clause grants permissions on functions.

  ```
  GRANT { { EXECUTE | ALTER | DROP | COMMENT } [, ...] | ALL [ PRIVILEGES ] }

    FROM { [ GROUP ] role_name | PUBLIC } [, ...]
    [ CASCADE | RESTRICT | CASCADE CONSTRAINTS ]
```

Parameters

- **target_role**

  Specifies an existing role name. If **FOR { ROLE | USER}** is not specified, the current role or user is used by default.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Value range: existing role names.

- **schema_name**

  Specifies an existing schema name.

  Value range: existing schema names.

  > NOTE
  >
  > The target role (**target_role**) must have the CREATE permission on the schema (**schema_name**).

- **role_name**

  Specifies the name of the role whose permissions need to be granted or revoked.

  Value range: existing role names.

NOTICE

To drop a role for which the default permissions have been granted, reverse the changes in its default permissions or use DROP OWNED BY to get rid of the default permission entry for the role.

Examples

```
-- Create a schema.
gaussdb=# CREATE SCHEMA tpcds;

-- Grant the SELECT permission on all the tables (and views) in tpcds to every user.
gaussdb=# ALTER DEFAULT PRIVILEGES IN SCHEMA tpcds GRANT SELECT ON TABLES TO PUBLIC;

-- Create a common user jack.
gaussdb=# CREATE USER jack PASSWORD '******';

-- Grant the INSERT permission on all the tables in tpcds to the user jack.
gaussdb=# ALTER DEFAULT PRIVILEGES IN SCHEMA tpcds GRANT INSERT ON TABLES TO jack;

-- Grant the INSERT permission on all tables created by jack in tpcds to user jake (assuming that the user already exists in the database).
gaussdb=#  GRANT USAGE,CREATE ON SCHEMA tpcds TO jack;
gaussdb=# ALTER DEFAULT PRIVILEGES FOR ROLE jack IN SCHEMA tpcds GRANT INSERT ON TABLES TO jake;

-- Revoke the preceding permissions.
gaussdb=# ALTER DEFAULT PRIVILEGES IN SCHEMA tpcds REVOKE SELECT ON TABLES FROM PUBLIC;
gaussdb=# ALTER DEFAULT PRIVILEGES IN SCHEMA tpcds REVOKE INSERT ON TABLES FROM jack;

-- Drop user jack.
gaussdb=# DROP USER jack CASCADE;

-- Drop a schema.
gaussdb=# DROP SCHEMA tpcds;
```

1.13.7.10 ALTER DIRECTORY

Description

Alters the attributes of a directory.

Precautions

- Currently, only the owner of a directory can be altered.
- When **enable_access_server_directory** is set to **off**, only the initial user is allowed to alter the owner of a directory. When **enable_access_server_directory** is set to **on**, users with the SYSADMIN permission and the directory owner can alter the directory owner, and the they must be a member of the new owner.

Syntax

```
ALTER DIRECTORY directory_name
    OWNER TO new_owner;
```

Parameters

- **directory_name**

  Specifies the directory whose attributes are to be altered.

  Value range: an existing directory name.
- **new_owner**

  Specifies the new owner of the directory.

Examples

```
-- Create a directory.
gaussdb=# CREATE OR REPLACE DIRECTORY dir as '/tmp/';

-- Create a user.
gaussdb=# CREATE USER jim PASSWORD '********';

-- Change the owner of the directory.
gaussdb=# ALTER DIRECTORY dir OWNER TO jim;

-- Delete the directory object.
gaussdb=# DROP DIRECTORY dir;

-- Delete the user.
gaussdb=# DROP USER jim;
```

CREATE DIRECTORY and **DROP DIRECTORY**

1.13.7.11 ALTER FOREIGN DATA WRAPPER

Description

Alters the attributes of a foreign data wrapper.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Precautions

A foreign data wrapper can be altered only during the internal initialization phase or within an upgrade script. In other scenarios, users cannot directly use this syntax.

Syntax

Set the attributes of a foreign data wrapper.

```
ALTER FOREIGN DATA WRAPPER name
[ HANDLER handler_function | NO HANDLER ]
[ VALIDATOR validator_function | NO VALIDATOR ]
[ OPTIONS ( { [ ADD | SET | DROP ] option ['value'] } [, ... ]) ];
```

Parameters

- **name**

  Specifies a name of an existing foreign data wrapper.

- **HANDLER handler_function**

  Specifies a new handler function for a foreign data wrapper.

- **NO HANDLER**

  Specifies that a foreign data wrapper no longer has the handler function.

  NOTICE

  Foreign tables that use foreign data wrapper but do not have handlers cannot be accessed.

- **VALIDATOR validator_function**

  Specifies a new validator function for a foreign data wrapper.

  NOTICE

  Depending on the new validator, an existing option for the foreign data wrapper or dependent server, user mapping, or foreign table may be invalid. Before using foreign data wrapper, ensure that these options are correct. However, any options specified in the **ALTER FOREIGN DATA WRAPPER** command will be checked using the new validator function.

- **NO VALIDATOR**

  Specifies that a foreign data wrapper no longer has the validator function.

- **OPTIONS ([ADD | SET | DROP] option ['value'] [, ...])**

  Alters the options of a foreign data wrapper. The option name must be unique. The actions are ADD, SET, and DROP. If no action is specified, ADD is used. When foreign data is used to wrap validator functions, names and values are also validated.

1.13.7.12 ALTER FOREIGN TABLE

Description

Alters foreign table attributes.

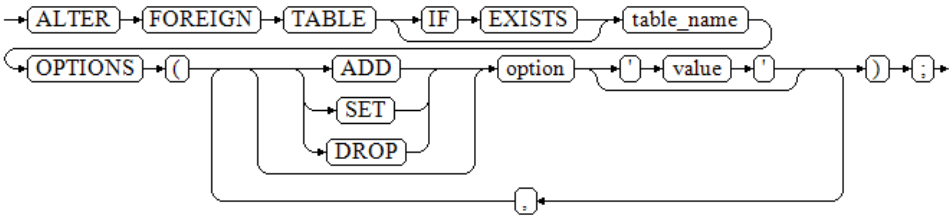
Precautions

When multi-layer quotation marks are used for sensitive columns (such as **password** and **secret_access_key**) in **OPTIONS**, the semantics is different from that in scenarios where quotation marks are not used. Therefore, these columns are not identified as sensitive columns for anonymization.

Syntax

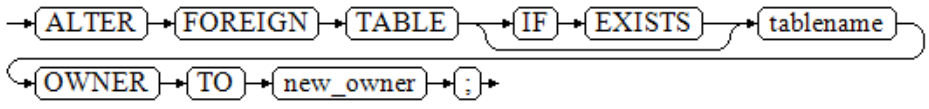
- Set the attributes of a foreign table.

```
ALTER FOREIGN TABLE [ IF EXISTS ]  table_name
    OPTIONS ( { [ ADD | SET | DROP ] option ['value']}[, ... ]);
```



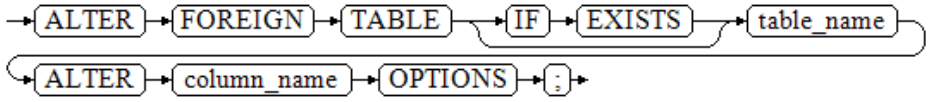
- Set a new owner.

```
ALTER FOREIGN TABLE [ IF EXISTS ] tablename
    OWNER TO new_owner;
```



- Set foreign table column options.

```
ALTER FOREIGN TABLE [ IF EXISTS ] table_name
    ALTER column_name OPTIONS;
```



Parameters

- **table_name**

  Specifies the name of an existing foreign table to be modified.

  Value range: an existing foreign table name.

- **OPTIONS ([ADD | SET | DROP] option ['value'] [, ...])**

  Specifies the option of a foreign table or foreign table column to be altered. **ADD**, **SET**, and **DROP** are operations to be performed. If not specified, **SET** is used by default.

  – **option**: specifies the name of the option to be altered.

    Value range: See **OPTIONS ({ option_name ' value ' } [, ...])** in **CREATE FOREIGN TABLE**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

  - **value**: specifies the new value of **option**.
- **new_owner**

  Specifies the new owner of a foreign table.
- **column_name**

  Specifies the name of an existing column.

  Value range: character strings complying with **Identifier Naming Conventions**.

Examples

```
-- Create a foreign table.
gaussdb=# CREATE SCHEMA tpcds;
gaussdb=# CREATE FOREIGN TABLE tpcds.customer_ft
(
    c_customer_sk             integer               ,
    c_customer_id             char(16)              ,
    c_current_cdemo_sk        integer               ,
    c_current_hdemo_sk        integer               ,
    c_current_addr_sk         integer               ,
    c_first_shipto_date_sk    integer               ,
    c_first_sales_date_sk     integer               ,
    c_salutation              char(10)              ,
    c_first_name              char(20)              ,
    c_last_name               char(30)              ,
    c_preferred_cust_flag     char(1)               ,
    c_birth_day               integer               ,
    c_birth_month             integer               ,
    c_birth_year              integer               ,
    c_birth_country           varchar(20)           ,
    c_login                   char(13)              ,
    c_email_address           char(50)              ,
    c_last_review_date        char(10)
)
    SERVER gsmpp_server
    OPTIONS
(
    location 'gsfs://10.185.179.143:5000/customer1*.dat',
    FORMAT 'TEXT' ,
    DELIMITER '|',
    encoding 'utf8',
    mode 'Normal')
READ ONLY;

-- Change foreign table attributes and delete the mode option.
gaussdb=# ALTER FOREIGN TABLE tpcds.customer_ft options(drop mode);

-- Delete the foreign table.
gaussdb=# DROP FOREIGN TABLE tpcds.customer_ft;
gaussdb=# DROP SCHEMA tpcds CASCADE;
```

Helpful Links

CREATE FOREIGN TABLE and **DROP FOREIGN TABLE**

1.13.7.13 ALTER FUNCTION

Description

Modifies the attributes of a user-defined function or recompiles a function.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

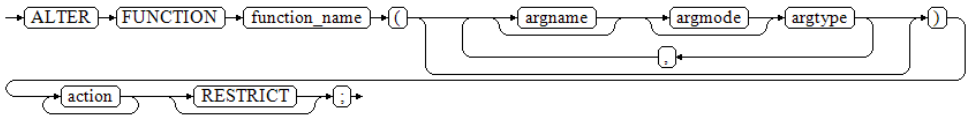
Precautions

- Only the function owner or a user with the ALTER permission can run the **ALTER FUNCTION** command. System administrators have this permission by default. Here are the permission limits for the attributes you want to alter:
  - If a function involves operations on temporary tables, ALTER FUNCTION cannot be used.
  - To change the owner or schema of a function, you must be a function owner or system administrator and a member of the new owner role.
  - Only system administrators and the initial user can change the schema of a function to public.
  - The modification of function attributes is affected by the GUC parameter **using_danger_feature**.
- When separation of duties is enabled, no role is allowed to modify the owner of a function with the definer permission.
- When separation of duties is disabled, only the initial user and system administrators can change the owner of a function that has the definer permission.
- Only the initial user can change the owner of a function to themselves.

Syntax

- Change the additional parameters of the user-defined function.

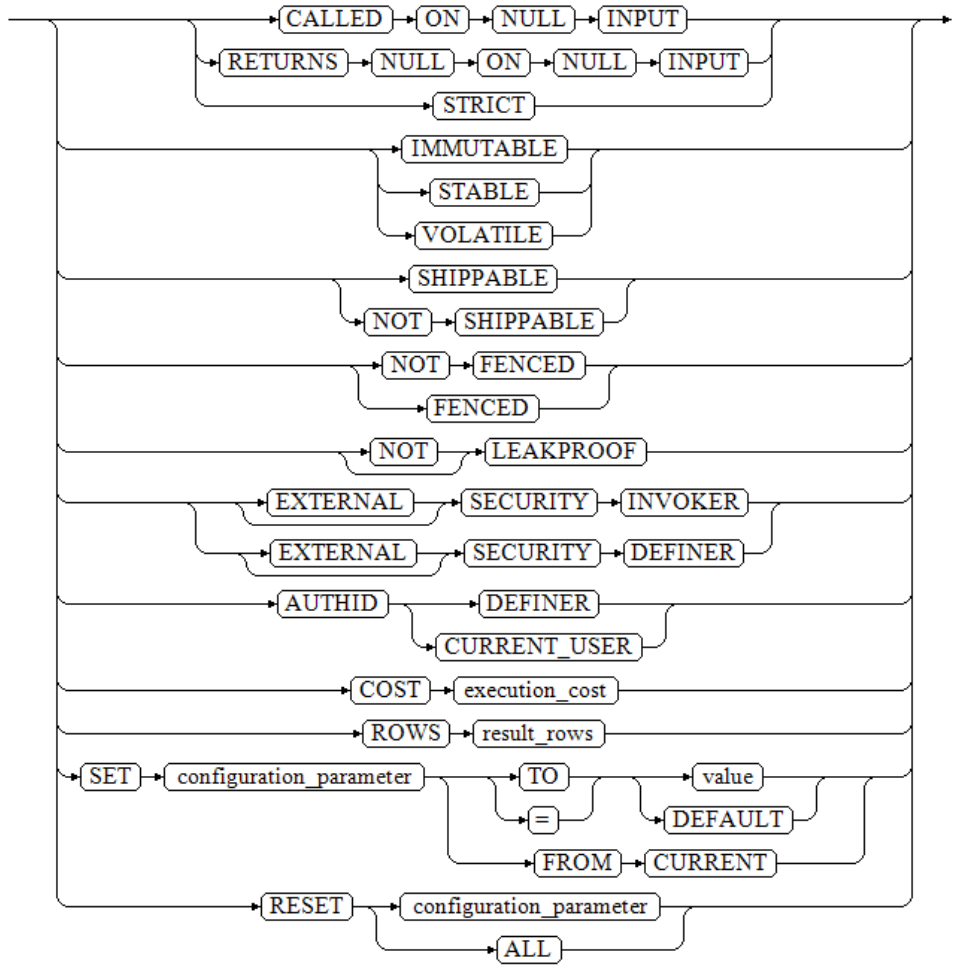
```
ALTER FUNCTION function_name ( [ { [ argname ] [ argmode ] argtype} [, ...] ] )
    action [ ... ] [ RESTRICT ];
```



The syntax of the ACTION clause is as follows:

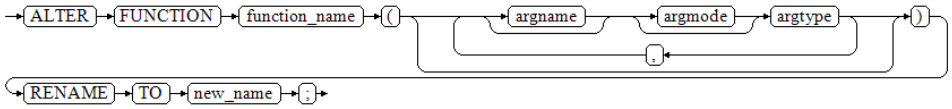
```
{{CALLED ON NULL INPUT | RETURNS NULL ON NULL INPUT | STRICT}
 | {IMMUTABLE | STABLE | VOLATILE}
 | {SHIPPABLE | NOT SHIPPABLE}
 | {NOT FENCED | FENCED}
 | [ NOT ] LEAKPROOF
 | { [ EXTERNAL ] SECURITY INVOKER | [ EXTERNAL ] SECURITY DEFINER }
 | AUTHID { DEFINER | CURRENT_USER }
 | COST execution_cost
 | ROWS result_rows
 | SET configuration_parameter { { TO | = } { value | DEFAULT }| FROM CURRENT}
 | RESET {configuration_parameter | ALL}}
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.



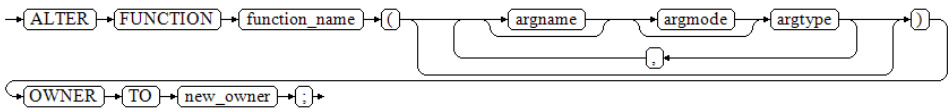
- Rename the user-defined function.

```
ALTER FUNCTION function_name ( [ { [ argname ] [ argmode ] argtype} [, ...] ] )
    RENAME TO new_name;
```



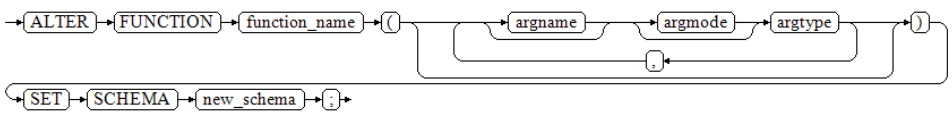
- Alter the owner of the user-defined function.

```
ALTER FUNCTION function_name ( [ { [ argname ] [ argmode ] argtype} [, ...] ] )
    OWNER TO new_owner;
```



- Alter the schema of the user-defined function.

```
ALTER FUNCTION function_name ( [ { [ argname ] [ argmode ] argtype} [, ...] ] )
    SET SCHEMA new_schema;
```



Parameters

- **function_name**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Specifies the name of the function to be modified.

Value range: an existing function name

- **argmode**

  Specifies whether a parameter is an input or output parameter.

  Value range:

  - **IN**: declares input parameters.
  - **OUT**: declares output parameters.
  - **INOUT**: declares INOUT parameters.
  - **VARIADIC**: declares parameters of the array type.

- **argname**

  Parameter name.

  Value range: character strings complying with **Identifier Naming Conventions**.

- **argtype**

  Specifies the type of the function parameter.

  Value range: a valid type. For details, see **Data Types**.

- **CALLED ON NULL INPUT**

  Specifies that the function can be called normally when some parameters of the function are NULL. Omitting this parameter is the same as specifying it.

- **RETURNS NULL ON NULL INPUT | STRICT**

  STRICT specifies that the function returns NULL when a parameter of the function is NULL. If this parameter is specified, the function is not executed when there are null parameters; instead a null result is returned automatically.

  RETURNS NULL ON NULL INPUT and **STRICT** have the same functions.

- **IMMUTABLE**

  Specifies that the function always returns the same result when given the same parameter values.

- **STABLE**

  Specifies that the function cannot modify the database, and that within a single table scan it will consistently return the same result for the same parameter value, but its result varies by SQL statements.

- **VOLATILE**

  Specifies that the function value can change in a single table scan and no optimization is performed.

- **SHIPPABLE | NOT SHIPPABLE**

  Specifies whether the function can be pushed down to DNs for execution.

  - Functions of the IMMUTABLE type can always be pushed down to DNs.
  - Functions of the STABLE or VOLATILE type can be pushed down to DNs only if their attribute is **SHIPPABLE**.

- **LEAKPROOF**

  Specifies that the function has no side effect and the parameter contains only the return value. **LEAKPROOF** can be set only by system administrators.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **EXTERNAL**

  (Optional) The purpose is to be compatible with SQL. This keyword applies to all functions, not only external functions.

- **SECURITY INVOKER | AUTHID CURRENT_USER**

  Specifies that the function will be executed with the permissions of the function calling user. Omitting this parameter is the same as specifying it.

  SECURITY INVOKER and **AUTHID CURRENT_USER** have the same functions.

- **SECURITY DEFINER | AUTHID DEFINER**

  Specifies that the function will be executed with the permissions of the function definer.

  AUTHID DEFINER and **SECURITY DEFINER** have the same functions.

- **COST execution_cost**

  Estimates the execution cost of a function.

  The unit of **execution_cost** is **cpu_operator_cost**.

  Value range: a positive integer

- **ROWS result_rows**

  Estimates the number of rows returned by the function. This is allowed when the function is declared to return a set.

  Value range: a positive number. The default value is **1000**.

- **configuration_parameter**
  - **value**

    Sets a specified database session parameter to a specific value.

    Value range: a string.

    - **DEFAULT**: The default system setting is used in the new session.
    - **OFF**: The setting is disabled.
    - **RESET**: The default system setting is used in the new session.
    - *User-specified value*: The value must comply with the parameter modification restrictions.

  - **FROM CURRENT**

    Uses the value of **configuration_parameter** of the current session.

- **new_name**

  Specifies the new name of a function. To change the schema of a function, you must have the CREATE permission on the new schema.

  Value range: character strings complying with **Identifier Naming Conventions**.

- **new_owner**

  Specifies the new owner of a function. To change the owner of a function, the new owner must have the CREATE permission on the schema to which the function belongs. Note that only the initial user can set the owner of a function to the initial user.

  Value range: an existing user role

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **new_schema**

  Specifies the new schema of a function.

  Value range: an existing schema name.

Examples

The following is an example of altering a function:

```
-- Create a function.
gaussdb=# CREATE OR REPLACE FUNCTION test_func(a int) RETURN int
IS
    proc_var int;
BEGIN
    proc_var := a;
    return 1;
END;
/

-- Change the name of the function test_func(a int) to test_func_tk(a int).
gaussdb=# ALTER FUNCTION test_func(a int) RENAME TO test_func_tk;

-- Create user jim.
gaussdb=# CREATE USER jim PASSWORD '********';

-- Create a schema named test.
gaussdb=# CREATE SCHEMA test;

-- Change the owner of the function to jim.
gaussdb=# ALTER FUNCTION test_func_tk(a int) OWNER TO jim;

-- Change the function schema to test.
gaussdb=# ALTER FUNCTION test_func_tk(a int) SET SCHEMA test;

-- Drop the function.
gaussdb=# DROP FUNCTION test.test_func_tk(a int);

-- Drop user jim.
gaussdb=# DROP USER jim;

-- Drop the schema.
gaussdb=# DROP SCHEMA test;
```

Helpful Links

CREATE FUNCTION and **DROP FUNCTION**

1.13.7.14 ALTER GLOBAL CONFIGURATION

Description

Adds or alters **key-value** of the gs_global_config system catalog. You can alter an existing parameter or add a new one.

Precautions

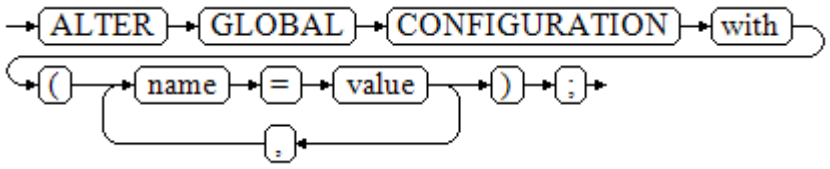
- Only the initial database user can run this command.
- The parameter name cannot be **weak_password** or **undostoragetype**.
- If a parameter name belongs to a parameter reserved for scale-out redistribution, set **enable_cluster_resize** to **on** or use the scale-out tool to modify the name. The involved parameters are **lockwait_timeout**,

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

lockwait_interval, **trylock_threshold**, **enable_cancel**, **last_catchup_threshold**, **catchup_times**, **write_error_mode**, **catchup_query_dop**, **parallel_catchup_threshold**, **parallel_reindex_jobs**, **redis_retry_times**, **redis_retry_interval**, **redis_bucket_expansion**, **redis_bucket_batchsize**, **redis_bucket_log_level**, **redis_bucket_lockhold_timeout**, **redis_bucket_timeout_penalty**, **redis_bucket_max_lockwait_timeout_retry**, **redis_bucket_max_lockhold_timeout_retry**, **redis_bucket_strategy_history_capacity**, **redis_bucket_strategy_recent_threshold**, **redis_bucket_workload_rule**, **redis_bucket_lsn_rule**, **redis_bucket_tx_bucket_min**, **redis_bucket_tx_bucket_max**, **redis_max_expected_tps**, **redis_bucket_sender_concurrency**, **redis_bucket_receiver_concurrency**, **redis_bucket_parse_redo_num**, **redis_bucket_workers_per_paser**, **redis_bucket_keep_bucketxlogs**, **redis_bucket_reindex_cbi_offline**, and **redis_bucket_reindex_parallel_workers**.

Syntax

```
ALTER GLOBAL CONFIGURATION with ( { name = value } [, ...] );
```



Parameters

- **name**

  Parameter name, which is of the text type. The value cannot be **weak_password** or **undostoragetype**.

  NOTE

  If a parameter name belongs to a parameter reserved for scale-out redistribution, set **enable_cluster_resize** to **on** or use the scaling tool to modify the name.

- **value**

  Parameter value, which is of the text type.

Examples

```
-- Insert.
gaussdb=# ALTER GLOBAL CONFIGURATION with(redis_is_ok = true);

-- Query.
gaussdb=# SELECT * FROM gs_global_config;
      name       | value
-----------------+-------
 buckets_len     | 16384
 undostoragetype | page
 redis_is_ok     | true
(3 rows)

-- Modify.
gaussdb=# ALTER GLOBAL CONFIGURATION with(redis_is_ok = false);

-- Query.
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gaussdb=# SELECT * FROM gs_global_config;
      name       | value
-----------------+-------
 buckets_len     | 16384
 undostoragetype | page
 redis_is_ok     | false
(3 rows)

-- Drop.
gaussdb=# DROP GLOBAL CONFIGURATION redis_is_ok;

-- Query.
gaussdb=# SELECT * FROM gs_global_config;
      name       | value
-----------------+-------
 buckets_len     | 16384
 undostoragetype | page
(2 rows)
```

Helpful Links

DROP GLOBAL CONFIGURATION

1.13.7.15 ALTER GROUP

Description

Modifies the attributes of a user group.

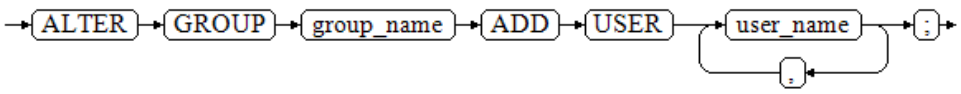
Precautions

- ALTER GROUP is not a standard SQL statement and is not recommended.
- Two clauses (ADD USER and DROP USER) are used to add users to or delete users from a user group. Any user can be a user or a user group. These two clauses are equivalent to granting or revoking the permissions of a user or role to other users or roles. Therefore, you are advised to replace them with GRANT or REVOKE.
- The RENAME TO clause changes the user group name, which is equivalent to renaming roles using ALTER ROLE.

Syntax

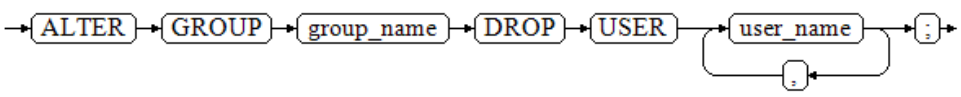
- Add users to a user group.

```
ALTER GROUP group_name
    ADD USER user_name [, ... ];
```



- Drop users from a user group.

```
ALTER GROUP group_name
    DROP USER user_name [, ... ];
```



- Rename a user group.

```
ALTER GROUP group_name
    RENAME TO new_name;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameters

- **user_name**

  Specifies an existing role name.

  Value range: an existing role name. If a role name contains uppercase letters, enclose the name with double quotation marks ("").

- **group_name**

  Specifies an existing user group name.

  Value range: an existing user group name. If a user group name contains uppercase letters, enclose the name with double quotation marks ("").

- **new_name**

  Specifies a new role name.

  Value range: a string that complies with **Identifier Naming Conventions** and can contain a maximum of 63 characters. If the role name exceeds 63 characters, the database will truncate it to the first 63 characters. If a role name contains uppercase letters, the database automatically converts them to lowercase letters. To create a role name that contains uppercase letters, enclose the name with double quotation marks ("").

Examples

- Rename a user group.

```
-- Create a user test.
gaussdb=# CREATE ROLE test PASSWORD '********';

-- Change the username, which is equivalent to ALTER ROLE RENAME.
gaussdb=# ALTER GROUP test RENAME TO tu_a1;
```

- Add users to or drops users from the user group.

```
-- Create users tu_a2 and tu_a3.
gaussdb=# CREATE ROLE tu_a2 PASSWORD '********';
gaussdb=# CREATE ROLE tu_a3 PASSWORD '********';

-- Add user tu_a2 to the user group tu_a1.
gaussdb=# ALTER GROUP tu_a1 ADD USER tu_a2;

-- The preceding SQL statement is equivalent to the GRANT statement.
gaussdb=# GRANT tu_a1 TO tu_a3;

-- Query.
gaussdb=# SELECT groname, grolist FROM pg_group WHERE groname = 'tu_a1';
 groname |    grolist
---------+---------------
 tu_a1   | {25590,25593}
(1 row)
gaussdb=# SELECT rolname, oid FROM gs_roles WHERE oid IN (25590,25593);
 rolname |  oid
---------+-------
 tu_a2   | 25590
 tu_a3   | 25593
(2 rows)

-- Drop.
gaussdb=# DROP ROLE tu_a1,tu_a2,tu_a3;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Helpful Links

CREATE GROUP, **DROP GROUP**, and **ALTER ROLE**

1.13.7.16 ALTER INDEX

Description

Modifies the definition of an existing index.

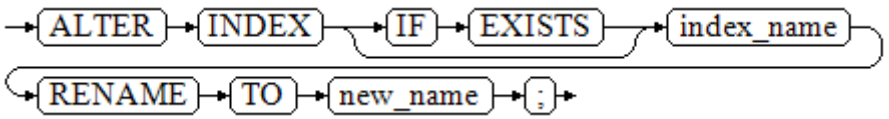
Precautions

- Only the index owner, a user who has the INDEX permission on the table where the index resides, or a user who has the ALTER ANY INDEX permission can run this command. When separation of duties is disabled, system administrators have this permission by default.
- Do not keep a large number of invisible indexes on the same base table. Otherwise, the performance of DML operations such as INSERT, UPDATE, and DELETE may be affected.
- For a **rowid** system column index, you can only change the tablespace to which the index belongs and rebuild the index or index partition.

Syntax

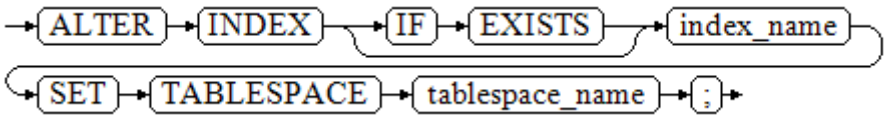
- Rename a table index.

```
ALTER INDEX [ IF EXISTS ] index_name
    RENAME TO new_name;
```



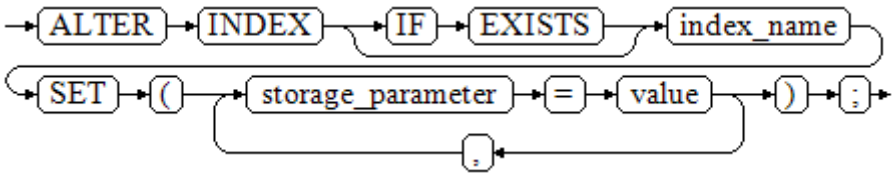
- Change the tablespace to which a table index belongs.

```
ALTER INDEX [ IF EXISTS ] index_name
    SET TABLESPACE tablespace_name;
```



- Change the storage parameter of a table index.

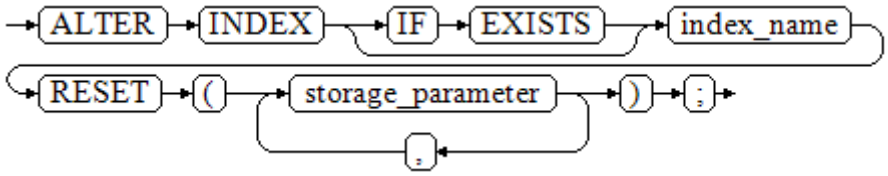
```
ALTER INDEX [ IF EXISTS ] index_name
    SET ( {storage_parameter = value} [, ... ] );
```



- Reset the storage parameter of a table index.

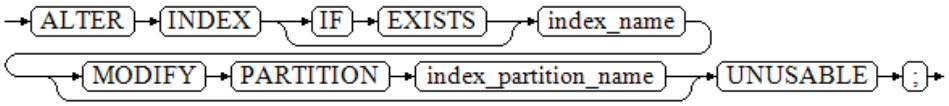
```
ALTER INDEX [ IF EXISTS ] index_name
    RESET ( storage_parameter [, ... ] );
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.



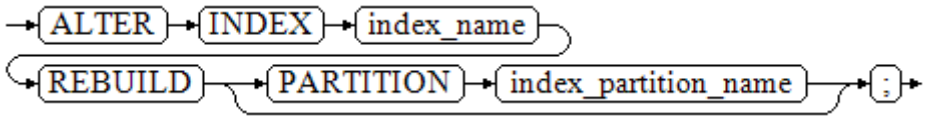
- Set a table index or an index partition to be unavailable.

```
ALTER INDEX [ IF EXISTS ] index_name
    [ MODIFY PARTITION index_partition_name ] UNUSABLE;
```



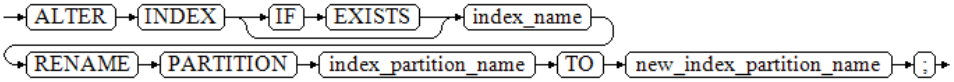
- Rebuild a table index or index partition.

```
ALTER INDEX index_name
    REBUILD [ PARTITION index_partition_name ];
```



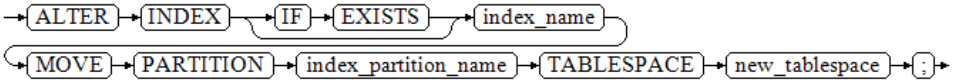
- Rename an index partition.

```
ALTER INDEX [ IF EXISTS ] index_name
    RENAME PARTITION index_partition_name TO new_index_partition_name;
```



- Change the tablespace to which an index partition belongs.

```
ALTER INDEX [ IF EXISTS ] index_name
    MOVE PARTITION index_partition_name TABLESPACE new_tablespace;
```



- Set the distributed global secondary index status.

```
ALTER INDEX [ IF EXISTS ] index_name GSIVALID;
```

```
ALTER INDEX [ IF EXISTS ] index_name GSIREADY;
```

> **NOTE**
>
> This syntax is called internally by the CREATE GLOBAL INDEX CONCURRENTLY/ REINDEX INDEX CONCURRENTLY function to modify the distributed global secondary index status. You are advised not to use this syntax. If it is used, an error message is displayed.

- Set the distributed global secondary index to be available.

```
ALTER INDEX [ IF EXISTS ] index_name GSIUSABLE;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

This syntax is internally called by the VACUUM FULL function to change the status of a global secondary index. You are advised not to use this syntax. Otherwise, the index data may be inconsistent with the table data. To enable a GSI in the UNUSABLE state, you are advised to use the REINDEX INDEX syntax to rebuild the GSI.

- Set the index to be visible.

```
ALTER INDEX [ IF EXISTS ] index_name VISIBLE;
```

NOTE

- This syntax can be set only in the ORA-compatible database (that is, **sql_compatibility** is set to **'ORA'**).
- When **disable_keyword_options** is set to **"visible"**, the VISIBLE keyword cannot be used.
- This syntax is not supported in the upgrade uncommitted phase.

- Set the index to be invisible.

```
ALTER INDEX [ IF EXISTS ] index_name INVISIBLE;
```

NOTE

- This syntax can be set only in the ORA-compatible database (that is, **sql_compatibility** is set to **'ORA'**).
- When **disable_keyword_options** is set to **"invisible"**, the INVISIBLE keyword cannot be used.
- This syntax is not supported in the upgrade uncommitted phase.
- In the read on standby scenario, after the index is set to invisible, the execution plan of the query statement may change, and the query performance of the standby node may be affected.

- Record the next unallocated xid and csn in reloption of the temporary user table on each node for pruning when temporary tables are merged.

```
ALTER INDEX [ IF EXISTS ] index_name GSIGETXID;
```

NOTE

This syntax is called internally by the CREATE GLOBAL INDEX CONCURRENTLY/ REINDEX INDEX CONCURRENTLY function. You are advised not to use this syntax. If it is used, an error message is displayed.

- Merge distributed global secondary indexes and temporary user tables.

```
ALTER INDEX [ IF EXISTS ] index_name GSIMERGE;
```

NOTE

This syntax is called internally by the CREATE GLOBAL INDEX CONCURRENTLY/ REINDEX INDEX CONCURRENTLY function. You are advised not to use this syntax. If it is used, an error message is displayed.

- Switch between the old and new distributed global secondary indexes during online rebuilding of distributed global secondary indexes.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
ALTER INDEX [ IF EXISTS ] index_name GSISWITCH;
```

NOTE

This syntax is called internally by the CREATE GLOBAL INDEX CONCURRENTLY/ REINDEX INDEX CONCURRENTLY function. You are advised not to use this syntax. If it is used, an error message is displayed.

Parameters

- **index_name**

  Specifies the index name to be modified.

- **IF EXISTS**

  Issues a notice rather than an error if the specified index does not exist.

- **RENAME TO new_name**

  Changes only the name of the index without affecting stored data.

  – **new_name**

    Specifies a new index name.

    Value range: character strings complying with **Identifier Naming Conventions**.

- **SET TABLESPACE tablespace_name**

  Changes the index tablespace to the specified tablespace and moves index-related data files to the new tablespace.

  – **tablespace_name**

    Specifies the tablespace name.

    Value range: an existing tablespace name.

- **SET ({storage_parameter = value} [, ...])**

  Changes one or more index-method-specific storage parameters of an index. Note that the index content will not be modified immediately by this statement. You may need to use REINDEX to rebuild the index based on different parameters to achieve the expected effect.

  – **storage_parameter**

    Specifies the name of an index-method-specific parameter. **ACTIVE_PAGES** indicates the number of index pages, which may be less than the actual number of physical file pages and can be used for optimization. Currently, this parameter is valid only for the local index of the Ustore partitioned table and will be updated by VACUUM and ANALYZE (including AUTOVACUUM). You are advised not to manually set this parameter because it is invalid in distributed mode. When ALTER is executed on GSI, the **INTERNAL_MASK**, **APPEND_MODE_INTERNAL**, **WAIT_CLEAN_GPI**, **PARTITION_DDL_FLAG**, **COLLATE**, **CROSSBUCKET**, and **DEDUPLICATION** parameters are not supported. The behavior is the same as that of UB-tree. The **FILLFACTOR**, and **INDEXSPLIT** parameters are supported. **ACTIVE_PAGES** and **WAIT_CLEAN_CBI** are not applicable to GSI.

  – **value**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Specifies the new value for an index-method-specific storage parameter. This might be a number or a word depending on the parameter.

- **RESET ({ storage_parameter } [, ...])**

  Resets one or more index-method-specific storage parameters of an index to the default value. Similar to the SET statement, REINDEX may be used to completely update the index.

- **[MODIFY PARTITION index_partition_name] UNUSABLE**

  Sets the indexes on a table or index partition to be unavailable.

  NOTE

  If a unique index is specified, the subsequent insert and update operations on the table are controlled by the GUC parameter **enable_unique_checking_of_unusable_index**.

- **REBUILD [PARTITION index_partition_name]**

  Rebuilds indexes on a table or an index partition. If the index contains the **lpi_parallel_method** option and the value is **PARTITION** when the index is rebuilt, and the **parallel_workers** value of the index's table is greater than 0, the index cannot be rebuilt in parallel. If the index does not contain the **lpi_parallel_method** option or the value of the option is set to **AUTO**, page-level parallel index is rebuilt by default. For details, see **LPI_PARALLEL_METHOD** in **CREATE INDEX**.

- **RENAME PARTITION index_partition_name TO new_index_partition_name**

  Renames an index partition.

- **MOVE PARTITION index_partition_name TABLESPACE new_tablespace**

  Modifies the tablespace to which an index partition belongs.

- **new_index_partition_name**

  Specifies a new index partition name.

- **index_partition_name**

  Specifies an index partition name.

- **new_tablespace**

  Specifies a new tablespace.

- **GSIVALID** | GSIREADY

  Internally called by the CREATE GLOBAL INDEX CONCURRENTLY or REINDEX INDEX CONCURRENTLY function to change the status of distributed global secondary indexes.

- **GSIUSABLE**

  This syntax is internally called by the VACUUM FULL function to modify the status of distributed global secondary indexes.

- **VISIBLE**

  Sets the index to be visible.

- **INVISIBLE**

  Set the index to be invisible.

- **GSIGETXID**

  Internally called by the CREATE GLOBAL INDEX CONCURRENTLY/REINDEX INDEX CONCURRENTLY function. It records the next unallocated xid and csn

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

in reloption of the temporary user table on each node for pruning when temporary tables are merged.

- **GSIMERGE**

  Internally called by the CREATE GLOBAL INDEX CONCURRENTLY/REINDEX INDEX CONCURRENTLY function to merge distributed global secondary indexes and temporary user tables.

- **GSISWITCH**

  Internally called by the CREATE GLOBAL INDEX CONCURRENTLY/REINDEX INDEX CONCURRENTLY function to switch between the old and new distributed global secondary indexes during online rebuilding of distributed global secondary indexes.

Examples

- Rename an index.

```
-- Create the test1 table and create an index for it.
gaussdb=# CREATE TABLE test1(col1 int, col2 int);
gaussdb=# CREATE INDEX aa ON test1(col1);

-- Rename the aa index as idx_test1_col1.
gaussdb=# ALTER INDEX aa RENAME TO idx_test1_col1;

-- Query the index information of the test1 table.
gaussdb=# SELECT tablename,indexname,tablespace FROM pg_indexes WHERE tablename = 'test1';
 tablename |   indexname    | tablespace
-----------+----------------+------------
 test1     | idx_test1_col1 |
(1 row)
```

- Change the tablespace to which the index belongs.

```
-- Create the tbs_index1 tablespace.
gaussdb=# CREATE TABLESPACE tbs_index1 RELATIVE LOCATION 'tablespace1/tbs_index1';

-- Change the tablespace to which the idx_test1_col1 index belongs to tbs_index1.
gaussdb=# ALTER INDEX IF EXISTS idx_test1_col1 SET TABLESPACE tbs_index1;

-- Query the index information of the test1 table.
gaussdb=# SELECT tablename,indexname,tablespace FROM pg_indexes WHERE tablename = 'test1';
 tablename |   indexname    | tablespace
-----------+----------------+------------
 test1     | idx_test1_col1 | tbs_index1
(1 row)
```

- Change and reset index storage parameters.

```
-- View details about the idx_test1_col1 index.
gaussdb=# \di idx_test1_col1                        List of relations
 Schema |      Name      | Type  | Owner | Table | Storage
--------+----------------+-------+-------+-------+---------
 public | idx_test1_col1 | index | omm   | test1 |
(1 row)

-- Change the fillfactor of the idx_test1_col1 index.
gaussdb=# ALTER INDEX IF EXISTS idx_test1_col1 SET (FILLFACTOR = 70);
-- View details about the idx_test1_col1 index.
gaussdb=# \di idx_test1_col1
                        List of relations
 Schema |      Name      | Type  | Owner | Table |     Storage
--------+----------------+-------+-------+-------+-----------------
 public | idx_test1_col1 | index | omm   | test1 | {fillfactor=70}
(1 row)
-- Reset the storage parameter of the idx_test1_col1 index.
gaussdb=# ALTER INDEX IF EXISTS idx_test1_col1 RESET (FILLFACTOR);
-- View details about the idx_test1_col1 index.
gaussdb=# \di idx_test1_col1
                    List of relations
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
 Schema |      Name      | Type  | Owner | Table | Storage
--------+----------------+-------+-------+-------+---------
 public | idx_test1_col1 | index | omm   | test1 |
(1 row)
```

- Change the index availability.

```
-- Set the idx_test1_col1 index to be unavailable.
gaussdb=# ALTER INDEX IF EXISTS idx_test1_col1 UNUSABLE;
-- Check the availability of the idx_test1_col1 index.
gaussdb=# SELECT indisusable FROM pg_index WHERE indexrelid = 'idx_test1_col1'::regclass;
 indisusable
-------------
 f
(1 row)

-- Rebuild the idx_test1_col1 index.
gaussdb=# ALTER INDEX idx_test1_col1 REBUILD;
-- Check the availability of the idx_test1_col1 index.
gaussdb=# SELECT indisusable FROM pg_index WHERE indexrelid = 'idx_test1_col1'::regclass;
 indisusable
-------------
 t
(1 row)

-- Drop.
gaussdb=# DROP INDEX idx_test1_col1;
gaussdb=# DROP TABLE test1;
gaussdb=# DROP TABLESPACE tbs_index1;
```

- Rename an index partition.

```
-- Create a partitioned table named test2.
gaussdb=# CREATE TABLE test2(col1 int, col2 int) PARTITION BY RANGE (col1)(
    PARTITION p1 VALUES LESS THAN (100),
    PARTITION p2 VALUES LESS THAN (200)
);
-- Create a partitioned index.
gaussdb=# CREATE INDEX idx_test2_col1 ON test2(col1) LOCAL(
    PARTITION p1,
    PARTITION p2
);
-- Rename an index partition.
gaussdb=# ALTER INDEX idx_test2_col1 RENAME PARTITION p1 TO p1_test2_idx;
gaussdb=# ALTER INDEX idx_test2_col1 RENAME PARTITION p2 TO p2_test2_idx;

-- Query the partition name of the idx_test2_col1 index.
gaussdb=# SELECT relname FROM pg_partition WHERE parentid = 'idx_test2_col1'::regclass;
   relname
--------------
 p1_test2_idx
 p2_test2_idx
(2 rows)
```

- Change the tablespace to which an index partition belongs.

```
-- Create tablespaces tbs_index2 and tbs_index3.
gaussdb=# CREATE TABLESPACE tbs_index2 RELATIVE LOCATION 'tablespace1/tbs_index2';
gaussdb=# CREATE TABLESPACE tbs_index3 RELATIVE LOCATION 'tablespace1/tbs_index3';

-- Change the tablespace to which the idx_test2_col1 index partition belongs.
gaussdb=# ALTER INDEX idx_test2_col1 MOVE PARTITION p1_test2_idx TABLESPACE tbs_index2;
gaussdb=# ALTER INDEX idx_test2_col1 MOVE PARTITION p2_test2_idx TABLESPACE tbs_index3;

-- Query the tablespace to which the idx_test2_col1 index partition belongs.
gaussdb=# SELECT t1.relname index_name,
       t2.spcname tablespace_name
FROM pg_partition t1, pg_tablespace t2
WHERE t1.parentid = 'idx_test2_col1'::regclass AND
      t1.reltablespace = t2.oid;
  index_name  | tablespace_name
--------------+-----------------
 p1_test2_idx | tbs_index2
 p2_test2_idx | tbs_index3
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
(2 rows)

-- Drop.
gaussdb=# DROP INDEX idx_test2_col1;
gaussdb=# DROP TABLE test2;
gaussdb=# DROP TABLESPACE tbs_index2;
gaussdb=# DROP TABLESPACE tbs_index3;
```

1.13.7.17 ALTER LANGUAGE

Description

Modifies the definition of a procedural language.

Precautions

This syntax is not supported currently.

1.13.7.18 ALTER MASKING POLICY

Description

Modifies a masking policy.

Precautions

- Only users with the POLADMIN or SYSADMIN permission, or the initial user can perform this operation.
- The masking policy takes effect only after the security policy is enabled, that is, **enable_security_policy** is set to **on**.

Syntax

- Modify the policy description.

```
ALTER MASKING POLICY policy_name COMMENTS policy_comments;
```

- Change the masking method.

```
ALTER MASKING POLICY policy_name { ADD | REMOVE | MODIFY } masking_actions[, ...];
```

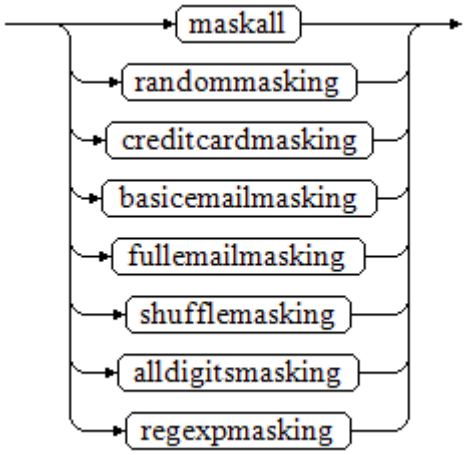
  - The syntax of **masking_actions**

```
masking_function ON LABEL(label_name[, ...])
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

  - The syntax of **masking_function**

    ```
    { maskall | randommasking | creditcardmasking | basicemailmasking | fullemailmasking |
    shufflemasking | alldigitsmasking | regexpmasking }
    ```

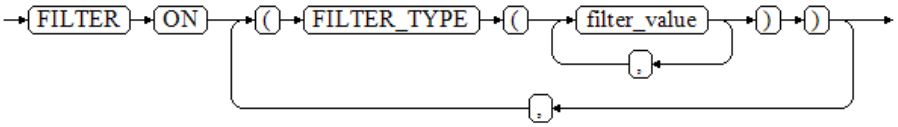
    


- Modify the scenarios where the masking policies take effect.

  ```
  ALTER MASKING POLICY policy_name MODIFY (filter_group_clause);
  ```

  
  - The syntax of filter_group_clause

    ```
    FILTER ON { ( FILTER_TYPE ( filter_value [, ... ] ) ) [, ... ] }
    ```

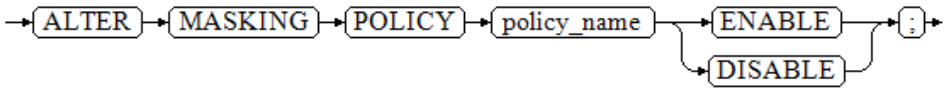
    


- Remove the filters of the masking policies for the policies to take effect.

  ```
  ALTER MASKING POLICY policy_name DROP FILTER;
  ```

  
- Enable or disable the masking policies.

  ```
  ALTER MASKING POLICY policy_name {ENABLE | DISABLE};
  ```

Parameters

- **policy_name**

  Specifies the masking policy name, which must be unique.

  Value range: character strings complying with **Identifier Naming Conventions**.

- **policy_comments**

  Adds or modifies description of masking policies.

- **masking_function**

  Specifies eight preset masking methods or user-defined functions. Schema is supported.

  The maskall function is not preset. It is in the code and cannot be displayed by running **\df**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

The preset masking methods are as follows:

```
{ maskall | randommasking | creditcardmasking | basicemailmasking | fullemailmasking |
shufflemasking | alldigitsmasking | regexpmasking }
```

- **label_name**

  Specifies the resource label name.

- **FILTER_TYPE**

  Specifies the types of information to be filtered by the policies: **IP**, **ROLES**, and **APP**.

- **filter_value**

  Indicates the detailed information to be filtered, such as the IP address, app name, and username.

- **ENABLE|DISABLE**

  Enables or disables the masking policy. If **ENABLE|DISABLE** is not specified, **ENABLE** is used by default.

Examples

- Modify the policy description.

```
-- Create table tb_for_masking.
gaussdb=# CREATE TABLE tb_for_masking(idx int, col1 text, col2 text, col3 text, col4 text, col5 text,
col6 text, col7 text,col8 text);

-- Insert data into the tb_for_masking table.
gaussdb=# INSERT INTO tb_for_masking VALUES(1, '9876543210', 'usr321usr', 'abc@huawei.com',

CREATE MASKING POLICY and DROP MASKING POLICY

1.13.7.19 ALTER MATERIALIZED VIEW

Description

Modifies multiple auxiliary attributes of an existing materialized view.

Statements and actions that can be used for ALTER MATERIALIZED VIEW are a subset of ALTER TABLE and have the same meaning when used for materialized views. For details, see ALTER TABLE.

Precautions

- Only the materialized view owner can execute the **ALTER MATERIALIZED VIEW** command. System administrators have this permission by default.
- The materialized view structure cannot be modified.

Syntax

- Change the owner of a materialized view.

```
ALTER MATERIALIZED VIEW [ IF EXISTS ] mv_name
    OWNER TO new_owner;
```

- Rename a column of a materialized view.

```
ALTER MATERIALIZED VIEW [ IF EXISTS ] mv_name
    RENAME [ COLUMN ] column_name TO new_column_name;
```

- Rename a materialized view.

```
ALTER MATERIALIZED VIEW [ IF EXISTS ] mv_name
    RENAME TO new_name;
```

Parameters

- **mv_name**

  Specifies the name of an existing materialized view, which can be schema-qualified.

  Value range: character strings complying with Identifier Naming Conventions.

- **column_name**

  Specifies the name of a new or existing column.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Value range: character strings complying with **Identifier Naming Conventions**.

- **new_column_name**

  Specifies the new name of an existing column.

- **new_owner**

  Specifies the username of the new owner of a materialized view.

- **new_name**

  Specifies the new name of a materialized view.

Examples

- Change the owner of a materialized view.

```
-- Create a table.
gaussdb=# CREATE TABLE my_table (c1 int, c2 int) WITH(STORAGE_TYPE=ASTORE);

-- Create a complete-refresh materialized view.
gaussdb=# CREATE MATERIALIZED VIEW foo AS SELECT * FROM my_table;

-- Create a user.
gaussdb=# CREATE USER test PASSWORD '********';

-- Change the owner of the complete-refresh materialized view.
gaussdb=# ALTER MATERIALIZED VIEW foo OWNER TO test;

-- View the information about the materialized view.
gaussdb=# \dm foo
                        List of relations
 Schema | Name |       Type        | Owner |             Storage
--------+------+-------------------+-------+-----------------------------------
 public | foo  | materialized view | test  | {orientation=row,compression=no}
(1 row)
```

- Rename a column of a materialized view.

```
-- Query the columns of the materialized view.
gaussdb=# \d foo;
Materialized view "public.foo"
 Column |  Type   | Modifiers
--------+---------+-----------
 c1     | integer |
 c2     | integer |
Rules:
    "_RETURN" AS
    ON SELECT TO foo DO INSTEAD  SELECT my_table.c1, my_table.c2
   FROM my_table
Replica Identity: NOTHING

-- Change column c1 of materialized view foo to col1 and column c2 to col2.
gaussdb=# ALTER MATERIALIZED VIEW foo RENAME c1 to col1;
gaussdb=# ALTER MATERIALIZED VIEW foo RENAME c2 to col2;

-- Use the SELECT statement to view the columns of the materialized view.
gaussdb=# SELECT * FROM foo WHERE 1=2;
 col1 | col2
------+------
(0 rows)
```

- Rename a materialized view.

```
-- Rename the materialized view foo to my_mview.
gaussdb=# ALTER MATERIALIZED VIEW foo RENAME TO my_mview;

-- Query information.
gaussdb=# \dm my_mview
                        List of relations
 Schema |   Name    |       Type        | Owner |             Storage
--------+-----------+-------------------+-------+-----------------------------------
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
 public | my_mview | materialized view | test  | {orientation=row,compression=no}
(1 row)

-- Delete.
gaussdb=# DROP MATERIALIZED VIEW my_mview;
gaussdb=# DROP TABLE my_table ;
gaussdb=# DROP USER test;
```

CREATE INCREMENTAL MATERIALIZED VIEW, **CREATE MATERIALIZED VIEW**, **DROP MATERIALIZED VIEW**, **REFRESH INCREMENTAL MATERIALIZED VIEW**, and **REFRESH MATERIALIZED VIEW**

1.13.7.20 ALTER NODE

Description

Changes the definition of an existing cluster node.

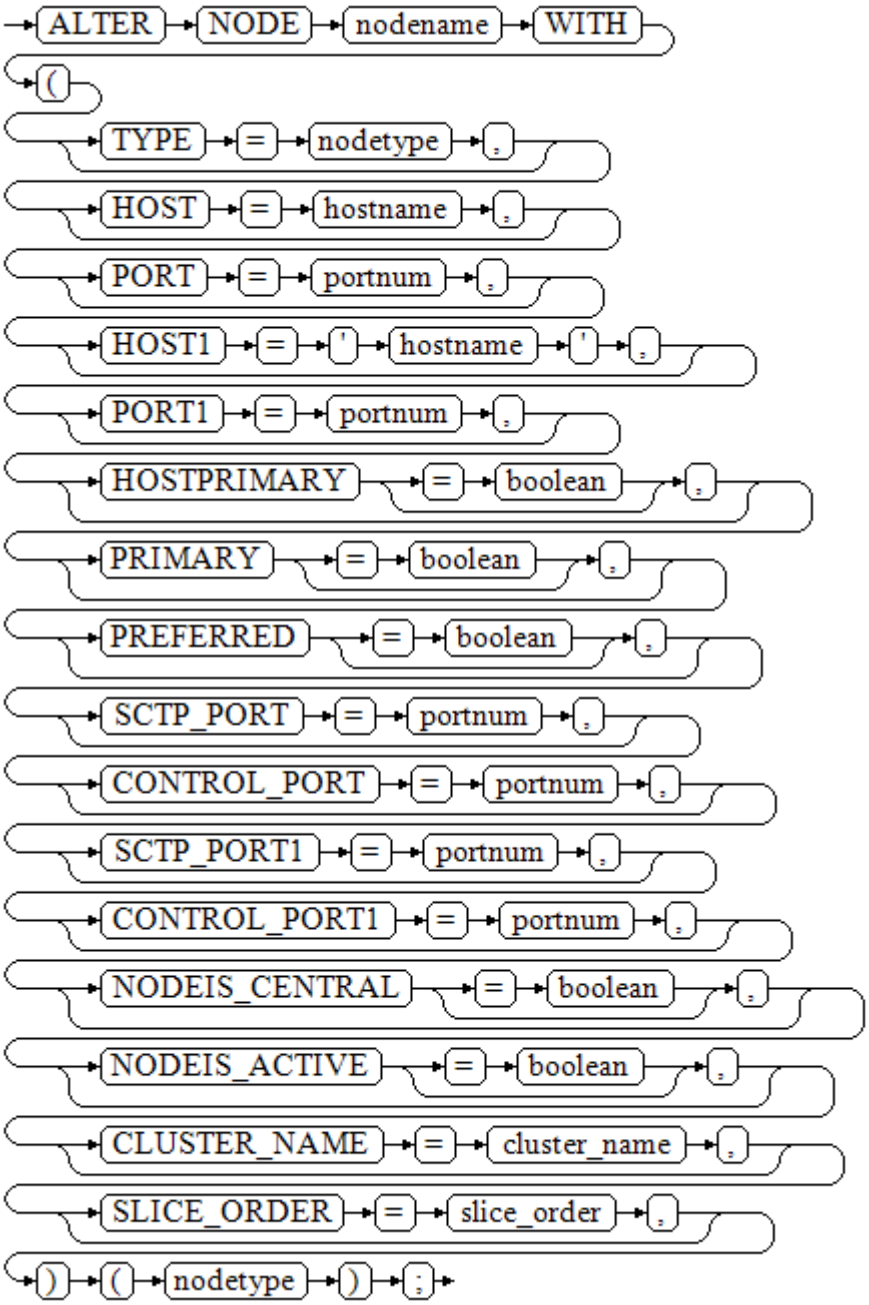
Precautions

ALTER NODE is an API of the cluster management tool and is used to manage clusters. Only administrators have the permission to use this API. Do not use this API directly. Otherwise, the cluster status may be affected and the database may be unavailable.

Syntax

```
ALTER NODE nodename WITH
  (
    [ TYPE = nodetype,]
    [ HOST = hostname,]
    [ PORT = portnum,]
    [ HOST1 = 'hostname',]
    [ PORT1 = portnum,]
    [ HOSTPRIMARY [ = boolean ],]
    [ PRIMARY [ = boolean ],]
    [ PREFERRED [ = boolean ],]
    [ SCTP_PORT = portnum,]
    [ CONTROL_PORT = portnum,]
    [ SCTP_PORT1 = portnum,]
    [ CONTROL_PORT1 = portnum, ]
    [ NODEIS_CENTRAL [ = boolean ],]
    [ NODEIS_ACTIVE [= boolean],]
    [ CLUSTER_NAME = cluster_name, ]
    [ SLICE_ORDER = slice_order, ]
  ) (nodetype);
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.



NOTE

The port whose number is specified by **PORT** is used for internal communications between nodes. Unlike the port connecting to an external client, it can be queried in the pgxc_node table.

Parameters

- **nodename**

  Node name.

  Value range: character strings complying with **Identifier Naming Conventions**.

- **TYPE = nodetype**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Specifies the type of a node.

Value range:

- 'coordinator'
- 'datanode'
- 'coordinator_standbycluster'
- 'datanode_standbycluster_main'
- 'datanode_standbycluster_other'

- **HOST = hostname**

  Specifies the name or IP address of the primary node corresponding to a node.

- **PORT = portnum**

  Specifies the port number of the primary node to which a node is bound.

- **HOST1 = hostname**

  Specifies the name or IP address of the standby node corresponding to a node.

- **PORT1 = portnum**

  Specifies the port number of the standby node to which a node is bound.

- **HOSTPRIMARY**

  Specifies whether the host name or IP address is the primary one.

  Value range:

  - **true**
  - **false** (default value)

- **PRIMARY = boolean**

  Specifies whether the node is a primary node or not. A primary node allows read/write operations. A non-primary node allows only read operations.

  Value range:

  - **true**
  - **false** (default value)

- **PREFERRED = boolean**

  Specifies whether the node is a preferred node for read operations.

  Value range:

  - **true**
  - **false** (default value)

- **SCTP_PORT = portnum**

  Specifies the port used by the TCP proxy communications library of the primary node to listen on the data transmission channel. TCP is used to listen on connections.

- **CONTROL_PORT = portnum**

  Specifies the port used by the TCP proxy communications library of the primary node to listen on the control transmission channel. The TCP protocol is used to listen on connections.

- **SCTP_PORT1 = portnum**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Specifies the port used by the TCP proxy communications library of the standby node to listen on the data transmission channel. TCP is used to listen on connections.

- **CONTROL_PORT 1= portnum**

  Specifies the port used by the TCP proxy communications library of the standby node to listen on the control transmission channel. The TCP protocol is used to listen on connections.

- **NODEIS_CENTRAL**

  Specifies whether the current node is a central control node. It is used only for CNs and is invalid for DNs.

  – **true**

  – **false** (default value)

- **NODEIS_ACTIVE**

  Specifies whether the current node is normal. It is used to mark whether the CN is removed and is invalid for DNs.

  – **true**

  – **false** (default value)

- **CLUSTER_NAME**

  Cluster name.

- **SLICE_ORDER**

  Specifies the sequence number of the slice to which a node belongs.

- **nodetype**

  Type of the node to be changed, which is the value of **node_type** in the pgxc_node system catalog.

  Value range: **"C"** (CN)

  NOTE

  In multi-CN environments, when you create a cluster node, it is only generated on the CN that is currently connected and is not synchronized with other CNs. This requires you to repeat the creation process on all CNs. However, to drop the cluster node created, you only need to connect to one CN. If a cluster node is created on only one CN, you need to define the current CN name and drop the cluster node on the current CN.

Examples

```
-- Create cluster nodes on all CNs.
gaussdb=# CREATE NODE datanode1 WITH(
   TYPE = datanode,
   PREFERRED = false
);

-- Query the initial cluster DN status.
gaussdb=# SELECT node_name, nodeis_preferred FROM pgxc_node WHERE node_type = 'D' ORDER BY 1;
 node_name | nodeis_preferred
-----------+------------------
 datanode1 | f
 datanode2 | f
(2 rows)

-- Set datanode1 as the preferred DN.
gaussdb=# ALTER NODE datanode1 WITH(preferred = true);
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
-- Query the cluster DN status after the change.
gaussdb=# SELECT node_name, nodeis_preferred FROM pgxc_node WHERE node_type = 'D' ORDER BY 1;
 node_name | nodeis_preferred
-----------+------------------
 datanode1 | t
 datanode2 | f
(2 rows)

-- Connect to only one CN to drop cluster nodes.
gaussdb=# DROP NODE datanode1;
```

Helpful Links

CREATE NODE and **DROP NODE**

1.13.7.21 ALTER NODE GROUP

Description

Changes the information about a cluster node group.

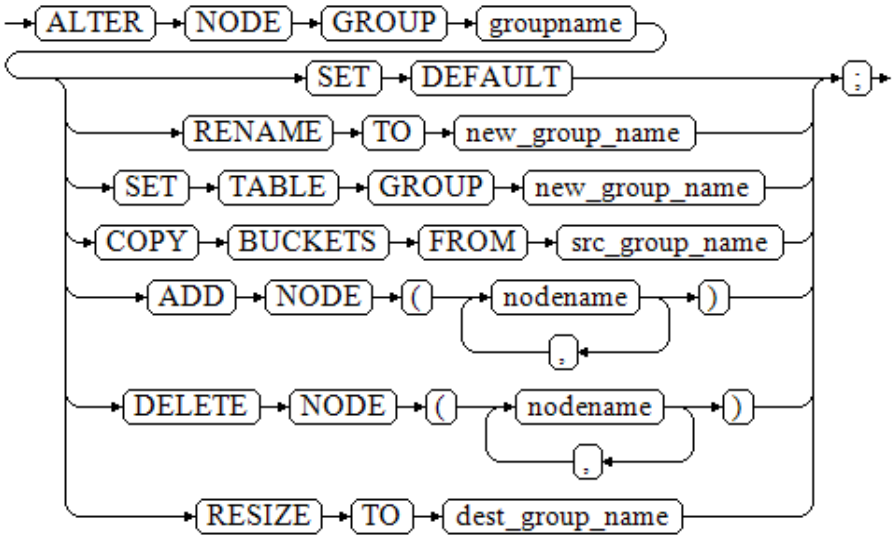
Precautions

- Only the system administrator or a user who has been granted the ALTER permission for the node group can modify the node group information.
- Node group modification is an internal operation of the system. Except SET DEFAULT, other operations must be performed in maintenance mode (by calling **SET xc_maintenance_mode=on;**).
- ALTER NODE GROUP can be used only within a database. To avoid data inconsistency in the database system, do not manually run this SQL statement.

Syntax

```
ALTER NODE GROUP groupname
{ SET DEFAULT
   | RENAME TO new_group_name
   | SET TABLE GROUP new_group_name
   | COPY BUCKETS FROM src_group_name
   | ADD NODE ( nodename [, ... ] )
   | DELETE NODE ( nodename [, ... ] )
   | RESIZE TO dest_group_name
};
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.



Parameters

- **groupname**

  Specifies the name of the cluster node group to be altered.

  Value range: character strings complying with **Identifier Naming Conventions**.

- **SET DEFAULT**

  Sets the **in_redistribution** column to **'y'** for all cluster node group objects except the one specified by **groupname**. To be compatible with earlier versions, this syntax is retained and does not need to be executed in maintenance mode.

- **RENAME TO new_group_name**

  Renames a specified cluster node group.

- **SET TABLE GROUP new_group_name**

  Changes all the **group_names** in the **pgroup** columns of the **pgxc_class** tables on all CNs to **new_group_name**.

- **COPY BUCKETS FROM src_group_name**

  Copies the content of the **group_members** and **group_buckets** columns from the cluster node group specified by **src_group_name** to the cluster node group specified by **groupname**.

- **ADD NODE (nodename [, ...])**

  Adds specified nodes to the cluster node group specified by **groupname**. These new nodes exist in the **PGXC_NODE** system catalog. This statement only modifies the system catalog and does not add nodes or redistribute data. Do not call this statement. You can observe the impact of the statement in the **PGXC_GROUP** system catalog.

- **DELETE NODE (nodename [, ...])**

  Deletes specified nodes from the cluster node group specified by **groupname**. The deleted nodes still exist in the **PGXC_NODE** system catalog. This statement only modifies the system catalog and does not delete nodes or redistribute data. Do not call this statement. You can observe the impact of the statement in the **PGXC_GROUP** system catalog.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **RESIZE TO dest_group_name**

  Resizes the cluster node group for redistribution from the source group (**groupname**) to the destination group (**dest_group_name**). The **is_installation** flag is removed from the source group and added to the destination group.

Examples

```
-- Query the initial cluster DN status.
gaussdb=# SELECT node_name, nodeis_preferred FROM pgxc_node WHERE node_type = 'D' ORDER BY 1;
 node_name | nodeis_preferred
-----------+------------------
 dn_6001_6002_6003 | f
 dn_6004_6005_6006 | f
 dn_6007_6008_6009 | f
(3 rows)

-- Create a node group and replace dn_6001_6002_6003 with the actual node name obtained in the previous step.
gaussdb=# CREATE NODE GROUP test_group WITH ( dn_6001_6002_6003 );

-- Changes the name of the created node group to test_group_new. This must be implemented in the maintenance mode (by calling SET xc_maintenance_mode=on;).
gaussdb=# SET xc_maintenance_mode=on;
gaussdb=# ALTER NODE GROUP test_group RENAME TO test_group_new;

-- Query the node group.
gaussdb=# SELECT group_name, group_members FROM pgxc_group;
   group_name   |   group_members
----------------+-------------------
 group_version1 | 16384 16388 16394
 test_group_new | 16384
(2 rows)

-- Delete the node group and disable the maintenance mode.
gaussdb=# DROP NODE GROUP test_group_new;
gaussdb=# SET xc_maintenance_mode=off;
```

CREATE NODE GROUP and **DROP NODE GROUP**

1.13.7.22 ALTER PACKAGE

Description

Alters attributes of a package or recompiles a package.

Precautions

- Currently, only ALTER PACKAGE OWNER is supported. System administrators have this permission by default. To execute this command, you must be the owner of the package or a system administrator and a member of the new owner role.
- When separation of duties is enabled, to alter the owner of a package, you must have the user group permission, even as a system administrator. The owner of a package of the DEFINER type cannot be altered.
- Only the initial user can alter the owner of a package to the initial user.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- When separation of duties is disabled, only a system administrator or a user with higher permissions can alter the owner of a package.
- A system administrator is not allowed to alter the owner of a package of the DEFINER type to the initial user or OPRADMIN.

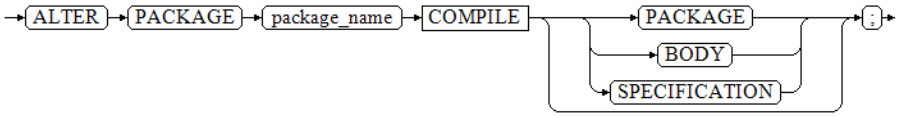
Syntax

- Alter the owner of a package.

```
ALTER PACKAGE package_name OWNER TO new_owner;
```

- Recompile the package.

```
ALTER PACKAGE package_name COMPILE [PACKAGE | BODY | SPECIFICATION];
```



Parameters

- **package_name**

  Specifies the name of the package to be altered.

  Value range: an existing package name. Only one package can be altered at a time.

- **new_owner**

  Specifies the new owner of a package. To alter the owner of a package, the new owner must have the CREATE permission on the schema to which the package belongs.

  Value range: an existing user role.

Examples

- Change the owner of a package.

```
-- Create a database.
gaussdb=# CREATE DATABASE test DBCOMPATIBILITY 'ORA';
gaussdb=# \c test

-- Create a package.
test=# CREATE OR REPLACE PACKAGE test_pkg AS
    pkg_var int := 1;
    PROCEDURE test_pkg_proc(var int);
END test_pkg;
/

test=# CREATE OR REPLACE PACKAGE BODY test_pkg AS
    PROCEDURE test_pkg_proc(var int) AS
    BEGIN
        pkg_var := 1;
    END;
END test_pkg;
/

-- Create a user.
test=# CREATE ROLE test PASSWORD '********';

-- Change the owner of a package.
test=# ALTER PACKAGE test_pkg OWNER TO test;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
-- Query the owner of test_pkg.
test=# SELECT t1.pkgname,t2.rolname FROM gs_package t1, gs_roles t2 WHERE t1.pkgname =
'test_pkg' AND t1.pkgowner = t2.oid;
 pkgname  | rolname
----------+---------
 test_pkg | test
(1 row)

-- Drop.
test=# DROP PACKAGE test_pkg;
test=# DROP ROLE test;
-- Switch to the default database. Change the database name based on the actual situation.
test=# \c postgres
gaussdb=# DROP DATABASE test;
```

Helpful Links

CREATE PACKAGE and **DROP PACKAGE**

1.13.7.23 ALTER PROCEDURE

Description

Changes the attributes of a user-defined stored procedure or recompiles a stored procedure.

Precautions

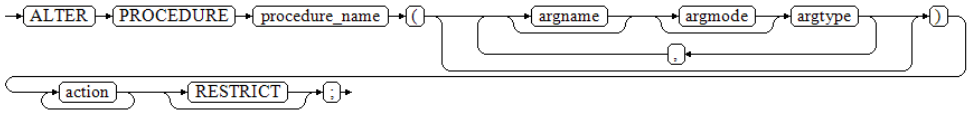
- Only the owner of a stored procedure or a user with the ALTER permission can run the **ALTER PROCEDURE** command. System administrators have this permission by default. The following are permission restrictions depending on attributes to be modified:
  - If a stored procedure involves operations on temporary tables, ALTER PROCEDURE cannot be used.
  - To modify the owner or schema of a stored procedure, you must be the owner of the stored procedure or system administrator and a member of the new owner role.
  - Only system administrators and the initial user can alter the schema of a stored procedure to public.
- Only the initial user or the user who creates the stored procedure can modify the stored procedure to a stored procedure that has the definer permission.
- When separation of duties is enabled, no role is allowed to alter the owner of a stored procedure with the definer permission.
- When separation of duties is disabled, only the initial user and system administrators can alter the owner of a stored procedure with the definer permission.
- Only the initial user can alter the owner of a stored procedure to the initial user.

Syntax

- Alter the additional parameters of a user-defined stored procedure.

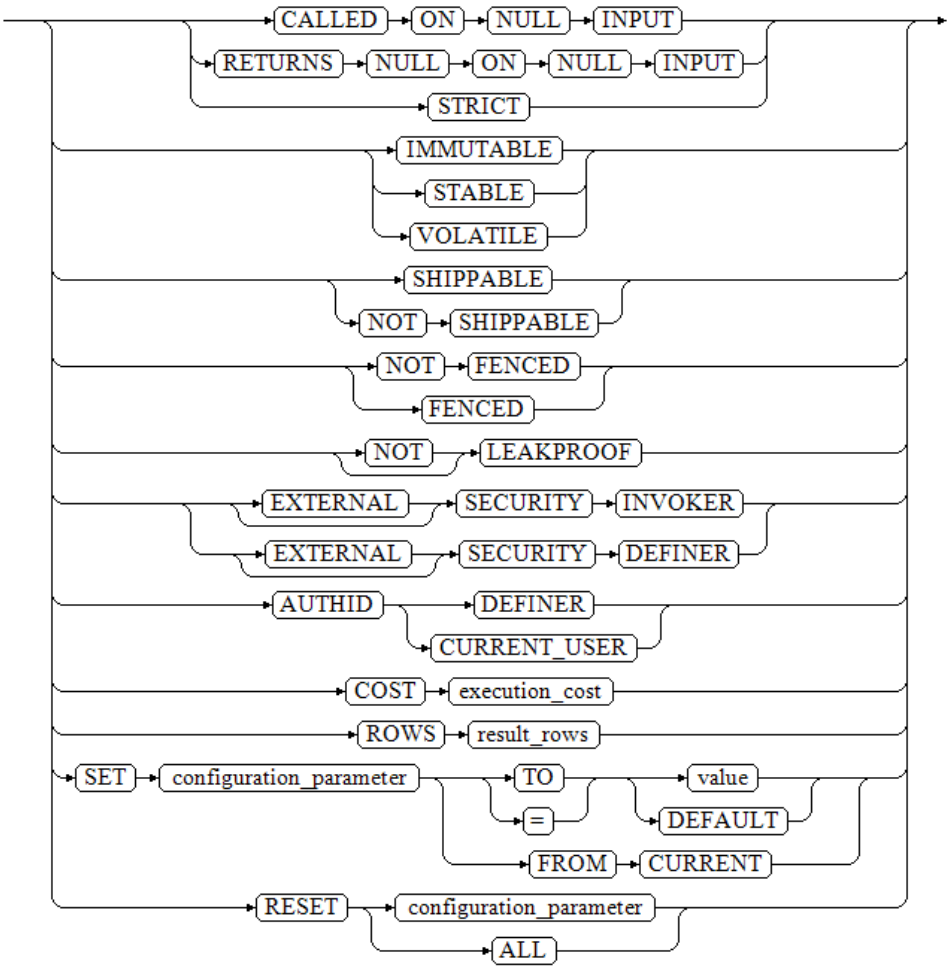
```
ALTER PROCEDURE procedure_name ( [ { [ argname ] [ argmode ] argtype} [, ...] ] )
    action [ ... ] [ RESTRICT ];
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.



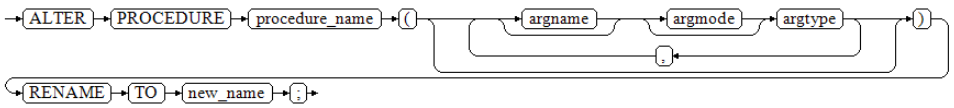
The syntax of the ACTION clause is as follows:

```
{{CALLED ON NULL INPUT  | RETURNS NULL ON NULL INPUT | STRICT}
 | {IMMUTABLE | STABLE | VOLATILE}
 | {SHIPPABLE | NOT SHIPPABLE}
 | {NOT FENCED | FENCED}
 | [ NOT ] LEAKPROOF
 | { [ EXTERNAL ] SECURITY INVOKER | [ EXTERNAL ] SECURITY DEFINER }
 | AUTHID { DEFINER | CURRENT_USER }
 | COST execution_cost
 | ROWS result_rows
 | SET configuration_parameter { { TO | = } { value | DEFAULT }| FROM CURRENT}
 | RESET {configuration_parameter | ALL}}
```



- Rename a user-defined stored procedure.

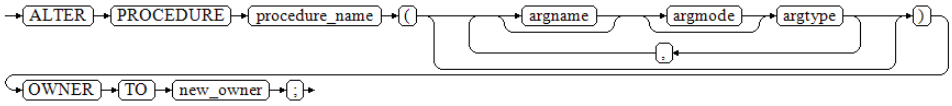
```
ALTER PROCEDURE procedure_name( [ { [ argname ] [ argmode ] argtype} [, ...] ] )
    RENAME TO new_name;
```



- Alter the owner of a user-defined stored procedure.

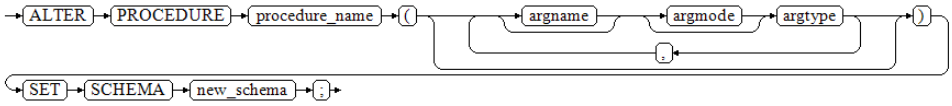
```
ALTER PROCEDURE procedure_name( [ { [ argname ] [ argmode ] argtype} [, ...] ] )
    OWNER TO new_owner;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.



- Alter the schema of a user-defined stored procedure.

```
ALTER PROCEDURE procedure_name( [ { [ argname ] [ argmode ] argtype} [, ...] ] )
    SET SCHEMA new_schema;
```



Parameters

- **procedure_name**

  Specifies the name of the stored procedure to be modified.

  Value range: an existing stored procedure name

- **argmode**

  Specifies whether a parameter is an input or output parameter.

  Value range: **IN**, **OUT**, **INOUT**, and **VARIADIC**

- **argname**

  Parameter name.

  Value range: character strings complying with **Identifier Naming Conventions**.

- **argtype**

  Specifies the type of the stored procedure parameter.

- **CALLED ON NULL INPUT**

  Specifies that the stored procedure can be called normally when some parameters of the stored procedure are **NULL**. Omitting this parameter is the same as specifying it.

- **RETURNS NULL ON NULL INPUT | STRICT**

  STRICT specifies that the stored procedure returns **NULL** when a parameter of the stored procedure is **NULL**. If this parameter is specified, the stored procedure is not executed when there are null parameters; instead a null result is returned automatically.

  RETURNS NULL ON NULL INPUT and **STRICT** have the same functions.

- **IMMUTABLE**

  Specifies that the stored procedure always returns the same result if the parameter values are the same.

- **STABLE**

  Specifies that the stored procedure cannot alter the database, and that within a single table scan it will consistently return the same result for the same parameter value, but its result varies by SQL statements.

- **VOLATILE**

  Specifies that the stored procedure value can change in a single table scan and no optimization is performed.

- **SHIPPABLE | NOT SHIPPABLE**, **FENCED | NOT FENCED**, etc.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Specifies a constraint. The function of each parameter is similar to that of **CREATE FUNCTION**. For details, see **CREATE FUNCTION**.

- **LEAKPROOF**

  Specifies that the stored procedure has no side effect and the parameter contains only the return value. LEAKPROOF can be set only by system administrators.

- **EXTERNAL**

  (Optional) The purpose is to be compatible with SQL. This feature applies to all functions, not only external functions.

- **SECURITY INVOKER | AUTHID CURRENT_USER**

  Specifies that the stored procedure will be executed with the permissions of the user who calls it. Omitting this parameter is the same as specifying it.

  SECURITY INVOKER and **AUTHID CURRENT_USER** have the same functions.

- **SECURITY DEFINER | AUTHID DEFINER**

  Specifies that the stored procedure will be executed with the permissions of the user who created it.

  AUTHID DEFINER and **SECURITY DEFINER** have the same functions.

- **COST execution_cost**

  Estimates the execution cost of a stored procedure.

  The unit of **execution_cost** is **cpu_operator_cost**.

  Value range: a positive integer

- **ROWS result_rows**

  Estimates the number of rows returned by the stored procedure. This is only allowed when the stored procedure is declared to return a set.

  Value range: a positive number. The default value is **1000**.

- **configuration_parameter**
  - **value**

    Sets a specified database session parameter to a specific value.

    Value range: a string.

    - **DEFAULT**: The default system setting is used in the new session.
    - **OFF**: The setting is disabled.
    - **RESET**: The default system setting is used in the new session.
    - User-specified value: The value must meet the restriction of the modified parameter.

  - **DEFAULT**

    Default value.

  - **FROM CURRENT**

    Uses the value of **configuration_parameter** of the current session.

- **ALL**

  Specifies all GUC parameters.

- **new_name**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Specifies the new name of the stored procedure. To change the schema of a stored procedure, you must have the CREATE permission on the new schema.

Value range: character strings complying with **Identifier Naming Conventions**.

- **new_owner**

  Specifies the new owner of the stored procedure. To change the owner of a stored procedure, the new owner must have the CREATE permission on the schema to which the stored procedure belongs.

  Value range: an existing user role

- **new_schema**

  Specifies the new schema of the stored procedure.

  Value range: an existing schema name.

- **RESTRICT**

  It is used solely for compliance with the SQL standard and can be ignored.

Examples

```
-- Create a stored procedure.
gaussdb=# CREATE OR REPLACE PROCEDURE test_proc(a int)
IS
    proc_var int;
BEGIN
    proc_var := a;
END;
/

-- Change the execution rule of a stored procedure to IMMUTABLE. That is, the returned results are the same when the parameters remain unchanged.
gaussdb=# ALTER PROCEDURE test_proc(a int) IMMUTABLE;

-- Create a user.
gaussdb=# CREATE USER joe PASSWORD '********';

-- Change the owner of a stored procedure.
gaussdb=# ALTER PROCEDURE test_proc(a int)  OWNER TO joe;

-- Create a schema.
gaussdb=# CREATE SCHEMA test;

-- Modify the schema of a stored procedure.
gaussdb=# ALTER PROCEDURE  test_proc(a int)  SET SCHEMA test;

-- Drop a stored procedure. The schema to which the function belongs must be specified.
gaussdb=# DROP PROCEDURE test.test_proc;

-- Drop the new user and schema.
gaussdb=# DROP USER joe;
gaussdb=# DROP SCHEMA test;
```

CREATE PROCEDURE and **DROP PROCEDURE**

1.13.7.24 ALTER RESOURCE LABEL

Description

Alters a resource label.

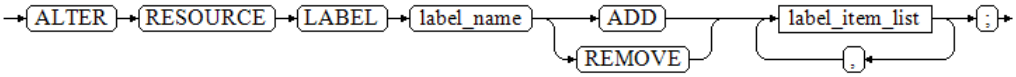
 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Precautions

Only users with the POLADMIN or SYSADMIN permission or the initial user can run the **ALTER RESOURCE LABEL** command.

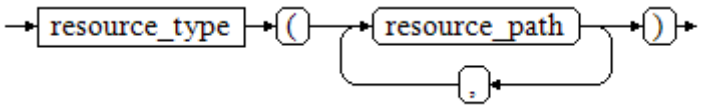
Syntax

```
ALTER RESOURCE LABEL label_name {ADD | REMOVE}
  label_item_list [, ...];
```



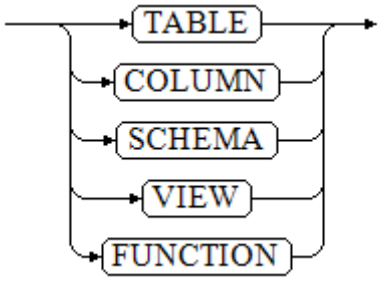
- label_item_list

  ```
  resource_type (resource_path [, ...])
  ```

- resource_type

  ```
  {TABLE | COLUMN | SCHEMA | VIEW | FUNCTION}
  ```

Parameters

- **label_name**

  Specifies a resource label name.

  Value range: character strings complying with **Identifier Naming Conventions**.

- **resource_type**

  Specifies the type of database resources to be labeled.

- **resource_path**

  Specifies the path of a specific database resource.

Examples

```
-- Create basic table table_for_label.
gaussdb=# CREATE TABLE table_for_label(col1 int, col2 text);

-- Create resource label table_label.
gaussdb=# CREATE RESOURCE LABEL table_label ADD COLUMN(table_for_label.col1);

-- Attach resource label table_label to col2.
gaussdb=# ALTER RESOURCE LABEL table_label ADD COLUMN(table_for_label.col2);

-- Remove an item from table_label.
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gaussdb=# ALTER RESOURCE LABEL table_label REMOVE COLUMN(table_for_label.col1);

-- Delete the resource label table_label.
gaussdb=# DROP RESOURCE LABEL table_label;

-- Delete the base table table_for_label.
gaussdb=# DROP TABLE table_for_label;
```

Helpful Links

CREATE RESOURCE LABEL and **DROP RESOURCE LABEL**

1.13.7.25 ALTER RESOURCE POOL

Description

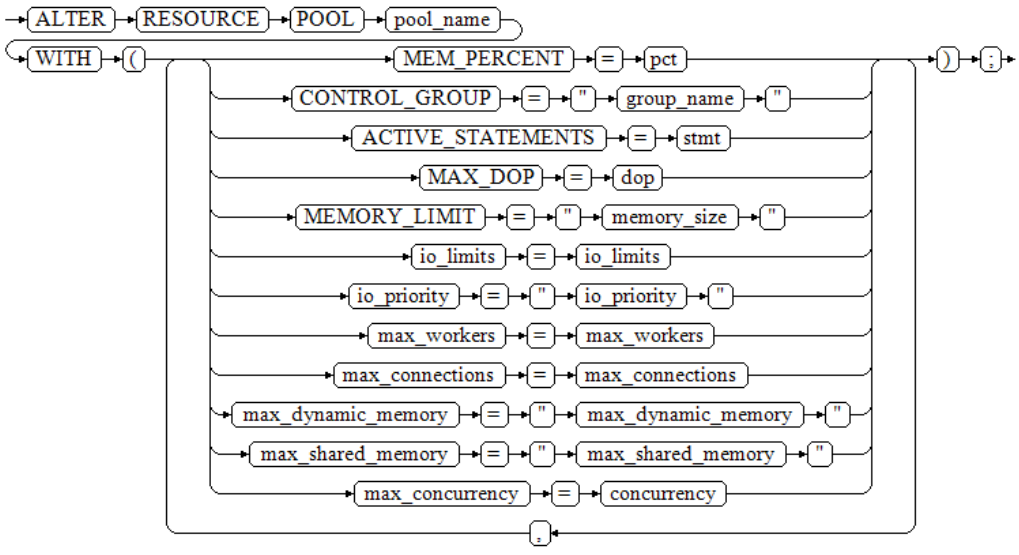
Changes the Cgroup of a resource pool.

Precautions

- Only users with the SYSADMIN permission or the initial user can run the **ALTER RESOURCE POOL** command.
- This syntax is not supported during upgrade.

Syntax

```
ALTER RESOURCE POOL pool_name
    WITH ({MEM_PERCENT = pct | CONTROL_GROUP = "group_name" | ACTIVE_STATEMENTS = stmt |
MAX_DOP = dop | MEMORY_LIMIT = "memory_size" | io_limits = io_limits | io_priority = "io_priority" |
max_worker = max_worker | max_connections = max_connections | max_dynamic_memory =
"max_dynamic_memory" | max_shared_memory = "max_shared_memory" | max_concurrency =
concurrency} [, ... ]);
```



Parameters

- **pool_name**

  Specifies the name of a resource pool. The resource pool must already exist.

  Value range: character strings complying with **Identifier Naming Conventions**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **group_name**

  Specifies the name of a Cgroup.

  Value range: an existing Cgroup.

  NOTE

  - You can use either double quotation marks ("") or single quotation marks (') in the syntax when setting the name of a Cgroup.
  - The value of **group_name** is case-sensitive.
  - If **group_name** is not specified, the default value **Medium** is used, indicating the **Medium Timeshare** Cgroup under the **DefaultClass** Cgroup.
  - If an administrator specifies a Workload Cgroup under Class, for example, **control_group** set to **class1:workload1**, the resource pool will be associated with the **workload1** Cgroup under **class1**. The level of **Workload** can also be specified. For example, **control_group** is set to **class1:workload1:1**.
  - If a database user specifies the Timeshare string (**Rush**, **High**, **Medium**, or **Low**) in the syntax, for example, **control_group** is set to **High**, the resource pool will be associated with the **High** Timeshare Cgroup under **DefaultClass**.
  - In multi-tenant scenarios, the Cgroup associated with a group resource pool is a Class Cgroup, and that associated with a service resource pool is a Workload Cgroup. Additionally, switching Cgroups between different resource pools is not allowed.

- **stmt**

  Specifies the maximum number of statements that can be concurrently executed in a resource pool.

  Value range: a number ranging from –1 to 2147483647. The value **–1** indicates no limit.

- **dop**

  Specifies the maximum statement concurrency degree for a resource pool, equivalent to the number of threads that can be created for executing a statement.

  Value range: numeric data ranging from 1 to 2147483647.

- **memory_size**

  Specifies the maximum memory size of a resource pool.

  Value range: a string of 1 KB to 2047 GB case-sensitive characters.

- **mem_percent**

  Specifies the proportion of available resource pool memory to the total memory or group user memory.

  – In multi-tenant scenarios, **mem_percent** of group users or service users ranges from 1 to 100. The default value is **20**.

  – In common scenarios, **mem_percent** of common users is an integer ranging from 0 to 100. The default value is **0**.

  NOTE

  When both of **mem_percent** and **memory_limit** are specified, only **mem_percent** takes effect.

- **io_limits**

  Specifies the maximum number of I/Os that can be triggered per second in a resource pool. The unit is 10,000.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Value range: a number ranging from 0 to 2147483647. The value **0** indicates no limit.

- **io_priority**

  Specifies the I/O priority set for jobs that consume many I/O resources. It takes effect when the I/O usage reaches 90%.

  Value range: enumerated type. The options are **None**, **Low**, **Medium**, and **High**. If you do not want to control I/O resources, use the default value **None**.

  NOTE

  The settings of **io_limits** and **io_priority** are valid only for complex jobs, such as batch import (using INSERT INTO SELECT, COPY FROM, or CREATE TABLE AS), complex queries involving over 500 MB data on each DN, and VACUUM FULL.

- **max_worker**

  Concurrency in a table during data redistribution. It is used only for scaling.

- **max_connections**

  Maximum number of connections allowed by a resource pool.

  NOTE

  The total number of connections in all resource pools cannot exceed the value of the GUC parameter **max_connections** set for the entire GaussDB process.

- **max_dynamic_memory**

  Maximum dynamic memory allowed by a resource pool.

- **max_shared_memory**

  Maximum shared memory allowed by a resource pool.

- **max_concurrency**

  Maximum number of concurrent tasks allowed by a resource pool.

Examples

The following example assumes that the user has created the **class1** Cgroup and three Workload Cgroups under **class1**: **Low**, **wg1**, and **wg2**. Contact an administrator to create a Cgroup.

```
-- Create a resource pool.
gaussdb=# CREATE RESOURCE POOL pool1;

-- Specify the High Timeshare Workload Cgroup under the DefaultClass Cgroup.
gaussdb=# ALTER RESOURCE POOL pool1 WITH (CONTROL_GROUP="High");

-- Specify the Low Timeshare Workload Cgroup under the class1 Cgroup.
gaussdb=# ALTER RESOURCE POOL pool1 WITH (CONTROL_GROUP="class1:Low");

-- Specify the wg1 Workload Cgroup under the class1 Cgroup.
gaussdb=# ALTER RESOURCE POOL pool1 WITH (CONTROL_GROUP="class1:wg1");

-- Specify the wg2 Workload Cgroup under the class1 Cgroup.
gaussdb=# ALTER RESOURCE POOL pool1 WITH (CONTROL_GROUP="class1:wg2:3");

-- Drop the resource pool pool1.
gaussdb=# DROP RESOURCE POOL pool1;
```

CREATE RESOURCE POOL and **DROP RESOURCE POOL**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

1.13.7.26 ALTER ROLE

Description

Alters role attributes, including renaming a role, locking or unlocking a role, and altering permissions of a role.

Syntax

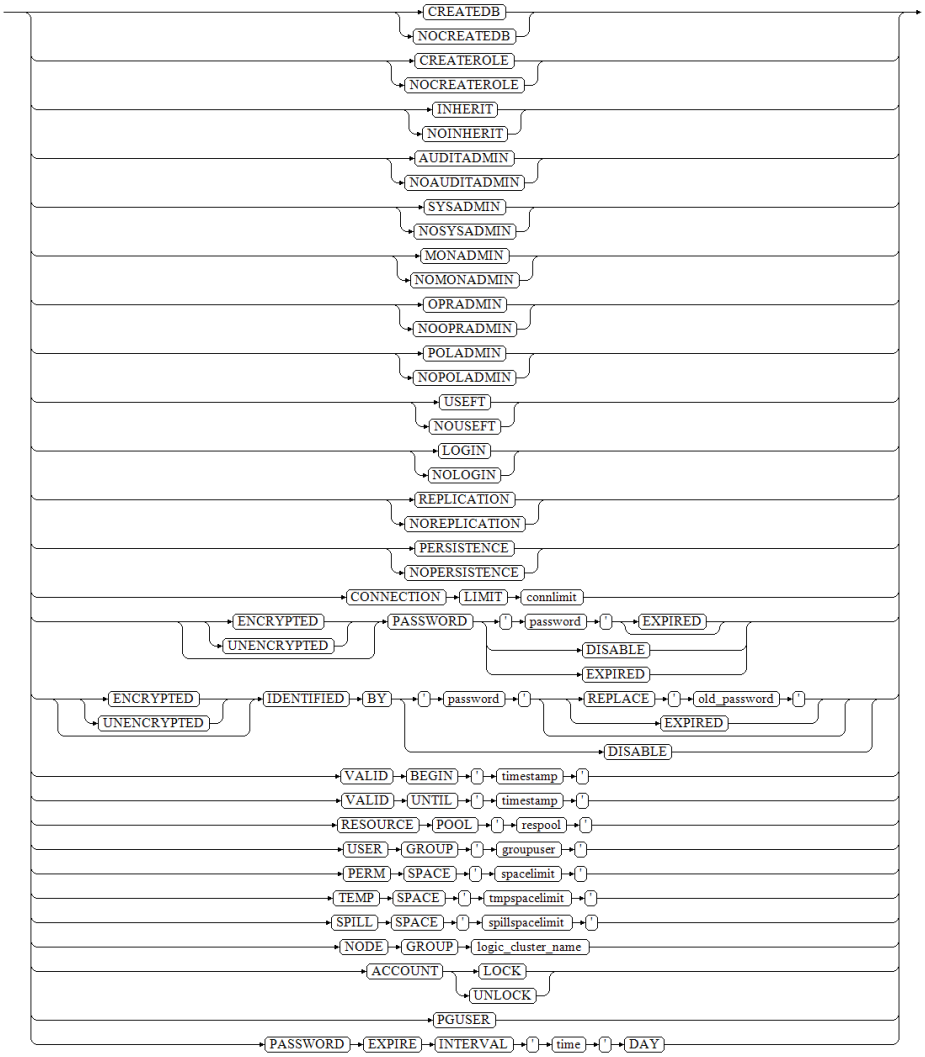
- Alter permissions of a role.

```
ALTER ROLE role_name [ [ WITH ] option [ ... ] ];
```

The option clause is as follows:

```
{
   {CREATEDB | NOCREATEDB}
   | {CREATEROLE | NOCREATEROLE}
   | {INHERIT | NOINHERIT}
   | {AUDITADMIN | NOAUDITADMIN}
   | {SYSADMIN | NOSYSADMIN}
   | {MONADMIN | NOMONADMIN}
   | {OPRADMIN | NOOPRADMIN}
   | {POLADMIN | NOPOLADMIN}
   | {USEFT | NOUSEFT}
   | {LOGIN | NOLOGIN}
   | {REPLICATION | NOREPLICATION}
   | {PERSISTENCE | NOPERSISTENCE}
   | CONNECTION LIMIT connlimit
   | [ ENCRYPTED | UNENCRYPTED ] PASSWORD { 'password' [EXPIRED] | DISABLE | EXPIRED }
   | [ ENCRYPTED | UNENCRYPTED ] IDENTIFIED BY { 'password' [ REPLACE 'old_password' |
EXPIRED ] | DISABLE }
   | VALID BEGIN 'timestamp'
   | VALID UNTIL 'timestamp'
   | RESOURCE POOL 'respool'
   | USER GROUP 'groupuser'
   | PERM SPACE 'spacelimit'
   | TEMP SPACE 'tmpspacelimit'
   | SPILL SPACE 'spillspacelimit'
   | NODE GROUP logic_cluster_name
   | ACCOUNT { LOCK | UNLOCK }
   | PGUSER
   | PASSWORD EXPIRE INTERVAL 'time' DAY
}
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

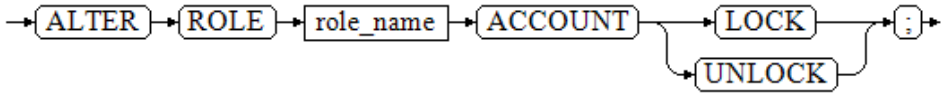


- Rename a role.

```
ALTER ROLE role_name
    RENAME TO new_name;
```

- Lock or unlock a role.

```
ALTER ROLE role_name
    ACCOUNT { LOCK | UNLOCK };
```



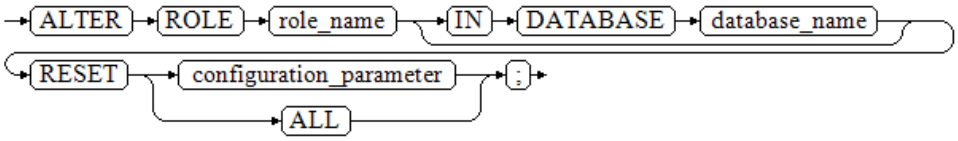
- Set parameters for a role.

```
ALTER ROLE role_name [ IN DATABASE database_name ]
    SET configuration_parameter {{ TO | = } { value | DEFAULT } | FROM CURRENT};
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- Reset parameters for a role.

```
ALTER ROLE role_name
    [ IN DATABASE database_name ] RESET {configuration_parameter|ALL};
```



Parameters

- **role_name**

  Specifies an existing role name.

  Value range: an existing role name. If a role name contains uppercase letters, enclose the name with double quotation marks ("").

  NOTICE

  Currently, the RENAME TO operation cannot be performed on **redisuser**, an object used for resource control during redistribution, and you also cannot rename other roles to **redisuser**.

- **IN DATABASE database_name**

  Modifies parameters of a role in a specified database.

- **SET configuration_parameter {{ TO | = } { value | DEFAULT } | FROM CURRENT}**

  Sets parameters for a role.

  NOTICE

  Session parameters modified using ALTER ROLE apply only to the specified role. The current version does not support user-level parameter settings.

  Value range:

  - **configuration_parameter**: For details about its value, see **SET**.
  - **value**: For details about its value, see **SET**.
  - **DEFAULT**: clears the value of **configuration_parameter**. **configuration_parameter** will inherit the default value of the new session generated for the role.
  - **FROM CURRENT**: uses the value of **configuration_parameter** in the current session.

- **RESET {configuration_parameter|ALL}**

  Clears the value of **configuration_parameter**. The statement has the same effect as that of **SET configuration_parameter TO DEFAULT**.

  NOTICE

  The current version does not support the resetting of user-level parameters.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Value range: **ALL** indicates that the values of all parameters are cleared.

- **ACCOUNT LOCK | ACCOUNT UNLOCK**
  - **ACCOUNT LOCK**: locks a role account to prevent the role from logging in to the database through password authentication.
  - **ACCOUNT UNLOCK**: unlocks a role account to allow the role to log in to the database.
- **PGUSER**

  In the current version, the **PGUSER** attribute of a role cannot be modified.
- **{PASSWORD|IDENTIFIED BY} 'password'**

  Resets or changes the user password.
  - Except for the initial user, other administrators and common users must enter the correct old passwords when changing their own passwords.
  - Only the initial user, SYSADMIN when separation of duties is disabled, or users who have the CREATEROLE permission can reset the password of a common user without entering the old password.
  - The initial user can reset passwords of system administrators. System administrators are prohibited from resetting passwords for each other.
  - User passwords must be enclosed within single quotation marks (') or double quotation marks (").
- **EXPIRED**

  Sets the password as expired.
  - Only the initial user, system administrators (SYSADMIN), and users with the CREATEROLE permission can set user passwords as expired. System administrator may perform this action for themselves or for other system administrators only when separation of duties is disabled.
  - The password of the initial user cannot be set as expired.
  - A user whose password has expired can log in to the database but cannot perform query operations. The user can perform query operations only after changing the password or asking an administrator to reset the password.
- For details about other parameters, see **CREATE ROLE** in section **Parameters**.

Examples

```
-- Create role test_role.
gaussdb=# CREATE ROLE test_role PASSWORD '********';

-- Set role test_role to log in to the database.
gaussdb=# ALTER ROLE test_role WITH LOGIN;

-- Create a database.
gaussdb=# CREATE DATABASE testdb1;

-- Lock role test_role.
gaussdb=# ALTER ROLE test_role ACCOUNT LOCK;

-- Unlock a locked role.
gaussdb=# ALTER ROLE test_role ACCOUNT UNLOCK;

-- Change the password of role test_role.
gaussdb=# ALTER ROLE test_role PASSWORD '********';

-- Rename role test_role to test_role2.
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gaussdb=# ALTER ROLE test_role RENAME TO test_role2;

-- Change role test_role2 to SYSADMIN.
gaussdb=# ALTER ROLE test_role2 SYSADMIN;

-- Drop.
gaussdb=# DROP ROLE test_role2;
gaussdb=# DROP DATABASE testdb1;
```

CREATE ROLE, **DROP ROLE**, and **SET ROLE**

1.13.7.27 ALTER ROW LEVEL SECURITY POLICY

Description

Alters an existing row-level security policy, including the policy name, users affected by the policy, and policy expression.

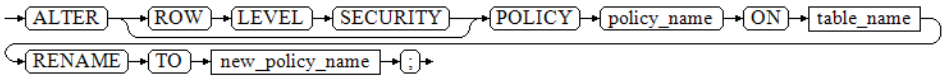
Precautions

Only the table owner or administrator can run the **ALTER ROW LEVEL SECURITY POLICY** command.

Syntax

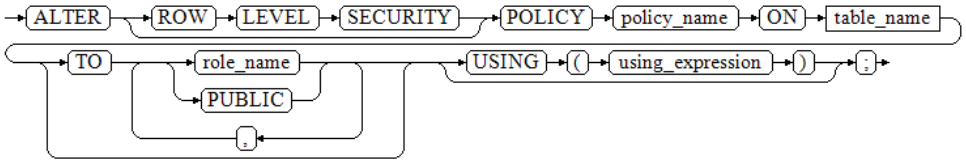
- Rename an existing row-level security policy.

```
ALTER [ ROW LEVEL SECURITY ] POLICY policy_name ON table_name RENAME TO new_policy_name;
```



- Alter the specified user and expression of an existing row-level security policy.

```
ALTER [ ROW LEVEL SECURITY ] POLICY policy_name ON table_name
    [ TO { role_name | PUBLIC } [, ...] ]
    [ USING ( using_expression ) ];
```



Parameters

- **policy_name**

  Specifies the name of a row-level security policy.

- **table_name**

  Specifies the name of a table to which a row-level security policy is applied.

- **new_policy_name**

  Specifies the new name of a row-level security policy.

- **role_name**

  Specifies names of users affected by a row-level security policy. **PUBLIC** indicates that the row-level security policy will affect all users.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **using_expression**

  Specifies a row-level security policy, which is similar to a Boolean expression in the WHERE clause.

Examples

```
-- Create the data table all_data.
gaussdb=# CREATE TABLE all_data(id int, role varchar(100), data varchar(100));

-- Create a row-level security policy to specify that the current user can view only their own data.
gaussdb=# CREATE ROW LEVEL SECURITY POLICY all_data_rls ON all_data USING(role = CURRENT_USER);
gaussdb=# \d+ all_data
                        Table "public.all_data"
 Column |          Type          | Modifiers | Storage  | Stats target | Description
--------+------------------------+-----------+----------+--------------+-------------
 id     | integer                |           | plain    |              |
 role   | character varying(100) |           | extended |              |
 data   | character varying(100) |           | extended |              |
Row Level Security Policies:
    POLICY "all_data_rls" FOR ALL
      TO public
      USING (((role)::name = "current_user"()))
Has OIDs: no
Distribute By: HASH(id)
Location Nodes: ALL DATANODES
Options: orientation=row, compression=no, storage_type=USTORE, segment=off

-- Change the name of the all_data_rls policy.
gaussdb=# ALTER ROW LEVEL SECURITY POLICY all_data_rls ON all_data RENAME TO all_data_new_rls;

-- Create users alice and bob.
gaussdb=# CREATE ROLE alice WITH PASSWORD '*********';
gaussdb=# CREATE ROLE bob WITH PASSWORD '*********';

-- Change the users affected by the row-level security policy.
gaussdb=# ALTER ROW LEVEL SECURITY POLICY all_data_new_rls ON all_data TO alice, bob;
gaussdb=# \d+ all_data
                        Table "public.all_data"

CREATE ROW LEVEL SECURITY POLICY and **DROP ROW LEVEL SECURITY POLICY**

1.13.7.28 ALTER SCHEMA

Description

Alters schema attributes, including the name, owner, and tamper-proof attribute of a schema.

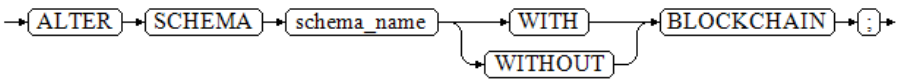
Precautions

- Only the owner of a schema and users with the ALTER permission on the schema are authorized to run the **ALTER SCHEMA** command. When separation of duties is disabled, system administrators have this authorization by default.
- To change the owner of a schema, you must be the owner of the schema or a system administrator and a member of the new owner role.
- Only the initial user can change the owner of a system schema (such as pg_catalog and sys) except PUBLIC. Changing the names of built-in system schemas may make some functions unavailable or even affect the normal running of the database. By default, the names of built-in system schemas cannot be changed. To ensure compatibility with earlier versions, you can change the names of the built-in system schemas only when the system is being started or upgraded, or when **allow_system_table_mods** is set to **on**.
- Only the initial user can change the owner of a schema to an O&M administrator.

Syntax

- Alter the tamper-proof attribute of a schema.

```
ALTER SCHEMA schema_name { WITH | WITHOUT } BLOCKCHAIN;
```



- Rename a schema.

```
ALTER SCHEMA schema_name
  RENAME TO new_name;
```

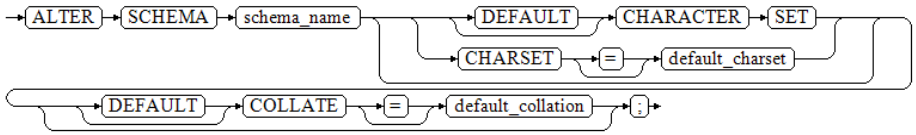
 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- Alter the owner of a schema.

```
ALTER SCHEMA schema_name
  OWNER TO new_owner;
```

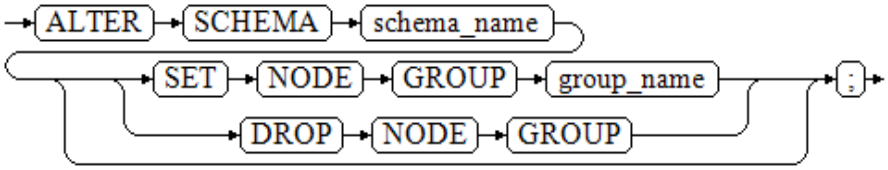
- Alter the default character set and collation of a schema.

```
ALTER SCHEMA schema_name
  [ [DEFAULT] CHARACTER SET | CHARSET [ = ] default_charset ] [ [DEFAULT] COLLATE [ = ]
default_collation ];
```



- Alter the single-node attribute of the schema.

```
ALTER SCHEMA schema_name
  [ SET NODE GROUP group_name | DROP NODE GROUP ];
```



Parameters

- **schema_name**

  Specifies the name of an existing schema.

  Value range: an existing schema name.

- **RENAME TO new_name**

  Rename a schema. **new_name** indicates the new name of a schema.

  Value range: character strings complying with **Identifier Naming Conventions**.

  The rules for naming a schema are as follows:

  – The schema name must be unique in the current database.

  – The new name cannot be the same as the initial username of the current database.

  – Do not use a new name starting with pg_, gs_role_, or data_redis.

- **OWNER TO new_owner**

  Change the owner of a schema. **new_owner** indicates the new owner of a schema.

  Value range: an existing username or role name.

  NOTE

  To do this as a non-SYSADMIN user, you must be a direct or indirect member of the new owner role, and that role must have the CREATE permission on the database.

- **{ WITH | WITHOUT } BLOCKCHAIN**

  Alter the tamper-proof attribute of a schema. **WITH BLOCKCHAIN** indicates the tamper-proof schema.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- To change a normal schema to a tamper-proof schema, set the GUC parameter **enable_ledger** to **on**. The default value is **off**, and the level is SIGHUP.
- Ordinary row-store tables with the tamper-proof attribute are tamper-proof history tables, excluding foreign tables, temporary tables, and system catalogs.
- You can modify or switch the tamper-proof attribute of a schema only when the schema does not contain any table.
- The tamper-proof attribute cannot be modified for the temporary table schema, TOAST table schema, dbe_perf schema, or blockchain schema.

- **default_charset**

  Changes the default character set of a schema.

  Value range: For details about the supported character sets, see **Table 1-398**.

  NOTICE

  - This syntax is supported only when **sql_compatibility** is set to **'MYSQL'** or **'M'**. The preceding information is displayed when **sql_compatibility** is set to **'MYSQL'**. For details about the information when **sql_compatibility** is set to **'M'**, see "SQL Reference > SQL Syntax > SQL Statements > A > ALTER SCHEMA" in *M Compatibility Developer Guide*.
  - If the default collation is not specified, the default collation of the specified character set is used as the default collation of the schema.

- **default_collate**

  Changes the default collation of the schema.

  Value range: For details about the supported collations, see **Table 1-398**.

  NOTICE

  - This syntax is supported only when **sql_compatibility** is set to **'MYSQL'** or **'M'**. The preceding information is displayed when **sql_compatibility** is set to **'MYSQL'**. For details about the information when **sql_compatibility** is set to **'M'**, see "SQL Reference > SQL Syntax > SQL Statements > A > ALTER SCHEMA" in *M Compatibility Developer Guide*.
  - If the default character set is not specified, the character set corresponding to the specified collation is used as the default character set of the schema.

- **SET NODE GROUP group_name | DROP NODE GROUP**
  - **SET NODE GROUP group_name**: sets the single-node attribute of the schema. **group_name** indicates the name of a single-node group. Only the single-node group whose type is 's' can be set.
  - **DROP NODE GROUP**: drops the single-node attribute of the schema.

  NOTE

  This syntax is supported only in M-compatible databases (**sql_compatibility = 'M'**).

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Examples

- Alter the tamper-proof attribute of a schema.

```
-- Create a schema test_schema1.
gaussdb=# CREATE SCHEMA test_schema1;

-- Change the schema test_schema1 to the tamper-proof mode.
gaussdb=# ALTER SCHEMA test_schema1 WITH BLOCKCHAIN;

-- Query mode information. The tamper-proof attribute is true.
gaussdb=# \dn+ test_schema1
                          List of schemas
     Name     | Owner | Access privileges | Description | WithBlockChain
--------------+-------+-------------------+-------------+----------------
 test_schema1 | omm   |                   |             | t
(1 row)
```

- Rename a schema.

```
-- Rename the schema test_schema1 to test_sch1.
gaussdb=# ALTER SCHEMA test_schema1 RENAME TO test_sch1;

-- Query schema information.
gaussdb=# \dn+ test*
                        List of schemas
   Name    | Owner | Access privileges | Description | WithBlockChain
-----------+-------+-------------------+-------------+----------------
 test_sch1 | omm   |                   |             | t
(1 row)
```

- Change the owner of a schema.

```
-- Create user test_user.
gaussdb=# CREATE ROLE test_user PASSWORD '********';

-- Change the owner of schema test_sch1 to test_user.
gaussdb=# ALTER SCHEMA test_sch1 OWNER TO test_user;

-- Query schema information.
gaussdb=# \dn+  test_sch1;
                          List of schemas
   Name    |   Owner   | Access privileges | Description | WithBlockChain
-----------+-----------+-------------------+-------------+----------------
 test_sch1 | test_user |                   |             | t
(1 row)

-- Drop the new schema and user.
gaussdb=# DROP SCHEMA test_sch1;
gaussdb=# DROP ROLE test_user;
```

- Alter the default character set and collation.

NOTICE

Except the binary character set and collation, only the character set that is the same as the database encoding can be specified.

```
-- Create and switch to the test database.
gaussdb=# CREATE DATABASE test1 WITH DBCOMPATIBILITY = 'MYSQL' ENCODING = 'UTF8'
LC_COLLATE = 'zh_CN.utf8' LC_CTYPE = 'zh_CN.utf8';
gaussdb=# \c test1

-- Create a schema test_sch2.
test1=# CREATE SCHEMA test_sch2;
-- Change the default character set to utf8mb4 and the default collation of characters to
utf8mb4_bin.
test1=# ALTER SCHEMA test_sch2 CHARACTER SET utf8mb4 COLLATE utf8mb4_bin;

-- Drop the new schema.
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
test1=# DROP SCHEMA test_sch2;

-- Switch to the default database (change the database name based on the actual situation) and drop the new database.
test1=# \c postgres
gaussdb=# DROP DATABASE test1;
```

- Modify the single-node attribute of the schema.

```
-- Create a schema test_schema1.
gaussdb=# CREATE SCHEMA test_schema1;

-- Modify the single-node attribute of the test_schema1 schema.
gaussdb=# ALTER SCHEMA test_schema1 SET NODE GROUP sys_single_group1;

-- Query the single-node attribute of the test_schema1 schema. The nspgroupoid column in the pg_namespace system catalog records the OID of the node group corresponding to the single-node attribute.
gaussdb=# SELECT * FROM pg_namespace WHERE nspname='test_schema1';
   nspname    | nspowner | nsptimeline | nspacl | in_redistribution | nspblockchain | nspcollation | nspgroupoid
--------------+----------+-------------+--------+-------------------+---------------+--------------+-------------
 test_schema1 |       10 |           0 |        | n                 | f             |              |       16389
(1 row)

-- Drop the single node attribute of the test_schema1 schema.
gaussdb=# ALTER SCHEMA test_schema1 DROP NODE GROUP;

-- Query the single node attribute of the test_schema1 schema.
gaussdb=# SELECT * FROM pg_namespace WHERE nspname='test_schema1';
   nspname    | nspowner | nsptimeline | nspacl | in_redistribution | nspblockchain | nspcollation | nspgroupoid
--------------+----------+-------------+--------+-------------------+---------------+--------------+-------------
 test_schema1 |       10 |           0 |        | n                 | f             |              |
(1 row)
```

Helpful Links

CREATE SCHEMA and **DROP SCHEMA**

1.13.7.29 ALTER SEQUENCE

Description

Alters parameters of a specified sequence.

Precautions

- To run the **ALTER SEQUENCE** command, you must be the sequence owner, a user with the ALTER permission on the sequence, or a user with the ALTER ANY SEQUENCE permission. When separation of duties is disabled, system administrators have this authorization by default. To modify the owner of a sequence, you must be the sequence owner (or a system administrator) and also a member of the new owner's role.
- In the current version, you can modify only the owner, owning column, and maximum value. To alter other parameters, delete the sequence and rebuild it. Then, use the setval function to restore parameter values.
- ALTER SEQUENCE MAXVALUE cannot be used in transactions, functions, or stored procedures.
- After the maximum value of a sequence is altered, the cache of the sequence in all sessions is cleared.

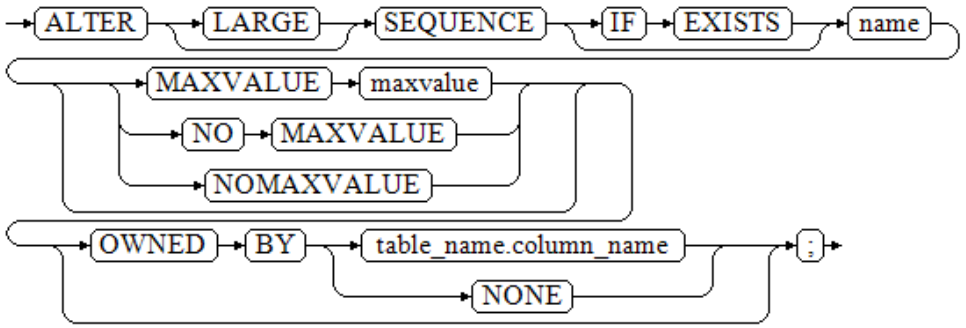
 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- If the LARGE flag is specified when a sequence is created, you also need to specify the LARGE flag when performing the ALTER operation.
- ALTER SEQUENCE blocks calls to the nextval, setval, currval, and lastval functions.

Syntax

- Alter the owning column and maximum value of a sequence.

```
ALTER [LARGE] SEQUENCE [ IF EXISTS ] name
    [MAXVALUE maxvalue | NO MAXVALUE | NOMAXVALUE]
    [ OWNED BY { table_name.column_name | NONE } ] ;
```



- Alter the owner of a sequence.

```
ALTER [LARGE] SEQUENCE [ IF EXISTS ] name OWNER TO new_owner;
```

Parameters

- **LARGE**

  If the LARGE flag is specified when a sequence is created, you also need to specify the LARGE flag when performing the ALTER operation.

- **name**

  Specifies the name of the sequence to be modified.

- **IF EXISTS**

  Issues a notice rather than an error if the specified sequence does not exist.

- **MAXVALUE maxvalue | NO MAXVALUE | NOMAXVALUE**

  Specifies the maximum value of the sequence. The new maximum value must be greater than the current maximum value stored by GTM. If this parameter is not specified, the original maximum value is retained.

  Value range: (gtm_last_value, 2^{63} – 1]. **gtm_last_value** indicates the maximum value that has been allocated in the sequence. You can run the **\d** *Sequence name* command to query the value. If the LARGE flag is specified when a sequence is created, the value range is (gtm_last_value, 2^{127} – 1].

- **OWNED BY { table_name.column_name | NONE }**

  Associates a sequence with a specified column of a table. When the column or the table is deleted, the associated sequence is automatically deleted.

  – If the sequence was previously associated with another table, this new association will overwrite the existing one.

  – The associated table and sequence must be owned by the same user and reside in the same schema.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

  - Using OWNED BY NONE removes any existing associations.
- **new_owner**

  Specifies the username of the new sequence owner. To change the owner, you must also be a direct or indirect member of the new role, and this role must have the CREATE permission on the sequence's schema.

Examples

```
-- Create an ascending sequence named serial, starting from 101.
gaussdb=# CREATE SEQUENCE serial START 101;

-- Create a table and specify default values for the sequence.
gaussdb=# CREATE TABLE t1(c1 bigint default nextval('serial'));

-- Change the owning column of serial to T1.C1.
gaussdb=# ALTER SEQUENCE serial OWNED BY t1.c1;

-- Delete a sequence and a table.
gaussdb=# DROP SEQUENCE serial CASCADE;
gaussdb=# DROP TABLE t1;

-- Create the seq_test sequence.
gaussdb=# CREATE SEQUENCE seq_test;

-- Query sequence information.
gaussdb=# \ds
              List of relations
 Schema |   Name   |   Type   | Owner | Storage
--------+----------+----------+-------+---------
 public | seq_test | sequence | omm   |
(1 row)

-- Create the user u_test and modify the sequence owner.
gaussdb=# CREATE USER u_test PASSWORD '********';
gaussdb=# ALTER SEQUENCE seq_test OWNER TO u_test;
gaussdb=# \ds
              List of relations
 Schema |   Name   |   Type   | Owner  | Storage
--------+----------+----------+--------+---------
 public | seq_test | sequence | u_test |
(1 row)

-- Delete the user and sequence.
gaussdb=# DROP SEQUENCE seq_test;
gaussdb=# DROP USER u_test;
```

CREATE SEQUENCE and **DROP SEQUENCE**

1.13.7.30 ALTER SERVER

Description

Adds, alters, and deletes parameters of a specified server. You can query existing servers from the pg_foreign_server system catalog.

Precautions

- Only the server owner or a user granted the ALTER permission can run the **ALTER SERVER** command. By default, system administrators have the

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

permission. To alter a server owner, you must be the server owner or system administrator and a member of the new owner role.

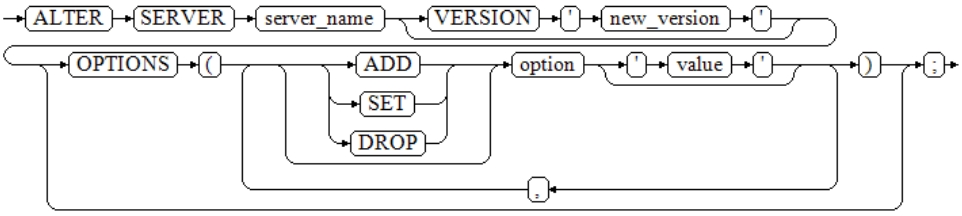
- When multi-layer quotation marks are used for sensitive columns (such as **password** and **secret_access_key**) in OPTIONS, the semantics is different from that in the scenario where quotation marks are not used. Therefore, sensitive columns are not identified for anonymization.

Syntax

- Alter parameters of a foreign server.

```
ALTER SERVER server_name [ VERSION 'new_version' ]
    [ OPTIONS ( {[ ADD | SET | DROP ] option ['value']} [, ... ] ) ];
```

In **OPTIONS**, **ADD**, **SET**, and **DROP** are operations to be performed. If these operations are not specified, ADD operations will be performed by default. **option** and **value** are the parameters of the corresponding operation.



- Alter the owner of a foreign server.

```
ALTER SERVER server_name
    OWNER TO new_owner;
```

- Alter the name of a foreign server.

```
ALTER SERVER server_name
    RENAME TO new_name;
```

Parameters

- **server_name**

  Specifies the name of the foreign server to be altered.

- **new_version**

  Specifies the new version of the altered foreign server.

- **OPTIONS**

  Options for altering the server. The option name must be unique. The actions are ADD, SET, and DROP. If no action is specified, ADD is used. The name and value are also validated with the foreign data wrapper library of the server.

  In addition to the connection parameters supported by libpq, the following parameters are provided:

  - **fdw_startup_cost**

    Estimates the startup time required for a foreign table scan. This value usually contains the time taken to establish a connection, analyze the request at the remote end, and generate a plan. The default value is **100**. The value is a real number greater than 0.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

  - **fdw_tuple_cost**

    Specifies the additional consumption when each tuple is scanned on a remote server. The value specifies the extra consumption of data transmission between servers. The default value is **0.01**. The value is a real number greater than 0.

- **new_owner**

  Specifies the new owner of the server.

  NOTE

  To alter the owner of a server, you must be the owner of the foreign server and a direct or indirect member of the new owner role, and you must have the USAGE permission on the foreign data wrapper of the foreign server.

- **new_name**

  Specifies the new name of the server.

Examples

```
-- Create my_server.
gaussdb=# CREATE SERVER my_server FOREIGN DATA WRAPPER log_fdw;

-- Change the name of an external server.
gaussdb=# ALTER SERVER my_server RENAME TO my_server_1;

-- Create a user.
gaussdb=# CREATE USER jack PASSWORD '********';

-- Change the owner of the external server.
gaussdb=# ALTER SERVER my_server_1 OWNER TO jack;

-- Add the dbname and dbuser information to the external server.
gaussdb=# ALTER SERVER my_server_1 OPTIONS(ADD dbname 'test',dbuser' test_user');

-- Query the external server information.
gaussdb=# SELECT * FROM pg_foreign_server WHERE srvname='my_server_1';
   srvname   | srvowner | srvfdw | srvtype | srvversion | srvacl |            srvoptions
-------------+----------+--------+---------+------------+--------+----------------------------------
 my_server_1 |    22060 |  11826 |         |            |        | {dbname=test,"dbuser= test_user"}
(1 row)

-- Change the dbname in the external server to 'db_test'.
gaussdb=# ALTER SERVER my_server_1 OPTIONS (SET dbname 'db_test');

-- Query the external server information.
gaussdb=# SELECT srvname,srvoptions FROM pg_foreign_server WHERE srvname='my_server_1';
   srvname   |             srvoptions
-------------+-----------------------------------
 my_server_1 | {dbname=db_test,"dbuser= test_user"}
(1 row)

-- Delete the dbname information from the external server.
gaussdb=# ALTER SERVER my_server_1 OPTIONS (DROP dbname);

-- Query the external server information.
gaussdb=# SELECT srvname,srvoptions FROM pg_foreign_server WHERE srvname='my_server_1';
   srvname   |     srvoptions
-------------+--------------------
 my_server_1 | {"dbuser= test_user"}
(1 row)

-- Delete my_server_1.
gaussdb=# DROP SERVER my_server_1;

-- Drop the user.
gaussdb=# DROP USER jack;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

CREATE SERVER and **DROP SERVER**

1.13.7.31 ALTER SESSION

Description

Defines or alters the conditions or parameters that affect the current session. Any modified session parameters remain effective until the session is disconnected.

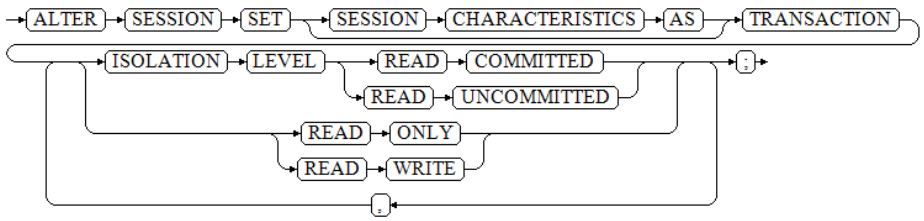
Precautions

- If SET TRANSACTION is executed without a prior START TRANSACTION, its effects will not be displayed, and the transaction will terminate immediately.
- To avoid using SET TRANSACTION, you may declare the required transaction mode(s) directly within START TRANSACTION. For details, see **START TRANSACTION**.

Syntax

- Set transaction parameters of a session.

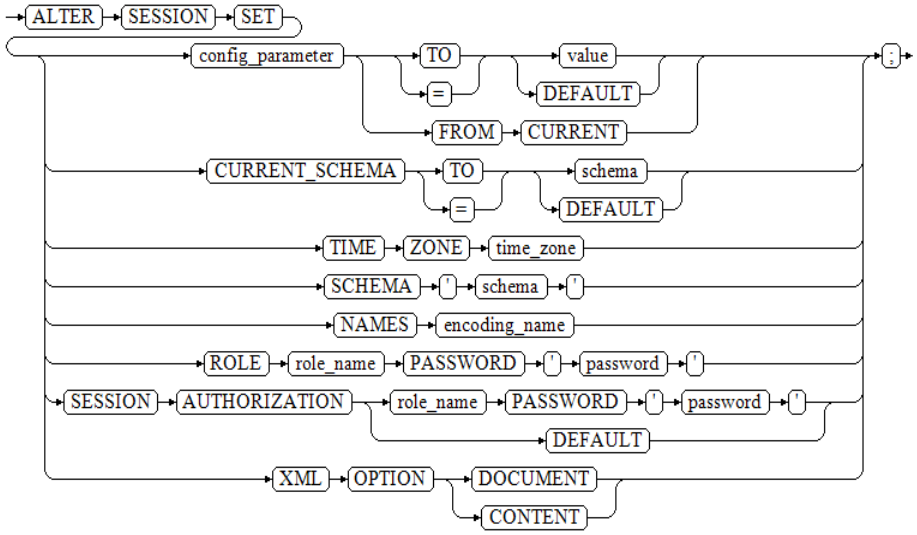
```
ALTER SESSION SET [ SESSION CHARACTERISTICS AS ] TRANSACTION
   { ISOLATION LEVEL { READ COMMITTED | READ UNCOMMITTED } | { READ ONLY  | READ
WRITE } } [, ...] ;
```



- Set other GUC parameters of a session.

```
ALTER SESSION SET
   {{config_parameter { { TO  | =  }  { value | DEFAULT } | FROM CURRENT }}
     | CURRENT_SCHEMA { TO | = } { schema | DEFAULT }
     | TIME ZONE time_zone
     | SCHEMA 'schema'
     | NAMES encoding_name
     | ROLE role_name PASSWORD 'password'
     | SESSION AUTHORIZATION { role_name PASSWORD 'password' | DEFAULT }
     | XML OPTION { DOCUMENT | CONTENT }
   } ;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.



Parameters

- **config_parameter**

  Specifies the name of a configurable GUC parameter. You can use SHOW ALL to view available GUC parameters.

  - **value**

    Specifies a new value for **config_parameter**. It can be a string constant, identifier, number, or comma-separated list.

    - **DEFAULT**
    - **OFF**
    - **RESET**
    - User-specified value: The value must meet the restriction of the modified parameter.

  - **DEFAULT**

    Sets the parameter specified by **config_parameter** to its default value.

  - **FROM CURRENT**

    Assigns the value in the current session to **configuration_parameter**.

- **CURRENT_SCHEMA**

  Specifies the current schema.

  Value range: existing schema names. If the schema name does not exist, the value of **CURRENT_SCHEMA** will be empty.

- **TIME ZONE timezone**

  Specifies the local time zone for the current session.

  Value range: valid local time zones. The corresponding GUC parameter is **TimeZone**. The default value is **PRC**.

- **SCHEMA schema**

  Specifies the schema. Same as **CURRENT_SCHEMA**, the schema here is a string.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **NAMES encoding_name**

  Specifies the client-side encoding. It is equivalent to **set client_encoding to encoding_name**.

  Value range: valid encoding names. The corresponding GUC parameter is **client_encoding**, and the default encoding is **UTF8**.

- **role_name**

  Name of a role.

  Value range: character strings complying with **Identifier Naming Conventions**.

- **password**

  Specifies the password for the role.

  Value range: It must comply with the password naming rules.

- **SESSION AUTHORIZATION**

  Specifies a user identifier for the current session.

- **XML OPTION { DOCUMENT | CONTENT }**

  Specifies the XML parsing mode.

  Value range: **CONTENT** (default value) or **DOCUMENT**.

- **ISOLATION LEVEL**

  Specifies the transaction isolation level, which determines the data that can be read (that is, data visibility) by a transaction when other concurrent transactions exist.

  Value range:

  – **READ COMMITTED** (default): Only committed data is read.

  – **READ UNCOMMITTED**: This isolation level behaves identically to **READ COMMITTED**.

Examples

- Set transaction parameters for a session.

  The keyword ALTER SESSION can be omitted in the example.

```
-- Start a transaction and set the transaction level.
gaussdb=# START TRANSACTION;
gaussdb=# ALTER SESSION SET TRANSACTION READ ONLY;
gaussdb=# END;
```

- Set other GUC parameters for a session.

  The keyword ALTER SESSION can be omitted in the example.

```
-- Create the ds schema.
gaussdb=# CREATE SCHEMA ds;

-- Set the search path of the schema.
gaussdb=# SET SEARCH_PATH TO ds, public;

-- Set the time/date type to the traditional postgres format (date before month).
gaussdb=# SET DATESTYLE TO postgres, dmy;

-- Set the encoding of the current session to UTF8.
gaussdb=# ALTER SESSION SET NAMES 'UTF8';

-- Set the time zone to PST8PDT.
gaussdb=# SET TIME ZONE 'PST8PDT';
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
-- Set the time zone to Europe/Rome.
gaussdb=# SET TIME ZONE 'Europe/Rome';

-- Set the current schema.
gaussdb=# ALTER SESSION SET CURRENT_SCHEMA TO tpcds;

-- Set XML OPTION to DOCUMENT.
gaussdb=# ALTER SESSION SET XML OPTION DOCUMENT;

-- Create the role joe, and set the session role to joe.
gaussdb=# CREATE ROLE joe WITH PASSWORD '********';
gaussdb=# ALTER SESSION SET SESSION AUTHORIZATION joe PASSWORD '********';

-- Switch to the default user.
gaussdb=> ALTER SESSION SET SESSION AUTHORIZATION default;

-- Drop the ds schema.
gaussdb=# DROP SCHEMA ds;

-- Drop joe.
gaussdb=# DROP ROLE joe;
```

SET

1.13.7.32 ALTER SYNONYM

Description

Alters attributes of a synonym.

Precautions

- Currently, only the owner of a synonym can be altered.
- Only system administrators have the permission to alter the owner of a synonym. When separation of duties is enabled, system administrators do not have the permission to alter the owner of a synonym by default.
- The new owner must have the CREATE permission on the schema where the synonym resides.
- PUBLIC synonyms cannot be modified.

Syntax

```
ALTER SYNONYM synonym_name
    OWNER TO new_owner;
```

Parameters

- **synonym_name**

  Specifies the name (optionally schema-qualified) of the synonym to be altered.

  Value range: character strings complying with **Identifier Naming Conventions**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **new_owner**

  Specifies the new owner of the synonym object.

  Value range: a string. It must be a valid username.

Examples

```
-- Create a system administrator.
gaussdb=# CREATE USER sysadmin WITH SYSADMIN PASSWORD '********';

-- Switch the system administrator.
gaussdb=#  \c - sysadmin

-- Create synonym t1.
gaussdb=#  CREATE OR REPLACE SYNONYM t1 FOR ot.t1;

-- Create user u1.
gaussdb=# CREATE USER u1 PASSWORD '********';

-- Assign permissions to the new user.
gaussdb=# GRANT ALL ON SCHEMA sysadmin TO u1;

-- Change the owner of synonym t1 to u1.
gaussdb=# ALTER SYNONYM t1 OWNER TO u1;

-- Delete synonym t1.
gaussdb=# DROP SYNONYM t1;

-- Revoke permissions from user u1.
gaussdb=# REVOKE ALL ON SCHEMA sysadmin FROM u1;

-- Delete user u1.
gaussdb=# DROP USER u1;

-- Switch to the initial user init_user. Replace init_user with the actual initial username.
gaussdb=# \c - init_user

-- Delete user sysadmin.
gaussdb=# DROP USER sysadmin;
```

CREATE SYNONYM and **DROP SYNONYM**

1.13.7.33 ALTER SYSTEM KILL SESSION

Description

ALTER SYSTEM KILL SESSION ends a session.

Syntax

```
ALTER SYSTEM KILL SESSION 'session_sid, serial' [ IMMEDIATE ];
```

Parameters

- **session_sid, serial**

  Specifies the SID and SERIAL of a session (for the format, see the example).

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

You can use the pg_stat_activity system catalog to query the current active threads (see the examples). However, when you run the **ALTER SYSTEM KILL SESSION** command, the threads may have ended.

Value range: SIDs and SERIALs of all sessions that can be queried from the system catalog dv_sessions.

- **IMMEDIATE**

  Specifies that a session will be ended instantly after the statement is executed.

Examples

```
-- Start two sessions, and create a table and start a transaction to insert data in the first session.
gaussdb=# CREATE TABLE tbl_test(id int);
gaussdb=# BEGIN;
gaussdb=# INSERT INTO tbl_test VALUES (1);

-- Query the session information in the second session. If the value of state is idle in transaction, the transaction is waiting to be committed.
gaussdb=# SELECT t1.datname,
       t1.usename,
       t1.pid,
       t2.serial#,
       t1.state
FROM pg_stat_activity t1,
     dv_sessions t2
WHERE t1.query LIKE 'INSERT INTO tbl_test%'
  AND t1.sessionid = t2.sid;
 datname  | usename |       pid       | serial# |        state
----------+---------+-----------------+---------+---------------------
 postgres | omm     | 139802072635136 |       0 | idle in transaction
(1 row)

-- End a session. If the IMMEDIATE parameter is not specified, the session and transactions in the session are forcibly ended.
gaussdb=# ALTER SYSTEM KILL SESSION '139802072635136,0';
 pg_terminate_backend
----------------------
 t
(1 row)

-- Perform the reconnection and query the tbl_test table. The transaction is forcibly ended and the data is rolled back.
gaussdb=# SELECT * FROM tbl_test;
 id
----
(0 rows)

-- Drop the table.
gaussdb=# DROP TABLE tbl_test;
```

1.13.7.34 ALTER TABLE

Description

Alters table attributes, including altering table definition, renaming a table, renaming a specified column in a table, renaming a table constraint, setting table schemas, adding or updating multiple columns, and enabling or disabling row-level security policies.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Precautions

- If the base table is distributed in hash mode and you want to create a primary key index or unique index that does not contain the distribution key of the base table, you need to use a global secondary index (specify the **BY GLOBAL INDEX** column). If you want to create a primary key index or unique index that contains the distribution key of the base table, you need to use an ordinary index (do not specify the **BY GLOBAL INDEX** column). In single-DN deployment mode, you can use either a global secondary index or an ordinary index to create a primary key index or unique index that does not contain the distribution key of the base table. If the base table is not distributed in hash mode, you can only use an ordinary index to create a primary key index or unique index that does not contain the distribution key of the base table. That is, the index key must contain the distribution key of the base table.
- The table owner, users with the ALTER permission on the table, and users with the ALTER ANY TABLE permission are authorized to run the **ALTER TABLE** command. System administrators have this authorization by default. To modify the owner or schema of a table, you must be the table owner or a system administrator. When separation of duties is enabled, you must also be a member of the new owner's role.
- You cannot modify the tablespace of a partitioned table, but you can modify the tablespaces of individual partitions.
- The storage parameter **ORIENTATION** cannot be modified.
- SET SCHEMA does not allow switching to system-internal schemas; it currently supports switching only between user-defined schemas.
- The distribution key (or column) of a table cannot be modified.
- The partition key columns of a partitioned table cannot be changed or the character set cannot be converted.
- The database does not allow adding an auto-increment column or a column with a default value that includes the NEXTVAL() expression.
- The **rowid** and **rowno** system columns cannot be renamed or deleted, their default values cannot be set, and their definitions cannot be modified.
- Row-level security cannot be enabled for foreign tables and temporary tables.
- Constraints cannot be added to system columns.
- Dropping a PRIMARY KEY constraint by name does not remove the NOT NULL constraint. If necessary, drop the NOT NULL constraint manually.
- When JDBC is used, the default value can be set through PrepareStatement.
- When a new column is added using ADD COLUMN, the existing rows associated with that column in the table will receive the default value specified in the DEFAULT clause. However, if no default value is specified, the existing rows will default to **NULL**.
- If the default value of the new column is **NULL**, no full table update will be triggered.
- If a default value is specified for a new column, the following requirements must be met. Otherwise, additional full table update overhead will be generated, affecting online services.
  - The length of the default value does not exceed 128 bytes.
  - The default value does not contain volatile functions. If you are not sure whether it contains volatile functions, check the **provolatile** attribute of

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

the functions in the PG_PROC system catalog. Volatile functions will have a value of **'v'**.

- If you add or modify an ILM policy for a data object and include a row-level expression, you must use only the whitelisted functions (in **Row Expression Function Whitelist**) as the expression.

  NOTE

  Among the functions supported by the row-level expression ON (EXPR) in the ILM policy, the output of some may be influenced by compatibility parameters. For instance, after you set **b_format_version** to **'5.7'** and **b_format_dev_version** to **'s2'** in MySQL-compatible mode, the upper function will be unable to convert data to uppercase as usual.

- The number of table constraints cannot exceed 32,767.
- When performing online DDL operations, reserve sufficient disk space. That is, the remaining space must be the total space of the tables to be operated and the accessories such as indexes on the tables.
- Online DDL operations cannot be executed within a transaction or a stored procedure. If you use the JDBC driver to run multiple SQL statements, a transaction is implicitly started, and these SQL statements cannot be executed together.
- If online DDL execution is canceled, the residual data clearance process starts first. If the execution is canceled again, the clearance process ends and residual data remains.
- Resource contention exists between online DDL operations and user services. Therefore, online DDL operations are not suitable for heavy-traffic scenarios. In scenarios where resources are limited, fine-grained resource control is recommended. Parallel acceleration is not recommended.
- Online DDL operations are not supported in M-compatible databases.
- In the following cases, online DDL operations do not take effect. By default, DDL operations are performed offline. If **ONLINE** is specified, a message is displayed, indicating that the operation is not allowed.
  - A clause contains column_constraint or any of the keywords COMMENT, AUTO_INCREMENT, CHARACTER SET, CHARSET, and COLLATE when you change column types, precisions, and lengths online by using either of the following syntaxes: MODIFY column_name data_type { { [COMMENT 'string'] [...] } |AUTO_INCREMENT } or MODIFY [COLUMN] column_name data_type [CHARACTER SET |CHARSET charset] [{[COLLATE collation] | [column_constraint]} [...]].
  - The following syntax is used to change column types, precisions, or lengths online: CHANGE [COLUMN] column_name new_column_name data_type[CHARACTER SET | CHARSET charset] [{[COLLATE collation] |[column_constraint]} [...]].
  - A column type is changed or converted to the SET data type online.
  - The ALTER TABLE statement contains operations that are not supported by the current online DDL feature. (The supported online DDL operations include changing column type, precision, or length, moving table-level tablespaces, and adding NOT NULL, CHECK, PRIMARY KEY, or UNIQUE constraints.)
  - A table on which online DDL operations (including changing column types, precisions, and lengths, and moving table-level tablespaces) are

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

performed contains GSI, or a statement contains the BY GLOBAL INDEX keyword.

- Online DDL operations do not take effect when they are conducted on database-level, index-level, subpartitioned, segment-page, hash bucket, temporary, or unlogged tables. (Such DDL operations include modifying the column type, precision, and length, moving tablespaces at the table level, and adding the NOT NULL, CHECK, PRIMARY KEY, or UNIQUE constraints.) By default, these DDL operations are executed offline, so a message will indicate that the current DDL statements cannot be executed online.
- Long transactions may block online DDL operations (including changing the column type, precision, and length online, moving table-level tablespaces online, and adding NOT NULL, CHECK, PRIMARY KEY, and UNIQUE constraints online). Therefore, you are advised not to perform online DDL operations when long transactions exist.
- At the later stage of execution, online DDL operations (including changing the column type, precision, or length, moving table-level tablespaces, and adding NOT NULL, CHECK, PRIMARY KEY, or UNIQUE constraints) of this feature will block DQL and DML operations. Therefore, for a service model with a timeout error reporting mechanism, requests may fail due to blocking. If such an issue occurs, you can retry the requests.
- During the execution of online DDL statements, avoid executing other DDL statements concurrently. If exceptions like no response or error reporting occur, reconnect to the client and try again.
- During the upgrade from a version that does not support the online DDL operations to a version that supports it, the operations (including changing the column type, precision, or length, moving table-level tablespaces, and adding NOT NULL, CHECK, PRIMARY KEY, or UNIQUE constraints) are not supported because they are under observation. By default, DDL operations are performed offline, and a message is displayed indicating that online DDL operations are not supported during the upgrade.
- During the execution of an online DDL operation for altering table partitions (including changing the column type, precision, or length, moving table-level tablespaces, and adding NOT NULL, CHECK, PRIMARY KEY, or UNIQUE constraints), a specific schema is generated. The schema naming format is online$$ddl$$[hash value of (*Name of the schema where the table is located Table name*)].
  - By default, the owner of the schema is the initial user. You are advised not to operate the schema during online DDL operations; otherwise, the online DDL operations may be terminated and an unknown error may occur. You are advised not to query tables in the schema. By default, using gs_dump will not export the schema.
  - Do not create a schema with the prefix online$$. Otherwise, an error message is displayed. If a schema with the same name already exists, online DDL operations will not take effect. By default, DDL operations are executed offline, and a message is displayed indicating that the current DDL statement cannot be executed online due to a schema name conflict.
- If an online DDL operation (including modifying the column type, precision, or length, or moving table-level tablespaces) fails or an online DDL operation (adding NOT NULL, CHECK, PRIMARY KEY, or UNIQUE constraints) is

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

performed, the table's storage space may bloat significantly. The bloat degree is proportional to the DDL statement execution duration and the number of concurrent write operations. You are advised not to perform online DDL operations when long transactions exist.

- If online DDL operations include adding NOT NULL, CHECK, PRIMARY KEY, or UNIQUE constraints, the error reported when data that violates the constraints may be different from that for offline DDL operations.
- In an online DDL operation for adding a PRIMARY KEY or UNIQUE constraint, if the constraint contains an expression, the DDL operation is performed offline by default. If the ONLINE keyword exists, a notice is displayed, indicating that the DDL operation cannot be performed online.
- Online DDL operations (including changing the column type, precision, or length, moving table-level tablespaces, and adding NOT NULL, CHECK, PRIMARY KEY, or UNIQUE constraints) inherit the usage restrictions from **CREATE TABLE LIKE**.
- Avoid performing online DDL operations and scaling operations simultaneously. Otherwise, such operations may fail.

Syntax

- Modify the definition of a table.

```
ALTER TABLE  [ OFFLINE | [ ONLINE [ WITH ( { online_parameter = value } [, ... ] ) ] ] ] [ IF EXISTS ]
 { table_name [*] | ONLY table_name | ONLY ( table_name ) }
    action [, ... ];

ALTER TABLE  [ OFFLINE | [ ONLINE [ WITH ( { online_parameter = value } [, ... ] ) ] ] ] [ IF EXISTS ]
table_name
    ADD ( { column_name data_type [ COLLATE collation ] [ column_constraint [ ... ] ] } [, ... ] );

ALTER TABLE  [ OFFLINE | [ ONLINE [ WITH ( { online_parameter = value } [, ... ] ) ] ] ] [ IF EXISTS ]
table_name
    MODIFY ( { column_name data_type | column_name [ CONSTRAINT constraint_name ] NOT NULL
[ ENABLE ] | column_name [ CONSTRAINT constraint_name ] NULL } [, ... ] );

ALTER TABLE  [ OFFLINE | [ ONLINE [ WITH ( { online_parameter = value } [, ... ] ) ] ] ] [ IF EXISTS ]
table_name
    RENAME [TO | AS | = ] new_table_name;
ALTER TABLE  [ OFFLINE | [ ONLINE [ WITH ( { online_parameter = value } [, ... ] ) ] ] ] [ IF EXISTS ]
    { table_name [*] | ONLY table_name | ONLY ( table_name ) }
    RENAME [ COLUMN ] column_name TO new_column_name;

ALTER TABLE  [ OFFLINE | [ ONLINE [ WITH ( { online_parameter = value } [, ... ] ) ] ] ] [ IF EXISTS ]
    { table_name [*] | ONLY table_name | ONLY ( table_name ) }
    RENAME CONSTRAINT constraint_name TO new_constraint_name;

ALTER TABLE  [ OFFLINE | [ ONLINE [ WITH ( { online_parameter = value } [, ... ] ) ] ] ] [ IF EXISTS ]
table_name
    SET SCHEMA new_schema;

ALTER TABLE  [ OFFLINE | [ ONLINE [ WITH ( { online_parameter = value } [, ... ] ) ] ] ] [ IF EXISTS ]
table_name
    GSIWAITALL;
```

  The table operation ACTION is as follows:

```
{ distribute_clause
    [ DISTRIBUTE BY { REPLICATION | HASH ( column_name [,...] )
    | RANGE ( column_name [,...] ) { SLICE REFERENCES tablename | ( slice_less_than_item [,...] )
    | ( slice_start_end_item [,...] ) }
    | LIST ( column_name [,...] ) { SLICE REFERENCES tablename | ( slice_values_item [,...] ) }
    } ]
    [ TO { GROUP groupname | NODE ( nodename [,...] ) } ]
column_clause
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
    | ADD table_constraint [ NOT VALID ]
    | ADD table_constraint_using_index
    | VALIDATE CONSTRAINT constraint_name
    | DROP CONSTRAINT [ IF EXISTS ]  constraint_name [ RESTRICT | CASCADE ]

    | NOCOLVIEW }
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- **ADD table_constraint [NOT VALID]**

  Adds a table constraint.

- **ADD table_constraint_using_index**

  Adds a PRIMARY KEY constraint or UNIQUE constraint to a table based on the existing unique index. Currently, an existing GSI index cannot be used to perform the ADD table_constraint_using_index operation on a table.

- **VALIDATE CONSTRAINT constraint_name**

  Validates a CHECK constraint created with the **NOT VALID** option, and scans the entire table to ensure that all rows meet the constraint. If a constraint is marked as valid, the syntax will not alter its behavior.

- **DROP CONSTRAINT [IF EXISTS] constraint_name [RESTRICT | CASCADE]**

  Drops a table constraint.

- **DROP PRIMARY KEY**

  Drops a PRIMARY KEY constraint from a table. This syntax is supported only in MySQL-compatible and ORA-compatible modes.

- **CLUSTER ON index_name**

  Selects the default index for CLUSTER operations. It does not actually re-cluster the table.

- **SET WITHOUT CLUSTER**

  Deletes the most recently used CLUSTER index from the table. This syntax affects CLUSTER operations where the default index is not declared.

- **SET WITH ROWID**

  Adds the system columns **rowid** and **rowno** to a table and sets the storage option **hasrowid** to **on** for the table.

  - This syntax cannot be used for system catalogs, local temporary tables, global temporary tables, unlogged tables, foreign tables, hash bucket tables, or replication tables.
  - This syntax cannot be used for tables that have the **OID** system column or the **gs_tuple_uid** system column enabled, that is, tables with the **oids** storage option (or the WITH OIDS clause) or the **hasuids** storage option specified.
  - This syntax cannot be used for tables that contain columns named **rowid** or **rowno**.
  - This syntax is valid only in ORA-compatible mode.
  - After the SET WITH ROWID operation is performed on compressed data, the data is automatically decompressed.

- **SET ({storage_parameter = value} [, ...])**

  Changes one or more storage parameters for the table.

  If the value of **table_name** is an index name, **ACTIVE_PAGES** specifies the number of index pages, which may be less than the actual number of physical file pages and can be used for optimizer optimization. Currently, this parameter takes effect only on the local indexes of Ustore partitioned tables and will be updated by ANALYZE and VACUUM (including AUTOVACUUM). You are advised not to manually set this parameter because it is invalid in distributed mode.

- **RESET (storage_parameter [, ...])**

  Resets one or more storage parameters to their defaults. As with SET, re-altering a table based on different parameters might be needed to meet the expectations.

- **OWNER TO new_owner**

  Changes the owner of a table, sequence, or view to the specified user.

  The following operations are not allowed. If you perform them, an error will be reported.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

1. A SYSADMIN changes the owner of the table to the initial user.

2. In separation-of-duties mode, a SYSADMIN changes the owner of a table to a CREATEROLE or an AUDITADMIN.

- **SET TABLESPACE new_tablespace**

  Changes the table's tablespace to the specified tablespace and moves the data files associated with the table to the specified tablespace. Indexes on the table are not moved; the index's tablespace can be modified using the **SET TABLESPACE** option of the ALTER INDEX syntax.

- **DISTRIBUTE BY { REPLICATION | HASH (column_name [, ...]) | RANGE (column_name [, ...]) { SLICE REFERENCES tablename | (slice_less_than_item [, ...]) | (slice_start_end_item [, ...]) } | LIST (column_name [, ...]) { SLICE REFERENCES tablename | (slice_values_item [, ...]) }}**

  Specifies how a table is distributed or replicated among nodes. For details, see the description of DISTRIBUTE BY in **CREATE TABLE**.

- **TO { GROUP groupname | NODE (nodename [, ...]) }**

  Only available in extended mode (when GUC parameter **support_extended_features** is **on**). Exercise caution when enabling the mode. It is mainly used for internal scale-out tools. You are advised not to use the mode. This command only modifies the logical mapping relationship of the table distribution nodes and does not migrate the table's metadata and data on the DN.

- **ADD NODE (nodename [, ...])**

  This syntax is primarily intended for internal scale-out tools. You are advised not to use it directly.

- **DELETE NODE (nodename [, ...])**

  This syntax is primarily intended for internal scale-in tools. You are advised not to use it directly.

- **UPDATE SLICE LIKE table_name**

  This syntax is primarily intended for internal scale-in and scale-out tools. You are advised not to use it directly.

- **DISABLE TRIGGER { trigger_name | ALL | USER }**

  Disables a specified trigger. **trigger_name** specifies a trigger to be disabled. **ALL** disables all triggers, and **USER** disables only user triggers (excluding internally generated constraint triggers, such as those for deferrable unique and exclusion constraints).

  Exercise caution when using this functionality. Once a trigger is disabled, the integrity of the expected constraints cannot be ensured.

- **ENABLE TRIGGER { trigger_name | ALL | USER }**

  Enables the specified trigger. **trigger_name** specifies a trigger to be enabled. **ALL** enables all triggers, and **USER** enables only user triggers.

- **ENABLE REPLICA TRIGGER trigger_name**

  The trigger mechanism is affected by the GUC parameter **session_replication_role**. When a session is in "replica" mode, only triggers configured with ENABLE REPLICA are triggered. When a session is in the "origin" (default) or "local" mode, only triggers that are not configured with ENABLE REPLICA are triggered.

- **ENABLE ALWAYS TRIGGER trigger_name**

  Specifies a trigger as **ENABLE ALWAYS TRIGGER**, so that it will be triggered consistently despite the current setting of **session_replication_role** in the **replica** mode.

- **{ DISABLE | ENABLE } [REPLICA | ALWAYS] RULE**

  Disables or enables a specified rule.

  - **Disable [Replica | Always] Rule**: disables a specified rule.
  - **ENABLE REPLICA**: The session is started only when the session is in **replica** mode.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **ENABLE ALWAYS**: specifies a trigger as **ENABLE ALWAYS TRIGGER**, so that it will be triggered consistently despite the current setting of **session_replication_role** in the **replica** mode.

The ON SELECT rule cannot be disabled because it is related to the view implementation. If a rewriting rule is configured for a table, disabled rules are visible in the system and are disabled only during query rewriting. The rule triggering mechanism is simultaneously affected by the configuration variable **session_replication_role**.

- **{ DISABLE | ENABLE } ROW LEVEL SECURITY**

  Enables or disables row-level security for a table. The setting status will be updated to PG_CLASS.RELOPTIONS on each execution node to ensure that the system catalog metadata is consistent.

  If row-level security is enabled for a data table but no row-level security policy is defined, the row-level access to the data table is not affected. If row-level security for a table is disabled, the row-level access to the table is not affected even if a row-level security policy has been defined. For details, see **CREATE ROW LEVEL SECURITY POLICY**.

- **{NO FORCE|FORCE} ROW LEVEL SECURITY**

  Forcibly enables or disables row-level security for a table. The setting status will be updated to the PG_CLASS.RELOPTIONS of each execution node synchronously to ensure the metadata consistency of system catalogs.

  By default, a table owner is not affected by row-level security feature. However, if the feature is forcibly enabled for a table, the table owner (unless this user is a system administrator) will be affected.

- **ENCRYPTION KEY ROTATION**

  Rotation of the transparent data encryption key.

  - The data encryption key of a table can be rotated only when the database's TDE feature is enabled and the table's **enable_tde** is set to **on**.
  - After the transparent data encryption key rotation operation, the system automatically requests KMS to create a key. Data encrypted with the old key is still decrypted using the old key, while newly written data requires decryption with the new key. To ensure the security of encrypted data, you can periodically update the key based on the amount of new data in the encrypted table.

- **REPLICA IDENTITY { DEFAULT | USING INDEX index_name | FULL | NOTHING }**

  Specifies the record level of old tuples in UPDATE and DELETE statements on a table in logical replication scenarios.

  - **DEFAULT**: records the old value of the primary key column. If there is no primary key, **DEFAULT** does not record the old value.
  - **USING INDEX**: records the old values of columns covered by **index_name** (columns specified as **NOT NULL**), only including unique, global, and final values.
  - **FULL**: records the old values of all columns in the row.
  - **NOTHING**: does not record information in old rows.

  In logical replication scenarios, when the UPDATE and DELETE statements of a table are parsed, the parsed old tuples consist of the information recorded. For tables with primary keys, this option can be set to **DEFAULT** or **FULL**. For a table without a primary key, set this parameter to **FULL**. Otherwise, the old tuple will be parsed as empty during decoding. In general scenarios, you are advised not to set this parameter to **NOTHING**, as old tuples will always be parsed as empty. You are advised to define PRIMARY KEY or UNIQUE constraints for user tables to ensure deterministic replay. Otherwise, SQL statement replay may modify multiple rows, compromising data accuracy. For a Ustore table, setting **NOTHING** has no effect; the actual outcome is the same as setting **FULL**. For tables without a primary key, setting **DEFAULT** records all columns in the row.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **AUTO_INCREMENT [=] value**

  Sets the next increment of the auto-increment column.

  - This syntax takes effect only when **sql_compatibility** is set to **'MYSQL'**.
  - The configured **value** takes effect only when it is greater than the current value of the auto-increment counter and must be a non-negative number less than $2^{127} - 1$.

- **[[DEFAULT] CHARACTER SET | CHARSET [=] default_charset] [[DEFAULT] COLLATE [=] default_collation]**

  Modifies the character set and collation of a table to the default ones. The modification does not affect existing columns in the table.

- **ILM ADD POLICY ROW STORE COMPRESS ADVANCED [MEDIUM | HIGH] ROW AFTER n { day | days | month | months | year | years } OF NO MODIFICATION [ON (EXPR)]**

  Adds a specified ILM policy to a table. A complete ILM policy comprises ILM actions and ILM conditions. An ILM action defines a specific data compression or movement behavior, while an ILM condition defines a data compression or movement behavior that triggers the ILM action. The ILM condition is a row-level condition, applying to each row in a table. EXPR supports only table columns and the whitelisted functions. For details, see **Row Expression Function Whitelist**. Adding an ILM policy between the flashback point and the current point does not affect the flashback function.

- **[MODIFY { PARTITION partition_name | SUBPARTITION subpartition_name }] ILM { ENABLE | DISABLE | DELETE } POLICY policy_name**

  Modifies an ILM policy of a table (partition or subpartition). **policy_name** is the POLICY_NAME information queried from the system view GS_ADM_ILMOBJECTS or GS_MY_ILMOBJECTS.

- **[MODIFY { PARTITION partition_name | SUBPARTITION subpartition_name }] ILM { ENABLE_ALL | DISABLE_ALL | DELETE_ALL}**

  Modifies all ILM policies of a table (partition or subpartition).

– column_clause is as follows:

```
ADD [ COLUMN ] [ IF NOT EXISTS ] column_name data_type [ CHARACTER SET | CHARSET
charset ] [ COLLATE collation ] [ column_constraint [ ... ] ]
| MODIFY column_name data_type
| MODIFY column_name [ CONSTRAINT constraint_name ] NOT NULL [ ENABLE ]
| MODIFY column_name [ CONSTRAINT constraint_name ] NULL
| MODIFY column_name data_type { { [ COMMENT 'string' ] [ ... ] }
| DROP [ COLUMN ] [ IF EXISTS ] column_name [ RESTRICT | CASCADE ]
| ALTER [ COLUMN ] column_name [ SET DATA ] TYPE data_type [ ENCRYPTED WITH
( COLUMN_ENCRYPTION_KEY = column_encryption_key, ENCRYPTION_TYPE =
encryption_type_value ) ] [ COLLATE collation ] [ USING expression ]
| ALTER [ COLUMN ] column_name { SET DEFAULT expression | DROP DEFAULT }
| ALTER [ COLUMN ] column_name { SET | DROP } NOT NULL
| ALTER [ COLUMN ] column_name SET STATISTICS [PERCENT] integer
| ADD STATISTICS (( column_1_name, column_2_name [, ...] ))
| DELETE STATISTICS (( column_1_name, column_2_name [, ...] ))
| DISABLE STATISTICS (( column_1_name, column_2_name [, ...] ))
| ENABLE STATISTICS (( column_1_name, column_2_name [, ...] ))
| ALTER [ COLUMN ] column_name SET ( {attribute_option = value} [, ... ] )
| ALTER [ COLUMN ] column_name RESET ( attribute_option [, ... ] )
| ALTER [ COLUMN ] column_name SET STORAGE { PLAIN | EXTERNAL | EXTENDED | MAIN }
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- **ADD [COLUMN] [IF NOT EXISTS] column_name data_type [CHARACTER SET | CHARSET [=] charset] [COLLATE collation] [column_constraint [...]]**

  Adds a column to a table. When a new column is added using ADD COLUMN, the existing rows associated with that column in the table will receive the default value of the new column. (However, if the DEFAULT clause is not declared, the existing rows will default to **NULL**.) When IF NOT EXISTS is specified and columns with the same name exist, a notice is returned, indicating that the column already exists. When IF NOT EXISTS is not specified and columns with the same name exist, an error is returned.

- **ADD ({ column_name data_type } [, ...])**

  Adds multiple columns to a table.

- **MODIFY ({ column_name data_type | column_name [CONSTRAINT constraint_name] NOT NULL [ENABLE] | column_name [CONSTRAINT constraint_name] NULL } [, ...])**

  Modifies the data type of an existing column in a table. Running this command will clear the statistics of the specified column. It is advisable to re-collect the statistics after the modification.

- **MODIFY column_name data_type { { [COMMENT 'string'] [...] }**
  - Replaces the definition of existing column in a table with a new definition. The indexes and independent object constraints, such as primary keys, unique key and CHECK constraints in the previous column are not deleted.
  - This syntax can be used only in MySQL-compatible databases (**sql_compatibility = 'MYSQL'**).
  - This syntax cannot modify foreign tables or encrypted columns.
  - This syntax cannot modify the data types or collations of partition key columns, or the data types or collations of columns referenced by rules or materialized views.
  - If a column referenced by a generated column undergoes a change in its data type or collation, data in the generated column will be regenerated.
  - If some objects (such as indexes, independent object constraints, views, triggers, and row-level security policies) depend on a modified column, these objects are rebuilt during column modification. If the definition of the modified column violates the constraints of this type of object, the modification fails. For example, the data type of the column that is used as the view result column cannot be modified. Evaluate the impact before making modifications.
  - In HASH, LIST, and RANGE distribution scenarios, the data type and comments of distribution keys cannot be modified.
  - If a modified column is called by some objects (such as user-defined functions and stored procedures), the modified column does not process these objects. After the column names are modified, these objects may be unavailable. Please evaluate the impact before modification.
  - This clause's syntax partially matches the MODIFY column_name data_type syntax from the previous clause but has different semantics. When the GUC parameter b_format_behavior_compat_options includes enable_modify_column, the system applies this clause's semantics.
  - Running this command will clear the statistics of the specified column. It is advisable to re-collect the statistics after the modification.

- **DROP [COLUMN] [IF EXISTS] column_name [RESTRICT | CASCADE]**

  Drops a column from a table. Indexes and constraints related to the column are automatically dropped. If an object not belonging to the table depends on the column (for example, view), CASCADE must be specified.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

The DROP COLUMN statement does not physically remove the column, but simply makes it invisible to SQL operations. Subsequent INSERT and UPDATE operations on the table will store a **NULL** value for the column. Therefore, dropping a column is a quick process, but it does not immediately free up the disk space occupied by the dropped column (because the space has not been recycled yet). The space will be recycled when VACUUM is executed.

- **ALTER [COLUMN] column_name [SET DATA] TYPE data_type [ENCRYPTED WITH (COLUMN_ENCRYPTION_KEY = column_encryption_key, ENCRYPTION_TYPE = encryption_type_value)] [COLLATE collation] [USING expression]**

  Modifies the type of a column in a table. Indexes and simple table constraints on the column will automatically use the new data type by reparsing the originally supplied expression.

  If the original data type of a column and the modified data type are binary compatible, you do not need to rewrite the entire table when running this statement. In other scenarios, the entire table is rewritten. You can check whether the original type and target type are binary compatible in the PG_CAST system catalog. If **castmethod** is **b**, they are binary compatible. For example, if the data type of the source table is text and is converted to int, table rewriting is triggered. If it is converted to clob, table rewriting is not triggered. If table rewriting is triggered, the deleted space on the table is recycled immediately.

  Running this command will clear the statistics of the specified column. It is advisable to re-collect the statistics after the modification.

  Encrypted columns cannot be modified.

- **ALTER [COLUMN] column_name { SET DEFAULT expression | DROP DEFAULT }**

  Sets or removes the default value for a column. This default applies only to subsequent INSERT operations and does not affect existing rows in the table. Defaults can also be created for views, in which case they are inserted into INSERT statements on the view before the view's ON INSERT rule is applied.

- **ALTER [COLUMN] column_name { SET | DROP } NOT NULL**

  Marks a column as allowing or rejecting NULL values. You can only use SET NOT NULL when the column contains no null values.

- **ALTER [COLUMN] column_name SET STATISTICS [PERCENT] integer**

  Specifies the per-column statistics-collection target for subsequent ANALYZE operations. The target can be set in the range from 0 to 10000. Set it to **–1** to revert to using the default system statistics target.

- **{ADD | DELETE} STATISTICS ((column_1_name, column_2_name [, ...]))**

  Adds or deletes the declaration of collecting multi-column statistics to collect multi-column statistics as needed when ANALYZE is performed for a table or a database. The statistics about a maximum of 32 columns can be collected at a time. You are not allowed to add or delete such declaration for system catalogs or foreign tables.

- **{DISABLE | ENABLE} STATISTICS ((column_1_name, column_2_name [, ...]))**

  Sets the status of multi-column statistics. If multi-column statistics are disabled, related statistics are not collected, and the optimizer does not use the multi-column statistics during plan generation.

- **ALTER [COLUMN] column_name SET ({attribute_option = value} [, ...])**

  ALTER [COLUMN] column_name RESET (attribute_option [, ...])

  Sets or resets per-attribute options.

  Currently, the only defined per-attribute options are **n_distinct** and **n_distinct_inherited**. **n_distinct** affects statistics of a table, while **n_distinct_inherited** affects the statistics of the table and its subtables.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Currently, only **SET/RESET n_distinct** is supported, and **SET/RESET n_distinct_inherited** is forbidden.

- **ALTER [COLUMN] column_name SET STORAGE { PLAIN | EXTERNAL | EXTENDED | MAIN }**

  Sets the storage mode for a column. It specifies whether this column is held inline or in an attached table, and whether the data should be compressed. SET STORAGE itself does not change anything in the table. It sets the strategy to be pursued during future table updates.

- **column_constraint**:

```
[ CONSTRAINT constraint_name ]
  { NOT NULL |
    NULL |
    CHECK ( expression ) |
    DEFAULT default_expr |
    ON UPDATE update_expr |
    AUTO_INCREMENT |
    COMMENT 'string' |
    COLVIEW |
    NOCOLVIEW |
    UNIQUE [KEY] index_parameters |
    PRIMARY KEY index_parameters |
    ENCRYPTED WITH ( COLUMN_ENCRYPTION_KEY = column_encryption_key,
ENCRYPTION_TYPE = encryption_type_value ) |
    REFERENCES reftable [ ( refcolumn ) ] [ MATCH FULL | MATCH PARTIAL | MATCH
SIMPLE ]
      [ ON DELETE action ] [ ON UPDATE action ] }
  [ DEFERRABLE | NOT DEFERRABLE ] [ INITIALLY DEFERRED | INITIALLY IMMEDIATE ]
```

  - **index_parameters**:

```
[ WITH ( {storage_parameter = value} [, ... ] ) ]
  [ USING INDEX TABLESPACE tablespace_name ]
```

  - **update_expr**:

```
{ CURRENT_TIMESTAMP | LOCALTIMESTAMP | NOW() }
```

- **table_constraint_using_index** used to add the PRIMARY KEY constraint or UNIQUE constraint based on the unique index is as follows:

```
[ CONSTRAINT constraint_name ]
  { UNIQUE | PRIMARY KEY } USING INDEX index_name
  [ DEFERRABLE | NOT DEFERRABLE ] [ INITIALLY DEFERRED | INITIALLY IMMEDIATE ]
```

- **table_constraint**:

```
[ CONSTRAINT [ constraint_name ] ]
  { CHECK ( expression ) |
    UNIQUE [ idx_name ] [ USING method ] ( { { column_name [ ( length ) ] | ( expression ) }
[ ASC | DESC ] } [, ... ] ) index_parameters |
    PRIMARY KEY [ USING method ] ( { column_name [ ASC | DESC ] } [, ... ] )
index_parameters |
    FOREIGN KEY [ idx_name ] ( column_name [, ... ] ) REFERENCES reftable [ ( refcolumn
[, ... ] ) ] }
  [ DEFERRABLE | NOT DEFERRABLE ] [ INITIALLY DEFERRED | INITIALLY IMMEDIATE ]
  { [ COMMENT 'string' ] [ ... ] }
```

index_parameters:

```
[ WITH ( {storage_parameter = value} [, ... ] ) ]
  [ USING INDEX TABLESPACE tablespace_name ][BY GLOBAL INDEX]
```

NOTE

If **index_parameters** is set to **BY GLOBAL INDEX**, the global secondary index is used to create constraints.

- Rename a table. The renaming does not affect stored data.

```
ALTER TABLE [ IF EXISTS ] table_name
  RENAME [ TO | AS | = ] new_table_name;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

If you specify this parameter in a version 5.7 MySQL-compatible database (**sql_compatibility** set to **'MYSQL'**, **b_format_version** set to **'5.7'**, and **b_format_dev_version** set to **'s2'**), the following situations may occur:

- If the character string corresponding to the new table name starts with "#mysql50#" and is followed by other characters, "#mysql50#" will be ignored.
- If the old and new table names are the same, no error is reported.

- Rename the specified column in the table.

```
ALTER TABLE [ IF EXISTS ] { table_name [*] | ONLY table_name | ONLY ( table_name ) }
    RENAME [ COLUMN ] column_name TO new_column_name;
```

- Rename the constraint of the table.

```
ALTER TABLE [ IF EXISTS ] { table_name [*] | ONLY table_name | ONLY ( table_name ) }
    RENAME CONSTRAINT constraint_name TO new_constraint_name;
```

- Set the schema of a table.

```
ALTER TABLE [ IF EXISTS ] table_name
    SET SCHEMA new_schema;
```

NOTE

- This form moves the table into another schema. Associated indexes and constraints are moved as well. Currently, modifying schemas for sequences is not supported. If the table has sequences, drop and rebuild them, or remove the ownership between the table and sequences to successfully modify the table's schema.
- To modify the schema of a table, you must have the CREATE permission on the new schema. To add the table as a new child of a parent table, you must own the parent table as well. To alter the owner, you must also be a direct or indirect member of the new owning role, and that member must have the CREATE permission on the table's schema. These restrictions ensure that you can only rebuild or drop the table. However, a system administrator can alter all permissions of any table anyway.
- All the forms of ALTER TABLE that act on a single table, except RENAME and SET SCHEMA, can be combined into a list of multiple modifications to be applied together. For example, it is possible to add several columns or modify the type of several columns in a single command. This is particularly useful with large tables, since only one pass over the tables need to be made.
- Adding a CHECK or NOT NULL constraint will scan the table to validate that existing rows meet the constraint.
- Adding a column with a non-null default or changing the type of an existing column will rewrite the entire table. Rewriting a large table may take much time and temporarily needs doubled disk space.

- Update columns.

```
ALTER TABLE [ IF EXISTS ] table_name
    MODIFY ( { column_name data_type | column_name [ CONSTRAINT constraint_name ] NOT NULL
[ ENABLE ] | column_name [ CONSTRAINT constraint_name ] NULL } [, ...] );
```

- Commit all DML transactions in the table when the SQL statement is executed.

```
ALTER TABLE [ IF EXISTS ] table_name GSIWAITALL IN lock_mode MODE;
```

NOTE

This syntax is primarily called by the internal CREATE GLOBAL INDEX CONCURRENTLY/REINDEX INDEX CONCURRENTLY to synchronize lock waits during online creation of GSIs. Based on the given lock level, you can obtain the list of transactions that conflict with that lock level on each node and wait for those transactions to complete. You are advised not to use it, as doing so may trigger an error.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameters

- **ONLINE | OFFLINE**

  Controls whether to enable online DDL operations.

  The keywords ONLINE and OFFLINE are used.

  – ONLINE: DDL operations are executed online. In this case, if the ALTER TABLE statement contains a scenario that is not supported by the current DDL feature, the DDL operations are executed offline and a notice is displayed, indicating that the ONLINE keyword is ignored.

  – OFFLINE: DDL operations are executed offline.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- Whether the data meets the data type conversion, length modification, or constraint requirements is checked during online DDL operations (including changing the column type, precision, and length, and adding NOT NULL, CHECK, PRIMARY KEY, and UNIQUE constraints). If the data does not meet the requirements, an error is reported during DDL operations. Online DDL operations support concurrent DML operations. Concurrent DML operations may delete data that does not meet conversion requirements or violates constraints, but an error may be still reported for the DDL operations.

  For example, when online DDL scans a table to change the column type, if the data of tuple A in the table does not meet data conversion requirements, an error is reported immediately when the online DDL transaction scans tuple A. At the same time, if tuple A is deleted by a parallel transaction DELETE after tuple A has been scanned by an online DDL operation, tuple A is not considered as deleted.
- Online DDL error troubleshooting: The system automatically creates a temporary schema as the DDL implementation tool and sets the table to the **append_mode** state during online DDL operations (including changing the column type, precision, and length, and adding NOT NULL, CHECK, PRIMARY KEY, and UNIQUE constraints). If the online DDL execution is complete, the temporary mode is automatically cleared and restored. Automatic cleanup may fail due to reasons such as lock timeout. In this case, manual cleanup is required. If a severe fault occurs, such as FATAL, PANIC, database fault, or node disconnection, the created temporary schema and table appending status may remain. In this case, you need to manually clear and restore the temporary schema and table. The scenarios are as follows:
  - Canceling online DDL operations: If you cancel online DDL operations during the execution, the system automatically clears the data. If the execution is canceled, the residual data clearance process starts first. If the execution is canceled again, the clearance process ends and residual data remains.
  - Operation error: If an error needs to be reported during the execution of a DDL command, for example, type conversion fails or length modification damages data, the system reports an error and automatically clears the data.
  - Major faults:
    1. Breakdown of a distributed system with one primary node and no standby node: If a CN or DN breaks down, you can manually clear the data using **online_ddl_cleanup()**, or the data will be automatically cleared when you run online DDL operations or online VACUUM FULL next time.
    2. Breakdown of a distributed system with one primary node and multiple standby nodes:
       - Breakdown of the CN where DDL operations are performed: You can manually clear the data using **online_ddl_cleanup()**, or the data will be automatically cleared when you run online DDL operations or online VACUUM FULL next time.
       - A CN where no DDL operation is executed is disconnected and breaks down in a distributed system with one primary node and multiple standby nodes and HA switchover. You need to wait until the switchover is complete and the cluster recovers (online DDL operation waits for 60s). You can retry up to three times. If the cluster recovers, you do not need to manually clear the fault. If the cluster fails to recover, you need to manually clear the fault using **online_ddl_cleanup()** after the cluster becomes normal. If the cluster is abnormal, retry may fail. In this case, you need to manually clear the fault.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

    - Adding PRIMARY KEY and UNIQUE constraints online: If an exception (for example, manual cancellation, duplicate unique index key values, insufficient resources, thread startup failure, or lock timeout) occurs during online index creation, the index fails to be created online. In this case, residual indexes and temporary tables may exist, occupying system resources. For details, see **CONCURRENTLY** in **CREATE INDEX**.
  - You are advised not to call **online_ddl_cleanup()** during online DDL execution. Otherwise, the online DDL operations may be terminated or an unknown error may occur.
  - When the column char type extension is modified online, the underlying data is not modified and rewritten. After online DDL operations, the underlying storage of existing data still retains the old length, and the underlying storage of new and modified data caused by DML operations complies with the extended length.

- **online_parameter**

  Specifies the online DDL option when the ONLINE keyword is specified. If the ONLINE keyword is not specified or online DDL conditions are not met, this parameter does not take effect.

  Value range:

  – **parallel_threads**: specifies the number of threads when parallelism is enabled. The value is an integer from 1 to 32, with **1** being the default.

    ▪ When **parallel_threads** is set to a value greater than **1**, multiple threads are enabled and the number of threads is specified.

    ▪ If **parallel_threads** is not set or is set to **1**, multi-thread acceleration is disabled.

      When a user enables resource and workload management, for example, I/O resource management (for example, **io_limits** > **0** or **io_priority** = **high**/**medium**/**low**), **parallel_threads** ignores resource and workload management under the user or session. In addition, a notice is displayed, indicating that the current resource and workload management is invalid and multi-thread acceleration is enabled. The multi-thread execution process of online DDL operations actually follows the resource and workload management of the initial user.

    ▪ This parameter can be used together with **parallel_workers** for acceleration. In this scenario, **parallel_workers** determines the maximum number of parallel threads within an index, while **parallel_threads** determines the maximum number of parallel threads between indexes.

  – **max_catchup_times**: specifies the maximum number of online DDL catchups to prevent long online DDL execution time. The value is an integer from 1 to *INT_MAX*, with **50** being the default.

    ▪ Online DDL execution records the DML incremental data generated during data reconstruction to a temporary table and performs multiple cyclic catchups to reconstruct the incremental data. If the amount of concurrent DML data is too large, online DDL catchup fails. To prevent this problem, you can set this parameter to limit the number of catchups.

  – **last_catchup_threshold**: specifies the upper limit of the time for triggering the last catchup. After a catchup round is complete, if the

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

duration of this round is less than the threshold, the last round of catchup and switchover is triggered. Value range: [1000,1200000] (unit: ms). The default value is **5000**.

- **online_ddl_lockwait_timeout**: specifies the lock wait timeout interval for online DDL operations. If the thread waiting for the lock fails to obtain the lock within the specified time, a lock timeout error is reported. When the **CANCEL** mode is used to obtain the lock, the actual timeout interval is twice the value of this parameter. Value range: [1,1200000] (unit: ms). The default value is **10000**.
- **lockwait_interval**: indicates the lock wait increment, that is, the retry interval after the lock wait times out. If the lock wait times out in the current round, the system waits for the period specified by this parameter and then attempts to obtain the lock in the next round. Value range: [0,300] (unit: seconds). The default value is **5**.
- **trylock_threshold**: indicates the maximum number of lock wait attempts. It must be used together with **enable_cancel**. If the lock cannot be obtained due to lock wait timeout after the maximum number of attempts is reached, the **CANCEL** mode will be used for the next attempt. If **enable_cancel** is not enabled, the lock fails to be obtained and an error is reported after the maximum number of attempts is reached. Value range: [1,*INT_MAX*] or **-1** (indicating that there is no upper limit). The default value is **-1**.
- **enable_cancel**: specifies whether services can be canceled. That is, when the number of lock attempts reaches the upper limit or the level-8 lock of the user table is obtained during the table switching transaction, user services are quickly terminated to ensure that the online DDL operation can successfully obtain the lock. The value can be **false** or **true**. The default value is **false**.

- **IF EXISTS**

  Issues a notice rather than an error if no tables have identical names. The notice indicates that the table does not exist.

- **table_name [*] | ONLY table_name | ONLY (table_name)**

  table_name is the name of the table to be modified.

  If **ONLY** is specified before the table name, only that table is modified. If **ONLY** is not specified, the table and all its descendant tables (if any) are modified. You can explicitly add the asterisk (*) option following the table name to specify that all subtables are scanned, which is the default operation.

- **constraint_name**
  - Specifies the name of an existing constraint to be dropped in the DROP CONSTRAINT operation.
  - Specifies the name of a new constraint in the ADD CONSTRAINT operation.

  NOTICE

  For each new constraint, **constraint_name** is optional in MySQL-compatible databases (**sql_compatibility = 'MYSQL'**) but required in other databases.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **index_name**

  Specifies the index name.

  NOTICE

  In the ADD CONSTRAINT operation:

  - **index_name** is supported only in MySQL-compatible databases (**sql_compatibility = 'MYSQL'**).
  - If both **constraint_name** and **index_name** are specified for a FOREIGN KEY constraint, the value of **constraint_name** will be used as the index name.
  - If both **constraint_name** and **index_name** are specified for a UNIQUE constraint, the value of **index_name** will be used as the index name.

- **USING method**

  Specifies the method used to create the index.

  For details about the value range, see **USING method** in **CREATE INDEX**.

  NOTICE

  In the ADD CONSTRAINT operation:

  - **USING method** is supported only in MySQL-compatible databases (**sql_compatibility = 'MYSQL'**).
  - In MySQL-compatible mode, when **USING method** is not specified, Astore will default to B-tree indexing, and Ustore will default to UB-tree indexing.
  - If the storage engine of a table is Ustore and the USING BTREE constraint is specified in an SQL statement, the underlying layer will automatically treat it as USING UBTREE.

- **ASC | DESC**

  ASC specifies an ascending (default) sort order. **DESC** specifies a descending sort order.

  NOTICE

  ADD CONSTRAINT supports **ASC | DESC** only in MySQL-compatible databases (**sql_compatibility = 'MYSQL'**).

- **expression**

  Specifies an expression based on one or more columns of the table. It must be written in parentheses.

  NOTICE

  Expression indexes in the UNIQUE constraint are supported only in MySQL-compatible databases (**sql_compatibility = 'MYSQL'**).

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **storage_parameter**

  Specifies the name of a storage parameter.

  The following options are added for online scale-out:

  - **append_mode** (enumerated type)

    Scales out a table online or offline, or stops scaling it. You can modify certain content in the table during online scale-out but cannot do so during offline scaling.

    To modify a table that is being scaled, append new data so that they can be recorded as incremental data.

    - **on**: scales out a table online. New data will be appended.
    - **off**: stops scaling. New data will be written in normal mode, and options for online scaling will not be displayed in **pg_class.reloptions**.
    - **read_only**: scales a table offline, during which no other operations can be performed on the table.
    - **end_catchup**: reports errors for the write service in the last catchup. The read service is executed normally.

  - **rel_cn_oid** (OID type)

    Records the OID of tables on the current CN to generate **delete_delta** on the DNs.

    If **append_mode** is set to **on**, **rel_cn_oid** must be specified.

    The **append_mode** and **rel_cn_oid** options are used only for online scale-out tools.

  - **exec_step** (integer)

    Records resumable transmission steps in **relOptions** of the temporary table.

    Value range: [1,4]

    It can be used only for data redistribution.

  - **create_time** (long integer)

    Records the time when the temporary table is created during resumable transmission in **relOptions** of the temporary table.

    It can be used only for data redistribution.

  - **redistribute_version** (long integer)

    Specifies the number of times that a table is successfully redistributed during logical scale-out. The value is used by the standby node to read and verify consistency. The value is incremented by 1 each time the table is redistributed.

    This option is set only in the scale-out process and is not recommended.

  - **enable_update_distkey**

    Determines whether the table supports the UPDATE operation on distribution keys. The distribution keys can be updated only when this attribute of the table is set to **on** and constraints are met. Otherwise, distribution keys do not support the UPDATE operation.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Value range: **on** and **off**.

Default value: **off**.

NOTE

The constraints on updating distribution keys are as follows:

- Distribution keys can be updated only when **enable_update_distkey** is set to **on**.
- The UPDATE statement cannot be pushed down to DNs for execution. Instead, a PGXC plan is directly generated, and it remains unchanged regardless of the values before and after the distribution key updates.
- Tables with row-level UPDATE TRIGGER are not supported. Otherwise, the execution fails and an error message is displayed. The row-level INSERT/DELETE TRIGGER does not take effect, and the update-statement-level TRIGGER is executed normally.
- Concurrent update of the same row is not supported. You need to obtain a lock first. The result (returning **0** or reporting an error) of obtaining a lock on DNs depends on the setting of the GUC parameter **concurrent_dml_mode**. If an error is reported, the possible causes are as follows: (1) The error message "update distribute column conflict" is reported. (2) When the lock obtaining time exceeds the threshold, an error is reported, indicating that the lock times out.
- Tables with global secondary indexes (GSIs) are not supported. Otherwise, an error is reported.
- Only hash distribution is supported. LIST/RANGE distributed tables are not supported. Otherwise, an error is reported.
- MERGE INTO and UPSERT cannot be used to update distribution keys. Otherwise, an error is reported.
- GTM_FREE is not supported. Otherwise, an error is reported.
- UPDATE RETURNING is not supported. Otherwise, an error is reported.
- Statements with joined tables are not supported. Otherwise, an error is reported.
- UPDATE+LIMIT is not supported. Otherwise, an error is reported.

The following option is added for creating an index:

– **parallel_workers** (int type)

  Specifies the number of bgworker threads started for index creation. For example, a value of **2** indicates that two bgworker threads will be started to create indexes in parallel.

  Value range: [0,32]. **0** indicates that parallel index creation is disabled.

  Default value: unspecified, indicating that parallel index creation is disabled.

The following option is added to the replication table:

– **primarynode** (Boolean type)

  Default value: **off**.

  When **primarynode** is set to **on**, the primary node is selected for the replication table. Typically, the primary node is the first entry in the **nodeoids** column of the pgxc_class system catalog. When the IUD operation is performed on the replication table, the operation is delivered to the primary node first. After the result is received, the operation is delivered to other DNs.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- logical_repl_node (string type)

  Specifies the name of the DN responsible for returning logical logs to the CN during logical decoding of a distributed replication table. For the replication table, if this parameter is not specified, the first node in the node group where the current table is located is used by default. When the RESET operation is performed on this option, the node is reset to the first node of current table.

  Value range: character strings.

  Default value: For the non-replication table, this parameter is empty by default. For the replication table, this parameter is set to the name of the first node by default.

TDE options:

- **enable_tde** (Boolean type)

  Specifies whether to set a table as an encrypted table. This parameter supports only row-store tables, segment-page tables, hash bucket tables, temporary tables, and unlogged tables. When setting **enable_tde** to **on**, ensure that the GUC parameter **enable_tde** is enabled and **tde_key_info** is properly set. For detailed usage, consult "Feature Usage Guidelines > Transparent Data Encryption" in *Developer Guide*.

  Value range: **on** and **off**.

  on: TDE is enabled.

  off: TDE is disabled.

  NOTE

  - When the value is switched from **on** to **off**, any inserted or updated data will remain encrypted when written to existing pages, but will no longer be encrypted on newly generated pages.
  - Conversely, switching the value from **off** to **on** means that inserted or updated data will not be encrypted when written to existing pages, but will be automatically encrypted on newly generated pages.

  In summary, newly generated pages follow the post-switch encryption status, whereas existing pages maintain the encryption status they had before the switch. You are advised to manually perform VACUUM FULL on the table after the encryption switchover to ensure that the encryption status of all data pages is consistent.

  Default value: **off**.

- **encrypt_algo** (string type)

  Specifies the algorithm for encrypting a table.

  Value range: **AES_128_CTR**, **SM4_CTR**, **AES_128_CTR_SHA256_HMAC**, **SM4_CTR_SM3_HMAC**, and **AES_128_GCM**.

  Default value: If **enable_tde** is **on** and the **table_algorithm** subparameter within the GUC parameter **tde_encrypt_config** is not empty, the default value is the same as that of **table_algorithm**. If **table_algorithm** is empty, the default value is **AES_128_CTR**. When **enable_tde** is **off**, the default is empty.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- Similar to **enable_tde**, after **encrypt_algo** is used, the old algorithm is still used when inserted or updated data is written to the old page, and the new algorithm is used when the data is written to the new page.
- You can also manually perform VACUUM FULL on the table to ensure that all data pages are encrypted using the new algorithm.

– **hasuids** (Boolean type)

Default value: **off**.

If this parameter is set to **on**, a unique table-level ID is allocated to a tuple when the tuple is updated.

– **statistic_granularity**

Records the default **partition_mode** when the table analyzes statistics. For details about **PARTITION_MODE**, see **ANALYZE | ANALYSE**. This parameter setting does not work for non-partitioned tables.

Value range: See the value range of **partition_mode**.

Default value: **AUTO**.

The following options are added for the ROWID feature:

– hasrowid

Specifies whether the table contains the **ROWID** and **ROWNO** system columns. If **hasrowid** is set to **on**, the **rowid** and **rowno** system columns are added to the table, and sequences and indexes are created on the **rowno** system column.

Value range: **on** and **off**.

Default value: **off**.

NOTE

- This parameter supports only ORA-compatible databases (that is, **sql_compatibility** is set to **ORA**).
- This parameter does not support local temporary tables, unlogged tables, global temporary tables, materialized views, hash bucket tables, or replication tables.
- This parameter cannot be specified together with **hasuids**.
- When this parameter is enabled, the ordinary column name cannot be defined as **rowno** or **rowid**.
- The **hasrowid** storage option of a table cannot be changed to a different value using the SET ({storage_parameter = value} [, ...]) or RESET (storage_parameter [, ...]) clause.

The following options are added to online DDL operations:

– **online_ddl_status** (enumerated type)

This parameter is used to update the online DDL execution status of a target table.

It is called in online DDL operations. You are advised not to use it.

- **on**: enables the online DDL status.
- **off**: disables the online DDL status.
- **init**: initializes online DDL temporary objects.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

  - **catchup**: synchronizes concurrent data increment for DDL operations.
  - **catchup_basedata**: synchronizes basic data of online DDL operations.
  - **scan_catchup**: performs catchup when NOT NULL or CHECK constraints are added online.
  - **scan_catchup_basedata**: checks the basic data about adding NOT NULL or CHECK constraints online.
  - **vacuum_catchup**: performs catchup when VACUUM FULL is performed online.
  - **vacuum_verbose_catchup**: performs catchup when VACUUM FULL VERBOSE is performed online.
  - **last_catchup**: reports errors for the write service in the last online DDL catchup.
  - **switch**: exchanges temporary tables in the last online DDL catchup.
  - **copy_switch**: exchanges temporary tables in the last online tablespace movement catchup.
  - **record_toast_oid**: records the OID of a TOAST table attached to a target table of online DDL operations.
  - **abort**: specifies that online DDL operations enter the abort state.
  - **flush_buffer**: forcibly flushes buffers to disks when tablespaces are moved online.
  - **tmp_rel**: indicates a temporary table created during an online DDL process.

- **online_ddl_lock_tag** (int type)

  Unique ID of a target table of online DDL operations, which is used to generate temporary objects. The ID is the hash value of (Table schema + Table name).

  It is called in online DDL operations. You are advised not to use it.

New options for VACUUM:

- vacuum_truncate

  Specifies whether to enable the VACUUM TRUNCATE function of a table.

  Value range: **on** and **off**.

  Default value: **on**

- **new_owner**

  Specifies the name of the new table owner.

- **new_tablespace**

  Specifies the new name of the tablespace to which the table belongs.

- **column_name**, **column_1_name**, **column_2_name**

  Specifies the name of a new or existing column.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **data_type**

  Specifies the type of a new column or a new type of an existing column.

- **charset**

  Assigns a character set to the column. If a character set is explicitly specified, the column will use the default collation associated with that character set.

  This syntax is supported only in MySQL-compatible databases (**sql_compatibility = 'MYSQL'**).

- **collation**

  Assigns a collation to the column. The optional COLLATE clause specifies a collation for the new column; if omitted, the collation is the default for the new column. You can run the **select * from pg_collation** command to query collations from the pg_collation system catalog. The row starting with **default** in the query result represents the default collation.

  MySQL-compatible databases (**sql_compatibility = 'MYSQL'**) also support the utf8mb4_bin, utf8mb4_general_ci, utf8mb4_unicode_ci, binary, gbk_chinese_ci, gbk_bin, gb18030_chinese_ci, and gb18030_bin collations. For details, see **Table 1-398**.

  NOTE

  - Only the character type supports specifying a character set. When you specify the binary character set or collation, the system will convert the character type to the binary type. If the system cannot find a matching type mapping, it will report an error. Currently, only the TEXT-to-BLOB mapping is supported.
  - In addition to the binary character set and collation, you can only specify the character set that matches the database encoding.
  - If the character set or collation of a column is not explicitly specified but the default character set or collation of the table is specified, the column will inherit the character set and collation from the table. If the default character set or collation of a table does not exist, the character set and collation of table columns inherit the character set and collation of the current database when **b_format_behavior_compat_options** contains **'default_collation'**.
  - If the modified character set or the character set corresponding to the modified collation differs from the character set of the current column, data in the column will be converted to the specified character set for encoding.

- **USING expression**

  Specifies how to compute the new column value from the old; if omitted, the default conversion is an assignment cast from old data type to new. A USING clause must be provided if there is no implicit or assignment cast from the old to new type.

  NOTE

  USING in ALTER TYPE can specify any expression involving the old values of the row; that is, it can refer to any columns other than the one being cast. This allows general casting to be done with the ALTER TYPE syntax. Because of this flexibility, the USING expression is not applied to the column's default value (if any); the result might not be a constant expression as required for a default. This means that when there is no implicit or assignment cast from old to new type, ALTER TYPE might fail to convert the default even though a USING clause is supplied. In such cases, drop the default with DROP DEFAULT, perform ALTER TYPE, and then use SET DEFAULT to add a suitable new default. Similar considerations apply to indexes and constraints involving the column.

- **NOT NULL | NULL**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Specifies whether the column allows null values.

- **ENABLE**

  Enables the constraint. This is the default.

- **integer**

  Specifies the constant value of a signed integer. When using **PERCENT**, the range of **integer** is from 0 to 100.

- **attribute_option**

  Specifies an attribute option.

- **PLAIN | EXTERNAL | EXTENDED | MAIN**

  Specifies a column-store mode.

  – **PLAIN** must be used for fixed-length values (such as integers). It must be inline and uncompressed.

  – **MAIN** is for inline, compressible data.

  – **EXTERNAL** is for external, uncompressed data. Use of **EXTERNAL** will make substring operations on **text** and **bytea** values run faster, at the penalty of increased storage space.

  – **EXTENDED** is for external, compressed data. **EXTENDED** is the default for most data types that support non-**PLAIN** storage.

- **CHECK (expression)**

  Ensures that for any inserted or updated row, the expression must evaluate to true. Otherwise, an exception is raised and no changes are made to the database.

  A CHECK constraint specified as a column constraint should reference that column's value only, while an expression appearing in a table constraint can reference multiple columns.

  Currently, **CHECK (expression)** does not include subqueries and cannot use variables apart from the current column.

- **DEFAULT default_expr**

  Assigns a default data value to a column.

  The data type of the default expression must match the data type of the column.

  The default expression will be used in any insert operation that does not specify a value for the column. If there is no default value for a column, then the default value is **NULL**.

- **ON UPDATE update_expr**

  Specifies an attribute constraint for a column.

  During an UPDATE operation on a tuple in a table, if the new values of the updated columns differ from the old values, columns (in the tuple) that have this attribute but are not part of the UPDATE will be automatically updated to the current timestamp. However, if the new values of the updated columns are the same as the old values, those columns will remain unchanged. If columns with this attribute are included in the UPDATE, their values will be updated to the specified value.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- This attribute can be specified in MySQL-compatible databases version 5.7 (**sql_compatibility = 'MYSQL'**, **b_format_version='5.7'**, and **b_format_dev_version='s1'**). It can also be specified in PG-compatible databases, but the syntax is not supported during upgrade observation.
- In terms of syntax, **update_expr** supports three keywords: CURRENT_TIMESTAMP, LOCALTIMESTAMP, and NOW(). You can also optionally specify the precision of a keyword with parentheses. The three types of keywords are synonyms of each other and have the same attribute effect. For example, ON UPDATE CURRENT_TIMESTAMP(), ON UPDATE CURRENT_TIMESTAMP(5), ON UPDATE LOCALTIMESTAMP(), and ON UPDATE LOCALTIMESTAMP(6). If a keyword does not contain parentheses or contains empty parentheses, the precision is 0. The NOW keyword cannot work without parentheses. In PG-compatible mode, ON UPDATE CURRENT_TIMESTAMP(), ON UPDATE LOCALTIMESTAMP(), and ON UPDATE NOW(5) are not supported.
- This attribute can be specified only for columns of the following types: timestamp, datetime, date, time without time zone, smalldatetime, and abstime.
- The CREATE TABLE AS syntax does not inherit the column attributes.
- The CREATE TABLE LIKE syntax can use **INCLUDING UPDATE** or **EXCLUDING UPDATE** to inherit or exclude a constraint. In PG-compatible mode, only the **EXCLUDING UPDATE** option can be used to exclude a constraint. The **INCLUDING ILM** option is added to copy ILM policy information from the source table. When combined with the **INCLUDING PARTITION** option, it can also copy the policy information of partition objects from the source table.
- The precision specified by this attribute can be different from the precision specified by the type in the corresponding column. After the column value is updated through this attribute, the minimum precision is displayed. For example, **ALTER TABLE t1 ADD col1 timestamp(6) ON UPDATE CURRENT_TIMESTAMP(3);**. If the UPDATE syntax triggers the attribute to take effect, three decimal places in the value of **col1** are displayed after the update.
- A column cannot be designated as both this attribute and a generated column constraint simultaneously.
- Specifying this attribute within the partition key of a partitioned table is not allowed.
- In distributed scenarios, this attribute cannot be specified for distribution keys or the primary key.

- **AUTO_INCREMENT**

  Marks a column as auto-increment.

  For details, see **AUTO_INCREMENT** in **CREATE TABLE**.

- **COLUMN_ENCRYPTION_KEY = column_encryption_key**

  Specifies the name of the column encryption key in the ENCRYPTED WITH constraint.

  Value range: character strings complying with **Identifier Naming Conventions**.

- **ENCRYPTION_TYPE = encryption_type_value**

  When setting the encryption type in the ENCRYPTED WITH constraint, you can choose between **DETERMINISTIC** or **RANDOMIZED** as **encryption_type_value**.

- **COMMENT [=] 'string'**
  - The COMMENT [=] 'string' clause is used to add comments to a table.
  - The **COMMENT 'string'** in **column_constraint** indicates that comments are added to a column.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

  - The **COMMENT 'string'** in **table_constraint** indicates that comments are added to the indexes corresponding to the primary key and unique key.

  For details, see **COMMENT [=] 'string'** in **CREATE TABLE**.

- **UNIQUE [KEY] index_parameters**

  Specifies that a column or a combination of columns must be unique across the entire table.

  For the purpose of a UNIQUE constraint, NULL is not considered equal.

  Semantically equivalent to UNIQUE, UNIQUE KEY is available only in MySQL-compatible databases (**sql_compatibility = 'MYSQL'**).

- **UNIQUE [index_name][USING method] ({ {column_name [(length)] | (expression) } [ASC | DESC] }[, ...]) index_parameters**

  Specifies that a column or a combination of columns must be unique across the entire table.

  column_name (length) serves as a prefix key. For details, see **column_name (length)** in **CREATE INDEX**.

  For the purpose of a UNIQUE constraint, NULL is not considered equal.

  NOTICE

  - **index_name** is supported only in MySQL-compatible databases (**sql_compatibility = 'MYSQL'**).
  - If both **constraint_name** and **index_name** are specified for a UNIQUE constraint, the value of **index_name** will be used as the index name.

- **PRIMARY KEY index_parameters**

  PRIMARY KEY [USING method] ({ column_name [ASC | DESC] } [, ...]) index_parameters

  Specifies that one or more columns in the table require unique, non-NULL values.

- **USING method**

  Specifies the method used to create the index.

  For details about the value range, see **Parameters** in **CREATE INDEX**.

  NOTICE

  - **USING method** is supported only in MySQL-compatible databases (**sql_compatibility = 'MYSQL'**).
  - In MySQL-compatible mode, when **USING method** is not specified, Astore will default to B-tree indexing, and Ustore will default to UB-tree indexing.
  - Since the underlying layer of GSIs is based on UB-tree storage, GSIs will be built with UB-tree storage, even if users specify B-tree storage.
  - If the storage engine of a table is Ustore and the USING BTREE constraint is specified in an SQL statement, the underlying layer will automatically treat it as USING UBTREE.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **ASC | DESC**

  ASC specifies an ascending (default) sort order. **DESC** specifies a descending sort order.

  NOTICE

  ASC | DESC is supported only in MySQL-compatible databases (**sql_compatibility = 'MYSQL'**).

- **expression**

  Specifies an expression based on one or more columns of the table. It must be written in parentheses.

  NOTICE

  Expression indexes in the UNIQUE constraint are supported only in MySQL-compatible databases (**sql_compatibility = 'MYSQL'**).

- **DEFERRABLE | NOT DEFERRABLE**

  Specifies whether the constraint can be deferred. A constraint that is not deferrable will be checked immediately after every command. Checking of constraints that are deferrable can be postponed until the end of the transaction (using the **SET CONSTRAINTS** command). **NOT DEFERRABLE** is the default. Currently, only the UNIQUE, PRIMARY KEY, and FOREIGN KEY constraints accept this clause. (That is, other constraints are not deferrable.)

- **INITIALLY IMMEDIATE | INITIALLY DEFERRED**

  Specifies the default time to check the constraint if it is deferrable. A constraint that is not deferrable is always **INITIALLY IMMEDIATE** and cannot be declared as **INITIALLY DEFERRED**.

  - If the constraint is **INITIALLY IMMEDIATE**, it is checked after each statement. This is the default.
  - If a constraint is **INITIALLY DEFERRED**, it is checked only at the end of the transaction.

- **WITH ({storage_parameter = value} [, ...])**

  Specifies an optional storage parameter for the table or an index.

- **tablespace_name**

  Specifies the name of the tablespace where the index locates.

- **NOCOMPRESS**

  Specifies that the existing compression feature of the table will not be modified.

- **new_table_name**

  Specifies a new name for the table.

- **new_column_name**

  Specifies a new name for a specific column in the table.

- **new_constraint_name**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Specifies the new name of a table constraint.

- **new_schema**

  Specifies a new schema name.

- **CASCADE**

  Automatically drops objects that depend on the dropped column or constraint (for example, views referencing the column).

- **RESTRICT**

  Refuses to drop the column if the column is referenced by other columns or constraints. **RESTRICT** is the default option. If **CASCADE** is not specified, the value is **RESTRICT**. An example of the statement is as follows:

  ```
  ALTER TABLE table_name [DROP [column] col_name [CASCADE | RESTRICT]];
  ```
  table_name indicates the table name, and **col_name** indicates the column name.

- **schema_name**

  Specifies the schema name of the table.

- **IF NOT EXISTS**

  When IF NOT EXISTS is specified and columns with the same name exist, a notice is returned, indicating that the column already exists. When IF NOT EXISTS is not specified and columns with the same name exist, an error is returned.

- **[DEFAULT] CHARACTER SET | CHARSET [=] default_charset**

  Changes the default character set of the table. If this parameter is specified separately, the table will use the default collation of the specified character set.

- **[DEFAULT] COLLATE [=] default_collation**

  Changes the default collation of the table. If this parameter is specified separately, the table will default to the character set corresponding to the specified collation.

  This syntax is supported only when **sql_compatibility** is set to **'MYSQL'**. For details about the collation, see **Table 1-398**.

  NOTE

  If the character set or collation of a table is not explicitly specified but the default character set or collation of the schema is specified, the table will inherit the character set and collation from the schema. If the default character set or collation of the schema cannot be found, the table will inherit the character set and its corresponding collation from the current database when **b_format_behavior_compat_options** includes **'default_collation'**.

- **GSIWAITALL**

  It is primarily called by the internal CREATE GLOBAL INDEX CONCURRENTLY/ REINDEX INDEX CONCURRENTLY to synchronize lock waits during online creation of GSIs. Based on the given lock level, you can obtain the list of transactions that conflict with that lock level on each node and wait for those transactions to complete.

Examples of Modifying a Table

- Rename a table.

  ```
  gaussdb=# CREATE TABLE aa(c1 int, c2 int);
  gaussdb=# ALTER TABLE IF EXISTS aa RENAME TO test_alt1;
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- Change the schema of a table.

```
-- Create the test_schema schema.
gaussdb=# CREATE SCHEMA test_schema;

-- Change the schema of the test_alt1 table to test_schema.
gaussdb=# ALTER TABLE test_alt1 SET SCHEMA test_schema;

-- Query table information.
gaussdb=# SELECT schemaname,tablename FROM pg_tables WHERE tablename = 'test_alt1';
 schemaname  | tablename
-------------+-----------
 test_schema | test_alt1
(1 row)
```

- Change the owner of a table.

```
-- Create user test_user.
gaussdb=# CREATE USER test_user PASSWORD '********';

-- Change the owner of the test_alt1 table to test_user.
gaussdb=# ALTER TABLE IF EXISTS test_schema.test_alt1 OWNER TO test_user;

-- Query.
gaussdb=# SELECT tablename, schemaname, tableowner FROM pg_tables WHERE tablename =
'test_alt1';
 tablename | schemaname  | tableowner
-----------+-------------+------------
 test_alt1 | test_schema | test_user
(1 row)
```

- Change the tablespace of a table.

```
-- Create the tbs_data1 tablespace.
gaussdb=# CREATE TABLESPACE tbs_data1 RELATIVE LOCATION 'tablespace1/tbs_data1';

-- Change the tablespace of the test_alt1 table to tbs_data1.
gaussdb=# ALTER TABLE test_schema.test_alt1 SET TABLESPACE tbs_data1;

-- Query.
gaussdb=# SELECT tablename, tablespace FROM pg_tables WHERE tablename = 'test_alt1';
 tablename | tablespace
-----------+------------
 test_alt1 | tbs_data1
(1 row)

-- Create a table.
gaussdb=# CREATE TABLE test(c1 int, c2 int);
-- Change the space of the test table to tbs_data1 online.
gaussdb=# ALTER TABLE ONLINE test SET TABLESPACE tbs_data1;

-- Query.
gaussdb=# SELECT tablename, tablespace FROM pg_tables WHERE tablename = 'test';
 tablename | tablespace
-----------+------------
 test| tbs_data1
(1 row)

-- Drop.
gaussdb=# DROP TABLE test ;
gaussdb=# DROP TABLE test_schema.test_alt1;
gaussdb=# DROP TABLESPACE tbs_data1;
gaussdb=# DROP SCHEMA test_schema;
gaussdb=# DROP USER test_user;
```

Examples of Modifying Columns

- Change column names.

```
-- Create a table.
gaussdb=# CREATE TABLE test_alt2(c1 INT,c2 INT);

-- Change column names.
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gaussdb=# ALTER TABLE test_alt2 RENAME c1 TO id;
gaussdb=# ALTER TABLE test_alt2 RENAME COLUMN c2 to areaid;

-- Query.
gaussdb=# \d test_alt2
   Table "public.test_alt2"
 Column |  Type   | Modifiers
--------+---------+-----------
 id     | integer |
 areaid | integer |
```

- Add a column.

```
-- Add a column to the test_alt2 table.
gaussdb=# ALTER TABLE IF EXISTS test_alt2 ADD COLUMN name VARCHAR(20);

-- Query.
gaussdb=# \d test_alt2
           Table "public.test_alt2"
  Column  |         Type          | Modifiers
----------+-----------------------+-----------
 id       | integer               |
 areaid   | integer               |
 name     | character varying(20) |
```

- Add an auto-increment column.

```
-- Add the AUTO_INCREMENT column to the local_autoinc table. (Change the DN name by running SELECT node_name FROM pgxc_node WHERE node_type = 'D' based on the actual situation.)
gaussdb=# CREATE TABLE local_autoinc(col1 int)
DISTRIBUTE BY LIST(col1)(
    SLICE s1 VALUES (1) DATANODE datanode1,
    SLICE s2 VALUES (2) DATANODE datanode2
);
-- Distribute data to DN1.
gaussdb=# INSERT INTO local_autoinc(col1) VALUES(1);

-- Add a local auto-increment column. The value starts from 1 for each DN.
gaussdb=# ALTER TABLE local_autoinc ADD COLUMN col int AUTO_INCREMENT;
gaussdb=# SELECT col,col1 FROM local_autoinc ORDER BY 2,1;
 col | col1
-----+------
   1 |    1
(1 row)

-- Set the next auto-increment value of all DNs to 10.
gaussdb=# ALTER TABLE local_autoinc AUTO_INCREMENT = 10;

-- Distribute data to DN1. NULL triggers auto-increment, and the auto-increment value is 10.
gaussdb=# INSERT INTO local_autoinc(col, col1) VALUES(NULL,1);

-- Distribute data to DN2. 0 triggers auto-increment, and the auto-increment value is 10.
gaussdb=# INSERT INTO local_autoinc(col, col1) VALUES(0,2);
gaussdb=# SELECT col,col1 FROM local_autoinc ORDER BY 2,1;
 col | col1
-----+------
   1 |    1
  10 |    1
  10 |    2
(3 rows)
```

- Change the data type of a column.

```
-- Change the type of the name column in the test_alt2 table.
gaussdb=# ALTER TABLE test_alt2 MODIFY name VARCHAR(50);

-- Query.
gaussdb=# \d test_alt2
          Table "public.test_alt2"
 Column |         Type          | Modifiers
--------+-----------------------+-----------
 id     | integer               |
 areaid | integer               |
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
 name   | character varying(50) |

-- Change the type of the name column in the test_alt2 table online.
gaussdb=# ALTER TABLE ONLINE test_alt2 MODIFY name VARCHAR(60);

-- Query.
gaussdb=# \d test_alt2
          Table "public.test_alt2"
 Column |         Type          | Modifiers
--------+-----------------------+-----------
 id     | integer               |
 areaid | integer               |
 name   | character varying(60) |
-- Change the type of the name column in the test_alt2 table.
gaussdb=# ALTER TABLE test_alt2 ALTER COLUMN name TYPE VARCHAR(25);

-- Query.
gaussdb=# \d test_alt2
          Table "public.test_alt2"
 Column |         Type          | Modifiers
--------+-----------------------+-----------
 id     | integer               |
 areaid | integer               |
 name   | character varying(25) |

-- Change the type of the name column in the test_alt2 table online.
gaussdb=# ALTER TABLE ONLINE test_alt2 ALTER COLUMN name TYPE VARCHAR(35);

-- Query.
gaussdb=# \d test_alt2
          Table "public.test_alt2"
 Column |         Type          | Modifiers
--------+-----------------------+-----------
 id     | integer               |
 areaid | integer               |
 name   | character varying(35) |
```

- Drop a column.

```
-- Drop the areaid column from test_alt2.
gaussdb=# ALTER TABLE test_alt2 DROP COLUMN areaid;

-- Query.
gaussdb=# \d test_alt2
          Table "public.test_alt2"
 Column |         Type          | Modifiers
--------+-----------------------+-----------
 id     | integer               |
 name   | character varying(25) |
```

- Change the column-store mode.

```
-- View table details.
gaussdb=# \d+ test_alt2
                          Table "public.test_alt2"
 Column |         Type          | Modifiers | Storage  | Stats target | Description
--------+-----------------------+-----------+----------+--------------+-------------
 id     | integer               |           | plain    |              |
 name   | character varying(35) |           | extended |              |
Has OIDs: no
Distribute By: HASH(id)
Location Nodes: ALL DATANODES
Options: orientation=row, compression=no, storage_type=USTORE, segment=off

-- Change the storage mode of the name column in the test_alt2 table.
gaussdb=# ALTER TABLE test_alt2 ALTER COLUMN name SET STORAGE PLAIN;

-- Query.
gaussdb=# \d+ test_alt2
                         Table "public.test_alt2"

-- Drop.
gaussdb=# DROP TABLE test_alt2;
```

Examples of Modifying Constraints

- Add a NOT NULL constraint to a column.

```
-- Create a table.
gaussdb=# CREATE TABLE test_alt3(pid INT, areaid CHAR(5), name VARCHAR(20));

Add a NOT NULL constraint to pid.
gaussdb=# ALTER TABLE test_alt3 MODIFY pid NOT NULL;

-- Query.
gaussdb=# \d test_alt3
          Table "public.test_alt3"
 Column |         Type          | Modifiers
--------+-----------------------+-----------
 pid    | integer               | not null
 areaid | character(5)          |
 name   | character varying(20) |

-- Cancel the NOT NULL constraint on a column.
gaussdb=# ALTER TABLE test_alt3 MODIFY pid NULL;

-- Add a NOT NULL constraint to the PID online.
gaussdb=# ALTER TABLE ONLINE test_alt3 MODIFY pid NOT NULL;

-- Query.
gaussdb=# \d test_alt3
          Table "public.test_alt3"
 Column |         Type          | Modifiers
--------+-----------------------+-----------
 pid    | integer               | not null
 areaid | character(5)          |
 name   | character varying(20) |
```

- Cancel the NOT NULL constraint on a column.

```
gaussdb=# ALTER TABLE test_alt3 MODIFY pid NULL;
-- Query.
gaussdb=# \d test_alt3
          Table "public.test_alt3"
 Column |         Type          | Modifiers
--------+-----------------------+-----------
 pid    | integer               |
 areaid | character(5)          |
 name   | character varying(20) |
```

- Change the default value of a column.

```
-- Change the default value of id in the test_alt3 table.
gaussdb=# ALTER TABLE test_alt3 ALTER COLUMN areaid SET DEFAULT '00000';

-- Query.
gaussdb=# \d test_alt3
                Table "public.test_alt3"
 Column |         Type          |        Modifiers
--------+-----------------------+-------------------------
 pid    | integer               |
 areaid | character(5)          | default '00000'::bpchar
 name   | character varying(20) |
-- Drop the default value of id.
gaussdb=# ALTER TABLE test_alt3 ALTER COLUMN areaid DROP DEFAULT;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
-- Query.
gaussdb=# \d test_alt3
          Table "public.test_alt3"
 Column |          Type          | Modifiers
--------+------------------------+-----------
 pid    | integer                |
 areaid | character(5)           |
 name   | character varying(20) |
```

- Add a table-level constraint.
  - Directly add a constraint.

    ```
    -- Add a PRIMARY KEY constraint to a table.
    gaussdb=# ALTER TABLE test_alt3 ADD CONSTRAINT pk_test3_pid PRIMARY KEY (pid);

    -- Query.
    gaussdb=# \d test_alt3
              Table "public.test_alt3"
     Column |          Type          | Modifiers
    --------+------------------------+-----------
     pid    | integer                | not null
     areaid | character(5)           |
     name   | character varying(20) |
    Indexes:
        "pk_test3_pid" PRIMARY KEY, ubtree (pid) WITH (storage_type=USTORE) TABLESPACE
    pg_default

    -- Drop the table.
    gaussdb=# DROP TABLE IF EXISTS test_alt3;

    -- Create a table.
    gaussdb=# CREATE TABLE test_alt3(pid INT, areaid CHAR(5), name VARCHAR(20));

    -- Add a primary key constraint to the table online.
    gaussdb=# ALTER TABLE ONLINE test_alt3 ADD CONSTRAINT pk_test3_pid PRIMARY KEY (pid);

    -- Query.
    gaussdb=# \d test_alt3
              Table "public.test_alt3"
     Column |          Type          | Modifiers
    --------+------------------------+-----------
     pid    | integer                | not null
     areaid | character(5)           |
     name   | character varying(20) |
    Indexes:
        "pk_test3_pid" PRIMARY KEY, ubtree (pid) WITH (storage_type=USTORE) TABLESPACE
    pg_default
    ```

  - Create an index and then add constraints.

    ```
    -- Create a table.
    gaussdb=# CREATE TABLE test_alt4(c1 INT, c2 INT);

    -- Create an index.
    gaussdb=# CREATE UNIQUE INDEX pk_test4_c1 ON test_alt4(c1);

    -- Associate the created index when adding a constraint.
    gaussdb=# ALTER TABLE test_alt4 ADD CONSTRAINT pk_test4_c1 PRIMARY KEY USING INDEX
    pk_test4_c1;

    -- Query.
    gaussdb=# \d test_alt4
       Table "public.test_alt4"
     Column |  Type   | Modifiers
    --------+---------+-----------
     c1     | integer | not null
     c2     | integer |
    Indexes:
        "pk_test4_c1" PRIMARY KEY, ubtree (c1) WITH (storage_type=USTORE) TABLESPACE
    pg_default
    ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
-- Drop.
gaussdb=# DROP TABLE test_alt4;
```

- Drop a table-level constraint.

```
-- Drop a constraint.
gaussdb=# ALTER TABLE test_alt3 DROP CONSTRAINT IF EXISTS pk_test3_pid;

-- Query.
gaussdb=# \d test_alt3
          Table "public.test_alt3"
 Column |         Type          | Modifiers
--------+-----------------------+-----------
 pid    | integer               | not null
 areaid | character(5)          |
 name   | character varying(20) |

-- Drop.
gaussdb=# DROP TABLE test_alt3;

-- Delete a primary key constraint. (This syntax is supported only in MySQL-compatible and ORA-compatible modes.)
gaussdb=# CREATE TABLE test_drop_primary_key(c1 INT PRIMARY KEY);
gaussdb=# \d test_drop_primary_key
Table "public.test_drop_primary_key"
 Column |  Type   | Modifiers
--------+---------+-----------
 c1     | integer | not null
Indexes:
    "test_drop_primary_key_pkey" PRIMARY KEY, ubtree (c1) WITH (storage_type=USTORE) TABLESPACE pg_default

gaussdb=# ALTER TABLE test_drop_primary_key DROP PRIMARY KEY;
gaussdb=# \d test_drop_primary_key
Table "public.test_drop_primary_key"
 Column |  Type   | Modifiers
--------+---------+-----------
 c1     | integer | not null
```

- Rename a constraint.

```
-- Create the tbl_test1 table and specify the primary key constraint.
gaussdb=# CREATE TABLE tbl_test1(
    id int,
    name varchar(50),
    CONSTRAINT aaa PRIMARY KEY (id)
);

-- Rename the constraint.
gaussdb=# ALTER TABLE tbl_test1 RENAME CONSTRAINT aaa TO pk_test1_id;

-- View the information.
gaussdb=# \d tbl_test1;
          Table "public.tbl_test1"
 Column |         Type          | Modifiers
--------+-----------------------+-----------
 id     | integer               | not null
 name   | character varying(50) |
Indexes:
    "pk_test1_id" PRIMARY KEY, ubtree (id) WITH (storage_type=USTORE) TABLESPACE pg_default

-- Drop the table.
gaussdb=# DROP TABLE tbl_test1;
```

CREATE TABLE and **DROP TABLE**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

1.13.7.35 ALTER TABLE PARTITION

Description

Modifies table partitions, including adding, deleting, splitting, merging, clearing, exchanging, and renaming partitions, moving partition tablespaces, and modifying partition attributes.

Precautions

- Only the partitioned table owner or a user with the ALTER permission can run the **ALTER TABLE PARTITION** command. When separation of duties is disabled, system administrators have this permission by default.
- The tablespace of the added partition cannot be PG_GLOBAL.
- The name of any added partition must differ from the names of existing partitions in the partitioned table.
- The partition key value of any added partition must match the partition key type of the partitioned table.
- When a range partition is added, its partition key value must be greater than the upper limit of the last range partition in the partitioned table.
- When a list partition is added, its partition key value must not overlap with existing partition key values.
- Hash partitions cannot be added.
- When the number of partitions in the target partitioned table reaches the maximum limit (1,048,575), no additional partitions can be added.
- If a partitioned table contains only one partition, that partition cannot be dropped.
- When you use PARTITION FOR() to select partitions, the number of values specified within the parentheses must match the number of columns specified in the partition definition, and they must correspond in a one-to-one manner.
- The **Value** partitioned table does not support the ALTER PARTITION operation.
- Hash partitioned tables do not support splitting, merging, adding, or dropping partitions.
- Deleting, splitting, merging, clearing, or exchanging partitions will make global indexes unusable. You can declare the UPDATE GLOBAL INDEX clause to update the indexes synchronously.
- If partitions are dropped, split, merged, truncated, or exchanged without declaring the UPDATE GLOBAL INDEX clause, concurrent DML statements may trigger errors due to unusable indexes.
- Deleting, splitting, merging, clearing, or exchanging partitions invalidates GSIs on partitioned tables. For exchanging partitions, all GSIs on ordinary tables become invalid. You can declare the UPDATE DISTRIBUTED GLOBAL INDEX clause to update indexes synchronously.
- If the UPDATE DISTRIBUTED GLOBAL INDEX clause is not used when you delete, split, merge, clear, or exchange partitions, concurrent DML services may report errors due to invalidated indexes.
- If **enable_gpi_auto_update** is set to **on**, the global index is automatically updated even if the UPDATE GLOBAL INDEX clause is not declared.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- If the **enable_drop_truncate_partition_keep_gpi** parameter is set to **on**, the global index remains valid when partitions are dropped or truncated. In this case, the global index is always valid, regardless of whether the DROP/TRUNCATE PARTITION statement contains the UPDATE GLOBAL INDEX clause. This priority is higher than that of the **enable_gpi_auto_update** parameter and the UPDATE GLOBAL INDEX clause explicitly specified by the user.
- If you add a row-level expression when adding or changing an ILM policy for a data object, note that the row-level expression supports only the functions listed in the whitelist. For details about the whitelist function list, see **Row Expression Function Whitelist**.

  NOTE

  Among the functions supported by the row-level expression ON (EXPR) in the ILM policy, the output of some may be influenced by compatibility parameters. For instance, after you set **b_format_version** to **'5.7'** and **b_format_dev_version** to **'s2'** in MySQL-compatible mode, the upper function will be unable to convert data to uppercase as usual.
- When executing online DDL operations for splitting or merging partitions, exchanging partitions, or moving partition tablespaces, reserve sufficient disk space, at least equal to the total space of the tables or partitions (and their accessories such as indexes).
- Online DDL operations cannot be executed within a transaction or a stored procedure. If you use the JDBC driver to run multiple SQL statements, a transaction is implicitly started, and these SQL statements cannot be executed together.
- If online DDL execution is canceled, the residual data clearance process starts first. If the execution is canceled again, the clearance process ends and residual data remains.
- Resource contention exists between online DDL operations and user services. Therefore, online DDL operations are not suitable for heavy-traffic scenarios. In scenarios where resources are limited, fine-grained resource control is recommended. Parallel acceleration is not recommended.
- Online DDL operations are not supported in M-compatible databases.
- In the following cases, online DDL operations do not take effect. By default, DDL operations are performed offline. If **ONLINE** is specified, a message is displayed, indicating that it is ignored.
  - The statement for altering table partitions online contains operations that are not supported by the current online DDL feature. (Splitting/merging partitions, exchanging partitions, and moving partition tablespaces are supported.)
  - A table on which online modifications to its partitions (including splitting/merging partitions, exchanging partitions, and moving partition tablespaces) are performed contains GSIs and requires synchronous updates to the GSIs.
  - The statement for modifying table partitions online contains operations of multiple clauses (for example, the statement involves both splitting and exchanging partitions online).
- Online DDL operations (including splitting/merging partitions, exchanging partitions, and moving partition tablespaces) will not take effect on database-

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

level, index-level, subpartitioned, segment-page, hash bucket, temporary, or unlogged tables. In this case, DDL operations are executed offline by default, and a message is displayed indicating that the current DDL statement cannot be executed online.

- Long transactions may block online DDL statement execution results, including splitting/merging partitions, exchanging partitions, and moving partition tablespaces. You are advised to avoid performing online DDL operations when long transactions exist.
- Performing online DDL operations to modify table partitions (including splitting/merging partitions, exchanging partitions, and moving partition tablespaces) will block DQL and DML operations at a later stage. Therefore, requests may fail due to blocking in service models with a timeout error reporting mechanism. Before using this feature, carefully evaluate the service model's tolerance for waiting locks to confirm whether this feature can be used.
- During the execution of online DDL statements for modifying table partitions, avoid executing other DDL statements concurrently. If exceptions like no response or error reporting occur, reconnect to the client and try again.
- During the upgrade from a version that does not support the online DDL operations for altering table partitions to a version that supports it, the operations (including splitting/merging partitions, exchanging partitions, and moving partition tablespaces) are not supported because they are under observation. By default, DDL operations are performed offline, and a message is displayed indicating that online DDL operations are not supported during the upgrade.
- During the execution of an online DDL operation for altering table partitions (including splitting/merging partitions, exchanging partitions, and moving partition tablespaces), a specific schema is generated. The schema naming format is online$$ddl$$[hash value of (*Name of the schema where the table is located Table name*)].
  - By default, the owner of the schema is the initial user. You are advised not to operate the schema during online DDL operations; otherwise, the online DDL operations may be terminated and an unknown error may occur.
  - Do not create a schema with the prefix online$$. Otherwise, an error message is displayed. If a schema with the same name already exists, online DDL operations will not take effect. By default, DDL operations are executed offline, and a message is displayed indicating that the current DDL statement cannot be executed online due to a schema name conflict.
- If an online DDL operation (including splitting or merging partitions or moving partition tablespaces) fails, the table's storage space may bloat significantly. Exchanging partitions online may cause significant storage space bloat on the table regardless of its success or failure. The bloat degree is proportional to the DDL statement execution duration and the number of concurrent write operations. You are advised not to perform online DDL operations when long transactions exist.
- Online DDL operations (including splitting/merging partitions, exchanging partitions, and moving partition tablespaces) inherit the restrictions of **CREATE TABLE**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- During the online DDL operation of merging partitions, if the data of the partitions to be merged has been compressed before the operation, the data may be decompressed after the operation.
- During online DDL operations (including splitting/merging partitions, exchanging partitions, and moving partition tablespaces), if global indexes are automatically updated, concurrent queries and DML services may be blocked for a long time at a later stage of the operations.

Syntax

Modifying a partition in a partitioned table includes modifying the table partition itself and the table partition name, and resetting the partition ID.

- Main syntax for modifying a partition:

```
ALTER TABLE [ OFFLINE | [ ONLINE [ WITH ( { online_parameter = value } [, ... ] ) ] ] ] [ IF EXISTS ]
{ table_name  [*] | ONLY table_name | ONLY ( table_name  )}
    action [, ... ];
```

  action includes the following partition maintenance clauses. For the partition continuity when multiple clauses are used for partition maintenance, GaussDB executes DROP PARTITION and ADD PARTITION first, and then the rest clauses in sequence.

```
{ move_clause  |
    exchange_clause  |
    row_clause  |
    merge_clause  |
    modify_clause  |
    split_clause  |
    add_clause  |
    drop_clause  |
    truncate_clause  |
    ilm_clause |
    set_partitioning_clause }
```

  - move_clause: moves the partition to a different tablespace.

```
MOVE PARTITION { partition_name | FOR ( partition_value [, ...] ) } TABLESPACE tablespacename
```

  - exchange_clause: moves data from an ordinary table to a specified partition.

```
EXCHANGE PARTITION { ( partition_name ) | partition_name | FOR ( partition_value [, ...] ) }
    WITH TABLE {[ ONLY ] ordinary_table_name | ordinary_table_name * | ONLY
( ordinary_table_name )}
    [ { WITH | WITHOUT } VALIDATION ] [ VERBOSE ] [ UPDATE GLOBAL INDEX ] [ UPDATE
DISTRIBUTED GLOBAL INDEX | NO UPDATE DISTRIBUTED GLOBAL INDEX ]
```

    The ordinary table and partition involved in the exchange must meet the following requirements:

    - The number of columns in the ordinary table must match that in the partition, with consistent column details including names, data types, constraints, collations, storage parameters, and compression information.
    - The compression information must be consistent between the ordinary table and partition.
    - The distribution key information of the ordinary table and partition should be consistent.
    - The number of indexes in the ordinary table must match the number of local indexes in the partition, with consistent index information.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- The number of table constraints must be consistent between the ordinary table and partition, with consistent constraint information.
- An ordinary table and a partitioned table cannot be associated with foreign key constraints of other tables.
- An ordinary table cannot be a temporary table. A partitioned table can only be a range partitioned table, list partitioned table, hash partitioned table, or interval partitioned table.
- When the built-in security policy is enabled, ordinary and partitioned tables cannot have dynamic data masking or row-level security constraints.

NOTICE

- After the exchange is completed, the data of the ordinary table and partition are swapped, along with their tablespace information. At this point, statistics on the ordinary table and partition become unreliable, necessitating an ANALYZE operation.
- Non-partition keys cannot be used to create local unique indexes; only global unique indexes are permitted. Therefore, if an ordinary table contains a unique index, its data may fail to be exchanged.

  To exchange data, you can create an intermediate table, insert partition data into the intermediate table, truncate partitions, insert ordinary table data into the partitioned table, drop the ordinary table, and rename the intermediate table.
- In a scenario where both an ordinary table and a partitioned table are Ustore tables, if the UB-tree index type (RCR or PCR, RCR by default) of the ordinary table is different from the local UB-tree index type (RCR or PCR, RCR by default) of the partitioned table, data cannot be exchanged.
- If the DROP COLUMN operation is performed on the ordinary or partitioned table, the dropped column still exists physically. Therefore, you need to ensure that the dropped column of the ordinary table is strictly aligned with that of the partition. Otherwise, the exchange will fail.
- The EXCHANGE PARTITION { (partition_name) | partition_name | FOR (partition_value [, ...]) } operation is available in MySQL-compatible database (that is, **sql_compatibility** set to **'MYSQL'**). In other modes, only the EXCHANGE PARTITION { (partition_name) | FOR (partition_value [, ...]) } operation is available. If **partition_name** is the name of a partition, the partition and ordinary table are exchanged.
- If the ordinary table and partition to be swapped contain the rowid column and are in the compressed state, the data in the ordinary table and partition is automatically decompressed after the partition is swapped.

– The row_clause syntax is used to set row movement of a partitioned table.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
{ ENABLE | DISABLE } ROW MOVEMENT
```

- merge_clause: merges multiple partitions into one. Each command can merge a maximum of 300 partitions.

```
MERGE PARTITIONS { partition_name } [, ...] INTO PARTITION partition_name
    [ ILM ADD POLICY ROW STORE COMPRESS { ADVANCED [ MEDIUM | HIGH ] ROW AFTER n
{ day | month | year } OF NO MODIFICATION [ ON ( EXPR )] | TURBO [ LOW | MEDIUM |
HIGH ] UNIT AFTER n { hour | day | month | year } OF NO MODIFICATION | NONE}]
[ TABLESPACE tablespacename ] [ UPDATE GLOBAL INDEX ] [ UPDATE DISTRIBUTED GLOBAL
INDEX | NO UPDATE DISTRIBUTED GLOBAL INDEX ]
```

NOTICE

- For range partitioning and interval partitioning, the ranges of the source partitions must increase continuously, and the partition name after MERGE can be the same as the name of the last source partition. For list partitioning, there is no such range requirement on the source partitions, and the partition name after MERGE can be the same as that of any source partition. If the partition name after MERGE is the same as that of a source partition, they are regarded as the same partition.
- If the GUC parameter **enable_ilm** is not enabled and the merge_clause syntax is used to merge multiple partitions with the ILM policy into one partition, the new partition does not inherit the ILM policy.
- Ustore tables do not support ALTER TABLE MERGE PARTITIONS within transaction blocks or stored procedures.

- The modify_clause syntax is used to set whether a partitioned index is usable.

```
MODIFY PARTITION partition_name { UNUSABLE LOCAL INDEXES | REBUILD UNUSABLE LOCAL
INDEXES | COLVIEW [ PRIORITY { HIGH | LOW | NONE } ] | NOCOLVIEW }
```

- split_clause: splits one partition into multiple.

```
SPLIT PARTITION { partition_name | FOR ( partition_value [, ...] ) } { split_point_clause |
no_split_point_clause } [ UPDATE GLOBAL INDEX ] [ UPDATE DISTRIBUTED GLOBAL INDEX |
NO UPDATE DISTRIBUTED GLOBAL INDEX ]
```

NOTICE

- The partition name after SPLIT can be the same as the source partition name, but they are regarded as different partitions.
- When the GUC parameter **enable_ilm** is disabled, the resulting partitions do not inherit the ILM policy, even if the source partition being split by split_clause has an ILM policy.

  - The split_point_clause syntax for specifying the split point for a range partitioned table is as follows:

```
AT ( partition_value ) INTO ( PARTITION partition_name [ ILM ADD POLICY ROW STORE
COMPRESS { ADVANCED [ MEDIUM | HIGH ] ROW AFTER n { day | month | year } OF NO
MODIFICATION [ ON ( EXPR )] | TURBO [ LOW | MEDIUM | HIGH ] UNIT AFTER n { hour |
day | month | year } OF NO MODIFICATION | NONE}] [ TABLESPACE tablespacename ] ,
PARTITION partition_name [ ILM ADD POLICY ROW STORE COMPRESS { ADVANCED
[ MEDIUM | HIGH ] ROW AFTER n { day | month | year } OF NO MODIFICATION [ ON
( EXPR )] | TURBO [ LOW | MEDIUM | HIGH ] UNIT AFTER n { hour | day | month | year }
OF NO MODIFICATION | NONE}] [ TABLESPACE tablespacename ] )
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTICE

The size of the split point must fall within the range of the partition key for the partition to be split. By specifying a split point, you can only split one partition into two new partitions.

- The no_split_point_clause syntax without specifying a split point for a range partitioned table is as follows:

```
INTO { ( partition_less_than_item [, ...] ) | ( partition_start_end_item [, ...] ) }
```

NOTICE

- When no split point is specified, the partition key of the first new partition specified in **partition_less_than_item** must be greater than that of the partition immediately preceding the one being split (if any); the partition key of the last partition specified in **partition_less_than_item** must equal that of the partition being split.
- When no split point is specified, the start point (if present) of the first new partition specified in **partition_start_end_item** must equal that of the partition immediately preceding the one being split (if any); the end point (if present) of the last partition specified in **partition_start_end_item** must equal that of the partition being split.
- **partition_less_than_item** supports a partition key with up to 16 columns, while **partition_start_end_item** supports a one-column partition key. For details about the supported data types, see **PARTITION BY RANGE(partition_key)** in **CREATE TABLE PARTITION**.
- **partition_less_than_item** and **partition_start_end_item** cannot be used in the same statement. This restriction does not apply across different SPLIT statements.

- The partition_less_than_item syntax is as follows (the range of the last partition is not defined, that is, the VALUES LESS THAN (partition_value) part is not defined; by default, the last partition inherits the upper boundary value of the range defined for the source partition):

```
PARTITION partition_name VALUES LESS THAN {( { partition_value | MAXVALUE }  [, ...] ) | MAXVALUE }
   [ ILM ADD POLICY ROW STORE COMPRESS { ADVANCED [ MEDIUM | HIGH ] ROW AFTER n { day | month | year } OF NO MODIFICATION [ ON ( EXPR )] | TURBO [ LOW | MEDIUM | HIGH ] UNIT AFTER n { hour | day | month | year } OF NO MODIFICATION | NONE}] [ TABLESPACE tablespacename ]
```

NOTICE

During range partitioning, the MAXVALUE keyword can be used without parentheses. It can be used only in MySQL-compatible mode. It cannot be used in subpartitions or in scenarios where multi-column partition keys are used.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- The syntax of **partition_start_end_item** is as follows. For details about the restrictions, see **START END syntax rules** in **CREATE TABLE PARTITION**.

```
PARTITION partition_name {
      {START(partition_value) END (partition_value) EVERY (interval_value)} |
      {START(partition_value) END ({partition_value | MAXVALUE})} |
      {START(partition_value)} |
      {END({partition_value | MAXVALUE})}
} [ ILM ADD POLICY ROW STORE COMPRESS { ADVANCED [ MEDIUM | HIGH ] ROW AFTER n { day | month | year } OF NO MODIFICATION [ ON ( EXPR )] | TURBO [ LOW | MEDIUM | HIGH ] UNIT AFTER n { hour | day | month | year } OF NO MODIFICATION | NONE}] [TABLESPACE tablespace_name]
```

- The split_point_clause syntax for specifying the split point for a list partitioned table is as follows:

```
VALUES ( partition_value_list ) INTO ( PARTITION partition_name [ ILM ADD POLICY ROW STORE COMPRESS { ADVANCED [ MEDIUM | HIGH ] ROW AFTER n { day | month | year } OF NO MODIFICATION [ ON ( EXPR )] | TURBO [ LOW | MEDIUM | HIGH ] UNIT AFTER n { hour | day | month | year } OF NO MODIFICATION | NONE}] [ TABLESPACE tablespacename ] , PARTITION partition_name [ ILM ADD POLICY ROW STORE COMPRESS { ADVANCED [ MEDIUM | HIGH ] ROW AFTER n { day | month | year } OF NO MODIFICATION [ ON ( EXPR )] | TURBO [ LOW | MEDIUM | HIGH ] UNIT AFTER n { hour | day | month | year } OF NO MODIFICATION | NONE}] [ TABLESPACE tablespacename ] )
```

NOTICE

The split point must be a non-empty true subset of the source partition. By specifying a split point, you can only split one partition into two new partitions.

- The no_split_point_clause syntax for not specifying the split point for a list partitioned table is as follows:

```
INTO ( PARTITION partition_name VALUES (partition_value_list) [ ILM ADD POLICY ROW STORE COMPRESS { ADVANCED [ MEDIUM | HIGH ] ROW AFTER n { day | month | year } OF NO MODIFICATION [ ON ( EXPR )] | TURBO [ LOW | MEDIUM | HIGH ] UNIT AFTER n { hour | day | month | year } OF NO MODIFICATION | NONE}] [ TABLESPACE tablespacename ][, ...] )
```

NOTICE

- Do not define the range of the last partition, that is, do not define the VALUES (partition_value_list) part; the partition range is equal to the remaining set of the source partition excluding other subpartitions.
- If no split point is specified, each new partition must be a non-empty true subset of the source partition and does not overlap with each other.

– add_clause: adds one or more partitions to a partitioned table.

```
ADD {{partition_less_than_item | partition_start_end_item} |
    PARTITION({partition_less_than_item | partition_start_end_item | partition_list_item})}
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTICE

- The PARTITION({partition_less_than_item | partition_start_end_item | partition_list_item}) syntax can be used only in MySQL-compatible mode.
- The ALTER TABLE table_name ADD PARTITION (partition_definition1, partition_definition2,…); syntax cannot be used to add multiple partitions. Only the original syntax for adding multiple partitions is supported: ALTER TABLE table_name ADD PARTITION (partition_definition1), ADD PARTITION (partition_definition2), …

Syntax for **partition_list_item**:

```
PARTITION partition_name VALUES [IN] (list_values_clause)
   [ ILM ADD POLICY ROW STORE COMPRESS { ADVANCED [ MEDIUM | HIGH ] ROW AFTER n
{ day | month | year } OF NO MODIFICATION [ ON ( EXPR )] | TURBO [ LOW | MEDIUM |
HIGH ] UNIT AFTER n { hour | day | month | year } OF NO MODIFICATION | NONE}]
[ TABLESPACE tablespacename ]
```

NOTICE

- **partition_list_item** supports a maximum of 16 partition keys. For details about the supported data types, see **PARTITION BY LIST [COLUMNS] (partition_key)** in **CREATE TABLE PARTITION**.
- Partitions cannot be added to a hash partitioned table.
- IN needs to be used in MySQL-compatible mode and cannot be used in subpartitions.

– drop_clause: drops a partition from a partitioned table.

```
DROP PARTITION  { partition_name | FOR (  partition_value [, ...] )  } [ UPDATE GLOBAL
INDEX ] [ UPDATE DISTRIBUTED GLOBAL INDEX | NO UPDATE DISTRIBUTED GLOBAL INDEX ]
```

NOTICE

- Partitions cannot be dropped from hash partitioned tables.
- If a partitioned table contains only one partition, that partition cannot be dropped.

– truncate_clause: truncates a partition in a partitioned table.

```
TRUNCATE PARTITION  { partition_name | FOR (  partition_value [, ...] )  } [ UPDATE GLOBAL
INDEX ] [ UPDATE DISTRIBUTED GLOBAL INDEX | NO UPDATE DISTRIBUTED GLOBAL INDEX ]
```

– The ilm_clause syntax adds an ILM policy to a partition. It supports the syntax for the OLTP table compression feature of data lifecycle management.

```
MODIFY PARTITION partition_name ILM ADD POLICY ROW STORE COMPRESS ADVANCED
[ MEDIUM | HIGH ] ROW AFTER n { day | month | year } OF NO MODIFICATION [ ON ( EXPR ) ]
```

– The set_partitioning_clause syntax is used to set storage parameters for partitions. It is called in online DDL operations. You are advised not to use it.

```
SET ({storage_parameter = value} )
```

- Alter the name of a partition.

```
ALTER TABLE [ IF EXISTS ] { table_name [*] | ONLY table_name | ONLY ( table_name  )}
   RENAME PARTITION { partition_name | FOR ( partition_value [, ...] ) } TO partition_new_name;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- Reset a partition ID.

```
ALTER TABLE [ IF EXISTS ] { table_name [*] | ONLY table_name | ONLY ( table_name  )} RESET PARTITION;
```

Parameters

- **ONLINE | OFFLINE**

  Controls whether to enable online DDL operations.

  The keywords ONLINE and OFFLINE are used.

  – ONLINE: DDL operations are executed online. In this case, if the ALTER TABLE statement contains a scenario that is not supported by the current DDL feature, the DDL operations are executed offline and a notice is displayed, indicating that the ONLINE keyword is ignored.

  – OFFLINE: DDL operations are executed offline.

  NOTE

  - During the online DDL operation of exchanging partitions, the system checks if the data falls within the range of the corresponding partitions. If the check result indicates that it falls outside the specified range, an error occurs during the DDL operation. Online DDL operations and DML operations can be performed concurrently. However, concurrent DML operations may delete data outside the corresponding partition range, whereas an error may be still reported for the DDL operations.

    For example, during the online DDL transaction of scanning a table, if the online DDL transaction detects that tuple A in the table is not within the range of the corresponding partitions, an error occurs immediately. If a parallel transaction deletes tuple A after an online DDL operation scans the tuple, tuple A is not considered as deleted.
  - Online DDL error troubleshooting: The system automatically creates a temporary schema as the DDL implementation tool and sets the table to the **append_mode** state during online DDL operations (including changing the column type, precision, and length, and adding NOT NULL, CHECK, PRIMARY KEY, and UNIQUE constraints). If the online DDL execution is complete, the temporary mode is automatically cleared and restored. Automatic cleanup may fail due to reasons such as lock timeout. In this case, manual cleanup is required. If a severe fault occurs, such as FATAL, PANIC, database fault, or node disconnection, the created temporary schema and table appending status may remain. In this case, you need to manually clear and restore the temporary schema and table. The scenarios are as follows:
    - Canceling online DDL operations: If you cancel online DDL operations during the execution, the system automatically clears the data. If the execution is canceled, the residual data clearance process starts first. If the execution is canceled again, the clearance process ends and residual data remains.
    - Operation error: If an error needs to be reported during the execution of a DDL command, for example, type conversion fails or length modification damages data, the system reports an error and automatically clears the data.
    - Major fault: After the cluster becomes normal, you can manually clear the data using **online_ddl_cleanup()**, or the data will be automatically cleared when you run online DDL operations or online VACUUM FULL next time.
  - You are advised not to call **online_ddl_cleanup()** during online DDL execution. Otherwise, the online DDL operations may be terminated or an unknown error may occur.

- **online_parameter**

  Specifies the online DDL option when the **ONLINE** keyword is specified. If the **ONLINE** keyword is not specified or online DDL conditions are not met, this parameter does not take effect.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Value range:

- **parallel_threads**: specifies the number of threads when parallelism is enabled. Value range: an integer ranging from 1 to 32. The default value is **1**.
  - When **parallel_threads** is set to a value greater than 1, multiple threads are enabled and the number of threads is specified.
  - If **parallel_threads** is not set or is set to **1**, multi-thread acceleration is disabled.

    When a user enables resource and workload management, for example, I/O resource management (for example, **io_limits** > **0** or **io_priority** = **high**/**medium**/**low**), **parallel_threads** ignores resource and workload management under the user or session. In addition, a notice is displayed, indicating that the current resource and workload management is invalid and multi-thread acceleration is enabled. The multi-thread execution process of online DDL operations actually follows the resource and workload management of the initial user.
  - When **parallel_workers** and **parallel_threads** are used together for acceleration, **parallel_workers** controls the maximum number of parallel threads in an index, and **parallel_threads** controls the maximum number of parallel threads between indexes.
- **max_catchup_times**: specifies the maximum number of online DDL catchups to prevent long online DDL execution time. Value range: an integer ranging from 1 to 50. The default value is **50**.
  - Online DDL execution records the DML incremental data generated during data reconstruction to a temporary table and performs multiple cyclic catchups to reconstruct the incremental data. If the amount of concurrent DML data is too large, online DDL catchup fails. To prevent this problem, you can set this parameter to limit the number of catchups.

- **table_name**

  Specifies the name of a partitioned table.

  Value range: existing partitioned table names.

- **partition_name**

  Specifies the name of a partition.

  Value range: existing partition names.

- **tablespacename**

  Specifies the destination tablespace for partition movement.

  Value range: existing tablespace names.

- **partition_value**

  Specifies partition key values.

  The values specified by PARTITION FOR (partition_value [, ...]) uniquely identify a partition.

  Value range: determined by the value range of the partition key for the involved partition.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **UNUSABLE LOCAL INDEXES**

  Sets all the indexes unusable in the partition.

- **REBUILD UNUSABLE LOCAL INDEXES**

  Rebuilds all the indexes in the partition.

- **{ ENABLE | DISABLE } ROW MOVEMENT**

  Specifies whether to enable row movement.

  If the tuple value is updated on the partition key during the UPDATE operation, the partition where the tuple is located is altered. Setting this parameter enables error messages to be reported or movement of the tuple between partitions.

  Value range:

  - **ENABLE**: Row movement is enabled.
  - **DISABLE**: Row movement is disabled.

  By default, this parameter is disabled.

- **ordinary_table_name**

  Specifies the name of the ordinary table involved in data migration.

  Value range: existing ordinary table names.

- **{ WITH | WITHOUT } VALIDATION**

  Checks whether data in the ordinary table falls within the partition key range of the partition involved in data migration.

  Value range:

  - **WITH**: The system checks whether data in the ordinary table falls within the partition key range of the target partition. If any data falls outside this range, an error is reported.
  - **WITHOUT**: The system does not check whether data in the ordinary table falls within the partition key range of the target partition.

  The default value is **WITH**.

  The check is time consuming, especially when the data volume is large. Therefore, if you are sure that all data in the ordinary table falls within the partition key range of the target partition, use **WITHOUT** to skip this check.

- **VERBOSE**

  When **VALIDATION** is **WITH**, if the ordinary table contains data that is out of the partition key range, insert the data to the correct partition. If there is no correct partition where the data can be inserted to, an error is reported.

  NOTICE

  Only when **VALIDATION** is **WITH**, **VERBOSE** can be specified.

- **partition_new_name**

  Specifies a new partition name.

  Value range: character strings complying with **Identifier Naming Conventions**.

- **UPDATE GLOBAL INDEX**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Updates all global indexes in the partitioned table to ensure accurate data queries using global indexes.

If this parameter is not used, all global indexes in the partitioned table will become invalid.

- **UPDATE DISTRIBUTED GLOBAL INDEX**

  Updates all available global secondary indexes in the partitioned table to ensure that the data in the global secondary indexes is consistent with that in the base table. EXCHANGE PARTITION also updates all available global secondary indexes in the ordinary table.

  If this parameter is not used, all global secondary indexes in the partitioned table become invalid. EXCHANGE PARTITION also invalidates all global secondary indexes in the ordinary table.

- **NO UPDATE DISTRIBUTED GLOBAL INDEX**

  If this parameter is used, all GSIs in the partitioned table become invalid. EXCHANGE PARTITION also invalidates all global secondary indexes in the ordinary table.

- **storage_parameter**

  Specifies the name of a storage parameter.

  It is called in online DDL operations. You are advised not to use it.

  – **online_ddl_status** (enumerated type)

    This parameter is used to update the online DDL execution status of a target table.

    It is called in online DDL operations. You are advised not to use it.

    - **on**: enables the online DDL status.
    - **off**: disables the online DDL status.
    - **init**: initializes online DDL temporary objects.
    - **catchup**: synchronizes incremental data for concurrent online DDL operations.
    - **catchup_basedata**: synchronizes basic data of online DDL operations.
    - **scan_catchup**: performs catchup when NOT NULL or CHECK constraints are added online.
    - **scan_catchup_basedata**: checks the basic data about adding NOT NULL or CHECK constraints online.
    - **vacuum_catchup**: performs catchup when VACUUM FULL is performed online.
    - **vacuum_verbose_catchup**: performs catchup when VACUUM FULL VERBOSE is performed online.
    - **last_catchup**: reports errors for the write service in the last online DDL catchup.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

  - **switch**: exchanges temporary tables in the last online DDL catchup.
  - **copy_switch**: exchanges temporary tables in the last online tablespace movement catchup.
  - **record_toast_oid**: records the OID of a TOAST table attached to a target table of online DDL operations.
  - **abort**: specifies that online DDL operations enter the abort state.
  - **flush_buffer**: forcibly flushes buffers to disks when tablespaces are moved online.
  - **tmp_rel**: indicates a temporary table created during an online DDL process.
  - **validate_constr**: validates the CHECK constraints created by the **NOT VALID** option.
  - **vacuum_switch**: performs the last round of incremental temporary table exchange using online VACUUM FULL.
- **online_ddl_lock_tag** (int type)

  Unique ID of a target table of online DDL operations, which is used to generate temporary objects. The ID is the hash value of (Table schema + Table name).

  It is called in online DDL operations. You are advised not to use it.

Examples

- Change the name of a table partition.

```
-- Create a partitioned table.
gaussdb=# CREATE TABLE test_p1 (col1 INT, col2 INT) PARTITION BY RANGE (col1)
(
    PARTITION p1 VALUES LESS THAN (10),
    PARTITION p2 VALUES LESS THAN (20),
    PARTITION p3 VALUES LESS THAN (MAXVALUE)
);

-- Modify a partition name.
gaussdb=# ALTER TABLE test_p1 RENAME PARTITION p3 TO pmax;

-- Query partition information.
gaussdb=# SELECT relname, boundaries, oid FROM pg_partition WHERE parentid='test_p1'::regclass
AND parttype <> 'r';
 relname | boundaries |  oid
---------+------------+-------
 p1      | {10}       | 17066
 p2      | {20}       | 17067
 pmax    | {NULL}     | 17068
(3 rows)
```

- Move partition tablespaces.

```
-- Create a partition.
gaussdb=# CREATE TABLESPACE tbs_data1 RELATIVE LOCATION 'tablespace1/tbs_data1';

-- Move partition tablespaces.
gaussdb=# ALTER TABLE test_p1 MOVE PARTITION P1 TABLESPACE tbs_data1;

-- Check the partition tablespace.
gaussdb=# SELECT relname, spcname FROM pg_partition t1, pg_tablespace t2 WHERE
T1.reltablespace=t2.oid and t1.parentid='test_p1'::regclass;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
 relname |  spcname
---------+-----------
 p1      | tbs_data1
(1 row)

-- Move a partition tablespace online.
gaussdb=# ALTER TABLE test_p1 MOVE PARTITION P1 TABLESPACE pg_default;
gaussdb=# ALTER TABLE ONLINE test_p1 MOVE PARTITION P1 TABLESPACE tbs_data1;
ALTER TABLE
gaussdb=# SELECT relname, spcname FROM pg_partition t1, pg_tablespace t2 WHERE
T1.reltablespace=t2.oid and t1.parentid='t1'::regclass;
 relname | spcname
---------+---------
 p1      | tbs_data1
(1 row)
```

- Exchange partitions.

```
-- Create an ordinary table and insert data.
gaussdb=# CREATE TABLE test_ep1(col1 INT,col2 INT);
gaussdb=# INSERT INTO test_ep1 VALUES (GENERATE_SERIES(1,30), 1000);

-- Migrate data from an ordinary table to a partition.
gaussdb=# ALTER TABLE test_p1 EXCHANGE PARTITION (p1) WITH TABLE test_ep1 VERBOSE;

-- Query.
gaussdb=# SELECT COUNT(*) FROM test_p1 PARTITION (p1);
 count
-------
     9
(1 row)

-- Truncate table data.
gaussdb=# TRUNCATE TABLE test_ep1;
TRUNCATE TABLE
-- Insert data.
gaussdb=# INSERT INTO test_ep1 VALUES (GENERATE_SERIES(1,30), 1000);
INSERT 0 30
-- Migrate ordinary table data to a specified partition online.
gaussdb=# ALTER TABLE ONLINE test_p1 EXCHANGE PARTITION (p1) WITH TABLE test_ep1 VERBOSE;
ALTER TABLE
-- Query.
gaussdb=# SELECT COUNT(*) FROM test_p1 PARTITION (p1);
 count
-------
     9
(1 row)

-- Drop the test_ep1 table.
gaussdb=# DROP TABLE test_ep1;
```

- Merge partitions.

```
-- Merge the p2 and pmax partitions in the test_p1 table into the pmax partition.
gaussdb=# ALTER TABLE test_p1 MERGE PARTITIONS p2,pmax INTO PARTITION pmax;

-- View the partitions.
gaussdb=# SELECT relname, boundaries, oid FROM pg_partition WHERE parentid='test_p1'::regclass
AND parttype <> 'r' order by 1;
 relname | boundaries |  oid
---------+------------+-------
 p1      | {10}       | 17066
 pmax    | {NULL}     | 17070
(2 rows)

-- Drop the table.
gaussdb=# DROP TABLE test_p1;
DROP TABLE
-- Create a partitioned table.
gaussdb=# CREATE TABLE test_p1 (col1 INT, col2 INT) PARTITION BY RANGE (col1)
(
    PARTITION p1 VALUES LESS THAN (10),
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
    PARTITION p2 VALUES LESS THAN (20),
    PARTITION p3 VALUES LESS THAN (MAXVALUE)
);
-- Merge the p2 and pmax partitions in the test_p1 table into pmax online.
gaussdb=# ALTER TABLE ONLINE test_p1 MERGE PARTITIONS p2,p3 INTO PARTITION pmax;
ALTER TABLE
gaussdb=# SELECT relname, boundaries FROM pg_partition WHERE parentid='test_p1'::regclass AND
parttype <> 'r' order by 1;
 relname | boundaries
---------+------------
 p1      | {10}
 pmax    | {NULL}
(2 rows)

-- Drop the table and tablespace.
gaussdb=# DROP TABLE test_p1;
gaussdb=# DROP TABLESPACE tbs_data1;
```

- Split partitions.

```
-- Create a table.
gaussdb=# CREATE TABLE test_r1 (col1 INT,col2 INT) PARTITION BY RANGE (col1)(
    PARTITION p1   VALUES LESS THAN (10),
    PARTITION pmax VALUES LESS THAN (MAXVALUE)
);

-- Split a partition.
gaussdb=# ALTER TABLE test_r1 SPLIT PARTITION pmax AT (20) INTO (PARTITION p2, PARTITION
pmax);
gaussdb=# ALTER TABLE test_r1 SPLIT PARTITION pmax INTO (
    PARTITION p3   VALUES LESS THAN (30),
    PARTITION pmax VALUES LESS THAN (MAXVALUE)
);

-- Query.
gaussdb=# SELECT relname, boundaries, oid FROM pg_partition WHERE parentid='test_r1'::regclass
AND parttype <> 'r' order by 1;
 relname | boundaries |  oid
---------+------------+-------
 p1      | {10}       | 17088
 p2      | {20}       | 17090
 p3      | {30}       | 17092
 pmax    | {NULL}     | 17093
(4 rows)

-- Drop the table.
gaussdb=# DROP TABLE test_r1;
DROP TABLE
-- Create a table.
gaussdb=# CREATE TABLE test_r1 (col1 INT,col2 INT) PARTITION BY RANGE (col1)(
    PARTITION p1   VALUES LESS THAN (10),
    PARTITION pmax VALUES LESS THAN (MAXVALUE)
);
-- Splite a partition online.
gaussdb=# ALTER TABLE ONLINE test_r1 SPLIT PARTITION pmax AT (20) INTO (PARTITION p2,
PARTITION pmax);
ALTER TABLE
gaussdb=# ALTER TABLE ONLINE test_r1 SPLIT PARTITION pmax INTO (
    PARTITION p3   VALUES LESS THAN (30),
    PARTITION pmax VALUES LESS THAN (MAXVALUE)
);
ALTER TABLE
gaussdb=#  SELECT relname, boundaries FROM pg_partition WHERE parentid='test_r1'::regclass AND
parttype <> 'r' order by 1;
 relname | boundaries
---------+------------
 p1      | {10}
 p2      | {20}

Helpful Links

CREATE TABLE PARTITION and **DROP TABLE**

1.13.7.36 ALTER TABLE SUBPARTITION

Description

Alters partitions of a subpartitioned table, including adding, dropping, clearing, splitting, merging, exchanging, renaming partitions, moving partition tablespaces, and modifying partition attributes.

Precautions

- The tablespace of the added partition cannot be PG_GLOBAL.
- The name of any added partition must differ from the names of existing partitions and subpartitions in the partitioned table.
- The partition key value of any added partition must match the partition key type of the partitioned table.
- If a range partition is added, the key value of the added partition must be greater than the upper limit of the last range partition in the partitioned

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

table. To add a partition to a table with the **MAXVALUE** partition, you are advised to use the SPLIT syntax.

- If a list partition is added, the key value of the added partition cannot be the same as that of an existing partition. To add a partition to a table with the **DEFAULT** partition, you are advised to use the SPLIT syntax.
- Hash partitions cannot be added. However, if the subpartition mode of a subpartitioned table is hash but the partition mode is not hash, you can add a partition and create the corresponding subpartition.
- When the number of partitions in the target partitioned table reaches the maximum limit (1,048,575), no additional partitions can be added.
- If a partitioned table contains only one partition or subpartition, that partition or subpartition cannot be dropped.
- Hash partitions cannot be deleted.
- When you use PARTITION FOR() or SUBPARTITION FOR() to select partitions, the number of values specified within the parentheses must match the number of columns specified in the partition definition, and they must correspond in a one-to-one manner.
- Only subpartitions (leaf nodes) can be split. Only range and list partitioning policies can be used and hash partitioning policies are not supported.
- Only subpartitions (leaf nodes) can be merged, and the source partitions must belong to the same partition.
- Only the owner of a partitioned table or users with the ALTER permission on the partitioned table can run the **ALTER TABLE PARTITION** command. System administrators have the permission to run the command by default.
- Deleting, splitting, clearing, and exchanging partitions will invalidate global indexes. The UPDATE GLOBAL INDEX clause can be used to update indexes synchronously.
- If partitions are dropped, split, truncated, or exchanged without declaring the UPDATE GLOBAL INDEX clause, concurrent DML statements may trigger errors due to unusable indexes.
- If **enable_gpi_auto_update** is set to **on**, the global index is automatically updated even if the UPDATE GLOBAL INDEX clause is not declared.
- If the **enable_drop_truncate_partition_keep_gpi** parameter is set to **on**, the global index remains valid when partitions are dropped or truncated. In this case, the global index is always valid, regardless of whether the DROP/TRUNCATE PARTITION statement contains the UPDATE GLOBAL INDEX clause. This priority is higher than that of the **enable_gpi_auto_update** parameter and the UPDATE GLOBAL INDEX clause explicitly specified by the user.
- If you add a row-level expression when adding or changing an ILM policy for a data object, note that the row-level expression supports only the functions listed in the whitelist. For details about the whitelist function list, see **Row Expression Function Whitelist**.

  NOTE

  Among the functions supported by the row-level expression ON (EXPR) in the ILM policy, the output of some may be influenced by compatibility parameters. For instance, after you set **b_format_version** to **'5.7'** and **b_format_dev_version** to **'s2'** in MySQL-compatible mode, the upper function will be unable to convert data to uppercase as usual.

Syntax

Modifying a partition in a subpartitioned table includes modifying the table partition itself and the table partition name, and resetting the partition ID.

- Main syntax for modifying a partition:

```
ALTER TABLE [ IF EXISTS ] { table_name  [*] | ONLY table_name | ONLY ( table_name  )}
    action [, ... ];
```

action includes the following partition maintenance clauses. For the partition continuity when multiple clauses are used for partition maintenance, GaussDB executes DROP PARTITION and ADD PARTITION first, and then the rest clauses in sequence.

```
{ move_clause |
    exchange_clause  |
    row_clause  |
    merge_clause  |
    modify_clause  |
    add_clause    |
    drop_clause   |
    split_clause  |
    truncate_clause  |
    ilm_clause }
```

  - move_clause: moves the partition to a different tablespace.

```
MOVE SUBPARTITION { subpartition_name | FOR ( subpartition_value [, ...] ) } TABLESPACE
tablespacename
```

  - exchange_clause: moves data from an ordinary table to a specified partition.

```
EXCHANGE SUBPARTITION { ( subpartition_name ) | FOR ( subpartition_value [, ...] ) }
    WITH TABLE {[ ONLY ] ordinary_table_name | ordinary_table_name * | ONLY
( ordinary_table_name )}
    [ { WITH | WITHOUT } VALIDATION ] [ VERBOSE ] [ UPDATE GLOBAL INDEX ]
```

    The ordinary table and partition involved in the exchange must meet the following requirements:

    - The number of columns in the ordinary table must match that in the partition, with consistent column details including names, data types, constraints, collations, storage parameters, and compression information.
    - The compression information must be consistent between the ordinary table and partition.
    - The number of indexes in the ordinary table must match the number of local indexes in the partition, with consistent index information.
    - The number of table constraints must be consistent between the ordinary table and partition, with consistent constraint information.
    - The ordinary table cannot be a temporary table, and the partitioned table should be a subpartitioned table.
    - Ordinary tables and partitioned tables do not support dynamic data masking and row-level security constraints.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTICE

- After the exchange is completed, the data of the ordinary table and partition are swapped, along with their tablespace information. At this point, statistics on the ordinary table and partition become unreliable, necessitating an ANALYZE operation.
- Non-partition keys cannot be used to create local unique indexes; only global unique indexes are permitted. Therefore, if an ordinary table contains a unique index, its data may fail to be exchanged.

  To exchange data, you can create an intermediate table, insert the partition's data into the intermediate table, truncate the partition, insert the ordinary table's data into the partitioned table, drop the ordinary table, and rename the intermediate table.
- If the DROP COLUMN operation is performed on an ordinary or partitioned table, the dropped column still exists physically. Therefore, you need to ensure that the dropped column of the ordinary table is strictly aligned with that of the partition. Otherwise, the exchange will fail.
- If the ordinary table and partition to be swapped contain the rowid column and are in the compressed state, the data in the ordinary table and partition is automatically decompressed after the partition is swapped.

– The row_clause syntax is used to set row movement of a partitioned table.

```
{ ENABLE | DISABLE } ROW MOVEMENT
```

– The merge_clause syntax is used to merge partitions into one. The maximum number of source partitions that can be merged in a command is 300.

```
MERGE SUBPARTITIONS { subpartition_name } [, ...] INTO SUBPARTITION subpartition_name
    [ ILM ADD POLICY ROW STORE COMPRESS { ADVANCED [ MEDIUM | HIGH ] ROW AFTER n
{ day | month | year } OF NO MODIFICATION [ ON ( EXPR )] | TURBO [ LOW | MEDIUM |
HIGH ] UNIT AFTER n { hour | day | month | year } OF NO MODIFICATION | NONE}]
[ TABLESPACE tablespacename ] [ UPDATE GLOBAL INDEX ]
```

NOTICE

- For range partitioning, the ranges of the source partitions must increase continuously, and the partition name after MERGE can be the same as the name of the last source partition. For list partitioning, there is no such range requirement on the source partitions, and the partition name after MERGE can be the same as that of any source partition. If the partition name after MERGE is the same as that of a source partition, they are considered as the same partition.
- If the GUC parameter **enable_ilm** is not enabled and the merge_clause syntax is used to merge multiple partitions with the ILM policy into one partition, the new partition does not inherit the ILM policy.
- Ustore tables do not support ALTER TABLE MERGE SUBPARTITIONS in transaction blocks and stored procedures.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- The modify_clause syntax is used to set whether a partitioned index is usable. Here is an example of applying the syntax to partitions:

```
MODIFY PARTITION partition_name { UNUSABLE LOCAL INDEXES | REBUILD UNUSABLE LOCAL INDEXES }
```

  It can also be applied to subpartitions:

```
MODIFY SUBPARTITION subpartition_name { UNUSABLE LOCAL INDEXES | REBUILD UNUSABLE LOCAL INDEXES }
```

- The add_clause syntax is used to add one or more partitions to a specified partitioned table. Here is an example of applying the syntax to partitions:

```
ADD {partition_less_than_item | partition_list_item } [ ( subpartition_definition_list ) ]
```

  It can also be applied to subpartitions:

```
MODIFY PARTITION partition_name ADD subpartition_definition
```

  partition_less_than_item defines a range partition. The syntax is as follows:

```
PARTITION partition_name VALUES LESS THAN ( partition_value | MAXVALUE )[ ILM ADD POLICY ROW STORE COMPRESS { ADVANCED [ MEDIUM | HIGH ] ROW AFTER n { day | month | year } OF NO MODIFICATION [ ON ( EXPR )] | TURBO [ LOW | MEDIUM | HIGH ] UNIT AFTER n { hour | day | month | year } OF NO MODIFICATION | NONE}] [ TABLESPACE tablespacename ]
```

  partition_list_item defines a list partition. The syntax is as follows:

```
PARTITION partition_name VALUES ( partition_value [, ...] | DEFAULT ) [ ILM ADD POLICY ROW STORE COMPRESS { ADVANCED [ MEDIUM | HIGH ] ROW AFTER n { day | month | year } OF NO MODIFICATION [ ON ( EXPR )] | TURBO [ LOW | MEDIUM | HIGH ] UNIT AFTER n { hour | day | month | year } OF NO MODIFICATION | NONE}] [ TABLESPACE tablespacename ]
```

  subpartition_definition_list contains the **subpartition_definition** object of one or more subpartitions. The syntax is as follows:

```
SUBPARTITION subpartition_name [ VALUES LESS THAN ( partition_value | MAXVALUE ) | VALUES ( partition_value [, ...] | DEFAULT )] [ ILM ADD POLICY ROW STORE COMPRESS { ADVANCED [ MEDIUM | HIGH ] ROW AFTER n { day | month | year } OF NO MODIFICATION [ ON ( EXPR )] | TURBO [ LOW | MEDIUM | HIGH ] UNIT AFTER n { hour | day | month | year } OF NO MODIFICATION | NONE}] [ TABLESPACE tablespace ]
```

  NOTICE

  If the partition is a hash partition, you cannot use ADD to add a partition. If the subpartition is a hash partition, you cannot use MODIFY to add a subpartition.

- The drop_clause syntax is used to remove a partition from a specified partitioned table. Here is an example of applying the syntax to partitions:

```
DROP PARTITION { partition_name | FOR ( partition_value ) } [ UPDATE GLOBAL INDEX ]
```

  It can also be applied to subpartitions:

```
DROP SUBPARTITION { subpartition_name | FOR ( partition_value, subpartition_value ) } [ UPDATE GLOBAL INDEX ]
```

  NOTICE

  - If the partition is a hash partition, the partition cannot be dropped. If the subpartition is a hash partition, the subpartition cannot be dropped.
  - At least one sub-partition must be retained.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

– The split_clause syntax is used to split one partition into multiple ones.

```
SPLIT SUBPARTITION { subpartition_name| FOR ( subpartition_value [, ...] ) } { split_point_clause | no_split_point_clause } [ UPDATE GLOBAL INDEX ]
```

NOTICE

- The partition name after SPLIT can be the same as the source partition name, but they are regarded as different partitions.
- When the GUC parameter **enable_ilm** is disabled, the resulting partitions do not inherit the ILM policy, even if the source partition being split by split_clause has an ILM policy.

▪ The split_point_clause syntax for specifying the split point for range partitioning is as follows:

```
AT ( subpartition_value ) INTO ( SUBPARTITION subpartition_name [ ILM ADD POLICY ROW STORE COMPRESS { ADVANCED [ MEDIUM | HIGH ] ROW AFTER n { day | month | year } OF NO MODIFICATION [ ON ( EXPR )] | TURBO [ LOW | MEDIUM | HIGH ] UNIT AFTER n { hour | day | month | year } OF NO MODIFICATION | NONE}] [ TABLESPACE tablespacename ] , SUBPARTITION subpartition_name [ ILM ADD POLICY ROW STORE COMPRESS { ADVANCED [ MEDIUM | HIGH ] ROW AFTER n { day | month | year } OF NO MODIFICATION [ ON ( EXPR )] | TURBO [ LOW | MEDIUM | HIGH ] UNIT AFTER n { hour | day | month | year } OF NO MODIFICATION | NONE}] [ TABLESPACE tablespacename ] )
```

NOTICE

The split point must be in the range of partition keys of the partition to be split. Specifying a split point can only split one partition into two partitions.

▪ The no_split_point_clause syntax for not specifying the split point for a list partitioned table is as follows:

```
INTO ( SUBPARTITION subpartition_name VALUES LESS THAN (subpartition_value) [ ILM ADD POLICY ROW STORE COMPRESS { ADVANCED [ MEDIUM | HIGH ] ROW AFTER n { day | month | year } OF NO MODIFICATION [ ON ( EXPR )] | TURBO [ LOW | MEDIUM | HIGH ] UNIT AFTER n { hour | day | month | year } OF NO MODIFICATION | NONE}] [ TABLESPACE tablespacename ][, ...] )
```

NOTICE

- The range defined for the first new partition must be greater than that of the previous partition (if any) of the partition being split.
- The range of the last partition is not defined, that is, the VALUES LESS THAN (subpartition_value) part is not defined; by default, the last partition inherits the upper boundary value of the range defined for the source partition.
- The new partition must meet the constraint of continuously increasing range.

▪ The split_point_clause syntax for specifying the split point for list-range partitioning is as follows:

```
VALUES ( subpartition_value_list ) INTO ( SUBPARTITION subpartition_name [ ILM ADD POLICY ROW STORE COMPRESS { ADVANCED [ MEDIUM | HIGH ] ROW AFTER n { day |
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
month | year } OF NO MODIFICATION [ ON ( EXPR )] | TURBO [ LOW | MEDIUM | HIGH ]
UNIT AFTER n { hour | day | month | year } OF NO MODIFICATION | NONE}]
[ TABLESPACE tablespacename ] , SUBPARTITION subpartition_name [ ILM ADD POLICY
ROW STORE COMPRESS { ADVANCED [ MEDIUM | HIGH ] ROW AFTER n { day | month |
year } OF NO MODIFICATION [ ON ( EXPR )] | TURBO [ LOW | MEDIUM | HIGH ] UNIT
AFTER n { hour | day | month | year } OF NO MODIFICATION | NONE}] [ TABLESPACE
tablespacename ] )
```

NOTICE

The split point must be a non-empty true subset of the source partition. By specifying a split point, you can only split one partition into two new partitions.

- The no_split_point_clause syntax for not specifying the split point for a list partitioned table is as follows:

```
INTO ( SUBPARTITION subpartition_name VALUES (subpartition_value_list) [ ILM ADD
POLICY ROW STORE COMPRESS { ADVANCED [ MEDIUM | HIGH ] ROW AFTER n { day |
month | year } OF NO MODIFICATION [ ON ( EXPR )] | TURBO [ LOW | MEDIUM | HIGH ]
UNIT AFTER n { hour | day | month | year } OF NO MODIFICATION | NONE}]
[ TABLESPACE tablespacename ][, ...] )
```

NOTICE

- Do not define the range for the last partition, that is, VALUES (subpartition_value_list), as it automatically covers the remaining portion of the source partition, excluding other subpartitions.
- If no split point is specified, each new partition must be a non-empty true subset of the source partition and does not overlap with each other.

– truncate_clause: truncates a partition in a partitioned table. Here is an example of applying the syntax to partitions:

```
TRUNCATE PARTITION  { partition_name | FOR (  partition_value [, ...] )  } [ UPDATE GLOBAL
INDEX ]
```

It can also be applied to subpartitions:

```
TRUNCATE SUBPARTITION  { subpartition_name | FOR (  subpartition_value [, ...] )  } [ UPDATE
GLOBAL INDEX ]
```

– The ilm_clause syntax adds an ILM policy to a partition. It supports the syntax for the OLTP table compression feature of data lifecycle management. Here is an example of applying the syntax to partitions:

```
MODIFY PARTITION partition_name ILM ADD POLICY ROW STORE COMPRESS ADVANCED
[ MEDIUM | HIGH ] ROW AFTER n { day | month | year } OF NO MODIFICATION [ ON ( EXPR ) ]
```

It can also be used in subpartitions.

```
MODIFY SUBPARTITION subpartition_name ILM ADD POLICY ROW STORE COMPRESS
ADVANCED [ MEDIUM | HIGH ] ROW AFTER n { day | month | year } OF NO MODIFICATION
[ ON ( EXPR ) ]
```

- Alter the name of a partition. This syntax can be used to change partitions of a partitioned table.

```
ALTER TABLE [ IF EXISTS ] { table_name [*] | ONLY table_name | ONLY ( table_name  )}
    RENAME PARTITION { partition_name | FOR ( partition_value [, ...] ) } TO partition_new_name;
```

It can also be used to modify subpartitions in a partitioned table:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
ALTER TABLE [ IF EXISTS ] { table_name [*] | ONLY table_name | ONLY ( table_name  )}
   RENAME SUBPARTITION { subpartition_name | FOR ( subpartition_value [, ...] ) } TO
subpartition_new_name;
```

- Reset a partition ID.

```
ALTER TABLE [ IF EXISTS ] { table_name [*] | ONLY table_name | ONLY ( table_name  )} RESET
PARTITION;
```

Parameters

- **table_name**

  Specifies the name of a partitioned table.

  Value range: existing partitioned table names.

- **subpartition_name**

  Specifies the name of a subpartition.

  Value range: existing subpartition names.

- **tablespacename**

  Specifies the destination tablespace for partition movement.

  Value range: existing tablespace names.

- **partition_value**

  Specifies partition key values.

  The values specified by PARTITION FOR (partition_value [, ...]) uniquely identify a partition.

  Value range: determined by the value range of the partition key for the involved partition.

- **subpartition_value**

  Specifies the values of the partition and subpartition keys.

  The values specified by SUBPARTITION FOR (subpartition_value [, ...]) uniquely identify a subpartition.

  Value range: determined by the value ranges of the partition keys for the involved partition and subpartition.

- **UNUSABLE LOCAL INDEXES**

  Sets all indexes in the partition as unusable.

- **REBUILD UNUSABLE LOCAL INDEXES**

  Rebuilds all indexes in the partition.

- **{ ENABLE | DISABLE } ROW MOVEMENT**

  Specifies whether to enable row movement.

  If an UPDATE operation changes the value of a tuple on the partition key, causing the tuple to move to a different partition, an error will occur based on the setting you have chosen, or the tuple will be transferred between partitions.

  Value range:

  - **ENABLE**: Row movement is enabled.
  - **DISABLE**: Row movement is disabled.

  By default, it is disabled.

- **ordinary_table_name**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Specifies the name of the ordinary table involved in data migration.

Value range: existing ordinary table names.

- **{ WITH | WITHOUT } VALIDATION**

  Checks whether data in the ordinary table falls within the partition key range of the partition involved in data migration.

  Value range:

  - **WITH**: The system checks whether data in the ordinary table falls within the partition key range of the target partition. If any data falls outside this range, an error is reported.
  - **WITHOUT**: The system does not check whether data in the ordinary table falls within the partition key range of the target partition.

  The default value is **WITH**.

  The check is time consuming, especially when the data volume is large. Therefore, if you are sure that all data in the ordinary table falls within the partition key range of the target partition, use **WITHOUT** to skip this check.

- **VERBOSE**

  When **VALIDATION** is **WITH**, if the ordinary table contains data that is out of the partition key range, insert the data to the correct partition. If there is no correct partition where the data can be inserted to, an error is reported.

  NOTICE

  Only when **VALIDATION** is **WITH**, **VERBOSE** can be specified.

- **partition_new_name**

  Specifies a new partition name.

  Value range: character strings complying with **Identifier Naming Conventions**.

- **subpartition_new_name**

  Specifies a new subpartition name.

  Value range: character strings complying with **Identifier Naming Conventions**.

- **UPDATE GLOBAL INDEX**

  Updates all global indexes in the partitioned table to ensure accurate data queries using global indexes. If this parameter is not used, all global indexes in the partitioned table will become invalid.

Examples

- Rename a partition.

```
-- Create a subpartitioned table tbl_rge_lst_test.
gaussdb=# CREATE TABLE tbl_lst_reg_test(
    area_id char(5),
    sdate char(8),
    eid char(5),
    sales_amt int
) PARTITION BY LIST(area_id) SUBPARTITION BY RANGE(sdate)(
    PARTITION p_1001 VALUES ('1001')(
        SUBPARTITION p_1001_201901 VALUES LESS THAN ('20190201'),
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
    SUBPARTITION p_1001_201902 VALUES LESS THAN ('20190301'),
    SUBPARTITION p_1001_201903 VALUES LESS THAN ('20190401')
  ),
  PARTITION p_1002 VALUES ('1002')(
    SUBPARTITION p_1002_201901 VALUES LESS THAN ('20190201'),
    SUBPARTITION p_1002_201902 VALUES LESS THAN ('20190301'),
    SUBPARTITION p_100w VALUES LESS THAN ('20190401')
  )
);

-- Change the name of the subpartition p_100w to p_1002_201903.
gaussdb=# ALTER TABLE tbl_lst_reg_test RENAME SUBPARTITION p_100w TO p_1002_201903;

-- Query.
gaussdb=# SELECT table_name,partition_name,subpartition_name FROM db_tab_subpartitions
WHERE table_name = 'tbl_lst_reg_test' AND partition_name = 'p_1002';
   table_name    | partition_name | subpartition_name
-----------------+----------------+-------------------
 tbl_lst_reg_test | p_1002         | p_1002_201901
 tbl_lst_reg_test | p_1002         | p_1002_201902
 tbl_lst_reg_test | p_1002         | p_1002_201903
(3 rows)
```

- Move partition tablespaces.

```
-- Create the tbs_data1 tablespace.
gaussdb=# CREATE TABLESPACE tbs_data1 RELATIVE LOCATION 'tablespace/tbs_data1';

-- Move the subpartition p_1002_201901 to the tablespace tbs_data1.
gaussdb=# ALTER TABLE tbl_lst_reg_test MOVE SUBPARTITION p_1002_201901 TABLESPACE
tbs_data1;

-- Move the subpartition p_1002_201902 to the tablespace tbs_data1.
gaussdb=# ALTER TABLE tbl_lst_reg_test MOVE SUBPARTITION FOR ('1002','20190325') TABLESPACE
tbs_data1;

-- Query the tablespace of the modified subpartition.
gaussdb=# SELECT subpartition_name,tablespace_name FROM db_tab_subpartitions WHERE
subpartition_name IN ('p_1002_201901','p_1002_201903');
 subpartition_name | tablespace_name
-------------------+-----------------
 p_1002_201901     | tbs_data1
 p_1002_201903     | tbs_data1
(2 rows)
```

- Exchange partitions.

```
-- Create an ordinary table and insert data into the table.
gaussdb=# CREATE TABLE tbl_test(
  area_id char(5),
  sdate char(8),
  eid char(5),
  sales_amt int
);

gaussdb=# INSERT INTO tbl_test VALUES ('1002','20190326','00001',9000);
gaussdb=# INSERT INTO tbl_test VALUES ('1002','20190326','00002',7500);
gaussdb=# INSERT INTO tbl_test VALUES ('1002','20190326','00003',6000);

-- Insert data into the partitioned table.
gaussdb=# INSERT INTO tbl_lst_reg_test VALUES ('1002','20190301','00001',126);

-- Exchange partitions.
gaussdb=# ALTER TABLE tbl_lst_reg_test EXCHANGE SUBPARTITION (p_1002_201903) WITH TABLE
tbl_test;

-- Query data. Data in the table and partition is exchanged.
gaussdb=# SELECT * FROM tbl_lst_reg_test;
 area_id |  sdate   |  eid  | sales_amt
---------+----------+-------+-----------
 1002    | 20190326 | 00001 |      9000
 1002    | 20190326 | 00002 |      7500
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
 1002    | 20190326 | 00003 |      6000
(3 rows)

gaussdb=# SELECT * FROM tbl_test;
 area_id |  sdate   |  eid  | sales_amt
---------+----------+-------+-----------
 1002    | 20190301 | 00001 |       126
(1 row)

-- Check that the partitioned table tablespace is exchanged.
gaussdb=# SELECT subpartition_name,tablespace_name FROM db_tab_subpartitions WHERE
subpartition_name = 'p_1002_201903';
 subpartition_name |  tablespace_name
-------------------+--------------------
 p_1002_201903     | DEFAULT TABLESPACE
(1 row)
```

- Merge partitions.

```
-- Merge partitions.
gaussdb=# ALTER TABLE tbl_lst_reg_test MERGE SUBPARTITIONS
p_1002_201901,p_1002_201902,p_1002_201903 INTO SUBPARTITION p_1002_20191;

-- Query subpartition information.
gaussdb=# SELECT table_name,partition_name,subpartition_name FROM db_tab_subpartitions
WHERE table_name = 'tbl_lst_reg_test';
    table_name    | partition_name | subpartition_name
------------------+----------------+-------------------
 tbl_lst_reg_test | p_1001         | p_1001_201901
 tbl_lst_reg_test | p_1001         | p_1001_201902
 tbl_lst_reg_test | p_1001         | p_1001_201903
 tbl_lst_reg_test | p_1002         | p_1002_20191
(4 rows)
```

- Add a partition.

```
-- Add a partition.
gaussdb=# ALTER TABLE tbl_lst_reg_test ADD PARTITION p_1003 VALUES('1003') (SUBPARTITION
p_1003_201901 VALUES LESS THAN ('20190201'));

-- Add a subpartition to a specific partition.
gaussdb=# ALTER TABLE tbl_lst_reg_test MODIFY PARTITION p_1003 ADD SUBPARTITION
p_1003_201902 VALUES LESS THAN ('20190301');

-- Query partition information.
gaussdb=# SELECT table_name,partition_name,subpartition_name FROM db_tab_subpartitions
WHERE table_name = 'tbl_lst_reg_test';
    table_name    | partition_name | subpartition_name
------------------+----------------+-------------------
 tbl_lst_reg_test | p_1001         | p_1001_201901
 tbl_lst_reg_test | p_1001         | p_1001_201902
 tbl_lst_reg_test | p_1001         | p_1001_201903
 tbl_lst_reg_test | p_1002         | p_1002_20191
 tbl_lst_reg_test | p_1003         | p_1003_201901
 tbl_lst_reg_test | p_1003         | p_1003_201902
(6 rows)
```

- Drop a partition.

```
-- Drop the subpartition p_1003_201902.
gaussdb=# ALTER TABLE tbl_lst_reg_test DROP SUBPARTITION p_1003_201902;

-- Query.
gaussdb=# SELECT table_name,partition_name,subpartition_name FROM db_tab_subpartitions
WHERE table_name = 'tbl_lst_reg_test' AND partition_name = 'p_1003';
    table_name    | partition_name | subpartition_name
------------------+----------------+-------------------
 tbl_lst_reg_test | p_1003         | p_1003_201901
(1 row)

-- Drop the partition p_1003.
gaussdb=# ALTER TABLE tbl_lst_reg_test DROP PARTITION p_1003;

-- Query.
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gaussdb=# SELECT table_name,partition_name,subpartition_name FROM db_tab_subpartitions
WHERE table_name = 'tbl_lst_reg_test';
    table_name    | partition_name | subpartition_name

(4 rows)
```

- Split partitions.

```
-- Specify the split point to split partitions.
gaussdb=# ALTER TABLE tbl_lst_reg_test SPLIT SUBPARTITION p_1002_20191
    AT ('20190201') INTO (SUBPARTITION p_1002_201901,SUBPARTITION p_1002_20191) UPDATE
GLOBAL INDEX;

-- Do not specify a point for splitting a partition.
gaussdb=# ALTER TABLE tbl_lst_reg_test SPLIT SUBPARTITION p_1002_20191 INTO (
    SUBPARTITION p_1002_201902 VALUES LESS THAN ('20190301'),
    SUBPARTITION p_1002_201903
) UPDATE GLOBAL INDEX;

-- Query partition information.
gaussdb=# SELECT table_name,partition_name,subpartition_name,high_value FROM
db_tab_subpartitions;
    table_name    | partition_name | subpartition_name | high_value
------------------+----------------+-------------------+------------
 tbl_lst_reg_test | p_1001         | p_1001_201901     | 20190201
 tbl_lst_reg_test | p_1001         | p_1001_201902     | 20190301
 tbl_lst_reg_test | p_1001         | p_1001_201903     | 20190401
 tbl_lst_reg_test | p_1002         | p_1002_201901     | 20190201
 tbl_lst_reg_test | p_1002         | p_1002_201902     | 20190301
 tbl_lst_reg_test | p_1002         | p_1002_201903     | 20190401
(6 rows)
```

- Clear partition data.

```
-- Clear the partition.
gaussdb=# ALTER TABLE tbl_lst_reg_test TRUNCATE PARTITION p_1001 UPDATE GLOBAL INDEX;

-- Clear the subpartition.
gaussdb=# ALTER TABLE tbl_lst_reg_test TRUNCATE SUBPARTITION p_1002_201903 UPDATE GLOBAL
INDEX;

-- Drop tables.
gaussdb=# DROP TABLE tbl_lst_reg_test;
gaussdb=# DROP TABLE tbl_test;

-- Drop the tablespace.
gaussdb=# DROP TABLESPACE tbs_data1;
```

Helpful Links

CREATE TABLE SUBPARTITION

1.13.7.37 ALTER TABLESPACE

Description

Modifies the attributes of a tablespace.

Precautions

- Only the tablespace owner or a user with the ALTER permission can run the **ALTER TABLESPACE** command. By default, system administrators have the permission. To modify a tablespace owner, you must be the tablespace owner or system administrator and a member of the new_owner role.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- The ALTER TABLESPACE operation on a row-store table cannot be performed in a transaction block.
- Only the initial user can change the owner of a system tablespace to itself. Other changes are not allowed.
- To change the owner, you must also be a direct or indirect member of the new owning role.

  NOTE

  If new_owner is the same as old_owner, the current user will not be verified. A message indicating successful ALTER execution is displayed.

Syntax

- The syntax of renaming a tablespace is as follows:

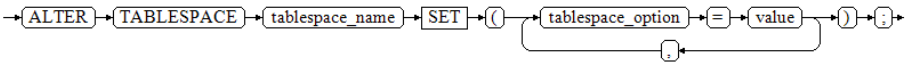
```
ALTER TABLESPACE tablespace_name
    RENAME TO new_tablespace_name;
```

- The syntax of setting the owner of a tablespace is as follows:

```
ALTER TABLESPACE tablespace_name
    OWNER TO new_owner;
```

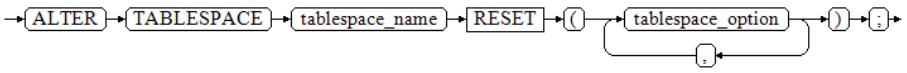
- The syntax of setting the attributes of a tablespace is as follows:

```
ALTER TABLESPACE tablespace_name
    SET ( { tablespace_option = value } [, ... ] );
```



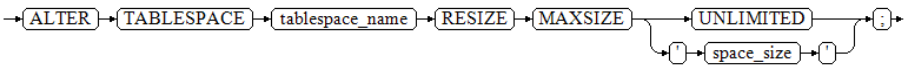
- The syntax of resetting the attributes of a tablespace is as follows:

```
ALTER TABLESPACE tablespace_name
    RESET ( { tablespace_option } [, ... ] );
```



- The syntax of setting the quota of a tablespace is as follows:

```
ALTER TABLESPACE tablespace_name
    RESIZE MAXSIZE { UNLIMITED | 'space_size'};
```



Parameters

- **tablespace_name**

  Specifies the tablespace to be modified.

  Value range: an existing tablespace name.

- **new_tablespace_name**

  Specifies the new name of the tablespace. The new name cannot start with **PG_**.

  Value range: character strings complying with **Identifier Naming Conventions**.

- **new_owner**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Specifies the new owner of the tablespace.

Value range: an existing username.

- **tablespace_option**

  Sets or resets the parameters of a tablespace.

  Value range:

  - seq_page_cost: sets the optimizer to calculate the cost of obtaining disk pages in sequence. The default value is **1.0**.
  - **random_page_cost**: sets the optimizer to calculate the cost of obtaining disk pages in a non-sequential manner. The default value is **4.0**.

    NOTE

    - The value of **random_page_cost** is relative to that of **seq_page_cost**. It is meaningless when the value is equal to or less than the value of **seq_page_cost**.
    - The prerequisite for the default value **4.0** is that the optimizer uses indexes to scan table data and the hit ratio of table data in the cache is about 90%.
    - If the size of the table data space is smaller than that of the physical memory, decrease the value to a proper level. On the contrary, if the hit ratio of table data in the cache is lower than 90%, increase the value.
    - If random-access memory like SSD is adopted, the value can be decreased to a certain degree to reflect the cost of true random scan.

  Value range: Positive number of the floating-point type.

- **RESIZE MAXSIZE**

  Resets the maximum size of tablespace.

  Value range:

  - **UNLIMITED**: No limit is set for the tablespace.
  - The value is determined by space_size. For details about the format, see **CREATE TABLESPACE**.

    NOTE

    - If the adjusted quota is smaller than the current tablespace usage, the adjustment is successful. You need to decrease the tablespace usage to a value less than the new quota before writing data to the tablespace.

Examples

- Rename a tablespace.

```
-- Create a tablespace.
gaussdb=# CREATE TABLESPACE tbs_data1 RELATIVE LOCATION 'tablespace1/tbs_data1';

-- Rename a tablespace.
gaussdb=# ALTER TABLESPACE tbs_data1 RENAME TO tbs_data2;

-- Query.
gaussdb=# \db tbs_data2
            List of tablespaces
   Name    | Owner |       Location
-----------+-------+-----------------------
 tbs_data2 | omm   | tablespace1/tbs_data1
```

- Set the tablespace owner.

  Example:

```
-- Create a user.
gaussdb=# CREATE USER test PASSWORD '********';
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
-- Change the owner of the tablespace.
gaussdb=# ALTER TABLESPACE tbs_data2 OWNER TO test;

-- Query.
gaussdb=# \db tbs_data2
            List of tablespaces
   Name    | Owner |       Location
-----------+-------+----------------------
 tbs_data2 | test  | tablespace1/tbs_data1
(1 row)
```

- Set tablespace attributes.

  Example:

```
-- Change the value of seq_page_cost.
gaussdb=# ALTER TABLESPACE tbs_data2 SET (seq_page_cost = 10);

-- Query.
gaussdb=# SELECT * FROM pg_tablespace WHERE spcname = 'tbs_data2';
  spcname  | spcowner | spcacl |     spcoptions     | spcmaxsize | relative
-----------+----------+--------+--------------------+------------+----------
 tbs_data2 |    16778 |        | {seq_page_cost=10} |            | t
(1 row)
```

- Reset tablespace attributes.

```
-- Reset the value of seq_page_cost to the default value.
gaussdb=# ALTER TABLESPACE tbs_data2 RESET (seq_page_cost);

-- Query.
gaussdb=# SELECT * FROM pg_tablespace WHERE spcname = 'tbs_data2';
  spcname  | spcowner | spcacl | spcoptions | spcmaxsize | relative
-----------+----------+--------+------------+------------+----------
 tbs_data2 |    16778 |        |            |            | t
(1 row)
```

- Set the tablespace limit.

  Example:

```
-- Set the maximum size of a tablespace.
gaussdb=# ALTER TABLESPACE tbs_data2 RESIZE MAXSIZE '10G';

-- Query.
gaussdb=# SELECT * FROM pg_tablespace WHERE spcname = 'tbs_data2';
  spcname  | spcowner | spcacl | spcoptions | spcmaxsize | relative
-----------+----------+--------+------------+------------+----------
 tbs_data2 |    16778 |        |            | 10485760 K | t
(1 row)

-- Drop the tablespace.
gaussdb=# DROP TABLESPACE tbs_data2;

-- Drop the user.
gaussdb=# DROP USER test;
```

CREATE TABLESPACE and **DROP TABLESPACE**

1.13.7.38 ALTER TEXT SEARCH CONFIGURATION

NOTICE

This function is for internal use only. You are advised not to use it.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description

Alters the definition of a text search configuration. You can modify its mappings from strings to dictionaries, change the configuration's name or owner, or modify the parameters.

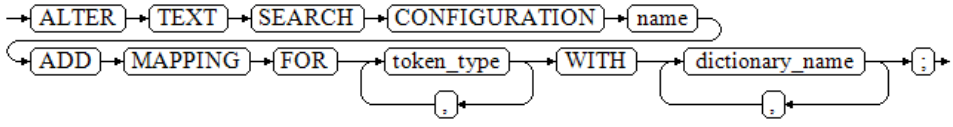
Precautions

- If a search configuration is referenced (to create indexes), users are not allowed to modify the text search configuration.
- To use ALTER TEXT SEARCH CONFIGURATION, you must be the owner of the configuration.
- The **ADD MAPPING FOR** option installs a list of string type mappings to be consulted for the specified token types; an error will be generated if there is already a mapping for any of the token types.
- The **ALTER MAPPING FOR** option removes the existing string type mappings for those token types and then adds specified string type mappings.
- The **ALTER MAPPING REPLACE ... WITH ...** and **ALTER MAPPING FOR ... REPLACE ... WITH ...** options replace **old_dictionary** with **new_dictionary**. Note that only when pg_ts_config_map has tuples corresponding to **maptokentype** and **old_dictionary**, the update will succeed. If the update fails, no messages are returned.
- The **DROP MAPPING FOR** option drops all string type mappings for the specified token types in the text search configuration. If **IF EXISTS** is not specified and the string type mappings specified by **DROP MAPPING FOR** do not exist in the text search configuration, an error will occur in the database.
- When the full-text search function is used, the return result of the text retrieval function is directly affected by the text search configuration. After the text search configuration is modified, the cached query plan is not updated immediately. As a result, when the function is called again for query, the return result of the function may not be updated synchronously. In this case, you need to clear the plan cache. For example, the related function exists in the PBE scenario or the scenario where automatic parameterization is enabled.

Syntax

- Add string type mappings to a text search configuration.

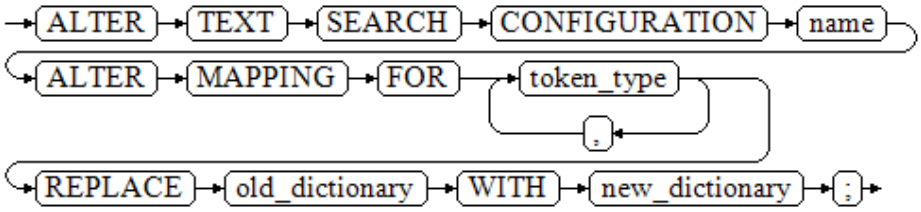
```
ALTER TEXT SEARCH CONFIGURATION name
    ADD MAPPING FOR { token_type } [, ... ] WITH { dictionary_name } [, ... ];
```



- Alter dictionaries in a text search configuration.

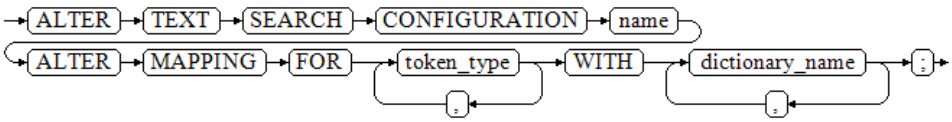
```
ALTER TEXT SEARCH CONFIGURATION name
    ALTER MAPPING FOR { token_type } [, ... ] REPLACE old_dictionary WITH new_dictionary;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.



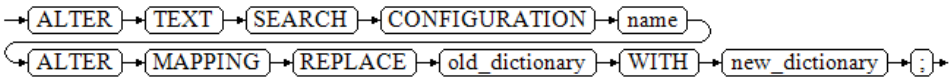
- Alter string type mappings in a text search configuration.

```
ALTER TEXT SEARCH CONFIGURATION name
    ALTER MAPPING FOR { token_type } [, ... ] WITH { dictionary_name } [, ... ];
```



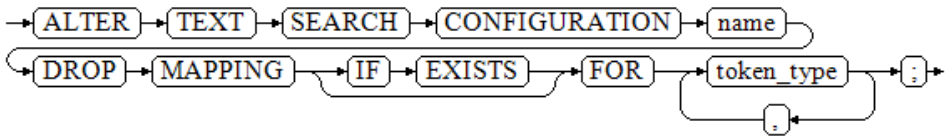
- Alter dictionaries in a text search configuration.

```
ALTER TEXT SEARCH CONFIGURATION name
    ALTER MAPPING REPLACE old_dictionary WITH new_dictionary;
```



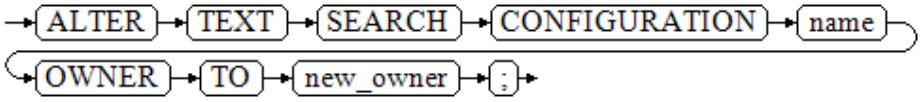
- Drop string type mappings from a text search configuration.

```
ALTER TEXT SEARCH CONFIGURATION name
    DROP MAPPING [ IF EXISTS ] FOR { token_type } [, ... ];
```



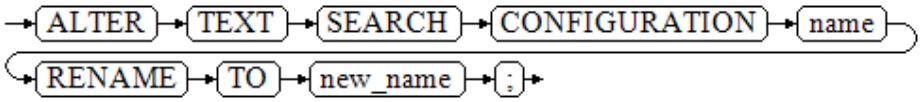
- Rename the owner of a text search configuration.

```
ALTER TEXT SEARCH CONFIGURATION name OWNER TO new_owner;
```



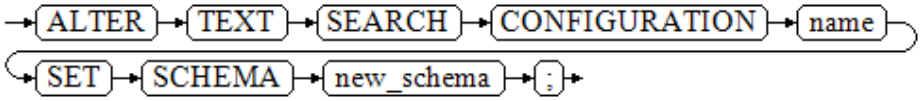
- Rename a text search configuration.

```
ALTER TEXT SEARCH CONFIGURATION name RENAME TO new_name;
```



- Rename the namespace of a text search configuration.

```
ALTER TEXT SEARCH CONFIGURATION name SET SCHEMA new_schema;
```



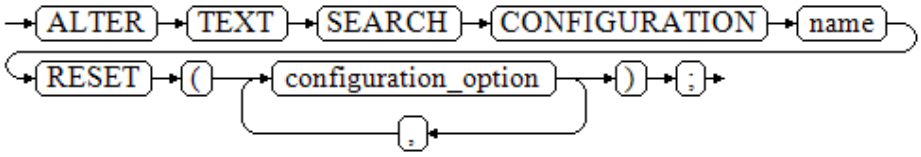
- Alter the attributes of a text search configuration.

```
ALTER TEXT SEARCH CONFIGURATION name SET ( { configuration_option = value } [, ...] );
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- Reset the attributes of a text search configuration.

```
ALTER TEXT SEARCH CONFIGURATION name RESET ( {configuration_option} [, ...] );
```



Parameters

- **name**

  Specifies the name (optionally schema-qualified) of an existing text search configuration.

- **token_type**

  Specifies the name of a token type that is emitted by the configuration's parser.

- **dictionary_name**

  Specifies the name of a text search dictionary. If multiple dictionaries are listed, they are searched in the specified order.

- **old_dictionary**

  Specifies the name of a text search dictionary to be replaced in the mapping.

- **new_dictionary**

  Specifies the name of a text search dictionary to be substituted for **old_dictionary**.

- **new_owner**

  Specifies the new owner of the text search configuration.

- **new_name**

  Specifies the new name of the text search configuration.

- **new_schema**

  Specifies the new schema for the text search configuration.

- **configuration_option**

  Specifies the text search configuration option.

- **value**

  Specifies the value of text search configuration option.

Examples

```
-- Create text search configuration english_1.
gaussdb=# CREATE TEXT SEARCH CONFIGURATION english_1 (parser=default);
CREATE TEXT SEARCH CONFIGURATION

-- Create text search configuration english_2.
gaussdb=# CREATE TEXT SEARCH CONFIGURATION english_2 (parser=default);
CREATE TEXT SEARCH CONFIGURATION

-- Add string type mappings to a text search configuration.
gaussdb=# ALTER TEXT SEARCH CONFIGURATION english_1 ADD MAPPING FOR word WITH
simple,english_stem;
ALTER TEXT SEARCH CONFIGURATION

gaussdb=# ALTER TEXT SEARCH CONFIGURATION english_1 ADD MAPPING FOR email WITH english_stem,
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
french_stem;
ALTER TEXT SEARCH CONFIGURATION

-- Query information about the text search configuration.
gaussdb=# SELECT b.cfgname,a.maptokentype,a.mapseqno,a.mapdict,c.dictname FROM pg_ts_config_map
a,pg_ts_config b, pg_ts_dict c WHERE a.mapcfg=b.oid AND a.mapdict=c.oid AND b.cfgname='english_1'
ORDER BY 1,2,3,4,5;
  cfgname  | maptokentype | mapseqno | mapdict |    dictname
-----------+--------------+----------+---------+--------------
 english_1 |            2 |        1 |    3765 | simple
 english_1 |            2 |        2 |   12960 | english_stem
 english_1 |            4 |        1 |   12960 | english_stem
 english_1 |            4 |        2 |   12964 | french_stem
(4 rows)

-- Alter string type mappings in a text search configuration.
gaussdb=# ALTER TEXT SEARCH CONFIGURATION english_1 ALTER MAPPING REPLACE french_stem with
german_stem;
ALTER TEXT SEARCH CONFIGURATION

-- Query information about the text search configuration.
gaussdb=# SELECT b.cfgname,a.maptokentype,a.mapseqno,a.mapdict,c.dictname FROM pg_ts_config_map
a,pg_ts_config b, pg_ts_dict c WHERE a.mapcfg=b.oid AND a.mapdict=c.oid AND b.cfgname='english_1'
ORDER BY 1,2,3,4,5;
  cfgname  | maptokentype | mapseqno | mapdict |    dictname
-----------+--------------+----------+---------+--------------
 english_1 |            2 |        1 |    3765 | simple
 english_1 |            2 |        2 |   12960 | english_stem
 english_1 |            4 |        1 |   12960 | english_stem
 english_1 |            4 |        2 |   12966 | german_stem
(4 rows)

-- Rename the text search configuration english_2 to english_3.
gaussdb=# ALTER TEXT SEARCH CONFIGURATION english_2 RENAME TO english_3;

-- Create a user joe.
gaussdb=# CREATE USER joe IDENTIFIED BY '********';

-- Rename the owner of a text search configuration to joe.
gaussdb=# ALTER TEXT SEARCH CONFIGURATION english_3 OWNER TO joe;

-- Rename the namespace of a text search configuration.
gaussdb=# ALTER TEXT SEARCH CONFIGURATION english_3 set schema joe;

-- Drop a schema.
gaussdb=# DROP SCHEMA IF EXISTS joe CASCADE;

-- Drop user joe.
gaussdb=# DROP ROLE IF EXISTS joe;

-- Drop a text search configuration.
gaussdb=# DROP TEXT SEARCH CONFIGURATION english_1;
```

1.13.7.39 ALTER TEXT SEARCH DICTIONARY

NOTICE

This function is for internal use only. You are advised not to use it.

Description

Alters the definition of a full-text search dictionary, including the parameters, name, owner, and schema.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

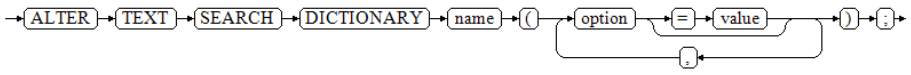
Precautions

- Predefined dictionaries do not support the ALTER operations.
- Only the owner of a dictionary or a system administrator can perform the ALTER operations. When separation of duties is disabled, system administrators have this permission by default.
- After a dictionary is created or modified, any modification to the customized dictionary definition file in the **filepath** directory does not affect the dictionary in the database. To use these modifications in the database, use the ALTER TEXT SEARCH DICTIONARY statement to update the definition file of the corresponding dictionary.
- When the full-text search function is used, the return result of the text search function is directly affected by the full-text search dictionary configuration. After the full-text search dictionary configuration is modified, the cached query plan is not updated immediately. As a result, when the function is called again for query, the return result of the function may not be updated synchronously. In this case, you need to clear the plan cache. For example, the related function exists in the PBE scenario or the scenario where automatic parameterization is enabled.

Syntax

- Modify the dictionary definition.

```
ALTER TEXT SEARCH DICTIONARY name (
    { option [ = value ] } [, ... ]
);
```



- Rename a dictionary.

```
ALTER TEXT SEARCH DICTIONARY name RENAME TO new_name;
```

- Set the schema of the dictionary.

```
ALTER TEXT SEARCH DICTIONARY name SET SCHEMA new_schema;
```

- Change the owner of a dictionary.

```
ALTER TEXT SEARCH DICTIONARY name OWNER TO new_owner;
```

Parameters

- **name**

  Specifies the name of an existing dictionary. (If you do not specify a schema name, the dictionary in the current schema will be used.)

  Value range: an existing dictionary name

- **option**

  Specifies the name of a parameter to be modified. Each type of dictionaries has a template containing their custom parameters. Parameters function in a way irrelevant to their setting sequence. For details, see **option** in **CREATE TEXT SEARCH DICTIONARY**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- The value of **TEMPLATE** in the dictionary cannot be changed.
- To specify a dictionary, specify both the dictionary definition file path (**FILEPATH**) and the file name.
- The name of a dictionary definition file can contain only lowercase letters, digits, and underscores (_).

- **value**

  Specifies the new value of a parameter. If the equal sign (=) and **value** are omitted, the previous settings of the option are deleted and the default value is used.

  Value range: valid values defined by **option**.

- **new_name**

  Specifies the new name of a dictionary.

  Value range: a string, which complies with the identifier naming convention. A value can contain a maximum of 63 characters.

- **new_owner**

  Specifies the new owner of a dictionary.

  Value range: an existing username.

- **new_schema**

  Specifies the new schema of a dictionary.

  Value range: an existing schema name.

Examples

```
-- Create the dictionary my_dict.
gaussdb=# CREATE TEXT SEARCH DICTIONARY my_dict ( TEMPLATE = Simple );

-- Create the dictionary my_dict1.
gaussdb=# CREATE TEXT SEARCH DICTIONARY my_dict1 ( TEMPLATE = Simple );

-- Rename the dictionary my_dict1 to my_dict2.
gaussdb=# ALTER TEXT SEARCH DICTIONARY my_dict1 RENAME TO my_dict2;

-- Modify the dictionary of the simple type, set non-stop words as recognized, and retain the values of other parameters.
gaussdb=# ALTER TEXT SEARCH DICTIONARY my_dict ( Accept = true );

-- Modify the dictionary of the simple type and reset the Accept parameter.
gaussdb=# ALTER TEXT SEARCH DICTIONARY my_dict ( Accept );

-- Update the dictionary definition and do not change any other content.
gaussdb=# ALTER TEXT SEARCH DICTIONARY my_dict ( dummy );

-- Drop dictionaries.
gaussdb=# DROP TEXT SEARCH DICTIONARY my_dict;
gaussdb=# DROP TEXT SEARCH DICTIONARY my_dict2;
```

1.13.7.40 ALTER TRIGGER

Description

ALTER TRIGGER is used to change the name and owner of a trigger.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

Currently, only the name and owner of a trigger can be modified.

Precautions

- The owner of the table where a trigger resides or a user with the ALTER ANY TRIGGER permission can perform the ALTER TRIGGER operation. A system administrator has this permission by default.
- To modify the owner of a trigger, you must be the owner of the trigger or a system administrator, and you must be a direct or indirect member of the role to which the new owner belongs. The new owner must have the CREATE permission on the schema where the trigger is. When separation of duties is disabled, system administrators have this authorization by default. When separation of duties is enabled, system administrators does not this permission by default.
- Only the initial user can change the owner of a trigger to the initial user.

Syntax

- Rename a trigger.

```
ALTER TRIGGER trigger_name ON table_name RENAME TO new_name;
```

- Change the owner of a trigger.

```
ALTER TRIGGER trigger_name ON table_name OWNER TO new_owner;
```

Parameters

- **trigger_name**

  Specifies the name of the trigger to be modified.

  Value range: an existing trigger

- **table_name**

  Specifies the name of the table where the trigger to be modified is located.

  Value range: an existing table having a trigger

- **new_name**

  New name of a trigger. The name cannot be the same as that of another trigger in the same table.

  Value range: character strings complying with **Identifier Naming Conventions** and not exceeding 63 characters.

- **new_owner**

  Name of the new owner of a trigger.

  Value range: an existing username in the database.

Examples

```
-- Create a source table and a target table.
gaussdb=# CREATE TABLE test_trigger_src_tbl(id1 INT, id2 INT, id3 INT);
gaussdb=# CREATE TABLE test_trigger_des_tbl(id1 INT, id2 INT, id3 INT);
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
-- Create a DELETE trigger function.
gaussdb=# CREATE OR REPLACE FUNCTION TRI_DELETE_FUNC() RETURNS TRIGGER AS
        $$
        DECLARE
        BEGIN
                DELETE FROM test_trigger_des_tbl WHERE id1=OLD.id1;
                RETURN OLD;
        END
        $$ LANGUAGE plpgsql;

-- Create a DELETE trigger.
gaussdb=# CREATE TRIGGER delete_trigger BEFORE DELETE ON test_trigger_src_tbl FOR EACH ROW
EXECUTE PROCEDURE tri_delete_func();

-- Rename a trigger.
gaussdb=# ALTER TRIGGER delete_trigger ON test_trigger_src_tbl RENAME TO delete_trigger_renamed;

-- Change the owner of the trigger to jack. (Ensure that jack is a user created in the database.)
gaussdb=# ALTER TRIGGER delete_trigger ON test_trigger_src_tbl OWNER TO jack;

-- Delete the trigger.
gaussdb=# DROP TRIGGER delete_trigger_renamed ON test_trigger_src_tbl;

-- Delete the function.
gaussdb=# DROP FUNCTION tri_delete_func;

-- Delete the source table and target table.
gaussdb=# DROP TABLE test_trigger_src_tbl;
gaussdb=# DROP TABLE test_trigger_des_tbl;
```

Helpful Links

CREATE TRIGGER, **DROP TRIGGER**, and **ALTER TABLE**

1.13.7.41 ALTER TYPE

Description

Changes the definition of a type.

Precautions

Only the owner of a type, a user granted the ALTER permission on a type, or a user granted the ALTER ANY TYPE permission on a sequence can run the **ALTER TYPE** command. When separation of duties is disabled, system administrators have this permission by default. To modify the owner or schema of a type, you must be a type owner or system administrator and a member of the new owner role.

Syntax

- Change a type.

  ```
  ALTER TYPE name action [, ... ];
  ```

  
  The clauses corresponding to **action** are as follows:

  – Add a new attribute to a composite type.

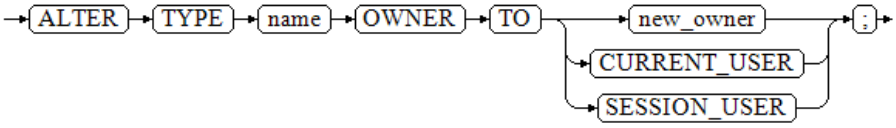
 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

ADD ATTRIBUTE attribute_name data_type [COLLATE collation] [CASCADE | RESTRICT]

  - Delete an attribute from a composite type.
    DROP ATTRIBUTE [IF EXISTS] attribute_name [CASCADE | RESTRICT]

  - Change the type of an attribute in a composite type.
    ALTER ATTRIBUTE attribute_name [SET DATA] TYPE data_type [COLLATE collation] [CASCADE | RESTRICT]

- Change the owner of a type.
  ALTER TYPE name OWNER TO { new_owner | CURRENT_USER | SESSION_USER };



- Change the name of a type.
  ALTER TYPE name RENAME TO new_name;

- Change the name of an attribute in a composite type.
  ALTER TYPE name RENAME ATTRIBUTE attribute_name TO new_attribute_name [CASCADE | RESTRICT];

- Move a type to a new schema.
  ALTER TYPE name SET SCHEMA new_schema;

- Add a new value to an enumerated type.
  ALTER TYPE name ADD VALUE [IF NOT EXISTS] new_enum_value [{ BEFORE | AFTER } neighbor_enum_value];

- Change an enumerated value in the value list.
  ALTER TYPE name RENAME VALUE existing_enum_value TO new_enum_value;

Parameters

- **name**

  Specifies the name of an existing type that needs to be modified (optionally schema-qualified).

- **new_name**

  Specifies the new name of the type.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **new_owner**

  Specifies the new owner of the type.
- **new_schema**

  Specifies the new schema of the type.
- **attribute_name**

  Specifies the name of the attribute to be added, modified, or deleted.
- **new_attribute_name**

  Specifies the new name of the attribute to be renamed.
- **data_type**

  Specifies the data type of the attribute to be added, or the new type of the attribute to be modified.
- **new_enum_value**

  Specifies a new enumerated value. It is a non-null string with a maximum length of 63 bytes.
- **neighbor_enum_value**

  Specifies an existing enumerated value before or after which a new enumerated value will be added.
- **existing_enum_value**

  Specifies an enumerated value to be changed. It is a non-null string with a maximum length of 63 bytes.
- **CASCADE**

  Determines that the type to be modified, its associated records, and subtables that inherit the type will all be updated.
- **RESTRICT**

  (Default) Refuses to update the associated records of the modified type.

NOTICE

- **ADD ATTRIBUTE**, **DROP ATTRIBUTE**, and **ALTER ATTRIBUTE** can be combined for modifying multiple attributes. For example, it is possible to add several attributes or change the types of several attributes at the same time in one command.
- To modify a schema of a type, you must have the CREATE permission on the new schema. To alter the owner, you must be a direct or indirect member of the new owner role, and that member must have CREATE permission on the schema of this type (these restrictions enforce that the operation of altering the owner cannot be done by other means other than deleting and rebuilding the type). However, the system administrators can change ownership of any type in any way when separation of duties is disabled. To add an attribute or modify the type of an attribute, you must also have the USAGE permission of this type.

- **CURRENT_USER**

  Specifies the current user.
- **SESSION_USER**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Specifies the current system user.

- **COLLATE collation**

  Assigns a collation to the column, which must be a sortable data type. If the collation is not specified, the default collation for the column's data type is used.

Examples

- Modify a composite type:

```
-- Create a composite type.
gaussdb=# CREATE TYPE typ_stu AS (name varchar(10),age int);

-- Create a table and insert data into the table. The data type of the info column is typ_stu.
gaussdb=# CREATE TABLE tbl_test (id int PRIMARY KEY,info typ_stu);
gaussdb=# INSERT INTO tbl_test VALUES (1,('Jim',16));

-- View data in the tbl_test table.
gaussdb=# SELECT * FROM tbl_test;
 id |   info
----+----------
  1 | (Jim,16)
(1 row)

-- Add an attribute to a composite type.
gaussdb=# ALTER TYPE typ_stu ADD ATTRIBUTE year int CASCADE;

-- Check data in the tbl_test table again. The info column contains an extra attribute.
gaussdb=# SELECT * FROM tbl_test;
 id |   info
----+-----------
  1 | (Jim,16,)
(1 row)

-- Delete an attribute from a composite type.
gaussdb=# ALTER TYPE typ_stu DROP ATTRIBUTE year;
```

- Change the type owner:

```
-- Create a user test.
gaussdb=# CREATE ROLE test PASSWORD '********';

-- Change the owner of typ_stu to test.
gaussdb=# ALTER TYPE typ_stu OWNER TO test;

-- Query the owner of typ_stu.
gaussdb=# SELECT t1.typname, t2.rolname AS owner
FROM pg_type t1, gs_roles t2
WHERE t1.typname = 'typ_stu' AND
      t1.typowner = t2.oid;
 typname | owner
---------+--------
 typ_stu | test
(1 row)
```

- Change a type or the name of an attribute in a composite type.

```
-- Rename one of the attributes age of typ_stu to age1.
gaussdb=# ALTER TYPE typ_stu RENAME ATTRIBUTE age to age1;

-- Run the following SQL statement to query the data whose age is 16 in the tbl_test table:
gaussdb=# SELECT id,(info).name,(info).age1 FROM tbl_test WHERE (info).age1 = 16;
 id | name | age1
----+------+------
  1 | Jim  |   16
(1 row)
```

- Move a type to a new schema.

```
-- Create a schema sctest.
gaussdb=# CREATE SCHEMA sctest;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
-- Move typ_stu to the sc_test schema.
gaussdb=# ALTER TYPE typ_stu SET SCHEMA sctest;

-- Query the schema of typ_stu.
gaussdb=# \dT sctest.*
         List of data types
 Schema |      Name      | Description

CREATE TYPE and **DROP TYPE**

1.13.7.42 ALTER USER

Description

Alters database user attributes, including the username and permission.

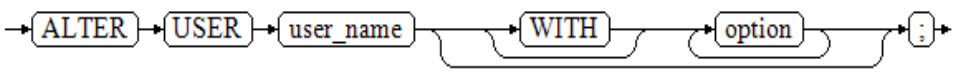
Precautions

When you use ALTER USER to modify session parameters, the changes will only apply to the specified user and will take effect in the next session.

Syntax

- Modify user permissions or other information.

```
ALTER USER user_name [ [ WITH ] option [ ... ] ];
```

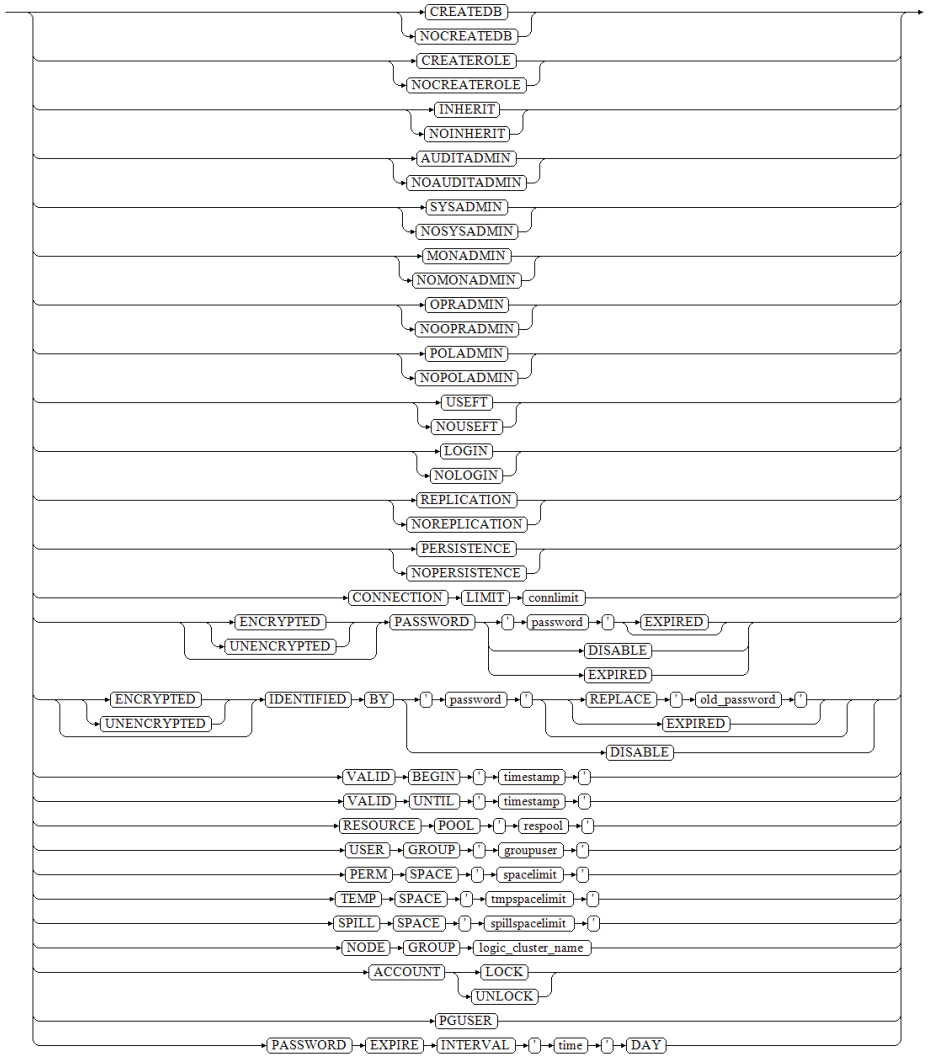


The option clause is as follows:

```
{
   { CREATEDB | NOCREATEDB }
   | { CREATEROLE | NOCREATEROLE }
   | { INHERIT | NOINHERIT }
   | { AUDITADMIN | NOAUDITADMIN }
   | { SYSADMIN | NOSYSADMIN }
   | { MONADMIN | NOMONADMIN }
   | { OPRADMIN | NOOPRADMIN }
   | { POLADMIN | NOPOLADMIN }
   | { USEFT | NOUSEFT }
   | { LOGIN | NOLOGIN }
   | { REPLICATION | NOREPLICATION }
   | { PERSISTENCE | NOPERSISTENCE }
   | CONNECTION LIMIT connlimit
   | [ ENCRYPTED | UNENCRYPTED ] PASSWORD { 'password' [EXPIRED] | DISABLE | EXPIRED }
   | [ ENCRYPTED | UNENCRYPTED ] IDENTIFIED BY { 'password' [ REPLACE 'old_password' |
EXPIRED ] | DISABLE }
   | VALID BEGIN 'timestamp'
   | VALID UNTIL 'timestamp'
   | RESOURCE POOL 'respool'
   | USER GROUP 'groupuser'
   | PERM SPACE 'spacelimit'
   | TEMP SPACE 'tmpspacelimit'
   | SPILL SPACE 'spillspacelimit'
   | NODE GROUP logic_cluster_name
   | ACCOUNT { LOCK | UNLOCK }
   | PGUSER
```

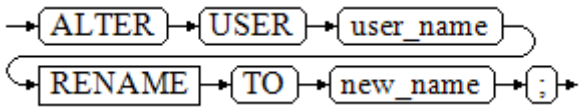
 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
  | PASSWORD EXPIRE INTERVAL 'time' DAY
}
```



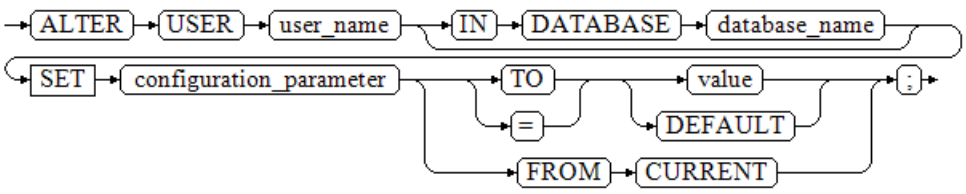
- Change the username.

```
ALTER USER user_name
  RENAME TO new_name;
```



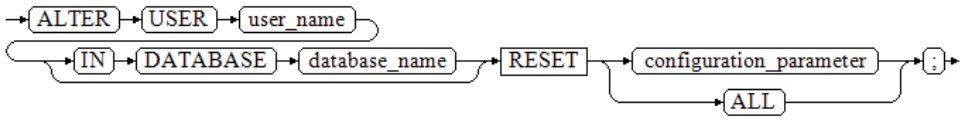
- Change the value of a session parameter associated with a user. The current version does not support the setting of user-level parameters.

```
ALTER USER user_name [ IN DATABASE database_name ]
  SET configuration_parameter {{ TO | = } { value | DEFAULT }|FROM CURRENT};
```



- Reset the value of a specified parameter associated with the user. The current version does not support the setting of user-level parameters.

```
ALTER USER user_name
    [ IN DATABASE database_name ] RESET {configuration_parameter|ALL};
```



Parameters

- **user_name**

  Specifies the current username.

  Value range: an existing username. If a username contains uppercase letters, declare the name with double quotation marks ("").

  NOTICE

  Currently, the RENAME TO operation cannot be performed on redisuser, an object used for resource control during redistribution. Performing the RENAME TO redisuser operation on other usernames is not supported.

- **new_password**

  Specifies a new password.

  Value range: character strings.

  Password rules:

  – Differ from the old password.
  – Contain at least eight characters. This is the default length.
  – Not be the same as or the reverse of the username.
  – Contain at least three types of the following: uppercase letters (A–Z), lowercase letters (a–z), digits (0–9), and special characters (limited to ~ ! @ # $ % ^ & * ( ) - _ = + \ | [{ }] ; : , < . > / ?). If the password contains characters other than the preceding characters, an error will be reported during statement execution.
  – The user password must be declared using single or double quotation marks.

- **old_password**

  Specifies the old password.

- **ACCOUNT { LOCK | UNLOCK }**

  – **ACCOUNT LOCK**: locks an account and prevents the account from logging in to the database using a password.
  – **ACCOUNT UNLOCK**: unlocks the account to allow database login.

- **PGUSER**

  In the current version, the **PGUSER** attribute of a user cannot be modified.

- For details about other parameters, see **Parameters** in **ALTER ROLE** and **Parameters** in **ALTER ROLE**.

Examples

```
-- Create user jim whose login password is ********.
gaussdb=# CREATE USER jim PASSWORD '********';
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
-- Create a database.
gaussdb=# CREATE DATABASE testdb1;

-- Change the login password of user jim.
gaussdb=# ALTER USER jim IDENTIFIED BY '**********' REPLACE '********';

-- Lock jim.
gaussdb=# ALTER USER jim ACCOUNT LOCK;

-- Unlock jim.
gaussdb=# ALTER USER jim ACCOUNT UNLOCK;

-- Change the username.
gaussdb=# ALTER USER jim RENAME TO lisa;

-- Drop the user.
gaussdb=# DROP USER lisa CASCADE;
```

CREATE ROLE, **CREATE USER**, and **DROP USER**

1.13.7.43 ALTER VIEW

Description

ALTER VIEW changes the auxiliary properties of a view or recompiles a view (use CREATE OR REPLACE VIEW to change the query definition of a view) or recompiles a view.

Precautions

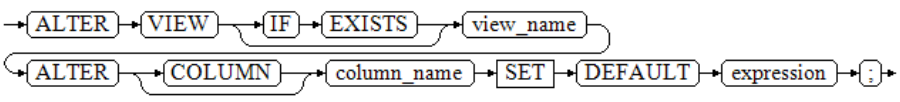
Only the owner of a view and users with the ALTER permission on the view are authorized to run the **ALTER VIEW** command. When separation of duties is disabled, system administrators have this authorization by default. Different permission restrictions may apply, depending on the specific attributes to modify.

- To modify the schema of a view, you must be either the view owner or a system administrator and have the CREATE permission on the new schema. However, when separation of duties is enabled, system administrators are restricted from making this modification.
- To modify the owner of a view, you must be either the view owner or a system administrator. Additionally, that user must be a member of the new owning role, and that role must have the CREATE permission on the view's schema. However, when separation of duties is enabled, system administrators are restricted from making this modification.

Syntax

- Set the default value of a column in a view.

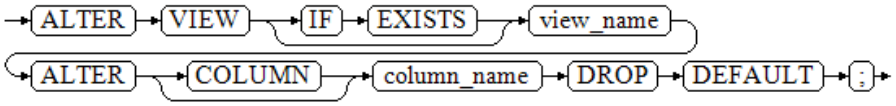
```
ALTER VIEW [ IF EXISTS ] view_name
    ALTER [ COLUMN ] column_name SET DEFAULT expression;
```



- Drop the default value of a column in a view.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
ALTER VIEW [ IF EXISTS ] view_name
    ALTER [ COLUMN ] column_name DROP DEFAULT;
```



- Modify the owner of a view.

```
ALTER VIEW [ IF EXISTS ] view_name
    OWNER TO new_owner;
```

- Rename a view.

```
ALTER VIEW [ IF EXISTS ] view_name
    RENAME TO new_name;
```

- Set the schema of a view.

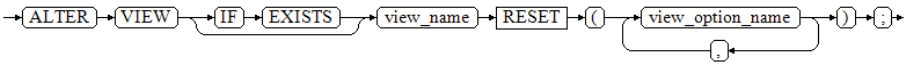
```
ALTER VIEW [ IF EXISTS ] view_name
    SET SCHEMA new_schema;
```

- Set the options of a view.

```
ALTER VIEW [ IF EXISTS ] view_name
    SET ( { view_option_name [ = view_option_value ] } [, ... ] );
```

- Reset the options of a view.

```
ALTER VIEW [ IF EXISTS ] view_name
    RESET ( view_option_name [, ... ] );
```



- Recompile a view.

```
ALTER VIEW view_name COMPILE;
```

Parameters

- **IF EXISTS**

  If this option is used, no error is generated when the view does not exist, and only a message is displayed.

- **view_name**

  Specifies a view name (optionally schema-qualified).

  Value range: existing view names (character string).

- **column_name**

  Specifies the column name.

  Value range: a string, which indicates the name of a column in an existing view.

- **SET/DROP DEFAULT**

  Sets or drops the default value of a column. This parameter currently has no practical effect.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **new_owner**

  Specifies the new owner of a view.
- **new_name**

  Specifies a new name for the view.
- **new_schema**

  Specifies a new schema for the view.
- **view_option_name [= view_option_value]**

  Specifies an optional parameter for a view.
  - **security_barrier**: specifies whether the view provides row-level security. The value is of the Boolean type. The default value is **true**.
  - **check_option**: controls the behavior of updating a view. This parameter can be set to **CASCADED** or **LOCAL**. This parameter cannot be left blank.
- **expression**

  Specifies constants, functions, or SQL expressions.
- COMPILE

  Recompiles the view manually.

  NOTE

  For details about how to recompile an invalid view, see "Feature Usage Guidelines > Recompilation upon Invalidation" in *Developer Guide*.

Examples

- Rename a view.

```
-- Create the test_tbl table.
gaussdb=# CREATE TABLE test_tb1(col1 INT,col2 INT);

-- Create a view.
gaussdb=# CREATE VIEW abc AS SELECT * FROM test_tb1;

-- Set the default value of the view column to 100.
gaussdb=# ALTER VIEW IF EXISTS  abc ALTER  COLUMN  col1 SET DEFAULT 100;

-- Cancel the default value of the view column.
gaussdb=# ALTER VIEW IF EXISTS  abc ALTER  COLUMN  col1 DROP DEFAULT;

-- Rename the view.
gaussdb=# ALTER VIEW IF EXISTS abc RENAME TO test_v1;

-- Query the view.
gaussdb=# \dv
            List of relations
 Schema |  Name   | Type | Owner | Storage
--------+---------+------+-------+---------
 public | test_v1 | view | omm   |
(1 row)
```

- Modify the owner of a view.

```
-- Create a user.
gaussdb=# CREATE ROLE role_test PASSWORD '********';

-- Modify the owner of a view.
gaussdb=# ALTER VIEW IF EXISTS test_v1 OWNER TO role_test;

-- Query the view information.
gaussdb=# \dv
              List of relations
 Schema |  Name   | Type |   Owner   | Storage
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
--------+---------+------+-----------+---------
 public | test_v1 | view | role_test |
(1 row)
```

- Set the schema of a view.

```
-- Create a schema.
gaussdb=# CREATE SCHEMA tcpds;

-- Modify the schema of a view.
gaussdb=# ALTER VIEW test_v1 SET SCHEMA tcpds;

-- Query the view information.
gaussdb=# \dv tcpds.test_v1;
              List of relations
 Schema |  Name   | Type |   Owner   | Storage
--------+---------+------+-----------+---------
 tcpds  | test_v1 | view | role_test |
(1 row)
```

- Set and reset view options.

```
-- Change view options.
gaussdb=# ALTER VIEW tcpds.test_v1 SET (security_barrier = TRUE);
ALTER VIEW

-- Query.
gaussdb=# \dv tcpds.test_v1
                     List of relations
 Schema |  Name   | Type |   Owner   |         Storage
--------+---------+------+-----------+-------------------------
 tcpds  | test_v1 | view | role_test | {security_barrier=true}
(1 row)

-- Change the check_option option.
gaussdb=# ALTER VIEW tcpds.test_v1 SET (check_option = 'LOCAL');

-- Query.
gaussdb=# \dv tcpds.test_v1
                              List of relations
 Schema |  Name   | Type |   Owner   |                 Storage
--------+---------+------+-----------+-------------------------------------------
 tcpds  | test_v1 | view | role_test | {security_barrier=true,check_option=LOCAL}
(1 row)

-- Reset view options.
gaussdb=# ALTER VIEW tcpds.test_v1 RESET (security_barrier);
ALTER VIEW
gaussdb=# ALTER VIEW tcpds.test_v1 RESET (check_option);
ALTER VIEW

-- Query.
gaussdb=# \dv tcpds.test_v1
              List of relations
 Schema |  Name   | Type |   Owner   | Storage
--------+---------+------+-----------+---------
 tcpds  | test_v1 | view | role_test |
(1 row)

-- Drop the test_v1 view.
gaussdb=# DROP VIEW tcpds.test_v1;
DROP VIEW

-- Drop the test_tb1 table.
gaussdb=# DROP TABLE test_tb1;
DROP TABLE

-- Delete the user.
gaussdb=# DROP ROLE role_test;
DROP ROLE
-- Delete the schema.
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gaussdb=# DROP SCHEMA tcpds;
DROP SCHEMA
```

- Recompile a view.

```
-- Enable view recompilation upon invalidation.
gaussdb=# SET enable_view_invalidation=on;

-- Create a table.
gaussdb=# CREATE TABLE test_tb1(col1 INT, col2 INT);

-- Create a view.
gaussdb=# CREATE VIEW test_v1 AS SELECT col1, col2 FROM test_tb1;

-- Drop the test_tb1 table.
gaussdb=# DROP TABLE test_tb1;
DROP TABLE

-- Check the view's validity.
gaussdb=# SELECT c.relname, o.valid FROM pg_catalog.pg_object o JOIN pg_catalog.pg_class c ON
c.oid = o.object_oid WHERE c.relname = 'test_v1';
 relname | valid
---------+-------
 test_v1 | f
(1 row)

-- Rebuild the test_tb1 table.
gaussdb=# CREATE TABLE test_tb1(col1 INT, col2 INT);

-- Recompile the view.
gaussdb=# ALTER VIEW test_v1 COMPILE;
ALTER VIEW

-- Check the view's validity again.
gaussdb=# SELECT c.relname, o.valid FROM pg_catalog.pg_object o JOIN pg_catalog.pg_class c ON
c.oid = o.object_oid WHERE c.relname = 'test_v1';
 relname | valid
---------+-------
 test_v1 | t
(1 row)

-- Drop the test_v1 view.
gaussdb=# DROP VIEW test_v1;
DROP VIEW

-- Drop the test_tb1 table.
gaussdb=# DROP TABLE test_tb1;
DROP TABLE
```

Helpful Links

CREATE VIEW and **DROP VIEW**

1.13.7.44 ANALYZE | ANALYSE

Description

- ANALYZE collects statistics about ordinary tables in a database and stores the results in the PG_STATISTIC and PG_STATISTIC_EXT system catalogs. After you run the **ANALYZE** command, you can query the collected statistics in the system catalogs or in the system views PG_STATS and PG_EXT_STATS. The execution plan generator uses these statistics to generate the most efficient execution plan.
- If no parameters are specified, ANALYZE analyzes each table and partitioned table in the database. You can narrow the analysis to a specific table, column,

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

or partitioned table by specifying **table_name**, **column_name**, or **partition_name**.

- ANALYZE|ANALYSE VERIFY is used to verify files related to the target table in the database. The following table lists the supported verification types.

Page Type/ Verification Type	Physical Page Damage	Page Logic Verification	Tuple Verification
UHEAP	Supported	Supported	Supported in COMPLETE mode
HEAP	Supported	-	Supported in COMPLETE mode
FSM	Supported	-	-
VM	-	-	-
UBTREE	Supported	Supported	-
UBTREE.FSM(URQ)	Supported	Supported	-
BTREE	Supported	-	-
BTREE.FSM	Supported	-	-

- The time required for executing ANALYZE|ANALYSE VERIFY depends on the size of the current operation object (target table or database) and the performance of the current machine.
- Statistics collected each time are stored in historical statistics tables (**GS_STATISTIC_HISTORY**, **GS_STATISTIC_EXT_HISTORY**, and **GS_TABLESTATS_HISTORY**). The number of historical tables and the retention period of statistics are specified by the **stats_history_record_limit** and **stats_history_retention_time** parameters.

Precautions

- Non-temporary tables cannot be analyzed in an anonymous block, transaction block, function, or stored procedure. Temporary tables can be analyzed during execution of stored procedures, but statistics cannot be rolled back.
- If remote read is not involved, the remote read parameter does not take effect. If a key system catalog page is damaged, an error is reported and the detection stops.
- If no parameter to be analyzed is specified, tables on which the current user has the corresponding permission are analyzed by default. With a table specified, ANALYZE processes the table only.
- To perform ANALYZE operation to a table, you must be a table owner or a user granted the VACUUM permission on the table. By default, a system administrator has this permission. However, database owners are allowed to

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

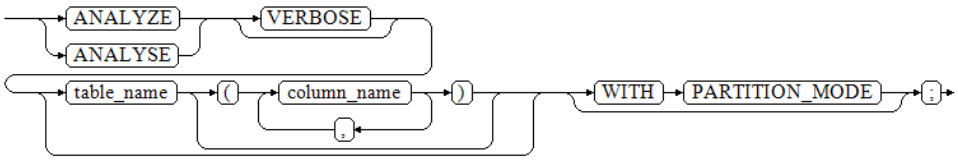
analyze all tables in their databases, except shared catalogs. (The restriction for shared catalogs implies that a true database-wide ANALYZE operation can only be performed by a system administrator). ANALYZE skips tables on which users do not have permissions.

- ANALYZE does not collect columns for which comparison or equivalent operations cannot be performed, for example, columns of the cursor type.
- If the table to be analyzed is empty, ANALYZE does not record the statistics of the table. The existing statistics are retained.

Syntax

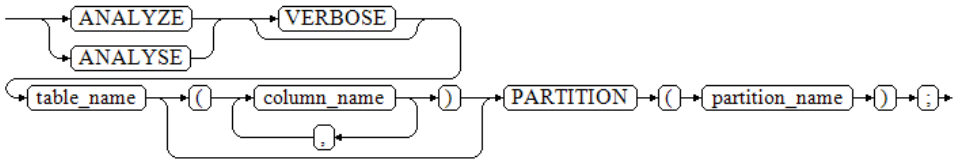
- Collect table statistics.

```
{ ANALYZE | ANALYSE } [ VERBOSE ]
    [ table_name [ ( column_name [, ...] ) ] ] [ WITH PARTITION_MODE ];
```



- Collect the partition statistics of a partitioned table.

```
{ ANALYZE | ANALYSE } [ VERBOSE ]
    table_name [ ( column_name [, ...] ) ] PARTITION ( partition_name ) ;
```

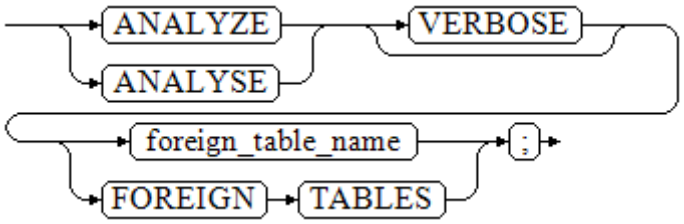


NOTE

- If the keyword PARTITION is included, **partition_name** must be the name of a partition.
- The distributed system does not support subpartitions.

- Collect statistics about a foreign table.

```
{ ANALYZE | ANALYSE } [ VERBOSE ]
    { foreign_table_name | FOREIGN TABLES };
```



- Collect statistics about global secondary indexes.

```
{ ANALYZE | ANALYSE } GLOBAL INDEX index_name FOR TABLE table_name;
```

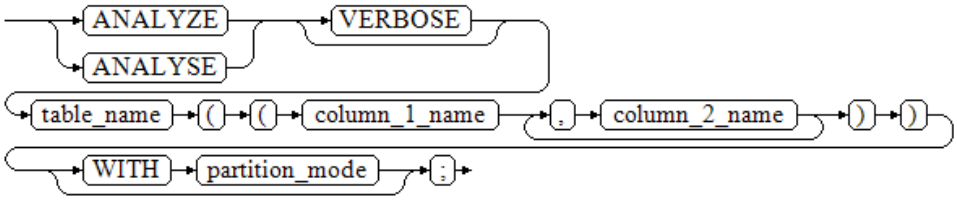
 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- Before performing ANALYZE on the global secondary index, you need to perform ANALYZE on the base table to ensure the accuracy of global secondary indexes.
- After performing the REINDEX/REBUILD operation on the global secondary indexes, you need to perform ANALYZE on the base table first before the global secondary indexes to ensure the accuracy of global secondary indexes.
- To collect statistics from global secondary indexes, you must specify **index_name** and **table_name**, and **index_name** must be the name of a global secondary index.
- The global secondary indexes include only the statistics (reltuple and relpages) in the pg_class system catalog.
- If a concurrent autoanalyze occurs within the execution time window of ANALYZE, there is a low probability that the following error is reported: Duplicate key value violates unique constraint "gs_tablestats_history_relid_kind_time_index". In this case, you can manually execute ANALYZE again.

- Manually collect multi-column statistics.

```
{ ANALYZE | ANALYSE } [ VERBOSE ]
    table_name (( column_1_name, column_2_name [, ...] )) [ WITH partition_mode ];
```



NOTE

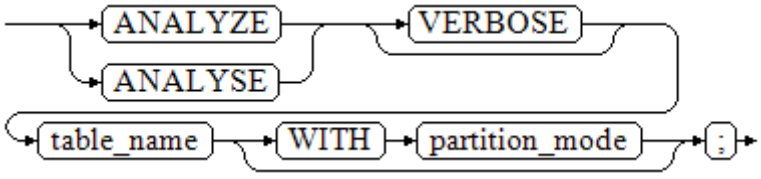
- If the GUC parameter **enable_functional_dependency** is disabled, each group of multi-column statistics supports a maximum of 32 columns.
- You are not allowed to collect statistics about multiple columns in system catalogs.

- Automatically collect multi-column statistics.

  If the ANALYZE statement is executed on a table after the **auto_statistic_ext_columns** parameter is enabled, multi-column statistics are automatically generated based on the index prefix of the table. The number of columns included in these statistics will not exceed the value of **auto_statistic_ext_columns**.

  For example, if table **t** has index (a,b,c,d) and **auto_statistic_ext_columns** is set to **4**, executing ANALYZE on table **t** will generate multi-column statistics for (a,b), (a,b,c), and (a,b,c,d).

```
{ ANALYZE | ANALYSE } [ VERBOSE ] table_name [ WITH partition_mode ];
```



- Verify data files in the current database.

```
{ ANALYZE | ANALYSE } VERIFY { FAST | COMPLETE };
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

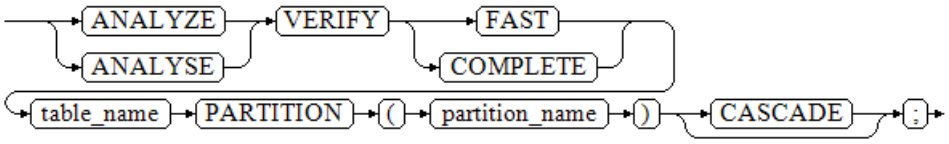
NOTE

- This operation reads data directly from disk. If concurrent DML operations are performed on the table being verified—that is, if disk files are modified concurrently—the retrieved data may be inaccurate, leading to false positives during verification. Therefore, you are advised to perform this operation when no database services are running or during off-peak hours.
- To ensure efficiency, it is advisable to run a checkpoint before performing this operation.
- You can perform operations on the entire database. Because a large number of tables are involved, you are advised to save the results in redirection mode.
  ```
  gsql -d database -p port -f sqlfile> sqllog.txt  2>&1
  ```
- NOTICE is displayed only for externally visible tables. The detection of internal tables is included in the foreign tables on which the internal tables depend and is not displayed externally.
- If any damage occurs during a database-wide operation, an error will be reported and the operation will halt.
- Only ordinary tables and ordinary indexes in the current database can be verified. Local temporary tables and unlogged tables are not supported. Any unsupported table types will be automatically skipped during verification.
- This operation can be performed on a standby node. When the database contains a large number of tables or a significant volume of data, the operation may take a long time. Due to the RECOVERY operation on the standby node, the ANALYZE VERIFY operation may be automatically canceled, with related error information displayed.

- Verify the data files of a table and an index.
  ```
  { ANALYZE | ANALYSE } VERIFY { FAST  | COMPLETE } { table_name  [ CASCADE ] | index_name };
  ```
  

  NOTE

  - This operation can be performed on ordinary tables and index tables. However, CASCADE is not permitted on the indexes of index tables, because it is intended to process all index tables associated with a main table. When verifying an index table only, the CASCADE mode is unnecessary.
  - When a main table is verified, its internal tables (such as TOAST tables) are also verified.
  - If the system indicates that index tables are damaged, it is advisable to run the **reindex** command to rebuild the indexes.
  - Local temporary tables and unlogged tables cannot be verified.
  - This operation can be performed on a standby node.

- Verify the data files of a table partition.
  ```
  { ANALYZE | ANALYSE } VERIFY { FAST | COMPLETE } table_name PARTITION (partition_name)
  [ CASCADE ];
  ```
  


NOTE

- You can verify a single partition within a table. However, CASCADE is not permitted on the indexes of index tables.
- Subpartitions cannot be specified.
- This operation can be performed on a standby node.

Parameters

- **VERBOSE**

  Enables the display of progress messages.

  NOTE

  When **VERBOSE** is specified, ANALYZE emits progress messages to indicate which table is currently being processed. Various statistics on the tables are printed as well.

- **table_name**

  Specifies a table name (optionally schema-qualified). If omitted, all non-foreign tables in the current database will be analyzed.

  Value range: existing table names.

- **column_name**, **column_1_name**, **column_2_name**

  Specify column names. All columns are analyzed by default.

  Value range: existing column names.

- **partition_name**

  Specifies a partition name after the keyword PARTITION to collect statistics on the corresponding partitioned table.

  Value range: names of partitions in the table.

- **foreign_table_name**

  Specifies the name of the specific table to be analyzed (possibly schema-qualified).

  Value range: existing table names.

- **FOREIGN TABLES**

  Analyzes all foreign tables accessible to the current user.

- **index_name**

  Specifies an index table name (optionally schema-qualified).

  Value range: existing table names.

- **FAST|COMPLETE**

  For a row-store table, the FAST mode verifies the CRC and page header of the row-store table. If the verification fails, an alarm is generated. In COMPLETE mode, the pointer and tuple of the row-store table are parsed and verified.

- **CASCADE**

  Verifies all indexes of the current table.

- **PARTITION_MODE**

  Cascadingly collects statistics about partitioned tables. **Table 1-392** describes the options and their meanings. This is not applicable to non-partitioned tables.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 1-392 PARTITION_MODE options

PARTITION_MODE Option	Description
ALL	Statistics about the entire table and partition are collected.
GLOBAL	Statistics about the entire table are collected.
PARTITION	Statistics about the partition are collected.
GLOBAL AND PARTITION	Statistics about the entire table and partition are collected.
ALL COMPLETE	Statistics about the entire table and partition are collected.
AUTO	Default value. The parameter configured in **statistic_granularity** or **default_statistic_granularity** is used. The priority of the table-level parameter **statistic_granularity** is higher than that of the global parameter **default_statistic_granularity**. For details about statistic_granularity, see **statistic_granularity**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- The difference between **ALL** and **ALL COMPLETE** is as follows: In **ALL** mode, the entire table is sampled once. In **ALL COMPLETE** mode, each partition is sampled once. For partitions, the statistics calculated in **ALL COMPLETE** mode are more accurate than those in **ALL** mode, but the former mode consumes more resources.
- Partition statistics are used when the Cplan is pruned to a single partition. You are advised to select a proper policy for collecting statistics about partitioned tables based on the statistics collection time and actual service requirements.
- After large-scale data import or export, you are advised to manually collect partition-level statistics in ALL COMPLETE mode.
- When a version earlier than 505.0.0 is upgraded to 505.0.0 or later, **PARTITION_MODE** does not take effect during the upgrade observation period. The behavior of **PARTITION_MODE** is the same as that of the source version.
- When the ANALYZE operation is performed on the entire database, **PARTITION_MODE** cannot be specified. That is, syntax such as ANALYZE WITH GLOBAL is not supported.
- When the entire database is analyzed, **default_statistic_granularity** can be set to **GLOBAL** or **ALL**. In this case, the ANALYZE behavior is the same as that defined in **default_statistic_granularity**. When **default_statistic_granularity** is set to other values, the ANALYZE behavior is degraded to the GLOBAL behavior.
- Subpartition statistics cannot be collected.
- In **ALL** mode, if the value of **partition_statistics_min_rows** in the partitioned table is not 0 and the GUC parameter **enable_partition_statistics_min_rows** is enabled, the minimum number of sampled rows in the partition is the value of **partition_statistics_min_rows**. However, the maximum number of sampled rows in the entire table is controlled by the GUC parameter **maintenance_work_mem**. In addition, if data skew occurs in different partitions, you are advised to run **ANALYZE** in **GLOBAL** mode for the entire table after running **ANALYZE** in **ALL** mode. This ensures that the statistics of the entire table can accurately reflect the data skew characteristics.

Examples

- Collect table statistics.

```
-- Create the customer_info table.
gaussdb=# CREATE TABLE customer_info(
wr_returned_date_sk INTEGER ,
wr_returned_time_sk INTEGER ,
wr_item_sk INTEGER NOT NULL
,wr_refunded_customer_sk INTEGER ) DISTRIBUTE BY HASH (wr_item_sk);

-- Run ANALYZE to update statistics.
gaussdb=# ANALYZE customer_info;

-- Run ANALYZE VERBOSE to update statistics and display information about the customer_info table.
gaussdb=# ANALYZE VERBOSE customer_info;
INFO: analyzing "public.customer_info"(cn_5002 pid=53078)

-- Run ANALYZE VERBOSE to export the wr_returned_time_sk column information in the customer_info table.
gaussdb=# ANALYZE VERBOSE customer_info(wr_returned_time_sk);
INFO:  analyzing "public.customer_info"(cn_5002 pid=53078)
```

- Collect statistics about a partitioned table.

```
-- Create a partitioned table.
gaussdb=# CREATE TABLE customer_par(
wr_returned_date_sk INTEGER ,
wr_returned_time_sk INTEGER ,
wr_item_sk INTEGER NOT NULL,
wr_returned_customer_sk INTEGER)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
DISTRIBUTE BY HASH (wr_item_sk)PARTITION BY RANGE(wr_returned_date_sk)(PARTITION P1
VALUES LESS THAN(2452275),PARTITION P2 VALUES LESS THAN(2452640),PARTITION P3 VALUES
LESS THAN(2453000),PARTITION P4 VALUES LESS THAN(MAXVALUE))ENABLE ROW MOVEMENT;

-- Run ANALYZE to update statistics.
gaussdb=# ANALYZE customer_par;

-- Run ANALYZE VERBOSE to export the information in the customer_par table.
gaussdb=# ANALYZE VERBOSE customer_par;
INFO:  analyzing "public.customer_par"(cn_5001 pid=446617)

-- Run ANALYZE VERBOSE to output information about the P1 partitioned table.
gaussdb=# ANALYZE VERBOSE customer_par PARTITION(P1);
INFO:  analyzing "public.customer_par"(cn_5001 pid=446617)
```

- Manually collect multi-column statistics.

```
-- Manually collect statistics in the wr_returned_date_sk and wr_returned_time_sk columns.
gaussdb=# ANALYZE VERBOSE customer_info (wr_returned_date_sk,wr_returned_time_sk);
INFO:  analyzing "public.customer_par"(cn_5001 pid=446617)
```

- Automatically collect multi-column statistics.

```
-- Create an index for the customer_info table.
gaussdb=# CREATE INDEX customer_index ON customer_info USING
btree(wr_returned_date_sk,wr_returned_time_sk,wr_item_sk,wr_refunded_customer_sk);

-- Set auto_statistic_ext_columns to 4.
gaussdb=# set auto_statistic_ext_columns=4;

-- Collect statistics about multiple columns automatically.
gaussdb=# ANALYZE VERBOSE customer_info;
INFO:  analyzing "public.customer_info"(cn_5001 pid=446617)
```

- Verify data files in the current database.

```
gaussdb=# ANALYZE VERIFY FAST;
```

- Verify the data files of a table and an index.

```
-- Check the customer_info table.
gaussdb=# ANALYZE VERIFY FAST customer_info;

-- Check the customer_index index.
gaussdb=# ANALYZE VERIFY FAST customer_index;
```

- Verify the data files of a table partition.

```
-- Check the P1 partition in the partitioned table customer_par.
gaussdb=# ANALYZE VERIFY FAST customer_par PARTITION (P1);
```

- Drop data.

```
-- Drop the index customer_index.
gaussdb=# DROP INDEX customer_index;

-- Drop the customer_info table.
gaussdb=# DROP TABLE customer_info;

-- Drop the customer_par partitioned table.
gaussdb=# DROP TABLE customer_par;
```

1.13.7.45 AUTOHINT

Description

AUTOHINT is used to explore hint combinations and outputs recommended hint combination that can accelerate the execution of the current SQL statement.

Precautions

- Only SELECT statements are supported. The user must have the super or administrator permission.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- When using any of the supported options, except for **ANALYZE**, remember to enclose them in parentheses, like in **AUTOHINT (VERBOSE) statement**.

Syntax

- Use AUTOHINT to recommend hints for an executing SQL statement. Multiple options are supported, regardless of their sequence.

```
AUTOHINT [ (  option  [, ...] )  ] statement;
```

The syntax of the option clause is as follows:

```
{
   ANALYZE [ boolean ] |
   VERBOSE [ boolean ] |
   SQLPATCH [ boolean ] |
   TEST [ boolean ] |
   DEBUG [ boolean ]
}
```

Parameters

- **statement**

  Specifies the SQL statement (limited to SELECT statements) that requires intelligent hint recommendation.

  NOTICE

  If the SQL statement already includes hints, AUTOHINT ignores the existing hints and recommends hints. For example, when being applied to the **SELECT /*+IndexScan(t1)*/* FROM t1, t2 where t1.id = t2.id and t1.a > 20;** statement, AUTOHINT will recommend hints based on the **SELECT * FROM t1, t2 where t1.id = t2.id and t1.a > 20;** statement rather than offering further recommendations based on the existing IndexScan(t1).

- **ANALYZE boolean**

  Before hint recommendation, hint exploration is performed. If hint exploration is disabled, hints are recommended for the current SQL statement based on historical hint exploration records.

  Value range:

  – **TRUE** (default value): Hint exploration is performed before recommendation.

  – **FALSE**: Hint exploration is not performed.

- **VERBOSE boolean**

  Displays additional information about hint exploration and recommendation.

  Value range:

  – **TRUE** (default): The additional information is displayed.

  – **FALSE**: It is not displayed.

- **SQLPATCH boolean**

  Outputs the corresponding SQLPATCH command after hint recommendation.

  Value range:

  – **TRUE** (default value): The SQLPATCH command is output.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

  - **FALSE**: It is not output.

- **TEST boolean**

  After hint recommendation, the initial query and the query with hints applied are executed to verify the recommendation result, and the actual plan execution time is output.

  Value range:

  - **TRUE** (default value): The recommendation result is verified and the verification result is output.
  - **FALSE**: Recommendations are not verified.

- **DEBUG boolean**

  Outputs more details than the **VERBOSE** option, including the initial plan tree and execution time of each round of exploration, the exploration subgraph obtained after each round of exploration ends, and the final merged exploration graph.

  Value range:

  - **TRUE** (default value): The details are output.
  - **FALSE**: It is not output.

Example 1

Use AUTOHINT to recommend hints for a slow SQL statement. The statement in the JOB data set is used as an example.

```
-- Import the JOB data set and use the ANALYZE option to explore and recommend hints for the 02a query.
gaussdb=# AUTOHINT ANALYZE SELECT MIN(t.title) AS movie_title
FROM company_name AS cn,
    keyword AS k,
    movie_companies AS mc,
    movie_keyword AS mk,
    title AS t
WHERE cn.country_code ='[de]'
  AND k.keyword ='character-name-in-title'
  AND cn.id = mc.company_id
  AND mc.movie_id = t.id
  AND t.id = mk.movie_id
  AND mk.keyword_id = k.id
  AND mc.movie_id = mk.movie_id;
-- Obtain the HINT recommendation result with expected improvement.
gaussdb=#
                      AUTOHINT
-------------------------------------------------------------
 Recommended hintset:
   MergeJoin(@sel$1 k@sel$1 mk@sel$1 mc@sel$1 cn@sel$1)

 Expected boost:
   planning:     0%
   execution:    50%
   overall:      50%
(7 rows)
```

1.13.7.46 AUTOHINT DROP MODEL

Description

Drop the historical hint exploration results of a specified SQL statement.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Precautions

Only SELECT statements are supported. The user must have the super or administrator permission.

Syntax

Drop the historical hint exploration results of a specified SQL statement.

```
AUTOHINT DROP MODEL statement;
```

Parameters

statement

Specifies the SQL statement (only SELECT statements are supported) whose exploration record is to be dropped.

Examples

Use AUTOHINT DROP MODEL to drop the historical HINT exploration results of a specified SQL statement.

```
gaussdb=# AUTOHINT DROP MODEL SELECT MIN(t.title) AS movie_title
FROM company_name AS cn,
    keyword AS k,
    movie_companies AS mc,
    movie_keyword AS mk,
    title AS t
WHERE cn.country_code ='[de]'
  AND k.keyword ='character-name-in-title'
  AND cn.id = mc.company_id
  AND mc.movie_id = t.id
  AND t.id = mk.movie_id
  AND mk.keyword_id = k.id
  AND mc.movie_id = mk.movie_id;
-- The deletion is successful.
AUTOHINT: 1 MODEL REMOVED
-- If no historical exploration result of the SQL statement exists, the deletion fails.
AUTOHINT: 0 MODELS REMOVE
```

1.13.7.47 AUTOHINT PURGE

Description

Purges the historical hint exploration results of AUTOHINT.

Precautions

The user must have the super permission or administrator permission.

Syntax

Purge the historical hint exploration results of AUTOHINT.

```
AUTOHINT PURGE;
```

Examples

Use AUTOHINT PURGE to purge all historical exploration results of AUTOHINT.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gaussdb=# AUTOHINT PURGE;
-- The PURGE operation is successful.
AUTOHINT: 12 MODELS REMOVED
-- The PURGE operation fails if no historical exploration result is available.
AUTOHINT: 0 MODELS REMOVE
```

1.13.8 B

1.13.8.1 BEGIN

Description

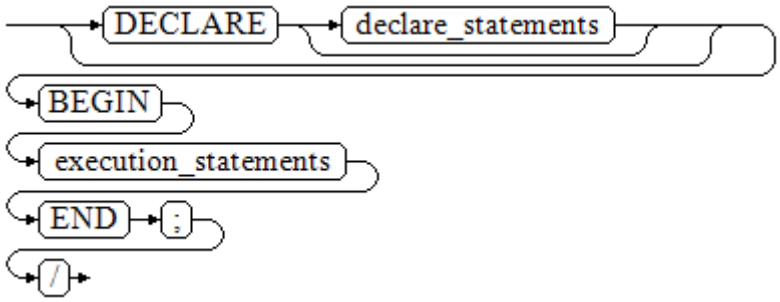
BEGIN may be used to initiate an anonymous block or a single transaction.

An anonymous block is a structure that can dynamically create and execute stored procedure code instead of permanently storing code as a database object in the database.

Syntax

- Enable an anonymous block.

```
[DECLARE [declare_statements]]
BEGIN
execution_statements
END;
/
```



- Start a transaction.

```
BEGIN [ WORK | TRANSACTION ]
 [
   {
     ISOLATION LEVEL { READ COMMITTED | READ UNCOMMITTED | SERIALIZABLE | REPEATABLE
READ }
     | { READ WRITE | READ ONLY }
    } [, ...]
 ];
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameters

- **declare_statements**

  Declares a variable, including its name and type, for example, **sales_cnt int**.

- **execution_statements**

  Specifies the statement to be executed in an anonymous block.

  Value range: DML operations (SELECT, INSERT, DELETE, and UPDATE) or registered functions in the system catalog.

- **WORK | TRANSACTION**

  Specifies the optional keyword in the BEGIN syntax, which is meaningless.

- **ISOLATION LEVEL**

  Specifies the transaction isolation level, which is used to control data visibility between concurrent transactions.

  NOTE

  The isolation level of a transaction cannot be reset after the first clause (INSERT, DELETE, UPDATE, FETCH, COPY) for modifying data is executed in the transaction.

  Value range:

  - **READ COMMITTED**: Only committed data can be read; uncommitted data remains invisible. If no isolation level is specified, **READ COMMITTED** is used by default.
  - **READ UNCOMMITTED**: This isolation level behaves identically to **READ COMMITTED**.
  - **REPEATABLE READ**: Only the data committed before transaction start is read. Uncommitted data or data committed in other concurrent transactions cannot be read.
  - **SERIALIZABLE**: Currently, this isolation level is not supported. Setting this isolation level is equivalent to **REPEATABLE READ**.

- **READ WRITE | READ ONLY**

  Specifies the transaction access mode (**READ WRITE** or **READ ONLY**).

Examples

- Start a transaction.

```
-- Create a table and insert data into the table.
gaussdb=# CREATE TABLE tbl_test1(col1 int, col2 int);
gaussdb=# INSERT INTO tbl_test1 VALUES (1,1), (2,2), (3,3);

-- Start a transaction in default mode.
gaussdb=# BEGIN;
INSERT INTO tbl_test1 VALUES (4,4);
END;

-- Start a transaction with the separation level being REPEATABLE READ.
gaussdb=# BEGIN ISOLATION LEVEL REPEATABLE READ;
SELECT * FROM tbl_test1;
END;

-- Drop the table.
gaussdb=# DROP TABLE tbl_test1;
```

- Use anonymous blocks.

```
-- Generate a string using anonymous blocks.
gaussdb=# BEGIN
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
dbe_output.print_line('Hello');
END;
/
```

START TRANSACTION

1.13.9 C

1.13.9.1 CALL

Description

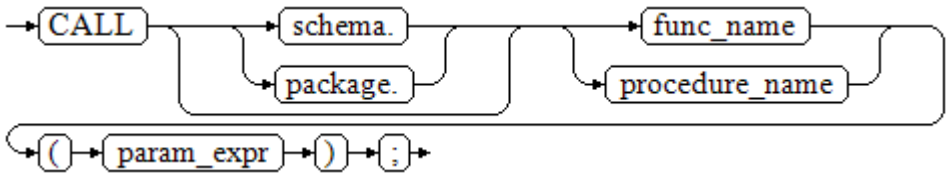
Calls defined functions and stored procedures.

Precautions

- Function or stored procedure owners, users with the EXECUTE permission on a function or stored procedure, or users with the EXECUTE ANY FUNCTION permission can call the function or stored procedure. When separation of duties is disabled, a system administrator has the permission to execute the **CALL** command by default.
- If the current database or pg_catalog is used, you can use database.schema.name to call functions or stored procedures. In this case, the objects called are those in the current database.

Syntax

```
CALL [ schema.|package.] { func_name | procedure_name } ( param_expr );
```



Parameters

- **schema.**

  Specifies the name of the schema where a function or stored procedure is located.

- **package.**

  Specifies the name of the package where a function or stored procedure is located.

- **func_name**

  Specifies the name of the function to be called.

  Value range: an existing function name.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- You can use database links to perform operations on remote functions or stored procedures. For details about the usage and limitations, see "Feature Usage Guidelines > Database Links" in *Developer Guide*.
- The function to be called can be an independent function or a member of a specified package or schema.
- When creating a function with the same name as a system function, you need to specify the schema of the function.

- **procedure_name**

  Specifies the name of the stored procedure to be called.

  Value range: character strings complying with **Identifier Naming Conventions**.

  NOTE

  - You can use database links to perform operations on remote functions or stored procedures. For details about the usage and limitations, see "Feature Usage Guidelines > Database Links" in *Developer Guide*.
  - The stored procedure to be called can be an independent procedure or a member of a specified package or schema.

- **param_expr**

  List of parameters.

  You can use the naming tag method to pass parameters. That is, use **:=** or **=>** to separate a parameter name and its value. This method allows parameters to be placed in any order.

  If parameters are passed by values, that is, only parameter values are in the list, the value order must be the same as that defined in the function or stored procedure.

  Value range: an existing function parameter name or stored procedure parameter name

  NOTE

  - The parameters include input parameters (whose name and type are separated by **IN**) and output parameters (whose name and type are separated by **OUT**). When you run the **CALL** command to call a function or stored procedure, the parameter list must contain an output parameter for non-overloaded functions. You can set the output parameter to a variable or any constant. For an overloaded package function, the parameter list can have no output parameter, but the function may not be matched. If an output parameter is contained, it must be a constant.
  - Packages can be used only in ORA-compatible databases.

Examples

```
-- Create the func_add_sql function, calculate the sum of two integers, and return the result.
gaussdb=# CREATE FUNCTION func_add_sql(num1 integer, num2 integer) RETURN integer
AS
BEGIN
RETURN num1 + num2;
END;
/

-- Pass by parameter value.
gaussdb=# CALL func_add_sql(1, 3);

-- Pass by naming tag method.
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gaussdb=# CALL func_add_sql(num1 => 1,num2 => 3);
gaussdb=# CALL func_add_sql(num2 := 2, num1 := 3);

-- Drop the function.
gaussdb=# DROP FUNCTION func_add_sql;

-- Create a function with output parameters.
gaussdb=# CREATE FUNCTION func_increment_sql(num1 IN integer, num2 IN integer, res OUT integer)
RETURN integer
AS
BEGIN
res := num1 + num2;
END;
/

-- Specify a constant as an output parameter.
gaussdb=# CALL func_increment_sql(1,2,1);

-- Pass a variable as an output parameter.
gaussdb=# DECLARE
res int;
BEGIN
func_increment_sql(1, 2, res);
dbe_output.print_line(res);
END;
/

-- Drop the function.
gaussdb=# DROP FUNCTION func_increment_sql;

-- Create overloaded functions.
gaussdb=# CREATE OR REPLACE PROCEDURE package_func_overload(col int, col2 out int) PACKAGE
AS
DECLARE
    col_type text;
BEGIN
    col := 122;
    dbe_output.print_line('two out parameters ' || col2);
END;
/

gaussdb=# CREATE OR REPLACE PROCEDURE package_func_overload(col int, col2 out varchar) PACKAGE
AS
DECLARE
    col_type text;
BEGIN
    col2 := '122';
    dbe_output.print_line('two varchar parameters ' || col2);
END;
/

-- Call the function.
gaussdb=# CALL package_func_overload(1, 'test');
gaussdb=# CALL package_func_overload(1, 1);

-- Drop the function.
gaussdb=# DROP FUNCTION package_func_overload;
```

CREATE FUNCTION and **CREATE PROCEDURE**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

1.13.9.2 CHECKPOINT

Description

Sets WAL checkpoints. A checkpoint is a point in the transaction log sequence at which all data files have been updated to reflect the information in the log. All data files will be flushed to a disk. By default, WAL checkpoints are placed in the Xlog at intervals. You can use the **gs_guc** command to set related GUC parameters (**checkpoint_segments**, **checkpoint_timeout**, and **incremental_checkpoint_timeout**) to adjust the atomic checkpoint interval.

Precautions

- Only SYSADMIN and OPRADMIN can call CHECKPOINT.
- CHECKPOINT performs an immediate checkpoint when the related command is issued, without waiting for a regular checkpoint scheduled by the system.

Syntax

```
CHECKPOINT;
```

Examples

```
-- Set a checkpoint.
gaussdb=# CHECKPOINT;
```

1.13.9.3 CLEAN CONNECTION

Description

Clears network connections between the CN and other specified CNs or DNs. This function can clear idle or invalid connections of specified databases or users on CNs, and forcibly clear active connections.

Precautions

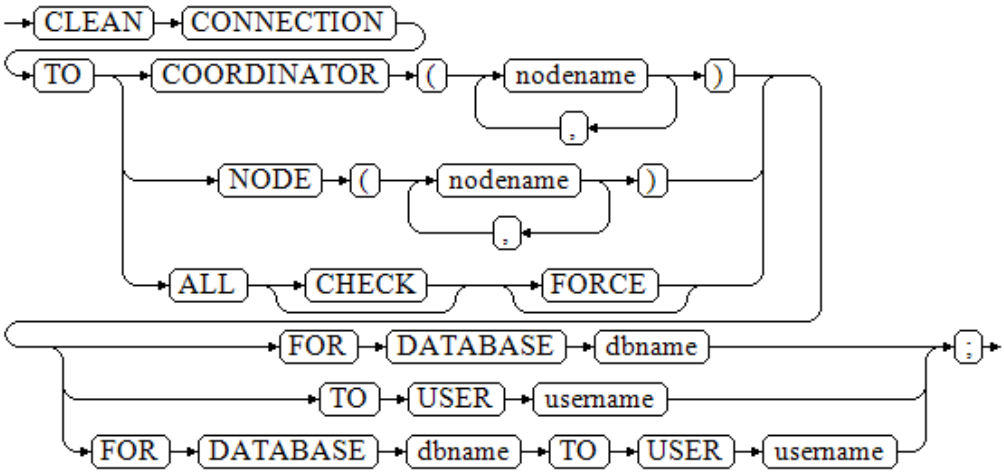
- You are advised to run the **CLEAN CONNECTION** command only when the database network connection is abnormal. You can query the pg_stat_get_pooler_status() function to view cached connections and check the cleanup effect.
- If the **FORCE** mode is not specified, the following results are obtained:
  - The CLEAN CONNECTION operation cleans up only the connections between database nodes (CNs or DNs) and does not affect the client connections.
  - In non-**FORCE** mode, the CLEAN CONNECTION operation cleans up only idle and invalid connections cached on CNs. Normal connections that are being used are not cleaned up.
- If the **FORCE** mode is specified, the following results are obtained:
  - The CLEAN CONNECTION operation forcibly cleans up normal connections and client connections that are being used.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

  - The CLEAN CONNECTION operation cleans up the connections of a specified database or user on the DN. If residual connections cannot be cleared on DNs, O&M personnel are advised to use the pg_terminate_session function to clear invalid sessions.

Syntax

```
CLEAN CONNECTION
   TO { COORDINATOR ( nodename [, ... ] ) | NODE ( nodename [, ... ] )| ALL [ CHECK ] [ FORCE ] }
   { FOR DATABASE dbname | TO USER username | FOR DATABASE dbname TO USER username };
```



Parameters

- **CHECK**

  Checks connections before **DROP DATABASE** is executed. If any sessions are detected, an error will be reported and the database will not be dropped. This parameter can be used only when the node list is specified as **TO ALL**. If this parameter is used, the system checks whether the database is accessed by other sessions before cleaning up connections.

- **FORCE**

  Specifies the cleanup mode. If this parameter is specified, all threads related to the specified databases and users on the current CN will receive the SIGTERM signal, and the corresponding sessions will be forcibly closed, transactions will be aborted, and network connections will be cleaned up. All threads related to the specified databases and users on the DN will receive the SIGTERM signal and be forcibly closed.

  This parameter can be specified only when the node list is specified as **TO ALL**.

- **COORDINATOR (nodename [, ...] }) | NODE (nodename [, ...]) | ALL**

  Specifies a list of nodes. Idle and invalid connections between the current CN and the specified nodes will be cleaned up. The following scenarios exist:

  - **COORDINATOR**: deletes the idle or invalid connections from the current CN to a specified CN.
  - **NODE**: deletes the idle or invalid connections from the current CN to a specified DN.
  - **ALL**: deletes the idle or invalid connections from the current CN to all nodes, including CNs and DNs.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Value range: names of existing nodes.

- **dbname**

  Deletes connections to a specified database from the current CN. If this parameter is not specified, connections to all databases will be deleted by default.

  Value range: existing database names.

- **username**

  Deletes connections to a specified user from the current CN. If this parameter is not specified, connections of all users will be deleted by default.

  Value range: existing usernames.

Examples

```
-- Create the test_clean_connection database.
gaussdb=# CREATE DATABASE test_clean_connection;

-- Create user jack.
gaussdb=# CREATE USER jack PASSWORD '********';

-- Log in to the database as the user jack in another session, and query the connection information in the view.
gaussdb=# SELECT datname,usename,application_name,waiting,state
          FROM pg_stat_activity
          WHERE datname = 'test_clean_connection';
        datname         | usename | application_name | waiting | state
------------------------+---------+------------------+---------+-------
 test_clean_connection | jack    | gsql             | f       | idle
(1 row)

-- If you directly delete the test_clean_connection database, the following error information is displayed:
gaussdb=# DROP DATABASE test_clean_connection;
ERROR:  Database "test_clean_connection" is being accessed by other users. You can stop all connections by command: "clean connection to all force for database XXXX;" or wait for the sessions to end by querying view: "pg_stat_activity".
DETAIL:  There is 1 other session using the database.

-- Delete the connections between the current CN and all nodes of the test_clean_connection database.
-- If the FORCE parameter is not used, connections whose stat is not in other states cannot be deleted.
gaussdb=# CLEAN CONNECTION TO ALL FORCE FOR DATABASE test_clean_connection;

-- Query the connection for logging in to the test_clean_connection database.
gaussdb=# SELECT datname,usename,application_name,waiting,state
          FROM pg_stat_activity
          WHERE datname = 'test_clean_connection';
 datname | usename | application_name | waiting | state
---------+---------+------------------+---------+-------
(0 rows)

-- Drop the test_clean_connection database.
gaussdb=# DROP DATABASE test_clean_connection;

-- Drop user jack.
gaussdb=# DROP USER jack;
```

1.13.9.4 CLOSE

Description

Frees all resources associated with a specified cursor.

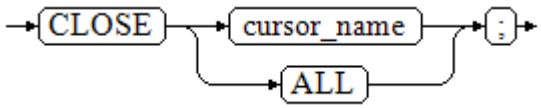
 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Precautions

- A cursor that is no longer used should be closed in time to free the database resources it occupies and avoid resource leakage.
- After a cursor is closed, no subsequent operations are allowed on it.
- The behavior of closing a cursor is closely related to its holdability. The details are as follows:
  - **WITHOUT HOLD**: a cursor that is not holdable. When the transaction that creates the cursor ends with COMMIT or ROLLBACK, the cursor is automatically closed. This is an implicit behavior.
  - **WITH HOLD**: a cursor that is holdable.
    - If the transaction ends with ROLLBACK, the cursor is implicitly closed.
    - If the transaction is successfully committed, the cursor remains open and valid until an explicit CLOSE operation is performed or the client connection is terminated.
- GaussDB does not specify the OPEN statement for opening a cursor because a cursor is opened when it is defined using the **CURSOR** command. You can query the PG_CURSORS system view to obtain all available cursors.

Syntax

```
CLOSE { cursor_name | ALL } ;
```



Parameters

- **cursor_name**

  Specifies the name of a cursor to be closed or released.
- **ALL**

  Closes or releases all open cursors.

Examples

For details, see **Examples**.

FETCH and **MOVE**

1.13.9.5 CLUSTER

Description

Clusters a table based on the specified index. The index must already exist in the target table.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- In GaussDB, after a table is clustered, the table is physically stored based on the index information. Clustering is a one-time operation. After a table is updated, the updated content is not clustered again. Therefore, the system does not attempt to re-cluster the new content and updated records in index order.
- In GaussDB, after a table is clustered, the index used for clustering the table is recorded. When **CLUSTER** *table_name***;** is executed subsequently, the database automatically performs re-clustering based on the previously recorded index. You can run **ALTER TABLE** *table_name* **CLUSTER ON** *index_name***;** to specify the index used for subsequent clustering operations, or run **ALTER TABLE** *table_name* **SET WITHOUT CLUSTER;** to clear the index set for table clustering.
- Running **CLUSTER** without any parameters will re-cluster all previously clustered tables in the database owned by the current user. If this command is called by system administrators, all previously clustered tables will be re-clustered.
- In GaussDB, when a table is clustered, the database requests an ACCESS EXCLUSIVE lock on the table, preventing any other operations (including reads and writes) on the table until the CLUSTER operation is complete.

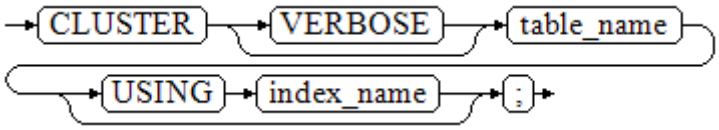
Precautions

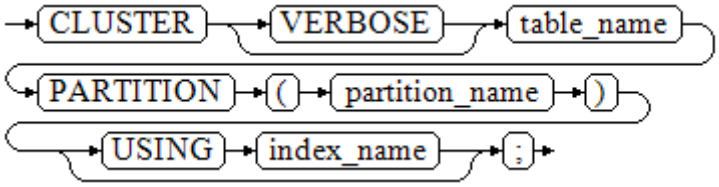
- Only row-store B-tree indexes can be used for clustering.
- When the table is randomly read, the data storage sequence has no significant impact. If it is accessed frequently based on a specific index and the index groups data, the CLUSTER operation can improve the query performance.
- When the query condition involves index-based range scan or the index key maps to multiple rows of data, the CLUSTER operation can effectively improve the query performance. If the index has identified the page storing the first matching row, other matching rows are easily located because they are usually stored on the same page, reducing disk I/O and accelerating query.
- When performing the CLUSTER operation on a table, GaussDB creates a temporary backup of the table created in the index sequence and a temporary backup of each index on the table. Therefore, it is crucial to ensure that the disk has sufficient free space (no less than the total size of the table and all indexes) during clustering.
- Optimizers rely on the sorting statistics of a table for query planning. After clustering a table, you must run **ANALYZE** to update the sorting statistics for optimizers. If the statistics are not updated in a timely manner, the optimizers may generate a non-optimal query execution plan based on outdated information.
- **CLUSTER** cannot be executed within a transaction.
- If the GUC parameter **xc_maintenance_mode** is not set to **on**, the CLUSTER operation will ignore all system catalogs.
- For a global secondary index (GSI):
  - After the **CLUSTER** command is executed on a single partition or the **CLUSTER [VERBOSE];** command is executed to recluster a table, an error will be reported if a query statement accesses the GSI. In this case, you need to run the **REINDEX INDEX** statement to rebuild the GSI to restore the query.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

  - After **CLUSTER** is executed on a table with a GSI, you need to collect GSI statistics again by calling the **ANALYZE GLOBAL INDEX** *gsi_name* **FOR TABLE** *table_name* statement. For details, see **ANALYZE | ANALYSE**.
- To use an expression index for clustering, you must have the REINDEX permission on that index.

Syntax

- Cluster a table.
  ```
  CLUSTER [ VERBOSE ] table_name [ USING index_name ];
  ```
  


- Cluster a partition.
  ```
  CLUSTER [ VERBOSE ] table_name PARTITION ( partition_name ) [ USING index_name ];
  ```
  


- Recluster a table.
  ```
  CLUSTER [ VERBOSE ];
  ```
  
Parameters

- **VERBOSE**

  (Optional) Specifies whether to output the detailed progress information of the operation.
- **table_name**

  Specifies the name of the table to be clustered.

  Value range: existing table names.
- **USING index_name**

  Specifies the name of the index used for clustering a table or partition.

  Value range: existing index names.

  > NOTE
  >
  > This parameter must be specified for the initial CLUSTER operation on a table. When clustering a table again, you can omit **index_name**, and the database will automatically recluster the table based on the index recorded for previous clustering.
- **partition_name**

  Specifies the name of the partition to be clustered.

  Value range: existing partition names.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Examples

- Cluster a table.

```
-- Create a table and insert data into the table.
gaussdb=# CREATE TABLE test_c1(id int, name varchar(20));
gaussdb=# CREATE INDEX idx_test_c1_id ON test_c1(id);
gaussdb=# INSERT INTO test_c1 VALUES (3,'Joe'),(1,'Jack'),(2,'Scott');

-- Query.
gaussdb=# SELECT * FROM test_c1;
 id | name
----+-------
  3 | Joe
  1 | Jack
  2 | Scott
(3 rows)

-- Perform clustering.
gaussdb=# CLUSTER test_c1 USING idx_test_c1_id;

-- Query.
gaussdb=# SELECT * FROM test_c1;
 id | name
----+-------
  1 | Jack
  2 | Scott
  3 | Joe
(3 rows)

-- Drop.
gaussdb=# DROP TABLE test_c1;
```

- Recluster a table.

```
-- Create a table.
gaussdb=# CREATE TABLE test(col1 int,CONSTRAINT pk_test PRIMARY KEY (col1));

-- An error is reported when the keyword USING is not contained in the first clustering.
gaussdb=# CLUSTER test;
ERROR:  there is no previously clustered index for table "test"

-- Perform clustering.
gaussdb=# CLUSTER test USING pk_test;

-- Insert data.
gaussdb=# INSERT INTO test VALUES (1),(99),(10),(8);

-- Recluster a table.
gaussdb=# CLUSTER VERBOSE test;
INFO:  clustering "public.test" using index scan on "pk_test"(dn_6001 pid=3672)
INFO:  "test": found 0 removable, 4 nonremovable row versions in 1 pages(dn_6001 pid=3672)
DETAIL:  0 dead row versions cannot be removed yet.
CPU 0.00s/0.00u sec elapsed 0.01 sec.
CLUSTER

-- Drop.
gaussdb=# DROP TABLE test;
```

- Cluster a partition.

```
-- Create a table and insert data into the table.
gaussdb=# CREATE TABLE test_c2(id int, info varchar(4)) PARTITION BY RANGE (id)(
    PARTITION p1 VALUES LESS THAN (11),
    PARTITION p2 VALUES LESS THAN (21)
);
gaussdb=# CREATE INDEX idx_test_c2_id1 ON test_c2(id);
gaussdb=# INSERT INTO test_c2 VALUES (6,'ABBB'),(2,'ABAB'),(9,'AAAA');
gaussdb=# INSERT INTO test_c2 VALUES (11,'AAAB'),(19,'BBBA'),(16,'BABA');

-- Query.
gaussdb=# SELECT * FROM test_c2;
 id | info
```

11 | AAAB
16 | BABA
19 | BBBA
(6 rows)

-- Drop.
gaussdb=# DROP TABLE test_c2;
```

1.13.9.6 COMMENT

Description

Creates or modifies the comment of an object.

Precautions

- Only one comment is stored for each object. To modify a comment, run the **COMMENT** command again for the same object. To drop a comment, set the comment text to **NULL**. When an object is dropped, its associated comment is automatically cleared.
- There is no security mechanism for viewing comments. Users connected to a database can view comments of all objects in the database. Comments of shared objects (such as databases, roles, and tablespaces) are stored globally, and users connected to any database can query the comments. Therefore, do not put security-critical information in comments.
- For most objects, only the object owner and users with the COMMENT permission are authorized to set comments. System administrators have this authorization by default.
- Roles do not have owners, so the rule for **COMMENT ON ROLE** is that you must be an administrator to comment on an administrator role, or have the CREATE ROLE permission to comment on non-administrator roles. System administrators can comment on all objects.

Syntax

```
COMMENT ON
{
  AGGREGATE agg_name (agg_type [, ...] ) |
  CAST (source_type AS target_type) |
  COLLATION object_name |
  COLUMN { table_name.column_name | view_name.column_name } |
```

```
  CONSTRAINT constraint_name ON table_name |
  CONVERSION object_name |
  DATABASE object_name |
  EXTENSION object_name |
  FOREIGN DATA WRAPPER object_name |
  FOREIGN TABLE object_name |
  FUNCTION function_name ( [ {[ argname ] [ argmode ] argtype} [, ...] ] ) |
  INDEX object_name |
   OPERATOR operator_name (left_type, right_type) |
  OPERATOR CLASS object_name USING index_method |
  OPERATOR FAMILY object_name USING index_method |
  [ PROCEDURAL ] LANGUAGE object_name |
  ROLE object_name |
  SCHEMA object_name |
  SERVER object_name |
  TABLE object_name |
  TABLESPACE object_name |
  TEXT SEARCH CONFIGURATION object_name |
  TEXT SEARCH DICTIONARY object_name |
  TEXT SEARCH PARSER object_name |
  TEXT SEARCH TEMPLATE object_name |
  TYPE object_name |
  VIEW object_name |
  TRIGGER trigger_name ON table_name
}
   IS 'text';
```

Parameters

- **agg_name**

  Specifies the new name of an aggregate function.
- **agg_type**

  Data type of the aggregate function parameters.
- **source_type**

  Specifies the source data type of the cast.
- **target_type**

  Specifies the target data type of the cast.
- **object_name**

  Specifies an object name.
- **table_name.column_name | view_name.column_name**

  Specifies a column name. You can prefix it with a table or view name.
- **constraint_name**

  Specifies the name of a table constraint.
- **table_name**

  Specifies a table name.
- **function_name**

  Function name.
- **argmode,argname,argtype**

  Specifies the schema, name, and type of the function parameters.
- **operator_name**

  Specifies the name of the operator.
- **left_type,right_type**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Specifies the data type (optionally schema-qualified) of GUC parameters. If the prefix or suffix operator does not exist, the **NONE** option can be added.

- **trigger_name**

  Specifies the trigger name.

- **text**

  Specifies the comment text.

Examples

```
-- Create a table.
gaussdb=# CREATE TABLE emp(
    empno varchar(7),
    ename varchar(50),
    job varchar(50),
    mgr varchar(7),
    deptno int
);

-- Add a comment to a table.
gaussdb=# COMMENT ON TABLE emp IS 'Department table';

-- Add comments to columns.
gaussdb=# COMMENT ON COLUMN emp.empno  IS  'Employee ID';
gaussdb=# COMMENT ON COLUMN emp.ename  IS  'Employee name';
gaussdb=# COMMENT ON COLUMN emp.job    IS  'Job';
gaussdb=# COMMENT ON COLUMN emp.mgr    IS  'Manager ID';
gaussdb=# COMMENT ON COLUMN emp.deptno IS  'Department ID';

-- View the comment of the table.
gaussdb=# \d+
 Schema |    Name     |   Type   | Owner |    Size    |              Storage               | Description
--------+-------------+----------+-------+------------+------------------------------------+-------------
 public | emp         | table    | omm   | 0 bytes    | {orientation=row,compression=no} | Department table

-- View the comments of columns.
gaussdb=# \d+ emp
                          Table "public.emp"
 Column |         Type          | Modifiers | Storage  | Stats target | Description
--------+-----------------------+-----------+----------+--------------+-------------
 empno  | character varying(7)  |           | extended |              | Employee ID
 ename  | character varying(50) |           | extended |              | Employee name
 job    | character varying(50) |           | extended |              | Job
 mgr    | character varying(7)  |           | extended |              | Manager ID
 deptno | integer               |           | plain    |              | Department ID
Has OIDs: no
Distribute By: HASH(empno)
Location Nodes: ALL DATANODES
Options: orientation=row, compression=no

-- Drop the emp table.
gaussdb=# DROP TABLE emp;
```

1.13.9.7 COMMIT | END

Description

Commits all operations of a transaction.

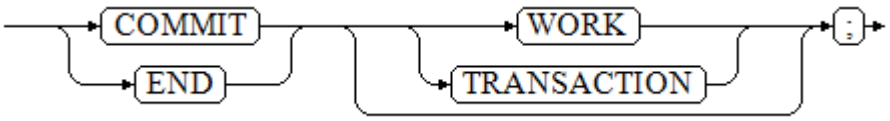
Precautions

Only the creator of a transaction or a system administrator can run the **COMMIT** command. The CREATE and COMMIT operations can be in different sessions.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Syntax

```
{ COMMIT | END } [ WORK | TRANSACTION ] ;
```



Parameters

- **COMMIT | END**

  Commits the current transaction and makes all changes made by the transaction become visible to others.

- **WORK | TRANSACTION**

  Optional keyword. It is only used for syntax compatibility and has no actual meaning.

Examples

```
-- Create a schema.
gaussdb=# CREATE SCHEMA tpcds;

-- Create a table.
gaussdb=# CREATE TABLE tpcds.customer_demographics_t2
(
    CD_DEMO_SK              INTEGER              NOT NULL,
    CD_GENDER               CHAR(1)                      ,
    CD_MARITAL_STATUS       CHAR(1)                      ,
    CD_EDUCATION_STATUS     CHAR(20)                     ,
    CD_PURCHASE_ESTIMATE    INTEGER                      ,
    CD_CREDIT_RATING        CHAR(10)                     ,
    CD_DEP_COUNT            INTEGER                      ,
    CD_DEP_EMPLOYED_COUNT   INTEGER                      ,
    CD_DEP_COLLEGE_COUNT    INTEGER
) DISTRIBUTE BY HASH (CD_DEMO_SK);

-- Start a transaction.
gaussdb=# START TRANSACTION;

-- Insert data.
gaussdb=# INSERT INTO tpcds.customer_demographics_t2 VALUES(1,'M', 'U', 'DOCTOR DEGREE', 1200,
'GOOD', 1, 0, 0);
gaussdb=# INSERT INTO tpcds.customer_demographics_t2 VALUES(2,'F', 'U', 'MASTER DEGREE', 300, 'BAD',
1, 0, 0);

-- Commit the transaction to make all changes permanent.
gaussdb=# COMMIT;

-- Query data.
gaussdb=# SELECT * FROM tpcds.customer_demographics_t2;

-- Delete the tpcds.customer_demographics_t2 table.
gaussdb=# DROP TABLE tpcds.customer_demographics_t2;

-- Drop the schema.
gaussdb=# DROP SCHEMA tpcds;
```

1.13.9.8 COMMIT PREPARED

Description

Commits a prepared two-phase transaction.

Precautions

- This functionality is for internal use only. You are advised not to use it.
- This function is available only in maintenance mode (when the GUC parameter **xc_maintenance_mode** is set to **on**). It is used only by maintenance personnel for troubleshooting. Common users should not use this mode.
- Only the creator of a transaction or a system administrator can run the command. The CREATE and COMMIT operations can be in different sessions.
- The transaction function is maintained automatically by the database, and should be not visible to users.

Syntax

```
COMMIT PREPARED transaction_id [ WITH commit_sequence_number ];
```

Parameters

- **transaction_id**

  Specifies the identifier of the transaction to be committed. The identifier cannot be the same as any one that has been used by any current prepared transaction.

- **commit_sequence_number**

  Sequence number of the transaction to be committed. The value is a 64-bit ascending unsigned number.

Examples

```
-- Start.
gaussdb=# SET XC_MAINTENANCE_MODE = ON;
SET

gaussdb=# BEGIN;

-- Create a table.
gaussdb=# CREATE TABLE item1(id int);

-- Prepare a transaction whose identifier is trans_test.
gaussdb=# PREPARE TRANSACTION 'trans_test';

-- Query the item1 table. The item1 table cannot be accessed.
gaussdb=# SELECT * FROM item1;
ERROR:  Relation "item1" does not exist on test.
LINE 1: SELECT * FROM item1;

-- Commit the transaction whose identifier is trans_test.
gaussdb=# COMMIT PREPARED 'trans_test';

-- Query the item1 table. The item1 table can be accessed.
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gaussdb=# SELECT * FROM item1;
 a
---
(0 rows)

-- Drop the table.
gaussdb=# DROP TABLE item1;
```

PREPARE TRANSACTION, **ROLLBACK PREPARED**

1.13.9.9 COPY

Description

Copies data between a table and a file.

Specifically, COPY FROM copies data from a file to a table, and COPY TO copies data from a table to a file.

Precautions

- When the **enable_copy_server_files** parameter is disabled, only the initial user can execute the **COPY FROM FILENAME** and **COPY TO FILENAME** commands. When the **enable_copy_server_files** parameter is enabled, users with the SYSADMIN permission or users inheriting permissions from the built-in role gs_role_copy_files can execute these commands. Nevertheless, to protect sensitive files from unauthorized access or modification, the use of the **COPY FROM FILENAME** and **COPY TO FILENAME** commands is restricted by default on database configuration files, key files, certificate files, environment variable files, and audit logs.
- The database administrator can set the GUC parameter **safe_data_path** to set the whitelist of paths that can be imported and exported by all users. The whitelist takes effect by default. If this parameter is left empty, the used paths are not intercepted, that is, the whitelist does not take effect. Exercise caution when setting this parameter. Note that an error will be reported when COPY uses a relative path of the designated path.
- COPY applies only to tables but not views.
- COPY TO requires the SELECT permission on the table to be read, and COPY FROM requires the INSERT permission on the table to be inserted.
- If a list of columns is specified, COPY will only copy the data in the specified columns to or from the file. If the table contains any columns that are not in the column list, COPY FROM will insert the default values for those columns.
- If a data source file is specified, the file must be accessible to the server. When **STDIN** is specified, data is transmitted via the connection between the client and the server. When entering data, use tab characters to separate the columns of the table and backslash-periods (\.) to indicate the end of the input.
- COPY FROM will raise an error if any row in the data file contains more or fewer columns than expected.
- The end of data can be represented by a single line containing just the backslash-period (\.). An end-of-data marker is not necessary when data is

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

read from a file. It is needed when data is coped to or from client applications.

- In COPY FROM, **\N** is an empty string. To enter the actual value **\N**, use **\\N**.
- COPY FROM can preprocess data using column expressions, but column expressions do not support subqueries.
- If a data format error occurs during COPY FROM, the transaction will be rolled back. However, the error information provided is insufficient, making it difficult to locate the error data within a large amount of raw data.
- COPY FROM and COPY TO are suitable for low-concurrency, local export and import of small data volumes.
- When COPY is used in binary format, transcoding in distributed mode is not supported.
- **COPY** is a server command that runs within the same environment as the database server processes. **\COPY** is a client meta-command that runs within the same environment as the client tool gsql. Note that when the database and gsql are used in the sandbox environment, the **COPY** and **\COPY** commands both use the paths in the sandbox. When the database is used in the sandbox environment and gsql is used outside the sandbox, the **COPY** command uses the path inside the sandbox, and the **\COPY** command uses the path outside the sandbox.
- When executing COPY to import data to a base table with a GSI, the **enable_stream_operator** parameter must be enabled to achieve optimal data import performance.
- During the export using COPY TO, if the GUC parameter **support_zero_character** is disabled and the column data in the table contains the '\0' characters, the column data will be truncated during the export. Only the data before '\0' will be exported. When the parameter is enabled, the '\0' characters are also exported. The performance loss is positively correlated with the number of '\0' characters.
- Changing the schema of the pgxc_copy_error_log system catalog from public to pg_catalog deprecates the original catalog in the public schema. A table in the public schema may have the same name as a user table. Therefore, you need to identify the table. If the table is not a user table, migrate data to the corresponding table in the pg_catalog schema and delete the corresponding table in the original public schema. If a table with the same name exists in the pg_catalog schema, the GSQL meta-command **\d(+)** preferentially matches pg_catalog.pgxc_copy_error_log, which is not displayed because it is a system catalog. As a result, pgxc_copy_error_log cannot be found in the list, but this table exists in the public schema. You can directly reference public.pgxc_copy_error_log.
- When exporting data of the float4 or float8 type, you are advised to set **extra_float_digits** to **3** to avoid loss of significant digits and ensure consistency between the data before and after import and export.
- In certain scenarios, you can set the GUC parameter **batch_insert_index_types** to **"rcr_ubtree"** to improve the performance of inserting indexes in batches. For details, see **Batch insertion index performance optimization** in **INSERT**.
- For security purposes, do not use COPY FROM to import data to the pg_authid, pg_auth_history, gs_global_config, and gs_workload_rule system catalogs.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- When the parameter **enable_security_policy** is enabled, and if a masking policy has been set, the system will perform data masking.
- When importing and exporting data, check whether the data contains escape characters. If you prepare the data file, you need to assess the import mode (import with or without escaping). If the data file is exported using the **COPY** command, the escape option set for import must be the same as that for export.
- When the **COPY** command is used to import or export data, the size of a single row of data tuples cannot exceed 1 GB – 1 byte in non-transcoding scenarios, and cannot exceed 256 MB – 1 byte in transcoding scenarios.
- When the **COPY** command is used to import data, error tables are involved. For details about the precautions and usage, see the corresponding sections. This involves the system view pg_catalog.pgxc_copy_error_log and the system catalog pg_catalog.gs_copy_error_log.
- During COPY FROM, data is inserted by DNs, and constraint exceptions are reported by DNs to the CN. Each DN can only view its own data. Therefore, the error line number reported by a DN to the CN is different from that in the data file.
- When you run the **\COPY** command with **detail_info** as a condition to query audit information, the command operates in a case-insensitive manner. Specifically, the SQL statement is converted to and displayed as the COPY keyword in audit information.
- Set-returning functions cannot be used in column expressions with the **COPY** command.
- Invalid characters cannot be imported as they were when they are exported using the COPY command and imported again.

Syntax

- Copy data from a file to a table.

```
COPY [BINARY] table_name [ ( column_name [, ...] ) ]
    [ WITH OIDS ]
    FROM { 'filename' | STDIN }
    [ LOAD_DISCARD 'discard_file_name' ]
    [ LOAD_BAD 'bad_file_name' ]
    [ USEEOF ]
    [ [ USING ] DELIMITERS 'delimiters' ]
    [ WITHOUT ESCAPING ]
    [ LOG ERRORS | LOG ERRORS DATA ]
    [ REJECT LIMIT 'limit' ]
    [ WITH ]
    [ copy_option [ ...] | ( option [, ...] ) ];
```

- Copy data from a table to a file.

```
COPY table_name [ ( column_name [, ...] ) ]
    [ WITH OIDS ]
    TO { 'filename' | STDOUT }
    [ [ USING ] DELIMITERS 'delimiters' ]
    [ WITHOUT ESCAPING ]
    [ WITH ]
    [ copy_option [ ...] | ( option [, ...] ) ];

COPY query {(SELECT) | (VALUES)}
    TO { 'filename' | STDOUT }
    [ WITHOUT ESCAPING ]
    [ WITH ]
    [ copy_option [ ...] | ( option [, ...] ) ];
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- The syntax constraints of COPY TO are as follows:

  (query) is incompatible with [USING] DELIMITERS. If the data comes from a query result, COPY TO cannot specify [USING] DELIMITERS.
- Use spaces to separate **copy_option** following FIXED FORMATTER.
- **copy_option** is a native parameter form in COPY, whereas **option** is a parameter form imported from a compatible foreign table.

copy_option can be as follows:

```
{ OIDS
| DELIMITER [ AS ] 'delimiter_string'
| NULL [ AS ] 'null_string'
| HEADER
| FILEHEADER 'header_file_string'
| FREEZE
| FORCE NOT NULL column_name [, ...]
| FORCE QUOTE { column_name [, ...] | * }
| BINARY
| CSV
| FIXED
| QUOTE [ AS ] 'quote_character'
| ESCAPE [ AS ] 'escape_character'
| EOL 'newline_character'
| ENCODING 'encoding_name'
| IGNORE_EXTRA_DATA
| FILL_MISSING_FIELDS [ { 'one' | boolean } ]
| COMPATIBLE_ILLEGAL_CHARS
| DATE_FORMAT 'date_format_string'
| TIME_FORMAT 'time_format_string'
| TIMESTAMP_FORMAT 'timestamp_format_string'
| DATEA_FORMAT 'datea_format_string'
| SMALLDATETIME_FORMAT 'smalldatetime_format_string'
| COPY_CUSTOM_ID 'custom_id_string'
| TABLE_COMPRESS_CLAUSE( ROW STORE COMPRESS ADVANCED [ MEDIUM | HIGH ] ROW [ON
(EXPR)])
| FORMATTER ( [ column_name( offset, length ) ] [, ...] )
| TRANSFORM ( [ column_name [ data_type ] [ AS transform_expr ] ] [, ...] )
| POSITION_KEEP_TRAILING_SPACE }
```

option can be as follows:

```
{ FORMAT 'format_name'
| OIDS [ boolean ]
| DELIMITER 'delimiter_character'
| NULL 'null_string'
| HEADER [ boolean ]
| USEEOF [ boolean ]
| FILEHEADER 'header_file_string'
| FREEZE [ boolean ]
| QUOTE 'quote_character'
| ESCAPE 'escape_character'
| EOL 'newline_character'
| NOESCAPING [ boolean ]
| FORCE_QUOTE { ( column_name [, ...] ) | * }
| FORCE_NOT_NULL ( column_name [, ...] )
| ENCODING 'encoding_name'
| IGNORE_EXTRA_DATA [ boolean ]
| FILL_MISSING_FIELDS [ { 'one' | boolean } ]
| COMPATIBLE_ILLEGAL_CHARS [ boolean ]
| DATE_FORMAT 'date_format_string'
| TIME_FORMAT 'time_format_string'
| TIMESTAMP_FORMAT 'timestamp_format_string'
| DATEA_FORMAT 'datea_format_string'
| SMALLDATETIME_FORMAT 'smalldatetime_format_string'
| COPY_CUSTOM_ID 'custom_id_string'
| POSITION_KEEP_TRAILING_SPACE }
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameters

- **query**

  Specifies that the results will be copied.

  Value range: Only one SELECT or VALUES command is supported. A semicolon (;) is not required at the end of the command.

- **table_name**

  Specifies a table name (optionally schema-qualified).

  Value range: existing table names.

- **column_name**

  Specifies an optional list of columns to be copied.

  Value range: existing columns. If no column list is specified, all columns will be used.

- **STDIN**

  Specifies that input comes from the standard input. In the input, table columns are separated by tab characters, and the end of data is represented by a new row containing only the backslash-period (\.).

  NOTE

  In parallel import mode, if data is imported through standard input (STDIN), the client sends data using multiple threads, which leads to lock contention. This may cause transaction commit failures in some threads, resulting in only partial data being imported. Additionally, the failed data cannot be re-imported subsequently. Therefore, it is not recommended to use standard input for parallel import when the table already contains data.

- **STDOUT**

  Specifies that output goes to the standard output.

- **LOAD_DISCARD 'discard_file_name'**

  This API is reserved and not recommended.

- **LOAD_BAD 'bad_file_name'**

  This API is reserved and not recommended.

- **USEEOF**

  If this parameter is set, no error is reported for a backslash followed by a period (\.). When importing a single column, if you enter "\." in **stdin** mode, it is considered as an end of line (EOL) character instead of data.

  Value range: **true/on** and **false/off**.

  Default value: **false**.

- **[USING] DELIMITERS 'delimiters'**

  String that separates columns within each row (line) of the file. It cannot be larger than 10 bytes.

  Value range:

  – The delimiter in text format cannot include any of the following characters: \.abcdefghijklmnopqrstuvwxyz0123456789, but has no restriction for the CSV format.

  – The delimiter cannot be set to **'\r'**, **'\n'**, or a user-defined newline character.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

  - A delimiter cannot contain the null string (refer to **NULL null_string**), nor can it be contained within the null string.
  - A delimiter cannot contain \0.
  - A delimiter cannot be an empty string.
  - When **COMPATIBLE_ILLEGAL_CHARS** is specified (see **COMPATIBLE_ILLEGAL_CHARS**), a delimiter cannot be set to a space or a question mark (?); otherwise, the delimiter may conflict with the characters after error tolerance conversion.
  - In CSV mode, a delimiter cannot contain QUOTE characters. For details, see **QUOTE [AS] 'quote_character'**.
  - The value of **delimiter** can be a multi-character delimiter whose length is less than or equal to 10 bytes.

  Value range: The default value is a tab character in text format and a comma in CSV format.

  NOTE

  - Both DELIMITER and DELIMITERS can specify delimiters. DELIMITERS can be followed by brackets, but DELIMITER cannot be directly followed by brackets. Otherwise, an error is reported.
  - Delimiters can be specified only in TEXT or CSV mode.
  - Within the data file, each row must not exceed 1 GB in length. Using long delimiters or having many columns may reduce the valid data length that can be exported.
  - You can use multi-character delimiters or invisible delimiters. For example, you can use multi-characters (such as $^&) and invisible characters (such as 0x07, 0x08, and 0x1b).
  - If a column to be exported in text format contains data that is the same as separators, a backslash (\) is added as an escape character before a conflicting data record, ensuring that the exported data can be properly identified.
  - You are advised not to import or export delimiters that use Chinese or other characters containing multiple bytes. Otherwise, if the data in a column is the same as the delimiter, an error may be reported after the data is imported or exported.
  - To use a multi-byte delimiter, you are advised to combine single-byte characters within the ASCII code range.

- **WITHOUT ESCAPING**

  Specifies, in the TEXT format, whether to escape the backslash (\) and its following characters.

  Value range: text only

  NOTE

  For options related to escape characters, pay attention to the following:

  - If you prepare a data file, you need to choose the desired import behavior (import with or without escaping).
  - If a data file is exported using the kernel COPY syntax, the escape options must be the same for both export and import.
  - If data is exported in text format, in the default scenario (WITHOUT ESCAPING is not used), the characters '\b', '\f', '\n', '\r', '\t', and '\v' in a column are exported as two bytes—a backslash (\) and the corresponding letter.

- **LOG ERRORS**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Specifies whether to enable the error tolerance mechanism for data type errors in the COPY FROM statement.

Value range: a value set while data is imported using COPY FROM.

NOTE

When using this error tolerance mechanism, pay attention to the following limitations:

- This error tolerance mechanism captures only the data type errors (**DATA_EXCEPTION**) that the primary database node identifies from the data parsed during COPY FROM.
- If the COPY statement already has an error tolerance option enabled (for example, **IGNORE_EXTRA_DATA**), that type of error will be processed accordingly and trigger no error. Therefore, the error table does not contain related data.
- This error tolerance mechanism does not support constraint conflicts.
- During a rolling upgrade from an earlier version to this version, do not use the COPY error tolerance import capability before all nodes are upgraded.
- If separation of duties is enabled, you need to run the following statement to create an error table in a schema with the same name as the user before using the fault tolerance mechanism (for details, see **GS_COPY_ERROR_LOG**):

```
CREATE TABLE load_user.pgxc_copy_error_log (relname varchar(64), begintime timestamptz, filename varchar, lineno int8, rawrecord text, detail text);
CREATE INDEX copy_error_log_relname_idx ON load_user.pgxc_copy_error_log(relname);
```

- You are advised to set the **backtrace_min_messages** parameter to a value higher than the **error** level. Otherwise, the performance will be affected.

- **LOG ERRORS DATA**

  The differences between LOG ERRORS DATA and LOG ERRORS are as follows:

  a. **LOG ERRORS DATA** fills the **rawrecord** column in the error tolerance table.

  b. Only users with the SYSADMIN permission can use **LOG ERRORS DATA**.

  NOTE

  - If error content is too complex, it may fail to be written to the error tolerance table by using **LOG ERRORS DATA**, causing the task failure.
  - For errors that cannot be read in certain code, the error codes are ERRCODE_CHARACTER_NOT_IN_REPERTOIRE and ERRCODE_UNTRANSLATABLE_CHARACTER. The rawrecord column is not recorded.
  - In batch insertion scenarios, the **rawrecord** column is not recorded for error data of the PRIMARY KEY constraint.
  - If data is imported in BINARY format and error data exists, the corresponding **rawrecord** column is not recorded in the error tolerance table.
  - During a rolling upgrade from an earlier version to this version, do not use the COPY error tolerance import capability before all nodes are upgraded.

- **REJECT LIMIT 'limit'**

  Used with the **LOG ERRORS** option to set the upper limit of the tolerated errors in the COPY FROM statement. If the number of errors exceeds the limit, any further errors will be reported based on the original mechanism.

  Value range: a positive integer in the range [1,2147483647] or **'unlimited'**

  Default value: If **LOG ERRORS** is not specified, an error will be reported. If LOG ERRORS is specified, the default value is **0**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

> **NOTE**
>
> In the error tolerance mechanism described in the description of LOG ERRORS, the count of **REJECT LIMIT** is calculated based on the number of data parsing errors on the primary database node where the **COPY FROM** statement is executed, not based on the number of all errors on the node.

- **copy_option**

  Specifies various native parameters for **COPY**.

  - OIDS

    Specifies whether to import and export OID hidden columns for tables (usually system catalogs) that contain OIDs.

    Value range: **true/on** and **false/off**.

    Default value: **false**.

    > **NOTE**
    >
    > - If the table to be exported does not have an OID, an error is reported.
    > - The exported OID defaults to the first column. If the **HEADER** option is specified, the exported **HEADER** row does not include the OID column description.

  - DELIMITER [AS] 'delimiter_string'

    Specifies the column delimiter of data in a data file line. The value range is the same as that of **[USING] DELIMITERS 'delimiters'**.

  - NULL [AS] 'null_string'

    Specifies the string that represents a null value.

    Value range:

    - The **NULL** value cannot contain '\r', '\n', or user-defined newline characters.
    - The **NULL** value contains a maximum of 100 characters.
    - **NULL** cannot contain delimiters (see **[USING] DELIMITERS 'delimiters'**) or be contained by delimiters.
    - In CSV mode, **NULL** cannot contain QUOTE characters. For details, see **QUOTE [AS] 'quote_character'**.
    - When **COMPATIBLE_ILLEGAL_CHARS** is specified (see **COMPATIBLE_ILLEGAL_CHARS**), **NULL** cannot be set to a space or a question mark (?); otherwise, it may conflict with the characters after error tolerance conversion.
    - The **NULL** value cannot contain the '\0' character.

    Default value:

    - Unquoted empty string in CSV format.
    - **\N** in text format.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- The **NULL** parameter can be specified only in TEXT or CSV mode.
- During COPY FROM, any data item that matches this string will be stored as a null value; therefore, ensure that you use the same string as you used with COPY TO.

– HEADER

Specifies whether the exported data file contains a header row and whether the first row in the data stream is the header row during import. A header row describes information about each column.

NOTE

- This parameter can be specified only in CSV or FIXED mode. The content in the header row of the FIXED file must meet the column length definition.
- When this option is specified, the first row of the data text is identified as a header row during import and will be ignored. The first row in the data file exported is the header row.
- If this option is not specified, the first row of the data text is identified as data and imported. The exported data file does not contain a header row.

– FILEHEADER 'header_file_string'

Specifies a file that defines the content in the header for exported data. The file contains data description of each column.

NOTICE

- This option is valid only when the header functionality is enabled.
- **fileheader** specifies an absolute path.
- The file can contain only one row of header information, and ends with a newline character. Excess rows will be discarded. (Header information cannot contain newline characters.)
- The file, including newline characters, cannot exceed 1 MB.

– FREEZE

Sets the COPY loaded data row as **frozen**, like these data have executed VACUUM FREEZE.

This is a performance option of initial data loading. The data will be frozen only when the following three requirements are met:

- The table being loaded has been created or truncated in the same transaction before copying.
- There are no cursors open in the current transaction.
- There are no original snapshots in the current transaction.

NOTE

When COPY is completed, all the other sessions will see the data immediately. However, this violates the general principle of MVCC visibility, and users should understand that this may cause potential risks.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- FORCE NOT NULL column_name [, ...]

  Forbids null values in the specified columns in CSV COPY FROM mode. Empty inputs will be regarded as zero-length strings.

  Value range: existing columns.

- FORCE QUOTE { column_name [, ...] | * }

  In CSV COPY TO mode, forces all non-**NULL** values to be surrounded by the quote characters (see **QUOTE [AS] 'quote_character'**) around each specified column. The asterisk (*) indicates all columns. **NULL** values are not enclosed in quote characters.

  Value range: existing columns.

- BINARY

  Specifies that data is stored and read in binary rather than text format.

  NOTE

  - In binary mode, you cannot declare **DELIMITER**, **NULL**, **CSV**, or **EOL**.
  - When **BINARY** is specified, **CSV**, **FIXED**, and **TEXT** cannot be specified through **option** or **copy_option**.
  - If the GUC parameter **support_binary_copy_version** is set to **'header_encoding'**, the header of the binary file exported using COPY TO will include the server-side encoding of the database. When the binary file is imported using COPY FROM, verification will be conducted to ensure that the encoding in the file is consistent with the server-side encoding.
  - If the GUC parameter **copy_special_character_version** is set to **'no_error'**, invalid characters will not be checked during the import and will be displayed as garbled characters in query results. The database server-side encoding must be consistent with the client-side encoding. Enable this parameter with caution only when you fully understand its implications.
  - In binary mode, **copy_special_character_version** is set to **'no_error'**, and it takes effect only for columns of the TEXT, CHAR, VARCHAR, NVARCHAR2, and CLOB types.
  - Exporting data to STDOUT or importing from STDIN is not supported.

  The following table lists the types of data that cannot be imported or exported in binary mode.

smgr	aclitem	gtsvector	any	trigger
language_handler	internal	opaque	anyelement	anynesttable
anyindexbytable	anynonarray	anyenum	fdw_handler	anyrange
hll_hashval	hash16	hash32	anyset	-

  The following table lists some options that do not support binary import and export.

DELIMITER	NULL	EOL	CSV	FIXED

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

SMALLDATETIME_FORMAT	DATE_FORMAT	TIME_FORMAT	TIMESTAMP_FORMAT	DATEA_FORMAT

– CSV

Enables the CSV mode. When **CSV** is specified, **BINARY**, **FIXED**, and **TEXT** cannot be specified through **option** or **copy_option**.

NOTE

The most common error in the CSV format is caused by the QUOTE characters, which are generally double quotation marks. If the data column contains such characters, escape them. Otherwise, COPY cannot parse the incorrect data format.

– FIXED

Fixes column length. When the column length is fixed, **DELIMITER**, **NULL**, and **CSV** cannot be specified. When **FIXED** is specified, **BINARY**, **CSV**, and **TEXT** cannot be specified by **option** or **copy_option**. Newline characters in data columns cannot be correctly processed when the column length is fixed. **FORMATTER** must be specified.

NOTE

- The definition of fixed length is as follows:
  - The column length of each record is the same.
  - Spaces are used for column padding. Columns of the numeric type and fixed-length columns of the string type are left-aligned, and variable-length columns of the string type are right-aligned.
  - No delimiters are used between columns.
- You are advised not to perform encoding conversion during import or export of fixed-length data. This is because encoding conversion changes the byte length of characters, causing incorrect truncation and parsing of columns in fixed-length format. In this case, you need to adjust the start and end positions specified in fixed-length columns or use other file formats of COPY.
- When **FIXED** is used, all columns in the table must be used. You cannot specify only some columns.

– FORMATTER ([column_name (offset, length)] [, ...])

Defines the place of each column in the data file only in fixed length mode. Defines the place of each column in the data file in the **column(***offset*,*length***)** format.

Value range:

- The value of **offset** must be larger than 0. The unit is byte.
- The value of **length** must be larger than 0. The unit is byte.

The total length of all columns must be less than 1 GB.

All columns must not overlap with each other.

Replace columns that are not in the file with null.

– QUOTE [AS] 'quote_character'

Specifies the quote character for a CSV file.

Value range:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- A single-byte character without '\0', '\r', '\n', or end-of-line characters. You are advised to set **quote** to an invisible character, such as **0x07**, **0x08**, or **0x1b**.
- The value cannot contain delimiters (see **[USING] DELIMITERS 'delimiters'**) or be contained by delimiters.
- The value cannot contain **NULL** (see **NULL [AS] 'null_string'**) or be included in **NULL**.
- When **COMPATIBLE_ILLEGAL_CHARS** is specified (see **COMPATIBLE_ILLEGAL_CHARS**), **NULL** cannot be set to a space or a question mark (?); otherwise, it may conflict with the characters after error tolerance conversion.

Default value: double quotation marks ("").

– ESCAPE [AS] 'escape_character'

Specifies the escape character in CSV format.

Value range:

- A single-byte character without '\0'. You are advised to set **ESCAPE** to an invisible character, such as **0x07**, **0x08**, or **0x1b**.
- The value cannot contain delimiters (see **[USING] DELIMITERS 'delimiters'**) or be contained by delimiters.
- The value cannot contain **NULL** (see **NULL [AS] 'null_string'**) or be included in **NULL**.
- When **COMPATIBLE_ILLEGAL_CHARS** is specified (see **COMPATIBLE_ILLEGAL_CHARS**), **NULL** cannot be set to a space or a question mark (?); otherwise, it may conflict with the characters after error tolerance conversion.
- If the quote character is set (see **QUOTE [AS] 'quote_character'**) but ESCAPE is not set, ESCAPE uses the same character as the QUOTE character.

Default value: double quotation marks ("").

– EOL 'newline_character'

Specifies the end-of-line character (newline character) style of the imported or exported data file.

Value range: Common end-of-line characters include **\r** (0x0D), **\n** (0x0A), and **\r\n** (0x0D0A). Special end-of-line characters include **$** and **#**.

- Value range: multi-character end-of-line characters within 10 bytes.
- The end-of-line character cannot be contained in the delimiter.
- The end-of-line character cannot be contained in a **NULL** string.
- In non-CSV mode, the end-of-line character cannot contain the following characters: .abcdefghijklmnopqrstuvwxyz0123456789.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- An end-of-line character cannot contain '\0'.
- Parallel import is not supported when a custom newline character is specified.

NOTE

The **EOL** parameter supports only the TEXT format for data import and export and does not support the CSV or FIXED format for data import. For compatibility with earlier versions, the **EOL** parameter can be set to **0x0A** or **0x0D0A** for data export in the CSV or FIXED format.

– ENCODING 'encoding_name'

Specifies the name of a file encoding format.

Value range: a valid encoding format. Common encoding formats are **utf8**, **gb18030**, and **gbk**.

Default value: *current client-side encoding format*.

NOTE

- After the **encoding** parameter is specified, the data from the data file or standard input is identified based on the specified encoding, and whether encoding conversion is required is determined based on the value of the server-side encoding.
- In BINARY format, the **encoding** parameter does not take effect. The conversion between the server-side encoding and client-side encoding depends on the settings of **server_encoding** and **client_encoding**.
- When COPY FROM is executed, the encoding format specified by **ENCODING** in the control file must be the same as that of the file. Otherwise, an error is reported or garbled characters are displayed in the imported data.

– IGNORE_EXTRA_DATA

Specifies that when the number of data source files exceeds the number of foreign table columns, excess columns at the end of the row are ignored. This parameter is used only during data import.

If this parameter is not used and the number of columns in the data source file is greater than that defined in the foreign table, the following error information is displayed:

```
extra data after last expected column
```

– POSITION_KEEP_TRAILING_SPACE

Specifies whether to remove spaces at the end of a column value during fixed-length import. If **POSITION_KEEP_TRAILING_SPACE** is not configured, spaces at the end of a column value are removed by default. If **POSITION_KEEP_TRAILING_SPACE** is configured, spaces at the end of a column value are retained. This parameter takes effect only for the character type and is invalid for the numeric and BLOB types.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

During data import, the system reads raw data from the data file, and then performs operations such as list expression calculation and data type conversion.

The behavior of trimming spaces at the end of the data occurs only in the data reading phase. This parameter takes effect only in this phase. Once the data is read, subsequent operations such as list expression processing and type conversion will not be affected by this parameter if they involve trimming spaces at the end of the data.

For example, if a column is defined as the char type in the control file, but the corresponding column in the table is of the varchar type, the spaces at the end of the data are automatically trimmed when the data is converted from the char type to the varchar type. This behavior is not affected by the preceding parameter. To retain the spaces at the end of the data in such type conversion scenarios, you can set the **behavior_compat_options** parameter to include the **char_coerce_compat** option.

- COMPATIBLE_ILLEGAL_CHARS

  Specifies whether to tolerate invalid characters during data import and export.

  Value range: **true/on** and **false/off**.

  - **true**/**on**: No error message is reported and data import is not interrupted when there are invalid characters. Invalid characters are converted into valid ones, and then imported to the database. Invalid characters are converted into valid ones, and then exported from the database. No error is reported and data export is not interrupted.
  - **false**/**off**: An error occurs when there are invalid characters, and the import stops. An error is reported and data export is interrupted when there are invalid characters and characters whose encodings do not exist.

  Default value: **false**/**off**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

The rules for converting invalid characters are as follows:

1. '\0' is converted to a space. When **support_zero_character** is enabled, data is imported in the original format.
2. Other invalid characters are converted to the characters specified by the GUC parameter **convert_illegal_char_mode**. The default value is **'?'**.
3. When **compatible_illegal_chars** is set to **true** or **on**, after invalid characters such as **NULL**, **DELIMITER**, **QUOTE**, and **ESCAPE** are converted to spaces or question marks, an error message stating "illegal chars conversion may confuse COPY escape 0x20" will be displayed to remind you of possible parameter confusion caused by the conversion.
4. If **compatible_illegal_chars** is set to **true** or **on**, data in binary format cannot be imported. The error message "cannot specify bulkload compatibility options in BINARY mode" is displayed.
5. If the GUC parameter **copy_special_character_version** is set to **'no_error'**, invalid characters will not be checked during the import and will be displayed as garbled characters in query results. Enable this parameter with caution only when you fully understand its implications.
6. If **copy_special_character_version** is set to **'no_error'** and **compatible_illegal_chars** is set to **true**, the former has a higher priority. That is, invalid characters will not be checked during the import.
7. If **copy_special_character_version** is set to **'no_error'** or **compatible_illegal_chars** is set to **true**, a record is written to the database run logs each time a row of data containing invalid characters is identified. The log writing behavior occupies a small amount of disk bandwidth. To eliminate the impact, set the GUC parameter **enable_log_copy_illegal_chars** to **off**, that is, do not write records to the database run logs. You are advised not to modify this configuration unless otherwise required.

The rules for exporting invalid characters are as follows:

The export is classified into the scenario where transcoding is required (the database server code is different from the client code) and the scenario where transcoding is not required (the database server code is the same as the client code). The export performance varies according to the scenario. You can run **show server_encoding;** to query the database server-side encoding and **show client_encoding;** to query the database client-side encoding.

- In scenarios where transcoding is required:

1. '\0' is converted to a space. When **support_zero_character** is enabled, data is exported in the original format.
2. Other invalid characters are converted to the characters specified by the GUC parameter **convert_illegal_char_mode**. The default value is **'?'**.
3. When **compatible_illegal_chars** is set to **true** or **on**, after invalid characters such as **NULL**, **DELIMITER**, **QUOTE**, and **ESCAPE** are exported to spaces or question marks, an error message stating "illegal chars conversion may confuse COPY escape 0x20" will be displayed to remind you of possible parameter confusion caused by the export.
4. If **compatible_illegal_chars** is set to **true** or **on**, data in binary format cannot be exported.
5. If **compatible_illegal_chars** is set to **true**, a record is written to the database run logs each time a row of data containing invalid characters is identified. The log writing behavior occupies a small amount of disk bandwidth. To eliminate the impact, set the GUC parameter **enable_log_copy_illegal_chars** to **off**, that is, do not write records to the database run logs. You are advised not to modify this configuration unless otherwise required.

- In scenarios where transcoding is not required:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

1. Data is exported as it is in the database, even if the data contains invalid characters and **compatible_illegal_chars** is set to **true**.
2. If **compatible_illegal_chars** is set to **true** or **on**, data in binary format cannot be exported.

- FILL_MISSING_FIELDS [{ 'one' | boolean }]

  Specifies how to handle the problem that a data row loses the last or multiple columns during data import. If only **FILL_MISSING_FIELDS** is specified but the option value is not as expected, or the specified option value is **one**, **true**, **on**, **null** is used to supplement the last missing column (an error is reported if multiple columns are missing).

  Value range: **one**, **true**/**on**, or **false**/**off**.

  Default value: **false**/**off**.

- DATE_FORMAT 'date_format_string'

  Specifies the DATE format for data import. This parameter is not supported for the binary format, as it would trigger the error "cannot specify bulkload compatibility options in BINARY mode." This parameter takes effect only during data import using COPY FROM.

  Value range: valid DATE formats. For details, see **Date and Time Processing Functions and Operators**.

- TIME_FORMAT 'time_format_string'

  Specifies the TIME format for data import. This parameter is not supported for the binary format, as it would trigger the error "cannot specify bulkload compatibility options in BINARY mode." This parameter takes effect only during data import using COPY FROM.

  Value range: a valid TIME value. Time zones cannot be used. For details, see **Date and Time Processing Functions and Operators**.

- TIMESTAMP_FORMAT 'timestamp_format_string'

  Specifies the TIMESTAMP format for data import. This parameter is not supported for the binary format, as it would trigger the error "cannot specify bulkload compatibility options in BINARY mode." This parameter takes effect only during data import using COPY FROM.

  Value range: a valid TIMESTAMP value. Time zones cannot be used. For details, see **Date and Time Processing Functions and Operators**.

- DATEA_FORMAT 'datea_format_string'

  Specifies the DATEA format for data import. This parameter is not supported for the binary format, as it would trigger the error "cannot specify bulkload compatibility options in BINARY mode." This parameter takes effect only during data import using COPY FROM.

  Value range: a valid DATEA value. For details, see **Date and Time Processing Functions and Operators**.

- SMALLDATETIME_FORMAT 'smalldatetime_format_string'

  Specifies the SMALLDATETIME format for data import. This parameter is not supported for the binary format, as it would trigger the error "cannot specify bulkload compatibility options in BINARY mode." This parameter takes effect only during data import using COPY FROM.

  Value range: a valid SMALLDATETIME value. For details, see **Date and Time Processing Functions and Operators**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- TABLE_COMPRESS_CLAUSE(ROW STORE COMPRESS ADVANCED [MEDIUM | HIGH] ROW [ON (EXPR)])

  Compresses the imported data. EXPR is an expression. Data that meets the expression is compressed, and data that does not meet the expression is not compressed. This parameter takes effect only during data import using COPY FROM.

  NOTE

  - This applies only to Astore tables.
  - TOAST data cannot be compressed.
  - This feature is not supported during the upgrade observation period.
  - When this feature is used, the new data page is used for storing the imported data.
  - When this feature is used together with the error tolerance mechanism (LOG ERRORS or LOG ERRORS DATA), compression may have no benefits if error data frequently occurs.
  - Compression is not supported when a single row is imported. For example, a partitioned table is imported and the function of non-rollback upon constraint violation is enabled, or the table contains triggers.
  - This feature cannot be used together with logical decoding. If logical decoding is enabled, an error will occur during compression of data imported using COPY.

- TRANSFORM ({ column_name [data_type] [AS transform_expr] } [, ...])

  Specifies the conversion expression of each column in the table. **data_type** specifies the data type of the column in the expression parameter. **transform_expr** is the target expression that returns the result value whose data type is the same as that of the target column in the table. For details about the expression, see **Expressions**.

  NOTE

  COPY FROM does not support conversion expressions specified for distribution keys.

- COPY_CUSTOM_ID 'custom_id_string'

  During data import, enter a user-defined character string, which is used as the identifier of the COPY import.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- In non-separation-of-duties scenarios, pg_catalog.pgxc_copy_error_log contains the **custom_id** column by default. If **copy_custom_id** is not used, **NULL** is inserted into the column.
- In separation-of-duties scenarios, if the schema with the same name as the current connection user contains the pgxc_copy_error_log table with the **custom_id** column, LOG ERRORS or LOG ERRORS DATA is used, and the error tolerance data volume is less than the value specified by **reject limit**, the character string input by this parameter is recorded to the **custom_id** column in the pgxc_copy_error_log table. One import may correspond to zero or multiple data records.
- This operation takes effect only for import. The error table and log table are not recorded during export.
- The length of a user-defined character string cannot exceed 64 bytes.
- If the error table and log table do not contain the **custom_id** column but the **copy_custom_id** parameter is set, an error message is displayed, prompting you to add a column to the table using a function or ALTER statement.
- The **custom_id** column in the error table and log table may not be unique. The column content can be duplicate.
- This parameter can be used only in ORA-compatible mode.

- **option**

  Specifies various parameters for a compatible foreign table.

  – FORMAT 'format_name'

    Specifies the format of the data source file.

    Value range: **CSV**, **TEXT**, and **BINARY**.

    - In CSV files, newline characters can be processed efficiently, but certain special characters may pose challenges. It is equivalent to the **CSV** parameter in **copy_option**.
    - In TEXT files, certain special characters can be processed efficiently, except newline characters.
    - In BINARY files, all data is stored/read as binary format rather than as text. It is somewhat faster than the text and CSV formats, but a binary-format file is less portable. It is equivalent to the **BINARY** parameter in **copy_option**.

    Default value: **TEXT**.

  – OIDS [boolean]

    Specifies whether to import and export OID hidden columns for tables (usually system catalogs) that contain OIDs.

    Value range: **true/on** and **false/off**.

    Default value: **false**.

  – DELIMITER 'delimiter_character'

    Specifies the column delimiter of data in a data file line. The value range is the same as that of **[USING] DELIMITERS 'delimiters'**.

  – NULL 'null_string'

    Specifies the string that represents a null value. The value is the same as that of **NULL null_string**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- HEADER [boolean]

  Specifies whether the exported data file contains a header row and whether the first row in the data stream is the header row during import. A header row describes information about each column.

  Value range: **true/on** and **false/off**.

  - If the parameter is set to **true** or **on**, the first row of the data text is identified as the header row during import and will be ignored. The first row in the data file exported is the header row.
  - If the parameter is set to **false** or **off**, the first row of the data text is identified as data and imported. The exported data file does not contain a header row.

  Default value: **false**.

  NOTE

  This parameter can be specified only in CSV or FIXED mode. The content in the header row of the FIXED file must meet the column length definition.

- FILEHEADER 'header_file_string'

  Specifies a file that defines the content in the header for exported data. The file contains data description of each column. It is equivalent to the **FILEHEADER 'header_file_string'** parameter in **copy_option**.

- FREEZE [boolean]

  Specifies a file that defines the content in the header for exported data. The file contains data description of each column.

  Value range: **true/on** and **false/off**. If the value is **true** or **on**, it is equivalent to the **FREEZE** parameter in **copy_option**.

  Default value: **false**.

- NOESCAPING [boolean]

  Specifies, in the TEXT format, whether to escape the backslash (\) and its following characters.

  Value range: **true/on** and **false/off**. If the value is **true** or **on**, it is equivalent to the **WITHOUT ESCAPING** parameter in **copy_option**.

  Default value: **false**.

- SKIP int_number

  Specifies that the first *int_number* rows of the data file are skipped during data import.

  Value range: an integer in the range [0,2147483647].

- USEEOF [boolean]

  If this parameter is set to **true** or **on**, no error is reported for a backslash followed by a period (\.). When importing a single column, if you enter "\." in **stdin** mode, it is considered as an end of line (EOL) character instead of data.

  Value range: **true/on** and **false/off**. If the value is **true** or **on**, this parameter is equivalent to the **USEEOF** parameter.

  Default value: **false**.

- QUOTE 'quote_character'

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Specifies a quote character for a CSV file. It is equivalent to the **QUOTE [AS] 'quote_character'** parameter in **copy_option**.

- ESCAPE 'escape_character'

  Specifies an escape character for a CSV file. It is equivalent to the **ESCAPE [AS] 'escape_character'** parameter in **copy_option**.

- EOL 'newline_character'

  Specifies the newline character style of the imported or exported data file. The value is the same as that of **EOL 'newline_character'**.

- FORCE_QUOTE { (column_name [, ...]) | * }

  In CSV COPY TO mode, forces all non-**NULL** values to be surrounded by the QUOTE characters (see **QUOTE [AS] 'quote_character'**) around each specified column.

  Value range: existing columns.

  NOTE

  - The asterisk (*) indicates all columns.
  - The **NULL** output is not enclosed in quotation marks. If the original data has the content as the **NULL** option, the original data is quoted.

- FORCE_NOT_NULL (column_name [, ...])

  In CSV COPY FROM mode, if the specified column is **NULL** during data writing, the content specified by **NULL** (see **NULL [AS] 'null_string'**) is written instead. That is, this column does not allow **NULL** to be written directly.

  Value range: existing columns.

- ENCODING 'encoding_name'

  Specifies the encoding format of a data file. The default value is the current client-side encoding format. When COPY FROM is executed, the encoding format specified by **ENCODING** in the control file must be the same as that of the file. Otherwise, an error is reported or garbled characters are displayed in the imported data.

- IGNORE_EXTRA_DATA [boolean]

  Specifies whether to ignore excessive columns when the number of data source files exceeds the number of foreign table columns. This parameter is used only during data import.

  Value range: **true**/**on** or **false**/**off**

  - **true**/**on**: If the number of columns in a data source file is greater than that defined by the foreign table, the extra columns at the end of a row are ignored.
  - **false**/**off**: If the number of columns in a data source file is greater than that defined by the foreign table, the following error message is reported:

    ```
    extra data after last expected column
    ```

  Default value: **false**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTICE

If a newline character at the end of a row is missing and the row and another row are integrated into one, data in another row is ignored after the parameter is set to **true**.

- POSITION_KEEP_TRAILING_SPACE

  Specifies whether to remove spaces at the end of a column value during fixed-length import. It is equivalent to the **POSITION_KEEP_TRAILING_SPACE** parameter in **copy_option**.

- COMPATIBLE_ILLEGAL_CHARS [boolean]

  Specifies whether to tolerate invalid characters during data import and export.

  Value range: **true/on** and **false/off**.

  - **true**/**on**: No error message is reported and data import is not interrupted when there are invalid characters. Invalid characters are converted into valid ones, and then imported to the database. Invalid characters are converted into valid ones, and then exported from the database. No error is reported and data export is not interrupted.
  - **false**/**off**: An error occurs when there are invalid characters, and the import stops. An error is reported and data export is interrupted when there are invalid characters and characters whose encodings do not exist.

  Default value: **false**/**off**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

The rules for converting invalid characters are as follows:

1. '\0' is converted to a space. When **support_zero_character** is enabled, data is imported in the original format.
2. Other invalid characters are converted to the characters specified by the GUC parameter **convert_illegal_char_mode**. The default value is **'?'**.
3. When **compatible_illegal_chars** is set to **true** or **on**, after invalid characters such as **NULL**, **DELIMITER**, **QUOTE**, and **ESCAPE** are converted to spaces or question marks, an error message stating "illegal chars conversion may confuse COPY escape 0x20" will be displayed to remind you of possible parameter confusion caused by the conversion.
4. If **compatible_illegal_chars** is set to **true** or **on**, data in binary format cannot be imported and an error message stating "cannot specify bulkload compatibility options in BINARY mode" will be displayed.
5. If the GUC parameter **copy_special_character_version** is set to **'no_error'**, invalid characters will not be checked during the import and will be displayed as garbled characters in query results. Enable this parameter with caution only when you fully understand its implications.
6. If **copy_special_character_version** is set to **'no_error'** and **compatible_illegal_chars** is set to **true**, the former has a higher priority. That is, invalid characters will not be checked during the import.
7. If **copy_special_character_version** is set to **'no_error'** or **compatible_illegal_chars** is set to **true**, a record is written to the database run logs each time a row of data containing invalid characters is identified. The log writing behavior occupies a small amount of disk bandwidth. To eliminate the impact, set the GUC parameter **enable_log_copy_illegal_chars** to **off**, that is, do not write records to the database run logs. You are advised not to modify this configuration unless otherwise required.

The rules for exporting invalid characters are as follows:

The export is classified into the scenario where transcoding is required (the database server code is different from the client code) and the scenario where transcoding is not required (the database server code is the same as the client code). The export performance varies according to the scenario. You can run the **show server_encoding;** statement to query the database server code and run the **show client_encoding;** statement to query the database client code.

- In scenarios where transcoding is required:

1. '\0' is converted to a space. When **support_zero_character** is enabled, data is exported in the original format.
2. Other invalid characters are converted to the characters specified by the GUC parameter **convert_illegal_char_mode**. The default value is **'?'**.
3. When **compatible_illegal_chars** is set to **true** or **on**, after invalid characters such as **NULL**, **DELIMITER**, **QUOTE**, and **ESCAPE** are exported to spaces or question marks, an error message stating "illegal chars conversion may confuse COPY escape 0x20" will be displayed to remind you of possible parameter confusion caused by the export.
4. If **compatible_illegal_chars** is set to **true** or **on**, data in binary format cannot be exported.
5. If **compatible_illegal_chars** is set to **true**, a record is written to the database run logs each time a row of data containing invalid characters is identified. The log writing behavior occupies a small amount of disk bandwidth. To eliminate the impact, set the GUC parameter **enable_log_copy_illegal_chars** to **off**, that is, do not write records to the database run logs. You are advised not to modify this configuration unless otherwise required.

- In scenarios where transcoding is not required:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

1. Data is exported as it is in the database, even if the data contains invalid characters and **compatible_illegal_chars** is set to **true**.
2. If **compatible_illegal_chars** is set to **true** or **on**, data in binary format cannot be exported.

- FILL_MISSING_FIELDS [{ 'one' | boolean }]

  Specifies how to handle the problem that the last column of a row in a source data file is lost during data import.

  Value range: **one**, **true**/**on**, or **false**/**off**.

  Default value: **false**/**off**.

- COPY_CUSTOM_ID 'custom_id_string'

  During data import, enter a user-defined character string, which is used as the identifier of the COPY import. It is equivalent to the **COPY_CUSTOM_ID 'custom_id_string'** parameter in **copy_option**.

- DATE_FORMAT 'date_format_string'

  Specifies the DATE format for data import. This parameter is not supported for the binary format, as it would trigger the error "cannot specify bulkload compatibility options in BINARY mode." This parameter takes effect only during data import using COPY FROM.

  Value range: valid DATE formats. For details, see **Date and Time Processing Functions and Operators**.

- TIME_FORMAT 'time_format_string'

  Specifies the TIME format for data import. This parameter is not supported for the binary format, as it would trigger the error "cannot specify bulkload compatibility options in BINARY mode." This parameter takes effect only during data import using COPY FROM.

  Value range: a valid TIME value. Time zones cannot be used. For details, see **Date and Time Processing Functions and Operators**.

- TIMESTAMP_FORMAT 'timestamp_format_string'

  Specifies the TIMESTAMP format for data import. This parameter is not supported for the binary format, as it would trigger the error "cannot specify bulkload compatibility options in BINARY mode." This parameter takes effect only during data import using COPY FROM.

  Value range: a valid TIMESTAMP value. Time zones cannot be used. For details, see **Date and Time Processing Functions and Operators**.

- SMALLDATETIME_FORMAT 'smalldatetime_format_string'

  Specifies the SMALLDATETIME format for data import. This parameter is not supported for the binary format, as it would trigger the error "cannot specify bulkload compatibility options in BINARY mode." This parameter takes effect only during data import using COPY FROM.

  Value range: a valid SMALLDATETIME value. For details, see **Date and Time Processing Functions and Operators**.

- DATEA_FORMAT 'datea_format_string'

  Specifies the DATEA format for data import (supported only in ORA-compatible mode). The BINARY format is not supported. When data of such format is imported, error "cannot specify bulkload compatibility options in BINARY mode" will occur. This parameter takes effect only during data import using COPY FROM.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Value range: a valid DATEAFORMAT value. For details, see **Date and Time Processing Functions and Operators**.

NOTE

The following special backslash sequences are recognized by COPY FROM:

- **\b**: Backslash (ASCII 8).
- **\f**: Form feed (ASCII 12).
- **\n**: Newline character (ASCII 10).
- **\r**: Carriage return character (ASCII 13).
- **\t**: Tab (ASCII 9).
- **\v**: Vertical tab (ASCII 11).
- **\digits**: Backslash followed by one to three octal digits specifies the character with that ASCII code
- **\xdigits**: Backslash *x* followed by one or two hex digits specifies the character with that numeric code

Permission Control Examples

```
gaussdb=> copy t1 from '/home/xy/t1.csv';
ERROR:  COPY to or from a file is prohibited for security concerns
HINT:  Anyone can COPY to stdout or from stdin. gsql's \copy command also works for anyone.
gaussdb=> grant gs_role_copy_files to xxx;
```

This error occurs because a non-initial user does not have the COPY permission. To use COPY, an administrator needs to enable the GUC parameter **enable_copy_server_files**, whereas a common user also needs to join the gs_role_copy_files group.

Examples

```
-- Create a schema.
gaussdb=# CREATE SCHEMA tpcds;

-- Create the tpcds.ship_mode table.
gaussdb=# CREATE TABLE tpcds.ship_mode
(
    SM_SHIP_MODE_SK          INTEGER              NOT NULL,
    SM_SHIP_MODE_ID          CHAR(16)             NOT NULL,
    SM_TYPE                  CHAR(30)                 ,
    SM_CODE                  CHAR(10)                   ,
    SM_CARRIER               CHAR(20)                   ,
    SM_CONTRACT              CHAR(20)
)
;

-- Insert a single data record into the tpcds.ship_mode table.
gaussdb=# INSERT INTO tpcds.ship_mode VALUES (1,'a','b','c','d','e');

-- Copy data from the tpcds.ship_mode table to the /home/omm/ds_ship_mode.dat file.
gaussdb=# COPY tpcds.ship_mode TO '/home/omm/ds_ship_mode.dat';

-- Output tpcds.ship_mode to STDOUT.
gaussdb=# COPY tpcds.ship_mode TO STDOUT;

-- Output the data of tpcds.ship_mode to STDOUT, with these settings: delimiter',' and encoding'utf8'.
gaussdb=# COPY tpcds.ship_mode TO STDOUT WITH (delimiter ',', encoding 'utf8');

-- Output the data of tpcds.ship_mode to STDOUT, with these settings: format 'CSV' and
force_quote(SM_SHIP_MODE_SK).
gaussdb=# COPY tpcds.ship_mode TO STDOUT WITH (format 'CSV', force_quote(SM_SHIP_MODE_SK));
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
-- Create the tpcds.ship_mode_t1 table.
gaussdb=# CREATE TABLE tpcds.ship_mode_t1
(
    SM_SHIP_MODE_SK           INTEGER               NOT NULL,
    SM_SHIP_MODE_ID           CHAR(16)              NOT NULL,
    SM_TYPE                   CHAR(30)                      ,
    SM_CODE                   CHAR(10)                      ,
    SM_CARRIER                CHAR(20)                      ,
    SM_CONTRACT               CHAR(20)
)
;

-- Copy data from STDIN to the tpcds.ship_mode_t1 table.
gaussdb=# COPY tpcds.ship_mode_t1 FROM STDIN;

-- Enter a row of data as an example.
--gaussdb=# COPY tpcds.ship_mode_t1 FROM STDIN;
--Enter data to be copied followed by a newline.
--End with a backslash and a period on a line by itself.
-->> 1    a a a a a
-->> \.
-- Note: Enter a tab between data.

-- Copy data from the /home/omm/ds_ship_mode.dat file to the tpcds.ship_mode_t1 table.
gaussdb=# COPY tpcds.ship_mode_t1 FROM '/home/omm/ds_ship_mode.dat';

-- Copy data from the /home/omm/ds_ship_mode.dat file to the tpcds.ship_mode_t1 table, convert the data using the TRANSFORM expression, and insert the 10 characters on the left of the SM_TYPE column into the table.
gaussdb=# COPY tpcds.ship_mode_t1 FROM '/home/omm/ds_ship_mode.dat' TRANSFORM (SM_TYPE AS LEFT(SM_TYPE, 10));

-- Copy data from the /home/omm/ds_ship_mode.dat file to the tpcds.ship_mode_t1 table, with these settings: format 'text', delimiter E'\t'), ignore_extra_data 'true', and noescaping 'true'.
gaussdb=# COPY tpcds.ship_mode_t1 FROM '/home/omm/ds_ship_mode.dat' WITH(format 'text', delimiter E'\t', ignore_extra_data 'true', noescaping 'true');

-- Copy data from the /home/omm/ds_ship_mode_fixed.dat file to the tpcds.ship_mode_t1 table, with the import format set to FIXED, fixed-length format specified (FORMATTER(SM_SHIP_MODE_SK(0, 2), SM_SHIP_MODE_ID(2,16), SM_TYPE(18,30), SM_CODE(50,10), SM_CARRIER(61,20), SM_CONTRACT(82,20))), excessive columns ignored (ignore_extra_data), and headers included (header).
gaussdb=# COPY tpcds.ship_mode TO '/home/omm/ds_ship_mode_fixed.dat' FIXED FORMATTER(SM_SHIP_MODE_SK(0, 2), SM_SHIP_MODE_ID(2,16), SM_TYPE(18,30), SM_CODE(50,10), SM_CARRIER(61,20), SM_CONTRACT(82,20)) header;
gaussdb=# COPY tpcds.ship_mode_t1 FROM '/home/omm/ds_ship_mode_fixed.dat' FIXED FORMATTER(SM_SHIP_MODE_SK(0, 2), SM_SHIP_MODE_ID(2,16), SM_TYPE(18,30), SM_CODE(50,10), SM_CARRIER(61,20), SM_CONTRACT(82,20)) header ignore_extra_data;

-- Drop tables and the schema.
gaussdb=# DROP TABLE tpcds.ship_mode;
gaussdb=# DROP TABLE tpcds.ship_mode_t1;
gaussdb=# DROP SCHEMA tpcds;
```

1.13.9.10 CREATE AGGREGATE

Description

Creates an aggregate function.

Syntax

```
CREATE AGGREGATE name ( input_data_type [ , ... ] ) (
    SFUNC = sfunc,
    -- SFUNC1 = sfunc,
    STYPE = state_data_type
    -- STYPE1 = state_data_type,
    [ , FINALFUNC = ffunc ]
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
    [ , INITCOND = initial_condition ]
    -- [ , INITCOND1 = initial_condition ]
    [ , SORTOP = sort_operator ]
    [ , CFUNC = collection_func ]
    [ , INITCOLLECT = initial_collection_condition ]
    [ , IFUNC = init_func ]
    [ , SHIPPABLE = is_shippable ]
);
```

Original syntax/earlier syntax format:

```
CREATE AGGREGATE name (
    BASETYPE = base_type,
    SFUNC = sfunc,
    -- SFUNC1 = sfunc,
    STYPE = state_data_type
    -- STYPE1 = state_data_type,
    [ , FINALFUNC = ffunc ]
    [ , INITCOND = initial_condition ]
    -- [ , INITCOND1 = initial_condition ]
    [ , SORTOP = sort_operator ]
    [ , CFUNC = collection_func ]
    [ , INITCOLLECT = initial_collection_condition ]
    [ , IFUNC = init_func ]
);
```

Parameters

- **name**

  Name of the aggregate function to be created, which can be specified using a schema.

- **input_data_type**

  Data type of the input to be processed by the aggregate function.

  To create an aggregate function without input parameters, you can use an asterisk (*) instead of a list of input data types. For example, count (*) is a zero-parameter aggregate function.

- **base_type**

  You can define the data type of the input to be processed by the aggregate function by specifying the **BASETYPE** keyword, instead of directly writing the input type after the aggregate function name (that is, by specifying **input_data_type**).

  When you define the input data type of an aggregate function in this way, the aggregate function must have one input parameter. If you create a zero-parameter aggregate function, set this keyword to **ANY** (instead of ***).

- **sfunc**

  Name of the state conversion function that will be called on each input line. For an aggregate function with *N* parameters, **sfunc** must have *N* + 1 parameters. The first parameter is of the type specified by **state_data_type**, and the other parameters match the declared input data types. The function must return a value of the **state_data_type** type. This function accepts the current state value and the current input data, and returns the next state value.

  The default behavior of the conversion function of an Oracle Database is **STRICT**, that is, the **NULL** input value is skipped. For GaussDB, you need to define the **STRICT** attribute of the conversion function.

- **state_data_type**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Data type of the aggregation status value.

- **ffunc**

  Final processing function called after all the input lines have been converted, which calculates the result of aggregation. This function must accept a parameter of **state_data_type**. The output data type of the aggregation is defined as the return type of this function. If **ffunc** is not specified, the state value of the aggregation result is used as the aggregation result, and the output type is **state_data_type**.

- **initial_condition**

  Initial setting (value) of a state value. It must be a text constant value acceptable to **state_data_type**. If not specified, the initial state value is **NULL**.

- **sort_operator**

  Sort operator (optionally schema-qualified) used for MIN or MAX aggregation.

- **collection_func**

  collection_func is essentially the status conversion result generated by combining DNs. If there is no final function, the result generated by **collection_func** is the aggregation result.

  If you want **collection_func** to skip null values, specify **collection_func** as **STRICT**.

  collection_func must have two input parameters of the **state_data_type** type. The first input parameter **state_data_type** will be passed to the first parameter of the next **collection_func** execution. If **is_shippable** is **false** (that is, the aggregate function does not support pushdown), **collection_func** will not be executed.

- **initial_collection_condition**

  Initial setting (value) of the state value of **collection_func**. It must be a text constant value acceptable to **state_data_type**. If not specified, the initial state value is **NULL**.

- **init_func**

  Initial setting function of the **sfunc** status value. It cannot return **NULL**. It must return the state_data_type type and have no input parameter. If both **init_func** and **initial_condition** are set, the return value of **init_func** is preferentially used as the initial value.

- **is_shippable**

  Specifies whether the aggregate function can be pushed down. The value can only be **true** or **false**. Currently, this parameter does not affect the promotion of built-in aggregate functions. It affects only the behavior of user-defined aggregate functions. The default value is **false**. User-defined aggregate functions can be pushed down only when **collection_func** is executed and **is_shippable** is set to **true**.

  NOTE

  If an aggregate function can be pushed down, it cannot reference package content, including variables and functions. Otherwise, an error may be reported during function execution. For example, sfunc, cfunc, finalfunc, and ifunc cannot be package functions, and sfunc, finalfunc, and ifunc cannot reference package variables or call package functions.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Examples

```
-- Create a user-defined function.
gaussdb=# CREATE OR REPLACE FUNCTION int_add(int,int)
 returns int as $BODY$
declare
begin
 return $1 + $2;
end;
$BODY$ language plpgsql;

-- Create an aggregate function.
gaussdb=# CREATE AGGREGATE sum_add(int)
(
    sfunc = int_add,

    stype = int,

    initcond = '0'

);

-- Create a test table and add data.
gaussdb=# CREATE TABLE test_sum(a int,b int,c int);
gaussdb=# INSERT INTO test_sum VALUES(1,2),(2,3),(3,4),(4,5);

-- Execute the aggregate function.
gaussdb=# SELECT sum_add(a) FROM test_sum;
  sum_add
-----------
   10

-- Drop the aggregate function.
gaussdb=# DROP AGGREGATE sum_add(int);

-- Drop the user-defined function.
gaussdb=# DROP FUNCTION int_add(int,int);

-- Drop the test table.
gaussdb=# DROP TABLE test_sum;
```

ALTER AGGREGATE and **DROP AGGREGATE**

1.13.9.11 CREATE AUDIT POLICY

Description

Creates an audit policy.

Precautions

- Only users with the POLADMIN or SYSADMIN permission, or the initial user can create and maintain audit policies.
- Before creating an audit policy, ensure that the security policy parameter has been enabled. That is, the audit policy takes effect only after the GUC parameter **enable_security_policy** is set to **on**.
- A system administrator or security policy administrator can access the GS_AUDITING_POLICY, GS_AUDITING_POLICY_ACCESS, GS_AUDITING_POLICY_PRIVILEGES, and GS_AUDITING_POLICY_FILTERS system catalogs to query the created audit policies.

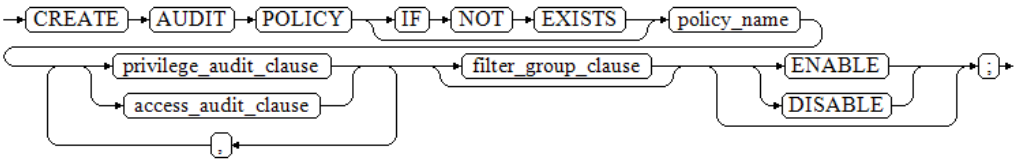
 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTICE

When you use database links to perform operations on remote objects, the client initiates a database link request. The actual sender is the server, and the attributes such as the IP address of the sender are the values of the server. For details, see "Feature Usage Guidelines > Database Links" in *Developer Guide*.

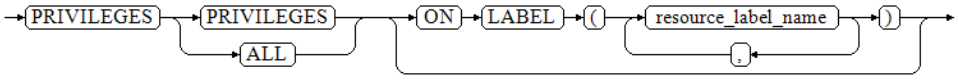
Syntax

```
CREATE AUDIT POLICY [ IF NOT EXISTS ] policy_name { { privilege_audit_clause | access_audit_clause }
[, ... ] [ filter_group_clause ] [ ENABLE | DISABLE ] };
```



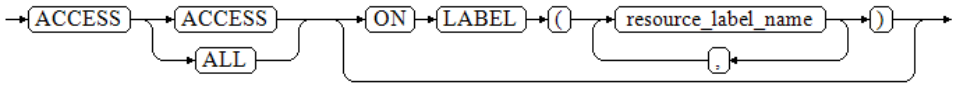
- privilege_audit_clause

  ```
  PRIVILEGES { PRIVILEGES | ALL } [ ON LABEL ( resource_label_name [, ... ] ) ]
  ```

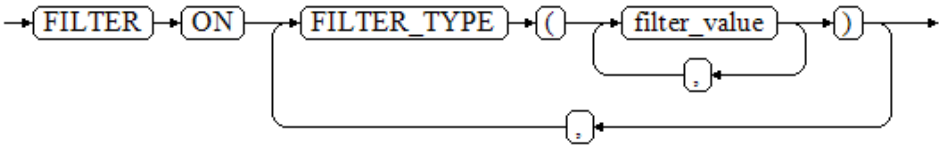
- access_audit_clause

  ```
  ACCESS { ACCESS | ALL } [ ON LABEL ( resource_label_name [, ... ] ) ]
  ```

- filter_group_clause

  ```
  FILTER ON { FILTER_TYPE ( filter_value [, ... ] ) } [, ... ]
  ```

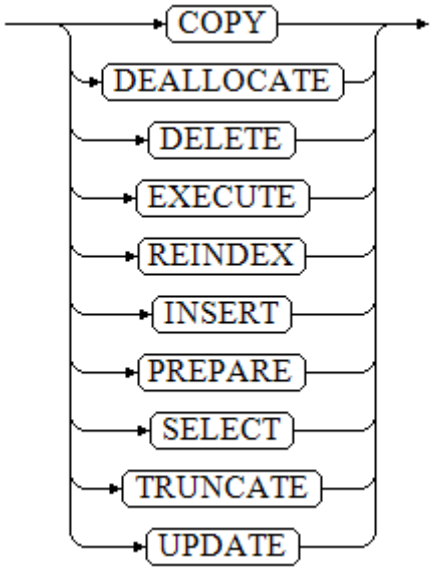
  


- PRIVILEGES:

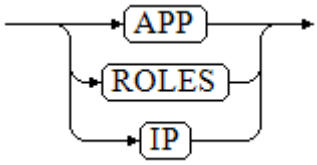
  ```
  { ALTER | ANALYZE | COMMENT | CREATE | DROP | GRANT | REVOKE | SET | SHOW }
  ```

  
 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- ACCESS:
  { COPY | DEALLOCATE | DELETE | EXECUTE | REINDEX | INSERT | PREPARE | SELECT | TRUNCATE | UPDATE }



- FILTER_TYPE
  { APP | ROLES | IP }



Parameters

- **IF NOT EXISTS**

  You can use this keyword to check whether a specified audit policy exists to avoid repeated creation.

- **policy_name**

  The audit policy name must be unique to avoid conflicts with existing policies.

  Value range: character strings complying with **Identifier Naming Conventions** and not exceeding 63 characters.

  NOTE

  - If the audit policy name contains more than 63 characters, the database truncates it and retains the first 63 characters as the audit policy name.
  - If the audit policy name contains uppercase letters, the database automatically converts the uppercase letters into lowercase letters. To create an audit policy name that contains uppercase letters, enclose the audit policy name with double quotation marks ("").
  - The audit policy name must start with a letter or underscore (_) and can contain only lowercase letters (a to z), uppercase letters (A to Z), underscores (_), digits (0 to 9), and dollar signs ($).

- **resource_label_name**

  Specifies the resource label name.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **PRIVILEGES**

  Specifies the operations that are audited in the database: CREATE, ALTER, DROP, ANALYZE, COMMENT, GRANT, REVOKE, SET, and SHOW.

  If the value is **ANALYZE**, the ANALYZE and VACUUM operations are audited.

- **ACCESS**

  Specifies the operations that are audited in the database: SELECT, COPY, DEALLOCATE, DELETE, EXECUTE, INSERT, PREPARE, REINDEX, TRUNCATE, and UPDATE.

- **ALL**

  Specifies the PRIVILEGES or ACCESS operations supported for the database. When the form is { PRIVILEGES | ALL }, **ALL** indicates all PRIVILEGES operations. When the form is { ACCESS | ALL }, **ALL** indicates all ACCESS operations.

- **FILTER_TYPE**

  Specifies the types of information to be filtered by the audit policy, including **APP**, **ROLES**, and **IP**.

- **filter_value**

  Specifies the detailed information to be filtered by the audit policy.

- **ENABLE | DISABLE**

  Enables or disables the unified audit policy. If not specified, **ENABLE** is used by default.

Examples

- Creates audit policy for executing **CREATE** on the database.

```
-- Create the adt1 policy.
gaussdb=# CREATE AUDIT POLICY adt1 PRIVILEGES CREATE;

-- View the adt1 policy.
gaussdb=# SELECT * FROM GS_AUDITING_POLICY;
 polname | polcomments |         modifydate         | polenabled
---------+-------------+----------------------------+------------
 adt1    |             | 2023-11-06 16:41:40.947417 | t

-- Check the location where audit logs are stored.
gaussdb=# SHOW audit_directory;

-- Drop the audit policy adt1.
gaussdb=# DROP AUDIT POLICY adt1;
```

- Create an audit policy to audit only the CREATE operation performed by the **dev_audit** user.

```
-- Create user dev_audit.
gaussdb=# CREATE USER dev_audit PASSWORD '********';

-- Create the tb_for_audit table.
gaussdb=# CREATE TABLE tb_for_audit(col1 text, col2 text, col3 text);

-- Create the adt_lb0 resource label based on the tb_for_audit table.
gaussdb=# CREATE RESOURCE LABEL adt_lb0 add TABLE(public.tb_for_audit);

-- Create the adt2 audit policy for the CREATE operation on the adt_lb0 resource.
gaussdb=# CREATE AUDIT POLICY adt2 PRIVILEGES CREATE ON LABEL(adt_lb0) FILTER ON
ROLES(dev_audit);

-- Drop the audit policy adt2.
gaussdb=# DROP AUDIT POLICY adt2;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
-- Drop the tb_for_audit table.
gaussdb=# DROP TABLE tb_for_audit;

-- Drop the dev_audit user.
gaussdb=# DROP USER dev_audit;
```

- Create an audit policy to audit only the SELECT, INSERT, and DELETE operations performed on the **adt_lb0** resource by user **dev_audit** using client tool gsql on the servers whose IP addresses are **10.20.30.40** and **127.0.0.0/24**, respectively.

```
-- Create user dev_audit.
gaussdb=# CREATE USER dev_audit PASSWORD '********';

-- Create the audit policy adt3.
gaussdb=# CREATE AUDIT POLICY adt3 ACCESS SELECT ON LABEL(adt_lb0), INSERT ON
LABEL(adt_lb0), DELETE FILTER ON ROLES(dev_audit), APP(gsql), IP('10.20.30.40', '127.0.0.0/24');

-- Drop the audit policy adt3.
gaussdb=# DROP AUDIT POLICY adt3;

-- Drop the dev_audit user.
gaussdb=# DROP USER dev_audit;
```

Helpful Links

ALTER AUDIT POLICY and **DROP AUDIT POLICY**

1.13.9.12 CREATE BARRIER

Description

Creates a barrier for new cluster nodes, which can be used for data restoration.

Precautions

- This functionality is designed for internal use only. Avoid direct use by users.
- Generally, this functionality is used only for backup and restoration. Therefore, it can be executed only in the following scenarios:
  - The database initial user can run this command.
  - If the backup and restoration mode is enabled on the CN, that is, the GUC parameter **operation_mode** is set to **on**, users with the OPRADMIN permission can run this command.

Syntax

```
CREATE BARRIER 'barrier_name';
```

Parameters

barrier_name

Specifies the name of a barrier.

Value range: character strings complying with **Identifier Naming Conventions**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Examples

```
-- Specify the barrier name.
gaussdb=# CREATE BARRIER 'barrier1';
```

1.13.9.13 CREATE CLIENT MASTER KEY

Description

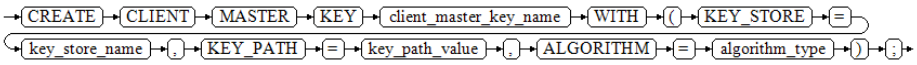
Creates a client master key (CMK).

Precautions

- This syntax is specific to the fully-encrypted database.
- Before using this syntax, set environment variables for the external key manager on the database driver side. For details, see "Feature Usage Guidelines > Setting Encrypted Equality Query" in *Developer Guide*.
- When connecting to the database, you need to enable the connection parameters for the encrypted equality query feature on the database driver side before running **CREATE CLIENT MASTER KEY**. The encrypted equality query feature adopts a multi-level encryption model. The master key encrypts the column key, and the column key encrypts data.
- The master key is provided by an external key manager. This syntax processes only information such as the key source and key ID. The following external key managers are supported:
  - Huawei Cloud KMS huawei_kms
  - Derived key from the user password or provided key user_token
  - Intrinsic key management based on the Kunpeng TEE and the SanSec SJJ1994 HSM sdf_kms

Syntax

```
CREATE CLIENT MASTER KEY client_master_key_name WITH (KEY_STORE = key_store_name, KEY_PATH =
key_path_value, ALGORITHM = algorithm_type);
```



Parameters

- **client_master_key_name**

  Specifies the name of the CMK to be created. In the same namespace, the CMK name must be unique.

  Value range: character strings complying with **Identifier Naming Conventions**.

- **KEY_STORE**

  External key manager.

  Value range: See **Table 1-393**.

  - If **KEY_STORE** is set to **user_token**, you do not need to provide the **KEY_PATH** parameter.
  - If **KEY_STORE** is set to **sdf_kms**, users do not need to provide the **ALGORITHM** parameters. By default, **SGD_SM4_ECB** is supported.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **KEY_PATH**

  Each key is managed by an external key manager and the key path format varies depending on the key manager.

  Value range: character strings. See **Table 1-393**. The value of **KEY_PATH** must be enclosed in single or double quotation marks. If the length of a character string exceeds 64 characters, only single quotation marks can be used.

- **ALGORITHM**

  Algorithm used by the key.

  Value range: See **Table 1-393**.

Table 1-393 Parameter values for different key managers

KEY_STORE	KEY_PATH	ALGORITHM
huawei_kms	Format: '{KmsApiUrl}/{*Key ID*}' Reference: 'https://kms.{*Project*}.myhuaweicloud.com/v1.0/{*Project ID*}/kms/{*Key ID*}' Example: 'https://kms.cn-north-4.myhuaweicloud.com/v1.0/00000000000000000000000000000000/kms/00000000-0000-0000-0000-000000000000'	AES_256 SM4
user_token	Users do not need to provide **KEY_PATH**.	Currently, the following algorithms are supported: • AES_256_CBC • AES_256_GCM • SM4 • SM4_HMAC_SM3 • SM4_CTR_HMAC_SM3
sdf_kms	Format: '{*ID of the key encryption key (KEK)*}' Note: This parameter can be generated by the key management tool provided by iTrustee or by the key management tool in the SanSec SJJ1994 HSM.	Users do not need to provide **ALGORITHM**.

Examples

- user_token scenario:

```
-- Decompress the installation package GaussDB-Kernel_Database version number_OS version number_64bit_Gsql.tar.gz to find the gsql_env.sh script.
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
-- Use the script to automatically configure the environment variables.
source gsql_env.sh

-- Connect to the database, use the privileged account, and create a user, for example, alice.
gsql -p Port number -d postgres -r
gaussdb=# CREATE USER alice PASSWORD '*******';
gaussdb=# \q

-- Connect to the database. The -C parameter must be used.
gsql -p Port number -d postgres -U alice -r -C

-- Set the user password or derived key. gsql can use password=stdin or key_token=stdin for interactive input.
-- Set the user password. The password must contain at least eight characters, including three types of the following: uppercase letters, lowercase letters, digits, and symbols.
gaussdb=> \key_info keyType=user_token,password=*********
-- Alternatively, connect to a key that meets the security strength requirements. The key is a hexadecimal code.
gaussdb=> \key_info keyType=user_token,key_token=********************************

-- Create a master key.
gaussdb=> CREATE CLIENT MASTER KEY alice_cmk WITH ( KEY_STORE = user_token , ALGORITHM = AES_256_GCM );

-- Delete the master key.
gaussdb=> DROP CLIENT MASTER KEY alice_cmk;
gaussdb=> \q

-- Connect to the database, use the privileged account, and delete user alice.
gsql -p Port number -d postgres -r
gaussdb=# DROP USER alice;
```

Helpful Links

DROP CLIENT MASTER KEY

1.13.9.14 CREATE COLUMN ENCRYPTION KEY

Description

Creates a column encryption key (CEK).

Precautions

- This syntax is specific to a fully-encrypted database.
- When using gsql to connect to a database server, you need to use the **-C** parameter to enable the fully-encrypted database so that CREATE COLUMN ENCRYPTION KEY can be used.
- When defining a column in a table, you can specify a CEK to encrypt the column.

Syntax

```
CREATE COLUMN ENCRYPTION KEY column_encryption_key_name WITH VALUES(CLIENT_MASTER_KEY = client_master_key_name, ALGORITHM = algorithm_type [, ENCRYPTED_VALUE = encrypted_value]);
```

Parameters

- **column_encryption_key_name**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Specifies the name of the CEK to be created. In the same namespace, the CEK name must be unique. The CEK created using this syntax can be used for column-level encryption.

Value range: character strings complying with **Identifier Naming Conventions**.

- **CLIENT_MASTER_KEY**

  Specifies a CMK to encrypt a CEK.

  Value range: a CMK name. The CMK is created using the **CREATE CLIENT MASTER KEY** syntax.

- **ALGORITHM**

  Algorithm used by the key.

  Value range: AEAD_AES_256_CBC_HMAC_SHA256, AEAD_AES_128_CBC_HMAC_SHA256, AEAD_AES_256_CTR_HMAC_SHA256, AES_256_GCM, SM4_SM3, SM4_HMAC_SM3, or SM4_CTR_HMAC_SM3.

  - The data expansion rates of different algorithms are sorted as follows: AEAD_AES_256_CTR_HMAC_SHA256 = SM4_CTR_HMAC_SM3 < AES_256_GCM < AEAD_AES_256_CBC_HMAC_SHA256 = AEAD_AES_128_CBC_HMAC_SHA256 = SM4_SM3 = SM4_HMAC_SM3. You are advised to use the AEAD_AES_256_CTR_HMAC_SHA256, SM4_CTR_HMAC_SM3, or AES_256_GCM algorithm.

- **ENCRYPTED_VALUE**

  (Optional) Specifies a user-defined key. The key contains 28 to 256 characters.

  - A key with 28 characters provides the same security strength as AES-128.
  - If you want to use AES-256, the key must contain 39 characters.
  - If this parameter is not specified, a 256-character key is automatically generated.
  - When the master key generated by Huawei KMS is used to encrypt the column key, the length of the key passed through the **ENCRYPTED_VALUE** field must be an integer multiple of 16 bytes.

NOTICE

SM algorithm restrictions: SM2, SM3, and SM4 are Chinese national cryptography standards. To avoid legal risks, these algorithms must be used together. If the SM4, SM4_HMAC_SM3, or SM4_CTR_HMAC_SM3 algorithm is specified for encrypting the column key during master key creation, the SM4_SM3, SM4_HMAC_SM3, or SM4_CTR_HMAC_SM3 algorithm must be specified for encrypting the data during column key creation. This restriction does not apply to sdf_kms key management.

1.13.9.15 CREATE CONVERSION

Description

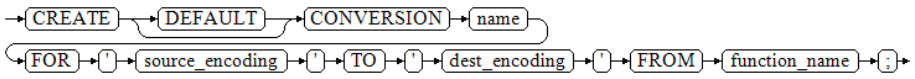
Creates a new encoding conversion rule to translate data from one character encoding (source encoding) to another character encoding (target encoding).

Precautions

- This functionality is for internal use only and cannot be directly used by users. Encoding conversion rules can only be created internally.

Syntax

```
CREATE [ DEFAULT ] CONVERSION name
   FOR 'source_encoding' TO 'dest_encoding' FROM function_name;
```



Parameters

- **DEFAULT**

  Sets the conversion executed between the source encoding and the target encoding by default between the client and the server.

  Within a schema, each encoding pair has only one default conversion.

- **name**

  Name of the conversion rule. The conversion rule name must be unique within a schema.

- **source_encoding**

  Source encoding format.

- **dest_encoding**

  Target encoding format.

- **function_name**

  Function that performs the actual encoding conversion.

  The function must be in the following format:

  ```
  conv_proc(
     integer, -- Source encoding ID
     integer, -- Target encoding ID
     cstring, -- Source character string (C character string ending with a null value)
     internal,-- Target (filled with a null-terminated C character string)
     integer  -- Length of the source string
  ) RETURNS void;
  ```

1.13.9.16 CREATE DATABASE

Description

Creates a database. By default, the new database is created by copying **template0** of the standard system database.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Precautions

- Only users with the CREATEDB permission can create a database. System administrators possess this permission by default.
- This command cannot be executed in transaction blocks.
- **templatem** cannot be used as the database name when a database is created.
- If the **DBCOMPATIBILITY** and **TEMPLATE** keywords are not specified when you create a database, the default compatible database type is determined by the value of the GUC parameter **distribute_default_compatibility**.
- If a compatible database you create is not ORA-compatible, M-compatible, or MySQL-compatible, some information of the following system objects is different. For details, see **Table 1-394**.

Table 1-394 System object differences

System Object Type	System Object Name	Difference
System views	pg_catalog.my_tab_modifications	When a database is created, the **timestamp** column in the view is of the timestamp(0) without time zone type. After the view is upgraded, the column type changes to date.
	pg_catalog.db_tab_modifications	
	pg_catalog.v$open_cursor	When a database is created, the **last_sql_active_time** column in the view is of the timestamp(0) without time zone type. After the view is upgraded, the column type changes to date.
	pg_catalog.my_audit_trail	When a database is created, the **timestamp** and **logoff_time** columns in the view are of the timestamp(0) without time zone type. After the view is upgraded, the column type changes to date.
	sys.v_session	When a database is created, the **logon_time** and **prev_exec_start** columns in the view are of the timestamp(0) without time zone type. After the view is upgraded, the column type changes to date.
	sys.gv_session	
	sys.db_indexes	When a database is created, the **last_analyzed** column in the view is of the timestamp(0) without time zone type. After the view is upgraded, the column type changes to date.
	sys.adm_indexes	
	sys.adm_tab_cols	

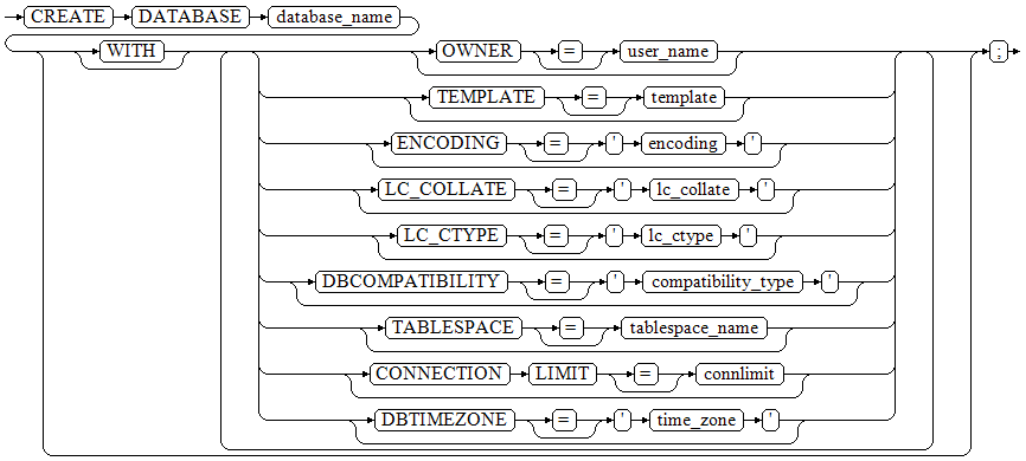
 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

System Object Type	System Object Name	Difference
	sys.db_tab_columns	
	sys.adm_tab_columns	
	sys.db_tab_col_statistics	
	sys.adm_tab_col_statistics	
	sys.db_part_col_statistics	
	sys.adm_part_col_statistics	
	sys.db_subpart_col_statistics	
	sys.adm_subpart_col_statistics	
Advanced package function	dbe_scheduler.set_attribute	When a database is created, the dbe_scheduler.set_attribute(name text, attribute text, value date) overloaded function is missing. After the packages plug-in is upgraded, the dbe_scheduler.set_attribute(name text, attribute text, value date) overloaded function exists.

Syntax

```
CREATE DATABASE database_name
   [ [ WITH ] { [ OWNER [=] user_name ] |
            [ TEMPLATE [=] template ] |
            [ ENCODING [=] 'encoding' ] |
            [ LC_COLLATE [=] 'lc_collate' ] |
            [ LC_CTYPE [=] 'lc_ctype' ] |
            [ DBCOMPATIBILITY [=] 'compatibility_type' ] |
            [ TABLESPACE [=] tablespace_name ] |
            [ CONNECTION LIMIT [=] connlimit ] |
            [ DBTIMEZONE [=] 'time_zone' ] }[...] ];
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.



Parameters

- **database_name**

  Specifies the database name.

  Value range: character strings complying with **Identifier Naming Conventions** and not exceeding 63 characters.

  NOTE

  - If the value contains more than 63 characters, the database truncates it and retains the first 63 characters as the database name.
  - If a database name contains uppercase letters, the database automatically converts the uppercase letters into lowercase letters. To create a database name that contains uppercase letters, enclose the database name with double quotation marks ("").

- **OWNER [=] user_name**

  (Optional) Specifies the owner of the new database.

  Value range: an existing username. If no username is specified, the owner of the new database is the current user.

- **TEMPLATE [=] template**

  (Optional) Creates a database based on the specified standard system database template.

  GaussDB creates a database by copying data from a template database. GaussDB contains default template databases **template0**, **template1**, **templatea**, and **templatem** and a default user database **postgres**.

  Value range: **template0**, **templatem**, and **templatea**.

- **ENCODING [=] 'encoding'**

  (Optional) Specifies the character encoding used by the database.

  Common values are **GBK**, **UTF8**, **Latin1**, and **GB18030**. The supported character encodings are listed in **Table 1-395**.

  - If no character encoding is specified, the M-compatible database uses the UTF-8 encoding by default, and other compatible databases use the encoding of the template database by default.
  - The default codes of the template databases **template0**, **template1**, and **templatea** are related to the OS environment.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

– The character encoding of the **template1** database cannot be changed. To modify the character encoding, use the **template0** or **templatea** database to create a database.

Table 1-395 Character encodings supported by GaussDB

Name	Description	Language	Server-side Encoding	ICU Support	Number of Bytes/ Characters	Alias
BIG5	Big Five	Traditional Chinese	No	No	1–2	WIN950 and Windows950
EUC_CN	Extended Unix Code-CN	Simplified Chinese	Yes	Yes	1–3	-

NOTICE

- Not all client APIs support the character encodings listed in **Table 1-395**.
- The setting of the SQL_ASCII encoding format is different from that of other encoding formats. If the character encoding of the server is SQL_ASCII, the server parses the byte values 0 to 127 according to the ASCII standard. The byte values 128 to 255 are regarded as the characters that cannot be parsed. If any non-ASCII data is used, do not set the character encoding to **SQL_ASCII**. If the character encoding is set to **SQL_ASCII**, the database cannot convert or verify non-ASCII characters.
- The newly specified database character encoding must be compatible with the local settings (**LC_COLLATE** and **LC_CTYPE**).
- When the specified character encoding is **GBK** or **ZHS16GBK**, some uncommon Chinese characters cannot be directly used as object names. This is because when the second byte of the GBK ranges from 0x40 to 0x7E, the byte encoding overlaps with the ASCII characters, including uppercase characters (A–Z), lowercase characters (a–z), and special characters @ [\ ] ^ _ ` { | } @, [, \, ], ^, _, `, {, |, and } are operators in the database. If they are directly used as object names, a syntax error will be reported.
- If the encoding format on the client is different from that on the server, the database must support encoding format conversion. You can view all supported encoding formats in the PG_CONVERSION system catalog. If the database does not support encoding format conversion, it is recommended that the client-side encoding be the same as the server-side encoding. You can change the client-side encoding by setting the GUC parameter **client_encoding**.
- If both the database character set encoding and client-side encoding are GB18030_2022, ensure that the client OS supports GB18030_2022. Otherwise, data inconsistency may occur due to incomplete compatibility between GB18030 character set versions. In addition, if historical data needs to be switched to the GB18030_2022 database, follow the database switchover process to migrate data.
- If the specified character encoding is **ZHS16GBK**, the euro sign (€) can be input, and the encoding value is **0x80**.

- **LC_COLLATE [=] 'lc_collate'**

  (Optional) Specifies the character set used by the new database.

  Value range: character sets supported by the OS. By default, the character set of the template database is used.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTICE

- The use of this parameter affects the sorting order of strings, such as the sorting of the ORDER BY operation results or the sorting of indexes on text columns.
- This parameter does not take effect for M-compatible databases.
- The value ranges of the **lc_collate** and **lc_ctype** parameters are related to the character sets supported by the local environment. For example, in the Linux OS, you can run the **locale -a** command to obtain the list of character sets supported by the OS. When the **LC_COLLATE** and **LC_CTYPE** keywords are specified, select the required character set and character type from the obtained character set list.
- If you want to set the character encoding to **GB18030_2022**, ensure that the value ranges of **lc_collate** and **lc_ctype** are the same as those of GB18030.
- If you want to set the character encoding to **ZHS16GBK**, ensure that the value ranges of **lc_collate** and **lc_ctype** are the same as those of GBK character encoding.

- **LC_CTYPE [=] 'lc_ctype'**

  (Optional) Specifies the character type used by the new database.

  Value range: character type supported by the OS. By default, the character type of the template database is used.

NOTICE

- The use of this parameter affects the classification of characters, such as uppercase letters, lowercase letters, and digits.
- This parameter does not take effect for M-compatible databases.
- The value ranges of the **lc_collate** and **lc_ctype** parameters are related to the character sets supported by the local environment. For example, in the Linux OS, you can run the **locale -a** command to obtain the list of character sets supported by the OS. When the **LC_COLLATE** and **LC_CTYPE** keywords are specified, select the required character set and character type from the obtained character set list.
- If you want to set the character encoding to **GB18030_2022**, ensure that the value ranges of **lc_collate** and **lc_ctype** are the same as those of GB18030.
- If you want to set the character encoding to **ZHS16GBK**, ensure that the value ranges of **lc_collate** and **lc_ctype** are the same as those of GBK character encoding.

- **DBCOMPATIBILITY [=] 'compatibility_type'**

  (Optional) Specifies the compatible database type. If this parameter is not specified, the default compatibility mode is affected by the **TEMPLATE** keyword and the GUC parameter **distribute_default_compatibility**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Value range: **MYSQL**, **TD**, **ORA**, **PG**, and **M**, indicating compatibilities with MySQL, Teradata, Oracle, PostgreSQL, and M-compatible databases, respectively.

NOTICE

- In an ORA-compatible database, empty strings are treated as **NULL**. When the GUC parameter **mapping_date_to_datea** parameter is disabled, the data type **DATE** is replaced by **TIMESTAMP(0) WITHOUT TIME ZONE**. When the GUC parameter **mapping_date_to_datea** is enabled, the data type **DATE** is replaced by **DATEA**.
- When a character string is converted to an integer, if the input is invalid, the MySQL-compatible database converts the input to 0. In other compatible databases, an error is reported.
- In PG-compatible databases, CHAR and VARCHAR are counted by character. In other compatible databases, CHAR and VARCHAR are counted by byte. For example, for the UTF-8 character encoding, CHAR(3) can store three Chinese characters in PG-compatible databases, but can store only one Chinese character in other compatible databases.
- If an error occurs during statement execution, some error messages may display "A-format" or "B-format", which represent "ORA-format" and "MYSQL-format", respectively.
- For details about M-compatible database features, see *M Compatibility Developer Guide*.

- **TABLESPACE [=] tablespace_name**

  (Optional) Specifies the tablespace of a database.

  Value range: an existing tablespace name.

- **CONNECTION LIMIT [=] connlimit**

  (Optional) Specifies the maximum number of concurrent connections that can be made to the database.

  Value range: an integer in the range [–1,2^{31} – 1]. The default value is **-1**, indicating that there is no limit.

NOTICE

- System administrators are not restricted by this parameter.
- **connlimit** of each node is calculated separately. The number of connections in a cluster is calculated using the following formula: Number of connections in a cluster = **connlimit** x Number of normal CNs.

- **DBTIMEZONE [=] 'time_zone'**

  Specifies the time zone of the new database. This parameter affects the time zone of the new database. The default value is **PRC**.

  The options are as follows:

  – Time zone names and abbreviations supported by the OS.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- [–15:59,+15:00]

> **NOTE**
>
> - This parameter is supported only when the ORA-compatible mode is used and **a_format_version** is set to **'10c'** and **a_format_dev_version** is set to **'s2'**.
> - The restrictions on character encoding are as follows:
>   - If the locale is set to **C** or **POSIX**, all encoding types are allowed. For other locale settings, the character encoding must be the same as that of the locale.
>   - The character encoding and locale settings must match the template database (except when **template0** is used as the template). When the database contains data that does not match the specified encoding or contains indexes whose sorting order is affected by **LC_COLLATE** and **LC_CTYPE**, copying data may result in the invalidation of indexes in the new database.

Examples

```
-- Create users jim and tom.
gaussdb=# CREATE USER jim PASSWORD '********';

-- Create the GBK-encoded database testdb1.
gaussdb=# CREATE DATABASE testdb1 ENCODING 'GBK' template = template0;

-- View information about the testdb1 database.
gaussdb=# SELECT datname,pg_encoding_to_char(encoding) FROM pg_database WHERE datname =
'testdb1';
 datname | pg_encoding_to_char
---------+---------------------
 testdb1 | GBK
(1 row)

-- Create the ORA-compatible database testdb2 and specify jim as the owner.
gaussdb=# CREATE DATABASE testdb2 OWNER jim DBCOMPATIBILITY = 'ORA';

-- View the information about testdb2.
gaussdb=# SELECT t1.datname,t2.usename,t1.datcompatibility
          FROM pg_database t1,gs_user t2
          WHERE t1.datname = 'testdb2' AND t1.datdba=t2.usesysid;
 datname | usename | datcompatibility
---------+---------+------------------
 testdb2 | jim     | ORA
(1 row)
gaussdb=# CREATE DATABASE testdb_tmp OWNER jim template=templatea;

-- View the information about testdb2.
gaussdb=# SELECT t1.datname,t2.usename,t1.datcompatibility
                  FROM pg_database t1,gs_user t2
                  WHERE t1.datname = 'testdb_tmp' AND t1.datdba=t2.usesysid;
  datname   | usename | datcompatibility
------------+---------+------------------
 testdb_tmp | jim     | ORA
(1 row)

-- Create a database that 1000 concurrent connections can be made.
gaussdb=# CREATE DATABASE testdb4 CONNECTION LIMIT=1000;

-- View the information about testdb4.
gaussdb=# SELECT datname,datconnlimit  FROM pg_database where datname = 'testdb4';
 datname | datconnlimit
---------+--------------
 testdb4 |         1000
(1 row)

-- Create a tablespace.
gaussdb=# CREATE TABLESPACE tbs_test RELATIVE LOCATION 'test_tablespace/tbs_test';
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
-- Create a database and specify tbs_test as the default tablespace.
gaussdb=# CREATE DATABASE testdb5 TABLESPACE = tbs_test;

-- View the information about testdb5.
gaussdb=# SELECT db.datname,ts.spcname FROM pg_database db JOIN pg_tablespace ts ON
db.dattablespace = ts.oid WHERE db.datname = 'testdb5';
 datname | spcname
---------+----------
 testdb5 | tbs_test
(1 row)

-- Switch to the ORA-compatible database testdb2 and set session parameters.
gaussdb=# \c testdb2
testdb2=# SET a_format_version='10c';
testdb2=# SET a_format_dev_version='s2';

-- Create the ORA-compatible database and specify the time zone.
testdb2=# CREATE DATABASE testdb3 DBCOMPATIBILITY 'ORA' DBTIMEZONE='+08:00';

-- View the information about testdb3.
testdb2=# SELECT datname,datcompatibility,dattimezone FROM pg_database WHERE datname = 'testdb3';
 datname | datcompatibility | dattimezone
---------+------------------+-------------
 testdb3 | ORA              | +08:00

ALTER DATABASE and **DROP DATABASE**

1.13.9.17 CREATE DATABASE LINK

Description

Creates a database link object.

Precautions

- For details about database links, see "Feature Usage Guidelines > Database Links" in *Developer Guide*.
- The database link feature can be used only in ORA-compatible databases.
- Do not use database links to connect to the initial user. The initial user is not allowed to create, modify, or delete database link objects.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- When a database link is created, the system does not check whether the link can be successfully connected. If related keywords are missing, an error may be reported when the link is used.
- If the upgrade is not committed, the database link cannot be created.
- In non-multi-primary mode, you can use the local IP address and port to connect to the current database instance. CNs and DNs may be deployed on different servers. Therefore, you are advised not to set the **host** parameter to **127.0.0.1** or **localhost**. Otherwise, the connection may fail.

Syntax

```
CREATE [ PUBLIC ] DATABASE LINK dblink
  [ CONNECT TO { CURRENT_USER | 'user' IDENTIFIED BY 'password' } ] [ USING ( {option 'value'} [, ...]) ];
```

option is as follows:

```
{ HOST | PORT | DBNAME | FETCH_SIZE }
```

Parameters

- **PUBLIC**

  Creates a public database link visible to all users. If this parameter is not specified, the database connection is private and available only to the current user.

- **dblink**

  Specifies the name of the database link to be created.

- **user**

  Specifies the name of the user for connecting to the remote database through the created database link.

- **password**

  Specifies the password of the user for connecting to the remote database through the created database link.

- **CURRENT_USER**

  Uses the initial username and empty password of the current database for connection.

  NOTE

  In the current version, after the **CURRENT_USER** option is specified, the database link can be created, but it is not connected.

- **USING ({option 'value'} [, ...])**

  (Optional) Specifies parameters such as the IP address, port number, and remote database name of the database to be connected. The supported options are as follows:

  - **host**: specifies the IP address of the database to be connected. If this parameter is not specified, it is left empty by default. You can specify multiple IP addresses and separate them with commas (,), except for IP addresses of encrypted databases, SSL settings, and certificate authentication.
  - **port**: specifies the port number for connection. If this parameter is not specified, the default value **5432** is used.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **dbname**: specifies the name of the database to be connected. If not specified, the username used for connecting to the remote end is used by default.
- **fetch_size**: specifies the amount of data obtained from the remote end each time. The value range is [0,2147483647]. The default value is **100**.

Examples

```
-- Create an ORA-compatible database.
gaussdb=# CREATE DATABASE ora_test_db DBCOMPATIBILITY 'ORA';
CREATE DATABASE

-- Switch to another database.
gaussdb=# \c ora_test_db

-- Create a user with the SYSADMIN permission.
ora_test_db=# CREATE USER local_user WITH SYSADMIN PASSWORD '********';
CREATE ROLE
ora_test_db=# SET ROLE local_user PASSWORD '********';
SET

-- Create a private database link. host can be an IPv6 address.
ora_test_db=> CREATE DATABASE LINK private_dblink CONNECT TO 'remote_user' IDENTIFIED BY '********'
USING (host '***.***.***.***',port '*****',dbname 'remote_db');
CREATE DATABASE LINK

-- Drop the private database link.
ora_test_db=> DROP DATABASE LINK private_dblink;
DROP DATABASE LINK

-- Create a public database link. host can be an IPv6 address.
ora_test_db=> CREATE PUBLIC DATABASE LINK public_dblink CONNECT TO 'remote_user' IDENTIFIED BY
'********' USING (host '***.***.***.***',port '*****',dbname 'remote_db');
CREATE DATABASE LINK

-- Drop the public database link.
ora_test_db=> DROP PUBLIC DATABASE LINK public_dblink;
DROP DATABASE LINK

-- Drop the created user.
ora_test_db=> RESET ROLE;
RESET
ora_test_db=# DROP USER local_user;
DROP ROLE

-- Switch back to the initial database and drop the test database. Replace postgres with the actual
database name.
ora_test_db=# \c postgres
gaussdb=# DROP DATABASE ora_test_db;
DROP DATABASE
```

ALTER DATABASE LINK and **DROP DATABASE LINK**

1.13.9.18 CREATE DIRECTORY

Description

Creates a directory, which can define an alias for a path in the server file system and is used to store data files used by users. Users can read and write these files through the DBE_FILE advanced package. You can view existing directory objects in the PG_DIRECTORY catalog.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Precautions

- The default owner of a directory object is the user who creates the directory object. By default, the user who creates the directory object has the permissions to read and write the directory object. When **enable_access_server_directory** is set to **off**, only the initial user is allowed to create the directory. When **enable_access_server_directory** is set to **on**, users with the SYSADMIN permission and users inheriting the permissions of the built-in role gs_role_directory_create can create directories.
- In the database scenario where the database is deployed by users, the initial configuration and management of the permission system are performed by users. When granting directory permissions, ensure that the target directory meets the following security conditions: The security baseline check is passed, the access control audit mechanism is available, and sensitive data is classified and graded. The permission configuration should comply with the least privilege principle, and a permission approval and tracing mechanism should be established.
- The READ and WRITE operation permissions can be granted to specified users on a directory object for DBE_FILE permission control. Create directory objects properly. If a directory object is created in a key directory (for example, the root directory) of the OS, unexpected security risks may occur when the configuration in the directory file is modified.

Syntax

```
CREATE [OR REPLACE] DIRECTORY directory_name
    AS 'path_name';
```

Parameters

- **directory_name**

  Specifies the name of the directory object to be created.

  Value range: character strings complying with **Identifier Naming Conventions**.

  NOTE

  The following validity check is performed during directory creation:

  - Check whether the path exists in the OS. If it does not exist, a message is displayed, indicating the potential risks.
  - Check whether the database initial user (for example, **omm**) has the read, write, and execute permissions on the created directory. If the user does not have all the permissions, a message is displayed, indicating the potential risks.

- **path_name**

  Specifies the directory path in the server file system.

  Value range: a valid OS path.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- In a cluster, ensure that the specified directory paths are the same on all the nodes. Otherwise, the path may fail to be matched on some nodes when the directory is used.
- The following directories cannot be created:
  - The path contains special characters.
  - The path is a relative path.

Examples

```
-- Create a directory.
gaussdb=# CREATE OR REPLACE DIRECTORY dir AS '/tmp/';

-- View the created directory.
gaussdb=# select * from pg_directory;
 dirname | owner | dirpath | diracl
---------+-------+---------+--------
 dir     |    10 | /tmp    |
(1 row)

-- Drop the directory.
gaussdb=# DROP DIRECTORY dir;
```

Helpful Links

ALTER DIRECTORY and **DROP DIRECTORY**

1.13.9.19 CREATE EXTENSION

NOTICE

Extensions are for internal use only. Only advanced packages or extensions in the database can be created (installed). Currently, only postgis, postgis_sfcgal, postgis_raster, postgis_topology, yukon_geomodel, yukon_geogridcoder, pkg_bpchar_opc, and tablefunc can be created or installed.

Description

Installs an extension.

Precautions

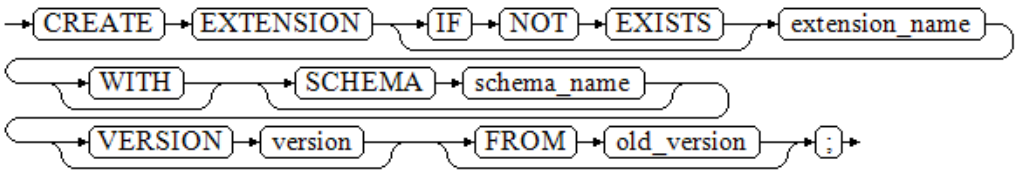
- Before running this command to install an extension to the database, you must install the files that the extension depends on.
- No duplicate extension is allowed in a database. To avoid extension installation failures caused by name conflicts, ensure that the target extension name is not occupied before installing the extension.
- If a database object (package, synonym, operator, directory, function, stored procedure, view, or table) with the same name as the extension to be installed exists in the database, the installation will fail.
- Installing an extension is to execute the corresponding extension script file. The script will create a new SQL entity, including but not limited to functions, data types, operators, and index-supported methods.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- Installing an extension requires the same permissions as creating the extension. For most extensions, this means that the database owner's permissions are required. For subsequent permission checks and entities created by the extension script, the role that runs the **CREATE EXTENSION** command becomes the owner of the extension.
- By default, direct creation of database extensions is prohibited because extensions may cause unexpected errors and compatibility issues after database upgrades. To create an extension, set **enable_extension** to **true**.
- When you create an extension, if the GUC parameter **enable_object_special_character** is set to **off** and the extension script file uses the @extschema@ placeholder, the value of the **schema** parameter in the extension control file cannot contain any of the following special characters: [" $ ' \ ]

Syntax

```
CREATE EXTENSION [ IF NOT EXISTS ] extension_name
[ WITH ] [ SCHEMA schema_name ]
[ VERSION version ]
[ FROM old_version ];
```



Parameters

- **IF NOT EXISTS**

  Checks whether an extension with the same name exists when creating an extension.

  If the **IF NOT EXISTS** keyword is specified, the system checks whether an extension with the same name exists in the current database before creating an extension. If an extension with the same name exists, the system does not create the extension and returns a NOTICE message. If the **IF NOT EXISTS** keyword is not specified and an extension with the same name exists, the system returns an ERROR alarm.

- **extension_name**

  Specifies the name of the extension to be installed. The database creates the extension by using the information in the **SHAREDIR/extension/extension_name.control** file.

- **schema_name**

  Specifies the schema to which the objects (such as functions and data types) created by the script file of the extension belong. The specified schema must exist. If the schema to which the objects created by the script file of the extension belong is not specified, and no schema is either specified in the control file of the extension, the default schema is used.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

> **NOTE**
>
> The files on which the extension depends (that is, the extension itself) do not belong to any schema. The name of the extension is unique in the database and is not restricted by the schema. However, the objects (such as functions and data types) created by the extension belong to a specific schema.

- **version**

  Specifies the version of the extension to install. It can be written as either an identifier or a string. The default version is whatever is specified in the extension's control file.

- **old_version**

  You need to specify **FROM old_version** only if the content that does not exist in the existing module needs to be upgraded. This option uses the **CREATE EXTENSION FROM old_version** command to run a script for installing new content into the extension of an existing module instead of creating an object. Note that **Schema** should be specified as the schema that includes these existing objects.

Examples

Install an extension in the current database. For example, install **security_plugin**:

```
-- Before installing the extension, set enable_extension to true.
gaussdb=# SET enable_extension = true;

-- Install the expansion.
gaussdb=# CREATE EXTENSION IF NOT EXISTS security_plugin;

-- Drop the extension.
gaussdb=# DROP EXTENSION security_plugin;
```

1.13.9.20 CREATE FOREIGN DATA WRAPPER

Description

Creates a foreign data wrapper.

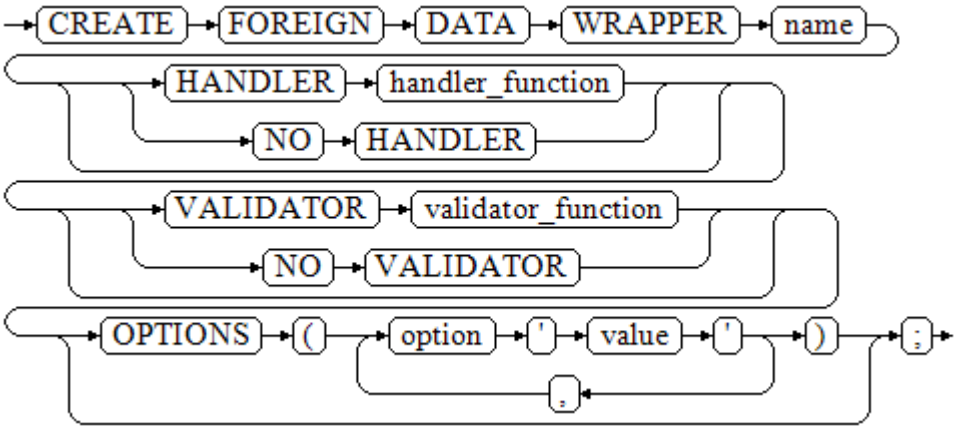
Precautions

A foreign data wrapper can be created only during the internal initialization phase or within an upgrade script. In other scenarios, users cannot directly use this syntax.

Syntax

```
CREATE FOREIGN DATA WRAPPER name
[ HANDLER handler_function | NO HANDLER ]
[ VALIDATOR validator_function | NO VALIDATOR ]
[ OPTIONS ( { option 'value' } [, ... ] ) ];
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.



Parameters

- **name**

  Specifies the name of the foreign data wrapper to be created.

  The name of the foreign data wrapper must be unique in the database.

- **HANDLER handler_function**

  handler_function is the name of a registered function used to retrieve handler functions for foreign tables. The handler function must have no parameter, and its return type must be fdw_handler.

  You can create foreign data wrappers without using a handler function. However, foreign tables using such foreign data wrappers can only be declared and cannot be accessed.

- **NO HANDLER**

  When you create a foreign data wrapper without specifying (or using) a handler function by specifying **NO HANDLER**, the foreign tables of the foreign data wrapper can only be declared and cannot be accessed.

- **VALIDATOR validator_function**

  validator_function is the name of a registered function used to check the common validation options provided to the foreign data wrapper, as well as the validation options for the foreign server, user mapping, and foreign table that use the foreign data wrapper. If there is no validator option (function) or **NO VALIDATOR** is declared, options are not checked at creation time (foreign data wrappers may ignore or reject invalid option descriptions at runtime).

  The validator option (function) **validator_function** must accept two parameters:

  – An array of options stored in the system directory. The value is of the text[] type.

  – OID of the system directory that contains these options. The value is of the oid type.

- **NO VALIDATOR**

  The validator function is not set during creation.

- **OPTIONS (option 'value' [, ...])**

  Declares options of the foreign data wrapper. **OPTIONS (option 'value' [, ...])** can be specific to each foreign data wrapper and is validated by the

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

validator function in the foreign data wrapper. **OPTIONS** must meet the UNIQUE constraint.

Helpful Links

ALTER FOREIGN DATA WRAPPER and **DROP FOREIGN DATA WRAPPER**

1.13.9.21 CREATE FOREIGN TABLE

Description

In GaussDB, CREATE FOREIGN TABLE is a convenient mechanism for accessing, managing, and querying foreign data sources in a unified manner. By creating a foreign table, you can integrate data stored in foreign data sources, such as file systems, tables, and views, into GaussDB and perform query, join, and parallel operations in the same way as you perform operations on ordinary tables. Creates a GDS foreign table in the current database for parallel data import and export. The GDS foreign table can be read-only or write-only, used for parallel data import and export, respectively. The foreign table is read-only by default.

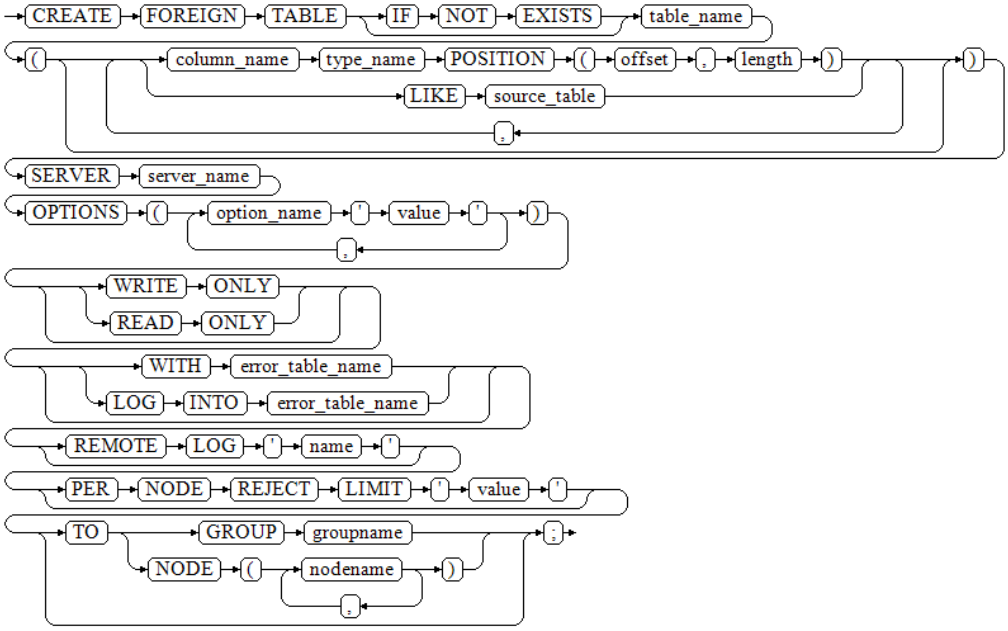
Precautions

- The user who creates the foreign table will be the owner of the foreign table.
- The distribution mode of a GDS foreign table does not need to be explicitly specified. The default mode is **ROUNDROBIN**.
- All constraints (including column and row constraints) are invalid to the GDS foreign table.
- When multi-layer quotation marks are used for sensitive columns (such as **password** and **secret_access_key**) in **OPTIONS**, the semantics is different from that in the scenario where quotation marks are not used. Therefore, sensitive columns are not identified for anonymization.
- When executing **GDS** to import data to a base table with a GSI, the **enable_stream_operator** parameter must be enabled to achieve optimal data import performance.
- When GDS is used to import or export data, the data cannot contain **\0** character. Otherwise, the data will be truncated.

Syntax

```
CREATE FOREIGN TABLE [ IF NOT EXISTS ] table_name
   ( [ { column_name type_name  POSITION ( offset, length ) | LIKE source_table } [, ...] ] )
   SERVER server_name
   OPTIONS ( { option_name 'value' } [, ...] )
   [ WRITE ONLY | READ ONLY  ]
   [ WITH error_table_name | LOG INTO error_table_name]
   [REMOTE LOG 'name']
   [PER NODE REJECT LIMIT 'value']
   [ TO { GROUP groupname | NODE ( nodename [, ... ] ) } ];
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.



Parameter Overview

The syntax for creating a foreign table provides multiple parameters. **Table 1-396** describes the common parameters.

Table 1-396 Foreign table parameters

Required/ Optional	Parameter	
Required	• **table_name** • **column_name** • **type_name** • **POSITION(offset,length)** • **LIKEsource_table** • **SERVER server_name** • **OPTIONS**	
Optional	Data source location parameter of a foreign table	**location**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Required/ Optional	Parameter	
	Data format parameters	• **format** • **header** (only for CSV and FIXED source data files) • **fileheader** (only for CSV and FIXED source data files) • **out_filename_prefix** • **delimiter** • **quote** (only for CSV source data files) • **escape** (only for CSV source data files) • **null** • **noescaping** (only for TEXT source data files) • **encoding** • **eol**
	Error-tolerance parameters	• **fill_missing_fields** • **ignore_extra_data** • **reject_limit** • **compatible_illegal_chars** • **WITH error_table_name** • **LOG INTO error_table_name** • **REMOTE LOG 'name'** • **PER NODE REJECT LIMIT 'value'**

Parameters

- **IF NOT EXISTS**

  Specifies whether a table with the same name exists. If a table with the same name already exists in the database, no error is reported. Instead, a message is displayed, indicating that the table relationship already exists.

- **table_name**

  Specifies the name of a foreign table.

  Value range: character strings complying with **Identifier Naming Conventions**.

- **column_name**

  Specifies the name of a column in the foreign table.

  Value range: character strings complying with **Identifier Naming Conventions**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **type_name**

  Specifies the data type of the column.

- **POSITION (offset, length)**

  Defines the place of each column in the data file in fixed length mode. **offset** is the start of the column in the source file, and **length** is the length of the column.

  Value range: **offset** must be greater than 0, and its unit is byte. The length of each record must be less than or equal to 1 GB. By default, columns not in the file are replaced with null.

- **LIKE source_table**

  Specifies a foreign table. A new foreign table automatically inherits all column names and their data types from this foreign table.

- **SERVER server_name**

  Specifies the server name of the foreign table. For the GDS foreign table, its server is created by the initial database, which is **gsmpp_server**.

  NOTE

  The name of the foreign-data wrapper corresponding to the server cannot be **file_fdw**.

- **OPTIONS ({ option_name ' value ' } [, ...])**

  Specifies all types of parameters of foreign table data.

  – location

    Specifies the data source location of the foreign table, which can be expressed through URLs or in local files. Multiple URLs and local files are separated by vertical bars (|).

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- For a read-only foreign table imported by GDS from a remote server in parallel, its URL must end with its corresponding schema or file name. (Read-only is the default file attribute.) For example: **gsfs://192.168.0.90:5000/***, **file:///data/data.txt**, or **gsfs:// 192.168.0.90:5000/* | gsfs:// 192.168.0.91:5000/***.
- For a writable foreign table exported by GDS to a remote server in parallel, its URL does not need to contain a file name. If the data source is local, for example, **file:///data/**, only one data source in the foreign table can be specified, and the hosting directory must be created in advance on each node. If the data source location is a remote URL, for example, **gsfs:// 192.168.0.90:5000/**, multiple data sources can be specified. If the number of exported data file locations is less than or equal to the number of DNs, when you use the foreign table for export, the system traverses nodes and distributes them to the data source locations one by one. After a round of distribution is complete, the system re-distributes nodes from the beginning. Therefore, the more nodes there are, the more evenly the distribution is. If the number of exported data file locations is greater than the number of DNs, when you export data, the data is evenly distributed to data source locations corresponding to the DNs. Blank data files are created on the excess data source locations.
- For a read-only foreign table imported by GDS from a remote server in parallel, the number of URLs must be less than the number of DNs, and URLs in the same location cannot be used.
- If the URL begins with **gsfss://**, data is imported and exported in encrypted mode, and concurrency cannot exceed 10.
- If SSL is used for encrypted transmission and the certificate is replaced, GDS must be restarted.

– format

Specifies the format of the data source file in a foreign table.

Value range: **CSV**, **TEXT**, and **FIXED**. The default value is **TEXT**.

- **CSV**: Escape sequences are processed as common strings. Therefore, newline characters are processed as data.
- **TEXT**: Escape sequences are processed as they are. Therefore, newline characters are not processed as data.
- **FIXED**: The column length of each record is the same, and spaces are used for padding.

NOTE

- An escape sequence is a string starting with a backslash (\), including **\b** (backspace), **\f** (form feed), **\n** (new line), **\r** (carriage return), **\t** (horizontal tab), **\v** (vertical tab), *****digit* (octal number), and **\x***digit* (hexadecimal number). In TEXT files, strings are processed as they are. In files of other formats, strings are processed as data.
- **POSITION** must be specified for each column when **FIXED** is used. **FIXED** is defined as follows:
  - The column length of each record is the same.
  - Spaces are used for column padding. Columns of the numeric type are left-aligned and columns of the string type are right-aligned.
  - No delimiters are used between columns.

– header

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Specifies whether a file contains a header with the information about each column in the file. **header** is available only for CSV and FIXED files.

- When data is imported, if **header** is set to **true** or **on**, the first row of the data text is identified as the header and ignored. If **header** is set to **false** or **off**, the first row is identified as data.
- When data is exported, if **header** is set to **true** or **on**, **fileheader** must be specified. **fileheader** specifies the format of the exported header file. If **header** is set to **false** or **off**, the exported data file does not contain the header.

Value range: **true**/**on** or **false**/**off**. The default value is **false**/**off**.

– fileheader

Specifies a file that defines the content in the header for exported data. The file contains one row of data description of each column.

For example, to add a header in a file containing product information, define the file as follows: **The information of products.\n**

NOTE

- This parameter is available only when **header** is **true** or **on**. The file must be prepared in advance.
- In **REMOTE** mode, the definition file must be put to the working directory of the GDS (the **-d** directory specified when the GDS is started).
- In **LOCAL** mode, the definition file must be put to the same path of each node, and **fileheader** specifies the absolute path.
- The file can contain only one row of header information, and end with a newline character. Excess rows will be discarded. (Header information cannot contain newline characters).
- The length of the file including newline characters cannot exceed 1 MB.

– out_filename_prefix

Specifies the name prefix of the data file exported using GDS from a write-only foreign table.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- The file name prefix must be valid and compliant with the restrictions of the file system in the physical environment where the GDS is deployed. Otherwise, the file will fail to be created.
  - The prefix of the exported file can contain lowercase letters, uppercase letters, digits, and underscores (_) but must not contain invalid characters, such as / ? * : | \\ < > @ # $ & ( ) + -
  - The prefix of the exported file cannot contain feature fields reserved for Windows and Linux, including but not limited to con, aux, nul, prn, com0, com1, com2, com3, com4, com5, com6, com7, com8, com9, lpt0, lpt1, lpt2, lpt3, lpt4, lpt5, lpt6, lpt7, lpt8, and lpt9.
  - The total length of the absolute path consisting of the exported file prefix, the path specified by **gds –d**, and **.dat.x** should be as required by the file system where GDS is deployed.
  - It is required that the prefix can be correctly parsed and identified by the receiver (including but not limited to the original database where it was exported using GDS) of the data file. Identify and modify the option that causes the file name resolution problem (if any).
- To concurrently perform export jobs, do not use the same file name prefix for them. Otherwise, the exported files may overwrite each other or be lost in the OS or file system.

– delimiter

Specifies the column delimiter of data. If no delimiter is specified, the default one will be used. The default delimiter in the TEXT format is a tab and that in the CSV format is a comma (,). No delimiter is used in the FIXED format.

NOTE

- The value of **delimiter** cannot be **\r** or **\n**.
- A delimiter cannot be the same as the null value. The delimiter for the CSV format cannot be same as the **quote** value.
- In TEXT format, the delimiter cannot contain backslashes (\), dots (.), letters (a to z), or digits (0 to 9).
- The data length of a single row should be less than 1 GB. A row that has many columns using long delimiters cannot contain much valid data.
- You are advised to use a multi-character or invisible characters, such as 0x07, 0x08, and 0x1b as the delimiter.

Value range: multi-character delimiters within 10 bytes.

– quote

Specifies a quote character in a CSV data source file. The default value is double quotation marks (").

NOTE

- The value of **quote** cannot be the same as that of the **delimiter** or **null** parameter.
- The value of **quote** must be a single-byte character.
- You are advised to use invisible characters (such as 0x07, 0x08, and 0x1b) as quotes.

– escape

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Specifies an escape character in a CSV data source file. Escape characters can only be single-byte characters. The default value is double quotation marks (").

If the escape character is the same as the quote character, the escape character is replaced with the **\0** character.

- null

  Specifies the null value in a data source file.

  NOTE

  - A null value cannot be **\r** or **\n**. The maximum length is 100 characters.
  - A null value cannot be the same as the **delimiter** or **quote** value.

  Value range:

  - The default value for the TEXT format is **\n**.
  - The default value for the CSV format is an empty string without quotation marks.

- noescaping

  Specifies that the backslash (\) and its following characters are not escaped in the TEXT format.

  NOTE

  noescaping is available only for TEXT source data files.

  Value range: **true**/**on** or **false**/**off**. The default value is **false**/**off**.

- encoding

  Specifies the encoding of a data source file, that is, the encoding used to parse, check, and generate a data source file. Its default value is the default **client_encoding** value of the current database.

  Value range: See **ENCODING [=] 'encoding'** in section **CREATE DATABASE**.

  NOTE

  - When importing a foreign table, you are advised to set **encoding** to the encoding format of the file or set **client_encoding** based on the character set of the file before the import. Otherwise, redundant parsing, verification errors, import errors, or rollback may occur, and even invalid data may be imported to the database.
  - When exporting a foreign table, you are advised to specify this option to avoid unexpected results caused by using the default character set.
  - If the **encoding** option is not specified when you create a foreign table, a warning message is displayed on the client.
  - Currently, GDS cannot parse or write in a file using multiple encoding formats during foreign table import or export, respectively.

- fill_missing_fields

  Specifies how to handle the missing of the last column in a row of a data source file during data import.

  Value range: **true**/**on** or **false**/**off**. The default value is **false**/**off**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **true** or **on**: If the last column in a row of a data source file is missing during data import, the column is set to **NULL** and no import error message is reported.
- **false** or **off**: If the last column in a row of a data source file is missing during data import, the following error message is reported:
  ```
  missing data for column "tt"
  ```

– ignore_extra_data

Specifies whether to ignore the extra columns in the source file if the number of columns in the source file is greater than that defined in the foreign table. This parameter is used only during data import.

Value range: **true**/**on** or **false**/**off**. The default value is **false**/**off**.

- **true**/**on**: If the number of columns in a data source file is greater than that defined by the foreign table, the extra columns at the end of a row are ignored.
- **false** or **off**: If the number of columns in a data source file is greater than that defined by the foreign table, the following error message is reported:
  ```
  extra data after last expected column
  ```

NOTE

If a newline character at the end of a row is missing and two rows of data are combined into one row, setting this parameter to **true** or **on** will cause the data in the latter row to be ignored.

– reject_limit

Specifies the maximum number of data format errors allowed during data import. If the number of errors does not reach the threshold, the data import is considered successful.

Value range: an integer or **unlimited**. The default value is **0**, indicating that an error message is returned immediately. Enclose positive integers with single quotation marks (').

NOTE

- You are advised to use PER NODE REJECT LIMIT 'value' to replace this syntax.
- Data format errors include the following: a column is lost, an extra column exists, a data type is incorrect, and encoding is incorrect. Once a non-data-format error occurs, the whole data import process is stopped.

– mode

Specifies the data import mode during a specific data import process.

Value range:

- **Normal** (default): supports all file formats (CSV, TEXT, FIXED). You need to enable GDS to help data import.
- **Shared**: supports the TEXT format. It does not need assistance from GDS, but requires that all the user data be added to the same path on all nodes through NFS.
- **Private**: User data has been stored in the same path under the local directory of the DN.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- If the shared or private mode is used, the creation of a local foreign table is controlled by the GUC parameters **enable_copy_server_files** and **safe_data_path**.
- When the GUC parameter **enable_copy_server_files** is disabled, only the initial user is allowed to create a local foreign table in shared or private mode. When **enable_copy_server_files** is enabled, users with the SYSADMIN permission or users inherited the permission of the built-in gs_role_copy_files role are allowed to create a local foreign table, preventing unauthorized users from viewing or modifying sensitive files.
- Database administrators can define an import/export path whitelist for all users by setting the GUC parameter **safe_data_path**. The file path must be a subpath of **safe_data_path**. If **safe_data_path** is left blank, no interception will occur on the path being used.

– eol

Specifies the newline character style of the imported or exported data file.

Value range: multi-character newline characters within 10 bytes. Common newline characters include **\r** (0x0D), **\n** (0x0A), and **\r\n** (0x0D0A). Special newline characters include **$** and **#**.

NOTE

- The **eol** parameter supports only TEXT data import and export and does not support CSV or FIXED data import. For compatibility with earlier versions, the **eol** parameter can be set to **0x0D** or **0x0D0A** for CSV or FIXED data export.
- The value of **eol** cannot be the same as that of the delimiter or **null** parameter.
- The **eol** parameter cannot contain dots (.), letters (a to z), or digits (0 to 9).

– fix

Specifies the length of fixed-length data in each row, in bytes. This parameter is available only for read-only foreign tables.

Value range: less than 1 GB, and greater than or equal to the total length specified by **POSITION** (The total length is the sum of **offset** and **length** in the last column of the table definition.)

– out_fix_alignment

Specifies how the columns of the types BYTEAOID, CHAROID, NAMEOID, TEXTOID, BPCHAROID, VARCHAROID, NVARCHAR2OID, and CSTRINGOID are aligned during fixed-length export.

Value range: **align_left** and **align_right**. The default value is **align_right**.

NOTE

When importing byte data that must strictly comply with the hexadecimal or octal format, ensure that the data is left-aligned and does not contain leading spaces. Therefore, if the exported file needs to be imported using a GDS foreign table and the file data length is less than that specified by the foreign table formatter, the exported file must be left aligned. Otherwise, an error is reported during the import.

– date_format

Specifies the DATE format for data import. This syntax is available only for read-only foreign tables.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Value range: valid DATE format. For details, see **Date and Time Processing Functions and Operators**.

NOTE

For a database in ORA-compatible mode:

- If the GUC parameter **mapping_date_to_datea** is set to **off**, the database creates the DATE type that will be implemented as the TIMESTAMP(0) WITHOUT TIME ZONE type. If you need to specify the format when importing data, see **timestamp_format**.
- If the GUC parameter **mapping_date_to_datea** is set to **on**, the database creates the DATE type that will be implemented like the DATEA type. If you need to specify the format when importing data, see **datea_format**.

– time_format

Specifies the TIME format for data import. This syntax is available only for read-only foreign tables.

Value range: a valid TIME value. Time zones cannot be used. For details, see **Date and Time Processing Functions and Operators**.

– timestamp_format

Specifies the TIMESTAMP format for data import. This syntax is available only for read-only foreign tables.

Value range: a valid TIMESTAMP value. Time zones cannot be used. For details, see **Date and Time Processing Functions and Operators**.

– datea_format

Specifies the DATEA format for data import. This syntax is available only for read-only foreign tables.

Value range: a valid DATEA value. Time zones are not supported. For details, see **Date and Time Processing Functions and Operators**.

– smalldatetime_format

Specifies the SMALLDATETIME format for data import. This syntax is available only for read-only foreign tables.

Value range: a valid SMALLDATETIME value. For details, see **Date and Time Processing Functions and Operators**.

– compatible_illegal_chars

Specifies whether to tolerate invalid characters during data import. This syntax is available only for read-only foreign tables.

Value range: **true**/**on** or **false**/**off**. The default value is **false**/**off**.

- **true** or **on**: No error message is reported and data import is not interrupted when there are invalid characters. Invalid characters are converted into valid ones, and then imported to the database.
- **false** or **off**: An error message is reported when there are invalid characters, and the import stops.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

The rules for converting invalid characters are as follows:

- Invalid characters are converted to the characters specified by the GUC parameter **convert_illegal_char_mode**. The default value is a question mark (?).
- Setting **compatible_illegal_chars** to **true** or **on** enables toleration of invalid characters. If **null**, **delimiter**, **quote**, and **escape** are set to spaces or question marks, error messages like "illegal chars conversion may confuse COPY escape 0x20" will be displayed to prompt you to modify parameters that may cause confusion, preventing importing errors.
- If the GUC parameter **copy_special_character_version** is set to **'no_error'**, invalid characters will not be checked during data import and query, and will be imported in the original format and displayed as garbled characters in query results. Therefore, exercise caution when enabling this parameter.
- The priority of the GUC parameter **copy_special_character_version** being set to **'no_error'** is higher than that of the GUC parameter **compatible_illegal_chars** being set to **true** or **on**.

- **READ ONLY**

  Specifies whether a foreign table is read-only. This parameter is available only for data import.

- **WRITE ONLY**

  Specifies whether a foreign table is write-only. This parameter is available only for data export.

- **WITH error_table_name**

  Specifies the table where data format errors generated during parallel data import are recorded. You can query the error information table after data is imported to obtain error details. This parameter is available only after **reject_limit** is set.

  Value range: character strings complying with **Identifier Naming Conventions**.

  NOTE

  To be compatible with PG open-source APIs, you are advised to replace this syntax with LOG INTO.

- **LOG INTO error_table_name**

  Specifies the table where data format errors generated during parallel data import are recorded. You can query the error information table after data is imported to obtain error details. This parameter is valid only when **PER NODE REJECT LIMIT 'value'** is set.

  Value range: character strings complying with **Identifier Naming Conventions**.

- **REMOTE LOG 'name'**

  Specifies that the data format error information is saved as files in GDS. **name** is the prefix of the error data file.

- **PER NODE REJECT LIMIT 'value'**

  Specifies the maximum number of data format errors allowed on each DN during data import. If the number of errors exceeds the specified value on any DN, data import fails, an error is reported, and the system exits data import.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Value range: an integer or **unlimited**. The default value is **0**, indicating that an error message is returned immediately.

NOTE

- This syntax specifies the error tolerance of a single node.
- Data format errors include the following: a column is lost, an extra column exists, a data type is incorrect, and encoding is incorrect. Once a non-data-format error occurs, the whole data scan process is stopped.

- **TO { GROUP groupname | NODE (nodename [, ...]) }**

  Currently, this syntax is not supported. It is only available for internal scale-out tools and should not be used by common users.

Examples

```
-- Create a foreign table to import data from GDS servers 192.168.0.90 and 192.168.0.91 in text format. Record errors that occur during data import to the err_HR_staffS table.
gaussdb=# CREATE FOREIGN TABLE foreign_HR_staffS
(
  staff_ID       NUMBER(6) ,
  FIRST_NAME     VARCHAR2(20),
  LAST_NAME      VARCHAR2(25),
  EMAIL          VARCHAR2(25),
  PHONE_NUMBER   VARCHAR2(20),
  HIRE_DATE      DATE,
  employment_ID  VARCHAR2(10),
  SALARY         NUMBER(8,2),
  COMMISSION_PCT NUMBER(2,2),
  MANAGER_ID     NUMBER(6),
  section_ID  NUMBER(4)
) SERVER gsmpp_server OPTIONS (location 'gsfs://192.168.0.90:5000/* | gsfs://192.168.0.91:5000/*', format 'TEXT', delimiter E'\x20',  null '') WITH err_HR_staffS;

-- Create a foreign table to import data from GDS servers 192.168.0.90 and 192.168.0.91 in text format and record error messages in the import process to the err_HR_staffS table. A maximum of two data format errors are allowed during the import.
gaussdb=# CREATE FOREIGN TABLE foreign_HR_staffS_ft3
(
  staff_ID       NUMBER(6) ,
  FIRST_NAME     VARCHAR2(20),
  LAST_NAME      VARCHAR2(25),
  EMAIL          VARCHAR2(25),
  PHONE_NUMBER   VARCHAR2(20),
  HIRE_DATE      DATE,
  employment_ID  VARCHAR2(10),
  SALARY         NUMBER(8,2),
  COMMISSION_PCT NUMBER(2,2),
  MANAGER_ID     NUMBER(6),
  section_ID  NUMBER(4)
) SERVER gsmpp_server OPTIONS (location 'gsfs://192.168.0.90:5000/* | gsfs://192.168.0.91:5000/*', format 'TEXT', delimiter E'\x20',  null '',reject_limit '2') WITH err_HR_staffS_ft3;

-- Create a foreign table to import all files in the input_data directory in CSV format.
gaussdb=# CREATE FOREIGN TABLE foreign_HR_staffS_ft1
(
  staff_ID       NUMBER(6) ,
  FIRST_NAME     VARCHAR2(20),
  LAST_NAME      VARCHAR2(25),
  EMAIL          VARCHAR2(25),
  PHONE_NUMBER   VARCHAR2(20),
  HIRE_DATE      DATE,
  employment_ID  VARCHAR2(10),
  SALARY         NUMBER(8,2),
  COMMISSION_PCT NUMBER(2,2),
  MANAGER_ID     NUMBER(6),
  section_ID     NUMBER(4)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
) SERVER gsmpp_server OPTIONS (location 'file:///input_data/*', format 'csv', mode 'private', delimiter ',')
WITH err_HR_staffS_ft1;

-- Create a foreign table to export data to the output_data directory in CSV format.
gaussdb=# CREATE FOREIGN TABLE foreign_HR_staffS_ft2
(
  staff_ID       NUMBER(6) ,
  FIRST_NAME     VARCHAR2(20),
  LAST_NAME      VARCHAR2(25),
  EMAIL          VARCHAR2(25),
  PHONE_NUMBER   VARCHAR2(20),
  HIRE_DATE      DATE,
  employment_ID  VARCHAR2(10),
  SALARY         NUMBER(8,2),
  COMMISSION_PCT NUMBER(2,2),
  MANAGER_ID     NUMBER(6),
  section_ID  NUMBER(4)
) SERVER gsmpp_server OPTIONS (location 'file:///output_data/', format 'csv', delimiter '|', header 'on')
WRITE ONLY;

-- Drop the foreign table.
gaussdb=# DROP FOREIGN TABLE foreign_HR_staffS;
gaussdb=# DROP FOREIGN TABLE foreign_HR_staffS_ft1;
gaussdb=# DROP FOREIGN TABLE foreign_HR_staffS_ft2;
gaussdb=# DROP FOREIGN TABLE foreign_HR_staffS_ft3;
```

Helpful Links

DROP FOREIGN TABLE

Suggestions

- delimiter
  - A delimiter cannot be **\r** or **\n**, or the same as the null value. The delimiter of CSV data cannot be same as the **quote** value.
  - The data length of a single row should be less than 1 GB. A row that has many columns using long delimiters cannot contain much valid data.
  - You are advised to use a multi-character or invisible characters, such as 0x07, 0x08, and 0x1b as the delimiter.
- quote
  - The value of **quote** cannot be the same as that of the **delimiter** or null parameter. The value must be a single-byte character.
  - You are advised to use invisible characters (such as 0x07, 0x08, and 0x1b) as quotes.
- mode Normal

  Supports all file formats (including CSV, TEXT, and FIXED). You need to enable GDS to help data import.
- mode Shared

  Supports the TEXT format. It does not need assistance from GDS, but requires that all the user data be mounted to the same path of the same nodes through NFS.
- mode Private

  User data has been stored in the same path under the local directory of the DN.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

1.13.9.22 CREATE FUNCTION

Description

Creates a function.

Precautions

- Permission:
  - By default, the EXECUTE permission on a function is granted to the **PUBLIC** role when the function is created. For details, see **GRANT**. Since users inherit permissions from **PUBLIC** by default, they gain the ability to execute the function and view its definition. However, to execute the function, users must also possess the USAGE permission on the schema where the function is located. It is possible to revoke the default EXECUTE permission from **PUBLIC** during function creation and grant it to specific users instead. To avoid having a window where the new function is accessible to all, create it and set the permissions within a single transaction. When the database object isolation attribute is enabled, common users can only view the definitions of functions for which they have the EXECUTE permission.
  - Users with the CREATE ANY FUNCTION permission can create or replace functions in the user schemas.
  - Non-initial users do not have the permission to perform the REPLACE operation on the functions of the initial user.
  - If a definer function is created in the schema of another user, it will be executed with that user's permissions, which may lead to unauthorized operations. Exercise caution.
  - The default permission on a function is SECURITY INVOKER. To change the default permission to SECURITY DEFINER, set the GUC parameter **behavior_compat_options** to **'plsql_security_definer'**.
- Compatibility:
  - Oracle Database-compatible functions are created for ORA-compatible databases, and PostgreSQL-compatible functions are created for PG-compatible databases. Hybrid creation is not recommended.
  - Functions compatible with Oracle Database support viewing, exporting, and importing parameter comments, and viewing, exporting, and importing comments between IS/AS and plsql_body.
- Function creation:
  - An agg function or a system function cannot be nested in another avg function.
  - You cannot create a function that has the same name and parameter list as a stored procedure.
  - The default value of the input parameter cannot be the function itself.
  - If the **current_schema** or **search_path** is set using the SET statement in a function, the setting takes effect only for the function during its execution. After the function execution is complete, the value is automatically restored to the value before the function is called. That is, the **search_path** and **current_schema** set in the function are the same before and after the function is executed.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

  - The type of the return value in the function is not checked. If the parameter or return value has precision, the precision is not checked.
  - In common cluster mode, return values, parameters, and variables cannot be set to the tables of the node groups that are not installed in the system by default. The internal statements of SQL functions cannot be executed on such tables.
- Function overloading:
  - Only the functions compatible with PG or those with the PACKAGE attribute can be overloaded. After **REPLACE** is specified, if the number of parameters, parameter type, or return value of a function is different, another function will be created instead of replacing the original one.
  - If a function supports overloading, you need to add the keyword PACKAGE. When an overloaded function is called, the variable type must be specified.
  - Overloaded functions cannot be created if they differ only in formal parameter names (that is, when function names and parameter list types are identical).
  - The following functions do not support function overloading: functions with only different return types, functions with only different default values, and functions with only different parameter forms in user-defined ref cursor and sys_refcursor.
- Function call:
  - Using an undeclared variable within a function will result in an error upon function calls. When a function without parameters is called in another function, you can directly call it by name (that is, you can omit the brackets).
  - The same function can be called via SELECT by specifying different parameters. The CALL syntax does not support calling identical functions without the PACKAGE attribute.
  - When the complex function is called, for example, func(x).a, a composite type is returned. Cross-schema call is supported, but the database.schema.package.func(x).b call is not supported.
  - In the RETURN statement of a function, when the constructor of the composite type is called, if the actual return type is different from the defined return type, the result can be implicitly converted to the defined return type. Cross-schema call, such as RETURN schema.record, is supported. Cross-database call, such as RETURN package.schema.record, is not supported. In the RETURN statement of a function, when the function is called, the function with the **OUT** parameter in an expression of an arithmetic operation is not supported, for example, **RETURN func(c out) + 1**.
  - A function with OUT parameters cannot be called in SQL statements (including the SELECT INTO syntax) and cannot be called in nested mode.
- GUC behavior control:
  - Functions contain syntax and functions that use GUC parameters to control features. If GUC parameters are modified in a session, the result may be inconsistent with the expected result. If the parameters are modified, the function may retain the behavior before the modification. Therefore, exercise caution when modifying GUC parameters.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

  - If a function has output parameters, the GUC parameter **behavior_compat_options** must be set to **'proc_outparam_override'** for the output parameters to take effect. When the function is called using SELECT or CALL, an argument must be provided in the position of the output parameter. Otherwise, the function fails to be called.
  - When other functions with output parameters are called in a function, specifically an assignment expression, set the GUC parameter **behavior_compat_options** to **'proc_outparam_override'**, define variables of the same type as the output parameters in advance, and use the variables as output parameters to call other functions with output parameters for the output parameters to take effect. Otherwise, the output parameters of the called functions will be ignored.
  - After the GUC parameter **behavior_compat_options** is set to **'proc_outparam_override'**, if the return type of the function is setof, the OUT parameter will not take effect. If the return value of the function is of the TABLE type, you must provide the actual parameter of the TABLE type when calling the function (SELECT or CALL). Otherwise, the function fails to be called.
  - If the GUC parameter **behavior_compat_options** does not contain **'proc_outparam_override'**, the OUT and INOUT parameters of the function directly called by an anonymous block or stored procedure cannot be of the composite type, and the return value is used as the first value of the OUT parameter. As a result, the call fails. To correctly use the OUT and INOUT parameters, set the GUC parameter **behavior_compat_options** to **'proc_outparam_override'**.
  - When a stored procedure with the OUT parameter is called, you can set the GUC parameter **behavior_compat_options** to **'proc_outparam_transfer_length'** to pass the parameter length. The specifications and constraints are as follows:
    - The following types are supported: CHAR(n), CHARACTER(n), NCHAR(n), VARCHAR(n), VARYING(n), VARCHAR2(n), and NVARCHAR2(n).
    - If the **OUT** parameter does not take effect (for example, **perform**), the length does not need to be passed.
    - Precisions cannot be specified for the following types: NUMERIC, DECIMAL, NUMBER, FLOAT, DEC, INTEGER, TIME, TIMESTAMP, INTERVAL, TIME WITH TIME ZONE, TIMESTAMP WITH TIME ZONE, TIME WITHOUT TIME ZONE, and TIMESTAMP WITHOUT TIME ZONE.
    - The parameter length can be specified regardless of whether the GUC parameter **behavior_compat_options** is set to **proc_outparam_override**.
    - To pass the length of elements of the collection type and the length of elements of the array type nested by the collection type, you need to set the GUC parameter **behavior_compat_options** to **tableof_elem_constraints**.

- Other behavior:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

The **OUT** parameter does not take effect in the following scenarios when it is used in an expression: The EXECUTE IMMEDIATE sqlv USING func syntax is used to execute a function. The SELECT func INTO syntax is used to execute a function. DML statements such as INSERT and UPDATE are used to execute a function. The SELECT WHERE a=func() method is used. A function with an OUT parameter is used as an input parameter (that is, fun(func(OUT b), a)) and the OUT parameter **b** does not take effect. A function with an OUT parameter is used to assign a default value to a variable.

Syntax

- PG-compatible syntax for creating a user-defined function:

```
CREATE [ OR REPLACE  ] FUNCTION function_name
   ( [  { argname [ argmode  ] argtype [  { DEFAULT  | :=  | =  } expression  ]}  [, ...]  ] )
   [ RETURNS rettype [ DETERMINISTIC  ]  | RETURNS TABLE (  { column_name column_type  }
[, ...] )]
   LANGUAGE lang_name
   [
     {IMMUTABLE  | STABLE  | VOLATILE }
      | {SHIPPABLE | NOT SHIPPABLE}
      | WINDOW
      | [ NOT  ] LEAKPROOF
      | {CALLED ON NULL INPUT  | RETURNS NULL ON NULL INPUT | STRICT }
      | {[ EXTERNAL  ] SECURITY INVOKER | [ EXTERNAL  ] SECURITY DEFINER | AUTHID DEFINER  |
AUTHID CURRENT_USER}
      | {fenced | not fenced}
      | {PACKAGE}
      | COST execution_cost
      | ROWS result_rows
      | SET configuration_parameter { {TO | =} value | FROM CURRENT }
   ][...]
   {
      AS 'definition'
      | AS 'obj_file', 'link_symbol'
   };
```

- Oracle-compatible syntax of creating a user-defined function:

```
CREATE [ OR REPLACE  ] FUNCTION function_name
   ( [  { argname [ argmode  ] argtype [  { DEFAULT | := | =  } expression  ] }  [, ...]  ] )
   RETURN rettype [ DETERMINISTIC  ]
   [
      {IMMUTABLE  | STABLE  | VOLATILE }
      | {SHIPPABLE | NOT SHIPPABLE}
      | {PACKAGE}
      | {FENCED | NOT FENCED}
      | [ NOT  ] LEAKPROOF
      | {CALLED ON NULL INPUT | RETURNS NULL ON NULL INPUT | STRICT }
      | {[ EXTERNAL  ] SECURITY INVOKER  | [ EXTERNAL  ] SECURITY DEFINER | AUTHID DEFINER |
AUTHID CURRENT_USER}
      | COST execution_cost
      | ROWS result_rows
      | SET configuration_parameter { {TO | =} value  | FROM CURRENT }
      | LANGUAGE lang_name
   ][...]
   {
     IS  | AS
   } plsql_body
/
```

Parameters

- **function_name**

  Name of the function to be created, which can be specified using a specific schema.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Value range: character strings complying with **Identifier Naming Conventions** and not exceeding 63 characters.

NOTE

- If the value contains more than 63 characters, the database truncates it and retains the first 63 characters as the function name.
- When creating a function for operations on tables, you are advised to explicitly specify the schemas of tables in the function definition. Otherwise, the function may fail to be executed.
- You are advised not to create a function with the same name as a system function. Otherwise, you need to specify the schema of the function when calling the function.

- **argname**

  Specifies the parameter name of the function.

  Value range: character strings complying with **Identifier Naming Conventions** and not exceeding 63 characters.

  NOTE

  If the value contains more than 63 characters, the database truncates it and retains the first 63 characters as the function parameter name.

- **argmode**

  Specifies the parameter mode of the function.

  Value range: **IN**, **OUT**, **INOUT**, and **VARIADIC**. The default value is **IN**.

  NOTE

  - **VARIADIC** specifies parameters of the array type.
  - **VARIADIC** can be added only to parameters in OUT mode, and parameters in OUT and INOUT modes cannot be used in the RETURNS TABLE function definition.

- **argtype**

  Specifies the data type of a function parameter. You can use **%ROWTYPE** to indirectly reference the type of a table, or **%TYPE** to indirectly reference the type of a column in a table or composite type.

  For details, see **Variable Definition Statements**.

- **expression**

  Specifies the default expression of a parameter.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- If **a_format_version** is set to **10c** and **a_format_dev_version** is set to **s2**, the default expression is not supported when the parameter is in INOUT mode.
- It is recommended that you define all default parameters after all non-default parameters.
- If a function with default parameters is called, input parameters are added to the function from left to right. If inputs of non-default parameters are missing, an error is reported.
- If **proc_uncheck_default_param** is enabled and a function with default parameters is called, input parameters are added to the function from left to right. The number of default inputs depends on the number of default parameters. If an input of a non-default parameter is missing, the previous default value is used to fill this parameter.
- When **a_format_version** is set to **10c**, **a_format_dev_version** is set to **s1**, **proc_outparam_override** is disabled, and the function parameters include **OUT** and **DEFAULT**, the default value cannot be used.

- **rettype**

  Specifies the return data type. Same as **argtype**, **%TYPE** or **%ROWTYPE** can also be used to indirectly reference types.

  When there is **OUT** or **INOUT** parameter, the RETURNS clause can be omitted. If the clause is not omitted, the result type of the clause must be the same as that of the output parameter. If there are multiple output parameters, the result type of the clause is RECORD. Otherwise, the result type of the clause is the same as that of a single output parameter. The SETOF modifier indicates that the function will return a set of items, rather than a single item.

- **column_name**

  Specifies the column name.

- **column_type**

  Specifies the column type.

  NOTE

  When the return type is RETURNS TABLE, each column is regarded as an **OUT** parameter. When the GUC parameter **behavior_compat_options** is set to **'proc_outparam_override'**, you must call functions using SELECT and CALL based on the actual parameters provided by the corresponding column. Otherwise, an error is reported, indicating that the function does not exist.

- **definition**

  Specifies a string constant defining a function. Its meaning depends on the language. It can be an internal function name, a path pointing to a target file, an SQL query, or text in a procedural language.

- **DETERMINISTIC**

  Specifies an API compatible with the SQL syntax, which is not supported in the current version.

- **LANGUAGE lang_name**

  Specifies the name of the language that the function is implemented in. It can be **SQL**, **C**, **internal**, or the name of a customized procedural language. To ensure compatibility, the name can be enclosed in single quotation marks (''). Contents in single quotation marks must be capitalized.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Due to compatibility issues, no matter which language is specified when an Oracle-compatible database is created, the language used is plpgsql.

NOTE

- When you define an internal function, if the AS clause specifies it as an internal system function, the parameter type, number of parameters, and return type of the new function must match those of the internal system function. Additionally, the user must have permission to execute the internal system function.
- Only users with the SYSADMIN permission can create internal functions.

- **WINDOW**

  Specifies that the function is a window function. This is currently only useful for functions written in C. The **WINDOW** attribute cannot be changed when replacing an existing function definition.

NOTICE

For a customized window function, the value of **LANGUAGE** can only be **internal**, and the referenced internal function must be a window function.

- **IMMUTABLE**

  Specifies that the function always returns the same result if the parameter values are the same.

- **STABLE**

  Specifies that the function cannot modify the database. Specifies that within a single table scan, it will consistently return the same result for the same parameter value, but its result varies by SQL statements.

- **VOLATILE**

  Specifies that the function value can change in a single table scan and no optimization is performed.

- **SHIPPABLE | NOT SHIPPABLE**

  Specifies whether the function can be pushed down to DNs for execution.

  – Functions of the IMMUTABLE type can always be pushed down to DNs.

  – Functions of the STABLE or VOLATILE type can be pushed down to DNs only if their attribute is **SHIPPABLE**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTICE

- If IMMUTABLE, STABLE, or VOLATILE is not specified, VOLATILE is used by default.
- If SHIPPABLE or NOT SHIPPABLE is not specified, NOT SHIPPABLE is used by default.
- The function or stored procedure of the SHIPPABLE or IMMUTABLE type cannot contain EXCEPTION or call functions or stored procedures that contain EXCEPTION.
- If you specify the IMMUTABLE or SHIPPABLE type when creating a function, do not perform INSERT, UPDATE, DELETE, MERGE, or DDL operations in the function. Otherwise, the execution result may be incorrect. The CN determines the execution node for the preceding operations. If DDL statements are executed in the function of the IMMUTABLE or SHIPPABLE type, database objects on each node may be inconsistent. To resolve this problem, create the VOLATILE PL/SQL function on the CN, run the EXECUTE statement in the function definition to dynamically execute the DDL operation for repairing system objects, and then use the EXECUTE DIRECT ON syntax to call the repair function on the specified DN.
- If the result of a function depends on the scanning of data tables or a function has modified data or performed DDL operations on data tables, do not set the function attribute to **IMMUTABLE** or **SHIPPABLE**. Otherwise, database execution may be abnormal.

- **PACKAGE**

  Specifies whether the function can be overloaded.

  – All PACKAGE and non-PACKAGE functions cannot be overloaded or replaced.

  – PACKAGE functions do not support parameters of the VARIADIC type.

  – The **PACKAGE** attribute of functions cannot be modified.

- **LEAKPROOF**

  Specifies that the parameters of the function include only the return value. Only users with the SYSADMIN permission can set **LEAKPROOF**.

- **CALLED ON NULL INPUT**

  Declares that some parameters of the function can be called in normal mode if the parameter values are **NULL**. This parameter can be omitted.

- **RETURNS NULL ON NULL INPUT | STRICT**

  Specifies that a function always returns **NULL** whenever any of its parameters is **NULL**. If **STRICT** is specified, the function is not executed when there is a NULL value. Instead, a NULL result is returned automatically.

  RETURNS NULL ON NULL INPUT and **STRICT** have the same functions.

- **EXTERNAL**

  (Optional) The purpose is to be compatible with SQL statements. **EXTERNAL** applies to all functions, not only external functions.

- **SECURITY INVOKER | AUTHID CURRENT_USER**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Specifies that the function will be executed with the permissions of the user who calls it. This parameter can be omitted.

SECURITY INVOKER and **AUTHID CURRENT_USER** have the same functions.

- **SECURITY DEFINER | AUTHID DEFINER**

  Specifies that the function will be executed with the permissions of the user who created it.

  AUTHID DEFINER and **SECURITY DEFINER** have the same functions.

- **FENCED | NOT FENCED**

  Specifies whether the function is executed in fenced mode or not fenced mode. In **NOT FENCED** mode, a function is executed in a CN or DN process. In **FENCED** mode, a function is executed in a new fork process, which does not affect CN or DN processes. You can choose **FENCED** or **NOT FENCED** by referring to the following:

  – Develop or debug a function in **FENCED** mode and execute it in **NOT FENCED** mode. This reduces the overhead of the fork process and communication.
  – Perform complex OS operations, such as opening a file, and processing signals and threads in **FENCED** mode; otherwise, the GaussDB database execution may be affected.
  – Customize PL/SQL functions. If this parameter is not specified, the default value **NOT FENCED** is used and the **FENCED** execution mode is not supported.

- **COST execution_cost**

  Estimates the execution cost of a function. The unit of **execution_cost** is **cpu_operator_cost**.

  Value range: a number greater than or equal to 0.

- **ROWS result_rows**

  Estimates the number of rows returned by the function. It is used only when the function returns a set.

  Value range: a number greater than or equal to 0. The default value is **1000**.

- **configuration_parameter**

  Set the parameters.

  – **value**

    Sets a specified database session parameter to a specified value.

    Value range: a string.

    - **DEFAULT**: The default system setting is used in the new session.
    - **OFF**: The setting is disabled.
    - **RESET**: The default system setting is used in the new session.
    - User-defined default value.

  – **FROM CURRENT**

    Uses the value of **configuration_parameter** of the current session.

- **plsql_body**

  Specifies the PL/SQL stored procedure body.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

When a stored procedure is created, the **PLSQL_BODY** can end with "END;" or "END function_name;". For details about the constraints for ending with "END function_name;", see **Note** in **CREATE PROCEDURE**.

NOTE

When you are performing operations in the function body related to passwords or keys, such as creating a user, changing a password, encrypting, or decrypting, the system catalogs and logs record plaintext information about the passwords or keys. To prevent sensitive information leakage, you are advised not to perform operations on the function body related to sensitive information, such as passwords or keys.

Examples

```
-- Create an ORA-compatible database.
gaussdb=# CREATE DATABASE ora_compatible_db DBCOMPATIBILITY 'ORA';
CREATE DATABASE

-- Switch to another database.
gaussdb=# \c ora_compatible_db

-- Define a function as SQL query.
ora_compatible_db=# CREATE FUNCTION func_add_sql(integer, integer) RETURNS integer
    AS 'select $1 + $2;'
    LANGUAGE SQL
    IMMUTABLE
    RETURNS NULL ON NULL INPUT;

-- Add an integer by parameter name using PL/pgSQL.
ora_compatible_db=# CREATE OR REPLACE FUNCTION func_increment_plsql(i integer) RETURNS integer AS
$$
        BEGIN
            RETURN i + 1;
        END;
    $$ LANGUAGE plpgsql;

-- Return the RECORD type.
ora_compatible_db=# CREATE OR REPLACE FUNCTION compute(i int, out result_1 bigint, out result_2
bigint)
    RETURNS SETOF RECORD
    AS $$
    BEGIN
        result_1 = i + 1;
        result_2 = i * 10;
    RETURN next;
    END;
    $$ LANGUAGE plpgsql;

-- Return a record containing multiple output parameters.
ora_compatible_db=# CREATE FUNCTION func_dup_sql(in int, out f1 int, out f2 text)
    AS $$ SELECT $1, CAST($1 AS text) || ' is text' $$
    LANGUAGE SQL;

-- Call the func_dup_sql function.
ora_compatible_db=# SELECT * FROM func_dup_sql(42);
 f1 |     f2
----+------------
 42 | 42 is text
(1 row)

-- Compute the sum of two integers and returning the result (if the input is null, the returned result is null):
ora_compatible_db=# CREATE FUNCTION func_add_sql2(num1 integer, num2 integer) RETURN integer
    AS
    BEGIN
        RETURN num1 + num2;
    END;
    /
```

ALTER FUNCTION and **DROP FUNCTION**

1.13.9.23 CREATE GLOBAL INDEX

Description

Creates a global secondary index (GSI) on a specified table.

The GSIs allow users to define indexes that are inconsistent with the distribution of base tables. In this way, single-node plans for querying non-distributed keys of base tables and unique/primary key constraints on non-distributed keys of base tables are achieved.

NOTE

You are advised to create GSIs on a base table as ordinary indexes to improve DML operation execution efficiency. In addition, after the GSIs are created on the base table, the DML operation performance is affected and deteriorates.

Limitations

- Only the GTM-lite mode is supported.
- GSIs can contain expressions but have the following constraints:
  - Similar to the base table limitations, distribution keys cannot contain expressions. In addition, GSIs must not contain expressions only because the distribution keys would be expressions definitely in this case.
  - Similar to ordinary index constraints, CONTAINING columns cannot contain expressions.
  - If any column name is prefixed with "expr", no GSI containing an expression can be created.
- Creating a GSI:
  - A GSI whose distribution is the same as that of the base table cannot be created.
  - The base table cannot be a replication table or list/range distributed table. GSIs support only hash distribution.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

  - If the base table is a partitioned non-hash bucket table, the GSI allows a maximum of 27 columns. If the base table is a non-partitioned hash bucket table, the GSI allows a maximum of 27 columns. If the base table is a partitioned hash bucket table, the GSI allows a maximum of 26 columns. If the base table is a non-partitioned non-hash bucket table, the GSI allows a maximum of 28 columns.

- Online GSI creation/rebuild:

  CREATE GSI CONCURRENTLY cannot be used for expression indexes or partial indexes.

Precautions

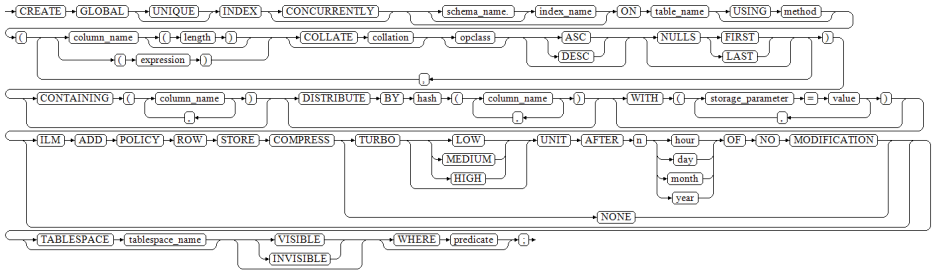
- For GSI creation, GSI rebuild, and operations related to GSI rebuild, for example, partitioning operations (such as DROP, TRUNCATE, MERGE, SPLIT, and EXCHANGE PARTITION) on a partitioned table, UPDATE DISTRIBUTED GLOBAL INDEX, ALTER TABLE involving data rebuild, as well as ALTER SET TABLESPACE and MOVE PARTITION operations on a hash bucket table, you are advised to enable the STREAM mode to achieve optimal performance. To enable the STREAM mode, set **enable_stream_operator** to **on** and **create_gsi_opt** to **build**.
- If the VACUUM FULL, CLUSTER, or REINDEX operation on a table is interrupted, the GSI on the table may turn to the **UNUSABLE** state. In this case, an error will be reported when the GSI is queried. You are advised to run **REINDEX INDEX** to rebuild the GSI.
- When executing **COPY** or **GDS** to import data to a base table with a GSI, the **enable_stream_operator** parameter must be enabled to achieve optimal data import performance.
- TABLE ACCESS BY INDEX ROWID supports STREAM and non-STREAM distributed plans. The STREAM plans utilizing TABLE ACCESS BY INDEX ROWID inherit STREAM-related limitations. Considering the STREAM communication latency, when the selectivity is too low or the number of predicate hit rows is small, the performance is not optimal. In this case, you are advised not to use a STREAM plan utilizing TABLE ACCESS BY INDEX ROWID. For a non-STREAM plan utilizing TABLE ACCESS BY INDEX ROWID, GSI table hints are required. This plan is applicable to scenarios where the number of predicate hit rows is small. If the performance of a STREAM plan utilizing TABLE ACCESS BY INDEX ROWID is not optimal, you can use a non-STREAM plan utilizing TABLE ACCESS BY INDEX ROWID. For details, see "Optimization Cases > Case: Using Global Secondary Indexes to Accelerate Query" in *SQL Optimization Guide*.
- In the batch INSERT INTO SELECT, UPDATE, DELETE, and UPSERT scenarios, you are advised to enable the **enable_stream_operator** parameter to execute the STREAM plan. (If the base table is a hash bucket table or tamper-proof table, the CN plan is still used.) If **enable_stream_operator** is disabled, the execution plan goes back to the CN, and the performance is poor.
- For the DELETE, UPDATE, and UPSERT statements executed on a base table with GSIs, if the STREAM plan is used, the restrictions are the same as those of UPDATE. The same row cannot be concurrently updated.
- GSI supports UPSERT. The restrictions are the same as those of common UPSERT. For details, see **Parameters**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- The following operations will invalidate GSIs: database-level REINDEX, database-level/partition-level CLUSTER, and ALTER TABLE PARTITION (DROP, TRUNCATE, MERGE, SPLIT, and EXCHANGE PARTITION). If **UPDATE DISTRIBUTED GLOBAL INDEX** is not specified, all GSIs on both partitioned and ordinary tables will be invalidated.
- GSIs cannot be created for a base table when any column name, such as **ctid**, **xc_node_hash**, **xmin**, **xmax**, **tableoid** (for a partitioned table), or **tablebucketid** (for a hash bucket table) of the base table is duplicate with an existing column name after it is suffixed with "_new$$" or "_NEW$$."
- Concurrent GSI rebuild using REINDEX INDEX is not supported, which may block services.
- GSI-based table access by index row ID is a cross-DN operation. When the optimizer preferentially generates a pushdown plan, it cannot generate a plan that uses the GSI for table access by index row ID.

Syntax

```
CREATE GLOBAL [ UNIQUE ] INDEX [ CONCURRENTLY ] [ [schema_name.]index_name ] ON table_name
[ USING method ]
    ({ { column_name [ ( length ) ] | ( expression ) } [ COLLATE collation ] [ opclass ] [ ASC | DESC ]
[ NULLS { FIRST | LAST } ] }[, ...] )
    [CONTAINING (column_name [ ,... ])] [DISTRIBUTE BY hash(column_name [ ,... ])][ WITH
( {storage_parameter = value} [, ... ] )] [ ILM ADD POLICY ROW STORE COMPRESS { TURBO [ LOW |
MEDIUM | HIGH ] UNIT AFTER n { hour | day | month | year } OF NO MODIFICATION| NONE}]
    [ TABLESPACE tablespace_name ] [ VISIBLE | INVISIBLE ] [ WHERE predicate];
```



Parameters

- **UNIQUE**

  Creates a unique index. This causes the system to check for duplicate values in the table each time data is added. If the inserted or updated value causes duplicate records, an error is reported.

- **CONCURRENTLY**

  Creates an index (with ShareUpdateExclusiveLock) in a mode that does not block DML statements. When an index is created, other statements cannot access the table on which the index depends. If this keyword is specified, DML statements are not blocked during the creation.

  – The CREATE GLOBAL INDEX statement can be run within a transaction, but CREATE GLOBAL INDEX CONCURRENTLY cannot.

  – An index may fail to be created online. The possible causes are as follows: A user issues an instruction for terminating the online creation command. The definition of the index is modified. The definition of the base table is modified and the definition of the index is affected. For a non-critical error, an error message is displayed when online index building fails and

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

the system attempts to automatically clear the index. For a critical error, such as FATAL, PANIC, and database fault, and a clearing failure, an unusable index is left. This index is ignored by queries, but it still consumes the IUD overhead. Therefore, you are advised to use the DROP INDEX IF EXISTS syntax to drop the index and create the index online, or use the REINDEX/REBUILD syntax to rebuild the index.

- Do not use CREATE GLOBAL INDEX CONCURRENTLY together with other DDL operations. Otherwise, deadlocks or errors may occur. In this case, reconnect to the client and try again.
- For other precautions, see **CONCURRENTLY** in **CREATE INDEX**.

- **schema_name**

  Specifies a schema name.

  Value range: existing schema names.

- **index_name**

  Specifies the name of the index to be created. No schema name can be included here; the index is always created in the same schema as its parent table.

  Value range: character strings complying with **Identifier Naming Conventions**.

- **table_name**

  Specifies the name (optionally schema-qualified) of the table to be indexed.

  Value range: existing table names.

- **USING method**

  Specifies the method used to create the index.

  Value range: UB-tree. The multi-version B-tree index is provided. The index page contains transaction information.

- **column_name**

  Specifies the name of the column on which the index is to be created.

  If the index mode supports composite indexes, multiple columns can be declared. A maximum of 28 columns can be declared for a non-partitioned base table, and a maximum of 27 columns can be declared for a partitioned base table.

- **column_name (length)**

  Prefix keys are supported. For details, see **column_name (length)** in **CREATE INDEX**.

  As an expression index, the prefix index has the same constraints as the expression key in GSI.

- **expression**

  Specifies an expression based on one or more columns of the table. The expression usually must be written with surrounding parentheses, as shown in the syntax. However, the parentheses can be omitted if the expression has the form of a function call. Expression indexes can be used to obtain fast access to data based on some transformation of the basic data. For example, an index computed on upper(col) would allow the clause WHERE upper(col) = 'JIM' to use an index. If the expression includes the IS NULL clause, the index will be invalid. In this case, you are advised to create a partial index.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **COLLATE collation**

  Specifies a collation for the column to be indexed (which must be of a collatable data type). If not specified, the default collation is used. You can run the **SELECT * FROM pg_collation;** command to query collations from the pg_collation system catalog. The row starting with **default** in the query result represents the default collation.

- **opclass**

  Specifies the name of an operator class. An operator class can be specified for each column of an index. The operator class identifies the operators to be used by the index for that column.

- **ASC**

  Sorts data in ascending order (default).

- **DESC**

  Sorts data in descending order.

- **NULLS FIRST**

  Specifies that null values appear before non-null values in the sort ordering. This is the default when **DESC** is specified.

- **NULLS LAST**

  Specifies that null values appear after non-null values in the sort ordering. This is the default when **DESC** is not specified.

- **CONTAINING**

  Specifies the base table attributes other than index keys contained in the GSI.

- **CONTAINING (column_name [, ...])**

  Specifies the base table attributes other than index keys contained in the GSI.

- **DISTRIBUTE BY**

  Specifies the distribution key of the GSI, which is different from that of the base table, and only the hash distribution can be used.

- **DISTRIBUTE BY hash(column_name [,...])**

  Specifies the distribution key of the GSI.

  It needs to be included in the index key.

- **WITH ({storage_parameter = value} [, ...])**

  Specifies the storage parameters of the GSI.

  Value range:

  - **FILLFACTOR**

    Specifies a fillfactor for the index. It is a percentage between 10 and 100.

    Value range: 10–100.

  - **STORAGE_TYPE**

    Specifies the GSI storage type.

    Value range: **USTORE**

  - **INDEXSPLIT**

    Controls the method of selecting a proper split point for UB-tree, which is the same as that for B-tree.

    Value range: **DEFAULT** or **INSERTPT**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **enable_tde**

  Specifies the index as an encryption index. The database automatically encrypts the data in the encrypted index before storing it. Before using this parameter, ensure that the TDE function has been enabled using the GUC parameter **enable_tde**, the information for accessing the key service has been set using the GUC parameter **tde_key_info**, and the **enable_tde** attribute has been set for the base table. For detailed usage, consult "Feature Usage Guidelines > Transparent Data Encryption" in *Developer Guide*. This parameter supports only B-tree and UB-tree indexes. Other indexes such as hash indexes are not supported.

  Value range: **on** and **off**. If **enable_tde** is set to **on**, the values of **key_type**, **tde_cmk_id**, and **dek_cipher** are automatically generated in the database.

  Default value: **off**

- **encrypt_algo**

  Specifies the algorithm for encrypting indexes. This parameter must be used together with **enable_tde**.

  Value range: a string. Valid values are **AES_128_CTR**, **SM4_CTR**, **AES_128_CTR_SHA256_HMAC**, **SM4_CTR_SM3_HMAC**, and **AES_128_GCM**.

  Default value: If **enable_tde** is set to **on** and the subparameter **table_algorithm** in the GUC parameter **tde_encrypt_config** is not empty, the default value is the same as that of **table_algorithm**. If **table_algorithm** is empty, the default value is **AES_128_CTR**. If **enable_tde** is set to **off**, the default value is null.

- **dek_cipher**

  Specifies the DEK ciphertext. This parameter cannot be manually set or modified. After you set the **enable_tde** parameter for the index, the index automatically copies **dek_cipher** from the base table.

  Value range: a string.

  Default value: null

- **key_type**

  Specifies the type of the master key. This parameter cannot be manually set or modified. After you set the **enable_tde** parameter for the index, the index automatically copies **key_type** from the base table.

  Default value: null

- **cmk_id**

  Specifies the ID of the master key. This parameter cannot be manually set or modified. After you set the **enable_tde** parameter for the index, the index automatically copies **cmk_id** from the base table.

  Value range: a string.

  Default value: null

- opt_with_pkey

  Specifies that the created GSI is a primary key optimization index. This parameter can be specified only during creation and cannot be set or modified.

  Value range: **on** and **off**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Default value: **off**

NOTE

- A primary key can be created on GSIs using the **opt_with_pkey** option (referred to as primary key optimization GSI). When a table is updated, if the updated columns do not involve the columns of the primary key optimization GSI, the primary key optimization GSI is not updated, thereby improving the update performance.
- When creating or rebuilding a primary key optimization GSI, ensure that a non-GSI primary key index in the USABLE state exists in the table.
- If the cluster upgrade is not committed, the primary key optimization GSI cannot be created.
- Expression index GSIs and partial index GSIs with primary key optimization cannot be created.
- If a primary key optimization GSI exists in the target table, the primary key cannot be directly deleted. It can only be deleted in cascading mode (CASCADE).
- If the primary key optimization GSI exists in the target table, the primary key index is invalidated (UNUSABLE), and all primary key optimization GSIs are invalidated.
- The primary key optimization status (**opt_with_pkey**) can only be specified during creation and cannot be changed.

– new_partbucket_gsi

Specifies whether the new data structure is used for the GSI created on the partitioned hash bucket table. This parameter is automatically specified when the GSI is created.

Value range: **on**.

Default value: **on**.

NOTE

- During the upgrade observation period of the first upgrade to a version that supports the **new_partbucket_gsi** option, the **new_partbucket_gsi** option cannot be specified.
- If you attempt to specify the **new_partbucket_gsi** option on a GSI that is not on a partitioned hash bucket table or a non-GSI, an error will be reported.
- REINDEX does not affect the value of the **new_partbucket_gsi** option.
- The value of the **new_partbucket_gsi** option cannot be changed using the ALTER syntax.

- **[ILM ADD POLICY ROW STORE COMPRESS { TURBO [LOW | MEDIUM | HIGH] UNIT AFTER n { hour | day | month | year } OF NO MODIFICATION | NONE}]**

  – When creating a GSI, you can call ILM ADD POLICY to add a cross-page transparent compression policy. For example:

  ```
  CREATE GLOBAL INDEX gsi_idx on t1(a) ILM ADD POLICY ROW STORE COMPRESS TURBO HIGH UNIT AFTER 3 HOUR OF NO MODIFICATION;
  ```

  The command creates the gsi_idx index and adds a cross-page transparent compression policy with a high policy level and a 3-hour cold and hot data management interval.

  Where, AFTER n { hour | day | month | year } OF NO MODIFICATION indicates the compression groups that are not modified in *n* hours, days, months, or years.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

  - When creating an index, you can call ILM ADD POLICY ROW STORE COMPRESS NONE to explicitly specify that no cross-page transparent compression policy is applied to the index.

- **TABLESPACE tablespace_name**

  Specifies a tablespace for the index. If not specified, the default tablespace is used.

  Value range: existing tablespace names.

- **VISIBLE**

  Sets the index to be visible. This is the default option.

  NOTE

  - VISIBLE can be set only in an ORA-compatible database (that is, **sql_compatibility** is set to **'ORA'**).
  - When **disable_keyword_options** is set to **"visible"**, this keyword cannot be used.
  - This keyword is not supported in the upgrade uncommitted phase.

- **INVISIBLE**

  Sets the index to be invisible.

  NOTE

  - INVISIBLE can be set only in an ORA-compatible database (that is, **sql_compatibility** is set to **'ORA'**).
  - When **disable_keyword_options** is set to **"invisible"**, this keyword cannot be used.
  - This keyword is not supported in the upgrade uncommitted phase.

- **WHERE predicate**

  Creates a partial index. A partial index contains entries for only a portion of a table, usually a portion that is more useful for indexing than the rest of the table. For example, if you have a table that contains both billed and unbilled orders where the unbilled orders take up a small portion of the total table and yet that is an often used portion, you can improve performance by creating an index on just that portion. In addition, the WHERE clause with a UNIQUE constraint can be used to enforce uniqueness over a subset of a table.

  Value range: The predicate expression can only refer to columns of the underlying table, but it can use all columns, not just the ones being indexed. Currently, subqueries and aggregate expressions are forbidden in the WHERE clause. You are advised not to use a predicate of numeric types such as int because such types can be implicitly converted to Boolean values (non-zero values are implicitly converted to **true** and **0** is implicitly converted to **false**), which may cause unexpected results.

Examples

```
-- Create a base table test1 that contains three columns.
gaussdb=# CREATE TABLE test1(c1 int, c2 int, c3 int);

-- Create a GSI on the c2 column of the test table containing the c3 column based on the hash distribution of the c2 column.
gaussdb=# CREATE GLOBAL INDEX idx_gsi_1 ON test1(c2) CONTAINING(c3) DISTRIBUTE BY HASH(c2);

-- Create a base table test2 that contains three columns.
gaussdb=# CREATE TABLE test2(c1 int, c2 int, c3 int);
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
-- Create a GSI on the c2 column of the test2 table containing the c3 column based on the hash distribution of the c2 column.
gaussdb=# CREATE GLOBAL INDEX idx_gsi_2 ON test2(c2) CONTAINING(c3);

-- Create a base table test3 that contains three columns.
gaussdb=# CREATE TABLE test3(c1 int, c2 int, c3 int);

-- Create a GSI in UNIQUE form on the c2 column of the test3 table, which is based on the hash distribution of the c2 column by default.
gaussdb=# CREATE GLOBAL UNIQUE INDEX idx_gsi_3 ON test3(c2) DISTRIBUTE BY HASH(c2);

-- Drop the index.
gaussdb=# DROP INDEX idx_gsi_1;
gaussdb=# DROP INDEX idx_gsi_2;
gaussdb=# DROP INDEX idx_gsi_3;

-- Drop the table.
gaussdb=# DROP TABLE test1;
gaussdb=# DROP TABLE test2;
gaussdb=# DROP TABLE test3;
```

1.13.9.24 CREATE GROUP

Description

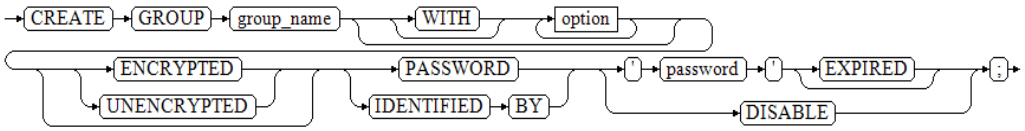
Creates a user group.

Precautions

CREATE GROUP is an alias for **CREATE ROLE** and is not a standard SQL syntax; its use is therefore discouraged. You are advised to use **CREATE ROLE** directly.

Syntax

```
CREATE GROUP group_name [ [ WITH ] option [ ... ] ]
    [ ENCRYPTED | UNENCRYPTED ] { PASSWORD | IDENTIFIED BY } { 'password' [ EXPIRED ] | DISABLE };
```



The syntax of the option clause (optional) is as follows:

```
{{SYSADMIN | NOSYSADMIN}
    | {MONADMIN | NOMONADMIN}
    | {OPRADMIN | NOOPRADMIN}
    | {AUDITADMIN | NOAUDITADMIN}
    | {CREATEDB | NOCREATEDB}
    | {USEFT | NOUSEFT}
    | {CREATEROLE | NOCREATEROLE}
    | {INHERIT | NOINHERIT}
    | {LOGIN | NOLOGIN}
    | {REPLICATION | NOREPLICATION}
    | {PERSISTENCE | NOPERSISTENCE}
    | CONNECTION LIMIT connlimit
    | VALID BEGIN 'timestamp'
    | VALID UNTIL 'timestamp'
    | RESOURCE POOL 'respool'
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
  | USER GROUP 'groupuser'
  | PERM SPACE 'spacelimit'
  | TEMP SPACE 'tmpspacelimit'
  | SPILL SPACE 'spillspacelimit'
  | NODE GROUP logic_group_name
  | IN ROLE role_name [, ...]
  | IN GROUP role_name [, ...]
  | ROLE role_name [, ...]
  | ADMIN role_name [, ...]
  | USER role_name [, ...]
  | SYSID uid
  | DEFAULT TABLESPACE tablespace_name
  | PROFILE DEFAULT
  | PROFILE profile_name
  | PGUSER}
```

Parameters

For details, see **CREATE ROLE** in **Parameters**.

Examples

```
-- Create a user group. The effect is the same as that of CREATE ROLE.
gaussdb=# CREATE GROUP test_group WITH PASSWORD "********";

-- Run CREATE ROLE to create a role. You cannot log in to the database by default.
-- Run ALTER ROLE role_name WITH LOGIN to enable users to log in to the database.
gaussdb=# CREATE ROLE test_role WITH PASSWORD "********";

-- Run CREATE USER to create a user. A schema with the same name is automatically created and the user has the login permission.
gaussdb=# CREATE USER test_user WITH PASSWORD "********";

-- View the user information.
gaussdb=# \du test*
            List of roles
 Role name  |  Attributes  | Member of
------------+--------------+-----------
 test_group | Cannot login | {}
 test_role  | Cannot login | {}
 test_user  |              | {}

-- Query the schema automatically created by the CREATE USER command.
gaussdb=# \dn test*
    List of schemas
   Name    |   Owner
-----------+-----------
 test_user | test_user
(1 row)

-- Drop.
gaussdb=# DROP ROLE test_role;
gaussdb=# DROP GROUP test_group;
gaussdb=# DROP USER test_user;
```

1.13.9.25 CREATE INCREMENTAL MATERIALIZED VIEW

Description

Creates a fast-refresh materialized view. You can refresh the data of a materialized view using REFRESH MATERIALIZED VIEW (complete-refresh) or REFRESH INCREMENTAL MATERIALIZED VIEW (fast-refresh).

The CREATE INCREMENTAL MATERIALIZED VIEW statement has similar functions as the CREATE TABLE AS statement. However, the CREATE INCREMENTAL MATERIALIZED VIEW statement persistently stores the initialization query statement to support subsequent data refresh operations. Materialized views have the same persistence property as ordinary tables. However, unlike temporary tables, the system does not support the creation of temporary materialized views.

NOTE

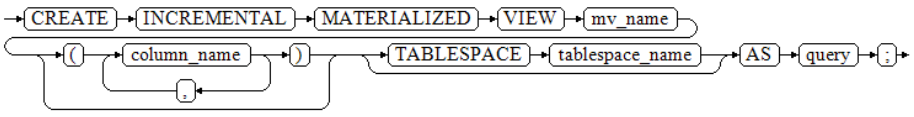
For details about the application scenarios, see "Basic Concepts > Materialized Views" in *Developer Guide*.

Precautions

- Fast-refresh materialized views cannot be created on database link tables, temporary tables, or global temporary tables.
- Fast-refresh materialized views support only simple filter queries and UNION ALL queries of base tables.
- Fast-refresh materialized views do not support clauses WITH, GROUP BY, ORDER BY, LIMIT, and WINDOW. Operators DISTINCT and AGG are not supported. Subqueries except UNION ALL are not supported.
- The distribution key cannot be specified when a fast-refresh materialized view is created.
- After a fast-refresh materialized view is created, most DDL operations in the base table are no longer supported.
- The IUD operation cannot be performed on fast-refresh materialized views.
- After a fast-refresh materialized view is created, you need to run the **REFRESH** command to synchronize the materialized view with the base table when the base table data changes.
- The Ustore does not support the creation and use of materialized views.

Syntax

```
CREATE INCREMENTAL MATERIALIZED VIEW mv_name
   [ (column_name [, ...] ) ]
   [ TABLESPACE tablespace_name ]
   AS query;
```



Parameters

- **mv_name**

Name of the created materialized view, which can be specified using a schema.

Value range: character strings complying with **Identifier Naming Conventions**.

- **column_name**

  Name of a column in the new materialized view. The materialized view supports specified columns. The number of specified columns must be the same as that of columns in the result of the subsequent query statement. If no column name is specified, the column name is obtained from the output column name of the query.

  Value range: character strings complying with **Identifier Naming Conventions**.

- **TABLESPACE tablespace_name**

  (Optional) Tablespace to which the new materialized view belongs. If it is not specified, the default tablespace is used.

- **AS query**

  SELECT or **TABLE** command. This query will be run in a security-constrained operation.

Examples

```
-- Create a tablespace.
gaussdb=# CREATE TABLESPACE tbs_data1 RELATIVE LOCATION 'tablespace1/tbs_data1';

-- Create an ordinary table.
gaussdb=# CREATE TABLE my_table (c1 int, c2 int);

-- Create a fast-refresh materialized view.
gaussdb=# CREATE INCREMENTAL MATERIALIZED VIEW my_imv (col1,col2) TABLESPACE tbs_data1 AS
SELECT * FROM my_table;

-- Write data to the base table.
gaussdb=# INSERT INTO my_table VALUES(1,1);

-- Query fast-refresh materialized view data.
gaussdb=# SELECT * FROM my_imv;
 col1 | col2
------+------
(0 rows)

-- Fast refresh the fast-refresh materialized view my_imv.
gaussdb=# REFRESH INCREMENTAL MATERIALIZED VIEW my_imv;

-- Query fast-refresh materialized view data.
gaussdb=# SELECT * FROM my_imv;
 col1 | col2
------+------
    1 |    1
(1 row)

-- Delete a fast-refresh materialized view.
gaussdb=# DROP MATERIALIZED VIEW my_imv;

-- Delete the ordinary table my_table.
gaussdb=# DROP TABLE my_table;

-- Delete the tablespace.
gaussdb=# DROP TABLESPACE tbs_data1;
```

ALTER MATERIALIZED VIEW, **CREATE MATERIALIZED VIEW**, **CREATE TABLE**, **DROP MATERIALIZED VIEW**, **REFRESH INCREMENTAL MATERIALIZED VIEW**, and **REFRESH MATERIALIZED VIEW**

1.13.9.26 CREATE INDEX

Description

Defines a new index.

Indexes are primarily used to enhance database performance (though inappropriate use can result in slower performance). You are advised to create indexes on:

- Columns that are often queried.
- Join conditions. For a query on joined columns, you are advised to create a composite index on the columns. For example, for **SELECT * FROM t1 JOIN t2 ON t1.a=t2.a AND t1.b=t2.b**, you can create a composite index on columns **a** and **b** in the **t1** table.
- Columns having filter criteria (especially scope criteria) of a WHERE clause.
- Columns that are frequently used after **ORDER BY**, **GROUP BY**, and **DISTINCT**
- The system determines whether to create an index on a partitioned table based on the following rules:
  - If the GLOBAL or LOCAL keyword is specified during index creation, the index of the corresponding type will be created.
  - If a partition name is specified during index creation, a local index will be created.
  - If a UNIQUE index contains all partition keys, a local index is created. Otherwise, a global index is created.
  - By default, a global index is created.

Precautions

- If the base table is a hash distributed table, to create a primary key or unique index that does not contain the distribution key of the base table, use a GSI (using CREATE GLOBAL INDEX); to create a primary key or unique index that contains the distribution key of the base table, use an ordinary index (using CREATE INDEX). In single-DN deployment mode, both the GSI and ordinary index can be successfully created. If the base table is a non-hash distributed table, you can only create the primary key or unique index as an ordinary index (using CREATE INDEX). That is, the index key must contain the distribution key of the base table.
- Indexes consume storage and computing resources. Creating excessive indexes may negatively impact database performance—particularly during data import. It is advisable to import data before creating indexes
- All functions and operators used in an index definition must be "immutable", that is, their results must depend only on their input parameters and never on any outside influence (such as the contents of another table or the current

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

time). To use a user-defined function in an index or WHERE clause, remember to mark the function immutable when you create it.

- Indexes on partitioned tables are classified into local or global indexes. A local index is specific to a partition within a partitioned table, while a global index spans the entire partitioned table.
- In the same set of columns, you cannot create both a local index and a global index.
- Users with the CREATE ANY INDEX permission can create indexes in the public and user schemas.
- If the base table is distributed in hash, range, or list mode, the distribution key of the base table must be included when a unique index is created, and no expression is allowed.
- If a user-defined function is called in an expression index, the expression index function is executed based on the permission of the table owner.
- All users can create expression indexes on their own tables. Non-initial user cannot create expression indexes on the tables of the initial user. The initial user can create expression indexes on all tables. When separation of duties is disabled, a system administrator can create expression indexes on non-initial user tables. When separation of duties is enabled, a system administrator can create expression indexes on tables of common users, but cannot create expression indexes on tables of the initial user and the AUDITADMIN and CREATEROLE roles.
- Data of the XML type cannot be used as ordinary indexes, unique indexes, global indexes, local indexes, or partial indexes.
- Only B-tree and UB-tree indexes can be created online. Only ordinary indexes of non-partitioned tables, as well as global and local indexes of partitioned tables can be created. PCR UB-tree indexes, subpartitions, and GSIs are not supported. Only ordinary indexes, global indexes, and local indexes of Astore and Ustore can be created online in parallel.
- Currently, UGINs support only the Ustore and single-column indexes. For details about other scenarios, see **Description for the USING ugin syntax**.
- GIN and GiST indexes are only supported by Astore. For details about other scenarios, see the syntax description.
- Creating an index using CREATE INDEX may change the table access mode. As a result, the query execution plan changes.
- Due to structural constraints, the B-tree index requires at least three index tuples per page, resulting in a maximum index length limitation. The maximum length of a single index tuple for B-tree and UB-tree indexes is 2696 bytes. However, for the UB-tree index of Ustore, the actual maximum length of a single index tuple is 2688 bytes due to the inclusion of transaction information. Creating an index for a field exceeding the maximum length triggers an error, and migrating from the Astore table to the Ustore table may cause the corresponding index creation to fail.
- Indexes containing **rowid** and **rowno** system columns cannot be created.
- If the SQL statement for creating an index is too long (greater than or equal to 5250 characters), a warning is reported. You are advised to shorten the SQL statement for creating an index.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

> **NOTE**
>
> If the SQL statement for creating an index is too long, it may cause failures during index backup and restoration. The statement for creating an index during backup and restoration is exported by gs_dump. When gs_dump exports the index definition, it adds quotation marks, parentheses, and column types to the function name, condition, and column name. Therefore, the original SQL statement becomes longer. As a result, the pg_index tuple corresponding to the statement cannot be stored on a page, and the index fails to be created.

- When creating a composite index, you need to create it based on query conditions and the leftmost matching principle of the composite index.

  > **NOTE**
  >
  > - Leftmost matching principle of a composite index: If a query condition contains one or more columns of a composite index, the leftmost consecutive columns of the composite index must match the query condition.
  > - When the query condition is **WHERE a = ?, b = ?,c = ?, d =?** or **WHERE a = ?, b = ?,c = ?**, the optimal index matching is used. When the query condition is WHERE **b = ?,c = ?, d =?** or **WHERE c = ?, d = ?**, the index **idx_test_abcd** may be executed after cost calculation. However, in such cases, all pages of the index are scanned, resulting in unsatisfactory SQL performance. In similar cases, you are advised to create a composite index suitable for the query condition based on the leftmost matching principle.
  >
  > ```
  > -- Create the test table.
  > gaussdb=# CREATE TABLE test(a int, b int, c int, d int, e int, f text);
  > Create a composite index.
  > gaussdb=# CREATE INDEX idx_test_abcd ON test(a,b,c,d);
  > ```

Syntax

- Create an index on a table.

```
CREATE [ UNIQUE ] INDEX [ CONCURRENTLY ] [ IF NOT EXISTS ] [ [schema_name.] index_name ]
ON table_name [ USING method ]
    ({ { column_name [ ( length ) ] | ( expression ) } [ COLLATE collation ] [ opclass ] [ ASC | DESC ]
[ NULLS { FIRST | LAST } ] }[, ...] )
    [ INCLUDE ( column_name [, ...] ) ]
    [ WITH ( {storage_parameter = value} [, ... ] ) ]
    [ ILM ADD POLICY ROW STORE COMPRESS
 { TURBO [ LOW | MEDIUM | HIGH ] UNIT AFTER n { hour | day | month | year } OF NO
MODIFICATION
 | NONE}]
    [ TABLESPACE tablespace_name ]
    [ COMMENT 'string' ] [ ... ]
    [ VISIBLE | INVISIBLE ]
    [ WHERE predicate ];
```

- Create an index on a partitioned table.

```
CREATE [ UNIQUE ] INDEX [ CONCURRENTLY ] [ IF NOT EXISTS ] [ [schema_name.] index_name ]
ON table_name [ USING method ]
    ( { { column_name [ ( length ) ] | ( expression ) } [ COLLATE collation ] [ opclass ] [ ASC | DESC ]
[ NULLS LAST ] } [, ...] )
    [ LOCAL
        [ ( PARTITION index_partition_name [ FOR { partition_name | ( partition_value [, ...] ) } ]
[ TABLESPACE index_partition_tablespace ]
              [ ( [SUBPARTITION index_subpartition_name] [ FOR { partition_name | ( partition_value
[, ...] ) } ]  [ TABLESPACE index_partition_tablespace ]
                    [, ...] ) ]
           [, ...] ) ]
       | GLOBAL ]
    [ INCLUDE ( column_name [, ...] ) ]
    [ WITH ( { storage_parameter = value } [, ...] ) ]
    [ ILM ADD POLICY ROW STORE COMPRESS
 { TURBO [ LOW | MEDIUM | HIGH ] UNIT AFTER n { hour | day | month | year } OF NO
MODIFICATION
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
| NONE}]
  [ TABLESPACE tablespace_name ]
  [ COMMENT 'string' ] [ ... ]
  [ VISIBLE | INVISIBLE ];
```

Parameters

- **UNIQUE**

  Creates a unique index. This causes the system to check for duplicate values in the table each time data is added. Attempts to insert or update data which would result in duplicate entries will generate an error.

  Currently, only B-tree indexes and UB-tree indexes in row-store tables support unique indexes.

- **CONCURRENTLY**

  Creates an index (with ShareUpdateExclusiveLock) in a mode that does not block DML statements. When an index is created, other statements cannot access the table on which the index depends. If this keyword is specified, DML statements are not blocked during the creation.

  – This option can only specify a name of one index.

  – The CREATE INDEX statement can be run within a transaction. However, CREATE INDEX CONCURRENTLY cannot be run within a transaction or in a stored procedure.

  – For temporary tables, you can use CONCURRENTLY to create indexes. However, indexes are created in blocking mode because no other sessions concurrently access the temporary tables and the blocking mode is more cost-effective.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- This keyword is specified when an index is created. The Astore needs to scan the entire table twice to build it. During the first scan, an index is created and the read and write operations are not blocked. During the second scan, changes that have occurred since the first scan are merged and updated. Ustore needs to scan the entire table only once. During the scan, the data generated by concurrent DML operations is inserted into the temporary table **index_oid_cctmp**. After the scan is complete, the data in the temporary table is merged to the primary index and the temporary table is deleted, the index is created. You can use the GUC parameter **delete_cctmp_table** to specify whether to delete temporary tables after indexes are created online. The default value of this parameter is **on**, indicating that temporary tables are deleted by default. If this parameter is set to **off**, temporary tables are retained.
- For Astore, the table needs to be scanned and built twice, and all existing transactions that may modify the table must be completed. This means that the creation of the index takes a longer time than normal. In addition, the CPU and I/O consumption also affects other services. Although the Ustore only needs to scan the entire table once to create indexes, the preceding consumption also exists.
- Exceptions may occur during online index creation (for example, manual cancellation, duplicate UNIQUE index key values, insufficient resources, thread startup failure, and lock timeout). As a result, online index creation fails. In this case, indexes in the **not valid** state may be retained to avoid occupying system resources. The system automatically clears the failed indexes. Before clearing the failed indexes, wait until the transaction in the table ends. If a long transaction exists, the system may keep waiting. If you cancel the thread, the failed indexes remain. Specifically, if the user cancels the online index creation thread and the three phases of online index creation are complete, the process of clearing failed indexes will not be started and the failed indexes will remain. If the three phases of online index creation are not complete, the process of clearing failed indexes will be started first. If the user cancels the thread again, the process will end and the failed indexes will remain. The automatic index clearing process includes a phase where the system must wait for other database transactions to end. As a result, issues such as lock timeout and deadlock may occur, causing automatic index clearing failures. For critical errors, such as FATAL, PANIC, and database faults, you need to manually clear indexes and temporary tables. If both online index creation and automatic residual clearing fail, indexes that are not valid are retained. The residual indexes may be ready or not ready (depending on the phase in which the online index creation fails. For example, the index failed in the first phase is not ready, and the index failed in the third phase is ready). If the residual indexes are ready, the DML statements still maintain the residual indexes. During the maintenance, other errors may occur (for example, the size of the index column exceeds the maximum value or the UNIQUE index constraint is violated). To prevent residual indexes from occupying system resources and generating unexpected errors, you need to manually delete them as soon as possible. In a distributed system, only DNs automatically clear failed indexes. (If an exception occurs on a DN and the three phases of online index creation have been completed, the failed indexes will not be automatically cleared.) Failed indexes on the CN need to be manually cleared. If a critical error occurs, the metadata of the failed indexes cannot be matched on some nodes in the distributed system. The DROP INDEX statement cannot be used to drop these indexes. You need to use the DROP INDEX IF EXISTS statement to drop them.
- For Astore, after the second scan, index creation must wait for any transaction that holds a snapshot earlier than the snapshot taken by the second scan to end. In addition, the ShareUpdateExclusiveLock (level 4) added during index creation conflicts with a lock whose level is greater than or equal to 4. Therefore, when such an index is created, the system is prone to hang or deadlock. Example:
  - If two sessions create an index by using CONCURRENTLY for the same table, a deadlock occurs.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

    - If a session creates an index by using CONCURRENTLY for a table and the other session drops a table, a deadlock occurs.
    - There are three sessions. Session 1 locks table **a** and does not commit it. Session 2 creates an index by using CONCURRENTLY for table **b**. Session 3 writes data to table **a**. Before the transaction of session 1 is committed, session 2 is blocked.
    - When an index is created by using CONCURRENTLY for a table concurrently with the TRUNCATE operation on the same table, a deadlock occurs.
    - The transaction isolation level is set to repeatable read (read committed by default). Two sessions are started. Session 1 writes data to table **a** and does not commit it. Session 2 creates an index by using CONCURRENTLY for table **b**. Until the transaction of session 1 is committed, session 2 is always blocked.
- When an index is being created or fails to be created, you need to check the index progress or status. You can call the gs_get_index_status('schema_name', 'index_name') function to check the index status on all nodes. The input parameters **schema_name** and **index_name** are used to specify the index schema name and index name, respectively. The return values are **node_name**, **indisready**, and **indisvalid**, indicating the node name, whether the index can be inserted on the node, and whether the index is available on the node. The index is available only when **indisready** and **indisvalid** on all nodes are set to **true**; otherwise, wait until the index creation is complete. If the index fails to be created, drop the index and create it again.
- When the I/O, CPU, and network bandwidth resources are not limited, the service performance deterioration caused by online index creation can be controlled within 10%. However, in special scenarios, the service performance deterioration may exceed 10%. This is because online index creation is a long transaction that consumes a large number of I/O, CPU, and network bandwidth resources. It consumes more resources than offline index creation. The longer the online index creation transaction lasts, the greater the impact on service performance. The time for creating indexes online is positively correlated with the data volume of base tables and the data volume generated by concurrent DML statements. When the I/O, CPU, and network bandwidth resources are not limited, the time for creating indexes online is about two to six times that for creating indexes offline. However, when the number of concurrent transactions is large (> 10000 TPS) or resource contention occurs, the time may be even longer. If a long transaction exists during online index creation, the long transaction running time must be added. In Astore and Ustore modes, you can create indexes in parallel to shorten the index creation time. The performance of online parallel index creation increases to a certain value and becomes stable as the number of parallel worker threads increases. Compared with the performance of creating indexes in serial mode, the performance of creating indexes in parallel online is improved by about 30%. You are advised to create indexes online during off-peak hours to avoid great impact on services. In addition, do not execute long transactions during online index creation. Although online index creation provides the capability of uninterrupted services to some extent, it still needs to be implemented with caution.
- When a unique index is created online (by using CREATE UNIQUE INDEX CONCURRENTLY), the table is scanned to check whether the data in the table is unique. If the data in the table is not unique, an error is reported and the online index creation exits. During online index creation, whether data in the table is unique may change. Whether the creation fails depends on whether duplicate data is scanned. Consider the following situations: 1. Tuple A and tuple B are inserted during table scan, and their index columns are the same. If both tuple A and tuple B are scanned during online index scan, a uniqueness violation may be reported. However, if tuple B is deleted later, in this case, an error may be reported during online index creation, indicating that the uniqueness is violated. However, after the online index creation fails and exits, the data in the table is found to be unique. 2. During online index creation, if tuple A in a table is inserted, deleted, and then inserted, and SnapshotNow is used to scan the table, tuple A may be scanned twice, which may violate the UNIQUE constraint. During online index creation,

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Astore uses SnapshotMVCC to scan tables, and Ustore uses SnapshotNow to scan tables.

- **IF NOT EXISTS**
  - When **IF NOT EXISTS** is specified, the system checks whether a relation with the same name already exists in the current schema before creating an index. If it finds such a relation, the table creation process will be halted, and a NOTICE will be returned.
  - When IF NOT EXISTS is not specified and a relation with the same name is present in the schema, an ERROR will be returned.
- **schema_name**

  Specifies the schema name.

  Value range: names of existing schemas.
- **index_name**

  Specifies the name of the index to be created. No schema name can be included here; the index is always created in the same schema as its parent table.

  Value range: character strings complying with **Identifier Naming Conventions**.
- **table_name**

  Specifies the name (optionally schema-qualified) of the table to be indexed.

  Value range: names of existing tables.
- **USING method**

  Specifies the name of the index method to be used.

  Value range:
  - **btree**: B-tree indexes store key values of data in a B+ tree structure. This structure helps users to quickly search for indexes. B-tree is applicable to comparison query and range query.
  - **ubtree**: multi-version B-tree index used only for Ustore tables. The index page contains transaction information and can be recycled. By default, the INSERTPT functionality is enabled for UB-tree indexes.
  - **ugin**: UGINs are generalized inverted indexes used only for Ustore tables.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- Currently, UGIN supports opclass of the character type ugin_trgm_ops.
  - **ugin_trgm_ops** is not the default **opclass**.
  - **ugin_trgm_ops** supports index keys of the text, varchar, nvarchar2, and clob data types and alias data types of the four types, but does not support the char(n) type (bpchar).
  - If the index key of ugin_trgm_ops is specified, the collation cannot be M-compatible, such as utf8mb4_bin, utf8mb4_general_ci, utf8mb4_unicode_ci, gbk_chinese_ci, gbk_bin, gb18030_chinese_ci and gb18030_bin. Otherwise, an error is reported during index creation.
- Currently, UGIN indexes support the opclass ugin_tsvector_ops of the text search type tsvector.
  - ugin_tsvector_ops is the default operator class.
  - ugin_tsvector_ops supports index keys of the tsvector data type and supports the @@/@@@ operator for index scans.
- Currently, UGIN support the following opclasses of the array type: _bool_ops, _bpchar_ops, _char_ops, _float4_ops, _float8_ops, _int2_ops, _int4_ops, _int8_ops, _interval_ops, _numeric_ops, _oid_ops, _text_ops, _time_ops, _timetz_ops, _timestamp_ops, _timestamptz_ops and _varchar_ops.
  - The preceding opclasses of the array type are default operator classes.
  - UGIN can be created for the following array types: bool[], char[], "char"[], float4[], float8[], int2[], int4[], int8[], interval[], numeric[], oid[], text[], time[], timestamp[], timestamptz[], timetz[] and varchar[].
  - The "&&", "@>", "<@", and "=" operators are supported.
- Only single-column indexes are supported. Index keys do not support the ASC/DESC syntax, NULLS FIRST/LAST syntax, or INCLUDE syntax.
- Only Bitmap Index Scan is supported.
- The GUC parameter **gin_fuzzy_search_limit** can only be set to the default value **0**. If the value is not 0, an error is reported during index scan for UGINs.
- Hash bucket tables, hash bucket scale-out, and segment-page are not supported.
- Only ordinary table indexes and local indexes are supported. Global indexes are not supported. It cannot be used as an index for unlogged tables or temporary tables.
- Online operations such as rebuild, creation, deletion, and VACUUM FULL are not supported, nor are parallel creation.
- UGINs cannot be used for flashback queries.
- It cannot be used as primary keys, unique keys, or virtual indexes, and does not support transparent data encryption or fully-encrypted databases.
- UGINs can be used only for LIKE fuzzy query.
- It cannot be created or used in the database where **sql_compatibility** is set to **'M'**.
- UGINs support strings of all character sets. Ensure that the character set settings (**server_encoding**, **LC_CTYPE**, and **LC_COLLATE**) of the database align with the data definition. In the word segmentation algorithm, the concept of a character is determined by the character set, and the letter is determined by **LC_CTYPE**. Mismatched database character set settings can cause abnormal word segmentation.

– **gin**: General inverted indexes, which can process values that contain multiple keys (for example, arrays).

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- GINs support the following data types and index operators:
  - Array types: abstime[], bit[], bool[], bpchar[], bytea[], char[], cidr[], date[], float4[], float8[], inet[], int2[], int4[], int8[], interval[], macaddr[], money[], name[], numeric[], oid[], oidvector[], reltime[], text[], time[], timestamp[], timestamptz[], timetz[], tinterval[], varbit[], and varchar[].

    Indexable operators: =, &&, @>, and <@.
  - Text search type: tsvector.

    Indexable operators: @@ and @@@.
  - JSON/JSONB type: jsonb.

    For the JSONB type, two indexable operator classes (jsonb_ops and jsonb_hash_ops) are provided. The default indexable operator class jsonb_ops supports the @>, ?, ?&, and ?| operators, while the non-default indexable operator class jsonb_hash_ops supports only the @> operator.
- Index keys do not support the ASC/DESC syntax, NULLS FIRST/LAST syntax, or INCLUDE syntax.
- Only Bitmap Index Scan is supported.
- Indexes of ordinary tables and local temporary tables, and local indexes of partitioned tables are supported. Global indexes, and indexes of global temporary tables and unlogged tables are not supported.
- Hash bucket tables and hash bucket scale-out are not supported.
- Online rebuild, creation, deletion, VACUUM FULL, and parallel creation are not supported.
- It cannot be used as a primary key, unique key, virtual index, or for transparent or full encryption.
- Index compression is not supported.
- The array, jsonb, and tsvector data types do not support collecting statistical information, making the cost estimation of GINs on these types inaccurate.

– **gist**: Suitable for the set data type and multidimensional data types, such as geometric and geographic data types. The following data types are supported: box, point, poly, circle, tsvector, tsquery, and range.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- GiST indexes support the following data types and index operators:
  - Box: Indexable operators include <<, &<, &&, &>, >>, ~=, @>, <@, &<|, <<|, |>>, |&>, ~, and @.
  - Circle: Indexable operators include <<, &<, &&, &>, >>, ~=, @>, <@, &<|, <<|, |>>, and |&>.
  - Point: Indexable operators include <<, >>, ~=, <@, <^, >^, and <->.
  - Polygon: Indexable operators include <<, &<, &>, >>, ~=, <<|, &<|, |&>, and |>>.
  - Range types include int4range, int8range, numrange, tsrange, tstzrange, daterange, and custom range types. Indexable operators include =, &&, @>, <@, <<, >>, @<, &>, and -|-.
  - Text search type tsquery: Indexable operators include <@ and @>.
  - Text search type tsvector: Indexable operator is @@.
- GiST-supported data types do not support collecting statistical information, making the cost estimation of GiST indexes created on these types is inaccurate.
- Only Astore is supported. Ustore, hash bucket, transparent data encryption, full-disk encryption, materialized views, parallel index creation, online rebuild, creation, deletion, and VACUUM FULL are not supported.
- Bitmap Index Scan and Index Scan are supported for executing planned scans.
- Indexes on ordinary tables/local temporary tables and partitioned indexes of partitioned tables are supported. Indexes on global temporary tables or unlogged tables are not supported.
- The ASC/DESC syntax, NULLS FIRST/LAST syntax, and INCLUDE syntax are not supported.
- Cannot be used as a primary key, unique key, or virtual index.
- gs_check_table and gs_check_index do not support GiST indexes.
- In ORA-compatible mode, **daterange** does not support **@>(daterange, date)**.
- Index compression is not supported.

NOTE

- B-tree and UB-tree are closely related to the table storage type Astore or Ustore. When an index is created, if the specified index type does not correspond to the main table, the index type is automatically converted.
- Row-store tables (Astore) support the index type B-tree (default), GIN, and GiST. Row-store tables (Ustore) support the index types UB-tree and UGIN.
- Recommendations for using GINs and UGINs:
  - Modifying indexes in high-concurrency environments is not advised, as synchronizing and converging incremental data can cause performance fluctuations.
  - Frequent index modifications are not recommended because space recycling and statistics updates depend on the VACUUM operation. Frequent insertions and deletions between VACUUM operations may cause space bloat and inaccurate execution plans.
  - If the scan performance is poor, manually clear the incremental cache, as its scan speed is lower than that of a B-tree scan.
  - Indexes are applicable only to scenarios where a small amount of data is returned from large datasets but are not suitable for retrieving large amounts of data.

- **column_name**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Specifies the name of the column on which an index is to be created.

Multiple columns can be specified if the index method supports multi-column indexes. A global index supports a maximum of 31 columns, and other indexes support a maximum of 32 columns.

- **column_name (length)**

  Creates a prefix key index based on a column in the table. **column_name** indicates the column name of the prefix key, and **length** indicates the prefix length.

  The prefix key uses the prefix of the specified column data as the index key value, which reduces the storage space occupied by the index. Indexes can be used for partial filter and join conditions that contain prefix key columns.

  NOTE

  - The index methods supported by the prefix key include B-tree and UB-tree.
  - The data type of the prefix key column must be binary or character (excluding special characters).
  - The prefix length must be a positive integer that does not exceed 2676 and cannot exceed the maximum length of the column. For the binary type, the prefix length is measured in bytes. For non-binary character types, the prefix length is measured in characters. The actual length of the prefix key value is restricted by the internal page. If a column contains multi-byte characters or an index has multiple keys, the length of the index row may exceed the upper limit. As a result, an error is reported. Consider this situation when setting a long prefix length.
  - In the CREATE INDEX syntax, the following keywords cannot be used as prefix keys for column names: COALESCE, EXTRACT, GREATEST, LEAST, LNNVL, NULLIF, NVL, NVL2, OVERLAY, POSITION, REGEXP_LIKE, SUBSTRING, TIMESTAMPDIFF, TREAT, TRIM, XMLCONCAT, XMLELEMENT, XMLEXISTS, XMLFOREST, XMLPARSE, XMLPI, XMLROOT and XMLSERIALIZE.
  - Prefix keys represent a special type of expression key. Certain constraints and limitations not explicitly outlined here align with those governing expression keys. For comprehensive information, refer to the documentation on expression indexes.
  - The prefix index is a kind of expression index and cannot be used as the unique index or primary key.

- **expression**

  Specifies an expression index based on one or more columns of the table. Generally, the expression index must be written in parentheses. However, the parentheses can be omitted if the expression is in the form of a function call.

  The expression index can be used to obtain fast access to certain transformation of basic data. For example, an index computed on upper(col) would allow the WHERE upper(col) = 'JIM' clause to use an index.

  If an expression contains the IS NULL clause, the index for this expression is invalid. In this case, you are advised to create a partial index.

- **COLLATE collation**

  Specifies a collation for the column to be indexed (which must be of a collatable data type). If no collation is specified, the default collation is used. You can run the **SELECT * FROM pg_collation;** command to query collations from the pg_collation system catalog. The default collation rule is the row starting with **default** in the query result.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

> **NOTE**
>
> In MYSQL-compatible mode (that is, **sql_compatibility** is set to **'MYSQL'**), when the MYSQL-compatible collation is used, ensure that the index collation is the same as the column collation. Otherwise, the index fails to be created and an error is reported.

- **opclass**

  Specifies the name of an operator class. You can specify an operator class for each column of an index to identify the operator used by that column. For example, a B-tree index on the type int4 would use the int4_ops class; this operator class includes comparison functions for values of type int4. In practice, the default operator class for the column's data type is sufficient. The operator class applies to data with multiple sorts. For example, users might want to sort a complex-number data type either by absolute value or by real part. They could do this by defining two operator classes for the data type and then selecting the proper class when making an index. In addition, if the value of **COLLATE** of an index of the string type (such as varchar, varchar2, and text) is not **C** or **POSIX**, but you want the index to support prefix matching, you need to specify the **varchar_pattern_ops** option.

- **ASC**

  Specifies an ascending (default) sort order.

- **DESC**

  Specifies a descending sort order.

- **NULLS FIRST**

  Specifies that null values appear before non-null values in the sort ordering. This is the default when **DESC** is specified.

- **NULLS LAST**

  Specifies that null values appear after non-null values in the sort ordering. This is the default when **DESC** is not specified.

- **LOCAL**

  Specifies that the partitioned index to be created is a local index.

- **GLOBAL**

  Specifies the partitioned index to be created as a global index. If no keyword is specified, a global index is created by default.

- **INCLUDE (column_name [, ...]**)

  The optional INCLUDE clause specifies that some non-key columns are included in indexes. Non-key columns cannot be used as search criteria for accelerating index scans, and they are omitted when the UNIQUE constraints of the indexes are checked.

  An index-only scan can directly return content in the non-key columns without accessing the heap table corresponding to the indexes.

  Exercise caution when adding non-key columns as INCLUDE columns, especially for wide columns. If the size of an index tuple exceeds the maximum size allowed by the index type, data insertion fails. Note that in any case, adding non-key columns to an index increases the space occupied by the index, which may slow down the search speed.

  Currently, only UB-tree index access mode supports this feature. Non-key columns are stored in the index leaf tuple corresponding to the heap tuple and are not included in the tuple on the upper-layer index page.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **PARTITION clause**

  PARTITION index_partition_name [FOR { partition_name | (partition_value [, ...]) }] [TABLESPACE index_partition_tablespace]

  If **FOR partition_name** or **FOR partition_value** is specified in the PARTITION clause, the created partitioned index has the sparsely partitioned index attribute. If **FOR partition_name** or **FOR partition_value** is not specified, the number of PARTITION clauses must be the same as the number of partitions in the target table.

  NOTE

  - A sparsely partitioned index is a type of local index for partitioned table. It is created only on a single partition, whereas an ordinary local index needs to be created on every partition of the table.
  - Sparsely partitioned indexes can be created only on a single partition, including a partition of a partitioned table or a partition and a subpartition of a subpartitioned table.
  - The sparsely partitioned index supports only B-tree and UB-tree indexes.
  - The sparsely partitioned index does not support the UNIQUE attribute.
  - Currently, the global index is not supported.
  - A created sparsely partitioned index contains the **sparsely_partitioned=true** option. A sparsely partitioned index created on the partition of a subpartitioned table contains the **level1_sparsely_partitioned=true** option. The **sparsely_partitioned=true** and **level1_sparsely_partitioned=true** options cannot be explicitly specified as sparsely partitioned indexes using the CREATE TABLE or ALTER TABLE statement. If the created index is a sparsely partitioned index, the **sparsely_partitioned=false** or **level1_sparsely_partitioned=false** option will be ignored even if it is specified.
  - If a version earlier than 505.0.0 is upgraded to 505.0.0 or later, sparsely partitioned indexes cannot be created during upgrade observation.
  - When a version is upgraded to 506.1.0 or later, sparsely partitioned indexes cannot be created on partitions of subpartitioned tables during the upgrade observation period.

  – **PARTITION index_partition_name**

    Specifies the name of an index partition.

    Value range: character strings complying with **Identifier Naming Conventions**.

  – **FOR partition_name**

    Specifies the name of the target partition. If the specified partition does not exist, an error is reported.

  – **FOR (partition_value [, ...])**

    Specifies the value of the specified partition key. The partition key value must be placed in the partition key value FOR list. If there are multiple columns of partition keys, multiple **partition_value** values must be specified.

  – **TABLESPACE index_partition_tablespace**

    Specifies the tablespace of an index partition.

    Value range: If this parameter is not specified, the value of **index_tablespace** is used.

- **WITH ({storage_parameter = value} [, ...])**

  Specifies the storage parameter used for an index.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Value range:

NOTE

- Indexes other than Psort, UGIN, and GIN support the **FILLFACTOR** parameter.
- Only UB-tree indexes support the **INDEXSPLIT** parameter.
- Only B-tree indexes on non-partitioned tables support the **DEDUPLICATION** parameter.
- Only UB-tree indexes support the **INDEX_TXNTYPE** parameter.
- UGINs and GINs also support the **gin_pending_list_limit**, **fastupdate**, **pending_pages**, **total_pages**, **entry_pages**, **data_pages**, and **entries** parameters.
- GiST indexes also support the **buffering** parameter.

– **STORAGE_TYPE**

Specifies the storage engine type of the table where the index is located. The storage engine type will be automatically corrected if it conflicts with the index type. Only B-Tree indexes, UB-Tree indexes, GINs, and UGINs are supported. You cannot modify this parameter after it is set.

Value range:

- **USTORE**: The table where the index is located uses an in-place update storage engine.
- **ASTORE**: The table where the index is located uses an append-only storage engine.

Default value: **USTORE** for Ustore tables and **ASTORE** for Astore tables.

– **FILLFACTOR**

Specifies a fill factor for the index. It is a percentage between 10 and 100. In the scenario where a large number of concurrent insertions are performed and the key value range is dense, the contention of the same index page is high during the insertion. Therefore, a smaller fill factor is more appropriate.

Value range: 10–100.

– FASTUPDATE

Specifies whether to enable fast update for a GIN/UGIN. Currently, the incremental cache (pending list) cannot be disabled for UGINs. Therefore, this parameter can only be set to **on**. If it is set to **off**, an error is reported.

Value range: **on** or **off**.

Default value: **on**

– **GIN_PENDING_LIST_LIMIT**

Sets the upper limit of the GIN/UGIN cache (pending list). If the pending list grows larger than this maximum size, it is cleaned up by moving the entries in it to the main index data structure in batches.

Value range: 64–2147483647. The unit is KB.

Default value: depends on the GUC parameter **gin_pending_list_limit** whose default value is **4**, in MB.

– **CROSSBUCKET**

Specifies whether cross-hash bucket indexes are used.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Value range: **on** or **off**.

Default value: **off**.

- **ACTIVE_PAGES**

  Specifies the number of index pages, which may be less than the actual number of physical file pages and can be used for optimization. Currently, this parameter is valid only for the local index of the Ustore partitioned table and will be updated by VACUUM (including AUTOVACUUM) and ANALYZE. You are advised not to manually set this parameter because it is invalid in the current mode.

- **DEDUPLICATION**

  Specifies whether to deduplicate and compress tuples with duplicate key values. This is an index parameter. When there are a large number of indexes with duplicate key values, enabling this parameter can effectively reduce the space occupied by indexes. This parameter does not take effect for primary key indexes and unique indexes. If non-unique indexes are used and the index key value duplication rate is low or the index key values are unique, enabling this parameter will slightly deteriorate the index insertion performance. Currently, local and global indexes of partitioned tables are not supported.

  Value range: Boolean value, depending on the value of the GUC parameter **enable_default_index_deduplication** (the default value is **off**).

- **INDEXSPLIT**

  Specifies the splitting policy of UB-tree indexes.

  Value range:

  - **INSERTPT**: The splitting policy is the same as that of B-tree.
  - **DEFAULT**: The index space usage can be significantly reduced in some scenarios.

  Default value: **INSERTPT**.

  Setting suggestion: In scenarios where a large amount of data with the same index key value is concurrently inserted at the same time, using the **INSERTPT** splitting algorithm may cause index bloat. In this case, you are advised to change the splitting policy to **DEFAULT**.

  For example:

  ```
  CREATE INDEX idx ON tbl(col) WITH (indexsplit=default);
  ```

- **INDEX_TXNTYPE**

  Specifies the UB-tree index type (only UB-tree indexes support this parameter). When the value is **PCR**, flashback queries can be performed using UB-tree. PCR UB-tree indexes do not support online index creation, GSIs, ultimate RTO replay, or read on standby. If this parameter is not specified, the type of the index to be created is specified by the GUC parameter **index_txntype**. **INDEX_TXNTYPE** cannot be modified using ALTER INDEX INDEX_NAME SET (INDEX_TXNTYPE=PCR or RCR).

  Type: character string (case-insensitive).

  Value range: **RCR** or **PCR**.

  Default value: **RCR**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

For example:

```
CREATE UNIQUE INDEX t2_b_pkey ON t(b) WITH(index_txntype='pcr');
```

- **STAT_STATE**

  Specifies whether index statistics are locked. If locked, the statistics cannot be updated. This parameter does not take effect in the current mode.

  Value range: **locked** or **unlock**.

  Default value: **unlock**.

- **enable_tde**

  Specifies whether the index is encrypted. If the index is encrypted, the database automatically encrypts the data in the encrypted index before storing it.

  Before using this parameter, ensure that the TDE functionality has been enabled using the GUC parameter **enable_tde**, the information for accessing the key service has been set using the GUC parameter **tde_key_info**, and the **enable_tde** attribute has been set for the base table. For details about how to use this parameter, see "Feature Usage Guidelines > Transparent Data Encryption" in *Developer Guide*. This parameter supports only B-tree and UB-tree indexes. Other indexes are not supported.

  Value range: **on** or **off**. If **enable_tde** is set to **on**, the values of **key_type**, **tde_cmk_id**, and **dek_cipher** are automatically generated in the database.

  Default value: **off**.

- **encrypt_algo**

  Specifies the cryptographic algorithm of the index. After you set the **enable_tde** parameter for the index, the index automatically copies **encrypt_algo** from the base table. This parameter cannot be manually set or modified.

  Value range: **AES_128_CTR**, **SM4_CTR**, **AES_128_CTR_SHA256_HMAC**, **SM4_CTR_SM3_HMAC**, and **AES_128_GCM** (character string).

  Default value: empty.

- **dek_cipher**

  Specifies the DEK ciphertext. This parameter cannot be manually set or modified. After you set the **enable_tde** parameter for an index, the index automatically copies the **dek_cipher** parameter in the base table.

  Value range: character strings.

  Default value: empty.

- **key_type**

  Specifies the type of the master key. This parameter cannot be manually set or modified. After you set the **enable_tde** parameter for the index, the index automatically copies **key_type** from the base table.

  Default value: empty.

- **cmk_id**

  Specifies the ID of the master key. This parameter cannot be manually set or modified. After you set the **enable_tde** parameter for the index, the index automatically copies **cmk_id** from the base table.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Value range: character strings.

Default value: empty.

- **LPI_PARALLEL_METHOD**

  Index parameter, which is used to set the parallel creation mode of local indexes for partitioned tables.

  Type: String

  Value range:

  - **PAGE**: creates page-level indexes in parallel. Multiple worker threads are started to scan and sort data. Each worker thread processes a data page at a time. After scanning and sorting, the main thread combines the sorting results in serial mode and inserts tuples into the indexes.
  - **PARTITION**: creates partition-level indexes in parallel. Multiple worker threads are started, and each worker thread scans, sorts, and inserts indexes into a partition.
  - **AUTO**: estimates the costs of parallel index creation at the page level and partition level based on the partitioned table statistics, and selects the parallel index creation mode with a lower cost. (The statistics may be different from the actual data, resulting in inaccurate calculation results.)

  Default value: **PAGE**

  Setting suggestion: Set this parameter to **PARTITION** if the partitioned table data is evenly distributed in each partition. This parameter supports only the B-tree local index of Astore partitioned tables. It does not support the global index of partitioned tables, non-partitioned table indexes, segment-page table indexes, hash bucket table indexes, or online index creation.

  For example:

  ```
  CREATE INDEX idx ON tbl(col) WITH (lpi_parallel_method = 'partition');
  ```

- **pending_pages**, **total_pages**, **entry_pages**, **data_pages**, and **entries**

  These parameters represent the number of UGIN and GIN fast cache pages, total index pages, word segmentation tree pages, posting tree pages, and total word segments.

  NOTE

  - The preceding parameters are page statistics unique to UGIN and GINs. They are updated by the **ANALYZE** command and cannot be manually set by using the **CREATE INDEX** or **ALTER INDEX** command.
  - **CREATE TABLE LIKE INCLUDING {index | all}** does not inherit the index statistics.
  - gs_dump does not export unique index information.
  - The pg_get_indexdef function does not obtain unique index information.
  - Running **\d+ table_name** does not display unique index information.
  - Transaction-level temporary tables do not support collection of page statistics for GINs.

- **buffering**

  Specifies whether GiST indexes use buffering technology to build indexes.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Value range:

- **off**: Buffering is disabled.
- **on**: Buffering is enabled.
- **auto**: Buffering is initially disabled, but is enabled immediately when the index size reaches **effective_cache_size**.

The default value is **auto**. The default behavior is suitable for most cases, but disabling the buffering feature can accelerate the building process if the input data is already sorted.

– wait_clean_cbi

Specifies whether the CBI contains residual tuples generated during bucket migration for scaling. After scale-out and redistribution, **wait_clean_cbi** is set to **y** for the CBIs that contain residual tuples. After these indexes are cleared using VACUUM or REINDEX, **wait_clean_cbi** automatically changes to **n**. This parameter can only be used in the scale-out tool and cannot be set or modified.

Value range: **y** or **n**.

Default value: **n**.

- **[ILM ADD POLICY ROW STORE COMPRESS { TURBO [LOW | MEDIUM | HIGH] UNIT AFTER n { hour | day | month | year } OF NO MODIFICATION | NONE}]**
  - When creating an index, you can call ILM ADD POLICY to add a cross-page transparent compression policy. For example:
    ```
    CREATE INDEX i1 on t1(a) ILM ADD POLICY ROW STORE COMPRESS TURBO HIGH UNIT AFTER 3 HOUR OF NO MODIFICATION;
    ```
    The command creates the i1 index and adds a cross-page transparent compression policy with a high policy level and a 3-hour cold and hot data management interval.
  - **AFTER n { hour | day | month | year } OF NO MODIFICATION**: indicates the compression groups that have not been modified for *n* hours, days, months, or years.
  - When creating an index, you can call ILM ADD POLICY ROW STORE COMPRESS NONE to explicitly specify that no cross-page transparent compression policy is applied to the index.
  - If an index compression policy is explicitly specified, the specified policy is used (the compression level is MEDIUM by default if no compression level is specified). If no index compression policy is explicitly specified, the index compression status and compression level are the same as those of the table.
- **TABLESPACE tablespace_name**

  Specifies the tablespace for an index. If no tablespace is specified, the default tablespace is used.

  Value range: names of existing tablespaces.
- **WHERE predicate**

  Creates a partial index.

  A partial index contains entries for only a portion of a table, usually a portion that is more useful for indexing than the rest of the table.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Value range: The predicate expression can only refer to columns of the table, but it can use all these columns, not just the ones being indexed. Currently, subqueries and aggregate expressions are forbidden in the WHERE clause. You are advised not to use numeric types such as INT as conditions because such types can be implicitly converted to Boolean (non-zero values are implicitly converted to **true** and **0** is implicitly converted to **false**), which may cause unexpected results.

For a partitioned table index, if the created index contains the GLOBAL keyword or the created index is a GLOBAL index, the WHERE clause cannot be used to create an index.

- **COMMENT 'string'**

  Adds comments to an index.

  NOTE

  - It is valid only in a MYSQL-compatible database (that is, **sql_compatibility** is set to **'MYSQL'**).
  - An index-level comment can contain a maximum of 1024 characters.

- **VISIBLE**

  Sets the index to be visible. This is the default option.

  NOTE

  - **VISIBLE** can be set only in an ORA-compatible database (that is, **sql_compatibility** is set to **'ORA'**).
  - When **disable_keyword_options** is set to **visible**, this keyword cannot be used.
  - This keyword is not supported in the upgrade uncommitted phase.

- **INVISIBLE**

  Sets the index to be invisible.

  NOTE

  - **INVISIBLE** can be set only in an ORA-compatible database (that is, **sql_compatibility** is set to **'ORA'**).
  - When **disable_keyword_options** is set to **invisible**, this keyword cannot be used.
  - This keyword is not supported in the upgrade uncommitted phase.

Examples

- Ordinary index

```
-- Create the tbl_test1 table.
gaussdb=# CREATE TABLE tbl_test1(
    id int,           -- User ID
    name varchar(50), -- Username
    postcode char(6)  -- Postal code
);

-- Create the tbs_index1 tablespace.
gaussdb=# CREATE TABLESPACE tbs_index1 RELATIVE LOCATION 'test_tablespace/tbs_index1';

-- Create the idx_test1 index for the tbl_test1 table and specify a tablespace.
gaussdb=# CREATE INDEX idx_test1 ON tbl_test1(name) TABLESPACE tbs_index1;

-- Query information about the idx_test1 index.
gaussdb=# SELECT indexname,tablename,tablespace FROM pg_indexes WHERE indexname =
'idx_test1';
 indexname | tablename | tablespace
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
-----------+-----------+------------
 idx_test1 | tbl_test1 | tbs_index1
(1 row)

-- Drop the index.
gaussdb=# DROP INDEX idx_test1;

-- Delete the tablespace.
gaussdb=# DROP TABLESPACE tbs_index1;
```

- Unique index

```
-- Create the unique index idx_test2 for the tbl_test1 table.
gaussdb=# CREATE UNIQUE INDEX idx_test2 ON tbl_test1(id);

-- Query index information.
gaussdb=# \d tbl_test1
          Table "public.tbl_test1"
  Column  |         Type          | Modifiers
----------+-----------------------+-----------
 id       | integer               |
 name     | character varying(50) |
 postcode | character(6)          |
Indexes:
    "idx_test2" UNIQUE, btree (id) TABLESPACE pg_default

-- Drop the index.
gaussdb=# DROP INDEX idx_test2;
```

- Expression index

```
-- Create an expression index for the tbl_test1 table.
gaussdb=# CREATE INDEX idx_test3 ON tbl_test1(substr(postcode,2));

-- Query index information.
gaussdb=# \d tbl_test1
          Table "public.tbl_test1"
  Column  |         Type          | Modifiers
----------+-----------------------+-----------
 id       | integer               |
 name     | character varying(50) |

ALTER INDEX and **DROP INDEX**

1.13.9.27 CREATE LANGUAGE

Description

Defines a new procedural language.

Precautions

This syntax is not supported currently.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

1.13.9.28 CREATE MASKING POLICY

Description

Creates a masking policy.

Precautions

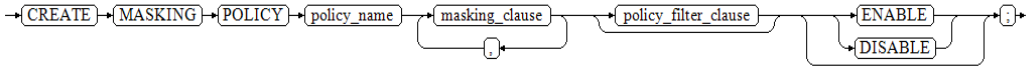
- Only users with the POLADMIN or SYSADMIN permission and the initial user can perform this operation.
- The masking policy takes effect only after the security policy is enabled, that is, the GUC parameter **enable_security_policy** is set to **on**.

NOTE

When you use database links to perform operations on remote objects, the client initiates a database link request. The actual sender is the server, and the attributes such as the IP address of the sender are the values of the server. For details, see "Feature Usage Guidelines > Database Links" in *Developer Guide*.

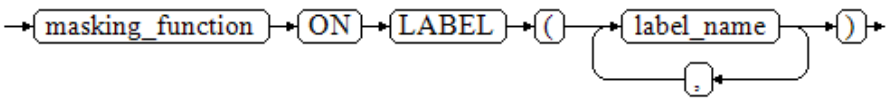
Syntax

```
CREATE MASKING POLICY policy_name masking_clause[, ...] [ policy_filter_clause ] [ENABLE | DISABLE];
```



- masking_clause

  ```
  masking_function ON LABEL(label_name[, ...])
  ```

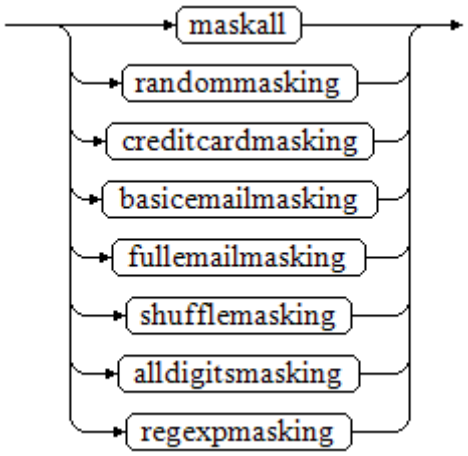
  


- masking_function

  maskall is not a preset function and cannot be displayed by running **\df**.

  The preset masking methods are as follows:

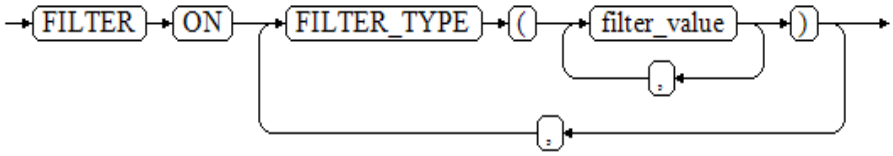
  ```
  { maskall | randommasking | creditcardmasking | basicemailmasking | fullemailmasking |
  shufflemasking | alldigitsmasking | regexpmasking }
  ```

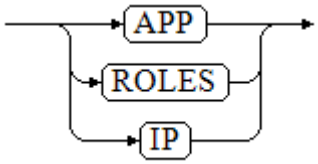
- policy_filter_clause:

  ```
  FILTER ON { FILTER_TYPE ( filter_value [, ...] ) } [, ...]
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.



- FILTER_TYPE:
  { APP | ROLES | IP }



Parameters

- **policy_name**

  Specifies the name of a masking policy, which must be unique.

  Value range: character strings complying with **Identifier Naming Conventions** and not exceeding 63 characters.

  NOTE

  - If a masking policy name contains more than 63 characters, the database truncates it and retains the first 63 characters.
  - If a masking policy name contains uppercase letters, the database automatically converts the uppercase letters into lowercase letters. To create a masking policy name that contains uppercase letters, enclose the masking policy name with double quotation marks ("").
  - The masking policy name must start with a letter or underscore (_) and can contain only lowercase letters (a to z), uppercase letters (A to Z), underscores (_), digits (0 to 9), and dollar signs ($).

- **label_name**

  Specifies the resource label name.

- **masking_clause**

  Specifies the identifier of the masking function used to mask specified database resources (**label_name**). You can specify the masking function by using schema.function.

- **policy_filter**

  Specifies the identifier of the user for whom the masking policy takes effect. If this parameter is left empty, the masking policy takes effect for all users.

- **FILTER_TYPE**

  Specifies the types of information to be filtered by the policy, including **IP**, **APP**, and **ROLES**.

- **filter_value**

  Specifies the detailed information to be filtered, such as the IP address, app name, and username.

- **ENABLE | DISABLE**

  Specifies whether to enable the masking policy. If **ENABLE** or **DISABLE** is not specified, **ENABLE** is used by default.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Examples

- Create a masking policy that uses maskall to mask all string values as **x** and display default values for other data types.

```
-- Create table tb_for_masking.
gaussdb=# CREATE TABLE tb_for_masking(idx int, col1 text, col2 text, col3 text, col4 text, col5 text,
col6 text, col7 text,col8 text);

-- Insert data into the tb_for_masking table.
gaussdb=# INSERT INTO tb_for_masking VALUES(1, '9876543210', 'usr321usr', 'abc@huawei.com',
'abc@huawei.com', '1234-4567-7890-0123', 'abcdef 123456 ui 323 jsfd321 j3k2l3',
'4880-9898-4545-2525', 'this is a llt case');

-- View data.
gaussdb=# SELECT * FROM tb_for_masking;
 idx |    col1    |   col2    |      col3      |      col4      |       col5         |               col6
     |        col7         |        col8

ALTER MASKING POLICY and **DROP MASKING POLICY**

1.13.9.29 CREATE MATERIALIZED VIEW

Creates a complete-refresh materialized view. You can use REFRESH MATERIALIZED VIEW (complete-refresh) to refresh the data in the materialized view.

The CREATE MATERIALIZED VIEW statement has similar functions as the CREATE TABLE AS statement. However, the CREATE MATERIALIZED VIEW statement persistently stores the initialization query statement to support subsequent data refresh operations. Materialized views have the same persistence property as ordinary tables. However, unlike temporary tables, the system does not support the creation of temporary materialized views.

NOTE

For details about the application scenarios, see "Basic Concepts > Materialized Views" in *Developer Guide*.

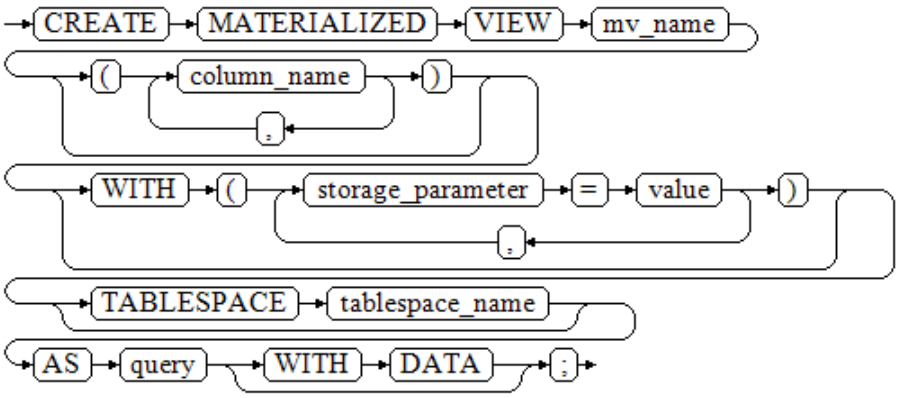
 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Precautions

- Complete-refresh materialized view cannot be created on temporary tables or global temporary tables.
- Complete-refresh materialized views do not support node groups.
- After a complete-refresh materialized view is created, some DDL operations in the base table are no longer supported.
- IUD operations cannot be performed on complete-refresh materialized views.
- After a complete-refresh materialized view is created, if the base table data changes, you need to run the refresh command to synchronize the materialized view with the base table.
- Ustore does not support the creation and use of materialized views.
- The segment-page does not support the creation and use of materialized views.

Syntax

```
CREATE MATERIALIZED VIEW mv_name
   [ (column_name [, ...] ) ]
   [ WITH ( {storage_parameter = value} [, ... ] ) ]
   [ TABLESPACE tablespace_name ]
   AS query
   [ WITH DATA ];
```



Parameters

- **mv_name**

  Name of the created materialized view, which can be specified using a schema.

  Value range: character strings complying with **Identifier Naming Conventions**.

- **column_name**

  Name of a column in the new materialized view. The materialized view supports specified columns. The number of specified columns must be the same as that of columns in the result of the subsequent query statement. If no column name is provided, the column name is obtained from the output column name of the query.

  Value range: character strings complying with **Identifier Naming Conventions**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **WITH (storage_parameter [= value] [, ...])**

  Specifies an optional storage parameter for a table or index. For details, see **CREATE TABLE**.

- **TABLESPACE tablespace_name**

  (Optional) Tablespace to which the new materialized view belongs. If it is not specified, the default tablespace is used.

- **AS query**

  A **SELECT**, **TABLE**, or **VALUES** command. This query will be run in a security-constrained operation.

Examples

```
-- Create a tablespace.
gaussdb=# CREATE TABLESPACE tbs_data1 RELATIVE LOCATION 'tablespace1/tbs_data1';

-- Create an ordinary table.
gaussdb=# CREATE TABLE my_table (c1 int, c2 int);

-- Create a complete-refresh materialized view.
gaussdb=# CREATE MATERIALIZED VIEW my_mv TABLESPACE tbs_data1 AS SELECT * FROM my_table;

-- Write data to the base table.
gaussdb=# INSERT INTO my_table VALUES(1,1),(2,2);

-- Query the complete-refresh materialized view.
gaussdb=# SELECT * FROM my_mv;
 c1 | c2
----+----
(0 rows)

-- Completely refresh the complete-refresh materialized view my_mv.
gaussdb=# REFRESH MATERIALIZED VIEW my_mv;

-- Query the complete-refresh materialized view.
gaussdb=# SELECT * FROM my_mv;
 c1 | c2
----+----
  1 |  1
  2 |  2
(2 rows)

-- Delete the complete-refresh materialized view.
gaussdb=# DROP MATERIALIZED VIEW my_mv;

-- Delete the ordinary table my_table.
gaussdb=# DROP TABLE my_table;

-- Delete the tablespace.
gaussdb=# DROP TABLESPACE tbs_data1;
```

ALTER MATERIALIZED VIEW, **CREATE INCREMENTAL MATERIALIZED VIEW**, **CREATE TABLE**, **DROP MATERIALIZED VIEW**, **REFRESH INCREMENTAL MATERIALIZED VIEW**, and **REFRESH MATERIALIZED VIEW**

1.13.9.30 CREATE MODEL

Description

Trains a machine learning model and saves it.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Precautions

This syntax is not supported currently.

1.13.9.31 CREATE NODE

Description

Creates a cluster node.

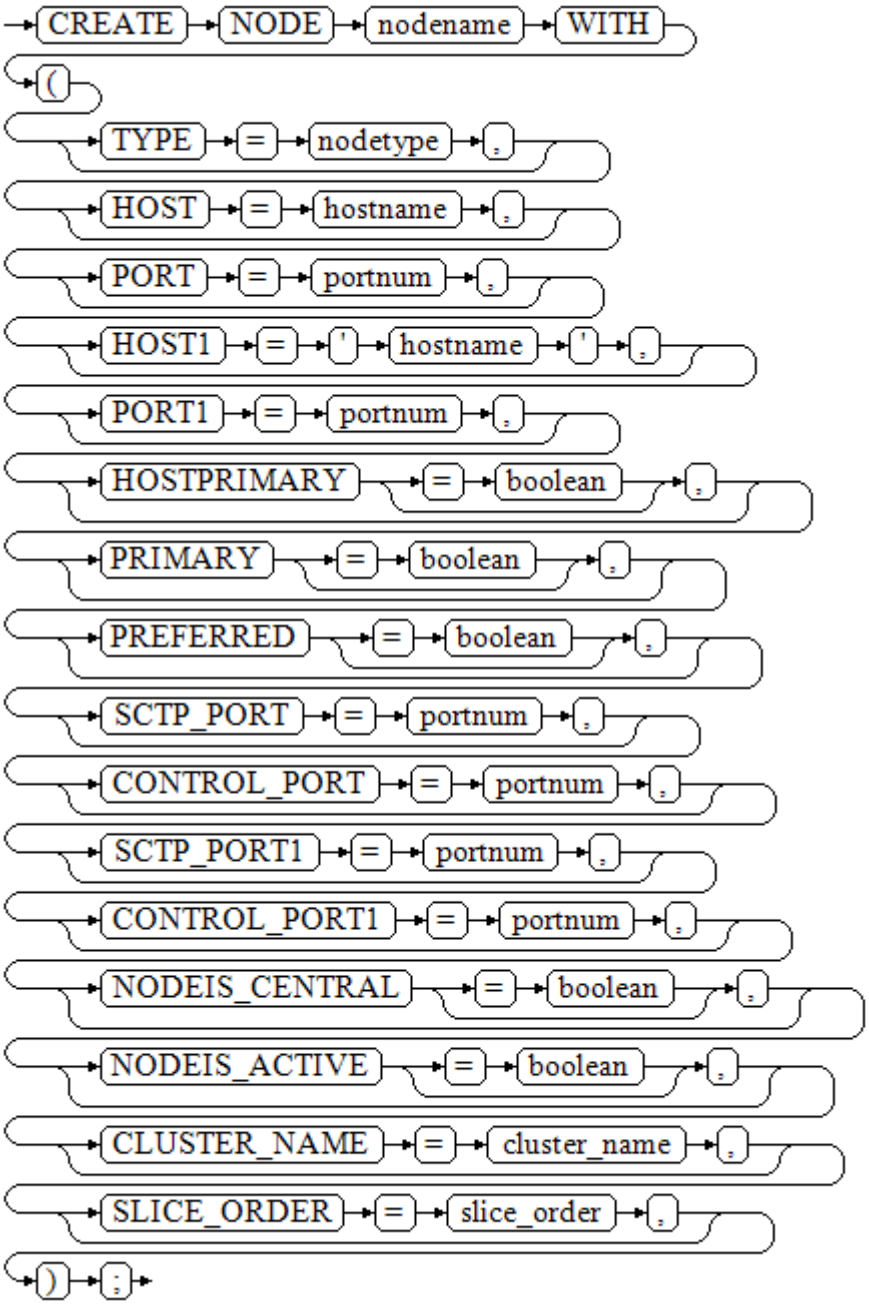
Precautions

- **CREATE NODE** is an API of the cluster management tool and is used to manage clusters. Only administrators have the permission to use this API.
- Do not use this API directly. Otherwise, the cluster status may be affected and the database may be unavailable.

Syntax

```
CREATE NODE nodename WITH
 (
   [ TYPE = nodetype,]
   [ HOST = hostname,]
   [ PORT = portnum,]
   [ HOST1 = 'hostname',]
   [ PORT1 = portnum,]
   [ HOSTPRIMARY [ = boolean ],]
   [ PRIMARY [ = boolean ],]
   [ PREFERRED [ = boolean ],]
   [ SCTP_PORT = portnum,]
   [ CONTROL_PORT = portnum,]
   [ SCTP_PORT1 = portnum,]
   [ CONTROL_PORT1 = portnum, ]
   [ NODEIS_CENTRAL [= boolean], ]
   [ NODEIS_ACTIVE [= boolean],]
   [ CLUSTER_NAME = cluster_name, ]
   [ SLICE_ORDER = slice_order, ]
 );
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.



NOTE

The port whose number is specified by **PORT** is used for internal communications between nodes. Unlike the port connecting to an external client, it can be queried in the **pgxc_node** table.

Parameters

- **nodename**

  Specifies the node name.

  Value range: character strings complying with **Identifier Naming Conventions**.

- **TYPE = nodetype**

Specifies the type of a node.

Value range:

- 'coordinator'
- 'datanode'
- 'coordinator_standbycluster'
- 'datanode_standbycluster_main'
- 'datanode_standbycluster_other'

- **HOST = hostname**

  Specifies the name or IP address of the primary node corresponding to a node.

- **PORT = portnum**

  Specifies the port number of the primary node to which a node is bound.

- **HOST1 = hostname**

  Specifies the name or IP address of the standby node corresponding to a node.

- **PORT1 = portnum**

  Specifies the port number of the standby node to which a node is bound.

- **HOSTPRIMARY**

  Specifies whether the host name or IP address is the primary one.

  Value range:

  - **true**
  - **false** (default value)

- **PRIMARY = boolean**

  Specifies whether the node is a primary node or not. A primary node allows read/write operations. A non-primary node allows only read operations.

  Value range:

  - **true**
  - **false** (default value)

- **PREFERRED = boolean**

  Specifies whether the node is a preferred node for read operations.

  Value range:

  - **true**
  - **false** (default value)

- **SCTP_PORT = portnum**

  Specifies the port used by the TCP proxy communications library of the primary node to listen on the data transmission channel. TCP is used to listen on connections.

- **CONTROL_PORT = portnum**

  Specifies the port used by the TCP proxy communications library of the primary node to listen on the control transmission channel. The TCP protocol is used to listen on connections.

- **SCTP_PORT1 = portnum**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Specifies the port used by the TCP proxy communications library of the standby node to listen on the data transmission channel. TCP is used to listen on connections.

- **CONTROL_PORT 1= portnum**

  Specifies the port used by the TCP proxy communications library of the standby node to listen on the control transmission channel. The TCP protocol is used to listen on connections.

- **NODEIS_CENTRAL**

  Specifies whether the current node is a central control node. It is used only for CNs and is invalid for DNs.

  - **true**
  - **false** (default value)

- **NODEIS_ACTIVE**

  Specifies whether the current node is normal. It is used to mark whether the CN is removed and is invalid for DNs.

  - **true**
  - **false** (default value)

- **CLUSTER_NAME**

  Specifies the cluster name.

- **SLICE_ORDER**

  Specifies the sequence number of the slice to which a node belongs.

  NOTE

  In multi-CN environments, when you create a cluster node, it is only generated on the CN that is currently connected and is not synchronized with other CNs. This requires you to repeat the creation process on all CNs. However, to drop the cluster node created, you only need to connect to one CN. If a cluster node is created on only one CN, you need to define the current CN name and drop the cluster node on the current CN. For details, see **DROP NODE**.

Examples

```
-- Create cluster nodes on all CNs.
gaussdb=# CREATE NODE datanode1 WITH(
   TYPE = datanode,
   PREFERRED = false
);
gaussdb=# CREATE NODE datanode2 WITH(
   TYPE = datanode,
   PREFERRED = false
);

-- Query the initial cluster DN status.
gaussdb=# SELECT node_name, nodeis_preferred FROM pgxc_node WHERE node_type = 'D' ORDER BY 1;
 node_name | nodeis_preferred
-----------+------------------
 datanode1 | f
 datanode2 | f
(2 rows)

-- Set datanode1 as the preferred DN.
gaussdb=# ALTER NODE datanode1 WITH(preferred = true);
-- Query the cluster DN status after the change.
gaussdb=# SELECT node_name, nodeis_preferred FROM pgxc_node WHERE node_type = 'D' ORDER BY 1;
 node_name | nodeis_preferred
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
-----------+------------------
 datanode1 | t
 datanode2 | f
(2 rows)

-- Connect to only one CN to drop cluster nodes.
gaussdb=# DROP NODE datanode1;
gaussdb=# DROP NODE datanode2;
```

Helpful Links

ALTER NODE and **DROP NODE**

1.13.9.32 CREATE NODE GROUP

Description

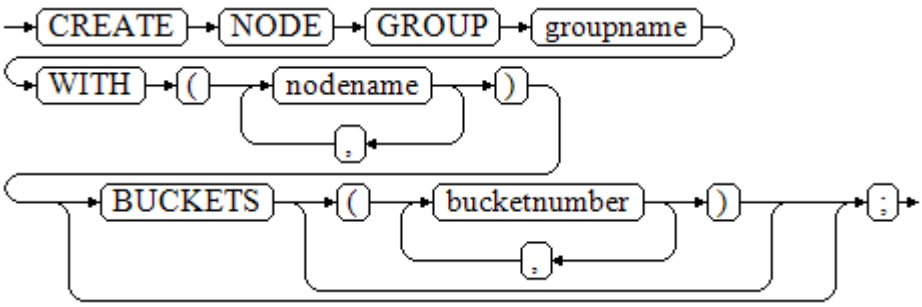
Creates a cluster node group.

Precautions

- CREATE NODE GROUP is an API of the cluster management tool.
- Only a system administrator has the permission.

Syntax

```
CREATE NODE GROUP groupname
   WITH ( nodename [, ... ] )
   [ BUCKETS [ ( bucketnumber [, ... ] ) ] ];
```



Parameters

- **groupname**

  Specifies the name of a node group.

  Value range: character strings complying with **Identifier Naming Conventions** and not exceeding 63 characters.

  NOTE

  A node group name supports all ASCII characters, but you are advised to name a node group according to the **Identifier Naming Conventions**.

- **nodename**

  Specifies the node name.

  Value range: character strings complying with **Identifier Naming Conventions** and not exceeding 63 characters.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **BUCKETS [(bucketnumber [, ...])]**

  This is an internal use of the cluster management tool and can be called only during scale-out.

Examples

```
-- Query the initial cluster DN status.
gaussdb=# SELECT node_name, nodeis_preferred FROM pgxc_node WHERE node_type = 'D' ORDER BY 1;
 node_name | nodeis_preferred
-----------+------------------
 dn_6001_6002_6003 | f
 dn_6004_6005_6006 | f
 dn_6007_6008_6009 | f
(3 rows)

-- Create a node group and replace dn_6001_6002_6003 with the actual node name obtained in the previous step.
gaussdb=# CREATE NODE GROUP test_group WITH ( dn_6001_6002_6003 );

-- Query the node group.
gaussdb=# SELECT group_name, group_members FROM pgxc_group;
   group_name   |   group_members
----------------+-------------------
 group_version1 | 16384 16388 16394
 test_group     | 16384
(2 rows)

-- Delete the node group.
gaussdb=# DROP NODE GROUP test_group;
```

Helpful Links

ALTER NODE GROUP and **DROP NODE GROUP**

1.13.9.33 CREATE PACKAGE

Description

Creates a package.

Precautions

- Packages can be used only in ORA-compatible databases.
- Functions or stored procedures declared in the package specification must be clearly defined in the package body.
- When a stored procedure is created, a write lock is added only to the stored procedure or package, and a read lock is added only to the functions and packages on which the functions depend during compilation and execution.
- During instantiation, stored procedures with COMMIT or ROLLBACK cannot be called.
- The PACKAGE function cannot be called in a trigger.
- Variables in a package cannot be directly used in external SQL statements.
- Private variables and stored procedures in a package cannot be called outside the package.
- If a usage is not supported in a stored procedure, it is not supported in a package. For example, if COMMIT/ROLLBACK cannot be called in a function, COMMIT/ROLLBACK cannot be called in a function of a package.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- The name of a schema cannot be the same as that of a package.
- Only stored procedures and function definitions compatible with Oracle Database are supported.
- Variables with the same name in a package, including parameters with the same name in a package, are not supported.
- The global variables in a package are at the session level. The variables in packages cannot be shared in different sessions.
- When a function of an autonomous transaction is called in a package, cursor variables in the package and functions that use cursor variables in the package cannot be used recursively.
- A package does not declare REF CURSOR variables.
- The default permission on a package is SECURITY INVOKER. To change the default permission to SECURITY DEFINER, set the GUC parameter **behavior_compat_options** to **'plsql_security_definer'**.
- A user with the CREATE ANY PACKAGE permission can create packages in the public and user schemas.
- If the name of a package to be created contains special characters, the special characters cannot contain spaces. You are advised to set the GUC parameter **behavior_compat_options** to **"skip_insert_gs_source"**. Otherwise, an error may occur.
- When you create a package function, the default parameter value can contain variables in the package but cannot contain cross-package variables.
- When the complex function is called in a package, for example, func(x).a, a composite type is returned. Cross-schema call is supported, but the database.schema.package.func(x).b call is not supported.
- When a stored procedure in a package is created, if the stored procedure name is in the *schema*.*func* or *package*.*func* format, only the value of *func* is obtained, and the declaration of *schema* or *package* is not obtained. To disable this behavior, set the GUC parameter **behavior_compat_options** to **'forbid_package_function_with_prefix'**.
- **view%RowType** cannot be used as a function parameter.
- Composite records cannot be used in INSERT VALUES in stored procedures or functions.
- SAVE EXCEPTIONS (used in called stored procedures) is not supported currently.
- Expressions do not support COMMIT/ROLLBACK.
- For a function without parameters, parentheses cannot be omitted.
- User-defined variables cannot be pushed down.
- When a stored procedure in a package is created, if the input parameters of the stored procedure contain pseudo-type parameters (for example, **anyelement**), variable-length parameters cannot be specified during a call.
- Cursors created in a package or cursors in functions with parameters can be referenced (**%RowType**) and opened across packages. The restrictions are as follows:
  - Currently, cursors cannot be called in database.schema.package.cursor mode.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

  - Cursors cannot be defined as function parameters.
  - **cursor %RowType** is not supported when a cursor is referenced.
- If the PRAGMA AUTONOMOUS_TRANSACTION syntax is declared in PACKAGE SPECIFICATION or PACKAGE BODY SPECIFICATION, a package can be created, but the autonomous transaction does not take effect.
- A non-initial user cannot perform the REPLACE operation on packages of the initial user.
- When a package is created, only the validity of the default values of the variables in the package specification and package body is checked (whether the function on which the default values depend exists and whether the function is valid). Related statements are not executed, the initialization of package header and package body variables and instantiation of the package body (PACKAGE BODY ANONYMOUS BLOCK) are executed only once when the API is called for the first time.
- During package creation, recompilation, and nested compilation, package instantiation (including packet header, package body variable initialization, and package body instantiation) is not executed.

Syntax

- CREATE PACKAGE SPECIFICATION syntax format.

```
CREATE [ OR REPLACE ] PACKAGE [ schema ] package_name
  [ invoker_rights_clause ] { IS | AS } item_list_1 END [ package_name ];
```

  - **invoker_rights_clause**: You can use **AUTHID DEFINER** or **AUTHID CURRENT_USER** to declare the caller's permission in the package header. **AUTHID DEFINER** indicates the creator's permissions, and **AUTHID CURRENT_USER** indicates the caller's permissions. Variables, functions, or stored procedures in the package header are executed with the permission specified during declaration (**AUTHID DEFINER** or **AUTHID CURRENT_USER**), while cursors in the package header are executed with the caller's permission (**AUTHID CURRENT_USER**).
  - **item_list_1** can be a declared variable, stored procedure, or function.
  - The **package_name** after END can be omitted. (For the SQL file generated by gs_dump, the package name after END is automatically added.) If **package_name** is not specified, the end character (/) must be added to the end of the CREATE PACKAGE SPECIFICATION syntax.

  NOTE

  PACKAGE SPECIFICATION (header) declares public variables, functions, and exceptions in a package, which can be called by external functions or stored procedures. It can only declare stored procedures and functions but cannot define them.

- CREATE PACKAGE BODY syntax format.

```
CREATE [ OR REPLACE ] PACKAGE BODY [ schema ] package_name
  { IS | AS } declare_section [ initialize_section ] END [ package_name ];
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

The **package_name** after END can be omitted. (For the SQL file generated by gs_dump, the package name after END is automatically added.) If **package_name** is not specified, the end character (/) must be added to the end of the CREATE PACKAGE BODY syntax.

NOTE

- The package body defines private variables and functions of the package. If a variable or function is not declared by the package specification, it is a private variable or private function.
- The package body also has an instantiation part to initialize the package.

Examples

- CREATE PACKAGE

```
-- Create a database.
gaussdb=# CREATE DATABASE test DBCOMPATIBILITY 'ORA';
gaussdb=# \c test

-- Create a test table tbl_test.
test=# CREATE TABLE tbl_test(uid varchar(6) PRIMARY KEY, area_id varchar(5), level int);

-- Create a package header.
test=# CREATE OR REPLACE PACKAGE pkg_test AS
    -- Public stored procedures can be called by external systems.
    PROCEDURE proc_ist_tbl_test(v_uid in varchar, v_area_id varchar, v_level int);
    PROCEDURE proc_del_tbl_test(v_uid in varchar);
    PROCEDURE proc_upd_tbl_test(v_uid in varchar, v_area_id varchar, v_level int);
END pkg_test;
/

-- Create a package body.
test=# CREATE OR REPLACE PACKAGE BODY pkg_test AS
    PROCEDURE proc_ist_tbl_test(v_uid in varchar, v_area_id varchar, v_level int) AS
    BEGIN
        INSERT INTO tbl_test VALUES (v_uid, v_area_id, v_level);
    END;
    PROCEDURE proc_del_tbl_test(v_uid in varchar) AS
    BEGIN
        DELETE FROM tbl_test WHERE uid = v_uid;
    END;
    PROCEDURE proc_upd_tbl_test(v_uid in varchar, v_area_id varchar, v_level int) AS
    BEGIN
        UPDATE tbl_test SET area_id = v_area_id, level = v_level WHERE uid = v_uid;
    END;
    var4 int := 10;
    -- The instantiation starts.
BEGIN
    var4 := 10;
    dbe_output.print_line(var4);
END pkg_test;
/
```

- Calling a package

```
-- Use CALL to call the stored procedure of a package.
test=# CALL pkg_test.proc_ist_tbl_test('0A00B1','01001',24);
test=# SELECT * FROM tbl_test;
  uid   | area_id | level
--------+---------+---------
 0A00B1 | 01001   |     24
(1 row)

-- Use SELECT to call the stored procedure of a package.
test=# SELECT pkg_test.proc_upd_tbl_test('0A00B1','01001','26');
test=# SELECT * FROM tbl_test;
  uid   | area_id | level
--------+---------+-------
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
 0A00B1 | 01001   |    26
(1 row)

-- Call a stored procedure of a package by using an anonymous block.
test=# BEGIN
pkg_test.proc_del_tbl_test('0A00B1');
END;
/
test=# SELECT * FROM tbl_test;
 uid | area_id | level
-----+---------+-------
(0 rows)

-- Drop.
test=# DROP TABLE tbl_test;
test=# DROP PACKAGE pkg_test;
-- Switch to the default database and drop the test database. Change the database name as required.
test=# \c postgres
gaussdb=# DROP DATABASE test;
```

ALTER PACKAGE and **DROP PACKAGE**

1.13.9.34 CREATE PROCEDURE

Description

Creates a stored procedure.

Precautions

- When a stored procedure is created, if the parameter or return value has precision, the precision is not checked.
- When creating a stored procedure, you are advised to specify the schemas of all operations on table objects in the stored procedure definition. Otherwise, the stored procedure may fail to be executed.
- When a stored procedure is created using CREATE, a write lock is added only to the stored procedure or package, and a read lock is added only to the functions and packages on which the functions depend during compilation and execution.
- **current_schema** and **search_path** specified by SET during stored procedure creation are invalid. **search_path** and **current_schema** before and after function execution should be the same.
- When the function is called by SELECT or CALL, an argument must be provided in the output parameter. The argument does not take effect.
- A stored procedure with the PACKAGE attribute can use overloaded functions.
- Do not create an overloaded stored procedure with different parameter names but same stored procedure name and parameter list type.
- Do not create a stored procedure that has the same name and parameter list as the function.
- Do not overload stored procedures with different default values.
- Only the IN, OUT, and INOUT parameters of the stored procedure cannot be reloaded after the GUC parameter **behavior_compat_options** is set to

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

'proc_outparam_override'. Overloading is supported after the GUC parameter is disabled.

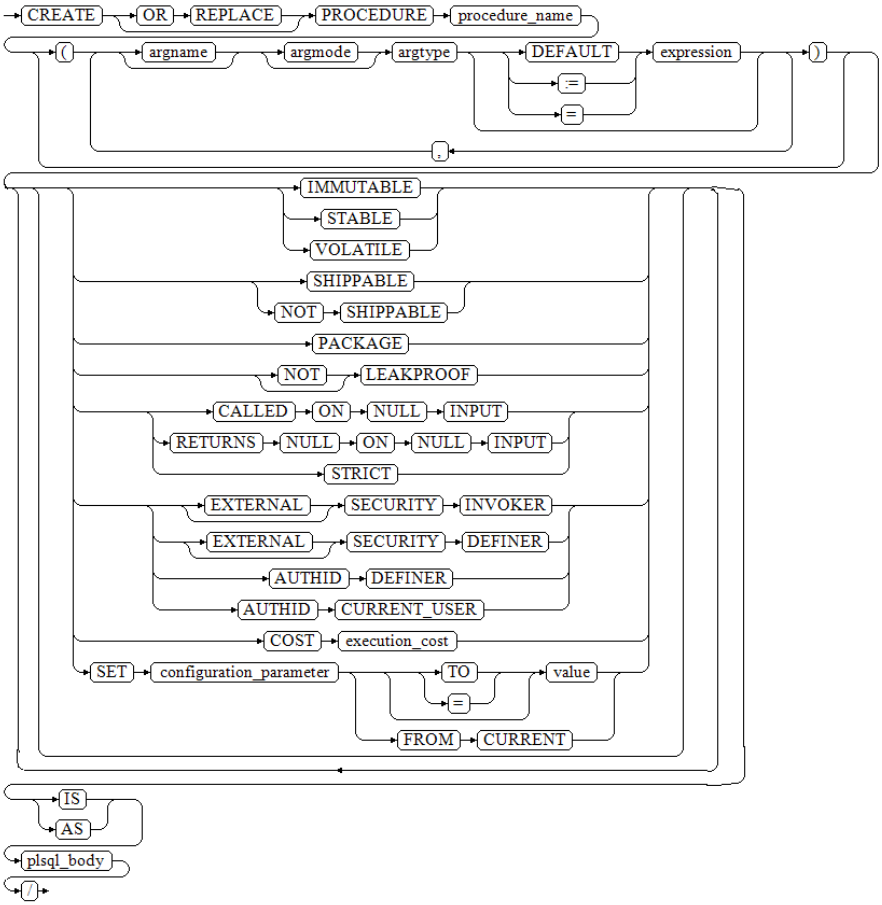
- Oracle-compatible functions are created for ORA-compatible databases and PostgreSQL-compatible functions are created for PG-compatible databases. Hybrid creation is not recommended.
- If a function supports overloading, you need to specify the keyword PACKAGE.
- When an overloaded stored procedure is called, the variable type must be specified.
- If an undeclared variable is used in a stored procedure, an error is reported when the stored procedure is called.
- When you create a procedure, you cannot nest average functions in aggregate or other functions.
- If the function is defined as the IMMUTABLE or SHIPPABLE type, avoid having INSERT, UPDATE, DELETE, MERGE, and DDL operations in the function. These operations require the CN to determine the execution node, and the execution result may be incorrect.
- The stored procedure does not support operations that will return a set.
- When stored procedures without parameters are called in another stored procedure, you can omit brackets and call stored procedures using their names directly.
- When other functions with output parameters are called in a stored procedure and an assignment expression, set the GUC parameter **behavior_compat_options** to **'proc_outparam_override'**, define variables of the same type as the output parameters, and use the variables as output parameters to call other functions with output parameters for the output parameters to take effect. Otherwise, the output parameters of the called functions will be ignored.
- The **OUT** parameter does not take effect in the following scenarios when it is used in an expression: The EXECUTE IMMEDIATE sqlv USING func syntax is used to execute a function. The SELECT func INTO syntax is used to execute a function. DML statements such as INSERT and UPDATE are used to execute a function. The SELECT WHERE a=func() method is used. A function with an **OUT** output parameter is used as an input parameter (that is, **fun(func(OUT b), a)**) and the **OUT b** parameter does not take effect. A function with an **OUT** output parameter is used to assign a default value to a variable.
- The stored procedure supports viewing, exporting, and importing parameter comments.
- The stored procedure supports viewing, exporting, and importing parameter comments between IS/AS and plsql_body.
- Users with the CREATE ANY FUNCTION permission can create or replace stored procedures in the user schemas.
- An **OUT** or **INOUT** parameter must be set to a variable but not a constant.
- The default permission on a stored procedure is SECURITY INVOKER. To change the default permission to SECURITY DEFINER, set the GUC parameter **behavior_compat_options** to **'plsql_security_definer'**.
- If a stored procedure with the definer specified is created in a schema of another user, the stored procedure will be executed by another user, which may cause unauthorized operations. Therefore, exercise caution when performing this operation.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- When the complex function is called in a stored procedure (for example, func(x).a), a composite type is returned. Cross-schema call is supported, but the database.schema.package.func(x).b call is not supported.
- When a stored procedure with the **OUT** parameter is called, you can set the GUC parameter **behavior_compat_options** to **'proc_outparam_transfer_length'** to pass the parameter length. The specifications and limitations are as follows:
  - The following types are supported: CHAR(n), CHARACTER(n), NCHAR(n), VARCHAR(n), VARYING(n), VARCHAR2(n), and NVARCHAR2(n).
  - If the **OUT** parameter does not take effect (for example, **PERFORM**), the length does not need to be passed.
  - Precisions cannot be specified for the following types: NUMERIC, DECIMAL, NUMBER, FLOAT, DEC, INTEGER, TIME, TIMESTAMP, INTERVAL, TIME WITH TIME ZONE, TIMESTAMP WITH TIME ZONE, TIME WITHOUT TIME ZONE, and TIMESTAMP WITHOUT TIME ZONE.
  - The parameter length can be passed regardless of whether the GUC parameter **behavior_compat_options** is set to **proc_outparam_override**.
  - To pass the length of elements of the collection type and the length of elements of the array type nested by the collection type, you need to set the GUC parameter **behavior_compat_options** to **tableof_elem_constraints**.
- Functions contain syntax and functions that use GUC parameters to control features. If GUC parameters are modified in a session, the function may retain the behavior before the modification. Therefore, exercise caution when modifying GUC parameters.
- Non-initial users do not have the permission to perform the REPLACE operation on the stored procedures of the initial user.
- When you perform operations related to passwords or keys, such as user creation, password change, and encryption/decryption, in a stored procedure body, the system catalogs and logs record plaintext information about the passwords or keys. To prevent sensitive information leakage, you are advised not to perform password-related operations in a stored procedure body.

Syntax

```
CREATE [ OR REPLACE ] PROCEDURE procedure_name
   [ ( {[ argname ] [ argmode ] argtype [ { DEFAULT | := | = } expression ]}[,...]) ]
   [
     { IMMUTABLE | STABLE | VOLATILE }
     | { SHIPPABLE | NOT SHIPPABLE }
     | {PACKAGE}
     | [ NOT ] LEAKPROOF
     | { CALLED ON NULL INPUT | RETURNS NULL ON NULL INPUT | STRICT }
     | {[ EXTERNAL ] SECURITY INVOKER | [ EXTERNAL ] SECURITY DEFINER | AUTHID DEFINER | AUTHID
CURRENT_USER}
     | COST execution_cost
     | SET configuration_parameter { [ TO | = ] value | FROM CURRENT }
   ][ ... ]
 { IS | AS }
plsql_body
/
```



Parameters

- **OR REPLACE**

  Replaces the original definition when two stored procedures are with the same name.

- **procedure_name**

  Specifies the name (optionally schema-qualified) of the stored procedure to be created.

  Value range: character strings complying with **Identifier Naming Conventions**.

  NOTE

  You are advised not to create a function with the same name as a system function. Otherwise, you need to specify the schema of the function when calling the function.

- **argname**

  Specifies the argument name.

  Value range: character strings complying with **Identifier Naming Conventions**.

- **argmode**

  Specifies the mode of an argument.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Value range: **IN**, **OUT**, **INOUT**, or **VARIADIC**. The default value is **IN**. **VARIADIC** can be added only to parameters in OUT mode, and parameters in OUT and INOUT modes cannot be used in the RETURNS TABLE procedure definition.

NOTE

VARIADIC specifies parameters of the array type.

- **argtype**

  Specifies the type of an argument. You can use **%RowType** to indirectly reference the type of a table, or **%Type** to indirectly reference the type of a column in a table or composite type.

  Value range: a valid data type.

  NOTE

  No specific order is applied to **argname** and **argname**. The following order is advised: **argname**, **argmode**, and **argtype**.

- **expression**

  Specifies the default expression of a parameter.

  NOTE

  - If **a_format_version** is set to **10c** and **a_format_dev_version** is set to **s2**, the default expression is not supported when the parameter is in INOUT mode.
  - It is recommended that you define all default parameters after all non-default parameters.
  - If a function with default parameters is called, input parameters are added to the function from left to right. If inputs of non-default parameters are missing, an error is reported.
  - If **proc_uncheck_default_param** is enabled and a function with default parameters is called, input parameters are added to the function from left to right. The default input parameters can be left empty. If any non-default parameter is left empty, it will be padded using a misplaced default value.
  - When **a_format_version** is set to **10c**, **a_format_dev_version** is set to **s1**, **proc_outparam_override** is disabled, and the function parameters include the output parameter **OUT** and **DEFAULT**, the default value cannot be omitted.

- **IMMUTABLE | STABLE**

  Specifies a constraint.

  The function of each parameter is similar to that of CREATE FUNCTION. For details, see **CREATE FUNCTION**.

- **plsql_body**

  Specifies the PL/SQL stored procedure body.

  When a stored procedure is created, the **PLSQL_BODY** can end with "END;" or "END procedure_name;".

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

Constraints for stored procedures ending with "END procedure_name;":

- It is supported only in ORA-compatible mode (database level).
- Only the syntax for creating Oracle-compatible databases is supported.
- Only the scenario where the stored procedure name is set after END is supported.
- In the **DBE_PLDEVELOPER.gs_source**, **my_source**, **db_source** and **adm_source** views, the definition of the stored procedure stays consistent (if the created procedure is "END+name", it is displayed as "END+name"). In the **pg_proc** and **\sf** views, the outermost END is not followed by a name in any case. The innermost END is displayed as defined during creation (if the created procedure is "END +name", it is displayed as "END+name").
- The stored procedure cannot retain the name following the outermost END in the SQL file generated by gs_dump.
- If a stored procedure is named IF/LOOP or a subprogram is nested, the stored procedure cannot be ended with END IF/LOOP.

Examples

- Create a stored procedure.

```
-- Create a stored procedure and return the sum of the input parameters.
gaussdb=# CREATE OR REPLACE PROCEDURE proc_add(i int, j int)
AS
BEGIN
    dbe_output.print_line('result is: '|| i+j);
END;
/

-- Use CALL to call a stored procedure.
gaussdb=# CALL proc_add(16,17);

-- Use a program block to call a stored procedure.
gaussdb=# BEGIN
   proc_add(16,17);
END;
/

-- Drop.
gaussdb=# DROP PROCEDURE proc_add;
```

- Create a stored procedure ending with END in an ORA-compatible database.

```
-- Create a stored procedure and print the sum of the input parameters.
gaussdb=# CREATE OR REPLACE PROCEDURE proc_add(i int, j int)
AS
BEGIN
    dbe_output.print_line('result is: '|| i+j);
END proc_add;
/

-- Use CALL to call a stored procedure.
gaussdb=# CALL proc_add(16,17);

-- Use a program block to call a stored procedure.
gaussdb=# BEGIN
   proc_add(16,17);
END;
/

-- Drop.
gaussdb=# DROP PROCEDURE proc_add;
```

- Create a stored procedure whose parameter model is **VARIADIC**.

```
-- Create the stored procedure pro_variadic.
gaussdb=# CREATE OR REPLACE PROCEDURE pro_variadic (var1 VARCHAR2(10) DEFAULT 'hello!',var4
VARIADIC int4[])
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
AS
BEGIN
    dbe_output.print_line(var1);
    for i in 1..array_length(var4,1) loop
        dbe_output.print_line(var4[i]);
    end loop;
END;
/

-- Execute the stored procedure.
gaussdb=# SELECT pro_variadic(var1=>'hello', VARIADIC var4=> array[3,5,11,2]);

-- Drop.
gaussdb=# DROP PROCEDURE pro_variadic;
```

- Parameter models: **IN** and **OUT**
  - **IN** (default) indicates that the parameter is an input parameter.
  - **OUT** indicates that the parameter is an output parameter.
  - **IN OUT** indicates that the parameter is an INOUT parameter.

```
-- Create the stored procedure proc_add1. num1 and num2 are input parameters, and num3 is an output parameter.
gaussdb=# CREATE PROCEDURE proc_add1 (num1 in int, num2 in int, num3 out int)
AS
BEGIN
    num3 := num1 + num2;
END;
/

-- Use a program block to call the stored procedure and use variable c to receive the parameters sent by the stored procedure.
gaussdb=# DECLARE
    a int := 20;
    b int := 32;
    c int := 0;
BEGIN
    proc_add1(a,b,c);
    dbe_output.put_line(c);
END;
/

-- Drop.
gaussdb=# DROP PROCEDURE proc_add1;
```

Helpful Links

ALTER PROCEDURE and **DROP PROCEDURE**

1.13.9.35 CREATE RESOURCE LABEL

Description

Creates a resource label.

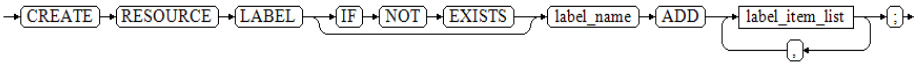
Precautions

Only users with the POLADMIN or SYSADMIN permission, or the initial user can perform this operation.

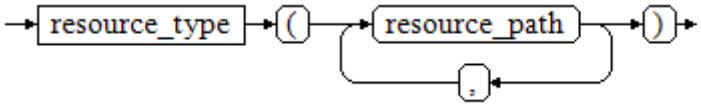
Syntax

```
CREATE RESOURCE LABEL [IF NOT EXISTS] label_name ADD label_item_list[, ...];
```

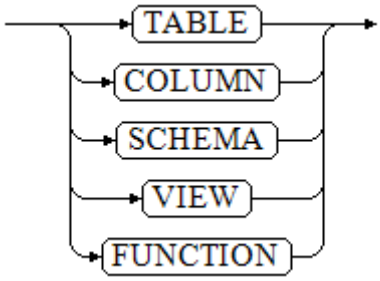
 Copyright © Huawei Cloud Computing Technologies Co., Ltd.



- label_item_list
  resource_type(resource_path[, ...])



- resource_type
  { TABLE | COLUMN | SCHEMA | VIEW | FUNCTION }



Parameters

- **IF NOT EXISTS**

  Checks whether a resource label with the same name already exists. If it exists, a prompt indicating that such resource label already exists will be displayed but no error will be generated.

- **label_name**

  Resource label name, which must be unique.

  Value range: character strings complying with **Identifier Naming Conventions** and not exceeding 63 characters.

  NOTE

  - If the value contains more than 63 characters, the database truncates it and retains the first 63 characters as the resource label name.
  - If a resource label name contains uppercase letters, the database automatically converts the uppercase letters into lowercase letters. To create a resource label name that contains uppercase letters, enclose the resource label name with double quotation marks ("").
  - The audit policy name must start with a letter or underscore (_) and can contain only lowercase letters (a to z), uppercase letters (A to Z), underscores (_), digits (0 to 9), and dollar signs ($).

- **resource_type**

  Specifies the type of the database resource to be labeled.

  Value range: **TABLE**, **COLUMN**, **Schema**, **VIEW**, and **FUNCTION**.

- **resource_path**

  Specifies the path of the database resource.

Examples

```
-- Create table tb_for_label.
gaussdb=# CREATE TABLE tb_for_label(col1 text, col2 text, col3 text);
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
-- Create a resource label based on a table.
gaussdb=# CREATE RESOURCE LABEL IF NOT EXISTS table_label add TABLE(public.tb_for_label);

-- Create an existing table resource label again and compare the differences between adding IF NOT EXISTS and not adding IF NOT EXISTS.
gaussdb=# CREATE RESOURCE LABEL IF NOT EXISTS table_label add TABLE(public.tb_for_label);
NOTICE:  table_label label already defined, skipping
CREATE RESOURCE LABEL
gaussdb=# CREATE RESOURCE LABEL table_label add TABLE(public.tb_for_label);
ERROR:  table_label label already defined

-- Create a resource label based on columns.
gaussdb=# CREATE RESOURCE LABEL IF NOT EXISTS column_label add COLUMN(public.tb_for_label.col1);

-- Create schema schema_for_label.
gaussdb=# CREATE SCHEMA schema_for_label;

-- Create a resource label based on a schema.
gaussdb=# CREATE RESOURCE LABEL IF NOT EXISTS schema_label add SCHEMA(schema_for_label);

-- Create view view_for_label.
gaussdb=# CREATE VIEW view_for_label AS SELECT 1;

-- Create a resource label based on a view.
gaussdb=# CREATE RESOURCE LABEL IF NOT EXISTS view_label add VIEW(view_for_label);

-- Create function func_for_label.
gaussdb=# CREATE FUNCTION func_for_label RETURNS TEXT AS $$ SELECT col1 FROM tb_for_label; $$ LANGUAGE SQL;

-- Create a resource label based on a function.
gaussdb=# CREATE RESOURCE LABEL IF NOT EXISTS func_label add FUNCTION(func_for_label);

-- Drop the table resource label table_label.
gaussdb=# DROP RESOURCE LABEL IF EXISTS table_label;

-- Drop the column resource label column_label.
gaussdb=# DROP RESOURCE LABEL IF EXISTS column_label;

-- Drop the function resource label func_for_label.
gaussdb=# DROP FUNCTION func_for_label;

-- Drop the view resource label view_for_label.
gaussdb=# DROP VIEW view_for_label;

-- Drop the schema resource label schema_for_label.
gaussdb=# DROP SCHEMA schema_for_label;

-- Drop the tb_for_label table.
gaussdb=# DROP TABLE tb_for_label;
```

Helpful Links

ALTER RESOURCE LABEL and **DROP RESOURCE LABEL**

1.13.9.36 CREATE RESOURCE POOL

Description

Creates a resource pool and specifies the Cgroup of the resource pool.

Precautions

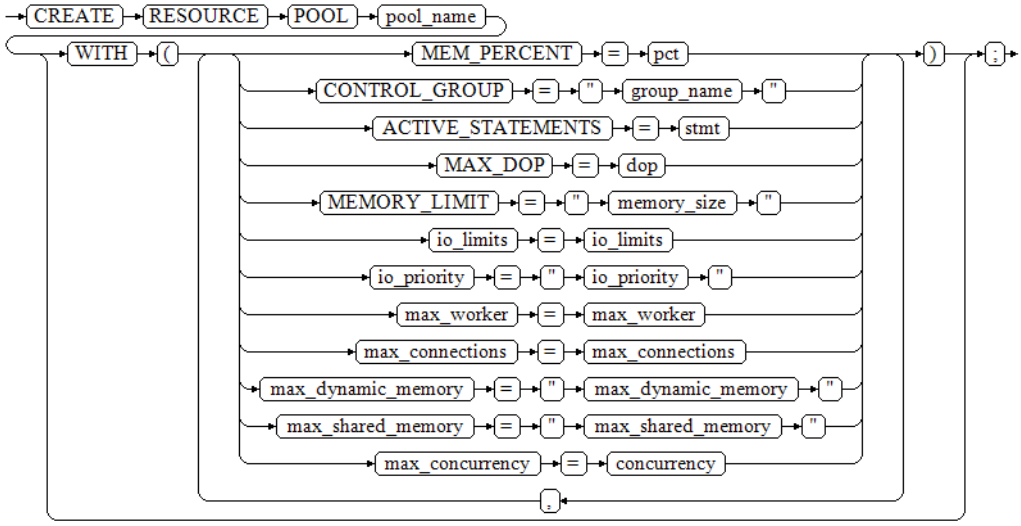
- Only users with the SYSADMIN permission or the initial user can perform this operation.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- This syntax is not supported during upgrade.

Syntax

```
CREATE RESOURCE POOL pool_name
    [WITH ({MEM_PERCENT=pct | CONTROL_GROUP="group_name" | ACTIVE_STATEMENTS=stmt |
MAX_DOP = dop | MEMORY_LIMIT="memory_size" | io_limits=io_limits | io_priority="io_priority" |
max_worker=max_worker | max_connections=max_connections |
max_dynamic_memory="max_dynamic_memory" | max_shared_memory="max_shared_memory" |
max_concurrency=concurrency}[, ... ])];
```



Parameters

- **pool_name**

  The resource pool name must be unique and cannot be the same as an existing resource pool name in the current database.

  Value range: character strings complying with **Identifier Naming Conventions**.

- **group_name**

  Specifies the name of a Cgroup.

  Value range: a string that complies with the following rules:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- You can use either double quotation marks ("") or single quotation marks (') in the syntax when setting the name of a Cgroup.
- The Cgroup name is case-sensitive.
- If **group_name** is not specified, the string "Medium" will be used by default in the syntax, indicating the **Medium** Timeshare Cgroup under **DefaultClass**.
- If an administrator specifies a Workload Cgroup under Class, for example, **control_group** set to **class1:workload1**, the resource pool will be associated with the **workload1** Cgroup under **class1**. The level of **Workload** can also be specified. For example, **control_group** is set to **class1:workload1:1**.
- If a database user specifies the Timeshare string (**Rush**, **High**, **Medium**, or **Low**) in the syntax, for example, **control_group** is set to **High**, the resource pool will be associated with the **High** Timeshare Cgroup under **DefaultClass**.
- In multi-tenant scenarios, the Cgroup associated with a group resource pool is a Class Cgroup, and that associated with a service resource pool is a Workload Cgroup. Additionally, switching Cgroups between different resource pools is not allowed.

- **stmt**

  Specifies the maximum number of statements that can be concurrently executed in a resource pool.

  Value range: an integer ranging from –1 to 2147483647. **–1** indicates no restriction and **0** indicates that no statement can be executed.

- **dop**

  Specifies the maximum statement concurrency degree for a resource pool, equivalent to the number of threads that can be created for executing a statement.

  Value range: a positive integer ranging from 1 to 2147483647.

- **memory_size**

  Specifies the maximum memory size of a resource pool.

  Value range: character strings occupying 1 KB to 2047 GB.

- **mem_percent**

  Specifies the proportion of available resource pool memory to the total memory or group user memory.

  – In multi-tenant scenarios, **mem_percent** of group users or service users ranges from 1 to 100. The default value is **20**.

  – In common scenarios, **mem_percent** of common users ranges from 0 to 100. The default value is **0**.

  NOTE

  If both **mem_percent** and **memory_limit** are specified, only **mem_percent** takes effect.

- **io_limits**

  Specifies the upper limit of IOPS in a resource pool. The unit is 10,000.

- **io_priority**

  I/O priority set for jobs that consume many I/O resources. It takes effect when the I/O usage reaches 50%. The options are **Low**, **Medium**, and **High**.

  If you do not want to control I/O resources, use the default value **None**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

> **NOTE**
>
> The settings of **io_limits** and **io_priority** are valid only for complex jobs, such as batch import (using **INSERT INTO SELECT**, **COPY FROM**, or **CREATE TABLE AS**), complex queries involving over 500 MB data on each DN, and **VACUUM FULL**.

- **max_worker**

  Concurrency in a table during data redistribution. This column is used only for scaling.

- **max_connections**

  Maximum number of connections that can be used by a resource pool.

  > **NOTE**
  >
  > The total number of connections in all resource pools cannot exceed the value of the GUC parameter **max_connections** set for the entire database process.

- **max_dynamic_memory**

  Specifies the maximum dynamic memory that can be used by a resource pool.

- **max_shared_memory**

  Specifies the maximum shared memory that can be used by a resource pool.

- **max_concurrency**

  Specifies the maximum concurrent requests that can be used by a resource pool.

Examples

This example assumes that Cgroups have been created by users in advance. Contact an administrator to create a Cgroup.

```
-- Create a Cgroup (by running commands).
gs_ssh -c "gs_cgroup -c -S class1 -s 40"
gs_ssh -c "gs_cgroup -c -S class1 -G wg1 -g 20"
gs_ssh -c "gs_cgroup -c -S class1 -G wg2 -g 20"

-- Use gsql to log in to the database as an administrator.
-- Create a default resource pool, and associate it with the Medium Timeshare Cgroup under Workload under DefaultClass.
gaussdb=# CREATE RESOURCE POOL pool1;

-- Create a resource pool and specify the High Timeshare Workload Cgroup under the DefaultClass Cgroup.
gaussdb=# CREATE RESOURCE POOL pool2 WITH (CONTROL_GROUP="High");

-- Create a resource pool, and associate it with the Low Timeshare Cgroup under Workload under class1.
gaussdb=# CREATE RESOURCE POOL pool3 WITH (CONTROL_GROUP="class1:Low");

-- Create a resource pool, and associate it with the wg1 Workload Cgroup under class1.
gaussdb=# CREATE RESOURCE POOL pool4 WITH (CONTROL_GROUP="class1:wg1");

-- Create a resource pool, and associate it with the wg2 Workload Cgroup under class1.
gaussdb=# CREATE RESOURCE POOL pool5 WITH (CONTROL_GROUP="class1:wg2:3");

-- Drop resource pools.
gaussdb=# DROP RESOURCE POOL pool1;
gaussdb=# DROP RESOURCE POOL pool2;
gaussdb=# DROP RESOURCE POOL pool3;
gaussdb=# DROP RESOURCE POOL pool4;
gaussdb=# DROP RESOURCE POOL pool5;

-- Drop the Cgroup (by running commands).
gs_ssh -c "gs_cgroup -d -S class1"
```

ALTER RESOURCE POOL and **DROP RESOURCE POOL**

1.13.9.37 CREATE ROLE

Description

Creates a role.

A role is an entity that has objects and permissions in GaussDB. In different environments, a role can represent a user, a group, or both.

Precautions

- By default, new roles added to the database do not have the **LOGIN** attribute. Only roles with the **LOGIN** attribute can log in to the database.
- Only the user who has the CREATE ROLE permission or a system administrator is allowed to create roles.

Syntax

```
CREATE ROLE role_name [ [ WITH ] option [ ... ] ] [ ENCRYPTED | UNENCRYPTED ] { PASSWORD |
IDENTIFIED BY } { 'password' [EXPIRED] | DISABLE }[ PASSWORD EXPIRE INTERVAL 'time' DAY ];
```

The syntax of role information configuration clause **option** is as follows:

```
{
   {SYSADMIN | NOSYSADMIN}
   | {MONADMIN | NOMONADMIN}
   | {OPRADMIN | NOOPRADMIN}
   | {POLADMIN | NOPOLADMIN}
   | {AUDITADMIN | NOAUDITADMIN}
   | {CREATEDB | NOCREATEDB}
   | {USEFT | NOUSEFT}
   | {CREATEROLE | NOCREATEROLE}
   | {INHERIT | NOINHERIT}
   | {LOGIN | NOLOGIN}
   | {REPLICATION | NOREPLICATION}
   | {PERSISTENCE | NOPERSISTENCE}
   | CONNECTION LIMIT connlimit
   | VALID BEGIN 'timestamp'
   | VALID UNTIL 'timestamp'
   | RESOURCE POOL 'respool'
   | USER GROUP 'groupuser'
   | PERM SPACE 'spacelimit'
   | TEMP SPACE 'tmpspacelimit'
   | SPILL SPACE 'spillspacelimit'
   | NODE GROUP logic_cluster_name
   | IN ROLE role_name [, ...]
   | IN GROUP role_name [, ...]
   | ROLE role_name [, ...]
   | ADMIN role_name [, ...]
   | USER role_name [, ...]
   | SYSID uid
   | DEFAULT TABLESPACE tablespace_name
   | PROFILE DEFAULT
   | PROFILE profile_name
   | PGUSER
}
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameters

- **role_name**

  Name of a role.

  Value range: character strings complying with **Identifier Naming Conventions** and not exceeding 63 characters.

  NOTE

  - If a role name contains more than 63 characters, the database truncates it and retains the first 63 characters as the role name.
  - If a role name contains uppercase letters, the database automatically converts the uppercase letters into lowercase letters. To create a role name that contains uppercase letters, enclose the role name with double quotation marks ("").
  - The role name must start with a letter or underscore (_) and can contain only lowercase letters (a to z), uppercase letters (A to Z), underscores (_), digits (0 to 9), and dollar signs ($).
  - The redisuser is an object used for resource control during redistribution. Currently, a role whose **role_name** is **redisuser** cannot be created.

- **password**

  Login password of a role.

  Value range: a character string that cannot be empty.

  A new password must:

  - Contain at least eight characters. This is the default length.
  - Differ from the role name or the role name spelled backward.
  - Contain at least three types of the following characters: uppercase letters (A to Z), lowercase letters (a to z), digits (0 to 9), and special characters (limited to ~ ! @ # $ % ^ & * ( ) - _ = + \ | [{ }] ; : , < . > / ?).
  - The password can also be a ciphertext character string that meets the format requirements. It is mainly used to import user data. You are advised not to use it directly. The database does not verify the complexity of the ciphertext password. Using the ciphertext password may cause data security risks. If you use the ciphertext password, you need to know the plaintext corresponding to the ciphertext password and ensure that the password meets the complexity requirements.
  - When creating a role, use single or double quotation marks to enclose the user password.

- **EXPIRED**

  You can specify **EXPIRED** to create a role with an expired password.

  After **EXPIRED** is specified, the role cannot perform simple and extended queries. The role can perform statements only after its password is changed.

- **PASSWORD EXPIRE INTERVAL 'time' DAY**

  When creating a role, you can set the password validity period. If the password validity period expires, the role is not allowed to log in to the system. You need to change the password before logging in to the system.

  The value of **time** is an integer ranging from 0 to 999. If the validity period is not specified, the default value **0** is used, indicating that the password is valid permanently.

- **DISABLE**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

By default, a role can change its own password. If **DISABLE** is specified, the role cannot change its own password, that is, disabling password changes for that role.

After **DISABLE** is specified, the password of the role is deleted from the system. The role cannot connect to the database using its own password. The role can connect to the database only through external authentication, such as Kerberos authentication.

Only the administrator can enable or disable the password. Common users cannot disable the password of an initial user. To enable a password, run **ALTER USER** and specify the password.

- **ENCRYPTED | UNENCRYPTED**

  Controls whether the password is stored encrypted in the system catalogs.

  According to product security requirements, passwords must be encrypted for storage. **UNENCRYPTED** cannot be used in GaussDB.

  Since the system cannot decrypt the specified encrypted password string, when the password string is already encrypted using SHA-256, it will be stored in that format regardless of whether **ENCRYPTED** or **UNENCRYPTED** is specified. The encrypted password will be reloaded during the dump/restore operation.

- **SYSADMIN | NOSYSADMIN**

  Specifies whether the role is a system administrator. The default value is **NOSYSADMIN**. After **SYSADMIN** is specified, the role has the highest permission in the system.

  – When separation of duties is disabled, the role with the SYSADMIN permission can create users with the SYSADMIN, REPLICATION, CREATEROLE, AUDITADMIN, MONADMIN, POLADMIN, or CREATEDB permission and common users.

  – When separation of duties is enabled, users with the SYSADMIN permission do not have the permission to create users.

- **MONADMIN | NOMONADMIN**

  Specifies whether the role is a monitor administrator. The default value is **NOMONADMIN**.

- **OPRADMIN | NOOPRADMIN**

  Specifies whether the role is an O&M administrator. The default value is **NOOPRADMIN**.

- **POLADMIN | NOPOLADMIN**

  Specifies whether the role is a security policy administrator. The default value is **NOPOLADMIN**.

- **AUDITADMIN | NOAUDITADMIN**

  Specifies whether a role has the audit and management attributes. The default value is **NOAUDITADMIN**.

- **CREATEDB | NOCREATEDB**

  Specifies whether a role can create databases. The default value is **NOCREATEDB**.

- **USEFT | NOUSEFT**

  This parameter is reserved and not used in this version.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **CREATEROLE | NOCREATEROLE**

  Specifies whether a role can create new roles, that is, whether the role can perform the CREATE ROLE and CREATE USER operations. The default value is **NOCREATEROLE**. After **CREATEROLE** is specified, the role can modify and delete other roles.

  - When separation of duties is disabled, users with the CREATEROLE permission can create users with the CREATEROLE, AUDITADMIN, MONADMIN, POLADMIN, or CREATEDB permission and common users.
  - When separation of duties is enabled, users with the CREATEROLE permission can create users with the CREATEROLE, MONADMIN, POLADMIN, or CREATEDB permission and common users.

- **INHERIT | NOINHERIT**

  Specifies whether a role inherits the permissions of roles in the same group. It is not recommended.

- **LOGIN | NOLOGIN**

  Specifies whether a role can log in to the database. Only roles with the **LOGIN** attribute can log in to the database. The default value is **NOLOGIN**.

  A role having the **LOGIN** attribute can be considered as a user.

- **REPLICATION | NOREPLICATION**

  Specifies whether a role is allowed to initiate streaming replication or put the system in and out of backup mode. A role having the **REPLICATION** attribute is specific to replication.

  The default value is **NOREPLICATION**.

- **PERSISTENCE | NOPERSISTENCE**

  Defines a permanent user. Only the initial user is allowed to create, modify, and delete permanent users with the PERSISTENCE attribute.

- **CONNECTION LIMIT connlimit**

  Specifies how many concurrent connections the role can make.

  Value range: an integer in the range [–1,2^{31} – 1]. The default value is **-1**, indicating that there is no limit.

  NOTICE

  - System administrators are not restricted by this parameter.
  - **connlimit** of each CN is calculated separately. The number of connections in a cluster is calculated using the following formula: Number of connections in a cluster = **connlimit** x Number of normal CNs.

- **VALID BEGIN 'timestamp'**

  Sets the effective time of a role. If the effective time is not specified, the role has no restriction on the valid start time.

  timestamp indicates the effective time in the format of 'YYYY-MM-DD HH:mm:ss'.

- **VALID UNTIL 'timestamp'**

  Sets the timestamp when a role expires. If the expiration time is not specified, there is no restriction on the expiration time of the role.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

timestamp indicates the expiration time in the format of 'YYYY-MM-DD HH:mm:ss'.

- **RESOURCE POOL 'respool'**

  Sets the name of resource pool used by the role. The name belongs to the system catalog pg_resource_pool.

- **USER GROUP 'groupuser'**

  Creates a sub-user.

- **PERM SPACE 'SPACELIMIT'**

  Sets the space available for a role.

- **TEMP SPACE 'tmpspacelimit'**

  Sets the space allocated to the temporary table of a role.

- **SPILL SPACE 'spillspacelimit'**

  Sets the operator disk flushing space of a role.

- **IN ROLE role_name**

  Lists one or more existing roles whose permissions will be inherited by a new role. It is not recommended.

- **IN GROUP role_name**

  IN GROUP is the outdated syntax of IN ROLE. It is not recommended.

- **ROLE role_name**

  Lists one or more existing roles which are automatically added as members of the new role.

- **ADMIN role_name**

  Similar to ROLE. However, ADMIN grants permissions of new roles to other roles.

- **USER role_name**

  Specifies an obsolete spelling of the ROLE clause.

- **SYSID uid**

  The SYSID clause is ignored.

- **DEFAULT TABLESPACE tablespace_name**

  The DEFAULT TABLESPACE clause is ignored.

- **PROFILE profile_name**

  The PROFILE clause is ignored.

- **PGUSER**

  In the current version, this attribute is reserved only for compatibility with earlier versions.

Examples

- Differences between CREATE ROLE and CREATE USER

```
-- Run CREATE ROLE to create role test_role.
gaussdb=# CREATE ROLE test_role PASSWORD '********';
-- Run CREATE USER to create user test_user.
gaussdb=# CREATE USER test_user PASSWORD '********';

-- View the information. Roles created by CREATE ROLE are not allowed to log in to the database by default.
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gaussdb=# \du test*
           List of roles
 Role name |  Attributes  | Member of
-----------+--------------+-----------
 test_role | Cannot login | {}
 test_user |              | {}

-- Enable the test_role role to log in to the database.
gaussdb=# ALTER ROLE test_role WITH LOGIN;

gaussdb=# \du test*
           List of roles
 Role name | Attributes | Member of
-----------+------------+-----------
 test_role |            | {}
 test_user |            | {}

-- View schema information. When CREATE USER is executed to create a user, a schema with the
same name is automatically created.
gaussdb=# \dn test*
    List of schemas
   Name    |   Owner
-----------+-----------
 test_user | test_user
(1 row)

-- Drop.
gaussdb=# DROP ROLE test_role;
gaussdb=# DROP USER test_user;
```

- Creating roles with permissions for the separation of duties

```
-- Create user lisa with the OPRADMIN permission and user bob with the SYSADMIN permission.
gaussdb=# CREATE ROLE lisa WITH OPRADMIN PASSWORD '********';
gaussdb=# CREATE ROLE bob WITH SYSADMIN PASSWORD '********';

-- Query the permissions.
gaussdb=# \du lisa;
                  List of roles
 Role name |         Attributes          | Member of
-----------+-----------------------------+-----------
 lisa      | Cannot login, Operatoradmin | {}

gaussdb=# \du bob
                List of roles
 Role name |       Attributes       | Member of
-----------+------------------------+-----------
 bob       | Cannot login, Sysadmin | {}

-- Create role role11 with the CREATEDB permission.
gaussdb=# CREATE ROLE role11 CREATEDB PASSWORD '********';
CREATE ROLE

-- Query the permissions.
gaussdb=# \du role11
                 List of roles
 Role name |       Attributes        | Member of
-----------+-------------------------+-----------
 role11    | Create DB, Cannot login | {}

-- Create role role12 using the ADMIN clause.
gaussdb=# CREATE ROLE role12 WITH  CREATEDB  ADMIN role11  PASSWORD '********';
CREATE ROLE
-- Query the permissions.
gaussdb=# \du role11
                 List of roles
 Role name |       Attributes        | Member of
-----------+-------------------------+-----------
 role11    | Create DB, Cannot login | {role12}

gaussdb=# \du role12
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
                List of roles
 Role name |       Attributes        | Member of
-----------+-------------------------+-----------
 role12    | Create DB, Cannot login | {}

-- Drop roles.
gaussdb=# DROP ROLE role11;
gaussdb=# DROP ROLE role12;
gaussdb=# DROP ROLE lisa;
gaussdb=# DROP ROLE bob;

-- Separation-of-duties configuration: If enableSeparationOfDuty is set to on, the separation of duties is enabled to restrict the permissions of system administrators. System administrators are not allowed to create or modify user configurations.

-- Check whether separation of duties is enabled.
gaussdb=# SHOW enableSeparationOfDuty;
 enableSeparationOfDuty
------------------------
 off
(1 row)
-- Run the following statement to modify parameters:
gs_guc set -Z coordinator -Z datanode -N all -I all -c "enableSeparationOfDuty = on"

-- After the setting is successful, the setting takes effect after a restart.
gs_om -t stop
gs_om -t start

-- Check the separation of duties again.
gaussdb=# SHOW enableSeparationOfDuty;
 enableSeparationOfDuty
------------------------
 on
(1 row)
```

- Creating a role with an expired password

```
-- Create the role test_role2 with an expired password.
gaussdb=# CREATE ROLE test_role2 PASSWORD '********' EXPIRED;
gaussdb=# ALTER ROLE test_role2 WITH LOGIN;

-- test_role2 cannot perform any operation after logging in to the database. You can perform operations only after changing the password as prompted.
gaussdb=# SET ROLE test_role2 PASSWORD '********';
gaussdb=> \d
ERROR:  Please use "ALTER ROLE user_name IDENTIFIED BY 'password' REPLACE 'old password';" to modify the expired password of user test_role2 before operation!

-- Change the password of role test_role2.
gaussdb=> ALTER ROLE test_role2 IDENTIFIED BY '********' REPLACE '********';

-- Drop.
gaussdb=> RESET ROLE;
gaussdb=# DROP ROLE test_role2;
```

- Creating a role and specifying the effective date and expiration date

```
-- Create a role with its validity from January 1, 2015 to January 1, 2026.
gaussdb=# CREATE ROLE test_role3 WITH LOGIN PASSWORD '********' VALID BEGIN '2015-01-01' VALID UNTIL '2026-01-01';
-- Drop.
gaussdb=# DROP ROLE test_role3;
```

- Creating a role and setting the password validity period

```
-- Create a role with a validity period of 30 days.
gaussdb=# CREATE ROLE role4 PASSWORD '********' PASSWORD EXPIRE INTERVAL 30 DAY;
```

1.13.9.38 CREATE ROW LEVEL SECURITY POLICY

Description

Creates a row-level security policy for a table.

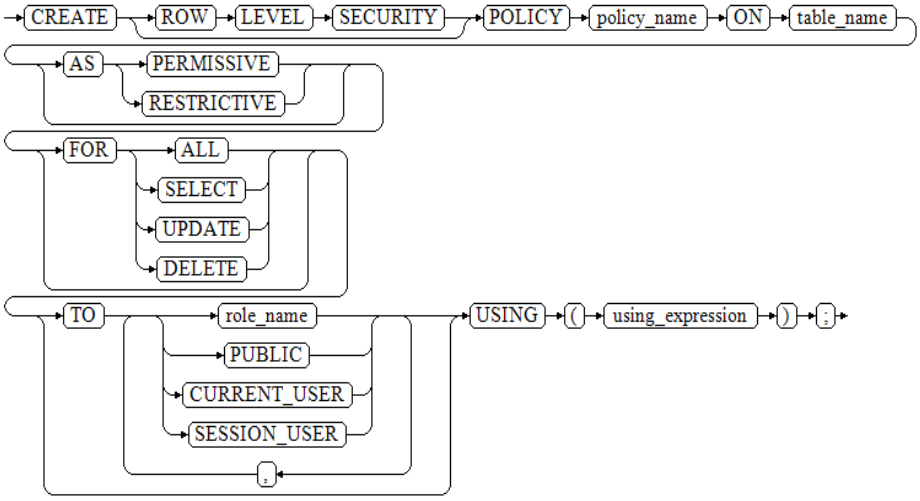
Precautions

- Row-level security policies can be created for row-store tables, row-store partitioned tables, replication tables, unlogged tables, and hash tables.
- Row-level security policies cannot be created for foreign tables and temporary tables.
- Row-level security policies cannot be created for views.
- A maximum of 100 row-level security policies can be defined for a table.
- System administrators are not affected by row-level security policies and can view all data in a table.
- Tables queried by using SQL statements, views, functions, and stored procedures are affected by row-level security policies.
- The data type of a table column to which a row-level security policy has been added cannot be changed.
- The policy takes effect only after row-level security is enabled (by running **ALTER TABLE ... ENABLE ROW LEVEL SECURITY**).
- Currently, row-level security affects the read (SELECT, UPDATE, and DELETE) of data tables and does not affect the write (INSERT and MERGE INTO) of data tables.
- The table owner or system administrators can create an expression in the USING clause. When the client reads the data table, the database server combines the expressions that meet the condition and applies it to the execution plan in the statement rewriting phase of a query. For each tuple in a data table, if the USING expression returns **TRUE**, the tuple is visible to the current user; if the USING expression returns **FALSE** or **NULL**, the tuple is invisible to the current user.
- A row-level security policy name is specific to a table. A data table cannot have row-level security policies with the same name. Different data tables can have the same row-level security policy.

Syntax

```
CREATE [ ROW LEVEL SECURITY ] POLICY policy_name ON table_name
    [ AS { PERMISSIVE | RESTRICTIVE } ]
    [ FOR { ALL | SELECT | UPDATE | DELETE } ]
    [ TO { role_name | PUBLIC | CURRENT_USER | SESSION_USER } [, ...] ]
    USING ( using_expression );
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.



Parameters

- **policy_name**

  Specifies the name of a row-level security policy to be created. The names of row-level security policies for a table must be unique.

- **table_name**

  Specifies the name of a table to which a row-level security policy is applied.

- **PERMISSIVE | RESTRICTIVE**
  - **PERMISSIVE** enables the permissive policy for row-level security. The conditions of the permissive policy are joined through the OR expression.
  - **RESTRICTIVE** enables the restrictive policy for row-level security. The conditions of the restrictive policy are joined through the AND expression.

  The join method is as follows:

  ```
  (using_expression_permissive_1 OR using_expression_permissive_2 ...) AND
  (using_expression_restrictive_1 AND using_expression_restrictive_2 ...)
  ```

  If not specified, the default value is **PERMISSIVE**.

- **command**

  Specifies the SQL operations affected by a row-level security policy, including **ALL**, **SELECT**, **UPDATE**, and **DELETE**. If not specified, the default value is **ALL**.
  - **ALL** indicates that all SELECT, UPDATE, and DELETE operations are affected.
  - **SELECT** indicates that SELECT operations are affected by row-level security policies. Only tuple data that meets the condition (the return value of **using_expression** is **true**) can be viewed. The affected operations include SELECT, SELECT FOR UPDATE/SHARE, UPDATE ... RETURNING, and DELETE ... RETURNING.
  - **UPDATE** indicates that UPDATE operations are affected by row-level security policies. Only tuple data that meets the condition (the return value of **using_expression** is **true**) can be updated. The affected operations include UPDATE, UPDATE ... RETURNING, and SELECT ... FOR UPDATE/SHARE.
  - **DELETE** indicates that DELETE operations are affected by row-level security policies. Only tuple data that meets the condition (the return

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

value of **using_expression** is **true**) can be deleted. The affected operations include DELETE and DELETE ... RETURNING.

For the relationship between row-level security policies and SQL statements, see **Table 1-397**.

Table 1-397 Relationship between the ROW LEVEL SECURITY policy and SQL statements

Command	SELECT/ALL Policy	UPDATE/ALL Policy	DELETE/ALL Policy
SELECT	Existing row	No	No
SELECT FOR UPDATE/SHARE	Existing row	Existing row	No
UPDATE	No	Existing row	No
UPDATE RETURNING	Existing row	Existing row	No
DELETE	No	No	Existing row
DELETE RETURNING	Existing row	No	Existing row

- **role_name | PUBLIC | CURRENT_USER | SESSION_USER**

  Specifies database users/roles affected by a row-level security policy. Row-level security policies can be applied to a specified user /role or to all users (**PUBLIC**). The default value **PUBLIC** will be used if you do not specify the user who will be affected.

  - **role_name**: the specified database user.
  - **CURRENT_USER**: username of the current operating environment.
  - **SESSION_USER**: session username.
  - **PUBLIC**: All database users are affected. You can specify multiple affected database users.

  NOTICE

  System administrators are not affected by row-level security.

- **using_expression**

  Specifies an expression defined for a row-level security policy (return type: Boolean).

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- The expression cannot contain aggregate functions or window functions.
- In the statement rewriting phase of a query, if row-level security for a data table is enabled, the expressions that meet the specified conditions will be added to the plan tree.
- The expression is calculated for each tuple in the data table. For SELECT, UPDATE, and DELETE, row data is visible to the current user only when the return value of the expression is **TRUE**. If the expression returns **FALSE**, the tuple is invisible to the current user. In this case, the user cannot view the tuple through the SELECT statement, update the tuple through the UPDATE statement, or delete the tuple through the DELETE statement.

Examples

```
-- Create user alice.
gaussdb=# CREATE USER alice PASSWORD '*********';

-- Create user bob.
gaussdb=# CREATE USER bob PASSWORD '*********';

-- Create data table all_data.
gaussdb=# CREATE TABLE public.all_data(id int, role varchar(100), data varchar(100));

-- Insert data into the data table.
gaussdb=# INSERT INTO all_data VALUES(1, 'alice', 'alice data');
gaussdb=# INSERT INTO all_data VALUES(2, 'bob', 'bob data');
gaussdb=# INSERT INTO all_data VALUES(3, 'peter', 'peter data');

-- Grant the read permission on the all_data table to users alice and bob.
gaussdb=# GRANT SELECT ON all_data TO alice, bob;

-- Enable the row-level security policy.
gaussdb=# ALTER TABLE all_data ENABLE ROW LEVEL SECURITY;

-- Create a row-level security policy to specify that the current user can view only their own data.
gaussdb=# CREATE ROW LEVEL SECURITY POLICY all_data_rls ON all_data USING(role = CURRENT_USER);

-- View information about the all_data table.
gaussdb=# \d+ all_data
                            Table "public.all_data"
 Column |          Type          | Modifiers | Storage  | Stats target | Description
--------+------------------------+-----------+----------+--------------+-------------
 id     | integer                |           | plain    |              |
 role   | character varying(100) |           | extended |              |
 data   | character varying(100) |           | extended |              |
Row Level Security Policies:
    POLICY "all_data_rls" FOR ALL
      TO public
      USING (((role)::name = "current_user"()))
Has OIDs: no
Distribute By: HASH(id)
Location Nodes: ALL DATANODES

DROP ROW LEVEL SECURITY POLICY and **ALTER ROW LEVEL SECURITY POLICY**

1.13.9.39 CREATE SCHEMA

Description

Creates a schema.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

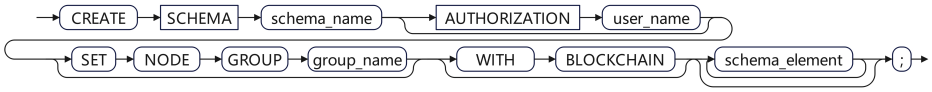
Precautions

- Users with the CREATE permission in the database can create schemas.
- The owner of an object created by a system administrator in a schema with the same name as a common user is the common user, not the system administrator.
- The schema name can be used as a prefix to access named objects. Without this prefix, the system will access named objects within the current schema. When creating a named object, you can also use the schema name as its prefix.
- CREATE SCHEMA can include a subcommand for creating an object in a new schema. Using this subcommand is the same as the executing the subcommand after a schema is created. If the AUTHORIZATION clause is used, all the created objects are owned by this user.

Syntax

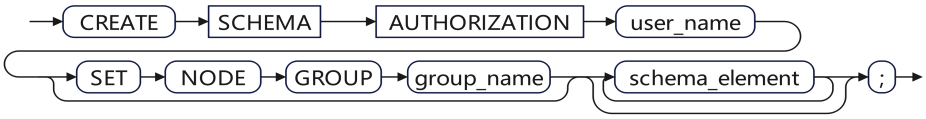
- Create a schema based on a specified schema name.

```
CREATE SCHEMA schema_name
   [ AUTHORIZATION user_name ] [SET NODE GROUP group_name] [WITH BLOCKCHAIN]
[ schema_element [ ... ] ];
```



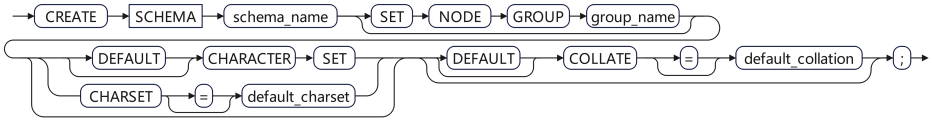
- Create a schema based on a username.

```
CREATE SCHEMA AUTHORIZATION user_name [SET NODE GROUP group_name] [ schema_element
[ ... ] ];
```



- Create a schema and specify the default character set and collation.

```
CREATE SCHEMA schema_name [SET NODE GROUP group_name]
   [ [DEFAULT] CHARACTER SET | CHARSET [ = ] default_charset ] [ [DEFAULT] COLLATE [ = ]
default_collation ];
```



Parameters

- **schema_name**

  Specifies the schema name.

  Value range: character strings complying with **Identifier Naming Conventions**.

  The rules for naming a schema are as follows:

  – The schema name must be unique in the current database.

  – The new name cannot be the same as the initial username of the current database.

  – Do not use a new name starting with pg_, gs_role_, or data_redis.

- **AUTHORIZATION user_name**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Specifies the owner of a schema. If **schema_name** is not specified (that is, **creating a schema based on a username**), **user_name** is used as the schema name. In this case, **user_name** can only be a role name.

Value range: an existing username or role name

- **SET NODE GROUP group_name**

  Sets the single-node attribute of a schema. **group_name** indicates the name of a single-node group. Only the single-node group whose type is 's' can be set. The prefix of the group name is **sys_single_group**.

  NOTE

  - This syntax is supported only in M-compatible databases (**sql_compatibility = 'M'**).
  - The CREATE SCHEMA syntax that includes the CREATE TABLE clause (referred to as a composite SQL statement) does not support the single-node table feature. This means it cannot be used to create single-node tables or set the single-node table attribute for schemas.

- **WITH BLOCKCHAIN**

  Specifies the tamper-proof attribute of a schema.

  NOTE

  - To change a normal schema to a tamper-proof schema, set the GUC parameter **enable_ledger** to **on**. The default value is **off**, and the level is SIGHUP.
  - Ordinary row-store tables in the tamper-proof mode are automatically extended to tamper-proof user tables.

- **schema_element**

  Specifies an SQL statement defining an object to be created within the schema.

  Currently, only the CREATE TABLE, CREATE VIEW, CREATE INDEX, CREATE TABLE PARTITION, CREATE SEQUENCE, CREATE TRIGGER, and GRANT clauses are supported.

  NOTE

  - Objects created by **schema_element** are owned by the **user_name** specified by **AUTHORIZATION user_name**.
  - If objects with the same name exist in the schemas in the current search path, you need to specify the schema where the referenced objects are located. You can run **SHOW search_path** to check the schemas on the current search path.

- **default_charset**

  Specifies the default character set of a schema. If this option is not specified, the schema will use the default character set corresponding to the specified collation.

  Value range: For details about the supported character sets, see **Table 1-398**.

  NOTE

  This syntax is supported only when **sql_compatibility** is set to **'MYSQL'** or **'M'**. The preceding information is displayed when **sql_compatibility** is set to **'MYSQL'**. For details about the information when **sql_compatibility** is set to **'M'**, see "SQL Reference > SQL Syntax > SQL Statements > C > CREATE SCHEMA" in *M Compatibility Developer Guide*.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **default_collation**

  Specifies the default collation of a schema. If this option is not specified, the schema will use the default collation corresponding to the specified character set.

  Value range: For details about the supported character sets, see **Table 1-398**.

  > NOTE
  >
  > This syntax is supported only when **sql_compatibility** is set to **'MYSQL'** or **'M'**. The preceding information is displayed when **sql_compatibility** is set to **'MYSQL'**. For details about the information when **sql_compatibility** is set to **'M'**, see "SQL Reference > SQL Syntax > SQL Statements > C > CREATE SCHEMA" in *M Compatibility Developer Guide*.

Examples

```
-- Create the role1 role.
gaussdb=# CREATE ROLE role1 IDENTIFIED BY '********';
CREATE ROLE

-- Create a schema named role1 for the role1 role. The owner of the films and winners tables created by the schema_element subcommand is role1.
gaussdb=# CREATE SCHEMA AUTHORIZATION role1
    CREATE TABLE films (title text, release date, awards text[])
    CREATE VIEW winners AS SELECT title, release FROM films WHERE awards IS NOT NULL;
CREATE SCHEMA

-- Create role2.
gaussdb=# CREATE ROLE role2 IDENTIFIED BY '********';
CREATE ROLE

-- Create schema1 based on the name and specify role2 as the owner.
gaussdb=# CREATE SCHEMA schema1 AUTHORIZATION role2;
CREATE SCHEMA

-- Create schema2 by name and explicitly set the single-node table attribute.
gaussdb=# CREATE SCHEMA schema2 SET NODE GROUP sys_single_group1;
CREATE SCHEMA

-- Modify the tamper-proof attribute.
-- Before modifying the tamper-proof attribute, you need to use gs_guc to set the GUC parameter enable_ledger to on. The default value is off.
gs_guc reload -Z coordinator -Z datanode -N all -I all -c "enable_ledger=on";

-- Check whether enable_ledger is on.
gaussdb=# SHOW enable_ledger;
 enable_ledger
---------------
 on
(1 row)

-- Create a schema and specify the tamper-proof attribute.
gaussdb=# CREATE SCHEMA ledgernsp WITH BLOCKCHAIN;
CREATE SCHEMA

-- Drop schemas.
gaussdb=# DROP SCHEMA role1 CASCADE;
gaussdb=# DROP SCHEMA schema1 CASCADE;
gaussdb=# DROP SCHEMA schema2 CASCADE;
gaussdb=# DROP SCHEMA ledgernsp CASCADE;

-- Drop users.
gaussdb=# DROP USER role1 CASCADE;
gaussdb=# DROP USER role2 CASCADE;
```

ALTER SCHEMA and **DROP SCHEMA**

1.13.9.40 CREATE SECURITY LABEL

Description

Creates a security label for the specified security policy in the current database.

Precautions

The initial user, users with the SYSADMIN permission, or users who inherit permissions of the built-in role gs_role_seclabel can create security labels.

Syntax

```
CREATE SECURITY LABEL label_name 'label_content';
```

Parameters

- **label_name**

  Security label name, which must be unique in the database.

  Value range: character strings complying with **Identifier Naming Conventions** and not exceeding 63 characters.

  NOTE

  - If the value contains more than 63 characters, the database truncates it and retains the first 63 characters as the security label name.
  - If a security label name contains uppercase letters, the database automatically converts the uppercase letters into lowercase letters. To create a resource label name that contains uppercase letters, enclose the security label name with double quotation marks ("").
  - The security label name must start with a letter or underscore (_) and can contain only lowercase letters (a to z), uppercase letters (A to Z), underscores (_), digits (0 to 9), and dollar signs ($).

- **label_content**

  Security label content. The requirements are as follows:

  A security label consists of a level and a range, which are separated by a colon (:). The format is "level:range" with only one level and at least one range, for example, "L1:G2,G41,G6-G27".

  - There are 1024 levels named **L***i*, where 1 ≤ *i* ≤ 1024. The levels meet a partial order relationship (if *i* ≤ *j*, then **L***i* ≤ **L***j*). For example, L1 is lower than L3.
  - There are 1024 ranges named **G***i*, where 1 ≤ *i* ≤ 1024. Ranges cannot be compared, but set operations can be performed. Multiple ranges are separated by commas (,). A hyphen (-) indicates an interval. For example, {G2-G5} indicates {G2, G3, G4, G5}, and {G1} is a subset of the set {G1, G6}.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

  - The letters L and G must be capitalized and followed by at least one non-zero digit. Other characters are not allowed. In the {Gxxx-Gyyy} format, yyy must be greater than or equal to xxx.
  - If the input levels and ranges do not meet the requirements, the system reports an error.

```
-- Example
gaussdb=# CREATE SECURITY LABEL sec_label3 'L3:'; // The label must contain at least one content range category.
ERROR:  in label text "L3:", there at least have one level and one group
```

Examples

```
-- Create a security label sec_label.
gaussdb=# CREATE SECURITY LABEL sec_label 'L1:G4';

-- Create security label sec_label with the content of 'L1:G2,G4'.
gaussdb=# CREATE SECURITY LABEL sec_label 'L1:G2,G4';
ERROR:  security label "sec_label" already exists
-- Create security label sec_label1 with the content of 'L1:G2,G4'.
gaussdb=# CREATE SECURITY LABEL sec_label1 'L1:G2,G4';

-- Create security label sec_label2 with the content of 'L3:G1-G5'.
gaussdb=# CREATE SECURITY LABEL sec_label2 'L3:G1-G5';

-- View the security labels created in the system.
gaussdb=# SELECT * FROM gs_security_label;
 label_name | label_content
------------+---------------
 sec_label  | L1:G4
 sec_label1 | L1:G2,G4
 sec_label2 | L3:G1-G5
(3 rows)

-- Delete the existing security labels sec_label, sec_label1, and sec_label2.
gaussdb=# DROP SECURITY LABEL sec_label;
gaussdb=# DROP SECURITY LABEL sec_label1;
gaussdb=# DROP SECURITY LABEL sec_label2;

-- View the security labels created in the system again.
gaussdb=# SELECT * FROM gs_security_label;
 label_name | label_content
------------+---------------
(0 rows)
```

DROP SECURITY LABEL and **SECURITY LABEL ON**

1.13.9.41 CREATE SEQUENCE

Description

Adds a sequence to the current database. A sequence is a special table that stores arithmetic progressions. It does not store regular data and is usually used to generate unique identifiers for rows or tables.

Precautions

- You can create sequences in the **PUBLIC** or user schemas only when you have the CREATE ANY SEQUENCE permission. The user who creates a sequence becomes its owner.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- After a sequence is created, when you use the nextval() and generate_series(1,*N*) functions of the sequence to insert data into a table, ensure that the number of times the nextval() function can be called is greater than or equal to *N* + 1. Otherwise, an error will be reported because the generate_series() function calls the nextval() function for *N* + 1 times.
- Sequences cannot be associated with the **rowid** and **rowno** system columns.

Syntax

```
CREATE [LARGE] SEQUENCE [ IF NOT EXISTS ] name [ INCREMENT [ BY ] increment ]
    [ MINVALUE minvalue | NO MINVALUE | NOMINVALUE ] [ MAXVALUE maxvalue | NO MAXVALUE |
NOMAXVALUE]
    [ START [ WITH ] start ] [ CACHE cache | NOCACHE ] [ [ NO ] CYCLE | NOCYCLE ] [ RESTART [ WITH
start ] ]
    [ OWNED BY { table_name.column_name | NONE } ];
```

Parameters

- **LARGE**

  If **LARGE** is specified, a 128-bit int sequence is created. If **LARGE** is not specified, a 64-bit int sequence is created by default.

  By default, the maximum value of **SEQUENCE** is $2^{63} - 1$. If a LARGE identifier is used, the maximum value can be $2^{127} - 1$.

- **IF NOT EXISTS**

  When the **IF NOT EXISTS** keyword is specified, the system checks the current schema for any sequence with the same name before you create a sequence. If it finds such a sequence, the sequence creation process will be halted, and a NOTICE message will be returned.

  When **IF NOT EXISTS** is not specified and a sequence with the same name exists in the schema, an ERROR is returned.

- **name**

  Specifies the name of the sequence to be created. The name can be schema-qualified. If a schema is qualified, the sequence is created in the specified schema; otherwise, it is created in the current schema. In the same schema, the sequence name must be unique and cannot be the same as that of other sequences, tables, indexes, views, or foreign tables in the schema.

  Value range: character strings complying with **Identifier Naming Conventions** and not exceeding 63 characters.

- **increment**

  (Optional) Step of the sequence.

  – Positive number: An ascending sequence is created.

  – Negative number: A descending sequence is created.

  The default value is **1**.

  NOTE

  In MySQL-compatible mode, any floating-point number used as a step will be automatically converted to an integer. In other modes, this parameter cannot be set to a floating-point number.

- **MINVALUE minvalue | NO MINVALUE| NOMINVALUE**

  (Optional) Determines the minimum value that the sequence can generate. **NOMINVALUE** is equivalent to **NO MINVALUE**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

If **minvalue** is not declared or **NO MINVALUE** is declared:

- If the keyword LARGE is not declared, the default value of an ascending sequence is **1**, and that of a descending sequence is **$-2^{63} + 1$**.
- If the keyword LARGE is declared, the default value of an ascending sequence is **1**, and that of a descending sequence is **-2^{127}**.

- **MAXVALUE maxvalue | NO MAXVALUE| NOMAXVALUE**

  (Optional) Determines the maximum value that the sequence can generate. **NOMAXVALUE** is equivalent to **NO MAXVALUE**.

  If **maxvalue** is not declared or **NO MAXVALUE** is declared:

  - If the keyword LARGE is not declared, the default value of an ascending sequence is **$2^{63} – 1$**, and that of a descending sequence is **-1**.
  - If the keyword LARGE is declared, the default value of an ascending sequence is **$2^{127} – 1$**, and that of a descending sequence is **-1**.

  NOTE

  When a sequence is bound to a table column, if the sequence value exceeds the maximum value of the column type, an error will be reported during data insertion. Therefore, the column type must be able to accommodate the maximum possible value of the sequence to prevent service exceptions.

- **START [WITH] start**

  (Optional) Specifies the starting value for the sequence.

  Default value: **minvalue** for an ascending sequence and **maxvalue** for a descending sequence.

- **CACHE cache | NOCACHE**

  (Optional) Specifies the number of sequences stored in the memory for quick access purposes. **NOCACHE** is equivalent to not specifying **CACHE**.

  Default value: **1** (only one value can be generated at a time, i.e., no cache).

  NOTE

  - It is not recommended that you define **cache** and **maxvalue** or **minvalue** at the same time. Doing so may disrupt the sequence's continuity and result in unused sequence numbers. If you have specific requirements on concurrency performance, set the GUC parameter **session_sequence_cache**.
  - **cache** determines the value that a single CN/DN can request from the GTM at a time. **session_sequence_cache** determines the value that a single session can request from a CN/DN at a time. This value will be automatically discarded once the session ends.
  - The larger the cache, the longer the time required for executing nextval () for the first time.

- **[NO] CYCLE | NOCYCLE**

  (Optional) Allows the sequence to wrap around when **maxvalue** or **minvalue** has been reached.

  If **NO CYCLE** is specified, any calls to nextval after the sequence has reached its maximum value will return an error.

  - **NOCYCLE** is equivalent to **NO CYCLE**. If the cycling option is not specified, the default value is **NO CYCLE**.
  - If **CYCLE** is specified, the sequence uniqueness cannot be ensured.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **RESTART [WITH start]**

  (Optional) Specifies the starting value for the sequence again.

  If **start** is not specified, the default value is **minvalue** for an ascending sequence and **maxvalue** for a descending sequence.

- **OWNED BY**

  (Optional) Joins a sequence with a specified column included in a table. In this way, the sequence will be deleted when you delete its joined column or the table where the column belongs to. The joined table and sequence must be owned by the same user and in the same schema. Note that OWNED BY only joins a table column with the sequence and does not automatically generate an auto-increment sequence when data is inserted.

  OWNED BY NONE, the default, specifies that there is no such join.

NOTICE

You are advised not to use the sequence created using OWNED BY in other tables. If multiple tables need to share a sequence, the sequence must not belong to a specific table.

Examples

- Create an ascending sequence named **seq1**. The sequence starts from 101 and the step is 10.

```
gaussdb=# CREATE SEQUENCE seq1
    START 101
    INCREMENT 10;

-- Select the next number from the sequence.
gaussdb=# SELECT nextval('seq1');
 nextval
---------
     101
(1 row)
gaussdb=# SELECT nextval('seq1');
 nextval
---------
     111

-- Delete the sequence.
gaussdb=# DROP SEQUENCE seq1;
```

- Implement the auto-increment column.

```
-- Create a table.
gaussdb=# CREATE TABLE test1(id int PRIMARY KEY, name varchar(20));

-- Create a sequence joined with the table.
gaussdb=# CREATE SEQUENCE test_seq2
    START 1
    NO CYCLE
    OWNED BY test1.id;

-- Set the default value of a column.
gaussdb=# ALTER TABLE test1 ALTER COLUMN id SET DEFAULT nextval('test_seq2'::regclass);

-- Insert data.
gaussdb=# INSERT INTO test1 (name) values ('Joe'),('Scott'),('Ben');

-- Query.
gaussdb=# SELECT * FROM test1;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
 id | name
----+-------
  3 | Ben
  1 | Joe
  2 | Scott
(3 rows)

-- Delete the sequence and the table.
gaussdb=# DROP SEQUENCE test_seq2 CASCADE;
gaussdb=# DROP TABLE test1;
```

- Create a cycle sequence.

```
-- Create an ascending sequence seq_test1. The maximum value is 3 and the sequence can be cycled.
gaussdb=# CREATE SEQUENCE seq_test1
    START 1
    MAXVALUE 3
    CYCLE;

-- Create a table and insert data into the table.
gaussdb=# CREATE TABLE tbl_test1(
    c1 int DEFAULT nextval('seq_test1'),
    c2 varchar
);
gaussdb=# INSERT INTO tbl_test1 (c2) values ('test');
gaussdb=# INSERT INTO tbl_test1 (c2) values ('test');
gaussdb=# INSERT INTO tbl_test1 (c2) values ('test');
gaussdb=# INSERT INTO tbl_test1 (c2) values ('test');
gaussdb=# INSERT INTO tbl_test1 (c2) values ('test');

-- Query table data. When the value of ascending sequence seq_test reaches the maximum value, the value starts from the minimum value again.
gaussdb=# SELECT ctid,* FROM tbl_test1 ORDER BY 1,2;
 ctid  | c1 |  c2
-------+----+------
 (0,1) |  1 | test
 (0,1) |  3 | test
 (0,2) |  2 | test
 (0,3) |  1 | test
 (0,4) |  2 | test
(5 rows)

-- Delete the table and sequence.
gaussdb=# DROP TABLE tbl_test1;
gaussdb=# DROP SEQUENCE seq_test1;
```

Helpful Links

DROP SEQUENCE and **ALTER SEQUENCE**

1.13.9.42 CREATE SERVER

Description

Creates a foreign server. A foreign server stores other homogeneous cluster information.

Precautions

- Only a system administrator and users with permission to use a specified FOREIGN DATA WRAPPER can create a foreign server. The authorization syntax is as follows:

  ```
  GRANT USAGE ON FOREIGN DATA WRAPPER fdw_name TO username
  ```

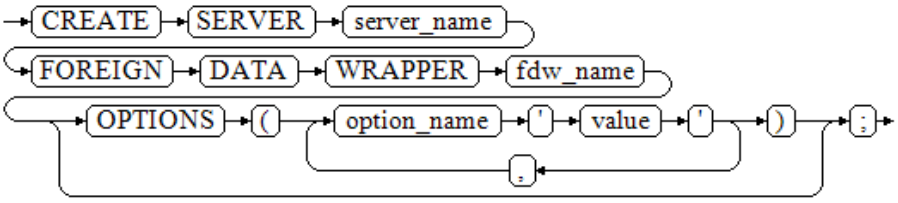
  fdw_name is the name of the FOREIGN DATA WRAPPER, and **username** is the name of the user creating a foreign server.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- When multi-layer quotation marks are used for sensitive columns (such as **password**) in **OPTIONS**, the semantics is different from that in the scenario where quotation marks are not used. Therefore, sensitive columns are not identified for anonymization.

Syntax

```
CREATE SERVER server_name
   FOREIGN DATA WRAPPER fdw_name
   [ OPTIONS ( { option_name ' value ' } [, ...] ) ];
```



Parameters

- **server_name**

  Name of the foreign server to be created.

  Value range: character strings complying with **Identifier Naming Conventions** and not exceeding 63 characters.

- **FOREIGN DATA WRAPPER fdw_name**

  Specifies the name of the foreign data wrapper.

  Value range: **fdw_name** is the data wrapper created by the system during database initialization. Currently, **fdw_name** can only be **gc_fdw** for other homogeneous clusters. You can also create **dist_fdw**, **file_fdw**, and **log_fdw**. **log_fdw** is used only for syntax compatibility and can be used to create foreign tables, but it is meaningless. **dist_fdw** is used to import GDS data. You do not need to manually create a server using **dist_fdw** because **gsmpp_server** is already built in.

- **OPTIONS ({ option_name ' value ' } [, ...])**

  Specifies the parameters of a foreign server.

  – address

    Address of the foreign server.

  – dbname

    Database name of the foreign server.

  – username

    Username of a foreign server.

  – password

    Password of the foreign server.

Examples

Create a foreign server, in which **file_fdw** is the FOREIGN DATA WRAPPER existing in the database.

```
-- Create a foreign server.
gaussdb=# CREATE SERVER my_server FOREIGN DATA WRAPPER file_fdw;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
-- Delete the foreign server.
gaussdb=# DROP SERVER my_server;
```

Create another foreign server in the homogeneous cluster, where **gc_fdw** is the foreign data wrapper in the database.

```
-- Create a foreign server.
gaussdb=# CREATE SERVER server_remote FOREIGN DATA WRAPPER GC_FDW OPTIONS
    (address '10.146.187.231:8000,10.180.157.130:8000' ,
  dbname 'test',
  username 'test',
  password '********'
);

-- Delete the foreign server.
gaussdb=# DROP SERVER server_remote;
```

Helpful Links

ALTER SERVER and **DROP SERVER**

1.13.9.43 CREATE SYNONYM

Description

Creates a synonym object. A synonym is an alias of a database object and is used to record the mapping between database object names. You can use synonyms to access associated database objects. To use a synonym, you must have the required permissions on the associated object. Currently, synonyms can be used to access the following database objects: tables, views, types, packages, functions, stored procedures, sequences, and other synonym objects.

Precautions

- Users granted the CREATE ANY SYNONYM permission can create synonyms in user schemas.
- The following DML statements support synonyms: SELECT, INSERT, UPDATE, DELETE, EXPLAIN, and CALL.
- DDL statements (CREATE, DROP, and ALTER) cannot be executed on associated objects through synonyms.
- Do not create synonyms in stored procedures or functions. Synonyms must be created in the pg_synonym system catalog in advance, so that they can be referenced in a stored procedure.
- To prevent sensitive information leakage, you are not allowed to create synonyms for functions that contain sensitive information such as passwords (for example, encryption and decryption functions gs_encrypt, gs_decrypt, gs_encrypt_bytea, and gs_decrypt_bytea) or call such functions through synonyms.
- You are advised not to create synonyms for temporary tables. To create a synonym, you need to specify the schema name of the target temporary table. Otherwise, the synonym cannot be used normally. In addition, you need to run the **DROP SYNONYM** command before the current session ends.
- Synonyms cannot be created for encrypted tables that contain encrypted columns and views, functions, and stored procedures based on encrypted tables.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- You cannot use meta-commands such as \d, \df, and \sf to access information about associated objects through synonyms.
- Synonyms can be nested. When a synonym is used, if the synonym points to another synonym, the system traces the synonym layer by layer until the final associated object is found.
- The synonym search and parsing rules are as follows:
  - If the **search_path** is set and the schema of the synonym is not specified, the parsing sequence is as follows:

    Stored procedures and functions: The pg_proc system catalog is preferentially searched by name. If no function with the same name is found, synonyms are searched. Finally, the search is performed on the **search_pat**h.

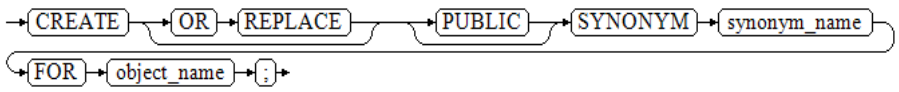
    Other objects (such as tables and views): The search is performed on the **search_path** first. In the same schema, the priority of objects themselves is higher than that of synonyms.
  - If the search statement specifies both an object and its schema, for example, **schema1.object1**:

    The system checks whether the object **schema1.object1** exists. If the object does not exist, it checks whether the synonym **schema1.object1** exists. If the synonym **schema1.object1** exists, the object **schema2.object2** associated with the synonym is searched. If neither **schema2.object2** nor the synonym **schema2.object2** exists and **schema2** is a username, the public synonym **object2** is searched.
  - If the search SQL statement does not give the schema of the object, for example, **object1**:

    The system traverses **search_path** to search for object **schema.object1** in the specified schema. If object **schema.object1** does not exist, the system searches for the synonym **schema.object1**. If the synonym **schema.object1** does not exist and the schema to be searched is a username, the public synonym **object1** is searched.

Syntax

```
CREATE [ OR REPLACE ] [PUBLIC] SYNONYM synonym_name
    FOR object_name;
```



Parameters

- **OR REPLACE**

  (Optional) Redefines the synonym if it already exists.
- **PUBLIC**

  (Optional) Creates a PUBLIC synonym.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- PUBLIC synonyms must be unique in the same database.
- If the database is upgraded from a version that does not support PUBLIC synonyms to a version that supports PUBLIC synonyms, PUBLIC synonyms cannot be created or deleted before the upgrade is committed.
- All users can access PUBLIC synonyms. Except the initial user and system administrators, you must have the CREATE PUBLIC SYNONYM and DROP PUBLIC SYNONYM permissions to create and drop PUBLIC synonyms, respectively.
- For the PUBLIC synonym, the values of **synnamespace** and **synowner** in the pg_synonym system catalog are **0**, the value of **owner** in the ADM_SYNONYMS and DB_SYNONYMS system views is **PUBLIC**, and the value of **schema_name** is **NULL**.
- If no synonym schema is specified, the system searches for objects with the same name to determine whether the objects exist. Then, the system searches for synonyms by **search_path**. Finally, the system searches for PUBLIC synonyms. If a synonym schema is specified, PUBLIC synonyms are not retrieved.

- **synonym_name**

  Name (optionally schema-qualified) of the synonym to be created.

  Value range: character strings complying with **Identifier Naming Conventions**.

  NOTE

  If a schema is specified, the synonym is created in the specified schema. Otherwise, the synonym is created in the current schema. If the schema of a synonym is the schema to which the user belongs, the owner of the synonym is also the owner of the schema. In other scenarios, the owner of the synonym is the creator of the synonym by default.

- **object_name**

  Name (optionally schema-qualified) of the associated object.

  Value range: character strings complying with **Identifier Naming Conventions**.

  NOTE

  - **object_name** can be the name of an object that does not exist.
  - **object_name** can be the name of a PACKAGE object, but cannot be associated with functions in the PACKAGE. You can use PACKAGE synonyms to access functions and variables in the PACKAGE.
  - **object_name** can be the name of a remote object accessed by using a database link. For details about database links, see "Feature Usage Guidelines > Database Links" in *Developer Guide*.
  - After the original object is deleted, the synonym associated with it will not be deleted cascadingly. If you continue to access the synonym, an error will be reported. If the original object is a table, a message is displayed indicating that the table has expired. If the original object is a function, stored procedure, or PACKAGE, a message is displayed indicating that the object does not exist.

Examples

```
-- Create schema ot.
gaussdb=# CREATE SCHEMA ot;

-- Create a table ot.test_tbl1.
gaussdb=# CREATE TABLE ot.test_tbl1(c1 INT, c2 INT);
gaussdb=# INSERT INTO ot.test_tbl1 values(1,1);
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
-- View the current value of search_path.
gaussdb=# SHOW search_path;
  search_path
----------------
 "$user",public
(1 row)

-- The current value of search_path does not contain ot, and the current user is not ot. Therefore, an error is reported when you directly view the table name.
gaussdb=# SELECT * FROM test_tbl1;
ERROR:  relation "test_tbl1" does not exist
LINE 1: SELECT * FROM test_tbl1;
                      ^
-- Create a synonym.
gaussdb=# CREATE OR REPLACE SYNONYM test_tbl1 FOR ot.test_tbl1;

-- Use the synonym.
gaussdb=# SELECT * FROM test_tbl1;
 c1 | c2
----+----
  1 |  1
(1 row)
gaussdb=# INSERT INTO test_tbl1 VALUES (2,2);

-- Query a created synonym.
gaussdb=# SELECT synname,synobjschema,synobjname FROM pg_synonym WHERE synname = 'test_tbl1';
  synname  | synobjschema | synobjname
-----------+--------------+------------
 test_tbl1 | ot           | test_tbl1
(1 row)

-- Drop.
gaussdb=# DROP SYNONYM test_tbl1;
gaussdb=# DROP TABLE ot.test_tbl1;
gaussdb=# DROP SCHEMA ot CASCADE;
```

ALTER SYNONYM and **DROP SYNONYM**

1.13.9.44 CREATE TABLE

Description

Creates an initially empty table in the current database. The table will be owned by the user executing the statement. Row-store tables are created by default.

Precautions

- If a PRIMARY KEY or UNIQUE constraint is added to a non-distribution key of a hash distributed table, a GSI is created by default. For details about the constraints on GSIs, see **Limitations**. For a non-hash distributed table, the PRIMARY KEY or UNIQUE constraint must contain distribution keys. Otherwise, an error is reported.
- In distributed mode, **HASH(column_name)** is used by default, where **column_name** can be the primary-key column of the table, a column with a UNIQUE constraint (if any), or the first column of a data type that can be used as the distribution key. The order of priority is: Primary-key column > Column with a UNIQUE constraint > First column of a data type that can be used as the distribution key. If the table contains a primary-key column and

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

multiple columns with UNIQUE constraints, and the distribution mode is not specified, GSIs will be created for the other columns with UNIQUE constraints once the primary-key column has been determined based on priority.

NOTICE

If a distribution key of the character type is used in MySQL-compatible mode (**sql_compatibility = 'MYSQL'**), avoid using case-insensitive collations (such as **utf8mb4_general_ci**, **utf8mb4_unicode_ci**, and **utf8mb4_0900_ai_ci**) because these collations are prone to data skew and cannot guarantee even distribution. It is advisable to use the **utf8mb4_bin** collation instead.

- Distribution keys can be updated only when the table attribute **enable_update_distkey** is set to **on**, and the constraints outlined below are met.

  NOTE

  - Distribution keys can be updated only when **enable_update_distkey** is set to **on**.
  - The UPDATE statement cannot be pushed down to DNs for execution. Instead, a PGXC plan is directly generated, and it remains unchanged regardless of the values before and after the distribution key updates.
  - Tables with row-level UPDATE TRIGGER are not supported. Any attempt to use them will result in an error.
  - Row-level INSERT/DELETE TRIGGER is not operational, but statement-level UPDATE TRIGGER can be executed without issue.
  - Concurrent updates on the same row are not supported. To proceed, you must acquire a lock first. The result of acquiring a lock on DNs, whether it returns **0** or reports an error, is determined by the setting of the GUC parameter **concurrent_dml_mode**. If an error is reported, the following scenarios may occur:
    - The error message is "update distribute column conflict."
    - The error message indicates lock timeout if the time taken to acquire the lock exceeds the threshold.
  - Tables with GSIs are not supported. Any attempt to use them will result in an error.
  - List distribution and range distribution are not supported. Any attempt to use them will result in an error. Only hash distribution is allowed.
  - MERGE INTO and UPSERT cannot be used to update distribution keys. Any attempt to use them will result in an error.
  - **gtm_free** is not supported. Any attempt to use it will result in an error.
  - UPDATE RETURNING is not supported. Any attempt to use it will result in an error.
  - JOIN is not supported. Any attempt to use it will result in an error.
  - UPDATE LIMIT is not supported. Any attempt to use it will result in an error.
- If a fault occurs during table creation, the system may be unable to automatically clear the created disk files and disk files with a size of 0, even after the fault has been rectified.
- When JDBC is used, the **DEFAULT** value can be set through PreparedStatement.
- Row-store tables do not support using foreign keys as table-level constraints.
- Foreign key constraints cannot be created on the **rowid** or **rowno** system columns.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- Users with the CREATE ANY TABLE permission can create tables in the schemas of user **PUBLIC** and other common users. To create a table that contains serial columns, you must also obtain the CREATE ANY SEQUENCE permission.
- Data of the XML type cannot be used as a primary key or foreign key.
- If you add or modify an ILM policy for a data object and include a row-level expression, you must use only the whitelisted functions (in **Row Expression Function Whitelist**) as the expression.

NOTICE

- If the database creates unlimited tables, CNs may be affected as follows:
  - Resource exhaustion: Each table occupies certain disk space. Unlimited table creation will occupy a large amount of memory and disk space, which may exhaust CN resources. As a result, the system breaks down or becomes unstable.
    - Performance deterioration: Unlimited table creation causes a large number of I/O operations and CPU computing, and the metadata information of the database becomes large, which may deteriorate the CN performance, including operations such as insert, query, update, and deletion. As a result, the system responds slowly or cannot meet service requirements.
    - Security issues: Excessive tables make database management and maintenance difficult. Creating unlimited tables may cause security issues such as data leakage or data loss. Database stability decreases, causing immeasurable loss to enterprises.

  Therefore, plan the number and size of tables in the database properly to avoid unlimited table creation and ensure system stability, reliability, and security.
- Among the functions supported by the row-level expression ON (EXPR) in the ILM policy, the output of some may be influenced by compatibility parameters. For instance, after you set **b_format_version** to **'5.7'** and **b_format_dev_version** to **'s2'** in MySQL-compatible mode, the upper function will be unable to convert data to uppercase as usual.

- The number of table constraints cannot exceed 32,767.

Syntax

Create a table.

```
CREATE [ [ GLOBAL | LOCAL ] { TEMPORARY | TEMP } | UNLOGGED ] TABLE [ IF NOT EXISTS ] table_name
    { ( { column_name data_type [ CHARACTER SET | CHARSET charset ] [ COLLATE collation ]
[ column_constraint [ ... ] ]
        | table_constraint
        | LIKE source_table [ like_option [...] ] }
        [, ... ] )
    | LIKE source_table }
    [ table_option [ ,... ] [ ... ] ]
    [ htap_option ]
    [ WITH ( {storage_parameter = value} [, ... ] ) ]
    [ WITHOUT OIDS ]
    [ ON COMMIT { PRESERVE ROWS | DELETE ROWS } ]
    [ ILM ADD POLICY ROW STORE COMPRESS
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
 { ADVANCED [ MEDIUM | HIGH ] ROW AFTER n { day | days | month | months | year | years } OF NO
MODIFICATION [ ON ( EXPR )]
 | TURBO [ LOW | MEDIUM | HIGH ] UNIT AFTER n { hour| hours | day | days | month | months | year |
years } OF NO MODIFICATION
 | NONE}]
   [ TABLESPACE tablespace_name ]
   [ DISTRIBUTE BY { REPLICATION | HASH ( column_name [, ...] )
   | MURMURHASH ( expression )
   | RANGE ( column_name [, ...] ) { SLICE REFERENCES tablename | ( slice_less_than_item [, ...] )
   | ( slice_start_end_item [, ...] ) }
   | LIST ( column_name [, ...] ) { SLICE REFERENCES tablename | ( slice_values_item [, ...] ) }
   } ]
   [ TO { GROUP groupname | NODE ( nodename [, ... ] ) } ];
```

- **table_option**:

  ```
  { COMMENT [ = ] 'string' |
    AUTO_INCREMENT [ = ] value |
    [ DEFAULT ] CHARACTER SET | CHARSET [ = ] default_charset |
    [ DEFAULT ] COLLATE [ = ] default_collation |
    ENGINE [ = ] { InnoDB | 'InnoDB' | "InnoDB" } }
  ```

- **htap_option**:

  ```
  { COLVIEW [ PRIORITY { HIGH | LOW | NONE } ] |
    NOCOLVIEW }
  ```

- **column_constraint**:

  ```
  [ CONSTRAINT constraint_name ]
  { NOT NULL |
    NULL |
    CHECK ( expression ) |
    DEFAULT default_expr |
    ON UPDATE update_expr |
    AUTO_INCREMENT |
    COMMENT 'string' |
    COLVIEW |
    NOCOLVIEW |
    UNIQUE [KEY] index_parameters |
    PRIMARY KEY index_parameters |
    ENCRYPTED WITH ( [DATATYPE_CL = client_logic_type,]COLUMN_ENCRYPTION_KEY =
  column_encryption_key, ENCRYPTION_TYPE = encryption_type_value ) |
    REFERENCES reftable [ ( refcolumn ) ] [ MATCH FULL | MATCH PARTIAL | MATCH SIMPLE ]
       [ ON DELETE action ] [ ON UPDATE action ] }
  [ DEFERRABLE | NOT DEFERRABLE ] [ INITIALLY DEFERRED | INITIALLY IMMEDIATE ]
  ```

- **table_constraint**:

  ```
  [ CONSTRAINT [ constraint_name ] ]
  { CHECK ( expression ) |
    UNIQUE [ index_name ] [ USING method ] ( { { column_name [ ( length ) ] | ( expression ) } [ ASC |
  DESC ] }[, ... ] ) index_parameters |
    PRIMARY KEY [ USING method ] ( { column_name [ ASC | DESC ] } [, ... ] ) index_parameters
  [ DEFERRABLE | NOT DEFERRABLE ] [ INITIALLY DEFERRED | INITIALLY IMMEDIATE ]
  { [ COMMENT 'string' ] [ ... ] }
  ```

- **like_option**:

  ```
  { INCLUDING | EXCLUDING } { DEFAULTS | CONSTRAINTS | INDEXES | STORAGE | COMMENTS |
  PARTITION | RELOPTIONS | DISTRIBUTION | UPDATE | ILM | ALL }
  ```

- **index_parameters**:

  ```
  [ WITH ( {storage_parameter = value} [, ... ] ) ]
  [ USING INDEX TABLESPACE tablespace_name ]
  ```

- Range distribution rules:

  - **slice_less_than_item**:

    ```
    SLICE name VALUES LESS THAN ({ expression | MAXVALUE } [, ...]) [ DATANODE
    datanode_name | ( datanode_name_list [, ... ] ) ]
    ```

  - **slice_start_end_item**:

    ```
    SLICE name {
    { START ( expression ) END ( expression ) EVERY ( expression ) } |
    { START ( literal ) END ( { literal | MAXVALUE } ) } |
    { START ( literal ) } |
    ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
    { END ( { literal | MAXVALUE } ) }
    }
```

- List distribution rules:

  slice_values_item:

```
[ ( SLICE name VALUES (expression [, ... ]) [DATANODE datanode_name | ( datanode_name_list )]
 [, ... ] ) |
  ( SLICE name VALUES (DEFAULT) [DATANODE datanode_name] | ( datanode_name_list ) )
]
```

- **update_expr**:

```
{ CURRENT_TIMESTAMP | LOCALTIMESTAMP | NOW() }
```

Parameters

- **UNLOGGED**

  Specifies whether to create the table as an unlogged table. Data written to unlogged tables is not written to the WALs, which makes them considerably faster than ordinary tables. However, in the event of a conflict, OS restart, database restart, primary/standby switchover, power supply interruption, or unclean shutdown, unlogged tables will be cleared, posing a risk of data loss. The contents of an unlogged table are not replicated to standby servers. Any indexes created on an unlogged table are automatically unlogged as well.

  Usage scenario: Considering the data security risks associated with unlogged tables, users should back up data before using such tables, for example, before a system upgrade.

  Troubleshooting: If data is missing in the indexes of unlogged tables due to some unexpected operations such as an unclean shutdown, users should rebuild the indexes with errors.

- **GLOBAL | LOCAL**

  Specifies whether to create a global or local temporary table by including the GLOBAL or LOCAL keyword before TEMP or TEMPORARY. If the GLOBAL keyword is specified, GaussDB will create a global temporary table. Otherwise, it will create a local temporary table.

- **TEMPORARY | TEMP**

  Specifies whether to create a temporary table by including the TEMP or TEMPORARY keyword. Temporary tables are categorized as global or local. When you use the GLOBAL keyword, a global temporary table is created; otherwise, it is a local table.

  The metadata of global temporary tables is visible to all sessions, and it remains in place even after the sessions have concluded. User data, indexes, and statistics are isolated between sessions, allowing each session to access or modify only the data it has committed. Global temporary tables operate in two modes. The first mode is **ON COMMIT PRESERVE ROWS** (session level), which automatically clears user data when sessions conclude. The second mode is **ON COMMIT DELETE ROWS** (transaction level), which automatically clears user data upon COMMIT or ROLLBACK. If the **ON COMMIT** option is not specified during table creation, the session level will be used by default. When creating global temporary tables, you have the flexibility to specify a schema, setting them apart from local temporary tables.

  Local temporary tables are visible only to the current session and will be automatically dropped at the end of the session. This allows you to create and utilize temporary tables within the current session, even if other CNs

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

encounter issues, provided that the CN connected to the session is operational. Temporary tables are created solely within the current session. If a DDL statement involves operations on temporary tables, it will result in a DDL error. Therefore, avoid performing operations on temporary tables through DDL statements. TEMP is equivalent to TEMPORARY.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTICE

- Local temporary tables are made visible to the current session through a schema that starts with **pg_temp**. Therefore, do not manually drop schemas that start with **pg_temp** or **pg_toast_temp** during routine operations.
- If a table is created without specifying the TEMPORARY or TEMP keyword but with a schema starting with **pg_temp** in the current session, the table will be considered a temporary table.
- You cannot ALTER or DROP global temporary tables or indexes if they are being used by other sessions (except for **ALTER INDEX index_name REBUILD**).
- DDL operations on global temporary tables affect only the user data and indexes of the current session. For example, TRUNCATE, REINDEX, and ANALYZE are restricted to the current session.
- You can control the global temporary table feature through the GUC parameter **max_active_global_temporary_table**. For example, setting **max_active_global_temporary_table** to **0** disables the feature.
- Temporary tables are visible only to the current session. Therefore, they cannot be used together with **\parallel on**.
- Temporary tables cannot withstand DN failures or primary/standby switchovers.
- Global temporary tables do not respond to automatic vacuum. In long link scenarios, you are advised to use global temporary tables of ON COMMIT DELETE ROWS or manually execute **VACUUM** periodically. Otherwise, Clogs may not be recycled. (You can set **vacuum_gtt_defer_check_age** to generate an alarm if global temporary tables are not cleared for a long time.)
- Global temporary tables do not support the following scenarios:
  - Global temporary sequences cannot be created. Global temporary tables use shared sequences across sessions, which can only ensure uniqueness but not continuity.
  - Global temporary views cannot be created.
  - Partitioned tables cannot be created.
  - Hash bucket tables cannot be created.
  - Extended statistics are not supported.
  - The ON COMMIT DROP attribute is not supported.
  - GSIs are not supported.
  - M compatibility is not supported.
  - Reading on the distributed standby node is not supported.
  - Stream plans are not supported.
  - Scaling is not supported because scaling rollback may cause data loss and the data will be cleared after scaling.
  - If a DN switchover, DN fault, or CN fault occurs, data may be lost. (Global temporary tables do not have Xlogs, so data is not synchronized between primary and standby nodes.)

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **IF NOT EXISTS**

  Sends a notice, but does not throw an error, if a table with the same name exists.

- **[ILM ADD POLICY ROW STORE COMPRESS { ADVANCED [MEDIUM | HIGH] ROW AFTER n { day | days | month | months | year | years } OF NO MODIFICATION [ON (EXPR)] | TURBO [LOW | MEDIUM | HIGH] UNIT AFTER n { hour | hours | day | days | month | months | year | years } OF NO MODIFICATION | NONE}]**

  When creating a table, you can call ILM ADD POLICY ROW STORE COMPRESS ADVANCED [MEDIUM | HIGH] ROW to add a medium-or high-level advanced compression policy for row store. For example:

  ```
  CREATE TABLE t1 (a int) ILM ADD POLICY ROW STORE COMPRESS ADVANCED ROW AFTER 3 DAY OF NO MODIFICATION ON (a != 0);
  ```

  The command creates the **t1** table and adds the advanced compression policy: rows that are not modified in three days and with **a != 0** specified.

  - AFTER n { day | month | year } OF NO MODIFICATION: rows that have not been modified for *n* days, months, or years. Advanced compression does not support **hour**.
  - ON (EXPR): a row-level expression used to determine whether a row is hot or cold.
  - EXPR supports only the whitelisted functions (in **Row Expression Function Whitelist**).

    NOTE

    - Among the functions supported by the row-level expression ON (EXPR) in the ILM policy, the output of some may be influenced by compatibility parameters. For instance, after you set **b_format_version** to **'5.7'** and **b_format_dev_version** to **'s2'** in MySQL-compatible mode, the upper function will be unable to convert data to uppercase as usual.
    - The compression level is optional. If not specified, the MEDIUM level will be used by default.

  When creating a table, you can call ILM ADD POLICY to add a cross-page transparent compression policy for row store. For example:

  ```
  CREATE TABLE t1 (a int) ILM ADD POLICY ROW STORE COMPRESS TURBO HIGH UNIT AFTER 3 HOUR OF NO MODIFICATION;
  ```

  The command creates the **t1** table and adds a cross-page transparent compression policy with a high policy level and a 3-hour cold and hot data management interval.

  - **AFTER n { hour | day | month | year } OF NO MODIFICATION**: indicates the compression groups that have not been modified for *n* hours, days, months, or years.
  - If the compression level is not specified, the MEDIUM level is used by default.

- **table_name**

  Specifies the name of the table to be created.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTICE

Based on prefixes in table names, the processing logic of materialized views determines whether the table is the logged table of a materialized view or whether the table is joined with a materialized view. Therefore, do not create tables with prefixes like **mlog_** or **matviewmap_**. Otherwise, certain functionalities of the tables may be affected.

- **column_name**

  Specifies the name of the column to be created in the new table.

- **data_type**

  Specifies the data type of the column.

- **CHARACTER SET | CHARSET charset**

  Assigns a character set to the column. If **COLLATE** is not specified separately, the column will use the default collation of the specified character set.

- **COLLATE collation**

  Assigns a collation to the column (which must be of a collatable data type). If not specified, the default collation will be used.

  You can run the **SELECT * FROM pg_collation;** command to query collations from the pg_collation system catalog. The row starting with **default** in the query result represents the default collation.

  NOTE

  - Only the character type supports specifying a character set.
  - When you specify the binary character set or collation, the system will convert the character type to the binary type. If the system cannot find a matching type mapping, it will report an error. Currently, only the TEXT-to-BLOB mapping is supported.
  - In addition to the binary character set and collation, you can only specify the character set that matches the database encoding.
  - If the character set or collation of a column is not explicitly specified and the default character set or collation of the table is specified, the character set or collation of the column is inherited from the table. If the default character set or collation of a table does not exist, the character set and collation of table columns inherit the character set and collation of the current database when **b_format_behavior_compat_options** contains **'default_collation'**.
  - MySQL-compatible databases (**sql_compatibility = 'MYSQL'**) also support the utf8mb4_bin, utf8mb4_general_ci, utf8mb4_unicode_ci, binary, gbk_chinese_ci, gbk_bin, gb18030_chinese_ci, gb18030_bin, utf8mb4_0900_ai_ci, utf8_general_ci, and utf8_bin collations. For details, see **Table 1-398**.

Table 1-398 Character sets and collations supported in MySQL-compatible mode (sql_compatibility = 'MYSQL')

Collation	Character Set	Description
utf8mb4_general_ci	utf8mb4 (utf8)	The general collation is used, which is case-insensitive.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Collation	Character Set	Description
utf8mb4_unicode_ci	utf8mb4 (utf8)	The general collation is used, which is case-insensitive.
utf8mb4_bin	utf8mb4 (utf8)	The binary collation is used, which is case-sensitive.
binary	binary	The binary collation is used.
gbk_chinese_ci	gbk	The Chinese collation is used.
gbk_bin	gbk	The binary collation is used, which is case-sensitive.
gb18030_chinese_ci	gb18030	The Chinese collation is used.
gb18030_bin	gb18030	The binary collation is used, which is case-sensitive.
utf8mb4_0900_ai_ci	utf8mb4	The unicode collation algorithm (UCA) rule is used, which is case-insensitive.
utf8_general_ci	utf8	The general collation is used, which is case-insensitive.
utf8_bin	utf8	The binary collation is used, which is case-sensitive.

- **LIKE source_table [like_option ...]**

  Specifies a table, known as the source table, from which the target table automatically inherits all column names, their data types, NOT NULL constraints, and default expressions declared as serial.

  The target table and source table are completely decoupled after creation is complete. Changes to the source table will not be applied to the target table, and it is not possible to include data of the target table in scans of the source table.

  The system does not merge inherited columns or constraints with those that share the same name. If the same name is specified explicitly or in another LIKE clause, an error is signaled.

  – Columns in the target table inherit the default expressions (except the serial ones) from the source table only when **INCLUDING DEFAULTS** is specified. The default behavior is to exclude the default expressions, causing all columns in the target table to default to **NULL**.

  – If **INCLUDING UPDATE** is specified, columns in the target table will inherit the **ON UPDATE CURRENT_TIMESTAMP** attribute from the source table. The default behavior is to exclude this attribute.

  – The target table inherits the CHECK constraints from the source table only when **INCLUDING CONSTRAINTS** is specified. Other types of constraints are not inherited, while NOT NULL constraints are always

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

inherited. This rule also applies to table constraints and column constraints.

- If **INCLUDING INDEXES** is specified, indexes on the source table will also be created on the target table. By default, no indexes are created. The tablespace where indexes on the target table are located is the same as that where indexes on the source table are located.
- If **INCLUDING STORAGE** is specified, columns in the target table will inherit **STORAGE** settings from the source table. The default behavior is to exclude **STORAGE** settings.
- If **INCLUDING COMMENTS** is specified, the target table will inherit comments on columns, constraints, and indexes from the source table. The default behavior is to exclude comments.
- If **INCLUDING PARTITION** is specified, the target table will inherit partition definitions from the source table and will no longer be able to use the PARTITION BY clause. The default behavior is to exclude partition definitions.
- If **INCLUDING RELOPTIONS** is specified, the target table will inherit storage parameters (WITH clause) from the source table. The default behavior is to exclude storage parameters.
- If **INCLUDING DISTRIBUTION** is specified, the target table will inherit distribution information (including distribution types and keys) from the source table and will no longer be able to use the DISTRIBUTE BY clause. The default behavior is to exclude distribution information.
- If **INCLUDING ILM** is specified, the target table will inherit ILM policy information from the source table. To also inherit the ILM policy information of partition objects, you will need to specify **INCLUDING PARTITION**.
- **INCLUDING ALL** is a condensed version that encompasses **INCLUDING DEFAULTS**, **INCLUDING UPDATE**, **INCLUDING CONSTRAINTS**, **INCLUDING INDEXES**, **INCLUDING STORAGE**, **INCLUDING COMMENTS**, **INCLUDING PARTITION**, **INCLUDING RELOPTIONS**, **INCLUDING DISTRIBUTION**, and **INCLUDING ILM**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTICE

- If **INCLUDING RELOPTIONS** is specified and the storage parameter (that is, the WITH clause of the source table) of the source table does not contain storage_type, the storage engine type of the target table is determined by the value of the GUC parameter **enable_default_ustore_table**.
- If the source table contains the serial, bigserial, or smallserial type, or if sequences created for the source table (using **CREATE SEQUENCE ... OWNED BY**) are set as default values for columns in the source table, these sequences will not be associated with the target table. Instead, the target table will rebuild its own sequences. To share sequences between the source and target tables, you must create shared sequences (without using **OWNED BY**) and set them as default values for columns in the source table.
- You are advised not to set the default value of a column in the source table to the sequence specific to another table especially when the table is distributed in specific node groups because doing so may result in CREATE TABLE ... LIKE execution failures. In addition, doing so may cause the sequence to become invalid in the source sequence because the sequence will also be deleted from the source table when it is deleted from the table that the sequence is specific to. To share a sequence among multiple tables, you are advised to create a shared sequence for them.
- If the source table is a ROWID table and INCLUDING ALL or INCLUDING RELOPTIONS is specified, the new table is also a ROWID table. If only INCLUDING INDEXES is specified, the new table is a non-ROWID table and the **ROWNO** index of the source table is not copied.
- **CREATE TABLE table_name LIKE source_table;** is supported only in MySQL-compatible databases (**sql_compatibility = 'MYSQL'**) where **b_format_version** is **5.7** and **b_format_dev_version** is **s2**.
- In MySQL-compatible databases where **b_format_version** is **5.7** and **b_format_dev_version** is **s2**, the **INCLUDING** and **EXCLUDING** options cannot be specified. The default setup is equivalent to specifying **INCLUDING ALL**.
- If **source_table** is a system catalog, **INCLUDING ALL** or **INCLUDING DISTRIBUTION** cannot be specified.

- **AUTO_INCREMENT [=] value**

  Specifies an initial value for an auto-increment column. The value must be a positive number no greater than $2^{127} - 1$.

NOTICE

This clause takes effect only when **sql_compatibility** is set to **'MYSQL'**.

- **COMMENT [=] 'string'**
  - The COMMENT [=] 'string' clause is used to add comments to a table.
  - COMMENT 'string' in **column_constraint**: adds a comment on a column.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

  - COMMENT 'string' in **table_constraint**: adds a comment on the indexes corresponding to the primary key and unique key.

NOTICE

- This clause takes effect only in MySQL-compatible databases (**sql_compatibility = 'MYSQL'**).
- A table-level comment can contain a maximum of 2,048 characters, while a column- or index-level comment can contain a maximum of 1,024 characters.
- Comments in **table_constraint** support only the primary and unique keys. Other constraints are not supported.

- **ENGINE**

  This parameter is supported in MySQL-compatible mode and is used solely for syntax adaptation. It is limited to InnoDB, but no actual impact has been noted.

NOTICE

The ENGINE syntax cannot be used in **CREATE TABLE table_name LIKE source_table;**.

- **COLVIEW | NOCOLVIEW**

  Specifies whether to create IMCV table metadata for a table, column, or partition. To create an IMCV table, you should enable the **enable_htap** parameter.

  This clause cannot be used together with the LIKE source_table syntax.

- **PRIORITY**

  Specifies a priority for loading data into the IMCV table. The options include high, low, and default.

- **WITH ({ storage_parameter = value } [, ...])**

  Specifies an optional storage parameter for the table or an index. The WITH clause for a table can also include **OIDS=FALSE** to specify that no OID will be allocated.

NOTICE

- The WITH clause does not support **OIDS=TRUE**.
- For numeric columns of arbitrary precision, it is advisable to specify precision **p** and scale **s**. If you do not specify precision **p** or scale **s**, the output directly follows the input format.

See details of parameters below.

  - FILLFACTOR

    Specifies a fillfactor for the table. It is a percentage between 10 and 100. **100** (complete packing) is the default. In the case of Ustore, the default

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

is **92**. When a smaller fillfactor is specified, INSERT operations pack table pages only to the indicated percentage; The remaining space on each page is reserved for updating rows on that page. This gives UPDATE a chance to place the updated copy of a row on the same page as the original, which is more efficient than placing it on a different page. For a table whose entries are never updated, complete filling (fillfactor = 100) is the best choice. However, in heavily updated tables, smaller fillfactors are appropriate.

Value range: 10–100.

- ORIENTATION

  Specifies the orientation for storing table data. Once set, this parameter cannot be modified.

  Value range:

  - **ROW**: Table data is stored in row orientation.

    Row store is ideal for OLTP workloads because they can handle a high volume of interactive transactions, each of which usually involves multiple table columns. Utilizing row store can enhance query performance.

  Default value: **ROW** (when an ordinary tablespace is specified).

- STORAGE_TYPE

  Specifies the storage engine type. Once set, this parameter cannot be modified.

  Value range:

  - **USTORE**: The table uses an in-place update storage engine. To prevent space bloat, be sure to enable the **track_counts** and **track_activities** parameters for Ustore tables.
  - **ASTORE**: The table uses an append-only storage engine.

  Default value: subject to the **enable_default_ustore_table** parameter, which defaults to in-place update storage.

- TOAST.TOAST_STORAGE_TYPE

  Specifies the storage type of the TOAST table. When the GUC parameter **enable_enhance_toast_table** is set to **on**, the storage type of the TOAST table can be changed to enhanced TOAST through the VACUUM FULL operation.

  Value range:

  - **ENHANCED_TOAST**: indicates that the storage type of the TOAST table is enhanced TOAST.
  - **TOAST**: indicates that the storage type of the TOAST table is TOAST.

  Default value:

  If **TOAST.TOAST_STORAGE_TYPE** is not specified during table creation, the storage type of the TOAST table depends on the GUC parameter **enable_enhance_toast_table**. If this parameter is set to **on**, the storage type of the TOAST table is ENHANCED_TOAST. If this parameter is set to **off**, the storage type of the TOAST table is TOAST.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- INIT_TD

  Specifies the number of TDs to be initialized when a Ustore table is created. This parameter can be modified by running the **ALTER TABLE** command. Note that this parameter affects the maximum size of a single tuple stored on the data page, calculated as **MAX_TUPLE_SIZE** = **BLCKSZ** – **INIT_TD** × **TD_SIZE**. For instance, if you increase **INIT_TD** from **4** to **8**, the maximum size of a single tuple will decrease by 4 × **INIT_TD**.

  Value range: 2–128. The default value is **4**.

- COMPRESSLEVEL

  Specifies a compression level within the selected compression tier. It determines the data compression ratio and time. Offering a more granular division within the same compression tier gives users greater flexibility in choosing the compression ratio and compression time. Typically, a higher value signifies a higher compression ratio and longer compression time within the same compression tier—and the reverse also applies.

  Value range: 0–3.

  Default value: **0**.

- segment

  Specifies that data is stored in segment-page mode. This parameter supports only row-store tables. Protection against unauthorized deletion and damage of physical files 1 to 5 is not supported. This parameter cannot be created during the upgrade observation period.

  Value range: **on** and **off**.

  Default value: **off**.

- hashbucket

  Creates a hash bucket table. This parameter supports only row-store tables.

  Value range: **on** and **off**.

  Default value: **off**.

NOTICE

- When creating a hash bucket table, ensure that the current database is bound to the default node group of the cluster. For details about how to bind a database to a node group, see **ALTER DATABASE**.
- In current version, DDL operations on hash bucket tables are affected. Therefore, you are advised not to frequently perform DDL operations on hash bucket tables.
- Hash bucket tables are bound to segmented paging storage, that is, when **hashbucket** is set to **on**, **segment** is set to **on**.
- You are advised not to create a small table (ordinary table: < 8 MB; partitioned table: < 8 MB x Number of partitions) as a hash bucket table. The sequential scan performance deteriorates twice that of an ordinary table.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- enable_tde

  Specifies that the table is an encrypted table. Before storing data in an encrypted table, the database will encrypt the data first. Before using this parameter, ensure that the GUC parameter **enable_tde** is enabled and **tde_key_info** is properly set. For detailed usage, consult "Feature Usage Guidelines > Transparent Data Encryption" in *Developer Guide*. This parameter supports only row-store tables, segment-page tables, hash bucket tables, temporary tables, and unlogged tables.

  Value range: **on** and **off**. When **enable_tde** is set to **on**, **key_type**, **cmk_id**, and **dek_cipher** are automatically generated by the database and cannot be manually specified or modified.

  Default value: **off**.

- **encrypt_algo**

  Specifies the algorithm for encrypting tables. This parameter must be used together with **enable_tde**.

  Value range: **AES_128_CTR**, **SM4_CTR**, **AES_128_CTR_SHA256_HMAC**, **SM4_CTR_SM3_HMAC**, and **AES_128_GCM** (character string).

  Default value:

  - When **enable_tde** is **on**:
    - If the **table_algorithm** subparameter within the GUC parameter **tde_encrypt_config** is not empty, the default value is the same as that of **table_algorithm**.
    - If the **table_algorithm** subparameter within the GUC parameter **tde_encrypt_config** is empty, the default value is **AES_128_CTR**.
  - When **enable_tde** is **off**, the default is empty.

- parallel_workers

  Specifies the number of bgworker threads started when an index is created. For example, value **2** indicates that two bgworker threads are started to create indexes concurrently.

  Value range: [0,32], int type. **0** indicates that parallel index creation is disabled.

  Default value: This parameter is not set, indicating that the parallel index creation function is disabled.

- **dek_cipher**

  Specifies the DEK ciphertext. This storage parameter cannot be manually set or modified. After a user sets the **enable_tde** parameter for a table, the database automatically generates a data key.

  Value range: character strings.

  Default value: empty.

- **key_type**

  Specifies the type of the master key. This storage parameter cannot be manually set or modified. After the **enable_tde** parameter is set for a table, the database automatically obtains the master key type from the GUC parameter **tde_key_info**.

  Value range: character strings.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Default value: empty.

- **cmk_id**

  Specifies the ID of the master key. This storage parameter cannot be manually set or modified. After the **enable_tde** parameter is set for a table, the database automatically obtains the master key ID from the GUC parameter **tde_key_info**.

  Value range: character strings.

  Default value: empty.

- hasuids

  If this parameter is set to **on**, a unique table-level ID is allocated to a tuple when the tuple is updated.

  Value range: **on** and **off**.

  Default value: **off**.

- logical_repl_node

  Specifies the name of the DN responsible for returning logical logs to the CN during logical decoding of a replication table. For the replication table, if this parameter is not specified, the first node in the node group where the current table is located is used by default. When the RESET operation is performed on this option, the node is reset to the first node of current table.

  Value range: character strings.

  Default value: For the non-replication table, this parameter is empty by default. For the replication table, this parameter is set to the name of the first node by default.

- skip_logical_deparse

  Skips this table during logical decoding in the database. You are advised not to use this parameter. Otherwise, logical decoding may miss some content.

  Value range: **on** and **off**.

  Default value: **off**.

- STAT_STATE

  Identifies whether table statistics are locked. If locked, the table statistics cannot be updated. This parameter does not take effect currently.

  Value range: **locked** and **unlock**.

  Default value: **unlock**.

- statistic_granularity

  Records the default **partition_mode** when the table analyzes statistics. For details about **PARTITION_MODE**, see **ANALYZE | ANALYSE**. This parameter setting does not work for non-partitioned tables.

  Value range: See **PARTITION_MODE** in **ANALYZE | ANALYSE**.

  Default value: **AUTO**.

- autovacuum_enabled

  Specifies whether to enable AUTOVACUUM for the table.

  Value range: **on** and **off**.

  Default value: **on**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- autovacuum_vacuum_threshold

  (Applicable when AUTOVACUUM is enabled) Specifies the minimum number of updated or deleted tuples needed to trigger a VACUUM in the table. (This parameter applies specifically to Astore tables.)

  Value range: 0–2147483647.

  Default value: consistent with the GUC parameter **autovacuum_vacuum_threshold**.

- autovacuum_analyze_threshold

  (Applicable when AUTOVACUUM is enabled) Specifies the minimum number of inserted, updated, or deleted tuples needed to trigger an ANALYZE in the table.

  Value range: 0–2147483647.

  Default value: consistent with the GUC parameter **autovacuum_analyze_threshold**.

- autovacuum_vacuum_scale_factor

  (Applicable when AUTOVACUUM is enabled) Specifies the ratio of inserted, updated, or deleted tuples needed to trigger a VACUUM in the table. (This parameter applies specifically to Astore tables.)

  Value range: 0.0–100.0.

  Default value: consistent with the GUC parameter **autovacuum_vacuum_scale_factor**.

- autovacuum_analyze_scale_factor

  (Applicable when AUTOVACUUM is enabled) Specifies the ratio of inserted, updated, or deleted tuples needed to trigger an ANALYZE in the table.

  Value range: 0.0–100.0.

  Default value: consistent with the GUC parameter **autovacuum_analyze_scale_factor**.

- autovacuum_freeze_min_age

  (Applicable when AUTOVACUUM is enabled) Specifies the minimum age of row versions. Rows older than this age will be frozen.

  Value range: 0–576460752303423487.

  Default value: consistent with the GUC parameter **vacuum_freeze_min_age**.

- autovacuum_freeze_max_age

  (Applicable when AUTOVACUUM is enabled) Specifies the maximum age (in transactions) that the table's **pg_class.relfrozenxid** field can reach before a VACUUM operation is forced. Note that the system will launch AUTOVACUUM processes even when AUTOVACUUM is otherwise disabled. The VACUUM operation also allows removal of old files from the **pg_clog/** subdirectory. (This parameter applies specifically to Astore tables.)

  Value range: 100000–576460752303423487.

  Default value: consistent with the GUC parameter **autovacuum_freeze_max_age**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- autovacuum_freeze_table_age

  (Applicable when AUTOVACUUM is enabled) Specifies the time when the table will remain unchanged, marked as not requiring AUTOVACUUM. (This parameter applies specifically to Astore tables.)

  Value range: 0–576460752303423487.

  Default value: consistent with the GUC parameter **vacuum_freeze_table_age**.

- vacuum_truncate

  Specifies whether to enable the VACUUM TRUNCATE function of a table to truncate the last empty page during VACUUM.

  Value range: **on** and **off**.

  Default value: **on**.

  NOTE

  - This parameter is valid only for Astore tables and does not take effect for hash bucket tables and segment tables.
  - During the upgrade from a version that does not support this parameter to a version that supports this parameter, this parameter cannot be created or modified during the upgrade observation period.
  - The toast.**vacuum_truncate** parameter can be used to independently control whether to truncate the last empty page of a TOAST table.

- skip_logical_deparse

  Skips the table during logical decoding of the kernel. This parameter is for kernel processing and is not recommended for users. If it is set improperly, logical decoding may be incomplete.

  Value range: **on** and **off**.

  Default value: **off**.

- enable_update_distkey

  Determines whether the table supports the UPDATE operation on distribution keys. The distribution keys can be updated only when this attribute of the table is set to **on** and constraints are met. Otherwise, distribution keys do not support the UPDATE operation.

  Value range: **on** and **off**.

  Default value: **off**.

  NOTE

  For details about the constraints on updating distributed columns, see **Precautions**.

- hasrowid

  Specifies whether the table is a rowid table. If **hasrowid** is set to **on**, the **rowid** and **rowno** system columns are added to the table, and sequences and indexes are created on the **rowno** system column.

  Value range: **on** and **off**.

  Default value: **off**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- This parameter supports only ORA-compatible databases (that is, **sql_compatibility** is set to **ORA**).
- This parameter does not support local temporary tables, unlogged tables, global temporary tables, materialized views, hash bucket tables, or replication tables.
- This parameter cannot be specified together with **hasuids** and **oids**.
- When this parameter is enabled, the ordinary column name cannot be defined as **rowno** or **rowid**.
- The number of data records in the **rowid** table cannot exceed 9223372036854775807.
- When the **ROWID_OPT** option is enabled for the GUC parameter **opt_behavior_knob** in the **rowid** table, the **ROWID** system column predicate condition rewriting, ORDER BY statement rewriting, max/min optimization, distribution pruning, and partition pruning are supported. For details, see **opt_behavior_knob**.

– partition_statistics_min_rows

Specifies the minimum number of rows to be sampled at the partition level when the ANALYZE statement is executed on a partitioned table.

Value range: [0,10000]

Default value: **50**

NOTE

- This parameter is valid only for partitioned tables.
- This parameter is valid only when **PARTITION_MODE** in the ANALYZE statement is set to **ALL** and the GUC parameter **enable_partition_statistics_min_rows** is enabled. For details about **PARTITION_MODE**, see **PARTITION_MODE** in **ANALYZE | ANALYSE**.
- Upper limit: The number of rows sampled from the entire partitioned table cannot exceed the number of rows allowed by the GUC parameter **maintenance_work_mem**.

- **WITHOUT OIDS**

  Specifies that no OID is allocated, equivalent to **WITH(OIDS=FALSE)**.

- **ON COMMIT { PRESERVE ROWS | DELETE ROWS }**

  Specifies subsequent operations on the temporary table when the temporary table is created in a transaction and the transaction is committed. Currently, **PRESERVE ROWS** and **DELETE ROWS** are supported.

  – **PRESERVE ROWS** (default): No action will be taken upon commit. The temporary table and its data will remain unchanged.

  – **DELETE ROWS**: Data in the temporary table will be deleted upon commit.

- **TABLESPACE tablespace_name**

  Specifies the name of the tablespace where the table is to be created. If not specified, the default tablespace will be used.

- **DISTRIBUTE BY**

  Specifies how the table is distributed or replicated between DNs.

  Value range:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **REPLICATION**: replicates each table row to all DNs, ensuring that each DN holds the full set of table data.
- **HASH (column_name)**: distributes data to DNs based on hash values in the specified column.
- **MURMURHASH (diskey_expr)**: distributes data to DNs based on MurmurHash values in the specified column. **diskey_expr** can be a single column name or a column name modified by the **lpad_s(string text, length int [, fill text])** function. When this function is used, only the first parameter can be a column name, for example, lpad_s(a,10,'0'). When **lpad_s** is used as a distribution key expression, the third parameter cannot be omitted.
- **RANGE(column_name)**: maps the specified column by range and distributes its data to the relevant DN.
- **LIST(column_name)**: maps the specified column by value and distributes its data to the relevant DN.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- In hash distribution, the maximum number of distribution keys equals the maximum number of columns, capped at 1,600. In MurmurHash distribution, a distribution key accepts only one column (either an expression or a table column). In RANGE(VALUE LESS THAN) distribution and list distribution, a distribution key can accept up to four columns. In RANGE(START END) distribution, a distribution key can only accept one column.
- Only the MURMURHASH distribution supports an expression as the distribution key. The distribution key expression supports only the **lpad_s(string text, length int [, fill text])** function.
- MurmurHash distribution has the following limitations:
  - Stream plans are not supported, but FQS and PGXC plans are supported.
  - Scale-out/in, hash bucket tables, GSIs, and materialized views are not supported.
  - If two hash tables are joined with an equality join condition on the distribution key, the FQS plan is not supported.
  - When working with a MurmurHash distributed table, you need to specify a user-defined node group, which must be a non-installation node group.
  - Tables cannot be created using CREATE TABLE AS.
  - The distribution key of the MURMURHASH distributed table must contain the NOT NULL constraint.
- MurmurHash distribution is designed to maintain consistent data distribution after the migration of a legacy system that employs the MurmurHash algorithm. Currently, scale-out and stream plans are not supported. You are advised to select hash distributed algorithms.
- For a RANGE distribution policy using the VALUE LESS THAN clause, the distribution rules are as follows:
  - The comparison starts from the first column of values to be inserted.
  - If the value of the inserted first column is smaller than the boundary value of the current column in the local slice, the values are directly inserted.
  - If the value of the inserted first column is equal to the boundary value of the current column in the local slice, compare the value of the inserted second column with the boundary value of the next column in the local slice. If the value of the inserted second column is smaller than the boundary value of the next column in the local slice, the values are directly inserted. If they are equal, the comparison of the next columns between the source and target continues.
  - If the value of the inserted first column is greater than the boundary value of the current column in the local slice, compare the value with that in the next slice.
- When a shard of a range distributed table corresponds to multiple DNs, the system calculates the hash value of the distribution key. This hash value is then used to perform modulo operations on the number of DNs to remap to a specific DN. For details, see the examples.
- When a shard of a list distributed table corresponds to multiple DNs, the system calculates the hash value of the distribution key for the default shard. This hash value is then used to perform modulo operations on the number of DNs to remap to a specific DN. For non-default shards, the system utilizes the round robin method to map values in the values list to DNs. For details, see the examples.
- Range/List distributed tables support only scale-out but not scale-in. For details about the slice scale-out rules, contact an administrator.
- When using a replication table, be aware of the following sufficient and necessary conditions for pushdown:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- In scenarios involving window functions, the sufficient and necessary conditions for pushdown may vary depending on the types of window functions:
  - For rank series functions and the ratio_to_report function, there are no restrictions, and all of them supports pushdown.
  - This is because window functions return the same calculation result for rows with the same PARTITION BY and ORDER BY conditions, regardless of the relative sequence of the data.
  - For the row_number and ntile functions, pushdown can be performed if any of the following conditions is met:
    - Only the projection columns of the window function are included.
    - Only the PARTITION BY or ORDER BY columns in the OVER clause (no other columns) and the projection columns of the window function are included.
    - If the OVER clause contains only PARTITION BY or ORDER BY, the PARTITION BY or ORDER BY column is the primary key.
    - If the OVER clause contains both PARTITION BY and ORDER BY, both the PARTITION BY and ORDER BY columns are primary keys.
  - When the column values of PARTITION BY or ORDER BY in the window function are the same but the values of other columns are different, if other columns appear in the projection columns of the window function, the data sequence on different DNs may be inconsistent. As a result, the window function results and data are inconsistent.
  - For the LAG and LEAD functions, pushdown is supported when the **offset** parameter is set to **0**.
  - When **offset** is **0**, a single column is queried independently of the relative data sequence. If **offset** is greater than 0, tuples with the same value may receive a NULL value because of different relative sequences.
  - The first_value, last_value, and nth_value functions supports pushdown if one of the following conditions is met:
    - The field in the parameter expression must be the PARTITION BY or ORDER BY field in the OVER clause.
    - If the OVER clause contains only PARTITION BY or ORDER BY, the PARTITION BY or ORDER BY column is the primary key.
    - If the OVER clause contains both PARTITION BY and ORDER BY, both the PARTITION BY and ORDER BY columns are primary keys.
- If the query of a replication table contains system columns and volatile functions, the query is not pushed down.
- In the context of concatenating aggregate functions, the sufficient and necessary condition for pushing down is that the columns to be concatenated matches the ORDER BY columns, or the ORDER BY columns form a primary key.
- If the UPDATE or DELETE statement uses the WHERE CURRENT OF cursor_name syntax, pushdown is not supported.

– In hash distribution, **column_name** accepts the following data types:

  - Integer types: TINYINT, SMALLINT, INT, BIGINT, and NUMERIC/DECIMAL
  - Character types: CHAR, BPCHAR, VARCHAR, VARCHAR2, NVARCHAR2, and TEXT
  - Date/Time types: DATE, DATEA (effective only in ORA-compatible mode), TIME, TIMETZ, TIMESTAMP, TIMESTAMPTZ, INTERVAL, and SMALLDATETIME

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- In MurmurHash distribution, the column name in **diskey_expr** accepts the following data types:
  - Integer types: TINYINT, SMALLINT, INT, and BIGINT
  - Character types: CHAR, BPCHAR, VARCHAR, VARCHAR2, and NVARCHAR2
- In RANGE(VALUES LESS THAN) distribution or list distribution, **column_name** accepts the following data types:
  - Integer types: TINYINT, SMALLINT, INT, BIGINT, and NUMERIC/DECIMAL
  - Character types: CHAR, BPCHAR, VARCHAR, VARCHAR2, NVARCHAR2, and TEXT
  - Date/Time types: DATE, DATEA (effective only in ORA-compatible mode), TIMESTAMP, and TIMESTAMPTZ
- In RANGE(START END) distribution, **column_name** accepts the following data types:
  - Integer types: TINYINT, SMALLINT, INT, BIGINT, and NUMERIC/DECIMAL
  - Date/Time types: DATE, DATEA (effective only in ORA-compatible mode), TIMESTAMP, and TIMESTAMPTZ

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

Distribution and partition keys can influence the performance of SQL queries. It is crucial to carefully select these keys based on service requirements when creating a table.

- **How to determine whether a distribution key is appropriate:**

  The distribution key of a hash table should evenly distribute data across all DNs to prevent data skew (that is, uneven data distribution among DNs). Here are principles to help you determine whether a distribution key is appropriate:

  1. Check whether data skew occurs.

     Connect to the database and use the following statement to check the number of tuples on each DN (replace *tablename* with the name of the table to be analyzed):

     ```
     gaussdb=# SELECT a.count,b.node_name FROM (SELECT count(*) AS count,xc_node_id FROM tablename GROUP BY xc_node_id) a, pgxc_node b WHERE a.xc_node_id=b.node_id ORDER BY a.count DESC;
     ```

     If there is a significant difference in tuple counts on each DN (for example, several times or dozens of times), it suggests data skew. In that event, follow **2** to adjust the distribution key.

  2. Select a different distribution key and rebuild the table. Currently, distribution keys cannot be adjusted using ALTER TABLE. Therefore, you must rebuild the table whenever adjustments to its distribution keys are required.

     Selection principles:

     Select a column with discrete values as the distribution key to ensure even data distribution to DNs. For instance, consider using the primary key of a table as the distribution key. In the context of a table containing personal information, the ID card number column is a suitable choice for the distribution key.

     In addition to meeting the above principle, you can utilize the join condition in a query as the distribution key. This approach allows join operations to be pushed down to DNs, reducing the amount of communication data between DNs.

- **How to determine whether a partition key is appropriate:**

  A table can be partitioned into "ranges" defined by a key column or set of columns, with no overlap between the ranges of values assigned to different partitions. A partition is created for each range to store corresponding data.

  By adjusting partition keys to store query results in the same or minimal partitions (a technique known as "partition pruning"), you can obtain consecutive I/O to significantly enhance query performance. In practical scenarios, time is commonly used as a filter for queries. Therefore, you can consider selecting the time column as the partition key, with the key value range being tailored based on the total data volume and the size of data queried at a time.

- Range/List distribution:

  If no DN is explicitly specified for the shards of a range/list distributed table, the database utilizes the round robin algorithm to allocate DNs to the shards. Moreover, in range/list distribution scenarios, it is advisable to define as many shards as possible when creating a table to meet future scale-out requirements. If the number of defined shards is less than the number of DNs before scale-out, data cannot be redistributed to new DNs. Of particular note is the fact that the sharding rules are designed by users. In certain extreme cases, scale-out may not resolve the issue of insufficient storage capacity.

- **TO { GROUP groupname | NODE (nodename [, ...]) }**

  Specifies the node group for which the table is to be created.

  TO NODE is intended only for use by internal scale-out tools and is not recommended for direct use by users.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **CONSTRAINT [constraint_name]**

  Specifies the name of a column constraint or table constraint. The optional CONSTRAINT clause specifies constraints that new or updated rows must satisfy for an INSERT or UPDATE operation to succeed.

  There are two ways to define constraints:

  – A column constraint is defined as part of a column definition, and it is bound to a particular column. You cannot add a constraint name to the clause AUTO_INCREMENT | COMMENT 'string' | ENCRYPTED WITH (COLUMN_ENCRYPTION_KEY = column_encryption_key, ENCRYPTION_TYPE = encryption_type_value).

  – A table constraint is not tied to a particular column, and it can encompass more than one column.

  NOTICE

  For each table constraint, **constraint_name** is optional in MySQL-compatible databases (**sql_compatibility = 'MYSQL'**) but required in other databases.

- **NOT NULL**

  Forbids NULL values in columns.

- **NULL**

  Allows NULL values in columns. This is the default.

  This clause is provided solely for compatibility with non-standard SQL databases and is not recommended for use.

- **CHECK (expression)**

  Specifies an expression producing a Boolean result which new or updated rows must satisfy for an INSERT or UPDATE operation to succeed. Expressions evaluating to TRUE or UNKNOWN succeed. Otherwise, an error exception is raised, and the INSERT or UPDATE does not alter the database.

  A CHECK constraint specified as a column constraint should reference that column's value only, while an expression appearing in a table constraint can reference multiple columns.

  NOTE

  - **<>NULL** and **!=NULL** are invalid to expressions and need to be rewritten as **IS NOT NULL**.
  - CHECK constraints cannot be added to system columns. For details about system columns, see "Basic Concepts > System Columns" in *Developer Guide*.

- **DEFAULT default_expr**

  Assigns a default value to a column. The value can be any variable-free expression (in particular, subqueries and cross-references to other columns in the current table are not allowed). The data type of the default expression must match the data type of the column.

  The default expression can be used in any INSERT operation that does not specify a value for the column. If no default value is specified, **NULL** will be used.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **ON UPDATE update_expr**

  Specifies an attribute constraint for the column.

  During an UPDATE operation on a tuple in a table:

  If the new values of the updated columns differ from the old values, columns (in the tuple) that have this attribute but are not part of the UPDATE will be automatically updated to the current timestamp. However, if the new values of the updated columns are the same as the old values, those columns will remain unchanged. If columns with this attribute are included in the UPDATE, their values will be updated to the specified value.

  NOTE

  - This attribute can be specified in MySQL-compatible databases version 5.7 (**sql_compatibility = 'MYSQL'**, **b_format_version='5.7'**, and **b_format_dev_version='s1'**). It can also be specified in PG-compatible databases, but the syntax is not supported during upgrade observation.
  - In terms of syntax, **update_expr** supports three keywords: CURRENT_TIMESTAMP, LOCALTIMESTAMP, and NOW(). You can also optionally specify the precision of a keyword with parentheses. The three types of keywords are synonyms of each other and have the same attribute effect. For example, ON UPDATE CURRENT_TIMESTAMP(), ON UPDATE CURRENT_TIMESTAMP(5), ON UPDATE LOCALTIMESTAMP(), and ON UPDATE LOCALTIMESTAMP(6). If the keyword does not contain parentheses or contains empty parentheses, the precision is 0. The NOW keyword cannot contain parentheses. In PG-compatible mode, ON UPDATE CURRENT_TIMESTAMP(), ON UPDATE LOCALTIMESTAMP(), and ON UPDATE NOW(5) are not supported.
  - This attribute can be specified only for columns of the following types: timestamp, datetime, date, time without time zone, smalldatetime, and abstime.
  - If the CREATE TABLE AS syntax is used, the column attributes will not be inherited.
  - The CREATE TABLE LIKE syntax can use **INCLUDING UPDATE** or **EXCLUDING UPDATE** to inherit or exclude a constraint. In PG-compatible mode, only **EXCLUDING UPDATE** can be used to exclude a constraint. The **INCLUDING ILM** option is added to copy ILM policy information from the source table. When combined with the **INCLUDING PARTITION** option, it can also copy the policy information of partition objects from the source table.
  - The precision specified by this attribute can be different from the precision specified by the type in the corresponding column. After the column value is updated through this attribute, the minimum precision is displayed. For example, **CREATE TABLE t1 (col1 timestamp(6) ON UPDATE CURRENT_TIMESTAMP(3));**. If the UPDATE syntax triggers the attribute to take effect, three decimal places in the value of **col1** are displayed after the update.
  - The same column cannot be specified for this attribute and the generated column constraint at the same time.
  - This attribute cannot be specified for the partition key in a partitioned table.
  - In distributed scenarios, this attribute cannot be specified for distribution keys and primary keys.

- **AUTO_INCREMENT**

  Marks a column as auto-increment.

  Currently, the auto-increment column is a local auto-increment column by default. The auto-increment column increases independently on each DN and does not affect each other. The auto-increment column is not unique globally.

  If the value of this column is not specified (or the value of this column is set to **0**, **NULL**, or **DEFAULT**), the value of this column is automatically increased by the auto-increment counter.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

If this column is inserted or updated to a value greater than the current auto-increment counter, the auto-increment counter is updated to this value after the command is executed successfully.

The initial auto-increment value is set by the AUTO_INCREMENT [=] value clause. If it is not set, the default value **1** is used.

NOTE

- The auto-increment column can be specified only when **sql_compatibility** is set to **'MYSQL'**.
- The data type of the auto-increment column can only be integer, 4-byte or 8-byte floating point, or Boolean.

  An error will occur if auto-increment continues after the column reaches the upper limit of the data type.
- Each table can have only one auto-increment column.
- It is recommended that the local auto-increment column be the first column of a non-global secondary index. Otherwise, errors may occur when some operations are performed on a table that contains auto-increment columns, for example, ALTER TABLE EXCHANGE PARTITION.
- The DEFAULT value cannot be specified for an auto-increment column.
- The expression of the CHECK constraint cannot contain auto-increment columns.
- You can specify that the auto-increment column can be NULL. If it is not specified, the auto-increment column contains the NOT NULL constraint by default.
- When you create a table with a local auto-increment column, the system automatically creates a local sequence on each DN to serve as the auto-increment counter. You cannot modify or delete this sequence using sequence-related functionalities, but you can view its current value. Do not configure other sequences to depend on or join with this auto-increment column.
- The auto-increment and refresh operations of the auto-increment counter are not rolled back.
  - Before data is inserted into a table, **0** or **NULL** triggers auto-increment. After data is inserted or updated to a table, the auto-increment counter is updated. If an error is reported after auto-increment, and data is not inserted or updated to the table, the auto-increment counter does not roll back. Subsequent insert statements trigger auto-increment based on the auto-increment counter. As a result, the values of the auto-increment columns in the table are discontinuous.
  - Inserting or importing reserved auto-increment cache values in batches can also lead to discontinuous values in the auto-increment column. For details, see the description of the **auto_increment_cache** parameter.
- An auto-increment column cannot be used as a distribution key.
- Currently, local temporary tables do not support auto-increment columns.
- DISTRIBUTE BY REPLICATION does not support auto-increment columns.

- **UNIQUE [KEY] index_parameters**

  Specifies that a column or a combination of columns must be unique across the entire table.

  For the purpose of a UNIQUE constraint, NULL is not considered equal.

  Semantically equivalent to UNIQUE, UNIQUE KEY is available only in MySQL-compatible databases (**sql_compatibility = 'MYSQL'**).

- **UNIQUE [index_name][USING method] ({ {column_name | (expression) } [ASC | DESC] }[, ...]) index_parameters**

  Specifies that a column or a combination of columns must be unique across the entire table.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

For the purpose of a UNIQUE constraint, NULL is not considered equal.

index_name indicates the index name.

NOTICE

- **index_name** is supported only in MySQL-compatible databases (**sql_compatibility = 'MYSQL'**).
- If both **constraint_name** and **index_name** are specified for the UNIQUE constraint, the value of **index_name** will be used as the index name.

- **PRIMARY KEY index_parameters**

  PRIMARY KEY [USING method] ({ column_name [ASC | DESC] } [, ...]) index_parameters

  Specifies that one or more columns in the table require unique, non-NULL values.

  Only one primary key can be specified for a table.
- **REFERENCES**

  The current version does not support the REFERENCES clause.
- **USING method**

  Specifies the name of the index method to be used.

  For details about the value range, see **USING method** in **CREATE INDEX**.

NOTICE

- **USING method** is supported only in MySQL-compatible databases (**sql_compatibility = 'MYSQL'**).
- In MySQL-compatible mode, when **USING method** is not specified, Astore will default to B-tree indexing, and Ustore will default to UB-tree indexing.
- Since the underlying layer of GSIs is based on UB-tree storage, GSIs will be built with UB-tree storage, even if users specify B-tree storage.
- If the storage mode of a table is Ustore and the USING BTREE constraint is specified in an SQL statement, the underlying layer will automatically treat it as USING UBTREE.

- **ASC | DESC**

  ASC specifies an ascending (default) sort order. **DESC** specifies a descending sort order.

NOTICE

ASC | DESC is supported only in MySQL-compatible databases (**sql_compatibility = 'MYSQL'**).

- **expression**

  Specifies an expression based on one or more columns of the table. It must be written in parentheses.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTICE

Expression indexes in the UNIQUE constraint are supported only in MySQL-compatible databases (**sql_compatibility = 'MYSQL'**).

- **DEFERRABLE | NOT DEFERRABLE**

  Specifies whether the constraint can be deferred. A constraint that is not deferrable will be checked immediately after every command. Checking of constraints that are deferrable can be postponed until the end of the transaction (using the **SET CONSTRAINTS** command). **NOT DEFERRABLE** is the default. Currently, only the UNIQUE and PRIMARY KEY constraints accept this clause. (That is, other constraints are not deferrable.)

- **INITIALLY IMMEDIATE | INITIALLY DEFERRED**

  Specifies the default time to check the constraint if it is deferrable. A constraint that is not deferrable is always **INITIALLY IMMEDIATE** and cannot be declared as **INITIALLY DEFERRED**.

  - If the constraint is **INITIALLY IMMEDIATE**, it is checked after each statement. This is the default.
  - If the constraint is **INITIALLY DEFERRED**, it is checked only at the end of the transaction.

  The constraint check time can be altered with the **SET CONSTRAINTS** command.

- **USING INDEX TABLESPACE tablespace_name**

  Specifies a tablespace in which an index associated with a UNIQUE or PRIMARY KEY constraint will be created. If this clause is not specified, the index will be created in the default tablespace named **default_tablespace**. If **default_tablespace** is empty, the default tablespace of the database will be consulted.

- DATATYPE_CL = client_logic_type

  Specifies the type of the column to be encrypted. This parameter is optional.

  Value range: **BYTEAWITHOUTORDER** or **BYTEAWITHOUTORDERWITHEQUAL**.

- **COLUMN_ENCRYPTION_KEY = column_encryption_key**

  Specifies the name of the CEK in the ENCRYPTED WITH constraint.

  Value range: character strings complying with **Identifier Naming Conventions**.

- **ENCRYPTION_TYPE = encryption_type_value**

  When setting the encryption type in the ENCRYPTED WITH constraint, you can choose between **DETERMINISTIC** or **RANDOMIZED** as **encryption_type_value**.

- **[DEFAULT] CHARACTER SET | CHARSET [=] default_charset**

  Specifies the default character set of the table. If this parameter is specified separately, the table will use the default collation of the specified character set.

- **[DEFAULT] COLLATE [=] default_collation**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Specifies the default collation of the table. If this parameter is specified separately, the table will default to the character set corresponding to the specified collation.

This syntax is supported only in MySQL-compatible databases (**sql_compatibility = 'MYSQL'**). For details about the collation, see **Table 1-398**.

NOTE

If the character set or collation of a table is not explicitly specified but the default character set or collation of the schema is specified, the table will inherit the character set and collation from the schema. If the default character set or collation of the schema cannot be found, the table will inherit the character set and its corresponding collation from the current database when **b_format_behavior_compat_options** includes **'default_collation'**.

Examples

- Create an ordinary table.

```
gaussdb=# CREATE TABLE tbl_test1(
    id       int,
    name     varchar(50),
    province varchar (60), -- Province
    country  varchar (60) DEFAULT 'China' -- Country
);

gaussdb=# DROP TABLE tbl_test1;
```

- **The WITH clause adds storage parameters to a table or index.**

```
-- Create a table and specify a fillfactor.
gaussdb=# CREATE TABLE tbl_test2(
    id       int,
    name     varchar(50),
    province varchar (60), -- Province
    country  varchar (60) DEFAULT 'China' -- Country
) WITH (FILLFACTOR = 70);

-- Create a table and specify a storage engine.
gaussdb=# CREATE TABLE tbl_test3(
    id       int,
    name     varchar(50),
    province varchar (60), -- Province
    country  varchar (60) DEFAULT 'China' -- Country
) WITH (STORAGE_TYPE = ASTORE);

-- Drop.
gaussdb=# DROP TABLE tbl_test2;
gaussdb=# DROP TABLE tbl_test3;
```

- Use an encrypted table.

  Before using this parameter, ensure that the GUC parameter **enable_tde** is enabled and **tde_key_info** is properly set. For detailed usage, consult "Feature Usage Guidelines > Transparent Data Encryption" in *Developer Guide*.

```
gaussdb=# CREATE TABLE  t1 (c1 TEXT) WITH (enable_tde=on);

-- Drop the table.
gaussdb=# DROP TABLE t1;
```

- Use a temporary table.

```
-- Create a temporary table and drop it when the transaction is committed.
gaussdb=# CREATE TEMPORARY TABLE test_t2(
    id       CHAR(7),
    name     VARCHAR(20),
    province VARCHAR(60),                    -- Province
    country   VARCHAR(30) DEFAULT 'China'       -- Country
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
) ON COMMIT DELETE ROWS;
gaussdb=# DROP TABLE test_t2;
```

- Specify a character set and collation during table creation.

```
-- Create a frontend database.
gaussdb=# CREATE DATABASE testdb1 ENCODING = 'UTF8';
gaussdb=# \c testdb1

-- Create table t1. Set the default character set of t1 to utf8mb4 and the default collation to utf8mb4_bin. Set the character set and collation of the c1 column to the default values of the table. Set the character set of the c2 column to utf8mb4, and its collation to utf8mb4_unicode_ci.
testdb1=# CREATE TABLE t1(c1 text, c2 text charset utf8mb4 collate utf8mb4_unicode_ci) charset utf8mb4 collate utf8mb4_bin;

-- Drop.
testdb1=# DROP TABLE t1;
testdb1=# \c postgres
gaussdb=# DROP DATABASE testdb1;
```

- IF NOT EXISTS keyword

  If this keyword is used, NOTICE is reported when the table does not exist. If this keyword is not used, ERROR is reported. In either case, the table fails to be created.

```
gaussdb=# CREATE TABLE test_t3(id INT);
-- Create a table named test_t3.
gaussdb=# CREATE TABLE test_t3(id INT);
ERROR:  Relation "test_t3" already exists in schema "public".
DETAIL:  Creating new table with existing name in the same schema.

-- Use the IF NOT EXISTS keyword.
gaussdb=# CREATE TABLE IF NOT EXISTS test_t3(id INT);
NOTICE:  Relation test_t3 already exists, skipping.
CREATE TABLE

-- Drop the table.
gaussdb=# DROP TABLE test_t3;
```

- Specifying a tablespace during table creation

```
-- Create a tablespace.
gaussdb=# CREATE TABLESPACE ds_tbs1 RELATIVE LOCATION 'tablespace/tablespace_1';

-- Specify a tablespace when creating a table.
gaussdb=# CREATE TABLE test(id CHAR(7), name VARCHAR(20)) TABLESPACE ds_tbs1;

-- Drop the table and tablespace.
gaussdb=# DROP TABLE test;
gaussdb=# DROP TABLESPACE ds_tbs1;
```

- Specifying the AUTO_INCREMENT column during table creation

```
-- The local auto-increment column is not used as the distribution key. The value starts from 10 for each DN. (Change the DN name by running SELECT node_name FROM pgxc_node WHERE node_type = 'D' based on the actual situation.)
gaussdb=# CREATE TABLE local_autoinc(col int AUTO_INCREMENT, col1 int) AUTO_INCREMENT = 10 DISTRIBUTE BY LIST(col1)(
    SLICE s1 VALUES (1) DATANODE datanode1,
    SLICE s2 VALUES (2) DATANODE datanode2
);

-- You are advised to use the auto-increment column as the first column of the index to create an index.
gaussdb=# CREATE INDEX local_autoinc_ai ON local_autoinc(col);

-- Distribute data to DN1. The value NULL triggers auto-increment, and the auto-increment value is 10.
gaussdb=# INSERT INTO local_autoinc(col, col1) VALUES(NULL,1);

-- Distribute data to DN2. The value 0 triggers auto-increment, and the auto-increment value is 10.
gaussdb=# INSERT INTO local_autoinc(col, col1) VALUES(1 - 1,2);
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
-- Distribute data to DN1. The value 100 does not trigger auto-increment. After data is inserted successfully, the auto-increment value is updated to 100.
gaussdb=# INSERT INTO local_autoinc(col, col1) VALUES(100,1);

-- Distribute data to DN1. The value 0 triggers auto-increment, and the auto-increment value is 101.
gaussdb=# INSERT INTO local_autoinc(col, col1) VALUES(0,1);

-- Distribute data to DN2. The value DEFAULT triggers auto-increment, and the auto-increment value is 11.
gaussdb=# INSERT INTO local_autoinc(col, col1) VALUES(DEFAULT,2);

gaussdb=# SELECT col,col1 FROM local_autoinc ORDER BY 2,1;
 col | col1
-----+------
  10 |    1
 100 |    1
 101 |    1
  10 |    2
  11 |    2
(5 rows)

-- Drop.
gaussdb=# DROP TABLE local_autoinc;
```

- Creating a table using CREATE TABLE ... LIKE

```
-- Create the source table t1.
gaussdb=# CREATE TABLE t1(col INT);
CREATE TABLE

gaussdb=# \d t1
      Table "public.t1"
 Column |  Type   | Modifiers
--------+---------+-----------
 col    | integer |

-- Create the target table t2.
gaussdb=# CREATE TABLE t2(LIKE t1);
CREATE TABLE

gaussdb=# \d t2
      Table "public.t2"
 Column |  Type   | Modifiers
--------+---------+-----------
 col    | integer |

-- Drop.
gaussdb=# DROP TABLE t1,t2;
```

Examples of Creating a Table and Adding Constraints to the Table

- NOT NULL constraint

  If no value is specified for a column with a NOT NULL constraint when data is added, an error is reported. You can add NOT NULL constraints to multiple columns in a table.

```
-- Create a table and add a NOT NULL constraint to the id column.
gaussdb=# CREATE TABLE test_t4(
    id       CHAR(7) NOT NULL,
    name     VARCHAR(20),
    province VARCHAR(60),                    -- Province
    country   VARCHAR(30) DEFAULT 'China'        -- Country
);

-- If the value of id is not specified or is NULL during data insertion, the NOT NULL constraint is triggered. As a result, the insertion fails.
gaussdb=# INSERT INTO test_t4 (name,province) VALUES ('scott','Shanghai');
ERROR: The null value in column "id" violates the not-null constraint.
DETAIL: Failing row contains (null, scott, Shanghai, China).
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
-- Drop the table.
gaussdb=# DROP TABLE test_t4;
```

- UNIQUE constraint

  The UNIQUE keyword applies a UNIQUE constraint to a column and automatically creates a unique index. This constraint prevents duplicate entries in the column, but multiple NULL values are not considered duplicate. You can add UNIQUE constraints to multiple columns in a table.

```
-- Create a table and add a UNIQUE constraint.
gaussdb=# CREATE TABLE test_t5(
    id       CHAR(7) UNIQUE USING INDEX TABLESPACE pg_default,
    name     VARCHAR(20),
    province VARCHAR(60),                    -- Province
    country   VARCHAR(30) DEFAULT 'China'        -- Country
);

-- You can also use the following writing to name a UNIQUE constraint and add the constraint to
multiple columns:
gaussdb=# CREATE TABLE test_t6(
    id       CHAR(7),
    name     VARCHAR(20),
    province VARCHAR(60),                     -- Province
    country   VARCHAR(30) DEFAULT 'China',        -- Country
    CONSTRAINT unq_test_id UNIQUE (id,name)
);
-- The constraint is enforced when data with duplicate IDs is inserted, causing the insertion to fail.
gaussdb=# INSERT INTO test_t5(id) VALUES('0000010');
INSERT 0 1
gaussdb=# INSERT INTO test_t5(id) VALUES('0000010');
ERROR:  Duplicate key value violates unique constraint "test_t5_id_key".
DETAIL:  Key (id)=(0000010) already exists.
-- The constraint is not enforced when multiple instances of data with a NULL ID are inserted.
gaussdb=# INSERT INTO test_t5(id) VALUES (NULL);
INSERT 0 1
gaussdb=# INSERT INTO test_t5(id) VALUES (NULL);
INSERT 0 1

-- Drop tables.
gaussdb=# DROP TABLE test_t5;
gaussdb=# DROP TABLE test_t6;
```

- PRIMARY KEY constraint

  The keyword PRIMARY KEY is used to add a UNIQUE constraint to a column. The column must be unique and cannot be empty. When a PRIMARY KEY constraint is added, a unique index is automatically created for the table, and a NOT NULL constraint is automatically added for the column.

  Only one PRIMARY KEY constraint can be defined in each table.

```
-- Create a table and add a PRIMARY KEY constraint.
gaussdb=# CREATE TABLE test_t6(
    id       CHAR(7) PRIMARY KEY,
    name     VARCHAR(20),
    province VARCHAR(60),                    -- Province
    country   VARCHAR(30) DEFAULT 'China'        -- Country
);
gaussdb=# INSERT INTO test_t6 (id,name,province) VALUES ('0000001','july','Beijing');

-- You can also use the following writing to manually name a UNIQUE constraint and add the
constraint to multiple columns:
gaussdb=# CREATE TABLE test_t7(
    id       CHAR(7),
    name     VARCHAR(20),
    province VARCHAR(60),                    -- Province
    country   VARCHAR(30) DEFAULT 'China',        -- Country
    CONSTRAINT pk_test_t6_id PRIMARY KEY (id,name)
);
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
-- The constraint is enforced when data with a NULL ID is inserted.
gaussdb=# INSERT INTO test_t6 (id,name,province) VALUES (NULL,'july','Beijing');
ERROR:  The null value in column "id" violates the not-null constraint.
DETAIL:  Failing row contains (null, july, Beijing, China).

-- The constraint is enforced when data with duplicate IDs is inserted.
gaussdb=# INSERT INTO test_t6 (id,name,province) VALUES ('0000001','ben','Shanghai');
ERROR:  Duplicate key value violates unique constraint "test_t6_pkey"
DETAIL:  Key (id)=(0000001) already exists.
-- Drop tables.
gaussdb=# DROP TABLE test_t6;
gaussdb=# DROP TABLE test_t7;
```

- CHECK constraint

  The keyword CHECK adds a constraint to a column. The CHECK constraint must reference one or more columns in the table, and the result returned by the expression must be a Boolean value. Currently, expressions cannot contain subqueries. Both CHECK and NOT NULL constraints can be defined for the same column.

```
-- Create a table and add a CHECK constraint.
gaussdb=# CREATE TABLE test_t8 (
    id       CHAR(7),
    name     VARCHAR(20),
    age      INT CHECK(age > 0 AND age < 150)
);

-- You can also use the following SQL statement to manually name a CHECK constraint and add the
constraint to one or more columns:
gaussdb=# CREATE TABLE test_t9 (
    id       CHAR(7),
    name     VARCHAR(20),
    age      INT,
    CONSTRAINT chek_test_t8_age CHECK(age > 0 AND age < 150)
);
-- The CHECK constraint is enforced when the inserted value does not comply with the expression,
causing the insertion to fail.
gaussdb=# INSERT INTO test_t8 (id,name,age) VALUES ('0000007','scott',200);
ERROR:  New row for relation test_t8 violates check constraint test_t8_age_check.
DETAIL:  N/A
-- Drop tables.
gaussdb=# DROP TABLE test_t8;
gaussdb=# DROP TABLE test_t9;
```

Table Data Distribution Examples

- REPLICATION

```
gaussdb=# CREATE TABLE test_replication(
    id       CHAR(7),
    name     VARCHAR(20),
    province VARCHAR(60),                    -- Province
    country   VARCHAR(30) DEFAULT 'China'        -- Country
)DISTRIBUTE BY REPLICATION;

-- Query table information.
gaussdb=# \d+ test_replication
                                  Table "public.test_replication"
  Column  |         Type          |             Modifiers              | Storage  | Stats target | Description
----------+-----------------------+------------------------------------+----------+--------------+-------------
 id       | character(7)          |                                    | extended |              |
 name     | character varying(20) |                                    | extended |              |
 province | character varying(60) |                                    | extended |              |
 country  | character varying(30) | default 'China'::character varying | extended |              |
Has OIDs: no
Distribute By: REPLICATION
Location Nodes: ALL DATANODES
Options: orientation=row, logical_repl_node=-1, compression=no, storage_type=USTORE, segment=off
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
-- Drop.
gaussdb=# DROP TABLE test_replication;
```

- **HASH**

```
-- Define a table using hash distribution.
gaussdb=# CREATE TABLE test_hash(
    id       CHAR(7),
    name     VARCHAR(20),
    province VARCHAR(60),                    -- Province
    country   VARCHAR(30) DEFAULT 'China'        -- Country
)DISTRIBUTE BY HASH(id);

-- Insert data.
gaussdb=# INSERT INTO test_hash VALUES ('0000001', 'Bob',   'Shanghai', 'China'),
                          ('0000002', 'Jack',  'Beijing',  'China'),
                          ('0000003', 'Scott', 'Beijing',  'China');
-- View data distribution.
gaussdb=# SELECT a.count,b.node_name
FROM (SELECT COUNT(*) AS count, xc_node_id FROM test_hash GROUP BY xc_node_id) a,
     pgxc_node b
WHERE a.xc_node_id=b.node_id ORDER BY a.count DESC;

count |     node_name
-------+-------------------
     2 | dn_6001_6002_6003
     1 | dn_6004_6005_6006
(2 rows)
-- Drop the table.
gaussdb=# DROP TABLE test_hash;
```

- **MURMURHASH**

```
-- The test environment contains one CN and six DNs.
-- Create a node group. You can run the SELECT node_name FROM PGXC_NODE WHERE node_type = 'D' command to query the DN name in the node group. In the query result, replace the DN name following WITH in the CREATE NODE GROUP statement as required.
gaussdb=# CREATE NODE GROUP NG1 WITH(datanode1, datanode2, datanode3, datanode4, datanode5, datanode6);
-- Define a table using MurmurHash distribution.
gaussdb=# CREATE TABLE test_murmurhash1 (a int NOT NULL, b int) DISTRIBUTE BY MURMURHASH(a) TO GROUP NG1;
gaussdb=# CREATE TABLE test_murmurhash2 (a int NOT NULL, b int) DISTRIBUTE BY MURMURHASH(lpad_s(a,10,'0')) TO GROUP NG1;
-- Insert data.
gaussdb=# INSERT INTO test_murmurhash1 VALUES(0,1);
gaussdb=# INSERT INTO test_murmurhash2 VALUES(1,2);
-- Query data.
gaussdb=# SELECT * FROM test_murmurhash1;

ALTER TABLE, **DROP TABLE**, and **CREATE TABLESPACE**

Suggestions

- UNLOGGED
  - Data written to unlogged tables or indexes on such tables is not written to WALs, which makes them considerably faster than ordinary tables. Therefore, they are ideal for storing the intermediate result sets of complex queries to enhance query performance.
  - However, unlogged tables lack the primary/standby mechanism, increasing the risk of data loss in case of system failures or unexpected breakpoints. As a result, unlogged tables are not recommended for storing basic data.
- TEMPORARY | TEMP
  - Temporary tables are visible only to the current session and will be automatically dropped at the end of the session.
  - Temporary tables are visible only to the current CN.
- LIKE
  - The target table automatically inherits all column names, their data types, and NOT NULL constraints from the declared table, known as the source table. The new table and source table are completely decoupled after creation is complete.
- LIKE INCLUDING DEFAULTS
  - Columns in the target table inherit the default expressions from the source table only when **INCLUDING DEFAULTS** is specified. The default behavior is to exclude the default expressions, causing all columns in the target table to default to **NULL**.
- LIKE INCLUDING CONSTRAINTS
  - The target table inherits the CHECK constraints from the source table only when **INCLUDING CONSTRAINTS** is specified. Other types of constraints are not inherited, while NOT NULL constraints are always inherited. This rule also applies to table constraints and column constraints.
- LIKE INCLUDING INDEXES
  - If **INCLUDING INDEXES** is specified, indexes on the source table will also be created on the target table. By default, no indexes are created. The tablespace where indexes on the target table are located is the same as that where indexes on the source table are located.
- LIKE INCLUDING STORAGE
  - If **INCLUDING STORAGE** is specified, columns in the target table will inherit **STORAGE** settings from the source table. The default behavior is to exclude **STORAGE** settings.
- LIKE INCLUDING COMMENTS
  - If **INCLUDING COMMENTS** is specified, the target table will inherit comments on columns, constraints, and indexes from the source table. The default behavior is to exclude comments.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- LIKE INCLUDING PARTITION
  - If **INCLUDING PARTITION** is specified, the target table will inherit partition definitions from the source table and will no longer be able to use the PARTITION BY clause. The default behavior is to exclude partition definitions.
- LIKE INCLUDING RELOPTIONS
  - If **INCLUDING RELOPTIONS** is specified, the target table will inherit storage parameters (WITH clause) from the source table. The default behavior is to exclude storage parameters.
- LIKE INCLUDING DISTRIBUTION
  - If **INCLUDING DISTRIBUTION** is specified, the target table will inherit distribution information (including distribution types and keys) from the source table and will no longer be able to use the DISTRIBUTE BY clause. The default behavior is to exclude distribution information.
- LIKE INCLUDING ALL
  - **INCLUDING ALL** is a condensed version that encompasses **INCLUDING DEFAULTS**, **INCLUDING CONSTRAINTS**, **INCLUDING INDEXES**, **INCLUDING STORAGE**, **INCLUDING COMMENTS**, **INCLUDING PARTITION**, **INCLUDING RELOPTIONS**, **INCLUDING DISTRIBUTION**, and **INCLUDING ILM**.
- ORIENTATION ROW
  - Create a row-store table. Row store is ideal for OLTP workloads because they can handle a high volume of interactive transactions, each of which usually involves multiple table columns. Utilizing row store can enhance query performance.
- DISTRIBUTE BY
  - When dealing with a fact table or a dimension table that holds a significant volume of data, it is advisable to create it as a distributed table. This table distributes data to the specified DNs based on hash values in the specified column. The syntax is DISTRIBUTE BY HASH(column_name).
  - When dealing with a dimension table that holds a small volume of data, it is advisable to create it as a replication table. This table replicates each table record to all DNs, ensuring that each DN holds the full set of table data. The syntax is DISTRIBUTE BY REPLICATION.

1.13.9.45 CREATE TABLESPACE

Description

Creates a tablespace in a database.

Precautions

- A system administrator or a user who inherits permissions of the built-in role gs_role_tablespace can create a tablespace.
- **CREATE TABLESPACE** cannot be executed within a transaction block.
- If internal directory or file operations succeed but subsequent steps fail during tablespace creation, residual directories or files may remain. Therefore, before

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

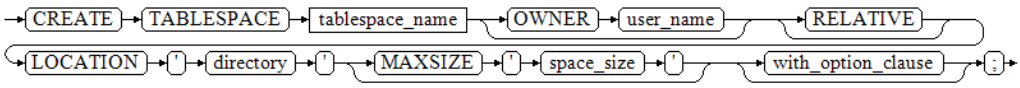
attempting to create a tablespace again, you will need to manually remove the residual content in the specified directory for the tablespace. If there are residual files of soft links for the tablespace in the data directory, delete the residual files, and then perform O&M operations.

- **CREATE TABLESPACE** cannot be used for two-phase transactions. If it fails on some nodes, the execution cannot be rolled back.
- When creating a tablespace, the system distributes the creation instruction to nodes in sequence. If the instruction fails to execute on a remote node, the system will return "CONTEXT: Error message received from nodes: *Node name*" to indicate the source of the error.
- You are advised not to use user-defined tablespaces in the Huawei Cloud scenario.

  This is because user-defined tablespaces are typically intended for use with storage media other than the main storage (device where the default tablespace is situated, like a disk) to isolate I/O resources for different services. In the Huawei Cloud scenario, however, storage devices follow standard configurations and lack additional storage media options. Improper use of user-defined tablespaces can lead to system instability over time and impact overall performance. Therefore, it is advisable to use the default tablespace.

Syntax

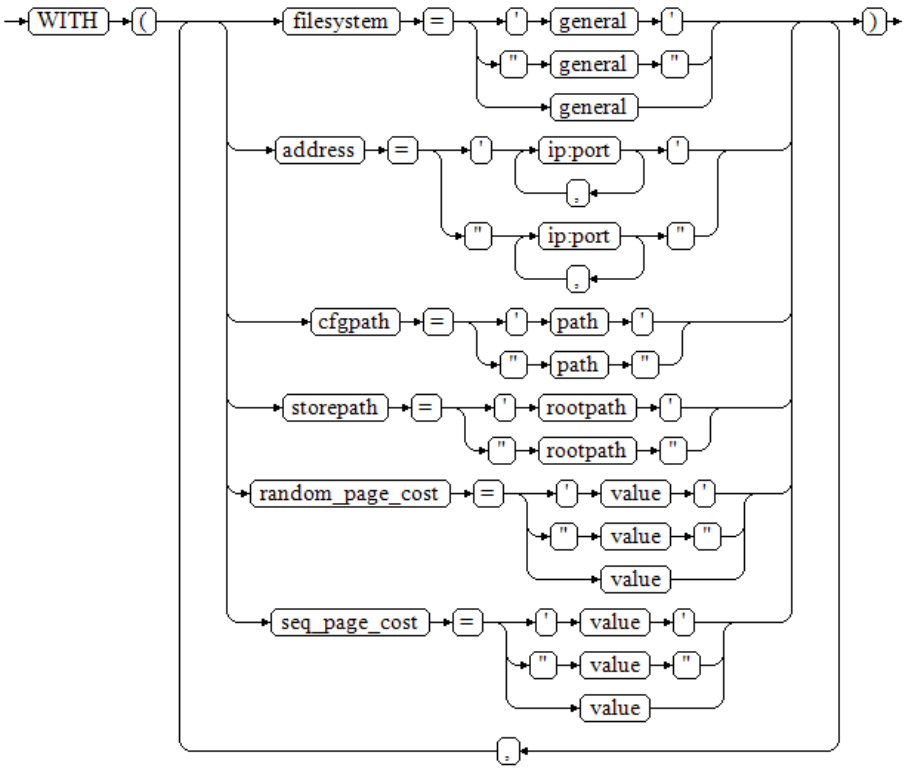
```
CREATE TABLESPACE tablespace_name
    [ OWNER user_name ] [ RELATIVE ] LOCATION 'directory' [ MAXSIZE 'space_size' ]
    [with_option_clause];
```



with_option_clause for creating an ordinary tablespace is as follows:

```
WITH ({filesystem= { ' general ' | '' general '' | general } | address = { ' ip:port [, ... ] ' | '' ip:port [, ... ] '' } |
cfgpath = { ' path ' | '' path '' } | storepath = { ' rootpath ' | '' rootpath '' } | random_page_cost = { ' value ' | ''
value '' | value } | seq_page_cost = { ' value ' | '' value '' | value }}[, ... ])
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.



Parameters

- **tablespace_name**

  Specifies name of the tablespace to be created.

  Value range: character strings complying with **Identifier Naming Conventions**.

  NOTE

  The tablespace name must be unique within the database and cannot start with **pg**.

- **OWNER user_name**

  Specifies the owner of the tablespace. By default, the new tablespace is owned by the current user.

  Value range: existing usernames.

  NOTE

  Only system administrators can create tablespaces, but they can assign the ownership of tablespaces to non-system administrators using the OWNER clause.

- **RELATIVE**
  - If this parameter is specified, a relative path will be used. The **LOCATION** directory of the tablespace is relative to each CN/DN's data directory.

    Directory hierarchy: relative path of the CNs and DNs directory **/pg_location/**. A relative path contains a maximum of two levels.
  - If this parameter is not specified, an absolute path will be used for the **LOCATION** directory of the tablespace.
- **LOCATION directory**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Specifies the directory for the table space. When an absolute path is used (that is, the **RELATIVE** parameter is not specified), the directory must meet the following requirements:

- The system user must have the read and write permissions on the directory, and the directory must be empty. If the directory does not exist, the system automatically creates it.
- The directory must be an absolute path, and must not contain special characters such as the dollar sign ($) or greater-than sign (>).
- The directory cannot be specified under the database data directory.
- The directory must be a local path.
- You are advised to use a directory in Ext4 format.

Value range: valid directories (character string).

- **MAXSIZE 'space_size'**

  Specifies the maximum size of the tablespace on a single DN.

  Value range: numbers in KB, MB, GB, TB, or PB. Once converted to KB, the numbers must stay within the range of signed integers represented by 64 bits, that is, 1 KB to 9007199254740991 KB.

- **address**

  Specifies the IP address and port number.

- **cfgpath**

  Specifies the configuration file path.

- **storepath**

  Specifies the root path.

- **filesystem**

  Specifies the file system used by the tablespace.

  Value range:

  - **general**: general file system.
  - **hdfs**: Hadoop distributed file system. It is not supported in the current version.

  Default value: **general**.

- **random_page_cost**

  Specifies the time and resources required for reading pages randomly.

  Value range: 0 to 1.79769e+308.

  Default value: *value of the GUC parameter* ***random_page_cost***.

- **seq_page_cost**

  Specifies the time and resources required for reading pages in sequence.

  Value range: 0 to 1.79769e+308.

  Default value: *value of GUC parameter* ***seq_page_cost***.

Examples

```
-- Create a tablespace.
gaussdb=# CREATE TABLESPACE tbs_location1 RELATIVE LOCATION 'test_tablespace/test_tablespace_1';

-- Create a tablespace and specify the maximum value.
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gaussdb=# CREATE TABLESPACE tbs_location2 RELATIVE LOCATION 'test_tablespace/test_tablespace_2'
MAXSIZE '10G';

-- Query tablespace information.
gaussdb=# SELECT * FROM pg_tablespace WHERE spcname = 'tbs_location2';
    spcname     | spcowner | spcacl | spcoptions | spcmaxsize | relative
----------------+----------+--------+------------+------------+----------
 tbs_location2 |       10 |        |            | 10485760 K | t
(1 row)

-- Create user joe.
gaussdb=# CREATE ROLE joe IDENTIFIED BY '********';

-- Create a tablespace and set its owner to user joe.
gaussdb=# CREATE TABLESPACE tbs_location3 OWNER joe RELATIVE LOCATION 'test_tablespace/
test_tablespace_3';

-- Create a tablespace and specify an absolute path. (Change the path based on the actual situation.)
gaussdb=# CREATE TABLESPACE tbs_location4 LOCATION '/tmp/tbs_location4';

-- Delete tablespaces and users.
gaussdb=# DROP TABLESPACE tbs_location1;
gaussdb=# DROP TABLESPACE tbs_location2;
gaussdb=# DROP TABLESPACE tbs_location3;
gaussdb=# DROP TABLESPACE tbs_location4;
gaussdb=# DROP ROLE joe;
```

Helpful Links

CREATE DATABASE, **CREATE TABLE**, **CREATE INDEX**, **DROP TABLESPACE**, and **ALTER TABLESPACE**

1.13.9.46 CREATE TABLE AS

Description

Creates a table from the results of a query.

It creates a table and fills it with data computed by a **SELECT** command. The table columns have the names and data types associated with the output columns of the **SELECT** (except that you can override the column names by giving an explicit list of new column names).

CREATE TABLE AS bears some resemblance to creating a view, but it is really quite different: it creates a new table and evaluates the query just once to fill the new table initially. The new table will not track subsequent changes to the source tables of the query. In contrast, a view re-evaluates its defining SELECT statement whenever it is queried.

Precautions

- The table created in this way inherits only column names and data types from the output columns of **SELECT**.
- CREATE TABLE AS cannot be used to create a partitioned table.
- If a fault occurs during table creation, the system may be unable to automatically clear the created disk files with a nonzero size, even after the fault has been rectified. This problem seldom occurs and does not affect system running of the database.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- If you add or modify an ILM policy for a data object and include a row-level expression, you must use only the whitelisted functions (in **Row Expression Function Whitelist**) as the expression.

  NOTE

  Among the functions supported by the row-level expression ON (EXPR) in the ILM policy, the output of some may be influenced by compatibility parameters. For instance, after you set **b_format_version** to **'5.7'** and **b_format_dev_version** to **'s2'** in MySQL-compatible mode, the upper function will be unable to convert data to uppercase as usual.

Syntax

```
CREATE [ [ GLOBAL | LOCAL ] [ TEMPORARY | TEMP ] | UNLOGGED ] TABLE [ IF NOT EXISTS ] table_name
    [ (column_name [, ...] ) ]
    [ { ENGINE [ = ] { InnoDB | 'InnoDB' | "InnoDB" } } [ ,... ] [ ... ] ]
    [ WITH ( {storage_parameter = value} [, ... ] ) ]
    [ ON COMMIT { PRESERVE ROWS | DELETE ROWS } ]
    [ ILM ADD POLICY ROW STORE COMPRESS
 { ADVANCED [ MEDIUM | HIGH ] ROW AFTER n { day | month | year } OF NO MODIFICATION [ ON
 ( EXPR )]
 | TURBO [ LOW | MEDIUM | HIGH ] UNIT AFTER n { hour | day | month | year } OF NO MODIFICATION
 | NONE}]
    [ TABLESPACE tablespace_name ]
    [ DISTRIBUTE BY { REPLICATION | { [HASH ] ( column_name ) } } ]
    [ TO { GROUP groupname | NODE ( nodename [, ... ] ) } ]
    AS query
    [ WITH [ NO ] DATA ];
```

For details about each column, see **Syntax**.

Parameters

- **UNLOGGED**

  Specifies whether to create the table as an unlogged table. Data written to unlogged tables is not written to WALs, which makes them considerably faster than ordinary tables. However, in the event of a conflict, OS restart, database restart, primary/standby switchover, power supply interruption, or unclean shutdown, unlogged tables will be cleared, posing a risk of data loss. Contents of an unlogged table are also not replicated to standby nodes. Any indexes created on an unlogged table are automatically unlogged as well.

  - Usage scenario: Considering the data security risks associated with unlogged tables, users should back up data before using such tables, for example, before a system upgrade.
  - Troubleshooting: If data is missing in the indexes of unlogged tables due to some unexpected operations such as an unclean shutdown, users should rebuild the indexes with errors.

- **GLOBAL | LOCAL**

  Specifies whether to create a global or local temporary table by including the GLOBAL or LOCAL keyword before TEMP or TEMPORARY. If the GLOBAL keyword is specified, GaussDB will create a global temporary table. Otherwise, it will create a local temporary table.

- **TEMPORARY | TEMP**

  Specifies whether to create a temporary table by including the TEMP or TEMPORARY keyword. Temporary tables are categorized as global or local.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

When you use the GLOBAL keyword, a global temporary table is created; otherwise, it is a local table.

- The metadata of global temporary tables is visible to all sessions, and it remains in place even after the sessions have concluded. User data, indexes, and statistics are isolated between sessions, allowing each session to access or modify only the data it has committed. Global temporary tables operate in two modes:
  - **ON COMMIT PRESERVE ROWS** (session level): User data is automatically cleared when sessions conclude.
  - **ON COMMIT DELETE ROWS** (transaction level): User data is automatically cleared upon COMMIT or ROLLBACK.

  If the **ON COMMIT** option is not specified during table creation, the session level will be used by default. When creating global temporary tables, you have the flexibility to specify a schema that does not have to start with **pg_temp_**, setting them apart from local temporary tables.
- Local temporary tables are visible only to the current session and will be automatically dropped at the end of the session. This allows you to create and utilize temporary tables within the current session, even if other CNs encounter issues, provided that the CN connected to the session is operational. Temporary tables are created solely within the current session. If a DDL statement involves operations on temporary tables, it will result in a DDL error. Therefore, avoid performing operations on temporary tables through DDL statements.

NOTICE

- Local temporary tables are made visible to the current session through a schema that starts with **pg_temp**. Therefore, users are advised against manually dropping schemas that start with **pg_temp** or **pg_toast_temp** during their routine operations.
- If a table is created without specifying the TEMPORARY or TEMP keyword but with a schema starting with **pg_temp** in the current session, the table will be considered a temporary table.
- Temporary tables are visible only to the current session. Therefore, they cannot be used together with **\parallel on**.
- Temporary tables cannot withstand DN failures or primary/standby switchovers.
- If a global temporary table or index is in use by another session, you cannot perform ALTER or DROP operations on it.
- DDL operations on global temporary tables affect only the user data and indexes of the current session. For example, TRUNCATE, REINDEX, and ANALYZE are restricted to the current session.

- **IF NOT EXISTS**

  Check whether a table with the same name exists. When the IF NOT EXISTS keyword is specified, the system checks the current schema for any dependency relation with the same name as the table you intend to create. If it finds such a relation, the table creation process will be halted, and a

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTICE will be returned. When IF NOT EXISTS is not specified and a relation with the same name is present in the schema, an ERROR will be returned.

- **table_name**

  Specifies the name of the table to be created.

  Value range: character strings complying with **Identifier Naming Conventions**.

- **column_name**

  (Optional) Specifies column names in the new table. If no column name is specified, the columns in the new table are the same as those entered in the SELECT statement.

  Value range: character strings complying with **Identifier Naming Conventions**.

- **ENGINE**

  This parameter is supported in MySQL-compatible mode and is used solely for syntax adaptation. It is limited to InnoDB, but no actual impact has been noted.

- **WITH (storage_parameter [= value] [, ...])**

  Specifies an optional storage parameter for the table or an index. See details of parameters below.

  NOTE

  These TDE-related storage parameters are supported: **enable_tde**, **encrypt_algo**, **dek_cipher**, **key_type**, and **cmk_id**.

  For details about these parameters, see **CREATE TABLE**.

  – FILLFACTOR

    Specifies a fillfactor for the table. It is a percentage between 10 and 100. **100** (complete packing) is the default. In the case of Ustore, the default is **92**. When a smaller fillfactor is specified, INSERT operations pack table pages only to the indicated percentage; the remaining space on each page is reserved for updating rows on that page. This gives UPDATE a chance to place the updated copy of a row on the same page as the original, which is more efficient than placing it on a different page. For a table whose entries are never updated, complete packing (fillfactor = 100) is the best choice. However, in heavily updated tables, smaller fillfactors are appropriate. The parameter takes effect only on row-store tables.

    Value range: 10–100.

  – ORIENTATION

    Value range: **ROW**, indicating that table data is stored in row orientation.

    Default value: **ROW**.

  – autovacuum_enabled

    Specifies whether to enable AUTOVACUUM for the table.

    Value range: **on** and **off**.

    Default value: **on**.

  – autovacuum_vacuum_threshold

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

(Applicable when AUTOVACUUM is enabled) Specifies the minimum number of updated or deleted tuples needed to trigger a VACUUM in the table. (This parameter applies specifically to Astore tables.)

Value range: 0–2147483647.

Default value: consistent with the GUC parameter **autovacuum_vacuum_threshold** unless otherwise specified.

- autovacuum_analyze_threshold

  (Applicable when AUTOVACUUM is enabled) Specifies the minimum number of inserted, updated, or deleted tuples needed to trigger an ANALYZE in the table.

  Value range: 0–2147483647.

  Default value: consistent with the GUC parameter **autovacuum_analyze_threshold** unless otherwise specified.

- autovacuum_vacuum_scale_factor

  (Applicable when AUTOVACUUM is enabled) Specifies the ratio of inserted, updated, or deleted tuples needed to trigger a VACUUM in the table. (This parameter applies specifically to Astore tables.)

  Value range: 0.0–100.0.

  Default value: consistent with the GUC parameter **autovacuum_vacuum_scale_factor** unless otherwise specified.

- autovacuum_analyze_scale_factor

  (Applicable when AUTOVACUUM is enabled) Specifies the ratio of inserted, updated, or deleted tuples needed to trigger an ANALYZE in the table.

  Value range: 0.0–100.0.

  Default value: consistent with the GUC parameter **autovacuum_analyze_scale_factor** unless otherwise specified.

- autovacuum_freeze_min_age

  (Applicable when AUTOVACUUM is enabled) Specifies the minimum age for rows to be frozen. Rows older than this age will be frozen.

  Value range: 0–576460752303423487.

  Default value: consistent with the GUC parameter **vacuum_freeze_min_age** unless otherwise specified.

- autovacuum_freeze_max_age

  (Applicable when AUTOVACUUM is enabled) Specifies the maximum age (in transactions) that the table's **pg_class.relfrozenxid** column can reach before a VACUUM operation is forced. Note that the system will launch AUTOVACUUM processes even when AUTOVACUUM is otherwise disabled. The VACUUM operation also allows removal of old files from the **pg_clog/** subdirectory. (This parameter applies specifically to Astore tables.)

  Value range: 100000–576460752303423487.

  Default value: consistent with the GUC parameter **autovacuum_freeze_max_age** unless otherwise specified.

- autovacuum_freeze_table_age

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

(Applicable when AUTOVACUUM is enabled) Specifies the time when the table will remain unchanged, marked as not requiring AUTOVACUUM. (This parameter applies specifically to Astore tables.)

Value range: 0–576460752303423487.

Default value: consistent with the GUC parameter **vacuum_freeze_table_age** unless otherwise specified.

- vacuum_truncate

  Specifies whether to enable the VACUUM TRUNCATE function of a table to truncate the last empty page during VACUUM.

  Value range: **on** and **off**.

  Default value: **on**.

  NOTE

  - This parameter is valid only for Astore tables and does not take effect for hash bucket tables and segment tables.
  - During the upgrade from a version that does not support this parameter to a version that supports this parameter, this parameter cannot be created or modified during the upgrade observation period.
  - The toast.**vacuum_truncate** parameter can be used to independently control whether to truncate the last empty page of a TOAST table.

- hashbucket

  Creates a hash bucket table. This parameter supports only row-store tables, including row-store range tables.

  Value range: **on** and **off**.

  Default value: **off**.

  NOTICE

  In current version, DDL operations on hash bucket tables are affected. Therefore, you are advised not to frequently perform DDL operations on hash bucket tables.

- hasrowid

  Specifies whether the table contains the **ROWID** and **ROWNO** system columns. If **hasrowid** is set to **on**, the **rowid** and **rowno** system columns are added to the table, and sequences and indexes are created on the **rowno** system column.

  Value range: **on** and **off**.

  Default value: **off**.

  NOTE

  - This parameter supports only ORA-compatible databases (that is, **sql_compatibility** is set to **ORA**).
  - This parameter does not support local temporary tables, unlogged tables, and global temporary tables.
  - This parameter cannot be specified together with **hasuids** and **oids**.
  - When this parameter is enabled, the ordinary column name cannot be defined as **rowno** or **rowid**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

  - partition_statistics_min_rows

    Specifies the minimum number of rows to be sampled at the partition level when the ANALYZE statement is executed on a partitioned table.

    Value range: [0,10000]

    Default value: **50**

    NOTE

    - This parameter is valid only for partitioned tables.
    - This parameter is valid only when **PARTITION_MODE** in the ANALYZE statement is set to **ALL** and the GUC parameter **enable_partition_statistics_min_rows** is enabled. For details about **PARTITION_MODE**, see **PARTITION_MODE** in **ANALYZE | ANALYSE**.
    - Upper limit: The number of rows sampled from the entire partitioned table cannot exceed the number of rows allowed by the GUC parameter **maintenance_work_mem**.

- **ON COMMIT { PRESERVE ROWS | DELETE ROWS }**

  Specifies subsequent operations on the temporary table when the temporary table is created in a transaction and the transaction is committed. Currently, only **PRESERVE ROWS** and **DELETE ROWS** are supported.

  - **PRESERVE ROWS** (default): No special action is taken at the ends of transactions. The temporary table and its table data are unchanged.
  - **DELETE ROWS**: All rows in the temporary table will be deleted at the end of each transaction block.

- **ILM ADD POLICY ROW STORE COMPRESS { ADVANCED [MEDIUM | HIGH] ROW AFTER n { day | month | year } OF NO MODIFICATION [ON (EXPR)] | TURBO [LOW | MEDIUM | HIGH] UNIT AFTER n { hour | day | month | year } OF NO MODIFICATION | NONE}**

  - When creating a row-store table, you can call ILM ADD POLICY ROW STORE COMPRESS ADVANCED [MEDIUM | HIGH] ROW to add a medium- or high-level advanced compression policy.

    - AFTER n { day | month | year } OF NO MODIFICATION: rows that have not been modified for *n* days, months, or years. Advanced compression does not support **hour**.
    - ON (EXPR): a row-level expression used to determine whether a row is hot or cold.

    NOTE

    - Among the functions supported by the row-level expression ON (EXPR) in the ILM policy, the output of some may be influenced by compatibility parameters. For instance, after you set **b_format_version** to **'5.7'** and **b_format_dev_version** to **'s2'** in MySQL-compatible mode, the upper function will be unable to convert data to uppercase as usual.
    - The compression level is optional. If not specified, the MEDIUM level will be used by default.

  - When creating a row-store table, you can call ILM ADD POLICY ROW STORE COMPRESS TURBO HIGH UNIT to add a cross-page transparent compression policy. Subpartitions will inherit this policy from partitions.

    AFTER n { hour | day | month | year } OF NO MODIFICATION: rows that have not been modified for *n* hours, days, months, or years.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

If the compression level is not specified, the MEDIUM level is used by default.

– When creating a row-store table, you can call ILM ADD POLICY ROW STORE COMPRESS NONE to explicitly specify that no cross-page transparent compression policy needs to be added.

- **TABLESPACE tablespace_name**

  Specifies the name of the tablespace where the table is to be created. If not specified, the default tablespace will be used.

- **DISTRIBUTE BY**

  For details, see **DISTRIBUTE BY** in **CREATE TABLE**.

- **TO { GROUP groupname | NODE (nodename [, ...]) }**

  Specifies the node group for which the table is to be created.

  This syntax is intended only for use by internal scale-out tools and is not recommended for direct use by users.

- **AS query**

  Specifies a **SELECT** or **VALUES** command, or an **EXECUTE** command that runs a prepared **SELECT** or **VALUES** query.

NOTICE

When data type conversion is required, especially when the CREATE TABLE AS SELECT statement is used, you are advised to use explicit type conversion to avoid unexpected results caused by implicit type conversion.

- **[WITH [NO] DATA]**

  Specifies whether to insert the queried data into the table being created. By default, the data is inserted. If you specify **NO**, the data will not be inserted.

Examples

- If no column name is specified, the columns in the new table are the same as those queried in the SELECT statement.

```
-- Create the test1 table and insert two records into the table.
gaussdb=# CREATE TABLE test1(col1 int PRIMARY KEY,col2 varchar(10));
gaussdb=# INSERT INTO test1 VALUES (1,'col1'),(101,'col101');
-- Query the data whose col1 is less than 100 in the table.
gaussdb=# SELECT * FROM test1 WHERE col1 < 100;
 col1 | col2
------+------
    1 | col1
(1 row)

-- Create the test2 table and insert the queried data into the table.
gaussdb=# CREATE TABLE test2 AS SELECT * FROM test1 WHERE col1 < 100;

-- Query the structure of the test2 table.
gaussdb=# \d test2;
 Column |         Type          | Modifiers
--------+-----------------------+-----------
 col1   | integer               |
 col2   | character varying(10) |
```

- Specify column names for the new table.

```
-- Use test1 to copy a new table test3 and specify column names.
gaussdb=# CREATE TABLE test3(c1,c2) AS SELECT * FROM test1;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
-- Query the structure of the test3 table.
gaussdb=# \d test3
           Table "public.test3"
 Column |         Type          | Modifiers
--------+-----------------------+-----------
 c1     | integer               |
 c2     | character varying(10) |

-- Drop.
gaussdb=# DROP TABLE test1,test2,test3;
```

- Create a table with the ILM policy enabled.

```
-- Create an ORA-compatible database.
gaussdb=# CREATE DATABASE ilmtabledb WITH dbcompatibility = 'ORA';
gaussdb=# \c ilmtabledb

-- Enable the ILM feature of the database.
ilmtabledb=#  ALTER DATABASE SET ILM = on;

-- Create a table ilm_table with the ILM policy enabled and insert the value of old_table.
ilmtabledb=# CREATE TABLE old_table (a int);
ilmtabledb=# CREATE TABLE ilm_table
  ILM ADD POLICY ROW STORE COMPRESS ADVANCED
  ROW AFTER 3 MONTHS OF NO MODIFICATION
  AS (SELECT * FROM old_table);

-- Drop.
ilmtabledb=# DROP TABLE old_table,ilm_table;
ilmtabledb=# \c postgres
gaussdb=# DROP DATABASE ilmtabledb;
```

Helpful Links

CREATE TABLE and **SELECT**

1.13.9.47 CREATE TABLE PARTITION

Description

Creates a partitioned table. Partitioning refers to splitting what is logically one large table into smaller physical pieces based on specific schemes. The initial table is known as a partitioned table, and the resulting pieces are called partitions. The partitioned table is a logical table, meaning it does not store data; instead, data is stored within these partitions.

Commonly used partitioning policies include range partitioning, interval partitioning, hash partitioning, list partitioning, and value partitioning. Currently, row-store tables support range partitioning, hash partitioning, and list partitioning.

- Range partitioning:

  In range partitioning, a table is partitioned based on ranges defined by one or more columns, with no overlap between the ranges of values assigned to different partitions. A partition is created for each range to store corresponding data.

  Range partitioning policy: It defines how records are inserted into partitions. Records are mapped to created partitions based on the value of the partition key. If a record is successfully mapped to a partition, it is inserted into that specific partition. If mapping is not possible, an error message will be generated. Range partitioning is the most commonly used partitioning policy.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- Hash Partitioning

  A table is partitioned by specifying a modulus and a remainder for each partition. Each partition will hold the rows for which the hash value of the partition key divided by the specified modulus will produce the specified remainder.

  Hash partitioning policy: Records are mapped to created partitions based on the value of the partition key. If a record is successfully mapped to a partition, it is inserted into that specific partition. If mapping is not possible, an error message will be generated.

- List Partitioning

  List partitioning involves partitioning a table by explicitly listing which key values appear in each partition, with no overlap between the key values assigned to different partitions. A partition is created for each group of key values to store corresponding data.

  List partitioning policy: Records are mapped to created partitions based on the value of the partition key. If a record is successfully mapped to a partition, it is inserted into that specific partition. If mapping is not possible, an error message will be generated.

Partitioning can provide several benefits:

- Query performance is improved, particularly when most of the heavily accessed rows of the table are in a single partition or a small number of partitions. Partitioning narrows the range of data search and improves data access efficiency.
- When queries or updates access a large percentage of a single partition, performance can be improved by taking advantage of sequential scan of that partition instead of accessing the whole table.
- If bulk load or DELETE operations are needed on a separate partition, you can directly read or delete data from that partition. It also entirely avoids the VACUUM overload caused by a bulk DELETE. (Hash partitioning does not support partition deletion.)

Precautions

- When a UNIQUE or PRIMARY KEY constraint key includes all partition keys, a local index will be created for the constraint. Otherwise, a global index will be created.
- Currently, hash partitioning supports only single-column partition keys, and does not support multi-column partition keys.
- In the PARTITION FOR (values) syntax for partitioned tables, **values** can only be a constant.
- If data type conversion is required for **values** in the PARTITION FOR (values) syntax for partitioned tables, it is advisable to employ forcible type conversion rather than implicit type conversion, as the latter can result in unexpected outcomes.
- Each table can accommodate a maximum of 1,048,575 partitions and subpartitions in total. It is advisable to keep the number of partitions per table at 400 or less by default. For details, see "Feature Usage Guidelines > Partitioned Table > Introduction to Partitioned Tables > Basic Usage of Partitions > Creating Partitioned Tables" in *Developer Guide*.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- Having too many partitions can lead to insufficient memory, which in turn results in a sharp decrease in performance.
- Data of the XML type cannot be used as partition keys or subpartition keys.
- Foreign key constraints cannot be created on the **rowid** or **rowno** system columns.
- When you perform an UPDATE or DELETE on a partitioned table and the generated plan is not an FQS or Stream plan, the efficiency of statement execution will be suboptimal. You are advised to check statements and eliminate factors that cannot be pushed down to generate FQS or Stream plans.
- If you add a row-level expression when adding or changing an ILM policy for a data object, note that the row-level expression supports only the functions listed in the whitelist. For details about the whitelist function list, see **Row Expression Function Whitelist**.

  NOTE

  Among the functions supported by the row-level expression ON (EXPR) in the ILM policy, the output of some may be influenced by compatibility parameters. For instance, after you set **b_format_version** to **'5.7'** and **b_format_dev_version** to **'s2'** in MySQL-compatible mode, the upper function will be unable to convert data to uppercase as usual.

Syntax

```
CREATE TABLE [ IF NOT EXISTS ] partition_table_name
{ ( [
   { column_name data_type [ CHARACTER SET | CHARSET charset ] [ COLLATE collation ]
[ column_constraint [ ... ] ]
   | table_constraint
   | LIKE source_table [ like_option [...] ] }
   [, ... ]
] )
   | LIKE source_table }
   [ table_option [ ,... ] [ ... ] ]
   [ htap_option ]
   [ WITH ( {storage_parameter = value} [, ... ] ) ]
   [ ILM ADD POLICY ROW STORE COMPRESS
 { ADVANCED [ MEDIUM | HIGH ] ROW AFTER n { day | month | year } OF NO MODIFICATION [ ON
( EXPR )]
 | TURBO [ LOW | MEDIUM | HIGH ] UNIT AFTER n { hour | day | month | year } OF NO MODIFICATION
 | NONE}]
   [ TABLESPACE tablespace_name ]
   [ DISTRIBUTE BY { REPLICATION | HASH ( column_name [, ...] )
   | MURMURHASH ( diskey_expr )
   | RANGE ( column_name [, ...] ) { SLICE REFERENCES tablename | ( slice_less_than_item [, ...] )
   | ( slice_start_end_item [, ...] ) }
   | LIST ( column_name [, ...] ) { SLICE REFERENCES tablename | ( slice_values_item [, ...] ) }
   } ]
   [ TO { GROUP groupname | NODE ( nodename [, ... ] ) } ]
   PARTITION BY {
      {RANGE [COLUMNS] (partition_key) [ PARTITIONS integer ] ( partition_less_than_item [, ... ] )} |
      {RANGE [COLUMNS] (partition_key) [ PARTITIONS integer ] ( partition_start_end_item [, ... ] )} |
      {LIST [COLUMNS] (partition_key) [ PARTITIONS integer ] ( PARTITION partition_name VALUES [IN]
(list_values) [ ILM ADD POLICY ROW STORE COMPRESS { ADVANCED [ MEDIUM | HIGH ] ROW AFTER n
{ day | month | year } OF NO MODIFICATION [ ON ( EXPR )] | TURBO [ LOW | MEDIUM | HIGH ] UNIT
AFTER n { hour | day | month | year } OF NO MODIFICATION | NONE}] [ htap_option ][TABLESPACE [=]
tablespace_name][, ... ])} |
      { HASH (partition_key) [ PARTITIONS integer ] ( PARTITION partition_name [ ILM ADD POLICY ROW
STORE COMPRESS { ADVANCED [ MEDIUM | HIGH ] ROW AFTER n { day | month | year } OF NO
MODIFICATION [ ON ( EXPR )] | TURBO [ LOW | MEDIUM | HIGH ] UNIT AFTER n { hour | day | month |
year } OF NO MODIFICATION | NONE}] [ htap_option ][TABLESPACE [=] tablespace_name][, ... ])}
   } [ { ENABLE | DISABLE } ROW MOVEMENT ];
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **table_option**:

```
{ COMMENT [ = ] 'string' |
  AUTO_INCREMENT [ = ] value |
  [ DEFAULT ] CHARACTER SET | CHARSET [ = ] default_charset |
  [ DEFAULT ] COLLATE [ = ] default_collation }
```

- **htap_option**:

```
{ COLVIEW [ PRIORITY { HIGH | LOW | NONE } ] |
  NOCOLVIEW }
```

- **column_constraint**:

```
[ CONSTRAINT constraint_name ]
{ NOT NULL |
  NULL |
  CHECK ( expression ) |
  AUTO_INCREMENT |
  COMMENT 'string' |
  DEFAULT default_expr |
  ON UPDATE update_expr |
  UNIQUE [KEY] [ index_parameters ] |
  PRIMARY KEY [ index_parameters] }
[ DEFERRABLE | NOT DEFERRABLE ][ INITIALLY DEFERRED | INITIALLY IMMEDIATE ]
```

- **table_constraint**:

```
[ CONSTRAINT constraint_name ]
{ CHECK ( expression ) |
  UNIQUE [ index_name ] [ USING method ] ( { column_name [ ASC | DESC ] } [, ... ] )
[ index_parameters ] |
  PRIMARY KEY ( column_name [, ... ] ) [ index_parameters]}
[ DEFERRABLE | NOT DEFERRABLE ][ INITIALLY DEFERRED | INITIALLY IMMEDIATE ]
{ [ COMMENT 'string' ] [ ... ] }
```

- **like_option**:

```
{ INCLUDING | EXCLUDING } { DEFAULTS | CONSTRAINTS | INDEXES | STORAGE | COMMENTS |
RELOPTIONS | DISTRIBUTION | UPDATE | ILM | ALL }
```

- **index_parameters**:

```
[ WITH ( {storage_parameter = value} [, ... ] ) ]
[ USING INDEX TABLESPACE tablespace_name ]
```

- **partition_less_than_item**:

```
PARTITION partition_name VALUES LESS THAN { ( { partition_value | MAXVALUE }[, ... ] ) |
MAXVALUE } [ ILM ADD POLICY ROW STORE COMPRESS { ADVANCED [ MEDIUM | HIGH ] ROW
AFTER n { day | month | year } OF NO MODIFICATION [ ON ( EXPR )] | TURBO [ LOW | MEDIUM |
HIGH ] UNIT AFTER n { hour | day | month | year } OF NO MODIFICATION | NONE}] [TABLESPACE
tablespace_name]
```

- **partition_start_end_item**:

```
PARTITION partition_name {
      {START(partition_value) END (partition_value) EVERY (interval_value)} |
      {START(partition_value) END ({partition_value | MAXVALUE})} |
      {START(partition_value)} |
      {END({partition_value | MAXVALUE})}
} [ ILM ADD POLICY ROW STORE COMPRESS { ADVANCED [ MEDIUM | HIGH ] ROW AFTER n { day |
month | year } OF NO MODIFICATION [ ON ( EXPR )] | TURBO [ LOW | MEDIUM | HIGH ] UNIT
AFTER n { hour | day | month | year } OF NO MODIFICATION | NONE}] [TABLESPACE
tablespace_name]
```

- **update_expr**:

```
{ CURRENT_TIMESTAMP | LOCALTIMESTAMP | NOW() }
```

Parameters

- **IF NOT EXISTS**

  Specifies how to handle name conflicts with tables.

  If you specify the IF NOT EXISTS keyword and the system detects a table with the same name, it will not issue an error during table creation; instead, it will return a NOTICE indicating that the table already exists.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **partition_table_name**

  Specifies the name of a partitioned table.

  Value range: character strings complying with **Identifier Naming Conventions**.

- **column_name**

  Specifies the name of a column to be created in the new table.

  Value range: character strings complying with **Identifier Naming Conventions**.

- **data_type**

  Specifies the data type of the column.

- **COLLATE collation**

  Assigns a collation to the column (which must be of a collatable data type). If not specified, the default collation is used. You can run the **SELECT * FROM pg_collation;** command to query collations from the pg_collation system catalog. The row starting with **default** in the query result represents the default collation.

- **CONSTRAINT constraint_name**

  Specifies the name of a column constraint or table constraint. The optional CONSTRAINT clause specifies constraints that new or updated rows must satisfy for an INSERT or UPDATE operation to succeed. You can run the **SELECT * FROM pg_collation** command to query collations from the pg_collation system catalog. The row starting with **default** in the query result represents the default collation.

  There are two ways to define constraints:

  – A column constraint is defined as part of a column definition, and it is bound to a particular column. You cannot add a constraint name to the clause AUTO_INCREMENT | COMMENT 'string' | ENCRYPTED WITH (COLUMN_ENCRYPTION_KEY = column_encryption_key, ENCRYPTION_TYPE = encryption_type_value).

  – A table constraint is not tied to a particular column, and it can encompass more than one column.

- **LIKE source_table [like_option ...]**

  Specifies a table, known as the source table, from which the target table automatically inherits all column names, their data types, and NOT NULL constraints.

  The target table and source table are completely decoupled after creation is complete. Changes to the source table will not be applied to the target table, and it is not possible to include data of the target table in scans of the source table.

  – The default expressions of columns are included only when **INCLUDING DEFAULTS** is specified. The default behavior is to exclude the default expressions, causing all columns in the target table to default to **NULL**.

  – The target table always inherits the NOT NULL constraints from the source table. The CHECK constraints are inherited only when **INCLUDING CONSTRAINTS** is specified. Other types of constraints are not inherited. This rule also applies to table constraints and column constraints.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

The system does not merge inherited columns or constraints with those that share the same name. If the same name is specified explicitly or in another LIKE clause, an error is signaled.

- If **INCLUDING UPDATE** is specified, columns in the target table will inherit the **ON UPDATE CURRENT_TIMESTAMP** attribute from the source table. The default behavior is to exclude this attribute.
- If **INCLUDING INDEXES** is specified, indexes on the source table will also be created on the target table. By default, no indexes are created. The tablespace where indexes on the target table are located is the same as that where indexes on the source table are located.
- If **INCLUDING STORAGE** is specified, columns in the target table will inherit **STORAGE** settings from the source table. The default behavior is to exclude **STORAGE** settings.
- If **INCLUDING COMMENTS** is specified, the target table will inherit comments on columns, constraints, and indexes from the source table. The default behavior is to exclude comments.
- If **INCLUDING RELOPTIONS** is specified, the target table will inherit storage parameters (WITH clause) from the source table. The default behavior is to exclude storage parameters.
- If **INCLUDING DISTRIBUTION** is specified, the target table will inherit distribution information (including distribution types and keys) from the source table and will no longer be able to use the DISTRIBUTE BY clause. The default behavior is to exclude distribution information.
- If **INCLUDING ILM** is specified, the target table will inherit ILM policy information from the source table. To also inherit the ILM policy information of partition objects, you will need to specify **INCLUDING PARTITION**.
- **INCLUDING ALL** is a condensed version that encompasses **INCLUDING DEFAULTS**, **INCLUDING UPDATE**, **INCLUDING CONSTRAINTS**, **INCLUDING INDEXES**, **INCLUDING STORAGE**, **INCLUDING COMMENTS**, **INCLUDING RELOPTIONS**, **INCLUDING DISTRIBUTION**, and **INCLUDING ILM**.

NOTICE

- If the source table is a ROWID table and INCLUDING ALL or INCLUDING RELOPTIONS is specified, the new table is also a ROWID table. If only INCLUDING INDEXES is specified, the new table is a non-ROWID table and the **ROWNO** index of the source table is not copied.
- **CREATE TABLE table_name LIKE source_table;** is supported only in MySQL-compatible databases (**sql_compatibility = 'MYSQL'**) where **b_format_version** is **5.7** and **b_format_dev_version** is **s2**.
- In MySQL-compatible databases where **b_format_version** is **5.7** and **b_format_dev_version** is **s2**, the **INCLUDING** and **EXCLUDING** options cannot be specified. The default setup is equivalent to specifying **INCLUDING ALL**.

- **AUTO_INCREMENT [=] value**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Specifies an initial value for an auto-increment column. The value must be a positive number no greater than $2^{127} - 1$.

NOTICE

This clause takes effect only when **sql_compatibility** is set to **'MYSQL'**.

- **COMMENT [=] 'string'**
  - COMMENT [=] 'string: adds a comment on the table.
  - COMMENT 'string' in **column_constraint**: adds a comment on a column.
  - COMMENT 'string' in **table_constraint**: adds a comment on the indexes corresponding to the primary key and unique key.

  For details, see **COMMENT [=] 'string'** in **CREATE TABLE**.
- **CHARACTER SET | CHARSET charset**

  Assigns a character set to the column. If a character set is explicitly specified, the column will use the default collation associated with that character set.
- **COLLATE collation**

  Assigns a collation to the column (which must be of a collatable data type). If not specified, the default collation is used. You can run the **SELECT * FROM pg_collation** command to query collations from the pg_collation system catalog. The row starting with **default** in the query result represents the default collation. MySQL-compatible databases (**sql_compatibility = 'MYSQL'**) also support the utf8mb4_bin, utf8mb4_general_ci, utf8mb4_unicode_ci, binary, gbk_chinese_ci, gbk_bin, gb18030_chinese_ci, and gb18030_bin collations.
- **WITH (storage_parameter [= value] [, ...])**

  Specifies an optional storage parameter for the table or index. See details of parameters below.

  NOTE

  These TDE-related storage parameters are supported: **enable_tde**, **encrypt_algo**, **dek_cipher**, **key_type**, and **cmk_id**.

  For details about the parameters, see **CREATE TABLE**.

  - FILLFACTOR

    Specifies a fillfactor for the table. It is a number between 10 and 100. **100** (complete packing) is the default. When you specify a smaller fillfactor, INSERT operations pack table pages only to the indicated percentage. The remaining space on each page is reserved for updating rows on that page. This gives UPDATE a chance to place the updated copy of a row on the same page as the original, which is more efficient than placing it on a different page. For a table whose entries are never updated, complete filling (fillfactor = 100) is the best choice. However, in heavily updated tables, smaller fillfactors are appropriate.

    Value range: 10–100.
  - ORIENTATION

    Specifies the orientation for storing table data.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Value range: **ROW** (default value), indicating that table data is stored in row orientation.

NOTICE

ORIENTATION cannot be modified.

- STORAGE_TYPE

  Specifies the storage engine type. Once set, this parameter cannot be modified.

  Value range:

  - **USTORE**: The table uses an in-place update storage engine. To prevent space bloat, be sure to enable the **track_counts** and **track_activities** parameters for Ustore tables.
  - **ASTORE**: The table uses an append-only storage engine.

  Default value:

  Subject to the **enable_default_ustore_table** parameter, which defaults to in-place update storage.

- statistic_granularity

  Records the default **partition_mode** when the table analyzes statistics. For details about **partition_mode**, see **PARTITION_MODE** in **ANALYZE | ANALYSE**. This parameter setting does not work for non-partitioned tables.

  Value range: See **PARTITION_MODE** in **ANALYZE | ANALYSE**.

  Default value: **AUTO**.

- autovacuum_enabled

  Specifies whether to enable AUTOVACUUM for the table.

  Value range: **on** and **off**.

  Default value: **on**.

- autovacuum_vacuum_threshold

  (Applicable when AUTOVACUUM is enabled) Specifies the minimum number of updated or deleted tuples needed to trigger a VACUUM in the table. (This parameter applies specifically to Astore tables.)

  Value range: 0–2147483647.

  Default value: consistent with the GUC parameter **autovacuum_vacuum_threshold**.

- autovacuum_analyze_threshold

  (Applicable when AUTOVACUUM is enabled) Specifies the minimum number of inserted, updated, or deleted tuples needed to trigger an ANALYZE in the table.

  Value range: 0–2147483647.

  Default value: consistent with the GUC parameter **autovacuum_analyze_threshold**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- autovacuum_vacuum_scale_factor

  (Applicable when AUTOVACUUM is enabled) Specifies the ratio of inserted, updated, or deleted tuples needed to trigger a VACUUM in the table. (This parameter applies specifically to Astore tables.)

  Value range: 0.0–100.0.

  Default value: consistent with the GUC parameter **autovacuum_vacuum_scale_factor**.

- autovacuum_analyze_scale_factor

  (Applicable when AUTOVACUUM is enabled) Specifies the ratio of inserted, updated, or deleted tuples needed to trigger an ANALYZE in the table.

  Value range: 0.0–100.0.

  Default value: consistent with the GUC parameter **autovacuum_analyze_scale_factor**.

- autovacuum_freeze_min_age

  (Applicable when AUTOVACUUM is enabled) Specifies the minimum age of row versions. Rows older than this age will be frozen.

  Value range: 0–576460752303423487.

  Default value: consistent with the GUC parameter **vacuum_freeze_min_age**.

- autovacuum_freeze_max_age

  (Applicable when AUTOVACUUM is enabled) Specifies the maximum age (in transactions) that the table's **pg_class.relfrozenxid** field can reach before a VACUUM operation is forced. Note that the system will launch AUTOVACUUM processes even when AUTOVACUUM is otherwise disabled. The VACUUM operation also allows removal of old files from the **pg_clog/** subdirectory. (This parameter applies specifically to Astore tables.)

  Value range: 100000–576460752303423487.

  Default value: consistent with the GUC parameter **autovacuum_freeze_max_age**.

- autovacuum_freeze_table_age

  (Applicable when AUTOVACUUM is enabled) Specifies the time when the table will remain unchanged, marked as not requiring AUTOVACUUM. (This parameter applies specifically to Astore tables.)

  Value range: 0–576460752303423487.

  Default value: consistent with the GUC parameter **vacuum_freeze_table_age**.

- vacuum_truncate

  Specifies whether to enable the VACUUM TRUNCATE function of a table to truncate the last empty page during VACUUM.

  Value range: **on** and **off**.

  Default value: **on**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- This parameter is valid only for Astore tables and does not take effect for hash bucket tables and segment tables.
- During the upgrade from a version that does not support this parameter to a version that supports this parameter, this parameter cannot be created or modified during the upgrade observation period.
- The toast.**vacuum_truncate** parameter can be used to independently control whether to truncate the last empty page of a TOAST table.

– hashbucket

Creates a hash bucket table. This parameter supports only row-store tables, including row-store range tables.

Value range: **on** and **off**.

Default value: **off**.

NOTICE

In current version, DDL operations on hash bucket tables are affected. Therefore, you are advised not to frequently perform DDL operations on hash bucket tables.

– hasrowid

Specifies whether the table is a rowid table. If **hasrowid** is set to **on**, the **rowid** and **rowno** system columns are added to the table, and sequences and indexes are created on the **rowno** system column.

Value range: **on** and **off**.

Default value: **off**.

NOTE

- This parameter supports only ORA-compatible databases (that is, **sql_compatibility** is set to **ORA**).
- This parameter does not support local temporary tables, unlogged tables, global temporary tables, materialized views, hash bucket tables, or replication tables.
- This parameter cannot be specified together with **hasuids** and **oids**.
- When this parameter is enabled, the ordinary column name cannot be defined as **rowno** or **rowid**.
- The number of data records in the **rowid** table cannot exceed 9223372036854775807.

– partition_statistics_min_rows

Specifies the minimum number of rows to be sampled at the partition level when the ANALYZE statement is executed on a partitioned table.

Value range: [0,10000]

Default value: **50**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- This parameter is valid only for partitioned tables.
- This parameter is valid only when **PARTITION_MODE** in the ANALYZE statement is set to **ALL** and the GUC parameter **enable_partition_statistics_min_rows** is enabled. For details about **PARTITION_MODE**, see **PARTITION_MODE** in **ANALYZE | ANALYSE**.
- Upper limit: The number of rows sampled from the entire partitioned table cannot exceed the number of rows allowed by the GUC parameter **maintenance_work_mem**.

- **[ILM ADD POLICY ROW STORE COMPRESS { ADVANCED [MEDIUM | HIGH] ROW AFTER n { day | month | year } OF NO MODIFICATION [ON (EXPR)] | TURBO [LOW | MEDIUM | HIGH] UNIT AFTER n { hour | day | month | year } OF NO MODIFICATION | NONE}]**
  - When creating a table, you can call ILM ADD POLICY ROW STORE COMPRESS ADVANCED [MEDIUM | HIGH] ROW to add a medium- or high-level advanced compression policy for row store. A policy can be separately specified for a partition. If no policy is specified, partitions inherit the policy of the table.
    - AFTER n { day | month | year } OF NO MODIFICATION: rows that have not been modified for *n* days, months, or years. Advanced compression does not support **hour**.
    - ON (EXPR): a row-level expression used to determine whether a row is hot or cold.

    NOTE

    - Among the functions supported by the row-level expression ON (EXPR) in the ILM policy, the output of some may be influenced by compatibility parameters. For instance, after you set **b_format_version** to **'5.7'** and **b_format_dev_version** to **'s2'** in MySQL-compatible mode, the upper function will be unable to convert data to uppercase as usual.
    - The compression level is optional. If not specified, the MEDIUM level will be used by default.
  - When creating a row-store table, you can call ILM ADD POLICY ROW STORE COMPRESS TURBO HIGH UNIT to add a cross-page transparent compression policy. Subpartitions will inherit this policy from partitions.

    AFTER n { hour | day | month | year } OF NO MODIFICATION indicates that rows have not been modified for *n* hours, days, months, or years.

    If the compression level is not specified, the MEDIUM level is used by default.
  - When creating a row-store table, you can call ILM ADD POLICY ROW STORE COMPRESS NONE to explicitly specify that no cross-page transparent compression policy needs to be added.
- **TABLESPACE tablespace_name**

  Specifies the name of the tablespace where the table is to be created. If not specified, the default tablespace will be used.
- **DISTRIBUTE BY**

  Specifies how the table is distributed or replicated between nodes.

  For details, see **DISTRIBUTE BY** in **CREATE TABLE**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **TO { GROUP groupname | NODE (nodename [, ...]) }**

  Specifies the node group for which the table is to be created. **TO NODE** is intended only for use by internal scale-out tools and is not recommended for direct use by users.

- **PARTITION BY RANGE [COLUMNS] (partition_key)**

  Creates a range partition. **partition_key** indicates the name of the partition key.

  NOTE

  The COLUMNS keyword is available only when **sql_compatibility** is **'MYSQL'**. PARTITION BY RANGE COLUMNS is semantically equivalent to PARTITION BY RANGE.

  – If the VALUES LESS THAN clause is present in the syntax:

    The range partitioning policy permits using up to 16 columns as the partition key.

    The partition key accepts the following data types:

    - Integer types: TINYINT, SMALLINT, INTEGER, BIGINT, DECIMAL, and NUMERIC
    - Float types: REAL, FLOAT4, FLOAT8, and DOUBLE PRECISION
    - Character types: CHARACTER VARYING, VARCHAR, CHARACTER, CHAR, BPCHAR, TEXT, NVARCHAR2, and NAME
    - Date/Time types: TIMESTAMP[(p)] [WITHOUT TIME ZONE], TIMESTAMP[(p)] [WITH TIME ZONE], YEAR, DATE, and DATEA (valid only in ORA-compatible mode)

  – If the START END clause is present in the syntax:

    The range partitioning policy only permits using a single column as the partition key.

    The partition key accepts the following data types:

    - Integer types: TINYINT, SMALLINT, INTEGER, BIGINT, DECIMAL, and NUMERIC
    - Float types: REAL, FLOAT4, FLOAT8, and DOUBLE PRECISION
    - Date/Time types: TIMESTAMP[(p)] [WITHOUT TIME ZONE], DATE, and DATEA (valid only in ORA-compatible mode)

- **PARTITION partition_name VALUES LESS THAN {({ partition_value | MAXVALUE } [,...]) | MAXVALUE }**

  Specifies the partition information. **partition_name** indicates the name of a range partition. **partition_value** indicates the upper limit of the range partition. The limit varies depending on the type of **partition_key**. **MAXVALUE** indicates the maximum value, which is typically the upper limit of the last range partition.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTICE

- Each partition requires an upper limit.
- The data type of the upper limit must be the same as that of the partition key.
- In a partition list, partitions are arranged in ascending order of upper limits. A partition with a smaller upper limit is placed before another partition with a larger one.
- MAXVALUE that is not in parentheses can be used only when **sql_compatibility** is set to **'MYSQL'** and can have only one partition key.

- **PARTITION partition_name {START (partition_value) END (partition_value) EVERY (interval_value)} | {START (partition_value) END (partition_value|MAXVALUE)} | {START(partition_value)} | {END (partition_value | MAXVALUE)}**

  Specifies the partition information, including:

  - **partition_name**: name or prefix of the range partition. It specifies the partition name, except in the following cases (assuming **partition_name** is **p1**):

    - If this definition is a START+END+EVERY clause, it semantically defines partition names as **p1_1**, **p1_2**, and so forth. For example, using **PARTITION p1 START(1) END(4) EVERY(1)** will generate partitions [1, 2), [2, 3), and [3, 4), named **p1_1**, **p1_2**, and **p1_3**, respectively. Here, **p1** acts as a name prefix.

    - If this is the first partition definition and it includes a **START** value, the (**MINVALUE**, **START**) range will be treated as the first partition, named **p1_0**. Subsequent partitions will be named **p1_1**, **p1_2**, and so forth. For example, using **PARTITION p1 START(1), PARTITION p2 START(2)** will generate partitions (**MINVALUE**, 1), [1, 2), and [2, **MAXVALUE**), named **p1_0**, **p1_1**, and **p2**, respectively. Here, **p1** acts as a name prefix, and **p2** is a partition name. **MINVALUE** indicates the minimum value.

  - **partition_value**: endpoint value (start or end) of the range partition. The value depends on the type of **partition_key** and must not be equal to **MAXVALUE**.
  - **interval_value**: width of each partition generated within the [**START**, **END**) range. It must not be equal to **MAXVALUE**. If the difference between **END** and **START** is not divisible by **EVERY**, only the width of the last partition will be less than **EVERY**.
  - **MAXVALUE**: maximum upper limit, which is typically the upper limit of the last range partition.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTICE

1. During the creation of a partitioned table, if the first partition definition includes a **START** value, the (**MINVALUE**, **START**) range will be treated as the first partition.
2. The START END syntax must comply with the following rules:
   - Given a specific **partition_start_end_item**, the value of **START** (if specified) must be less than the value of **END**.
   - Given two consecutive **partition_start_end_item** instances, the value of the first **END** must be equal to the value of the second **START**.
   - For **partition_start_end_item**, the value of **EVERY** must increment in a positive direction and be less than **END** – **START**.
   - Each partition includes its start value but excludes its end value, following the format [**START**, **END**). If the start value is **MINVALUE**, it will also be excluded.
   - Partitions created by the same **partition_start_end_item** belong to the same tablespace.
   - When **partition_name** serves as the prefix of partition names, its length must not exceed 57 bytes; otherwise, it will be automatically truncated.
   - When creating or modifying partitioned tables, keep in mind that the total number of partitions in the tables must not exceed the maximum limit of 1,048,575.
3. Do not mix the START END and LESS THAN syntaxes when creating partitioned tables.
4. Even if a partitioned table is created with the START END syntax, the SQL statement backed up (by gs_dump) will still use the VALUES LESS THAN syntax.

- **PARTITION BY LIST [COLUMNS] (partition_key)**

  Creates a list partition, with **partition_key** indicating the name of the partition key.

  The COLUMNS keyword can be used only when **sql_compatibility** is set to **'MYSQL'**. The semantics of PARTITION BY LIST COLUMNS is the same as that of PARTITION BY LIST.

  – The list partitioning policy allows up to 16 columns as **partition_key**.
  – In the presence of the VALUES [IN] (list_values) clause, **list_values** contains the key values of partitions. Each partition can have a maximum of 64 key values.
  – Semantically equivalent to VALUES, the VALUES IN clause is available only when **sql_compatibility** is **'MYSQL'**.

  The partition key accepts the following data types:

  – Integer types: TINYINT, SMALLINT, INTEGER, BIGINT, and NUMERIC
  – Character types: VARCHAR, CHAR, BPCHAR, and NVARCHAR2
  – Date/Time types: TIMESTAMP[(p)] [WITHOUT TIME ZONE], TIMESTAMP[(p)] [WITH TIME ZONE], YEAR, DATE, and DATEA (valid only in ORA-compatible mode)

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

The number of partitions cannot exceed 1,048,575.

- **PARTITION BY HASH(partition_key)**

  Creates a hash partition, with **partition_key** indicating the name of the partition key.

  The hash partitioning policy only permits using a single column as **partition_key**.

  The partition key accepts the following data types:

  – Integer types: TINYINT, SMALLINT, INTEGER, BIGINT, and NUMERIC

  – Character types: VARCHAR, CHAR, BPCHAR, TEXT, and NVARCHAR2

  – Date/Time types: TIME, TIMESTAMP[(p)] [WITHOUT TIME ZONE], TIMESTAMP[(p)] [WITH TIME ZONE], YEAR, DATE, DATEA (valid only in ORA mode)

  The number of partitions cannot exceed 1,048,575.

- **PARTITIONS integer**

  Specifies the number of partitions.

  integer must be an integer within (0,1048575].

  – When this clause is specified after range or list partitions, each partition must be explicitly defined, and the number of defined partitions must be equal to **integer**. This clause can be specified only when **sql_compatibility** is **'MYSQL'**, and it must come after range or list partitions.

  – When this clause is specified after hash/key partitions, the following scenarios may occur: If you do not list the definition of each partition, the system will automatically generate *integer* partitions, named in **p**+*number* format, where *number* ranges from 0 to (**integer** – 1). These partitions will be placed within the tablespace of the table by default. If you explicitly list the partition definitions, the number of defined partitions must be equal to **integer**. If you neither list the partition definitions nor specify the number of partitions, the system will create only one partition.

- **{ ENABLE | DISABLE } ROW MOVEMENT**

  Specifies whether to enable row movement.

  If an UPDATE operation changes the value of a tuple on the partition key, causing the tuple to move to a different partition, an error will occur based on the setting you have chosen, or the tuple will be transferred between partitions.

  Value range:

  – **ENABLE**: Row movement is enabled.

  – **DISABLE** (default): Row movement is disabled.

  If row movement is enabled, concurrent UPDATE and DELETE operations may result in an error. Possible causes include:

  Both UPDATE and DELETE operations mark old data as deleted. In addition, if changing the partition key leads to cross-partition updates, the kernel will mark the old data in the original partition as deleted and generate a new record in a different partition, making it impossible to locate the new data based on the old data.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

If concurrent UPDATE+UPDATE, DELETE+DELETE, or UPDATE+DELETE operations are performed on the same row, the behavior differs based on whether the data is distributed across partitions.

a. When data is not distributed across partitions, performing the second operation after the first operation will not result in an error.

   If the first operation is UPDATE, the most recent data can be found and accessed during the second operation.

   If the first operation is DELETE, the system will terminate the second operation because it detects that the current data has been deleted but cannot match it with the most recent data.

b. When data is distributed across partitions, performing the second operation after the first operation will result in an error.

   If the first operation is UPDATE, the system will report an error during the second operation because it cannot find the most recent data, which is stored in a different partition.

   If the first operation is DELETE, the system can detect that the current data has been deleted during the second operation, but cannot match it with the most recent data or determine whether the data was deleted by an UPDATE or DELETE operation. If the operation is UPDATE, an error is reported. If the operation is DELETE, the operation is terminated. However, to ensure data correctness, it can only report an error.

In UPDATE+UPDATE and UPDATE+DELETE concurrency scenarios, you can solve the problem by performing these operations sequentially. In the DELETE +DELETE concurrency scenario, you can solve the problem by disabling row movement.

- **NOT NULL**

  Forbids NULL values in columns. **ENABLE** is provided solely for syntax compatibility and can be omitted.

- **NULL**

  Allows NULL values in columns. This is the default.

  This clause is provided solely for compatibility with non-standard SQL databases and is not recommended for use.

- **CHECK (condition) [NO INHERIT]**

  Specifies an expression producing a Boolean result which new or updated rows must satisfy for an INSERT or UPDATE operation to succeed. Expressions evaluating to TRUE or UNKNOWN succeed. Otherwise, an error exception is raised, and the INSERT or UPDATE does not alter the database.

  A CHECK constraint specified as a column constraint should reference that column's value only, while an expression appearing in a table constraint can reference multiple columns.

  A constraint marked with **NO INHERIT** will not propagate to child tables.

  ENABLE is provided solely for syntax compatibility and can be omitted.

- **DEFAULT default_expr**

  Assigns a default value to a column. The value can be any variable-free expression (in particular, subqueries and cross-references to other columns in the current table are not allowed). The data type of the default expression must match the data type of the column.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

The default expression can be used in any INSERT operation that does not specify a value for the column. If no default value is specified, **NULL** will be used.

- **ON UPDATE update_expr**

  Specifies an attribute constraint for the column.

  During an UPDATE operation on a tuple in a table, if the new values of the updated columns differ from the old values, columns (in the tuple) that have this attribute but are not part of the UPDATE will be automatically updated to the current timestamp. However, if the new values of the updated columns are the same as the old values, those columns will remain unchanged. If columns with this attribute are included in the UPDATE, their values will be updated to the specified value.

  NOTE

  - This attribute can be specified only in MySQL-compatible databases version 5.7 (**sql_compatibility = 'MYSQL'**, **b_format_version='5.7'**, and **b_format_dev_version='s1'**).
  - In terms of syntax, **update_expr** supports three keywords: CURRENT_TIMESTAMP, LOCALTIMESTAMP, and NOW(). You can also optionally specify the precision of a keyword with parentheses. For example, ON UPDATE CURRENT_TIMESTAMP(), ON UPDATE CURRENT_TIMESTAMP(5), ON UPDATE LOCALTIMESTAMP(), and ON UPDATE LOCALTIMESTAMP(6). If the keyword does not contain parentheses or contains empty parentheses, the precision is 0. The NOW keyword cannot contain parentheses. The three types of keywords are synonyms of each other and have the same attribute effect.
  - This attribute can be specified only for columns of the following types: timestamp, datetime, date, time without time zone, smalldatetime, and abstime.
  - If the CREATE TABLE AS syntax is used, the column attributes will not be inherited.
  - The CREATE TABLE LIKE syntax can use **INCLUDING UPDATE** or **EXCLUDING UPDATE** to inherit or exclude a constraint. The **INCLUDING ILM** option is added to copy ILM policy information from the source table. When combined with the **INCLUDING PARTITION** option, it can also copy the policy information of partition objects from the source table.
  - The precision specified by this attribute can be different from the precision specified by the type in the corresponding column. After the column value is updated through this attribute, the minimum precision is displayed. For example, **CREATE TABLE t1 (col1 timestamp(6) ON UPDATE CURRENT_TIMESTAMP(3));**. If the UPDATE syntax triggers the attribute to take effect, three decimal places in the value of **col1** are displayed after the update.
  - The same column cannot be specified for this attribute and the generated column constraint at the same time.
  - This attribute cannot be specified for the partition key in a partitioned table.
  - In distributed scenarios, this attribute cannot be specified for distribution keys or the primary key.

- **AUTO_INCREMENT**

  Marks a column as auto-increment.

  For details, see **AUTO_INCREMENT** in **CREATE TABLE**.

- **UNIQUE [KEY] index_parameters**

  UNIQUE (column_name [, ...]) index_parameters

  Specifies that a column or a combination of columns must be unique across the entire table.

  For the purpose of a UNIQUE constraint, NULL is not considered equal.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Semantically equivalent to UNIQUE, UNIQUE KEY is available only in MySQL-compatible databases (**sql_compatibility = 'MYSQL'**).

- **PRIMARY KEY index_parameters**

  PRIMARY KEY (column_name [, ...]) index_parameters

  Specifies that one or more columns in the table require unique, non-NULL values.

  Only one primary key can be specified for a table.

- **DEFERRABLE | NOT DEFERRABLE**

  Specifies whether the constraint can be deferred. A constraint that is not deferrable will be checked immediately after every command. Checking of constraints that are deferrable can be postponed until the end of the transaction (using the **SET CONSTRAINTS** command). **NOT DEFERRABLE** is the default. Currently, only the UNIQUE and PRIMARY KEY constraints accept this clause. (That is, other constraints are not deferrable.)

- **INITIALLY IMMEDIATE | INITIALLY DEFERRED**

  Specifies the default time to check the constraint if it is deferrable. A constraint that is not deferrable is always **INITIALLY IMMEDIATE** and cannot be declared as **INITIALLY DEFERRED**.

  – If the constraint is **INITIALLY IMMEDIATE**, it is checked after each statement. This is the default.

  – If the constraint is **INITIALLY DEFERRED**, it is checked only at the end of the transaction.

  The constraint check time can be altered with the **SET CONSTRAINTS** command.

- **USING INDEX TABLESPACE tablespace_name**

  Specifies a tablespace in which an index associated with a UNIQUE or PRIMARY KEY constraint will be created. If this clause is not specified, the index will be created in the default tablespace named **default_tablespace**. If **default_tablespace** is empty, the default tablespace of the database will be consulted.

Range Partitioning

- VALUES LESS THAN

```
-- Create a tablespace.

Helpful Links

ALTER TABLE PARTITION and **DROP TABLE**

1.13.9.48 CREATE TABLE PARTITION | SUBPARTITION AS

Description

Creates a partitioned table from the results of a query.

CREATE TABLE PARTITION | SUBPARTITION AS creates a partitioned table, fills it with the result of a **SELECT** command, and partitions data based on the specified

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

partitioning policy. The table columns have the names and data types associated with the output columns of the **SELECT** (except that you can override the column names by giving an explicit list of new column names).

Syntax

- Use CREATE TABLE PARTITION AS to create a partitioned table and fill it with data from a subquery.

```
CREATE TABLE [ IF NOT EXISTS ] partition_table_name
    [ (column_name [, ...] ) ]
    [ { ENGINE [ = ] { InnoDB | 'InnoDB' | "InnoDB" } } [ ,... ] [ ... ] ]
    [ WITH ( {storage_parameter = value} [, ... ] ) ]
    [ ILM ADD POLICY ROW STORE COMPRESS
 { ADVANCED [ MEDIUM | HIGH ] ROW AFTER n { day | month | year } OF NO MODIFICATION [ ON
( EXPR )]
 | TURBO [ LOW | MEDIUM | HIGH ] UNIT AFTER n { hour | day | month | year } OF NO
MODIFICATION
 | NONE}]
    [ TABLESPACE tablespace_name ]
    [ DISTRIBUTE BY { REPLICATION | { [HASH ] ( column_name ) } } ]
    [ TO { GROUP groupname | NODE ( nodename [, ... ] ) } ]
    PARTITION BY partition_clause partition_definition_list
    AS query
    [ WITH [ NO ] DATA ];
```

- Use CREATE TABLE SUBPARTITION AS to create a subpartitioned table and fill it with data from a subquery.

```
CREATE TABLE [ IF NOT EXISTS ] partition_table_name
    [ (column_name [, ...] ) ]
    [ { ENGINE [ = ] { InnoDB | 'InnoDB' | "InnoDB" } } [ ,... ] [ ... ] ]
    [ WITH ( {storage_parameter = value} [, ... ] ) ]
    [ ILM ADD POLICY ROW STORE COMPRESS
 { ADVANCED [ MEDIUM | HIGH ] ROW AFTER n { day | month | year } OF NO MODIFICATION [ ON
( EXPR )]
 | TURBO [ LOW | MEDIUM | HIGH ] UNIT AFTER n { hour | day | month | year } OF NO
MODIFICATION
 | NONE}]
    [ TABLESPACE tablespace_name ]
     PARTITION BY partition_clause
     SUBPARTITION BY subpartition_clause
     partition_subpartition_definition_list
    AS query
    [ WITH [ NO ] DATA ];
```

For details about each column, see **Syntax**.

Parameters

- **IF NOT EXISTS**

  Specifies how to handle name conflicts with relations.

  When the IF NOT EXISTS keyword is specified, the system checks the current schema for any relation with the same name as the table you intend to create. If it finds such a relation, the table creation process will be halted, and a NOTICE will be returned. When IF NOT EXISTS is not specified and a relation with the same name is present in the schema, an ERROR will be returned.

- **partition_table_name**

  Specifies the name of the partitioned table to be created.

  Value range: character strings complying with **Identifier Naming Conventions**.

- **column_name**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

(Optional) Specifies the name of a column to be created in the new table. If no column name is specified, the columns in the new table are the same as those entered in the SELECT statement.

Value range: character strings complying with **Identifier Naming Conventions**.

- **ENGINE**

  This parameter is supported in MySQL-compatible mode and is used solely for syntax adaptation. It is limited to InnoDB, but no actual impact has been noted.

- **WITH (storage_parameter [= value] [, ...])**

  Specifies an optional storage parameter for the table or an index. See details of parameters below.

  NOTE

  These TDE-related storage parameters are supported: **enable_tde**, **encrypt_algo**, **dek_cipher**, **key_type**, and **cmk_id**.

  For details about the parameters, see **CREATE TABLE**.

  – FILLFACTOR

    Specifies a fillfactor for the table. It is a percentage between 10 and 100. **100** (complete packing) is the default. In the case of Ustore, the default is **92**. When a smaller fillfactor is specified, INSERT operations pack table pages only to the indicated percentage; the remaining space on each page is reserved for updating rows on that page. This gives UPDATE a chance to place the updated copy of a row on the same page as the original, which is more efficient than placing it on a different page. For a table whose entries are never updated, complete packing (fillfactor = 100) is the best choice. However, in heavily updated tables, smaller fillfactors are appropriate. The parameter takes effect only on row-store tables.

    Value range: 10–100.

  – ORIENTATION

    Value range: **ROW**, indicating that table data is stored in row orientation.

    Default value: **ROW**.

  – autovacuum_enabled

    Specifies whether to enable AUTOVACUUM for the table.

    Value range: **on** and **off**.

    Default value: **on**.

  – autovacuum_vacuum_threshold

    (Applicable when AUTOVACUUM is enabled) Specifies the minimum number of updated or deleted tuples needed to trigger a VACUUM in the table. (This parameter applies specifically to Astore tables.)

    Value range: 0–2147483647.

    Default value: consistent with the GUC parameter **autovacuum_vacuum_threshold** unless otherwise specified.

  – autovacuum_analyze_threshold

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

(Applicable when AUTOVACUUM is enabled) Specifies the minimum number of inserted, updated, or deleted tuples needed to trigger an ANALYZE in the table.

Value range: 0–2147483647.

Default value: consistent with the GUC parameter **autovacuum_analyze_threshold** unless otherwise specified.

- autovacuum_vacuum_scale_factor

  (Applicable when AUTOVACUUM is enabled) Specifies the ratio of inserted, updated, or deleted tuples needed to trigger a VACUUM in the table. (This parameter applies specifically to Astore tables.)

  Value range: 0.0–100.0.

  Default value: consistent with the GUC parameter **autovacuum_vacuum_scale_factor** unless otherwise specified.

- autovacuum_analyze_scale_factor

  (Applicable when AUTOVACUUM is enabled) Specifies the ratio of inserted, updated, or deleted tuples needed to trigger an ANALYZE in the table.

  Value range: 0.0–100.0.

  Default value: consistent with the GUC parameter **autovacuum_analyze_scale_factor** unless otherwise specified.

- autovacuum_freeze_min_age

  (Applicable when AUTOVACUUM is enabled) Specifies the minimum range of row versions. Rows beyond this range will be frozen.

  Value range: 0–576460752303423487.

  Default value: consistent with the GUC parameter **vacuum_freeze_min_age** unless otherwise specified.

- autovacuum_freeze_max_age

  (Applicable when AUTOVACUUM is enabled) Specifies the maximum age (in transactions) that the table's **pg_class.relfrozenxid** field can reach before a VACUUM operation is forced. Note that the system will launch AUTOVACUUM processes even when AUTOVACUUM is otherwise disabled. The VACUUM operation also allows removal of old files from the **pg_clog/** subdirectory. (This parameter applies specifically to Astore tables.)

  Value range: 100000–576460752303423487.

  Default value: consistent with the GUC parameter **autovacuum_freeze_max_age** unless otherwise specified.

- autovacuum_freeze_table_age

  (Applicable when AUTOVACUUM is enabled) Specifies the time when the table will remain unchanged, marked as not requiring AUTOVACUUM. (This parameter applies specifically to Astore tables.)

  Value range: 0–576460752303423487.

  Default value: consistent with the GUC parameter **vacuum_freeze_table_age** unless otherwise specified.

- vacuum_truncate

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Specifies whether to enable the VACUUM TRUNCATE function of a table to truncate the last empty page during VACUUM.

Value range: **on** and **off**.

Default value: **on**.

NOTE

- This parameter is valid only for Astore tables and does not take effect for hash bucket tables and segment tables.
- During the upgrade from a version that does not support this parameter to a version that supports this parameter, this parameter cannot be created or modified during the upgrade observation period.
- The toast.**vacuum_truncate** parameter can be used to independently control whether to truncate the last empty page of a TOAST table.

– hashbucket

Creates a hash bucket table. This parameter supports only row-store tables, including row-store range tables.

Value range: **on** and **off**.

Default value: **off**.

NOTICE

In current version, DDL operations on hash bucket tables are affected. Therefore, you are advised not to frequently perform DDL operations on hash bucket tables.

– hasrowid

Specifies whether the table is a rowid table. If **hasrowid** is set to **on**, the **rowid** and **rowno** system columns are added to the table, and sequences and indexes are created on the **rowno** system column.

Value range: **on** and **off**.

Default value: **off**.

NOTE

- This parameter supports only ORA-compatible databases (that is, **sql_compatibility** is set to **ORA**).
- This parameter does not support local temporary tables, unlogged tables, global temporary tables, materialized views, hash bucket tables, or replication tables.
- This parameter cannot be specified together with **hasuids** and **oids**.
- When this parameter is enabled, the ordinary column name cannot be defined as **rowno** or **rowid**.
- The number of data records in the **rowid** table cannot exceed 9223372036854775807.

– partition_statistics_min_rows

Specifies the minimum number of rows to be sampled at the partition level when the ANALYZE statement is executed on a partitioned table.

Value range: [0,10000]

Default value: **50**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- This parameter is valid only for partitioned tables.
- This parameter is valid only when **PARTITION_MODE** in the ANALYZE statement is set to **ALL** and the GUC parameter **enable_partition_statistics_min_rows** is enabled. For details about **PARTITION_MODE**, see **PARTITION_MODE** in **ANALYZE | ANALYSE**.
- Upper limit: The number of rows sampled from the entire partitioned table cannot exceed the number of rows allowed by the GUC parameter **maintenance_work_mem**.

- **ILM ADD POLICY ROW STORE COMPRESS { ADVANCED [MEDIUM | HIGH] ROW AFTER n { day | month | year } OF NO MODIFICATION [ON (EXPR)] | TURBO [LOW | MEDIUM | HIGH] UNIT AFTER n { hour | day | month | year } OF NO MODIFICATION | NONE}**
  - When creating a row-store table, you can call ILM ADD POLICY ROW STORE COMPRESS ADVANCED [MEDIUM | HIGH] ROW to add a medium- or high-level advanced compression policy.
    - AFTER n { day | month | year } OF NO MODIFICATION: rows that have not been modified for *n* days, months, or years. Advanced compression does not support **hour**.
    - ON (EXPR): a row-level expression used to determine whether a row is hot or cold.

      NOTE

      - Among the functions supported by the row-level expression ON (EXPR) in the ILM policy, the output of some may be influenced by compatibility parameters. For instance, after you set **b_format_version** to **'5.7'** and **b_format_dev_version** to **'s2'** in MySQL-compatible mode, the upper function will be unable to convert data to uppercase as usual.
      - The compression level is optional. If not specified, the MEDIUM level will be used by default.
  - When creating a row-store table, you can call ILM ADD POLICY ROW STORE COMPRESS TURBO HIGH UNIT to add a cross-page transparent compression policy. Subpartitions will inherit this policy from partitions.

    AFTER n { hour | day | month | year } OF NO MODIFICATION: rows that have not been modified for *n* hours, days, months, or years.

    If the compression level is not specified, the MEDIUM level is used by default.
  - When creating a row-store table, you can call ILM ADD POLICY ROW STORE COMPRESS NONE to explicitly specify that no cross-page transparent compression policy needs to be added.
- **TABLESPACE tablespace_name**

  Specifies the name of the tablespace where the table is to be created. If not specified, the default tablespace will be used.
- **DISTRIBUTE BY**

  For details, see **DISTRIBUTE BY** in **CREATE TABLE**.
- **TO { GROUP groupname | NODE (nodename [, ...]) }**

  Specifies the node group for which the table is to be created.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

This syntax is intended only for use by internal scale-out tools and is not recommended for direct use by users.

- **PARTITION BY**

  For details about the columns of partition_clause and partition_definition_list, see **Parameters**.

- **AS query**

  Specifies a **SELECT** or **VALUES** command, or an **EXECUTE** command that runs a prepared **SELECT** or **VALUES** query.

- **[WITH [NO] DATA]**

  Specifies whether to insert the queried data into the partitioned table being created. By default, the data is inserted. If you specify **NO**, the data will not be inserted.

Examples

- Create a partitioned table and fill it with data from a subquery.

```
-- Create source table t1 and insert three data records.
gaussdb=# CREATE TABLE t1(a int, b int) DISTRIBUTE BY HASH(a);

CREATE TABLE AS, **CREATE TABLE PARTITION**, and **CREATE TABLE SUBPARTITION**

1.13.9.49 CREATE TABLE SUBPARTITION

Description

Creates a subpartitioned table. Partitioning refers to splitting what is logically one large table into smaller physical pieces based on specific schemes. The initial table is known as a partitioned table, and the resulting pieces are called partitions. The partitioned table is a logical table, meaning it does not store data; instead, data is stored within these partitions. For any given subpartitioned table, the top-level node table and partitions are logical tables and do not store data. Only subpartitions (leaf nodes) store data.

The partitioning solution of a subpartitioned table is a combination of the partitioning solutions of two partitions. For details about the partitioning solution of a partitioned table, see **CREATE TABLE PARTITION**.

Common combination solutions for subpartitioned tables include range-range partitioning, range-list partitioning, range-hash partitioning, list-range partitioning, list-list partitioning, list-hash partitioning, hash-range partitioning, hash-list partitioning, and hash-hash partitioning. Currently, subpartitions are applicable only to row-store tables.

Precautions

- A subpartitioned table has two partition keys. A range/list partition key supports only 16 columns, and a hash partition key supports only one column.
- When a UNIQUE or PRIMARY KEY constraint key includes all partition keys, a local index will be created for the constraint. Otherwise, a global index will be created. If a local unique index is created, all partition keys must be included.
- If a subpartitioned table is created without explicitly specifying a subpartition within the corresponding partition, a subpartition with the same range will be created automatically.
- Each table can accommodate a maximum of 1,048,575 partitions and subpartitions in total. It is advisable to keep the number of partitions per table at 400 or less by default. For details, see "Feature Usage Guidelines >

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Partitioned Table > Introduction to Partitioned Tables > Basic Usage of Partitions > Creating Partitioned Tables" in *Developer Guide*.

- Subpartitioned tables support only row store and do not support hash bucket.
- Foreign key constraints cannot be created on the **rowid** or **rowno** system columns.
- Clusters are not supported.
- When executing a query on a specified partition, such as **SELECT * FROM** *table name* **PARTITION/SUBPARTITION** *(partition name)*, be sure to spell the keywords PARTITION and SUBPARTITION correctly. If they are misspelled, the query will not trigger an error. Instead, it will proceed with the corresponding alias rather than the specified partition.
- Encrypted databases, ledger databases, and row-level security are not supported.
- In the PARTITION/SUBPARTITION FOR (VALUES) syntax for subpartitioned tables, **VALUES** can only be a constant.
- If data type conversion is required for **VALUES** in the PARTITION/SUBPARTITION FOR (VALUES) syntax for subpartitioned tables, it is advisable to employ forcible type conversion rather than implicit type conversion, as the latter can result in unexpected outcomes.
- When creating a subpartitioned table, you can define partitions with VALUES LESS THAN (val1_1) under the range policy, or with VALUES (val1[, …]) under the list policy. The hash policy, on the other hand, does not involve defining VALUES.
- If you add or modify an ILM policy for a data object and include a row-level expression, you must use only the whitelisted functions (in **Row Expression Function Whitelist**) as the expression.

  NOTE

  Among the functions supported by the row-level expression ON (EXPR) in the ILM policy, the output of some may be influenced by compatibility parameters. For instance, after you set **b_format_version** to **'5.7'** and **b_format_dev_version** to **'s2'** in MySQL-compatible mode, the upper function will be unable to convert data to uppercase as usual.

Syntax

```
CREATE TABLE [ IF NOT EXISTS ] subpartition_table_name
{(
{ column_name data_type [ CHARACTER SET | CHARSET charset ] [ COLLATE collation ]
[ column_constraint [ ... ] ]
    | table_constraint
    | LIKE source_table [ like_option [...] ] }[, ... ]
)
    | LIKE source_table }
    [ table_option [ ,... ] [ ... ] ]
    [ WITH ( {storage_parameter = value} [, ... ] ) ]
    [ ILM ADD POLICY ROW STORE COMPRESS
 { ADVANCED [ MEDIUM | HIGH ] ROW AFTER n { day | month | year } OF NO MODIFICATION [ ON
( EXPR )]
 | TURBO [ LOW | MEDIUM | HIGH ] UNIT AFTER n { hour | day | month | year } OF NO MODIFICATION
 | NONE}][ htap_option ]
    [ TABLESPACE tablespace_name ]
    PARTITION BY {RANGE [ COLUMNS ] | LIST [ COLUMNS ] | HASH | KEY} (partition_keys) [ PARTITIONS
integer ]
    SUBPARTITION BY {RANGE | LIST | HASH | KEY} (subpartition_keys) [ SUBPARTITIONS integer ]
    (
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
    PARTITION partition_name1 [ VALUES LESS THAN { (val1 | MAXVALUE) | MAXVALUE } | VALUES [ IN ]
(val1[, ...]) ]
[ ILM ADD POLICY ROW STORE COMPRESS
 { ADVANCED [ MEDIUM | HIGH ] ROW AFTER n { day | month | year } OF NO MODIFICATION [ ON
( EXPR )]
 | TURBO [ LOW | MEDIUM | HIGH ] UNIT AFTER n { hour | day | month | year } OF NO MODIFICATION
 | NONE}][ htap_option ]
[ TABLESPACE [=] tablespace ]
    [(
      { SUBPARTITION subpartition_name1 [ VALUES LESS THAN (val1_1) | VALUES (val1_1[, ...])]
[ ILM ADD POLICY ROW STORE COMPRESS
 { ADVANCED [ MEDIUM | HIGH ] ROW AFTER n { day | month | year } OF NO MODIFICATION [ ON
( EXPR )]
 | TURBO [ LOW | MEDIUM | HIGH ] UNIT AFTER n { hour | day | month | year } OF NO MODIFICATION
 | NONE}][ htap_option ]
[ TABLESPACE [=] tablespace ] } [, ...]
)][, ...]
)[ { ENABLE | DISABLE } ROW MOVEMENT ];
```

- **table_option**:

  ```
  { COMMENT [ = ] 'string' |
    AUTO_INCREMENT [ = ] value |
    [ DEFAULT ] CHARACTER SET | CHARSET [ = ] default_charset |
    [ DEFAULT ] COLLATE [ = ] default_collation |
    ENGINE [ = ] { InnoDB | 'InnoDB' | "InnoDB" } }
  ```

- **htap_option**:

  ```
  { COLVIEW [ PRIORITY { HIGH | LOW | NONE } ] |
    NOCOLVIEW }
  ```

- **column_constraint**:

  ```
  [ CONSTRAINT constraint_name ]
  { NOT NULL |
    NULL |
    CHECK ( expression ) |
    DEFAULT default_expr |
    ON UPDATE update_expr |
    AUTO_INCREMENT |
    COMMENT 'string' |
    UNIQUE [KEY] index_parameters |
    PRIMARY KEY index_parameters |
    REFERENCES reftable [ ( refcolumn ) ] [ MATCH FULL | MATCH PARTIAL | MATCH SIMPLE ]
      [ ON DELETE action ] [ ON UPDATE action ] }
  [ DEFERRABLE | NOT DEFERRABLE ] [ INITIALLY DEFERRED | INITIALLY IMMEDIATE ]
  ```

- **table_constraint**:

  ```
  [ CONSTRAINT [ constraint_name ] ]
  { CHECK ( expression ) |
    UNIQUE [ index_name ] [ USING method ] ( { column_name [ ASC | DESC ] } [, ... ] )
  index_parameters |
    PRIMARY KEY [ USING method ] ( { column_name [ ASC | DESC ] } [, ... ] ) index_parameters |
    FOREIGN KEY [ index_name ] ( column_name [, ... ] ) REFERENCES reftable [ ( refcolumn [, ... ] ) ]
      [ MATCH FULL | MATCH PARTIAL | MATCH SIMPLE ] [ ON DELETE action ] [ ON UPDATE action ] }
  [ DEFERRABLE | NOT DEFERRABLE ] [ INITIALLY DEFERRED | INITIALLY IMMEDIATE ]
  { [ COMMENT 'string' ] [ ... ] }
  ```

- **like_option**:

  ```
  { INCLUDING | EXCLUDING } { DEFAULTS | CONSTRAINTS | INDEXES | STORAGE | COMMENTS |
  RELOPTIONS | UPDATE | ALL }
  ```

- **index_parameters**:

  ```
  [ WITH ( {storage_parameter = value} [, ... ] ) ]
  [ USING INDEX TABLESPACE tablespace_name ]
  ```

- **update_expr**:

  ```
  { CURRENT_TIMESTAMP | LOCALTIMESTAMP | NOW() }
  ```

Parameters

- **IF NOT EXISTS**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Issues a notice rather than an error if a table with the same name already exists.

- **subpartition_table_name**

  Specifies the name of a subpartitioned table.

  Value range: character strings complying with **Identifier Naming Conventions**.

- **column_name**

  Specifies the name of the column to be created in the new table.

  Value range: character strings complying with **Identifier Naming Conventions**.

- **data_type**

  Specifies the data type of the column.

- **COLLATE collation**

  Assigns a collation to the column (which must be of a collatable data type). If not specified, the default collation is used. You can run the **SELECT * FROM pg_collation;** command to query collations from the pg_collation system catalog. The row starting with **default** in the query result represents the default collation.

- **CONSTRAINT constraint_name**

  Specifies the name of a column constraint or table constraint. The optional CONSTRAINT clause specifies constraints that new or updated rows must satisfy for an INSERT or UPDATE operation to succeed.

  There are two ways to define constraints:

  – A column constraint is defined as part of a column definition, and it is tied to a particular column.

  – A table constraint can apply to multiple columns.

  NOTICE

  The **constraint_name** parameter is optional in MYSQL-compatible mode (that is, **sql_compatibility** is set to **'MYSQL'**). For other modes, **constraint_name** must be added.

- **index_name**

  Specifies an index name.

  NOTICE

  - **index_name** is supported only in MySQL-compatible databases (**sql_compatibility = 'MYSQL'**).
  - If both **constraint_name** and **index_name** are specified for a UNIQUE constraint, the value of **index_name** will be used as the index name.

- **USING method**

  Specifies the method used to create the index.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Value range: Refer to **USING method** in **CREATE INDEX**.

NOTICE

- **USING method** is supported only in MySQL-compatible databases (**sql_compatibility = 'MYSQL'**).
- In MYSQL-compatible mode, if USING method is not specified, the default index method is B-tree for Astore or UB-tree for Ustore.

- **ASC | DESC**

  ASC specifies an ascending (default) sort order. **DESC** specifies a descending sort order.

NOTICE

ASC|DESC is supported only in a MYSQL-compatible database (that is, **sql_compatibility** is set to **'MYSQL'**).

- **LIKE source_table [like_option ...]**

  Specifies a table, known as the source table, from which the target table automatically inherits all column names, their data types, and NOT NULL constraints.

  The target table and source table are completely decoupled after creation is complete. Changes to the source table will not be applied to the target table, and it is not possible to include data of the target table in scans of the source table.

  - The default expressions of columns are included only when **INCLUDING DEFAULTS** is specified. The default behavior is to exclude the default expressions, causing all columns in the target table to default to **NULL**.
  - If **INCLUDING UPDATE** is specified, columns in the target table will inherit the **ON UPDATE CURRENT_TIMESTAMP** attribute from the source table. The default behavior is to exclude this attribute.
  - The target table always inherits the NOT NULL constraints from the source table. The CHECK constraints are inherited only when **INCLUDING CONSTRAINTS** is specified. Other types of constraints are not inherited. This rule also applies to table constraints and column constraints.

  The system does not merge inherited columns or constraints with those that share the same name. If the same name is explicitly specified or in another LIKE clause, an error is reported.

  - If **INCLUDING INDEXES** is specified, indexes on the source table will also be created on the target table. By default, no indexes are created. The tablespace where indexes on the target table are located is the same as that where indexes on the source table are located.
  - If **INCLUDING STORAGE** is specified, columns in the target table will inherit **STORAGE** settings from the source table. The default behavior is to exclude **STORAGE** settings.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

  - If **INCLUDING COMMENTS** is specified, the target table will inherit comments on columns, constraints, and indexes from the source table. The default behavior is to exclude comments.
  - If **INCLUDING RELOPTIONS** is specified, the target table will inherit storage parameters (WITH clause) from the source table. The default behavior is to exclude storage parameters.
  - If **INCLUDING IDENTITY** is specified, the target table will inherit the IDENTITY functionality from the source table and create a **SEQUENCE** parameter that matches the one in the source table. The default behavior is to exclude the IDENTITY functionality.
  - If **INCLUDING ILM** is specified, the target table will inherit ILM policy information from the source table. To also inherit the ILM policy information of partition objects, you will need to specify **INCLUDING PARTITION**.
  - **INCLUDING ALL** is a condensed version that encompasses **INCLUDING DEFAULTS**, **INCLUDING UPDATE**, **INCLUDING CONSTRAINTS**, **INCLUDING INDEXES**, **INCLUDING STORAGE**, **INCLUDING COMMENTS**, **INCLUDING PARTITION**, **INCLUDING RELOPTIONS**, **INCLUDING IDENTITY**, and **INCLUDING ILM**.

- **AUTO_INCREMENT [=] value**

  Specifies an initial value for an auto-increment column. The value must be a positive integer no greater than $2^{127} - 1$.

  NOTICE

  This clause takes effect only when **sql_compatibility** is set to **'MYSQL'**.

- **COMMENT [=] 'string'**
  - COMMENT [=] 'string: adds a comment on the table.
  - COMMENT 'string' in **column_constraint**: adds a comment on a column.
  - COMMENT 'string' in **table_constraint**: adds a comment on the indexes corresponding to the primary key and unique key.

  For details, see **COMMENT [=] 'string'** in **CREATE TABLE**.

- **WITH (storage_parameter [= value] [, ...])**

  Specifies an optional storage parameter for the table or index. See details of parameters below.

  NOTE

  These TDE-related storage parameters are supported: **enable_tde**, **encrypt_algo**, **dek_cipher**, **key_type**, and **cmk_id**.

  For details about the parameters, see **CREATE TABLE**.

  - FILLFACTOR

    Specifies a fillfactor for the table. It is a percentage between 10 and 100. In the case of Ustore, the default is **92**. In the case of Astore, the default is **100** (complete packing). When you specify a smaller fillfactor, INSERT operations pack table pages only to the indicated percentage. The remaining space on each page is reserved for updating rows on that

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

page. This gives UPDATE a chance to place the updated copy of a row on the same page as the original, which is more efficient than placing it on a different page. For a table whose entries are never updated, complete filling (fillfactor = 100) is the best choice. However, in heavily updated tables, smaller fillfactors are appropriate.

Value range: 10–100.

- ORIENTATION

  Specifies the orientation for storing table data.

  Value range:

  - **ROW** (default): Table data is stored in row orientation.

    NOTICE

    ORIENTATION cannot be modified.

- STORAGE_TYPE

  Specifies the storage engine type. Once set, this parameter cannot be modified.

  Value range:

  - **USTORE**: The table uses an in-place update storage engine.

    NOTICE

    To prevent space bloat, be sure to enable the **track_counts** and **track_activities** parameters for Ustore tables.

  - **ASTORE**: The table uses an append-only storage engine.

  Default value:

  In-place update storage unless otherwise specified.

- segment

  Specifies that data is stored in segment-page mode. This parameter applies only to row-store tables. Temporary tables and unlogged tables are not supported.

  Value range: **on** and **off**.

  Default value: **off**.

- statistic_granularity

  Records the default **partition_mode** when the table analyzes statistics. For details about **partition_mode**, see **PARTITION_MODE** in **ANALYZE | ANALYSE**. This parameter setting does not work for non-partitioned tables.

  Value range: See **PARTITION_MODE** in **ANALYZE | ANALYSE**.

  Default value: **AUTO**.

- hasrowid

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Specifies whether the table is a rowid table. If **hasrowid** is set to **on**, the **rowid** and **rowno** system columns are added to the table, and sequences and indexes are created on the **rowno** system column.

Value range: **on** and **off**.

Default value: **off**.

NOTE

- This parameter supports only ORA-compatible databases (that is, **sql_compatibility** is set to **ORA**).
- This parameter does not support local temporary tables, unlogged tables, global temporary tables, materialized views, hash bucket tables, or replication tables.
- This parameter cannot be specified together with **hasuids** and **oids**.
- When this parameter is enabled, the ordinary column name cannot be defined as **rowno** or **rowid**.
- The number of data records in the **rowid** table cannot exceed 9223372036854775807.

– vacuum_truncate

Specifies whether to enable the VACUUM TRUNCATE function of a table to truncate the last empty page during VACUUM.

Value range: **on** and **off**.

Default value: **on**.

NOTE

- This parameter is valid only for Astore tables and does not take effect for hash bucket tables and segment tables.
- During the upgrade from a version that does not support this parameter to a version that supports this parameter, this parameter cannot be created or modified during the upgrade observation period.
- The toast.**vacuum_truncate** parameter can be used to independently control whether to truncate the last empty page of a TOAST table.

– partition_statistics_min_rows

Specifies the minimum number of rows to be sampled at the partition level when the ANALYZE statement is executed on a partitioned table.

Value range: [0,10000]

Default value: **50**

NOTE

- This parameter is valid only for partitioned tables.
- This parameter is valid only when **PARTITION_MODE** in the ANALYZE statement is set to **ALL** and the GUC parameter **enable_partition_statistics_min_rows** is enabled. For details about **PARTITION_MODE**, see **PARTITION_MODE** in **ANALYZE | ANALYSE**.
- Upper limit: The number of rows sampled from the entire partitioned table cannot exceed the number of rows allowed by the GUC parameter **maintenance_work_mem**.

- **[ILM ADD POLICY ROW STORE COMPRESS { ADVANCED [MEDIUM | HIGH] ROW AFTER n { day | month | year } OF NO MODIFICATION [ON (EXPR)] | TURBO [LOW | MEDIUM | HIGH] UNIT AFTER n { hour | day | month | year } OF NO MODIFICATION | NONE}]**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

  - When creating a table, you can call ILM ADD POLICY ROW STORE COMPRESS ADVANCED [MEDIUM | HIGH] ROW to add a medium- or high-level advanced compression policy for row store. A policy can be separately specified for a subpartition. If no policy is specified for a subpartition, subpartitions inherit the policy of the partition. If no policy is specified for a partition, subpartitions inherit the policy of the table.

    - AFTER n { day | month | year } OF NO MODIFICATION: rows that have not been modified for *n* days, months, or years. Advanced compression does not support **hour**.
    - ON (EXPR): a row-level expression used to determine whether a row is hot or cold.

    NOTE

    - Among the functions supported by the row-level expression ON (EXPR) in the ILM policy, the output of some may be influenced by compatibility parameters. For instance, after you set **b_format_version** to **'5.7'** and **b_format_dev_version** to **'s2'** in MySQL-compatible mode, the upper function will be unable to convert data to uppercase as usual.
    - The compression level is optional. If not specified, the MEDIUM level will be used by default.
  - When creating a table, you can call ILM ADD POLICY ROW STORE COMPRESS TURBO HIGH UNIT to add a cross-page transparent compression policy for row store. Subpartitions inherit the policy of partitions.

    AFTER n { hour | day | month | year } OF NO MODIFICATION: rows that have not been modified for *n* hours, days, months, or years.

    If the compression level is not specified, the MEDIUM level is used by default.
  - When creating a row-store table, you can call ILM ADD POLICY ROW STORE COMPRESS NONE to explicitly specify that no cross-page transparent compression policy needs to be added.

- **TABLESPACE tablespace_name**

  Specifies the name of the tablespace where the table is to be created. If not specified, the default tablespace is used.

- **PARTITION BY {RANGE [COLUMNS] | LIST [COLUMNS] | HASH | KEY} (partition_keys)**
  - For **partition_keys**, only 16 columns are supported for the range and list partition keys, and only one column is supported for the hash partition key.
  - The data types supported by the partition key are the same as those supported by the partitioned table constraints.
  - The COLUMNS keyword can be used only when **sql_compatibility** is set to **'MYSQL'** and can be added only after RANGE or LIST. The semantics of RANGE COLUMNS is the same as that of RANGE, and the semantics of LIST COLUMNS is the same as that of LIST.
  - The KEY keyword can be used only when **sql_compatibility** is set to **'MYSQL'**. The meaning of KEY is the same as that of HASH.
- **SUBPARTITION BY {RANGE | LIST | HASH | KEY} (subpartition_keys)**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

  - For **subpartition_keys**, only 16 columns are supported for the range and list partition keys, and only one column is supported for the hash partition key.
  - The data types supported by the partition key are the same as those supported by the partitioned table constraints.
  - The KEY keyword can be used only when **sql_compatibility** is set to **'MYSQL'**. The meaning of KEY is the same as that of HASH.

- **PARTITIONS integer**

  Specifies the number of partitions.

  integer must be an integer within (0,1048575].

  - When this clause is specified after range or list partitions, each partition must be explicitly defined, and the number of defined partitions must be equal to **integer**. This clause can be specified after the range and list partitions only when **sql_compatibility** is set to **'MYSQL'**.
  - When this clause is specified after hash/key partitions, the following scenarios may occur: If you do not list the definition of each partition, the system will automatically generate *integer* partitions, named in **p**+*number* format, where *number* ranges from 0 to (**integer** – 1). These partitions will be placed within the tablespace of the table by default. If you explicitly list the partition definitions, the number of defined partitions must be equal to **integer**. If you neither list the partition definitions nor specify the number of partitions, the system will create only one partition.

- **SUBPARTITIONS integer**

  Specifies the number of subpartitions.

  integer must be an integer within (0,1048575].

  - This clause must come after hash/key subpartitions.
    - If you do not list the subpartition definitions, the system will automatically generate *integer* subpartitions within each partition, named in *partition name*+**sp**+*number* format, where *number* ranges from 0 to (**integer** – 1). These subpartitions will be placed within the tablespace of the table by default.
    - If you list the subpartition definitions, the number of defined subpartitions must be equal to **integer**.
    - If you neither list the subpartition definitions nor specify the number of subpartitions, the system will create only one subpartition.

- **{ ENABLE | DISABLE } ROW MOVEMENT**

  Specifies whether to enable row movement.

  If the tuple value is updated on the partition key during the UPDATE operation, the partition where the tuple is located is altered. Setting this parameter enables error messages to be reported or movement of the tuple between partitions.

  Value range:

  - **ENABLE**: Row movement is enabled.
  - **DISABLE** (default value): Row movement is disabled.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

If row movement is enabled, concurrent UPDATE and DELETE operations may result in an error. Possible causes include:

Both UPDATE and DELETE operations mark old data as deleted. In addition, if changing the partition key leads to cross-partition updates, the kernel will mark the old data in the original partition as deleted and generate a new record in a different partition, making it impossible to locate the new data based on the old data.

If concurrent UPDATE+UPDATE, DELETE+DELETE, or UPDATE+DELETE operations are performed on the same row, the behavior differs based on whether the data is distributed across partitions.

a. When data is not distributed across partitions, performing the second operation after the first operation will not result in an error.

   - If the first operation is UPDATE, the most recent data can be found and accessed during the second operation.
   - If the first operation is DELETE, the system will terminate the second operation because it detects that the current data has been deleted but cannot match it with the most recent data.

b. When data is distributed across partitions, performing the second operation after the first operation will result in an error.

   - If the first operation is UPDATE, the system will report an error during the second operation because it cannot find the most recent data, which is stored in a different partition.
   - If the first operation is DELETE, the system can detect that the current data has been deleted during the second operation, but cannot match it with the most recent data or determine whether the data was deleted by an UPDATE or DELETE operation. If the operation is UPDATE, an error is reported. If the operation is DELETE, the operation is terminated. However, to ensure data correctness, it can only report an error.

In UPDATE+UPDATE and UPDATE+DELETE concurrency scenarios, you can solve the problem by performing these operations sequentially. In the DELETE +DELETE concurrency scenario, you can solve the problem by disabling row movement.

- **NOT NULL**

  Forbids NULL values in columns. **ENABLE** is provided solely for syntax compatibility and can be omitted.

- **NULL**

  Allows NULL values in columns. This is the default.

  This clause is provided solely for compatibility with non-standard SQL databases and is not recommended for use.

- **CHECK (condition) [NO INHERIT]**

  Specifies an expression producing a Boolean result which new or updated rows must satisfy for an INSERT or UPDATE operation to succeed. Expressions evaluating to TRUE or UNKNOWN succeed. Otherwise, an error exception is raised, and the INSERT or UPDATE does not alter the database.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

A CHECK constraint specified as a column constraint should reference that column's value only, while an expression appearing in a table constraint can reference multiple columns.

A constraint marked with **NO INHERIT** will not propagate to child tables.

ENABLE is provided solely for syntax compatibility and can be omitted.

- **DEFAULT default_expr**

  Assigns a default value to a column. The value can be any variable-free expression (in particular, subqueries and cross-references to other columns in the current table are not allowed). The data type of the default expression must match the data type of the column.

  The default expression can be used in any INSERT operation that does not specify a value for the column. If no default value is specified, **NULL** will be used.

- **ON UPDATE update_expr**

  Specifies an attribute constraint for the column.

  During an UPDATE operation on a tuple in a table, if the new values of the updated columns differ from the old values, columns (in the tuple) that have this attribute but are not part of the UPDATE will be automatically updated to the current timestamp. However, if the new values of the updated columns are the same as the old values, those columns will remain unchanged. If columns with this attribute are included in the UPDATE, their values will be updated to the specified value.

  NOTE

  - This attribute can be specified only in MySQL-compatible databases version 5.7 (**sql_compatibility = 'MYSQL'**, **b_format_version='5.7'**, and **b_format_dev_version='s1'**).
  - In terms of syntax, **update_expr** supports three keywords: CURRENT_TIMESTAMP, LOCALTIMESTAMP, and NOW(). You can also optionally specify the precision of a keyword with parentheses. For example, ON UPDATE CURRENT_TIMESTAMP(), ON UPDATE CURRENT_TIMESTAMP(5), ON UPDATE LOCALTIMESTAMP(), and ON UPDATE LOCALTIMESTAMP(6). If a keyword does not contain parentheses or contains empty parentheses, the precision is 0. The NOW keyword cannot work without parentheses. The three types of keywords are synonyms of each other and have the same attribute effect.
  - This attribute can be specified only for columns of the following types: timestamp, datetime, date, time without time zone, smalldatetime, and abstime.
  - If the CREATE TABLE AS syntax is used, the column attributes will not be inherited.
  - The CREATE TABLE LIKE syntax can use **INCLUDING UPDATE** or **EXCLUDING UPDATE** to inherit or exclude a constraint. The **INCLUDING ILM** option is added to copy ILM policy information from the source table. When combined with the **INCLUDING PARTITION** option, it can also copy the policy information of partition objects from the source table.
  - The precision specified by this attribute can be different from the precision specified by the type in the corresponding column. After the column value is updated through this attribute, the minimum precision is displayed. For example, **CREATE TABLE t1 (col1 timestamp(6) ON UPDATE CURRENT_TIMESTAMP(3));**. If the UPDATE syntax triggers the attribute to take effect, three decimal places in the value of **col1** are displayed after the update.
  - A column cannot be designated as both this attribute and a generated column constraint simultaneously.
  - Specifying this attribute within the partition key of a partitioned table is not allowed.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **AUTO_INCREMENT**

  Marks a column as auto-increment.

  For details, see **AUTO_INCREMENT** in **CREATE TABLE**.

- **UNIQUE [KEY] index_parameters**

  UNIQUE (column_name [, ...]) index_parameters

  Specifies that a column or a combination of columns must be unique across the entire table.

  For the purpose of a UNIQUE constraint, NULL is not considered equal.

  UNIQUE KEY can be used only when **sql_compatibility** is set to **'MYSQL'**, which has the same semantics as UNIQUE.

- **PRIMARY KEY index_parameters**

  PRIMARY KEY (column_name [, ...]) index_parameters

  Specifies that one or more columns in the table require unique, non-NULL values.

  Only one primary key can be specified for a table.

- **DEFERRABLE | NOT DEFERRABLE**

  Specifies whether the constraint can be deferred. A constraint that is not deferrable will be checked immediately after every command. Checking of constraints that are deferrable can be postponed until the end of the transaction (using the **SET CONSTRAINTS** command). **NOT DEFERRABLE** is the default. Currently, only the UNIQUE, PRIMARY KEY, and FOREIGN KEY constraints accept this clause. (That is, other constraints are not deferrable.)

- **INITIALLY IMMEDIATE | INITIALLY DEFERRED**

  Specifies the default time to check the constraint if it is deferrable. A constraint that is not deferrable is always **INITIALLY IMMEDIATE** and cannot be declared as **INITIALLY DEFERRED**.

  – If the constraint is **INITIALLY IMMEDIATE**, it is checked after each statement. This is the default.

  – If the constraint is **INITIALLY DEFERRED**, it is checked only at the end of the transaction.

  The constraint check time can be altered with the **SET CONSTRAINTS** command.

- **USING INDEX TABLESPACE tablespace_name**

  Specifies a tablespace in which an index associated with a UNIQUE or PRIMARY KEY constraint will be created. If this clause is not specified, the index will be created in the default tablespace named **default_tablespace**. If **default_tablespace** is empty, the default tablespace of the database will be consulted.

Examples

- Creating a subpartitioned table

```
-- Create a subpartitioned table tbl_list_list. Both of the partitions and subpartitions are of the LIST type.
gaussdb=# CREATE TABLE tbl_list_list(
    sal_year    varchar(4)  NOT NULL,
    area_id     char(5)     NOT NULL,
    emp_id      char(5)     NOT NULL,
    sales_amt   int
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
) PARTITION BY LIST (sal_year) SUBPARTITION BY LIST(area_id)(
   PARTITION P_2019 VALUES ('2019')(
      SUBPARTITION p_2019_01001 VALUES ('01001'),
      SUBPARTITION p_2019_01002 VALUES ('01002'),
      SUBPARTITION p_2019_01003 VALUES ('01003')
   ),
   PARTITION p_2020 VALUES ('2020')(
      SUBPARTITION p_2020_01001 VALUES ('01001'),
      SUBPARTITION p_2020_01002 VALUES ('01002'),
      SUBPARTITION p_2020_01003 VALUES ('01003')
   )
);

-- Create a subpartitioned table tbl_range_list. The partition is of the RANGE type and subpartition is of the LIST type.
gaussdb=# CREATE TABLE tbl_range_list(
   sal_date    varchar(6)  NOT NULL,
   area_id     char(5)     NOT NULL,
   emp_id      char(5)     NOT NULL,
   sales_amt   int
) PARTITION BY RANGE (sal_date) SUBPARTITION BY LIST(area_id)(
   PARTITION p_201901 VALUES LESS THAN (201902)(
      SUBPARTITION p_201901_01001 VALUES ('01001'),
      SUBPARTITION p_201901_01002 VALUES ('01002'),
      SUBPARTITION p_201901_01003 VALUES ('01003')
   ),
   PARTITION p_201902 VALUES LESS THAN (201903)(
      SUBPARTITION p_201902_01001 VALUES ('01001'),
      SUBPARTITION p_201902_01002 VALUES ('01002'),
      SUBPARTITION p_201902_01003 VALUES ('01003')
   )
);

-- Create a subpartitioned table multi_range_list for multi-column partition keys. The partition is of the RANGE type and subpartition is of the LIST type.
gaussdb=# CREATE TABLE multi_range_list(c1 int, c2 int, c3 int)
PARTITION BY RANGE (c1,c2) SUBPARTITION BY LIST (c2, c3)
(
   PARTITION P_RANGE1 VALUES LESS THAN (10,10)
   (
      SUBPARTITION P_RANGE1_LIST1 VALUES ((1,1),(2,2)),
      SUBPARTITION P_RANGE1_LIST2 VALUES ((5,5),(6,6)),
      SUBPARTITION P_RANGE1_LIST3 VALUES ((8,8),(9,9))
   ),
   PARTITION P_RANGE2 VALUES LESS THAN (20,20)
   (
      SUBPARTITION P_RANGE2_LIST1 VALUES ((11,11),(12,12)),
      SUBPARTITION P_RANGE2_LIST2 VALUES ((15,15),(16,16)),
      SUBPARTITION P_RANGE2_LIST3 VALUES ((18,18),(19,19))
   ),
   PARTITION P_RANGE3 VALUES LESS THAN (30,30)
   (
      SUBPARTITION P_RANGE3_LIST1 VALUES ((21,21),(22,22)),
      SUBPARTITION P_RANGE3_LIST2 VALUES ((25,25),(26,26)),
      SUBPARTITION P_RANGE3_LIST3 VALUES ((28,28),(29,29))
   )
);
```

- Specifying partitions in a subpartitioned table using DML statements
  - INSERT

    ```
    -- Insert data to a specified partition.
    gaussdb=# INSERT INTO tbl_range_list PARTITION(p_201901) VALUES('201901', '01001', '0001', 75000 );

    -- The actual partition is inconsistent with the specified partition. An error is reported.
    gaussdb=# INSERT INTO tbl_range_list PARTITION(p_201902) VALUES('201901', '01001', '0002', 6000);
    ERROR:  inserted partition key does not map to the table partition
    DETAIL:  N/A.
    ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
-- Insert data to a specified subpartition.
gaussdb=# INSERT INTO tbl_range_list SUBPARTITION(p_201902_01001) VALUES('201902',
'01001', '0002', 8000);
```

- SELECT

```
-- Query data in a specified partition.
gaussdb=# SELECT * FROM tbl_range_list PARTITION(p_201902);
 sal_date | area_id | emp_id | sales_amt
----------+---------+--------+-----------
 201902   | 01001   | 0002   |      8000
(1 row)

gaussdb=# SELECT * FROM tbl_range_list SUBPARTITION(p_201901_01001);
 sal_date | area_id | emp_id | sales_amt
----------+---------+--------+-----------
 201901   | 01001   | 0001   |     75000
(1 row)
```

- UPDATE

```
-- Update data in a specified partition.
gaussdb=# UPDATE tbl_range_list PARTITION(p_201901) SET sales_amt = 7000;

gaussdb=# SELECT * FROM tbl_range_list;
 sal_date | area_id | emp_id | sales_amt
----------+---------+--------+-----------
 201901   | 01001   | 0001   |      7000
 201902   | 01001   | 0002   |      8000
(2 rows)

gaussdb=# UPDATE tbl_range_list SUBPARTITION FOR('201902','01001') SET sales_amt = 6000;

gaussdb=# SELECT * FROM tbl_range_list;
 sal_date | area_id | emp_id | sales_amt
----------+---------+--------+-----------

Helpful Links

ALTER TABLE SUBPARTITION

1.13.9.50 CREATE TEXT SEARCH CONFIGURATION

Description

Creates a custom text search configuration, which specifies a text search parser and a list of dictionaries.

NOTICE

This functionality is designed for internal use only. Avoid direct use by users.

Precautions

- When only **PARSER** is declared, the text search configuration created will not have any mapping between string types and dictionaries. In this situation, you need to run the **ALTER TEXT SEARCH CONFIGURATION** command to create a dictionary mapping for the configuration to take effect. If you declare **COPY**, the text search configuration created will automatically copy information such as the parser, mappings, and options from the specified text search configuration.
- If a schema name is specified, the text search configuration is created in the specified schema. Otherwise, it is created in the current schema.
- The user who creates a custom text search configuration will automatically be designated as its owner.
- The **PARSER** and **COPY** options are mutually exclusive because copying an existing text search configuration also copies its text search parser.

Syntax

```
CREATE TEXT SEARCH CONFIGURATION name
    ( {PARSER = parser_name | COPY = source_config} )
    [ WITH ( {configuration_option = value} [, ...] )];
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameters

- **name**

  Specifies the name of the text search configuration to be created. The name can be schema-qualified.

- **parser_name**

  Specifies the name of the text search parser used by the text search configuration.

- **source_config**

  Specifies the name of an existing text search configuration to copy.

- **configuration_option**

  Specifies the options of the text search configuration.

  Value range: default and ngram parsers along with their parameters, as described in **Table 1-399**.

  Table 1-399 Parameters specific to different parsers

Parser	Parameter	Description	Value Range
default	-	-	-
ngram	gram_size	Token length.	Positive integer from 1 to 4 Default value: **2**
	punctuation_ignore	Specifies whether to ignore punctuations.	• **true** (default): ignored. • **false**: not ignored.
	grapsymbol_ignore	Specifies whether to ignore graphical characters.	• **true**: ignored. • **false** (default): not ignored.

Examples

```
-- Create a text search configuration named ngram2.
gaussdb=# CREATE TEXT SEARCH CONFIGURATION ngram2 (PARSER=ngram) WITH (GRAM_SIZE = 2,
GRAPSYMBOL_IGNORE = false);

-- Create a text search configuration named ngram3.
gaussdb=# CREATE TEXT SEARCH CONFIGURATION ngram3 (COPY=ngram2) WITH (GRAM_SIZE = 2,
GRAPSYMBOL_IGNORE = false);

-- Add a type mapping.
gaussdb=# ALTER TEXT SEARCH CONFIGURATION ngram2 ADD MAPPING FOR multisymbol WITH simple;

-- Create user joe.
gaussdb=# CREATE USER joe IDENTIFIED BY '********';

-- Change the owner of a text search configuration.
gaussdb=# ALTER TEXT SEARCH CONFIGURATION ngram2 OWNER TO joe;

-- Change the schema of a text search configuration.
gaussdb=# ALTER TEXT SEARCH CONFIGURATION ngram2 SET SCHEMA joe;

-- Rename a text search configuration.
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gaussdb=# ALTER TEXT SEARCH CONFIGURATION joe.ngram2 RENAME TO ngram_2;

-- Drop a type mapping.
gaussdb=# ALTER TEXT SEARCH CONFIGURATION joe.ngram_2 DROP MAPPING IF EXISTS FOR
multisymbol;

-- Drop a text search configuration.
gaussdb=# DROP TEXT SEARCH CONFIGURATION joe.ngram_2;
gaussdb=# DROP TEXT SEARCH CONFIGURATION ngram3;

-- Drop a schema and user joe.
gaussdb=# DROP SCHEMA IF EXISTS joe CASCADE;
gaussdb=# DROP ROLE IF EXISTS joe;
```

1.13.9.51 CREATE TEXT SEARCH DICTIONARY

Description

Creates a full-text search dictionary. A dictionary is used to identify and process particular words during full-text search.

NOTICE

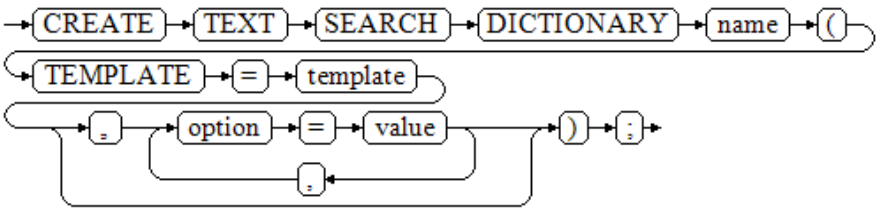
This functionality is designed for internal use only. Avoid direct use by users.

Precautions

- A user with the SYSADMIN permission can create a dictionary. Then, the user automatically becomes the owner of the dictionary.
- To create dictionaries, you will need predefined templates from the pg_ts_template system catalog. Currently, you can create various types of dictionaries, including Simple, Ispell, Synonym, Thesaurus, Snowball, and Tokenweight. Each type serves a distinct purpose.
- Dictionaries cannot be created in the temporary schema pg_temp.
- If a dictionary's **FILEPATH** requires further modifications after the dictionary is created or modified, use the ALTER statement to update **FILEPATH**.

Syntax

```
CREATE TEXT SEARCH DICTIONARY name (
    TEMPLATE = template
    [, { option = value } [, ... ]]
);
```



Parameters

- **name**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Specifies the name of the dictionary to be created. The name can be schema-qualified. If no schema is qualified, the dictionary will be created in the current schema.

Value range: character strings complying with **Identifier Naming Conventions** and not exceeding 63 characters.

- **template**

  Specifies the template used to create the dictionary.

  Value range: templates predefined in the pg_ts_template system catalog, including:

  - Simple: Simple dictionary/stop word dictionary. This dictionary template operates by converting the input token to lowercase and checking it against a file of stop words. If it is found in the file, then an empty array is returned, causing the token to be discarded. If not, the lower-cased form of the word is returned as the normalized lexeme. Alternatively, the Simple dictionary can be configured to report non-stop-words as unrecognized, allowing them to be passed on to the next dictionary in the list.
  - Synonym: This dictionary template is used to create dictionaries that replace a word with a synonym.
  - Thesaurus: A Thesaurus dictionary (sometimes abbreviated as TZ) is a collection of words that includes information about the relationships of words and phrases, i.e., broader terms (BT), narrower terms (NT), preferred terms, non-preferred terms, related terms, etc. Basically, a Thesaurus dictionary replaces all non-preferred terms by one preferred term and, optionally, preserves the original terms for indexing as well.
  - Ispell: The Ispell dictionary template supports morphological dictionaries, which can normalize many different linguistic forms of a word into the same lexeme. For example, an English Ispell dictionary can match all declensions and conjugations of the search word **bank**, e.g., **banking**, **banked**, **banks**, **banks'**, and **bank's**.
  - Snowball: A Snowball dictionary provides stemming algorithms for many languages. Each algorithm understands how to reduce common variant forms of words to a base, or stem, spelling within its language. A Snowball dictionary requires a **LANGUAGE** parameter to identify which stemmer to use, and optionally can specify a **STOPWORDS** file that gives a list of words to eliminate.
  - Tokenweight: A Tokenweight dictionary can be used to adjust the weights of specific tokens in natural language processing or information retrieval. It relies on manual intervention to optimize algorithms and determine the importance of keywords.

- **option**

  Specifies an option name. The list of options varies depending on **template**.

  - Options for a Simple dictionary:

    - STOPWORDS

      Specifies the name of the stop-words file. The default file name extension is .stop.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

The file format is simply a list of words, one per line. Blank lines and trailing spaces are ignored, and uppercase is folded to lowercase, but no other processing is done on the file contents.

- ACCEPT

  Specifies whether to accept a non-stop word as recognized. The default value is **true**.

  With the default setting of **ACCEPT=true**, it is only useful to place a Simple dictionary at the end of a dictionary list, since it will never pass on any token to a following dictionary. Conversely, setting **ACCEPT=false** will cause the Simple dictionary to pass on the token to the following dictionary. However, if the Simple dictionary is placed at the end of a dictionary list, **ACCEPT** will not be operational. In this scenario, it is not advisable to place the Simple dictionary at the end of the dictionary list.

- FILEPATH

  Specifies the directory storing the Simple dictionary definition file. It can be specified as a local directory in **file://***absolute_path* format. The default value is the directory where predefined dictionary files are located. If any of the **FILEPATH** and **STOPWORDS** parameters is specified, the other one must also be specified.

– Options for a Synonym dictionary:

- SYNONYM

  Specifies the name of the Synonym dictionary definition file. The default file name extension is .syn.

  The file format is simply a list of synonyms, with each line structured in *token synonym* format (each token and its corresponding synonym are separated by a space).

- CASESENSITIVE

  Specifies whether tokens and synonyms are case-sensitive. With the default value of **false**, tokens and synonyms in the synonym file are folded to lowercase. When it is **true**, words and tokens are not folded to lowercase.

- FILEPATH

  Specifies the directory storing the Synonym dictionary definition file. It can be specified as a local directory in **file://***absolute_path* format. The default value is the directory where predefined dictionary files are located.

– Options for a Thesaurus dictionary:

- DICTFILE

  Specifies the name of the Thesaurus dictionary definition file. The default file name extension is .ths.

  The file format is simply a list of synonyms, with each line structured in *sample words : indexed words* format, where the colon (:) acts as a delimiter between a phrase and its replacement. The Thesaurus dictionary chooses the longest match if there are multiple sample words matching the input.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- DICTIONARY

  Specifies the name of a subdictionary used to normalize the input text. This parameter is required, and it is only possible to select one subdictionary. The specified subdictionary must exist. It is used to identify and normalize input text before phrase matching.

  An error is reported if the subdictionary fails to recognize a word. In that case, you should remove the use of the word or teach the subdictionary about it. You can place an asterisk (*) at the beginning of an indexed word to skip applying the subdictionary to it, but all sample words must be known to the subdictionary.

  If sample words in the Thesaurus dictionary definition file (**DICTFILE**) include any stop word defined in the subdictionary; use question marks (?) to replace the stop word. For example, assuming that "a" and "the" are stop words according to the subdictionary:

  ```
  ? one ? two : swsw
  ```

  matches "a one the two" and "the one a two"; both would be replaced by "swsw".

- FILEPATH

  Specifies the directory storing the Thesaurus dictionary definition file. It can be specified as a local directory in **file://***absolute_path* format. The default value is the directory where predefined dictionary files are located.

– Options for an Ispell dictionary:

- DICTFILE

  Specifies the name of the dictionary definition file. The default file name extension is .dict.

- AFFFILE

  Specifies the name of an .affix file. The default file name extension is .affix.

- STOPWORDS

  Specifies the name of the stop-words file. The default file name extension is .stop. The stop-words file has the same format explained above for the Simple dictionary type.

- FILEPATH

  Specifies the directory storing the Ispell dictionary definition file. It can be specified as a local directory in **file://***absolute_path* format. The default value is the directory where predefined dictionary files are located.

– Options for a Snowball dictionary:

- LANGUAGE

  Specifies the name of a language whose stemming algorithm will be used. According to spelling rules in the language, the algorithm normalizes the variants of an input word into a basic word or a stem.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- STOPWORDS

  Specifies the name of the stop-words file. The default file name extension is .stop. The stop-words file has the same format explained above for the Simple dictionary type.

- FILEPATH

  Specifies the directory storing the Snowball dictionary definition file. It can be specified as a local directory in **file://***absolute_path* format. The default value is the directory where predefined dictionary files are located. If any of the **FILEPATH** and **STOPWORDS** parameters is specified, the other one must also be specified.

– Options for a Tokenweight dictionary:

- TOKENFILE

  Specifies the name of the Tokenweight dictionary definition file. The default file name extension is .tokw.

  The file format is simply a list of token weights and synonym similarities, with each line representing a token weight or synonym similarity. When processing a specific file, the dictionary will ignore empty lines, comments starting with "#", and spaces at the beginning or end of each line.

  ○ Token weight format: *<token words> [: <token weight>]*. *token weight* can be a decimal or an integer, with a default value of **3**. The colon (:) acts as a delimiter in the middle. Increasing the token weight enhances the probability of the character string being segmented into a single word.

  ○ Synonym similarity format: *<token words 1> :: <token words 2> [: <similarity>]*, indicating that **token words 2** is a synonym of **token words 1**. The value of **similarity** ranges from 0 to 1, with a default of **0.8**. Note that synonym similarities only denote one-way synonymy; to represent two-way synonymy, two lines of definitions with reversed word positions are necessary.

- STOPFILE

  Specifies the name of the stop-words file. The default file name extension is .stop. The stop-words file has the same format explained above for the Simple dictionary type.

- FILEPATH

  Specifies the directory storing the Tokenweight dictionary definition file. It can be specified as a local directory in **file://***absolute_path* format. The default value is the directory where predefined dictionary files are located. The **FILEPATH** parameter must be specified together with parameter **STOPFILE** or **TOKENFILE**.

NOTE

The name of the dictionary definition file can contain only lowercase letters, digits, and underscores (_).

- **value**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Specifies the option value. If the value is of the character string type, it must be enclosed in single quotation marks (identifiers and numbers can also be enclosed in single quotation marks).

Examples

Text search configuration specifies the following components required for converting a document into a tsvector:

- A parser, used for breaking a text into tokens.
- A list of dictionaries, used for converting each token into a lexeme.

Each time when the to_tsvector or to_tsquery function is called, a text search configuration is required to specify a processing procedure. The GUC parameter **default_text_search_config** specifies the default text search configuration, which will be used if the text search function does not explicitly specify a text search configuration.

GaussDB provides some predefined text search configurations. You can also create user-defined text search configurations. In addition, to facilitate the management of text search objects, multiple gsql meta-commands are provided to display information about text search objects. (For details, see **Meta-Command Reference**.)

Procedure

Step 1 Create a text search configuration **ts_conf** by copying the predefined text search configuration **english**.

```
gaussdb=# CREATE TEXT SEARCH CONFIGURATION ts_conf ( COPY = pg_catalog.english );
CREATE TEXT SEARCH CONFIGURATION
```

Step 2 Create a Synonym dictionary.

Assume that the definition file **gs_dict.syn** of the Synonym dictionary contains the following contents:

```
gaussdb    gs
gauss      gs
```

Create the Synonym dictionary.

```
gaussdb=# CREATE TEXT SEARCH DICTIONARY gs_dict (
    TEMPLATE = synonym,
    SYNONYMS = gs_dict,
    FILEPATH = 'file:///home/dicts'
);
```

Step 3 Create an Ispell dictionary named **english_ispell** (the dictionary definition file is from the open source dictionary).

```
gaussdb=# CREATE TEXT SEARCH DICTIONARY english_ispell (
   TEMPLATE = ispell,
   DictFile = english,
   AffFile = english,
   StopWords = english,
   FILEPATH = 'file:///home/dicts'
);
```

Step 4 Alter the text search configuration **ts_conf** and change the dictionary list for tokens of certain types.

```
gaussdb=# ALTER TEXT SEARCH CONFIGURATION ts_conf
   ALTER MAPPING FOR asciiword, asciihword, hword_asciipart,
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
                word, hword, hword_part
  WITH gs_dict, english_ispell, english_stem;
```

Step 5 In the text search configuration, set no indexing or searching for tokens of certain types.

```
gaussdb=# ALTER TEXT SEARCH CONFIGURATION ts_conf
   DROP MAPPING FOR email, url, url_path, sfloat, float;
```

Step 6 Use the text search debugging function ts_debug() to test the text search configuration **ts_conf**.

```
gaussdb=# SELECT * FROM ts_debug('ts_conf', '
GaussDB, the highly scalable, SQL compliant, open source object-relational
database management system, is now undergoing beta testing of the next
version of our software.
');
```

Step 7 You can set the default text search configuration of the current session to **ts_conf**. This setting is valid only in the current session.

```
gaussdb=# \dF+ ts_conf
     Text search configuration "public.ts_conf"
Parser: "pg_catalog.default"
      Token      |            Dictionaries
-----------------+------------------------------------
 asciihword      | gs_dict,english_ispell,english_stem
 asciiword       | gs_dict,english_ispell,english_stem
 file            | simple
 host            | simple
 hword           | gs_dict,english_ispell,english_stem
 hword_asciipart | gs_dict,english_ispell,english_stem
 hword_numpart   | simple
 hword_part      | gs_dict,english_ispell,english_stem
 int             | simple
 numhword        | simple
 numword         | simple
 uint            | simple
 version         | simple
 word            | gs_dict,english_ispell,english_stem

gaussdb=# SET default_text_search_config = 'public.ts_conf';
SET
gaussdb=# SHOW default_text_search_config;
 default_text_search_config
----------------------------
 public.ts_conf
(1 row)
```

----End

1.13.9.52 CREATE TRIGGER

Description

CREATE TRIGGER is used to create a trigger. A trigger is a specialized stored procedure used for complex service rules and requirements to ensure reference integrity. It is associated with a specified table or view and executes a specified function under specific conditions. Triggers help preserve predefined relationships within a table when rows are added, updated, or deleted.

Precautions

- Currently, triggers can be created only on ordinary tables and views, instead of on temporary tables or unlogged tables.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- If multiple triggers of the same kind are defined for the same event, they will be fired in alphabetical order by name.
- Triggers are usually used for data synchronization between multiple tables, which impact SQL execution performance greatly. Therefore, you are advised not to use them when a large amount of data needs to be synchronized and performance requirements are high.
- When a trigger meets the following conditions, the trigger statement and trigger itself can be pushed together down to a DN for execution, improving the trigger execution performance:
  - The GUC parameters **enable_trigger_shipping** and **enable_fast_query_shipping** are enabled.
  - The trigger function used by the source table is a PL/pgSQL function (recommended).
  - The source and target tables have the same type and number of distribution keys, are both row-store tables, and belong to the same node group.
  - The **INSERT**, **UPDATE**, or **DELETE** statement on the source table contains an expression about equality comparison between all the distribution keys and the *NEW* or *OLD* variable.
  - The INSERT, UPDATE, or DELETE statement on the source table can be used to query shipping without a trigger.
  - There are only six types of triggers on the source table: **BEFORE INSERT FOR EACH ROW**, **AFTER INSERT FOR EACH ROW**, **BEFORE UPDATE FOR EACH ROW**, **AFTER UPDATE FOR EACH ROW**, **BEFORE DELETE FOR EACH ROW**, and **AFTER DELETE FOR EACH ROW**. All triggers can be pushed down.
- When a trigger statement is executed, the permission is determined by the trigger creator.
- To create a trigger, you must have the TRIGGER permission on the specified table or have the CREATE ANY TRIGGER permission.
- A row-level trigger function triggered by BEFORE can return a **NULL** value, indicating that operations on the row are ignored. Subsequent triggers will not be executed and no INSERT, UPDATE, or DELETE action will be generated on the row.

  The return value of the trigger function triggered by AFTER is not affected.
- In the case of a BEFORE DELETE trigger, the return value **NEW** of the trigger function indicates **NULL**. In the case of a BEFORE INSERT trigger, the return value **OLD** of the trigger function indicates **NULL**. In the case of a BEFORE UPDATE trigger, the return value of the trigger function is **NULL** only when it is displayed as **NULL**.
- For a trigger function whose event is INSERT or UPDATE, the normal return value is **NEW**. For a row returning a value other than **NULL**, a BEFORE trigger modifies the inserted or updated row, while an AFTER trigger does not. For a trigger function whose event is DELETE, the normal return value is **OLD**.
- INSTEAD OF triggers can only work on views. Their trigger functions can also return **NULL**, indicating that subsequent triggers will not be executed.
- Package functions cannot be used as trigger functions.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- If there are overloaded functions, the implicit variables in triggers, such as *old* and *new*, cannot be used as input parameters of the overloaded functions.
- In a distributed PGXC plan, if a BEFORE ROW trigger modifies the same row in the target table, the modification of the trigger does not take effect.
- The MERGE INTO statement does not support triggers.
- The REPLACE INTO statement does not support ROW triggers. For STATEMENT triggers, only INSERT STATEMENT is supported, and DELETE STATEMENT is not supported.
- The INSERT ... ON DUPLICATE KEY UPDATE | ON CONFLICT statement supports STATEMENT triggers but does not support ROW triggers.
- In a trigger function or anonymous block, **cursor%RowType** is considered as a composite type (record), and the specific type of the cursor cannot be parsed. The corresponding column information is obtained only when this type is used to define variables and assign values.

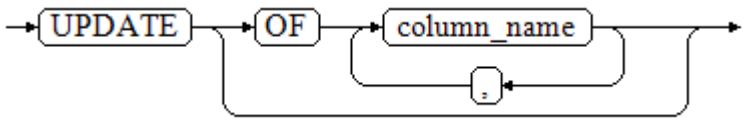
Syntax

```
CREATE [OR REPLACE] [ CONSTRAINT ] TRIGGER name { BEFORE | AFTER | INSTEAD OF } { event [ OR
event ] [ ... ] }
   ON table_name
   [ FROM referenced_table_name ]
   [ NOT DEFERRABLE [ INITIALLY IMMEDIATE ] | [ DEFERRABLE ] [ INITIALLY IMMEDIATE | INITIALLY
DEFERRED ] ]
   [ FOR [ EACH ] { ROW | STATEMENT } ]
   [ WHEN ( condition ) ]
   [ EXECUTE PROCEDURE function_name ( arguments ) | AnonyBlock ];
```

Events include:

```
INSERT
```

```
UPDATE [ OF column_name [, ... ] ]
```



```
DELETE
```

```
TRUNCATE
```

Parameters

- **OR REPLACE**

  (Optional) If this parameter is specified, the existing trigger will be modified.

  Constraint triggers and internal triggers cannot be created or modified using the OR REPLACE syntax. A constraint trigger is a trigger created using CREATE

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

CONSTRAINT TRIGGER. An internal trigger is a trigger implicitly created by some SQL statements. For example, if a foreign key constraint is added to a table, four triggers are implicitly created. The four triggers are internal triggers.

- **CONSTRAINT**

  (Optional) Creates a constraint trigger. That is, the trigger is used as a constraint. This is the same as a regular trigger except that the timing of the trigger firing can be adjusted using SET CONSTRAINTS. Constraint triggers must be AFTER ROW triggers.

- **name**

  Specifies the name of the trigger to be created. This must be distinct from the name of any other trigger for the same table. The name cannot be schema-qualified because the trigger inherits the schema of its table. For a constraint trigger, this is also the name to use when modifying the trigger's behavior using **SET CONSTRAINTS**.

  Value range: a string, which complies with **Identifier Naming Conventions**. A value can contain a maximum of 63 characters.

- **BEFORE**

  Specifies that the function is called before the event.

- **AFTER**

  Specifies that the function is called after the event. A constraint trigger can only be specified as **AFTER**.

- **INSTEAD OF**

  Specifies that the function is called instead of the event.

- **event**

  Specifies the event that will fire the trigger. Values are **INSERT**, **UPDATE**, **DELETE**, and **TRUNCATE**. Multiple events can be specified using **OR**.

  For UPDATE events, it is possible to specify a list of columns using this syntax:

  ```
  UPDATE OF column_name1 [, column_name2 ... ]
  ```

  The trigger will only fire if at least one of the listed columns is mentioned as a target of the UPDATE statement. INSTEAD OF UPDATE events do not allow a list of columns. If the column specified by UPDATE OF contains a generated column, the trigger is also fired when the column on which the generated column depends is the target column of the UPDATE statement.

- **table_name**

  Specifies the name of the table for which the trigger is created.

  Value range: existing table names in the database.

- **referenced_table_name**

  Specifies the name of another table referenced by the constraint. This option is used for foreign-key constraints. It can only be specified for constraint triggers. Because foreign keys are not supported currently, this option is not recommended for general use.

  Value range: existing table names in the database.

- **DEFERRABLE | NOT DEFERRABLE**

  Specifies the start time of the trigger. It can only be specified for constraint triggers. Determines whether the constraint can be deferred.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

For details, see **CREATE TABLE**.

- **INITIALLY IMMEDIATE | INITIALLY DEFERRED**

  If the constraint is deferrable, the two clauses specify the default time to check the constraint. It can only be specified for constraint triggers.

  For details, see **CREATE TABLE**.

- **FOR EACH ROW | FOR EACH STATEMENT**

  Specifies the frequency of firing the trigger.

  - **FOR EACH ROW** indicates that the trigger should be fired once for every row affected by the trigger event.
  - **FOR EACH STATEMENT** indicates that the trigger should be fired just once per SQL statement.

  If not specified, **FOR EACH STATEMENT** is the default. Constraint triggers can only be specified as **FOR EACH ROW**.

- **condition**

  Specifies whether the trigger function will actually be executed. If WHEN is specified, the function will be called only when **condition** returns **true**.

  In FOR EACH ROW triggers, the WHEN condition can refer to columns of the old and/or new row values by writing **OLD.***column_name* or **NEW.***column_name* respectively. In addition, INSERT triggers cannot refer to OLD, and DELETE triggers cannot refer to NEW.

  INSTEAD OF triggers do not support WHEN conditions.

  Currently, WHEN expressions cannot contain subqueries.

  Note that for constraint triggers, evaluation of the WHEN condition is not deferred, but occurs immediately after the row update operation is performed. If the condition does not evaluate to **true**, then the trigger is not queued for deferred execution.

- **function_name**

  Specifies a user-defined function, which must be declared as taking no parameters and returning type trigger. This is executed when a trigger fires.

- **arguments**

  Specifies an optional comma-separated list of parameters to be provided to the function when the trigger is executed. The parameters are literal string constants. Simple names and numeric constants can also be written here, but they will all be converted to strings. Check the description of the implementation language of the trigger function to find out how these parameters can be accessed within the function.

  NOTE

  The following details trigger types:

  - INSTEAD OF triggers must be marked as FOR EACH ROW and can be defined only on views.
  - BEFORE and AFTER triggers on a view must be marked as FOR EACH STATEMENT.
  - TRUNCATE triggers must be marked as FOR EACH STATEMENT.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 1-400 Types of triggers supported on tables and views

When	Event	Row-Level	Statement-Level
BEFORE	INSERT/UPDATE/DELETE	Tables	Tables and views
	TRUNCATE	Not supported.	Tables
AFTER	INSERT/UPDATE/DELETE	Tables	Tables and views
	TRUNCATE	Not supported.	Tables
INSTEAD OF	INSERT/UPDATE/DELETE	Views	Not supported.
	TRUNCATE	Not supported.	Not supported.

Table 1-401 Special variables in PL/pgSQL functions

Variable	Description
NEW	New tuple for INSERT and UPDATE operations. This variable is **NULL** for **DELETE** operations and statement-level triggers.
OLD	Old tuple for UPDATE and DELETE operations. This variable is **NULL** for **INSERT** operations and statement-level triggers.
TG_NAME	Trigger name.
TG_WHEN	Trigger timing (**BEFORE**, **AFTER**, or **INSTEAD OF**).
TG_LEVEL	Trigger frequency (**ROW** or **STATEMENT**).
TG_OP	Trigger event (**INSERT**, **UPDATE**, **DELETE**, or **TRUNCATE**).
TG_RELID	OID of the table where the trigger resides.
TG_RELNAME	Name of the table where the trigger is located. (Currently, it is replaced by *TG_TABLE_NAME*, which has the same function. You are advised to use *TG_TABLE_NAME*.)

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Variable	Description
TG_TABLE_NAME	Name of the table where the trigger resides.
TG_TABLE_SCHEMA	Schema of the table where the trigger resides.
TG_NARGS	Number of parameters for the trigger function.
TG_ARGV[]	List of parameters for the trigger function.

Examples

```
-- Create a source table and a destination table.
gaussdb=# CREATE TABLE test_trigger_src_tbl(id1 INT, id2 INT, id3 INT);
gaussdb=# CREATE TABLE test_trigger_des_tbl(id1 INT, id2 INT, id3 INT);
```

Using the INSERT trigger

```
-- Create an INSERT trigger function.
gaussdb=# CREATE OR REPLACE FUNCTION tri_insert_func() RETURNS TRIGGER AS
        $$
        DECLARE
        BEGIN
                INSERT INTO test_trigger_des_tbl VALUES(NEW.id1, NEW.id2, NEW.id3);
                RETURN NEW;
        END
        $$ LANGUAGE plpgsql;

-- Create an INSERT trigger.
gaussdb=# CREATE TRIGGER insert_trigger
        BEFORE INSERT ON test_trigger_src_tbl
        FOR EACH ROW
        EXECUTE PROCEDURE tri_insert_func();

-- Execute the INSERT event and check the trigger results.
gaussdb=# INSERT INTO test_trigger_src_tbl VALUES(100,200,300);

gaussdb=# SELECT * FROM test_trigger_src_tbl;
 id1 | id2 | id3
-----+-----+-----
 100 | 200 | 300
(1 row)

gaussdb=# SELECT * FROM test_trigger_des_tbl; // Check whether the trigger operation takes effect.
 id1 | id2 | id3
-----+-----+-----
 100 | 200 | 300
(1 row)
```

Using the UPDATE trigger

```
-- Create an UPDATE trigger function.
gaussdb=# CREATE OR REPLACE FUNCTION tri_update_func() RETURNS TRIGGER AS
$$
DECLARE
BEGIN
UPDATE test_trigger_des_tbl SET id3 = NEW.id3 WHERE id1=OLD.id1;
RETURN OLD;
END
$$ LANGUAGE plpgsql;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
-- Create an UPDATE trigger.
gaussdb=# CREATE TRIGGER update_trigger
        AFTER UPDATE ON test_trigger_src_tbl
        FOR EACH ROW
        EXECUTE PROCEDURE tri_update_func();

-- Execute the UPDATE event and check the trigger results.
gaussdb=# UPDATE test_trigger_src_tbl SET id3=400 WHERE id1=100;

gaussdb=# SELECT * FROM test_trigger_src_tbl;
 id1 | id2 | id3
-----+-----+-----
 100 | 200 | 400
(1 row)

gaussdb=# SELECT * FROM test_trigger_des_tbl; // Check whether the trigger operation takes effect.
 id1 | id2 | id3
-----+-----+-----
 100 | 200 | 400
(1 row)
```

Using the DELETE trigger

```
-- Create a DELETE trigger function.
gaussdb=# CREATE OR REPLACE FUNCTION TRI_DELETE_FUNC() RETURNS TRIGGER AS
        $$
        DECLARE
        BEGIN
                DELETE FROM test_trigger_des_tbl WHERE id1=OLD.id1;
                RETURN OLD;
        END
        $$ LANGUAGE plpgsql;

-- Create a DELETE trigger.
gaussdb=# CREATE TRIGGER delete_trigger BEFORE DELETE ON test_trigger_src_tbl FOR EACH ROW
EXECUTE PROCEDURE tri_delete_func();

-- Execute the DELETE event and check the trigger results.
gaussdb=# DELETE FROM test_trigger_src_tbl WHERE id1=100;

gaussdb=# SELECT * FROM test_trigger_src_tbl;
 id1 | id2 | id3
-----+-----+-----
(0 rows)

gaussdb=# SELECT * FROM test_trigger_des_tbl; // Check whether the trigger operation takes effect.
 id1 | id2 | id3
-----+-----+-----
(0 rows)
```

Renaming a trigger

```
-- Rename a trigger.
gaussdb=# ALTER TRIGGER delete_trigger ON test_trigger_src_tbl RENAME TO delete_trigger_renamed;
```

Disabling triggers

```
-- Disable insert_trigger.
gaussdb=# ALTER TABLE test_trigger_src_tbl DISABLE TRIGGER insert_trigger;

gaussdb=# INSERT INTO test_trigger_src_tbl VALUES(100,200,300);

gaussdb=# SELECT * FROM test_trigger_src_tbl;
 id1 | id2 | id3
-----+-----+-----
 100 | 200 | 300
(1 row)

gaussdb=# SELECT * FROM test_trigger_des_tbl; // View that the trigger does not take effect.
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
 id1 | id2 | id3
-----+-----+-----
(0 rows)

-- Disable all triggers on the current table.
gaussdb=# ALTER TABLE test_trigger_src_tbl DISABLE TRIGGER ALL;
```

Dropping triggers

```
gaussdb=# DROP TRIGGER insert_trigger ON test_trigger_src_tbl;

gaussdb=# DROP TRIGGER update_trigger ON test_trigger_src_tbl;

gaussdb=# DROP TRIGGER delete_trigger_renamed ON test_trigger_src_tbl;
```

Dropping functions

```
gaussdb=# DROP FUNCTION tri_insert_func;

gaussdb=# DROP FUNCTION tri_update_func;

gaussdb=# DROP FUNCTION tri_delete_func;
-- Drop the source table and destination table.
gaussdb=# DROP TABLE test_trigger_src_tbl;
gaussdb=# DROP TABLE test_trigger_des_tbl;
```

ALTER TRIGGER, **DROP TRIGGER**, and **ALTER TABLE**

1.13.9.53 CREATE TYPE

Description

Defines a new data type for use in the current database.

Currently, only these types are available: composite type, base type, shell type, enumerated (enum) type, and set type. Here are the details for each type:

- Composite type

  A composite type is specified by a list of attribute names and data types. If the data type of an attribute is collatable, the attribute's collation can also be specified. This is essentially the same as the row type of a table, but using CREATE TYPE avoids the need to create an actual table when all that is wanted is to define a type. A stand-alone composite type is useful as the parameter or return type of a function.

  To create a composite type, you must have the USAGE permission on all of its attribute types.

- Base type

  You can create a base type (scalar type).

- Shell type

  A shell type is simply a placeholder for a type to be defined later; it is created by issuing CREATE TYPE with no parameters except for the type name. Shell types are needed as forward references when base types are created.

- Enumerated type

  An enumerated type is a list of one or more quoted labels, each of which must be 1 to 64 bytes long.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- Set type

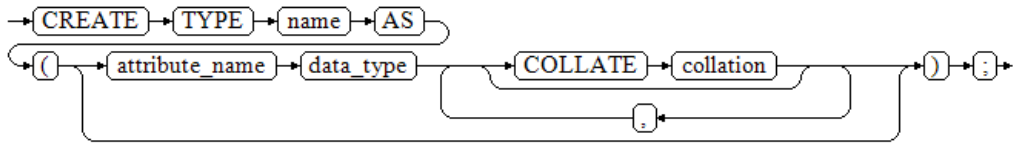
  It is similar to an array but has no length limit. It is mainly used in stored procedures.

Precautions

- If a schema name is specified, the type is created in the specified schema. Otherwise, it is created in the current schema.
- The type name must be distinct from the name of any existing type or table in the same schema. (Because tables have associated data types, the name of the new type must also be distinct from the name of any existing table in the same schema.)
- The user who defines a type becomes its owner.
- Users with the CREATE ANY TYPE permission can create types in the PUBLIC and user schemas.
- Types are designed only for row-store tables.
- When creating a non-system type by associating a function, the user needs to understand the definition of the new type and the associated function. If the operation is improper, permissions may be abused due to the associated function.

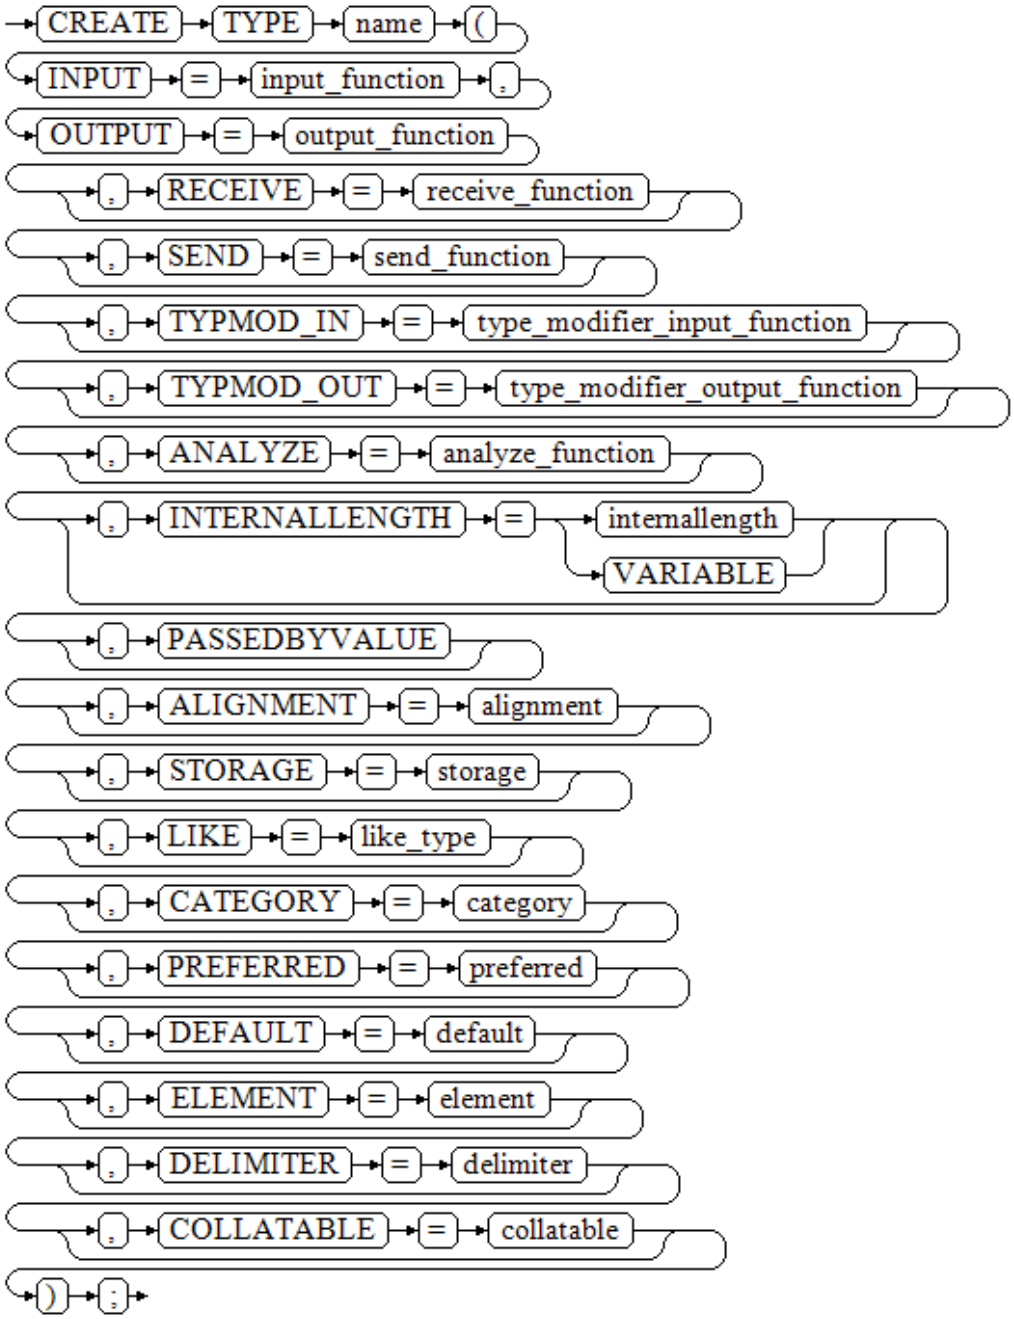
Syntax

```
CREATE TYPE name AS
    ( [ attribute_name data_type [ COLLATE collation ] [, ... ] ] );
```



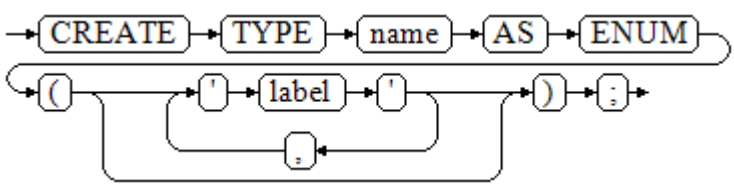
```
CREATE TYPE name (
    INPUT = input_function,
    OUTPUT = output_function
    [ , RECEIVE = receive_function ]
    [ , SEND = send_function ]
    [ , TYPMOD_IN = type_modifier_input_function ]
    [ , TYPMOD_OUT = type_modifier_output_function ]
    [ , ANALYZE = analyze_function ]
    [ , INTERNALLENGTH = { internallength | VARIABLE } ]
    [ , PASSEDBYVALUE ]
    [ , ALIGNMENT = alignment ]
    [ , STORAGE = storage ]
    [ , LIKE = like_type ]
    [ , CATEGORY = category ]
    [ , PREFERRED = preferred ]
    [ , DEFAULT = default ]
    [ , ELEMENT = element ]
    [ , DELIMITER = delimiter ]
    [ , COLLATABLE = collatable ]
);
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.



```
CREATE TYPE name;
```

```
CREATE TYPE name AS ENUM
    ( [ {'label'} [, ... ] ] );
```



```
CREATE TYPE name AS TABLE OF data_type;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameters

- Composite type
  - **name**

    Specifies the name (optionally schema-qualified) of the type to be created.
  - **attribute_name**

    Specifies the name of an attribute (column) for the composite type.
  - **data_type**

    Specifies the name of an existing data type to become a column of the composite type. You can use **%RowType** to indirectly reference the type of a table, or **%Type** to indirectly reference the type of a column in a table or a composite type.
  - **collation**

    Specifies the name of an existing collation to be associated with a column of the composite type. You can run the **SELECT * FROM pg_collation;** command to query collations from the pg_collation system catalog. The row starting with **default** in the query result represents the default collation.

    NOTE

    The constructor of the composite type can use the => to assign values. The restrictions are as follows:

    - The => function is used when the constructor of a composite type assigns values. This function is supported only in an ORA-compatible database (**sql_compatibility** set to **'ORA'**).
    - The constructor of the composite type uses the => function to assign values. This function is supported only when => is consecutively used to assign values to input parameters, for example, **composite_name(elename1 => val1, elename2 => val2, elename3 => val3)** or **composite_name(val1, elename2 => val2, elename3 => val3)**. Discontinuous use of => or => is not supported. The last input parameter, for example, **composite_name(elename1 => val1, elename2 => val2, val3)** or **composite_name(val1, elename2 => val2, val3)**, is not assigned a value.
- Base type: When creating a base type, you can place parameters in any order. The **input_function** and **output_function** parameters are required, and other parameters are optional.
  - **input_function**

    Specifies the name of a function that converts data from the type's external textual form to its internal form.

    The input function can be declared as taking one parameter of the CSTRING type, or as taking three parameters of the CSTRING, OID, and INTEGER types.

    - The CSTRING-type parameter is the input text as a C string.
    - The OID-type parameter is the type's own OID (except for array types, which instead receive their element type's OID).

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- The INTEGER-type parameter is the typmod of the destination column, if known (**-1** will be passed if not).

The input function must return a value of the data type itself. Usually, an input function should be declared STRICT; if it is not, it will be called with a NULL first parameter when reading a NULL input value. The function must still return NULL in this case, unless it raises an error.

NOTE

- The input and output functions can be declared to have results or parameters of the new type, when they have to be created before the new type can be created. The type should first be defined as a shell type, which is a placeholder type that has no attributes except a name and an owner. This is done by issuing the **CREATE TYPE** *name* command, with no additional parameters. Then, the I/O functions written in C can be defined as referencing the shell type. Finally, CREATE TYPE with a full definition replaces the shell entry with a complete, valid type definition, after which the new type can be used normally.
- If the input and output functions are of the INTERNAL type and specified as internal system functions, they must share the same parameter types. Additionally, **INTERNALLENGTH** and **PASSEDBYVALUE** of the new type should also match the parameter types of the input and output functions.

– **output_function**

Specifies the name of a function that converts data from the type's internal form to its external textual form.

The output function must be declared as taking one parameter of the new data type. The output function must return type CSTRING. Output functions are not called for **NULL** values.

– **receive_function**

(Optional) Specifies the name of a function that converts data from the type's external binary form to its internal form.

If this function is not supplied, the type cannot participate in binary input. The binary representation should be chosen to be cheap to convert to internal form, while being reasonably portable. (For example, the standard integer data types use network byte order as the external binary representation, while the internal representation is in the machine's native byte order.) The receive function should perform adequate checking to ensure that the value is valid.

The receive function can be declared as taking one parameter of the INTERNAL type, or as taking three parameters of the INTERNAL, OID, and INTEGER types.

- The INTERNAL-type parameter is a pointer to a StringInfo buffer holding the received byte string.
- The OID- and INTEGER-type parameters are the same as for the text input function.

The receive function must return a value of the data type itself. Usually, a receive function should be declared STRICT; if it is not, it will be called with a NULL first parameter when reading a NULL input value. The function must still return NULL in this case, unless it raises an error.

– **send_function**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

(Optional) Specifies the name of a function that converts data from the type's internal form to its external binary form.

If this function is not supplied, the type cannot participate in binary output. The send function must be declared as taking one parameter of the new data type. The send function must return type BYTEA. Send functions are not called for **NULL** values.

- **type_modifier_input_function**

  (Optional) Specifies the name of a function that converts an array of modifiers for a type to its internal format.

- **type_modifier_output_function**

  (Optional) Specifies the name of a function that converts the internal format of modifiers for a type to its external text format.

  NOTE

  type_modifier_input_function and **type_modifier_output_function** are needed if the type supports modifiers, that is optional constraints attached to a type declaration, such as char(5) or numeric(30,2). GaussDB allows user-defined types to take one or more simple constants or identifiers as modifiers. However, this information must be capable of being packed into a single non-negative integer value for storage in the system catalogs. The **type_modifier_input_function** is passed the declared modifiers in the form of a CSTRING array. It must check the values for validity (throwing an error if they are wrong), and if they are correct, return a single non-negative integer value that will be stored as the column "typmod". Type modifiers will be rejected if the type does not have a **type_modifier_input_function**. The **type_modifier_output_function** converts the internal integer typmod value back to the correct form for user display. It must return a CSTRING value that is the exact string to append to the type name. For example, a numeric function may return (30,2). It is allowed to omit the **type_modifier_output_function**, in which case the default display format is just the stored typmod integer value enclosed in parentheses.

- **analyze_function**

  (Optional) Specifies the name of a function that performs type-specific statistics collection for columns of the data type.

  By default, ANALYZE will attempt to collect statistics using the type's "equals" and "less-than" operators, if there is a default B-tree operator class for the type. For non-scalar types, this behavior is likely to be unsuitable, so it can be overridden by specifying a custom analysis function. The analysis function must be declared to take a single parameter of the INTERNAL type and return a Boolean result.

- **internallength**

  (Optional) Specifies the length in bytes of the new type's internal representation. The default assumption is that it is variable-length.

  While the details of the new type's internal representation are only known to the I/O functions and other functions you create to work with the type, there are several attributes of the internal representation that must be declared to GaussDB. Foremost of these is **INTERNALLENGTH**. Base data types can be fixed-length, in which case **internallength** is a positive integer, or variable-length, indicated by setting **INTERNALLENGTH** to **VARIABLE**. (Internally, this is represented by setting **typlen** to **-1**.) The internal representation of all variable-length types must start with a 4-byte integer and follow the total length defined by **internallength**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **PASSEDBYVALUE**

  (Optional) Indicates that values of this data type are passed by value, rather than by reference. Types passed by value must be fixed-length, and their internal representation cannot be larger than the size of the Datum type (4 bytes on some machines, 8 bytes on others).

- **alignment**

  (Optional) Specifies the storage alignment requirement of the data type. If specified, it must be **CHAR**, **INT2**, **INT4**, or **DOUBLE**; the default is **INT4**.

  The allowed values equate to alignment on 1, 2, 4, or 8 byte boundaries. Note that variable-length types must have an alignment of at least 4, since they necessarily contain an INT4 as their first component.

- **storage**

  (Optional) Specifies the storage strategy for the data type.

  If specified, it must be **plain**, **external**, **extended**, or **main**; the default is **plain**.

  - **plain** specifies that data of the type will always be stored in-line and not compressed. (Only **plain** is allowed for fixed-length types.)
  - **extended** specifies that the system will first attempt to compress a long data value, and will move the value out of the main table row if it is still too long.
  - **external** allows the value to be moved out of the main table, but the system will not attempt to compress it.
  - **main** allows compression, but discourages moving the value out of the main table. (Data items with this storage strategy might still be moved out of the main table if there is no other way to make a row fit, but they will be kept in the main table preferentially over **extended** and **external** items.)

  All **storage** values other than **plain** imply that the functions of the data type can handle values that have been toasted. The specific other value given merely determines the default TOAST storage strategy for columns of a TOAST data type; users can pick other strategies for individual columns using ALTER TABLE SET STORAGE.

- **like_type**

  (Optional) Specifies the name of an existing data type that the new type will have the same representation as. The values of **internallength**, **passedbyvalue**, **alignment**, and **storage** are copied from that type, unless overridden by explicit specification elsewhere in this **CREATE TYPE** statement.

  Specifying representation this way is especially useful when the low-level implementation of the new type "piggybacks" on an existing type in some fashion.

- **category**

  (Optional) Specifies the category code (a single ASCII character) for this type. The default is **U** for a user-defined type. You may also choose other ASCII characters to create custom categories.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **preferred**

  (Optional) Specifies whether a type is preferred within its type category. If it is, the value will be **true**, else **false**. The default is **false**. Be very careful about creating a preferred type within an existing type category, as this could cause surprising changes in behavior.

  NOTE

  The **category** and **preferred** parameters can be used to help control which implicit cast will be applied in ambiguous situations. Each data type belongs to a category named by a single ASCII character, and each type is either preferred or not within its category. The parser will prefer casting to preferred types (but only from other types within the same category) when this rule is helpful in resolving overloaded functions or operators. For types that have no implicit casts to or from any other types, it is sufficient to leave these settings at the defaults. However, for a group of related types that have implicit casts, it is often helpful to mark them all as belonging to a category and select one or two of the most general types as being preferred within the category. The **category** parameter is especially useful when adding a user-defined type to an existing built-in category, such as the numeric or string types. However, it is also possible to create entirely-user-defined type categories. Select any ASCII character other than an uppercase letter to name such a category.

- **default**

  (Optional) Specifies the default value for the data type. If this is omitted, the default is null.

  A default value can be specified, in case a user wants columns of the data type to default to something other than the null value. Specify the default with the DEFAULT keyword. (Such a default can be overridden by an explicit DEFAULT clause attached to a particular column.)

- **element**

  (Optional) Specifies the type of array elements when an array type is created. For example, to define an array of 4-byte integers (INT4), specify **ELEMENT = INT4**.

- **delimiter**

  (Optional) Specifies the delimiter character to be used between values in arrays made of this type.

  delimiter can be set to a specific character. The default delimiter is the comma (,). Note that the delimiter is associated with the array element type, not the array type itself.

- **collatable**

  (Optional) Specifies whether this type's operations can use collation information. If they can, the value will be **true**. The default is **false**.

  If **collatable** is **true**, column definitions and expressions of the type may carry collation information through use of the COLLATE clause. It is up to the implementations of the functions operating on the type to actually make use of the collation information; this does not happen automatically merely by marking the type collatable.

- **label**

  (Optional) Represents the textual label associated with one value of an enumerated type. It is a string of 1 to 63 characters.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

Whenever a user-defined type is created, GaussDB automatically creates an associated array type whose name consists of the element type's name prepended with an underscore (_).

Examples

```
-- Create a composite type, create a table, insert data, and make a query.
gaussdb=# CREATE TYPE compfoo AS (f1 int, f2 text);
gaussdb=# CREATE TABLE t1_compfoo(a int, b compfoo);
gaussdb=# CREATE TABLE t2_compfoo(a int, b compfoo);
gaussdb=# INSERT INTO t1_compfoo values(1,(1,'demo'));
gaussdb=# INSERT INTO t2_compfoo SELECT * FROM t1_compfoo;
gaussdb=# SELECT (b).f1 FROM t1_compfoo;
gaussdb=# SELECT * FROM t1_compfoo t1 JOIN t2_compfoo t2 ON (t1.b).f1=(t1.b).f1;

-- Rename the data type.
gaussdb=# ALTER TYPE compfoo RENAME TO compfoo1;

-- Change the owner of the user-defined type compfoo1 to usr1.
gaussdb=# CREATE USER usr1 PASSWORD '********';
gaussdb=# ALTER TYPE compfoo1 OWNER TO usr1;

-- Change the schema of the user-defined type compfoo1 to usr1.
gaussdb=# ALTER TYPE compfoo1 SET SCHEMA usr1;

-- Add a new attribute to the data type.
gaussdb=# ALTER TYPE usr1.compfoo1 ADD ATTRIBUTE f3 int;

-- Drop the compfoo1 type.
gaussdb=# DROP TYPE usr1.compfoo1 CASCADE;

-- Drop related tables and users.
gaussdb=# DROP TABLE t1_compfoo;
gaussdb=# DROP TABLE t2_compfoo;
gaussdb=# DROP SCHEMA usr1;
gaussdb=# DROP USER usr1;

-- Create an enumerated type.
gaussdb=# CREATE TYPE bugstatus AS ENUM ('create', 'modify', 'closed');

-- Add a label.
gaussdb=# ALTER TYPE bugstatus ADD VALUE IF NOT EXISTS 'regress' BEFORE 'closed';

-- Rename a label.
gaussdb=# ALTER TYPE bugstatus RENAME VALUE 'create' TO 'new';

-- Create a set type.
gaussdb=# CREATE TYPE bugstatus_table AS TABLE OF bugstatus;

-- Drop a set type.
gaussdb=# DROP TYPE bugstatus_table;
-- Drop an enumerated type.
gaussdb=# DROP TYPE bugstatus CASCADE;
-- Create an ORA-compatible database and switch to this database.

ALTER TYPE and **DROP TYPE**

1.13.9.54 CREATE USER

Description

Creates a user with a specified password.

A user is a basic element for GaussDB authentication. A user can use the correct username and password to log in to the GaussDB and grant different permissions to different users so that different users can perform different operations.

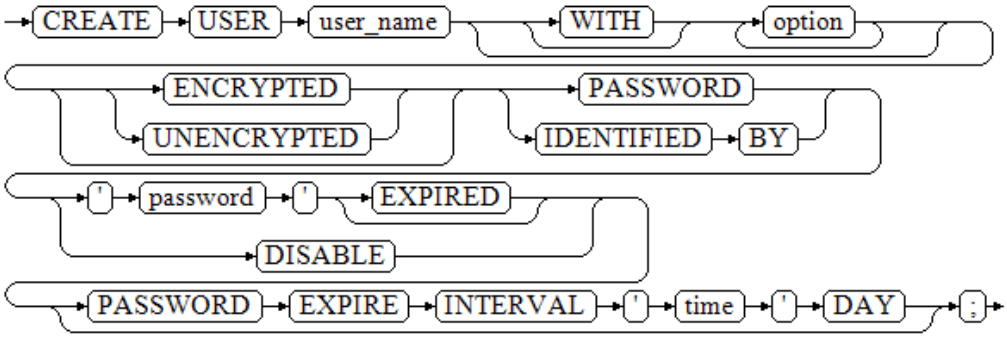
 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Precautions

- A user created using the CREATE USER statement has the LOGIN permission by default.
- When you run the **CREATE USER** command to create a user, the system creates a schema with the same name as the user in the database where the command is executed.
- If a system administrator creates an object in the schema with the same name as a common user, the ownership of the object will be assigned to the common user rather than the system administrator.

Syntax

```
CREATE USER user_name [ [ WITH ] option [ ... ] ] [ ENCRYPTED | UNENCRYPTED ] { PASSWORD |
IDENTIFIED BY } { 'password' [EXPIRED] | DISABLE }[ PASSWORD EXPIRE INTERVAL 'time' DAY ];
```



The option clause is used to configure information, including permissions and properties.

```
{
   {SYSADMIN | NOSYSADMIN}
   | {MONADMIN | NOMONADMIN}
   | {OPRADMIN | NOOPRADMIN}
   | {POLADMIN | NOPOLADMIN}
   | {AUDITADMIN | NOAUDITADMIN}
   | {CREATEDB | NOCREATEDB}
   | {USEFT | NOUSEFT}
   | {CREATEROLE | NOCREATEROLE}

}
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameters

- **user_name**

  Name of the user to be created.

  Value range: character strings complying with **Identifier Naming Conventions** and not exceeding 63 characters.

  If the username entered exceeds 63 characters, the database will truncate it and keep the first 63 characters.

  If a username contains uppercase letters, the database automatically converts the uppercase letters into lowercase letters. To create a username that contains uppercase letters, declare the username with double quotation marks ("").

  NOTICE

  redisuser is used for managing redistributed resources. It is currently not possible to create a user with **user_name** set as **redisuser**.

- **password**

  Specifies the login password.

  Value range: character strings.

  Password rules:

  – Contain at least eight characters. This is the default length.

  – Differ from the username or the username spelled backward.

  – Contain at least three of the following character types: uppercase characters, lowercase characters, digits, and special characters (limited to ~!@#$%^&*()-_=+\|[{}];:,<.>/?). If the password contains characters other than the preceding characters, an error will be reported during statement execution.

  – The password can also be a ciphertext character string that meets the format requirements. It is mainly used to import user data. You are advised not to use it directly. The database does not verify the complexity of the ciphertext password. Using the ciphertext password may cause data security risks. If you use the ciphertext password, you need to know the plaintext corresponding to the ciphertext password and ensure that the password meets the complexity requirements.

  – When creating a user, use single or double quotation marks to declare the user password.

- For details about other parameters, see **CREATE ROLE**.

Examples

```
-- Create user jim whose login password is ********.
gaussdb=# CREATE USER jim PASSWORD '********';

-- Create user kim whose login password is ********.
gaussdb=# CREATE USER kim IDENTIFIED BY '********';

-- Create user tom.
gaussdb=# CREATE USER TOM PASSWORD '********';
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
-- Create user TOM.
gaussdb=# CREATE USER "TOM" PASSWORD '********';

-- To create a user with the CREATEDB permission, add the CREATEDB keyword.
gaussdb=# CREATE USER dim CREATEDB PASSWORD '********';

-- Query the permissions of the dim user.
gaussdb=#  \du dim

ALTER USER, **CREATE ROLE**, and **DROP USER**

1.13.9.55 CREATE VIEW

Description

Creates a view. A view is a virtual table, not a base table. A database stores only the view definition but not the view data. The view data is stored in a base table. If data in the base table changes, the data in the view changes accordingly. In this

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

sense, a view is like a window through which users can know their interested data and data changes in the database.

- You can define frequently used data as views to encapsulate complex query SQL statements, which simplifies operations.
- You can query only data defined in a view, which is secure. Columns in a base table are hidden to protect the data structure of the database.
- User permission management is simplified. Only the permission to use views is granted to users.

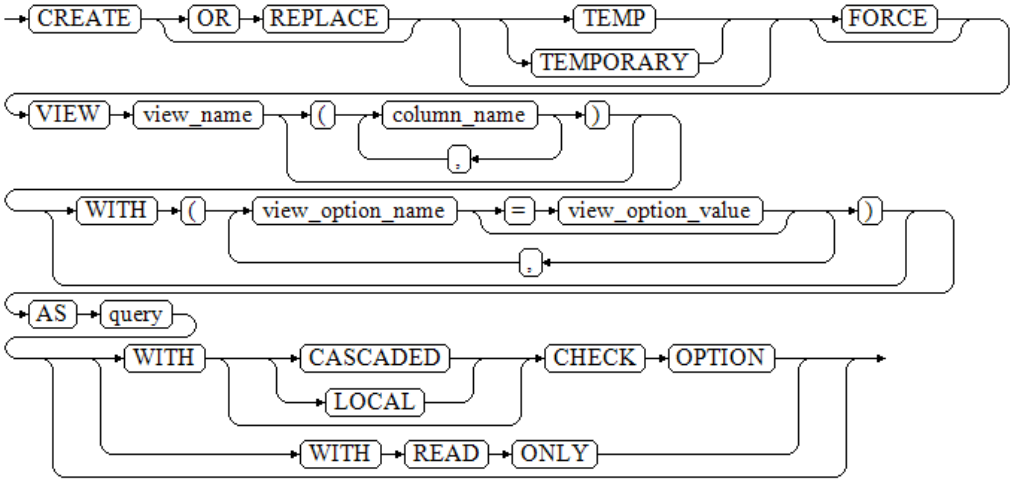
Precautions

A user with the CREATE ANY TABLE permission can create views in the public and user schemas.

Non-initial users are not allowed to perform the CREATE OR REPLACE operation on system views in the SYS, DBE_PERF, and INFORMATION_SCHEMA schemas.

Syntax

```
CREATE [ OR REPLACE ] [ TEMP | TEMPORARY ] [ FORCE ] VIEW view_name [ ( column_name [, ...] ) ]
    [ WITH ( {view_option_name [= view_option_value]} [, ... ] ) ]
    AS query
    [ WITH [ CASCADED | LOCAL ] CHECK OPTION  | WITH READ ONLY ];
```



NOTE

- You can use WITH(security_barrier) to create a relatively secure view. This prevents attackers from printing base table data by using the RAISE statement of low-cost functions.
- Modifying column names or types, or dropping columns from a base view will automatically invalidate dependent views, regardless of the **enable_view_invalidation** setting.

Parameters

- **OR REPLACE**

  (Optional) Redefines the view if it already exists.

- **TEMP | TEMPORARY**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

(Optional) Creates a temporary view. The view is automatically deleted when the current session ends. If any table referenced by a view is a temporary table, the view is created as a temporary view (regardless of whether **TEMP|TEMPORARY** is specified in the SQL statement).

NOTE

- Temporary views do not support automatic recompilation.
- To recompile an invalid view, refer to "Feature Usage Guidelines > Recompilation upon Invalidation" in *Developer Guide*.

- **FORCE**

  (Optional) Successfully creates the view even if the objects it depends on are absent or the required query permissions are missing.

- **view_name**

  Specifies the name of the view to be created. It is optionally schema-qualified.

  Value range: character strings complying with **Identifier Naming Conventions**.

- **column_name**

  Specifies an optional list of names to be used for columns of the view. If not given, the column names are deduced from the query.

  Value range: character strings complying with **Identifier Naming Conventions**.

- **view_option_name [= view_option_value]**

  Specifies an optional parameter for a view.

  Currently, view_option_name supports only **security_barrier** and **check_option**.

  security_barrier: This parameter is used when the view attempts to provide row-level security. Value range: Boolean (**true** or **false**).

  check_option: controls the behavior of updating a view. Value range: **CASCADED** and **LOCAL**.

- **query**

  Specifies a SELECT or VALUES statement that will provide the columns and rows of the view.

NOTICE

If **query** contains a clause specifying the partition of a partitioned table, the OID of the specified partition is directly written to the system catalog when the view is created. However, using any DDL syntax that changes the OID of the specified partition—for example, DROP, SPLIT, or MERGE PARTITION—will render the view invalid. (Refer to "Feature Usage Guidelines > Recompilation upon Invalidation" in *Developer Guide*.)

- **WITH [CASCADED | LOCAL] CHECK OPTION**

  Controls the behavior of updatable views. INSERT and UPDATE on the view will be checked to ensure that new rows meet the view-defining condition, that is, the new rows are visible through the view. If the check fails, the update is rejected. If this option is not included, INSERT and UPDATE

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

operations on the view are permitted to create rows that are not visible through the view. When DELETE is performed on a view, if the base table from which data is to be deleted is duplicate in a multi-table join view and the duplicate base tables are not all key-reserved tables in the view, data cannot be deleted when **WITH CHECK OPTION** is specified. The **WITH CHECK OPTION** option can be specified as **CASCADED** or **LOCAL**.

CASCADED: New rows are checked against the conditions of the view and all underlying views. If **CHECK OPTION** is specified, and neither **LOCAL** nor **CASCADED** is specified, then **CASCADED** is used by default.

LOCAL: Only the conditions directly defined by the view itself are checked. If **CHECK OPTION** is also defined in the underlying views, the conditions defined in the underlying views are checked.

- **WITH READ ONLY**

  A read-only view is defined. You cannot insert, update, or delete data in the view.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- The concepts involved in the constraints on updating, inserting, and deleting views are described as follows:
  - Join view: view created with multiple tables using JOIN.
  - Key-preserved table: Insertion, update, and deletion of multi-table join views are restricted by key-preserved tables. In a multi-table view, if each row in the source table corresponds to each row in the view, and a row in the source table does not correspond to multiple rows in the view after the JOIN, the source table is a key-preserved table.
  - Currently, you can determine whether a target table is a key-preserved table only by using the JOIN condition. The equivalence class (that is, combining JOIN and WHERE) cannot be used to determine whether a target table is a key-preserved table.
  - Relationship between the top layer and the bottom layer: A view may be nested at multiple layers. For example, a view consists of one or more views or subqueries. The view that is directly operated by the DML is called the top layer. The tables and views that form the view and the tables and views in the WITH clause are called the corresponding bottom layer.
  - Columns that can be updated: Columns that are not system columns or whole-row references and directly reference user columns in the base table can be updated. You can query the **is_updatable** column in **information_schema.columns** to check whether a column in a view or table can be updated.
  - Updatable view: view that can be inserted, updated, or deleted. Updatable views do not contain DISTINCT, GROUP BY, HAVING, LIMIT, OFFSET, UNPIVOT, FOR UPDATE, FETCH and START WITH CONNECT BY clauses, set operations (UNION, INTERSECT, and EXCEPT), aggregate functions, window functions, and return set functions (array_agg, json_agg, and generate_series), and flashback. **WITH CHECK OPTION** can be defined only on updatable views. To check whether a view can be updated, query the **is_updatable** and **is_insertable_into** columns in **information_schema.views** or the **information_schema.tables.is_insertable_into** column. In **information_schema.views**, **is_updatable** specifies whether a view can be updated or deleted, **is_insertable_into** specifies whether data can be inserted into a view, and **information_schema.tables.is_insertable_into** specifies whether data can be inserted into a relationship.
- If an updatable view has an INSTEAD OF trigger or INSTEAD rule, using CHECK OPTION does not check the conditions on that view.
- If an underlying view of an updatable view has an INSTEAD OF trigger and the updatable view defines the **CHECK OPTION** option of the CASCADED type, in non-ORA-compatible mode, the conditions of the underlying view with the INSTEAD OF trigger are recursively checked, and the conditions of the underlying view with the trigger are not checked. In ORA-compatible mode, the **CHECK OPTION** option of all views is invalid and no check is performed.
- If an updatable view or any of its underlying relationships has an INSTEAD rule that causes INSERT or UPDATE rewriting, specifying **CHECK OPTION** will not check the conditions on all views.
- If **CASCADED CHECK OPTION** is defined in the upper-layer view and **LOCAL CHECK OPTION** is defined in the lower-layer view, **LOCAL CHECK OPTION** in the lower-layer view is overwritten by **CASCADED CHECK OPTION** in the upper-layer view.
- If **CHECK OPTION** is specified, insert and update operations cannot be performed on join columns in multi-table join views or multi-table join subqueries.
- If **CHECK OPTION** is specified, duplicate base tables exist in a multi-table join view or multi-table join subquery, and the duplicate base tables are not all key-preserved tables, the view or subquery cannot be deleted.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Examples

- Ordinary view

```
-- Create the test_tb1 table and insert 100 data records into the table.
gaussdb=# CREATE TABLE test_tb1(col1 int, col2 int);
gaussdb=# INSERT INTO test_tb1 VALUES (generate_series(1,100),generate_series(1,100));
-- Create a view whose value of col1 is less than 3.
gaussdb=# CREATE VIEW test_v1 AS SELECT * FROM test_tb1 WHERE col1 < 3;
-- Query a view.
gaussdb=# SELECT * FROM test_v1;
 col1 | col2
------+------
    1 |    1
    2 |    2
(2 rows)

-- Drop the table and view.
gaussdb=# DROP VIEW test_v1;
gaussdb=# DROP TABLE test_tb1;
```

- Read-only view

```
-- Create the test_tb table.
gaussdb=# CREATE TABLE test_tb(c1 int, c2 int);

-- Create the test_v read-only view.
gaussdb=# CREATE  VIEW test_v AS SELECT * FROM test_tb WITH READ ONLY;

-- Write data to the view to check whether the view is read-only.
gaussdb=# INSERT INTO test_v VALUES (1, 1);
ERROR:  DML operation cannot be performed on a read-only view.

-- Drop the table and view.
gaussdb=# DROP VIEW test_v;
gaussdb=# DROP TABLE test_tb;
```

- REPLACE application

```
-- Create tables a and b.
gaussdb=# CREATE TABLE a(c1 int, c2 int);

1.13.9.56 CREATE WEAK PASSWORD DICTIONARY

Description

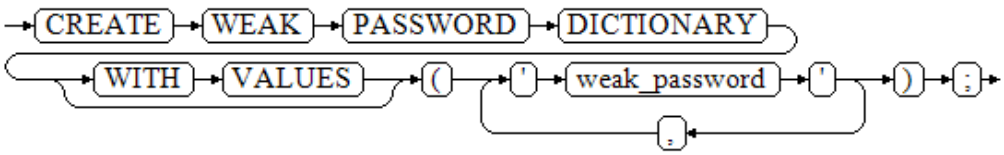
Creates a weak password dictionary. The weak password dictionary is empty by default. You can use this syntax to add one or more weak passwords to the gs_global_config system catalog.

Precautions

- Only the initial user, system administrators, and security administrators can execute it.
- Passwords in the weak password dictionary are stored in the gs_global_config system catalog.
- The weak password dictionary is empty by default. You can use this syntax to add one or more weak passwords to the gs_global_config system catalog.
- When a user attempts to execute this syntax to insert a weak password that already exists in the gs_global_config catalog, only one weak password is retained in the table.

Syntax

```
CREATE WEAK PASSWORD DICTIONARY
    [WITH VALUES] ( {'weak_password'} [, ...] );
```



Parameters

weak_password

Specifies a weak password.

Value range: character strings.

Examples

```
-- Insert a single weak password into the gs_global_config system catalog.
gaussdb=# CREATE WEAK PASSWORD DICTIONARY WITH VALUES ('********');

-- Check weak passwords in the gs_global_config system catalog.
gaussdb=# SELECT * FROM gs_global_config WHERE NAME LIKE 'weak_password';
     name       |    value
----------------+--------------
 weak_password   | ********
(1 rows)

-- Insert multiple weak passwords into the gs_global_config system catalog.
gaussdb=# CREATE WEAK PASSWORD DICTIONARY WITH VALUES ('********'),('********');
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
-- Check the weak password in the gs_global_config system catalog again. The asterisk (*) in a weak
password does not represent the password content.
gaussdb=# SELECT * FROM gs_global_config WHERE NAME LIKE 'weak_password';
     name       |     value
----------------+----------------
 weak_password   | ********
 weak_password   | ********
 weak_password   | ********
(3 rows)

-- Clear all weak passwords in the gs_global_config system catalog.
gaussdb=# DROP WEAK PASSWORD DICTIONARY;

-- View existing weak passwords.
gaussdb=# SELECT * FROM gs_global_config WHERE NAME LIKE 'weak_password';
 name | value
------+-------
(0 rows)
```

DROP WEAK PASSWORD DICTIONARY

1.13.9.57 CURSOR

Description

Creates a cursor to retrieve specified rows of data from a query.

To process SQL statements, the stored procedure thread assigns a memory segment to store context association. Cursors are handles or pointers pointing to context areas. With cursors, stored procedures can control alterations in context areas.

Precautions

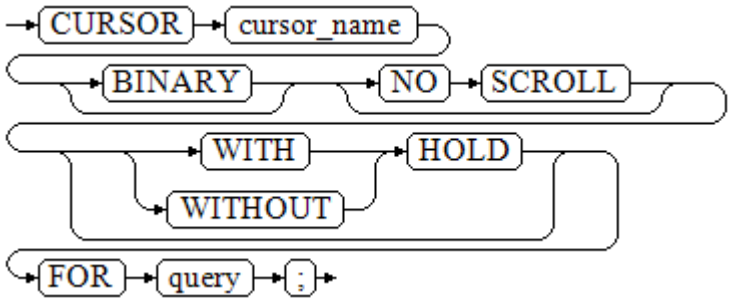
- CURSOR can only be in transaction blocks.
- Generally, CURSOR and SELECT both have text returns. Since data is stored in binary format in the system, the system needs to convert the data from the binary format to the text format. If data is returned in text format, client applications need to convert the data back to the binary format for processing. FETCH implements conversion between binary data and text data.
- Be cautious when using binary cursors. Text usually occupies larger space than binary data. A binary cursor returns internal binary data, which is easier to operate. A text cursor returns text, which is easier to retrieve and therefore reduces workload on the client. As an example, if a query returns a value of one from an integer column, you would get a string of 1 with a default cursor, whereas with a binary cursor you would get a 4-byte value containing the internal representation of the value (in big-endian byte order).
- Parameters can be defined for static cursors. The parameters support default values. However, the default value of a parameter cannot be a variable outside the package. You can define a variable in the package, assign the variable outside the package to the defined variable, and use the variable as the default value.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- The definition of a cursor generates a query object. Currently, packages or stored procedures do not support the creation of dependencies on query objects.

Syntax

```
CURSOR cursor_name
    [ BINARY ]  [ NO SCROLL ]  [ { WITH | WITHOUT } HOLD ]
    FOR query;
```



Parameters

- **cursor_name**

  Specifies the name of the cursor to be created.

  Value range: character strings complying with **Identifier Naming Conventions**.

- **BINARY**

  Specifies that the cursor returns data in binary format rather than text format.

- **NO SCROLL**

  Specifies how the cursor retrieves rows.

  - **NO SCROLL**: specifies that the cursor cannot be used to retrieve rows in a nonsequential fashion.
  - Unspecified: Based on the query's execution plan, the system automatically determines whether the cursor can be used to retrieve rows in a nonsequential fashion.

- **WITH HOLD | WITHOUT HOLD**

  Specifies whether the cursor can continue to be used after the transaction that created it successfully commits. If neither **WITH HOLD** nor **WITHOUT HOLD** is specified, **WITHOUT HOLD** is the default.

  - **WITH HOLD**: The cursor can continue to be used after the transaction that created it successfully commits.
  - **WITHOUT HOLD**: The cursor cannot be used outside of the transaction that created it. It will be automatically closed when the transaction ends.

  Cross-node transactions (like those created with DDL statements in a cluster deployed with multiple Coordinators) do not support **WITH HOLD**.

- **query**

  Uses the SELECT or VALUES clause to specify the rows to be returned by a cursor.

  Value range: SELECT or VALUES clause

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Examples

Example 1:

```
-- Create a table and insert data into the table.
gaussdb=# CREATE TABLE tbl_test(c1 int);
gaussdb=# INSERT INTO tbl_test VALUES (generate_series(1,20));

-- Set up cursor1.
gaussdb=# BEGIN;
gaussdb=# CURSOR cursor1 FOR SELECT * FROM tbl_test ORDER BY 1;

-- Run the FETCH command to retrieve three rows of data.
gaussdb=# FETCH FORWARD 3 FROM cursor1;
 c1
----
  1
  2
  3
(3 rows)

-- Run the MOVE command to move the cursor backwards by two rows. No result is returned.
gaussdb=# MOVE FORWARD 2 FROM cursor1;
MOVE 2

-- Run the FETCH command to retrieve two rows of data.
gaussdb=# FETCH FORWARD 2 FROM cursor1;
 c1
----
  6
  7
(2 rows)

-- Close the cursor and end the transaction.
gaussdb=# CLOSE cursor1;
gaussdb=# END;
```

Example 2: Cursor with the WITH HOLD attribute

```
-- Set up a WITH HOLD cursor named cursor2.
gaussdb=# BEGIN;
gaussdb=# CURSOR cursor2 WITH HOLD FOR SELECT * FROM tbl_test ORDER BY 1;

-- Run the FETCH command to retrieve three rows of data.
gaussdb=# FETCH FORWARD 3 FROM cursor2;
 c1
----
  1
  2
  3
(3 rows)

-- Different from common cursors, cursors with the WITH HOLD attribute can still be used after a
transaction ends.
gaussdb=# END;
gaussdb=# FETCH FORWARD 2 FROM cursor2;
 c1
----
  4
  5
(2 rows)

-- Close the cursor.
gaussdb=# CLOSE cursor2;

-- Drop.
gaussdb=# DROP TABLE tbl_test;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

FETCH, **CLOSE**, and **MOVE**

1.13.10 D

1.13.10.1 DEALLOCATE

Description

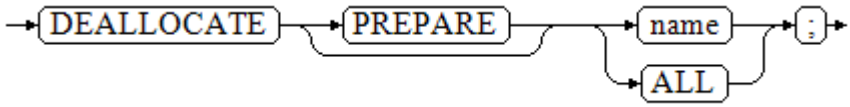
Deallocates a prepared statement from the database.

Precautions

You can use DEALLOCATE to manually deallocate prepared statements created using PREPARE. If not explicitly deallocated, these statements will be automatically cleared when the session ends.

Syntax

```
DEALLOCATE [ PREPARE ] { name | ALL };
```



Parameters

- **PREPARE**

  (Optional) It is provided solely for syntax compatibility and will be ignored during actual execution.

- **name**

  Specifies the name of the prepared statement to be deallocated.

- **ALL**

  Deallocates all prepared statements.

Examples

```
-- View existing prepared statements.
gaussdb=# SELECT name, statement, parameter_types FROM pg_prepared_statements;
 name | statement | parameter_types
------+-----------+-----------------
(0 rows)

-- Create four prepared statements q1, q2, q3, and q4.
gaussdb=# PREPARE q1 AS SELECT 1 AS a;
PREPARE
gaussdb=# PREPARE q2 AS SELECT 1 AS a;
PREPARE
gaussdb=# PREPARE q3 AS SELECT 1 AS a;
PREPARE
gaussdb=# PREPARE q4 AS SELECT 1 AS a;
PREPARE

-- View existing prepared statements again.
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gaussdb=# SELECT name, statement, parameter_types FROM pg_prepared_statements;
 name |          statement          | parameter_types
------+-----------------------------+-----------------
 q1   | PREPARE q1 AS SELECT 1 AS a; | {}
 q4   | PREPARE q4 AS SELECT 1 AS a; | {}
 q3   | PREPARE q3 AS SELECT 1 AS a; | {}
 q2   | PREPARE q2 AS SELECT 1 AS a; | {}
(4 rows)

-- Deallocate the prepared statement q4 and view the remaining prepared statements.
gaussdb=# DEALLOCATE q4;
gaussdb=# SELECT name, statement, parameter_types FROM pg_prepared_statements;
 name |          statement          | parameter_types
------+-----------------------------+-----------------
 q1   | PREPARE q1 AS SELECT 1 AS a; | {}
 q3   | PREPARE q3 AS SELECT 1 AS a; | {}
 q2   | PREPARE q2 AS SELECT 1 AS a; | {}
(3 rows)

-- Deallocate all prepared statements and view the remaining prepared statements.
gaussdb=# DEALLOCATE ALL;
DEALLOCATE ALL
gaussdb=# SELECT name, statement, parameter_types FROM pg_prepared_statements;
 name | statement | parameter_types
------+-----------+-----------------
(0 rows)
```

1.13.10.2 DECLARE

Description

Defines a cursor to retrieve a small number of rows at a time out of a larger query or declares an anonymous block (DECLARE must lead the statement of the anonymous block).

This section describes usage of cursors. The usage of anonymous blocks is available in **BEGIN**.

To process SQL statements, the stored procedure thread allocates a memory area to store context relationships. A cursor is a handle or pointer that points to the context area. With cursors, stored procedures can control alterations in context areas.

Normal cursors return data in text format, the same as a SELECT would produce. Since data is stored in binary format in the system, the system needs to convert the data from the binary format to the text format. If data is returned in text format, client applications need to convert the data back to the binary format for processing. Cursors can return data in either text or binary format using FETCH.

Precautions

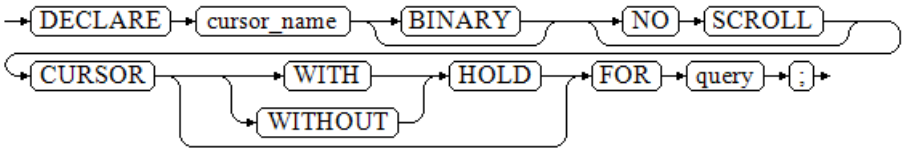
- CURSOR is used only in transaction blocks.
- Be cautious when using binary cursors. Text usually occupies larger space than binary data. A binary cursor returns internal binary data, which is easier to operate. A text cursor returns text, which is easier to retrieve and therefore reduces workload on the client. As an example, if a query returns a value of one from an integer column, you would get a string of 1 with a default cursor, whereas with a binary cursor you would get a 4-byte value containing the internal representation of the value (in big-endian byte order).

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Syntax

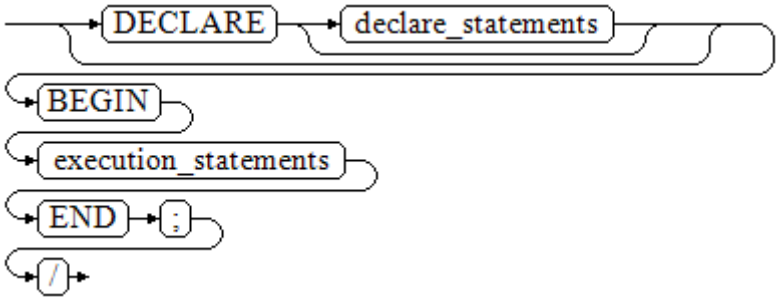
- Define a cursor.

```
DECLARE cursor_name [ BINARY ] [ NO SCROLL ]
    CURSOR [ { WITH | WITHOUT } HOLD ] FOR query;
```



- Enable an anonymous block.

```
[DECLARE [declare_statements]]
BEGIN
execution_statements
END;
/
```



Parameters

- **cursor_name**

  Specifies the name of the cursor to be created.

  Value range: character strings complying with **Identifier Naming Conventions**.

- **BINARY**

  Specifies that the cursor returns data in binary rather than text format.

- **NO SCROLL**

  Specifies how the cursor retrieves rows.

  – **NO SCROLL**: The cursor cannot be used to retrieve rows in a nonsequential fashion.

  – Unspecified: Based on the query's execution plan, the system automatically determines whether the cursor can be used to retrieve rows in inverse order.

- **WITH HOLD | WITHOUT HOLD**

  Specifies whether the cursor can continue to be used after the transaction that created it successfully commits. If neither **WITH HOLD** nor **WITHOUT HOLD** is specified, **WITHOUT HOLD** is the default.

  – **WITH HOLD**: The cursor can continue to be used after the transaction that created it successfully commits.

  – **WITHOUT HOLD**: The cursor cannot be used outside of the transaction that created it. It will be automatically closed when the transaction commits.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTICE

For a cursor declared as **WITH HOLD**, all its data is cached when the transaction ends. If the cursor has a large amount of data, this caching process may take a long time.

- **query**

  Uses the SELECT or VALUES clause to specify the rows to be returned by a cursor.

  Value range: SELECT or VALUES clause.

- **declare_statements**

  Declares a variable, including its name and type, for example, **sales_cnt int**.

- **execution_statements**

  Specifies the statement to be executed in an anonymous block.

  Value range: names of existing functions.

Examples

- Define a cursor.

```
-- Create the test table and insert 10 data records into the table.
gaussdb=# CREATE TABLE test(c1 int, c2 int);
gaussdb=# INSERT INTO test VALUES (generate_series(1,10),generate_series(1,10));

-- Start a transaction and create a cursor named cursor1.
gaussdb=# START TRANSACTION;
gaussdb=# DECLARE cursor1 CURSOR FOR SELECT * FROM test ORDER BY 1;

-- The cursor retrieves three rows of data from the associated position.
gaussdb=# FETCH FORWARD 3 FROM cursor1;
 c1 | c2
----+----
  1 |  1
  2 |  2
  3 |  3
(3 rows)

-- Close the cursor and commit the transaction.
gaussdb=# CLOSE cursor1;
gaussdb=# END;

-- Drop a table.
gaussdb=# DROP TABLE test;
```

- Enable an anonymous block.

```
-- Declare and output a variable.
gaussdb=# DECLARE num INTEGER := 10;
BEGIN
    dbe_output.print_line(num);
END;
/
```

Helpful Links

BEGIN and **FETCH**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

1.13.10.3 DELETE

Description

Deletes rows that satisfy the WHERE clause from the specified table. If the WHERE clause is absent, the effect is to delete all rows in the table. The result is a valid, but an empty table.

Precautions

- The owner of a table, users granted the DELETE permission on the table or the DELETE ANY TABLE permission can delete data from the table. When separation of duties is disabled, system administrators have this permission by default. To perform the DELETE operation, you must have the SELECT permission on the table referenced by the USING clause and the table read in the condition.
- For row-store tables, DELETE can be used if the tables have primary key constraints or the execution plan can be pushed down.
- For a DELETE statement with a subquery executed as a STREAM plan, UPDATE cannot be performed on the deleted row data.

Syntax

```
[ WITH [ RECURSIVE ] with_query [, ...] ]
DELETE [/*+ plan_hint */] [FROM] [ ONLY ] {table_name [ * ] subquery [ [ AS ] alias ] | view_name [ [ AS ] alias ]}
    [ USING using_list ]
    [ WHERE condition | WHERE CURRENT OF cursor_name ]
    [ ORDER BY {expression [  ASC | DESC | USING operator ] } ]
    [ LIMIT row_count ]
    [ RETURNING { * | { output_expr [ [ AS ] output_name ] } [, ...] } ];
```

- Format of **with_query**:

  ```
  with_query_name [ ( column_name [, ...] ) ] AS [ [ NOT ] MATERIALIZED ]
  ( {select | values | insert | update | delete} )
  ```

- Format of **subquery**:

  ```
  [ WITH [ RECURSIVE ] with_query [, ...] ]
  SELECT [/*+ plan_hint */] [ ALL ]
  { * | {expression [ [ AS ] output_name ]} [, ...] }
  [ into_option ]
  [ FROM from_item [, ...] ]
  [ WHERE condition ]
  [ [ START WITH condition ] CONNECT BY [NOCYCLE] condition [ ORDER SIBLINGS BY expression ] ]
  [ ORDER BY {expression [ [ ASC | DESC | USING operator ] | nlssort_expression_clause ] [ NULLS
  { FIRST | LAST } ]} [, ...] ]
  [ OFFSET start [ ROW | ROWS ] ]
  [ FETCH { FIRST | NEXT } [ count ] { ROW | ROWS } ONLY ]
  [ into_option ];
  ```

  The specified subquery source **from_item** is as follows:

  ```
  {[ ONLY ] {table_name | view_name} [ * ] [ partition_clause ] [ [ AS ] alias [ ( column_alias [, ...] ) ] ]
  |( select ) [ AS ] alias [ ( column_alias [, ...] ) ]
  |with_query_name [ [ AS ] alias [ ( column_alias [, ...] ) ] ]
  |from_item [ NATURAL ] join_type from_item [ ON join_condition | USING ( join_column [, ...] ) ]}
  ```

Parameters

- **WITH [RECURSIVE] with_query [, ...]**

  Specifies one or more subqueries that can be referenced by name in the primary query. The subqueries effectively act as temporary tables. If

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

RECURSIVE is specified, it allows a SELECT subquery to reference itself by name.

- **with_query_name** specifies the name of the result set generated by the subquery. The name can be used to access the result set of the subquery in the query.
- **column_name** specifies the column names displayed in the subquery result set.
- Each subquery can be a SELECT, VALUES, INSERT, UPDATE, or DELETE statement.
- You can use MATERIALIZED or NOT MATERIALIZED to modify the CTE.
  - If **MATERIALIZED** is specified, the WITH query will be materialized, and a copy of the subquery result set is generated. The copy is directly queried at the reference point. Therefore, the WITH subquery cannot be jointly optimized with the SELECT statement trunk (for example, predicate pushdown and equivalence class transfer). In this scenario, you can use **NOT MATERIALIZED** for modification. If the WITH query can be executed as a subquery inline, the preceding optimization can be performed.
  - If the user does not explicitly specify the materialized attribute, comply with the following rules: If the CTE is referenced only once in the trunk statement to which it belongs and semantically supports inline execution, it will be rewritten as subquery inline execution. Otherwise, the materialized execution will be performed in CTE Scan mode.

- **plan_hint**

  Follows the DELETE keyword in the /*+ *plan_hint* */ format. It is used to optimize the plan of a DELETE statement block using hints. For details, see "Hint-based Optimization" in *SQL Optimization Guide*. Only the first /*+ *plan_hint* */ comment block in each statement takes effect as a hint. Multiple hints can be written in the comment block.

- **ONLY**

  If **ONLY** is specified, only that table is deleted. If **ONLY** is not specified, that table and all its subtables are deleted.

- **table_name**

  Specifies the name (optionally schema-qualified) of the target table.

  Value range: existing table names.

  NOTE

  You can use database links to perform operations on remote tables. For details, see "Feature Usage Guidelines > Database Links" in *Developer Guide*.

- **subquery**

  The object to be deleted can be a subquery. When data in a subquery is deleted, the subquery is regarded as a temporary view. The **CHECK OPTION** option can be added to the end of the subquery.

  If there is only one table in the subquery, the table is deleted. If there are multiple tables or nested tables in the subquery, the system determines whether the table can be deleted by checking whether there is a key-

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

preserved table. For details about key-preserved tables and **WITH CHECK OPTION**, see **CREATE VIEW**.

- **view_name**

  Specifies name of the target view.

  NOTE

  The restrictions on deleting views and subqueries are as follows:

  - The DELETE operation can be performed only on columns that directly reference user columns in the base table.
  - A subquery or view must contain at least one updatable column. For details about updatable columns, see **CREATE VIEW**.
  - The view or subquery must not contain the DISTINCT, GROUP BY, HAVING, LIMIT, or OFFSET clause at the top layer.
  - Views and subqueries that contain set operations (UNION, INTERSECT, EXCEPT, and MINUS) at the top layer are not supported.
  - Views and subqueries whose target lists contain aggregate functions, window functions, or return set functions (such as array_agg, json_agg, and generate_series) are not supported.
  - Views with BEFORE or AFTER triggers but without INSTEAD OF triggers or INSTEAD rules are not supported.
  - Table types supported in views and subqueries include ordinary tables, temporary tables, global temporary tables, partitioned tables, subpartitioned tables, Ustore tables, and Astore tables.
  - In a join view or subquery, only data in key-preserved tables can be deleted. If there is only one key-preserved table, the data in the table is deleted. If there are multiple key-preserved tables, only the data in the first key-preserved table following FROM is deleted.
  - If the **CHECK OPTION** option is specified in the join view or subquery, the base table is duplicate, and the duplicate base table has attributes inconsistent with the key-preserved table in the view or subquery, rows cannot be deleted from the join view or subquery. For details about the key-preserved table, see **CREATE VIEW**.
  - The DELETE operation cannot be performed on the system view.
  - Deleting multiple tables is not supported.

- **alias**

  Specifies the alias of the target table.

  Value range: character strings complying with **Identifier Naming Conventions**.

- **using_list**

  Specifies the USING clause.

- **condition**

  Specifies an expression that returns a Boolean value, which is used to determine the row to be deleted. You are advised not to use numeric types such as INT as conditions because such types can be implicitly converted to Boolean values (non-zero values are implicitly converted to **true** and **0** is implicitly converted to **false**), which may cause unexpected results.

- **WHERE CURRENT OF cursor_name**

  When the cursor points to a row in a table, you can use this syntax to delete the row. For details about restrictions, see **UPDATE**.

- **ORDER BY**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Refer to **SELECT**.

- **LIMIT**

  Refer to **SELECT**.

  NOTE

  If you want to perform DELETE on a replication table, the LIMIT keyword cannot be used to specify the table.

- **output_expr**

  Specifies an expression to be computed and returned by the DELETE statement after each row is deleted. The expression can use any column names of the table. Write * to return all columns.

- **output_name**

  Specifies a name to use for a returned column.

  Value range: character strings complying with **Identifier Naming Conventions**.

Examples

- Deleting some data records

```
-- Create a table.
gaussdb=# CREATE TABLE test_t1(col1 INT,col2 INT);
gaussdb=# INSERT INTO test_t1 VALUES (1, 1), (2, 2), (3, 3), (4, 4), (4, 6);

-- Delete some data records from the table.
gaussdb=# DELETE FROM test_t1 WHERE col1 = 4;

-- Query.
gaussdb=# SELECT * FROM test_t1;
 col1 | col2
------+------
    1 |    1
    2 |    2
    3 |    3
(3 rows)
```

- Deleting all data

```
-- Delete all data.
gaussdb=# DELETE FROM test_t1;

-- Query.
gaussdb=# SELECT * FROM test_t1;
 col1 | col2
------+------
(0 rows)

-- Drop the table.
gaussdb=# DROP TABLE test_t1;
```

- WITH [RECURSIVE] with_query [, ...]

```
-- Create a student table.
gaussdb=# CREATE TABLE student(id INT,name varchar(50));

-- Create a score table.
gaussdb=# CREATE TABLE grade(id INT,score CHAR);

gaussdb=# INSERT INTO student VALUES (1, 'tom'), (2, 'jerry'), (3, 'david');
gaussdb=# INSERT INTO grade VALUES (1, 'A'), (2, 'B'), (3, 'b');

-- Delete the data of the student whose id is 2 from the student table and the grade table.
gaussdb=# WITH del_stu AS(DELETE FROM student WHERE id = 2 RETURNING id)
    DELETE FROM grade WHERE id = (SELECT id FROM del_stu);
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
-- Query data.
gaussdb=# SELECT * FROM student;
 id | name
----+-------
  1 | tom
  3 | david
(2 rows)

gaussdb=# SELECT * FROM grade;
 id | score
----+-------
  1 | A
  3 | b
(2 rows)

-- Drop the table.
gaussdb=# DROP TABLE grade;
gaussdb=# DROP TABLE student;
```

- Deleting a subquery

```
-- Create a schema.
gaussdb=# CREATE SCHEMA del_subqry;
CREATE SCHEMA
gaussdb=# SET CURRENT_SCHEMA = 'del_subqry';
SET

-- Create a table and insert data into the table.
gaussdb=# CREATE TABLE t1 (x1 int, y1 int);
NOTICE:  The 'DISTRIBUTE BY' clause is not specified. Using 'x1' as the distribution column by default.
HINT:  Please use 'DISTRIBUTE BY' clause to specify suitable data distribution column.
CREATE TABLE
gaussdb=# CREATE TABLE t2 (x2 int PRIMARY KEY, y2 int);
NOTICE:  CREATE TABLE / PRIMARY KEY will create implicit index "t2_pkey" for table "t2"

```

Suggestions

To delete all records in a table, use the **TRUNCATE** syntax.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

1.13.10.4 DO

Description

Executes an anonymous code block. A code block is regarded as a function body without parameters. The return type is VOID. It is parsed and executed at the same time.

Precautions

- Before using a procedural language, you must install it in the current database by running the **CREATE LANGUAGE** command. PL/pgSQL is installed by default. To install another language, you must specify it.
- To use an untrusted language, you must have the USAGE permission on the programming language or the SYSADMIN permission.

Syntax

```
DO [ LANGUAGE lang_name ] code;
```

Parameters

- **lang_name**

  Specifies the name of the programming language that is used to parse the code. If no language is specified, the default language is **plpgsql**.

- **code**

  Specifies the programming language code that can be executed. The value must be a character string.

Examples

```
-- Create the webuser user.
gaussdb=# CREATE USER webuser PASSWORD '********';

-- Grant all permissions on all views in the tpcds schema to the webuser user.
gaussdb=# DO $$DECLARE r record;
BEGIN
    FOR r IN SELECT c.relname,n.nspname FROM pg_class c,pg_namespace n
            WHERE c.relnamespace = n.oid AND n.nspname = 'tpcds' AND relkind IN ('r','v')
    LOOP
        EXECUTE 'GRANT ALL ON ' || quote_ident(r.table_schema) || '.' || quote_ident(r.table_name) || ' TO
webuser';
    END LOOP;
END$$;

-- Delete the webuser user.
gaussdb=# DROP USER webuser CASCADE;
```

1.13.10.5 DROP AGGREGATE

Description

Drops an aggregate function from the database.

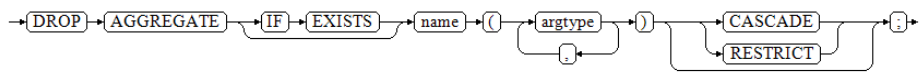
 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Precautions

Only the owner of an aggregate function can perform the DROP AGGREGATE operation.

Syntax

```
DROP AGGREGATE [ IF EXISTS ] name ( argtype [ , ... ] ) [ CASCADE | RESTRICT ];
```



Parameters

- **IF EXISTS**

  Checks whether a specified aggregate function exists.
  - If the aggregate function exists, it will be dropped successfully.
  - If the aggregate function does not exist, the DROP operation will not be performed. Only a NOTICE message will be generated, indicating that the aggregate function does not exist.
- **name**

  Specifies the aggregate function to be dropped (optionally schema-qualified).
- **argtype**

  Specifies the input data type of the aggregate function. If the specified aggregate function is of the zero-parameter type, use an asterisk (*) instead of an input data type list.
- **CASCADE | RESTRICT**

  (Optional) Specifies whether to cascadingly drop objects that depend on the aggregate function. The default value is **RESTRICT**.
  - **CASCADE**: The database cascadingly drops objects that depend on the aggregate function.
  - **RESTRICT**: The database refuses to drop the aggregate function if any objects depend on it.

Examples

```
-- Create a user-defined function.
gaussdb=# CREATE OR REPLACE FUNCTION int_add(int,int)
 RETURNS int AS $BODY$
DECLARE
BEGIN
 RETURN $1 + $2;
END;
$BODY$ language plpgsql;

-- Create an aggregate function.
gaussdb=# CREATE AGGREGATE myavg (int)
(
    sfunc = int_add,
    stype = int,
    initcond = '0'
);

-- Drop the aggregate function myavg of the int type.
gaussdb=# DROP AGGREGATE myavg(int);
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
-- Drop the user-defined function.
gaussdb=# DROP FUNCTION int_add(int,int);
```

Helpful Links

ALTER AGGREGATE and **CREATE AGGREGATE**

Compatibility

The SQL standard does not provide the DROP AGGREGATE statement.

1.13.10.6 DROP AUDIT POLICY

Description

Drops an audit policy from the database.

Precautions

Only users with the POLADMIN or SYSADMIN permission, or the initial user, can perform this operation.

Syntax

```
DROP AUDIT POLICY [IF EXISTS] policy_name;
```

Parameters

- **policy_name**

  Specifies the name of an audit policy, which must be unique.

  Value range: character strings complying with **Identifier Naming Conventions**.

- **IF EXISTS**

  Checks whether the specified audit policy exists.

  – If the audit policy exists, it will be dropped successfully.

  – If the audit policy does not exist, the DROP operation will not be performed. Only a NOTICE message will be generated, indicating that the audit policy does not exist.

Examples

```
-- Create the adt1 policy.
gaussdb=# CREATE AUDIT POLICY adt1 PRIVILEGES CREATE;
CREATE AUDIT POLICY

-- Drop the audit policy adt1.
gaussdb=# DROP AUDIT POLICY adt1;
DROP AUDIT POLICY

-- When you drop the audit policy adt0 that does not exist, the system displays a message indicating that the operation fails because the audit policy does not exist.
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gaussdb=# DROP AUDIT POLICY adt0;
ERROR:  adt0 policy does not exist, drop failed
```

Helpful Links

CREATE AUDIT POLICY and **ALTER AUDIT POLICY**

1.13.10.7 DROP CLIENT MASTER KEY

Description

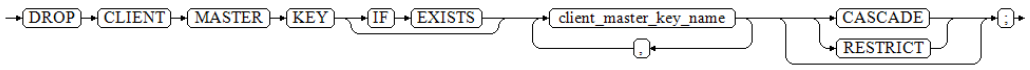
Drops a client master key (CMK).

Precautions

- Only the CMK owner and users with the DROP permission can perform this operation. System administrators have this permission by default.
- This command can only be used to drop the metadata information recorded in the system catalog of the database, but cannot be used to drop the CMK file. You need to use keytool to drop the CMK file.

Syntax

```
DROP CLIENT MASTER KEY [ IF EXISTS ] client_master_key_name [, ...] [ CASCADE | RESTRICT ];
```



Parameters

- **IF EXISTS**

  Checks whether a specified CMK exists.

  - If the CMK exists, it will be dropped successfully.
  - If the CMK does not exist, the DROP operation will not be performed. Only a NOTICE message will be generated, indicating that the CMK does not exist.

- **client_master_key_name**

  Specifies the name of a CMK to be dropped.

  Value range: names of existing CMKs (character strings).

- **CASCADE** | **RESTRICT**

  (Optional) Specifies whether to drop objects that depend on the CMK when dropping the CMK itself. The default value is **RESTRICT**.

  - **CASCADE**: The database cascadingly drops objects that depend on the CMK.
  - **RESTRICT**: refuses to drop the CMK if any objects depend on it.

Helpful Links

CREATE CLIENT MASTER KEY

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

1.13.10.8 DROP COLUMN ENCRYPTION KEY

Description

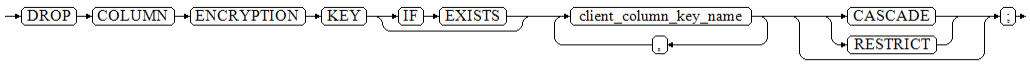
Drops a column encryption key (CEK).

Precautions

Only the CEK owner and users with the DROP permission can perform this operation. System administrators have this permission by default.

Syntax

```
DROP COLUMN ENCRYPTION KEY [ IF EXISTS ] client_column_key_name [, ...] [ CASCADE | RESTRICT ];
```



Parameters

- **IF EXISTS**

  Checks whether a specified CEK exists.

  - If the CEK exists, it will be dropped successfully.
  - If the CEK does not exist, the DROP operation will not be performed. Only a NOTICE message will be generated, indicating that the CEK does not exist.

- **client_column_key_name**

  Specifies the name of a CEK to be dropped.

  Value range: names of existing CEKs (character strings).

- **CASCADE | RESTRICT**

  (Optional) Specifies whether to drop objects that depend on a CEK when dropping the CEK itself.

  For fully-encrypted databases, this syntax is high-risk operation. Actually, encrypted columns that depend on a CEK cannot be dropped.

Helpful Links

ALTER COLUMN ENCRYPTION KEY and **CREATE COLUMN ENCRYPTION KEY**

1.13.10.9 DROP DATABASE

Description

Drops a database.

Precautions

- Only the database owner and users with the DROP permission on the database can perform this operation. System administrators have this permission by default.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- The default installed template and user databases (**template0**, **template1**, **templatea**, **templatem**, and **postgres**) cannot be dropped. To check databases in the current service, run the gsql command **\l**.
- If a user is currently accessing the database, the database cannot be dropped. You can check the current database connection in the DV_SESSIONS view.
- This operation cannot be performed in transaction blocks.
- Before dropping a database, run the **CLEAN CONNECTION TO ALL FORCE FOR DATABASE** *XXXX*; command to forcibly stop the existing user connections and background threads, preventing operation failures caused by running background threads.

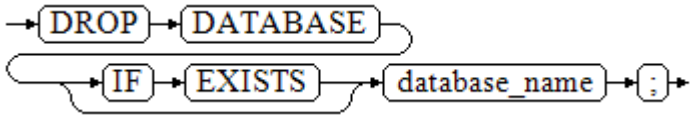
  NOTICE

  DROP DATABASE cannot be undone. Forcibly stopping background threads may cause data inconsistency in the current database. **CLEAN CONNECTION TO ALL FORCE FOR DATABASE** *XXXX*; is executed only when you are sure that the database needs to be dropped.

- If **DROP DATABASE** fails and is rolled back, run **DROP DATABASE IF EXISTS** again.

Syntax

```
DROP DATABASE [ IF EXISTS ] database_name;
```



Parameters

- **IF EXISTS**

  Checks whether the specified database exists. This parameter can be used to avoid errors.

  - If the database exists, it will be dropped successfully.
  - If the database does not exist, the DROP operation will not be performed. Only a NOTICE message will be generated, indicating that the database does not exist.

- **database_name**

  Specifies the name of the database to be dropped.

  Value range: existing database names.

Examples

```
-- Create a database.
gaussdb=# CREATE DATABASE testdb1;

-- Drop a database.
gaussdb=# DROP DATABASE testdb1;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Helpful Links

CREATE DATABASE

1.13.10.10 DROP DATABASE LINK

Description

Drops a database link.

Syntax

```
DROP [ PUBLIC ] DATABASE LINK [ IF EXISTS ] dblink_name;
```

Parameters

- **dblink_name**

  Specifies the name of a connection object.

- **IF EXISTS**

  Checks whether a specified database link exists.

  – If the database link exists, it will be dropped successfully.

  – If the database link does not exist, the DROP operation will not be performed. Only a NOTICE message will be generated, indicating that the database link does not exist.

- **PUBLIC**

  Specifies the connection type. If **PUBLIC** is not specified, **PRIVATE** is the default.

Examples

```
-- Create an ORA-compatible database.
gaussdb=# CREATE DATABASE ora_test_db DBCOMPATIBILITY 'ORA';
CREATE DATABASE

-- Switch to another database.
gaussdb=# \c ora_test_db

-- Create a user with the SYSADMIN permission.
ora_test_db=# CREATE USER local_user WITH SYSADMIN PASSWORD '********';
CREATE ROLE
ora_test_db=# SET ROLE local_user PASSWORD '********';
SET

-- Create a private database link. host can be an IPv6 address.
ora_test_db=> CREATE DATABASE LINK private_dblink CONNECT TO 'remote_user' IDENTIFIED BY '********'
USING (host '***.***.***.***',port '*****',dbname 'remote_db');
CREATE DATABASE LINK

-- Drop the private database link.
ora_test_db=> DROP DATABASE LINK private_dblink;
DROP DATABASE LINK

-- Create a public database link. host can be an IPv6 address.
ora_test_db=> CREATE PUBLIC DATABASE LINK public_dblink CONNECT TO 'remote_user' IDENTIFIED BY
'********' USING (host '***.***.***.***',port '*****',dbname 'remote_db');
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
CREATE DATABASE LINK

-- Drop the public database link.
ora_test_db=> DROP PUBLIC DATABASE LINK public_dblink;
DROP DATABASE LINK

-- Drop the created user.
ora_test_db=> RESET ROLE;
RESET
ora_test_db=# DROP USER local_user;
DROP ROLE

-- Switch back to the initial database and drop the test database. Replace postgres with the actual database name.
ora_test_db=# \c postgres
gaussdb=# DROP DATABASE ora_test_db;
DROP DATABASE
```

Helpful Links

ALTER DATABASE LINK and **CREATE DATABASE LINK**

1.13.10.11 DROP DIRECTORY

Description

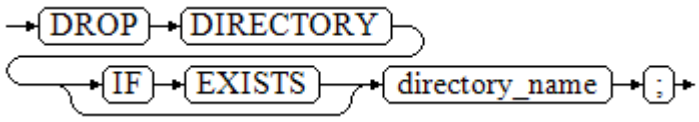
Drops a directory from the database.

Precautions

- When **enable_access_server_directory** is set to **off**, only the initial user can perform this operation.
- When **enable_access_server_directory** is set to **on**, users with the SYSADMIN permission, the directory object owner, users with the DROP permission on a directory, and users inheriting permissions from the built-in role gs_role_directory_drop can drop a directory object.

Syntax

```
DROP DIRECTORY [ IF EXISTS ] directory_name;
```



Parameters

- **directory_name**

  Specifies the directory name.

  Value range: names of existing directories.

- **IF EXISTS**

  Checks whether a specified directory exists.

  – If the directory exists, it will be dropped successfully.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

  - If the directory does not exist, the DROP operation will not be performed. Only a NOTICE message will be generated, indicating that the directory does not exist.

Examples

```
-- Create a directory object.
gaussdb=# CREATE OR REPLACE DIRECTORY  dir  as '/tmp/';

-- Drop a directory object.
gaussdb=# DROP DIRECTORY dir;
```

Helpful Links

CREATE DIRECTORY and **ALTER DIRECTORY**

1.13.10.12 DROP EXTENSION

NOTICE

Extensions are for internal use only. Only advanced packages or extensions in the database can be dropped. Currently, only postgis, postgis_sfcgal, postgis_raster, postgis_topology, yukon_geomodel, yukon_geogridcoder, pkg_bpchar_opc, and tablefunc are supported.

Description

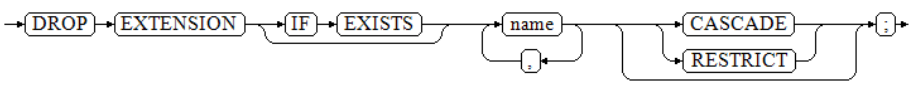
Drops an extension from the database.

Precautions

- Only the extension owner and initial user can perform this operation.
- When you drop an extension, the components that make up the extension are also dropped.

Syntax

```
DROP EXTENSION [ IF EXISTS ] name [, ...] [ CASCADE | RESTRICT ];
```



Parameters

- **IF EXISTS**

  Checks whether a specified extension exists.

  - If the extension exists, it will be dropped successfully.
  - If the extension does not exist, the DROP operation will not be performed. Only a NOTICE message will be generated, indicating that the extension does not exist.

- **name**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Specifies the name of an installed extension.

- **CASCADE | RESTRICT**

  (Optional) Specifies whether to drop objects that depend on the extension when dropping the extension itself. If this parameter is not specified, the default value is **RESTRICT**.

  - **CASCADE**: The database cascadingly drops objects that depend on the extension.
  - **RESTRICT**: The database refuses to drop the extension if any objects depend on it (unless all member objects and other extension objects are simultaneously dropped in the same **DROP** command).

Helpful Links

CREATE EXTENSION

1.13.10.13 DROP FOREIGN DATA WRAPPER

Description

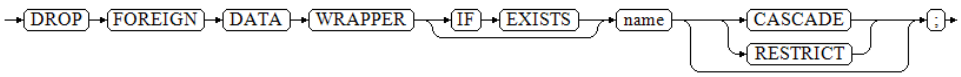
Drops a foreign data wrapper (FDW) from the database.

Precautions

- This operation can be successfully performed only when the GUC parameter **support_extended_features** is set to **on**.
- A foreign data wrapper can be dropped only during the internal initialization phase or within an upgrade script. In other scenarios, users cannot directly use this syntax.

Syntax

```
DROP FOREIGN DATA WRAPPER [ IF EXISTS ] name [ CASCADE | RESTRICT ];
```



Parameters

- **IF EXISTS**

  Checks whether the specified FDW exists.

  - If the FDW exists, it will be dropped successfully.
  - If the FDW does not exist, the DROP operation will not be performed. Only a NOTICE message will be generated, indicating that the FDW does not exist.

- **name**

  Specifies the name of an existing FDW.

- **CASCADE | RESTRICT**

  (Optional) Specifies whether to drop objects that depend on the FDW when dropping the FDW itself. If this parameter is not specified, the default value is **RESTRICT**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

  - **CASCADE**: The database cascadingly drops objects (such as servers) that depend on the FDW.
  - **RESTRICT**: The database refuses to drop the FDW if any objects that depend on it.

Examples

```
-- Create a FDW dbi.
gaussdb=# CREATE FOREIGN DATA WRAPPER dbi OPTIONS (bar 'true');

-- Drop the FDW dbi. (Prerequisite: The GUC parameter support_extended_features is set to on.)
gaussdb=# DROP FOREIGN DATA WRAPPER dbi;
```

Helpful Links

CREATE FOREIGN DATA WRAPPER and ALTER FOREIGN DATA WRAPPER

1.13.10.14 DROP FOREIGN TABLE

Description

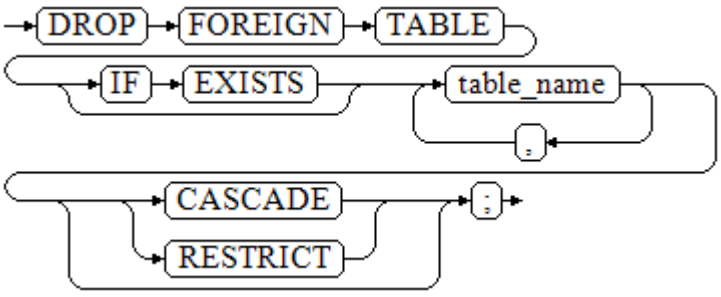
Drops a foreign table from the database.

Precautions

This operation forcibly drops the specified table, resulting in the removal of any dependent indexes. Functions and stored procedures that use this table will become unexecutable.

Syntax

```
DROP FOREIGN TABLE [ IF EXISTS ] table_name [, ...] [ CASCADE | RESTRICT ];
```



Parameters

- **IF EXISTS**

  Checks whether a specified foreign table exists.
  - If the foreign table exists, it will be dropped successfully.
  - If the foreign table does not exist, the DROP operation will not be performed. Only a NOTICE message will be generated, indicating that the foreign table does not exist.
- **table_name**

  Specifies the name of the table to be dropped.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Value range: names of existing tables.

- **CASCADE | RESTRICT**

  (Optional) Specifies whether to drop objects that depend on the foreign table when dropping the table itself. If this parameter is not specified, the default value is **RESTRICT**.

  - **CASCADE**: The database cascadingly drops the objects (such as views) that depend on the table.
  - **RESTRICT**: The database refuses to drop the table if any objects depend on it.

Examples

For details, see **CREATE FOREIGN TABLE** in **Examples**.

Helpful Links

CREATE FOREIGN TABLE

1.13.10.15 DROP FUNCTION

Description

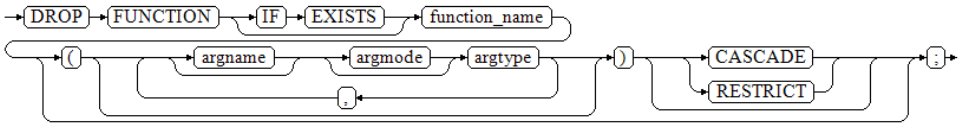
Drops an existing function from the database.

Precautions

- If a function involves operations on temporary tables, DROP FUNCTION cannot be used.
- Only the function owner and users with the DROP permission on the function can perform this operation. System administrators have this permission by default.
- The functions of the initial user can only be dropped by the initial user itself.

Syntax

```
DROP FUNCTION [ IF EXISTS ] function_name
[ ( [ { [ argname ] [ argmode ] argtype} [, ...] ] ) [ CASCADE | RESTRICT ] ];
```



Parameters

- **IF EXISTS**

  Checks whether a specified function exists.

  - If the function exists, it will be dropped successfully.
  - If the function does not exist, the DROP operation will not be performed. Only a NOTICE message will be generated, indicating that the function does not exist.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **function_name**

  Specifies the name of the function to be dropped.

  Value range: existing function names.

- **argmode**

  Specifies the parameter mode of the function.

- **argname**

  Specifies the parameter name of the function.

- **argtype**

  Specifies the data type of a function parameter.

- **CASCADE | RESTRICT**

  (Optional) Specifies whether to drop objects that depend on the function when dropping the function itself. If this parameter is not specified, the default value is **RESTRICT**.

  – **CASCADE**: The database cascadingly drops objects that depend on the function.

  – **RESTRICT**: The database refuses to drop the function if any objects depend on it.

Examples

- Delete the list of parameters that can be omitted when a function.

```
-- Create a function.
gaussdb=# CREATE FUNCTION func_test(varchar) RETURN VARCHAR AS
BEGIN
    RETURN $1||_'test';
END;
/

-- Delete the function.
gaussdb=# DROP FUNCTION func_test;
```

- Delete a function with the same name.

  If a function with the same name exists, add a parameter list when deleting the function. Otherwise, an error is reported.

```
-- Create a function.
gaussdb=# CREATE FUNCTION func_add(int) RETURNS int AS $$
BEGIN
    RETURN $1+10;
END;
$$ LANGUAGE PLPGSQL;

-- func_add is an overloaded function.
gaussdb=# CREATE FUNCTION func_add(int,int) RETURNS int AS $$
BEGIN
    RETURN $1+$2;
END;
$$ LANGUAGE PLPGSQL;

-- Delete the function.
gaussdb=# DROP FUNCTION func_add(int);
gaussdb=# DROP FUNCTION func_add(int,int);
```

ALTER FUNCTION and **CREATE FUNCTION**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

1.13.10.16 DROP GLOBAL CONFIGURATION

Description

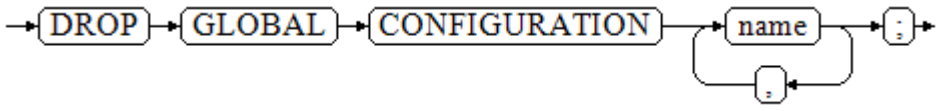
Drops parameter values from the gs_global_config system catalog.

Precautions

- Only the initial database user can run this command.
- The parameter name cannot be **weak_password** or **undostoragetype**.
- If the name of parameter for redistribution after scale-out is used, set **enable_cluster_resize** to **on**. The involved parameters are **lockwait_timeout**, **lockwait_interval**, **trylock_threshold**, **enable_cancel**, **last_catchup_threshold**, **catchup_times**, **write_error_mode**, **catchup_query_dop**, **parallel_catchup_threshold**, **parallel_reindex_jobs**, **redis_retry_times**, **redis_retry_interval**, **redis_bucket_expansion**, **redis_bucket_batchsize**, **redis_bucket_log_level**, **redis_bucket_lockhold_timeout**, **redis_bucket_timeout_penalty**, **redis_bucket_max_lockwait_timeout_retry**, **redis_bucket_max_lockhold_timeout_retry**, **redis_bucket_strategy_history_capacity**, **redis_bucket_strategy_recent_threshold**, **redis_bucket_workload_rule**, **redis_bucket_lsn_rule**, **redis_bucket_tx_bucket_min**, **redis_bucket_tx_bucket_max**, **redis_max_expected_tps**, **redis_bucket_sender_concurrency**, **redis_bucket_receiver_concurrency**, **redis_bucket_parse_redo_num**, **redis_bucket_workers_per_paser**, **redis_bucket_keep_bucketxlogs**, **redis_bucket_reindex_cbi_offline**, and **redis_bucket_reindex_parallel_workers**.

Syntax

```
DROP GLOBAL CONFIGURATION name [, ...];
```



Parameters

name

The parameter must exist in the gs_global_config system catalog. If you drop a parameter that does not exist, an error will be reported. If the name of parameter for redistribution after scale-out is used, set **enable_cluster_resize** to **on**.

Examples

For details, see **ALTER GLOBAL CONFIGURATION** in **Examples**.

Helpful Links

ALTER GLOBAL CONFIGURATION

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

1.13.10.17 DROP GROUP

Description

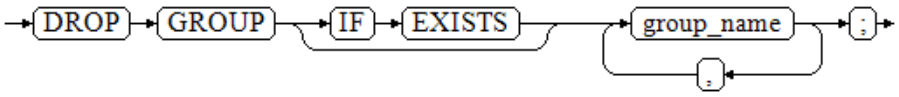
Drops a user group. DROP GROUP is synonymous with DROP ROLE.

Precautions

It is available only to users with the CREATE ROLE permission granted by the administrator.

Syntax

```
DROP GROUP [ IF EXISTS ] group_name [, ...];
```



Parameters

- **IF EXISTS**

  Checks whether a specified user group exists.

  - If the user group exists, it will be dropped successfully.
  - If the user group does not exist, the DROP operation will not be performed. Only a NOTICE message will be generated, indicating that the user group does not exist.

- **group_name**

  Specifies the name of the user group to be dropped.

  Value range: existing user groups and roles.

Examples

For details, see **CREATE GROUP** in **Examples**.

Helpful Links

CREATE GROUP, **ALTER GROUP**, and **DROP ROLE**

1.13.10.18 DROP INDEX

Description

Drops an index.

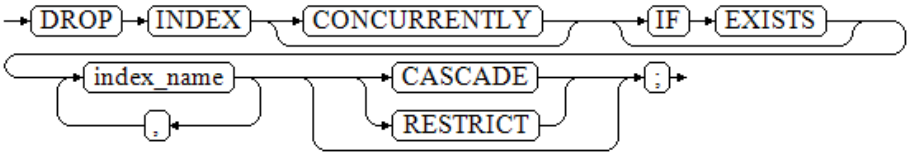
Precautions

Only the index owner, owner of the schema where the index resides, users with the INDEX permission on the table where the index resides, or users with the DROP ANY INDEX permission can perform this operation. When separation of duties is disabled, system administrators have this permission by default.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Syntax

```
DROP INDEX [ CONCURRENTLY ] [ IF EXISTS ]
    index_name [, ...] [ CASCADE | RESTRICT ];
```



Parameters

- **CONCURRENTLY**

  Deletes an index (with a level-4 lock) online in a mode that does not block DML statements. When an index is deleted, other statements cannot access the table on which the index depends. With this option, the statement does not lock the table during index deletion.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- When the **CONCURRENTLY** option is specified for dropping an index, only one index name can be specified and the **CASCADE** option is not supported.
- The **DROP INDEX** statement can be run within a transaction, but **DROP INDEX CONCURRENTLY** cannot.
- For temporary tables, you can use **CONCURRENTLY** to delete indexes. However, indexes are deleted in blocking mode because no other sessions concurrently access the temporary tables and the blocking mode is more cost-effective.
- Similar to online index creation, the online index deletion process also includes a phase where the system must wait for the end of other related transactions in the table corresponding to the index. As a result, the lock timeout may occur, causing online index deletion failures.
- Similar to online index creation, the online index deletion process also includes a phase where the system must wait for the end of other related transactions in the table corresponding to the index. As a result, deadlocks with other DDL statements may occur, causing online index deletion failures. The cause is as follows: The online index deletion process holds the level-4 lock and waits for the concurrent DDL transactions to end. The concurrent DDL transactions hold the transaction lock and wait for the online index deletion process to release the level-4 lock.
- When a fault such as lock timeout, deadlock, or database exception occurs or a user cancels an operation, online index dropping may fail, resulting in invalid residual indexes. The status of remaining indexes on CNs and DNs may be inconsistent. For example, indexes on CNs are invalid and those on DNs are valid, or indexes on some CNs are valid and those on some CNs are invalid and those on DNs are valid. Alternatively, remaining indexes exist on some nodes but do not exist on other nodes, but this does not cause inconsistency. To prevent occupying system resources, you need to clear the invalid indexes as soon as possible. You can continue to use **DROP INDEX CONCURRENTLY** or **DROP INDEX** to delete invalid indexes. If **DROP INDEX CONCURRENTLY** fails to be used to delete indexes continuously, you can use **DROP INDEX** instead.
- The online index deletion time is related to the concurrent service volume and concurrent service running time. If there is no concurrent service, the online index deletion is complete within seconds. If there are concurrent services, you need to wait until all concurrent services are complete at a certain time. Therefore, the online index deletion time needs to include the running time of these concurrent services.
- Only B-tree and UB-tree indexes can be dropped online in a distributed system. GSIs are not supported.
- During the execution of DROP INDEX CONCURRENTLY, an error may be reported for the stream plan involving the index. Before performing this operation, you are advised to disable the stream plan using an SQL patch or by adding hints to the relevant SQL statements, forcing the execution to fall back to the pgxc plan.
- If an online index drop operation is performed during the generation of a WDR snapshot, the error message "Could not open relation with OID %u." may be displayed, causing the WDR snapshot generation to fail. This is an expected behavior. After the index drop is complete, generate the WDR snapshot again.

- **IF EXISTS**

  Checks whether a specified index exists.

  – If the index exists, it will be dropped successfully.

  – If the index does not exist, the DROP operation will not be performed. Only a NOTICE message will be generated, indicating that the index does not exist.

  If an index fails to be created or dropped online, its metadata may not be matched on some nodes. The index cannot be dropped using the DROP INDEX statement. Instead, it must be dropped using DROP INDEX IF EXISTS.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **index_name**

  Specifies the name of the index to be dropped.

  Value range: existing indexes.

- **CASCADE | RESTRICT**

  (Optional) Specifies whether to drop objects that depend on the index when dropping the index itself. If this parameter is not specified, the default value is **RESTRICT**.

  – **CASCADE**: The database cascadingly drops objects that depend on the index.

  – **RESTRICT**: The database refuses to drop the index if any objects depend on it.

Examples

```
-- Create a table.
gaussdb=# CREATE TABLE test1_index (id INT, name VARCHAR(20));

-- Create an index.
gaussdb=# CREATE INDEX idx_test1 ON test1_index(id);

-- Drop an index.
gaussdb=# DROP INDEX IF EXISTS idx_test1 CASCADE;

-- Create an index online.
gaussdb=# CREATE INDEX CONCURRENTLY idx_test2 ON test1_index(name);

-- Drop an index online.
gaussdb=# DROP INDEX CONCURRENTLY idx_test2;

-- Drop a table.
gaussdb=# DROP TABLE test1_index;
```

Helpful Links

ALTER INDEX and **CREATE INDEX**

1.13.10.19 DROP LANGUAGE

Description

Drops a procedural language.

Precautions

This syntax is not supported currently.

1.13.10.20 DROP MASKING POLICY

Description

Drops a masking policy.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Precautions

Only users with the POLADMIN or SYSADMIN permission, or the initial user can perform this operation.

Syntax

```
DROP MASKING POLICY [ IF EXISTS ] policy_name;
```

Parameters

policy_name

Specifies the masking policy name, which must be unique.

Value range: names of existing policies (character strings).

Example

```
-- Create table tb_for_masking.
gaussdb=# CREATE TABLE tb_for_masking(idx int, col1 text, col2 text, col3 text, col4 text, col5 text, col6 text, col7 text,col8 text);

-- Insert data into the tb_for_masking table.
gaussdb=# INSERT INTO tb_for_masking VALUES(1, '9876543210', 'usr321usr', 'abc@huawei.com', 'abc@huawei.com', '1234-4567-7890-0123', 'abcdef 123456 ui 323 jsfd321 j3k2l3', '4880-9898-4545-2525', 'this is a llt case');

-- Create a resource label for sensitive column col1.
gaussdb=# CREATE RESOURCE LABEL mask_lb1 ADD COLUMN(tb_for_masking.col1);

-- Create a resource label for sensitive column col2.
gaussdb=# CREATE RESOURCE LABEL mask_lb2 ADD COLUMN(tb_for_masking.col2);

-- Create a resource label for sensitive column col3.
gaussdb=# CREATE RESOURCE LABEL mask_lb3 ADD COLUMN(tb_for_masking.col3);

-- Create a data masking policy named maskpol1.
gaussdb=# CREATE MASKING POLICY maskpol1 maskall ON LABEL(mask_lb1);

-- Create a data masking policy named maskpol2.
gaussdb=# CREATE MASKING POLICY maskpol2 randommasking ON LABEL(mask_lb2);

-- Create a data masking policy named maskpol3.
gaussdb=# CREATE MASKING POLICY maskpol3 basicemailmasking ON LABEL(mask_lb3);

-- Drop a masking policy.
gaussdb=# DROP MASKING POLICY IF EXISTS maskpol1;

-- Drop a group of masking policies.
gaussdb=# DROP MASKING POLICY IF EXISTS maskpol2, maskpol3;

-- Drop resource labels.
gaussdb=# DROP RESOURCE LABEL mask_lb1;
gaussdb=# DROP RESOURCE LABEL mask_lb2;
gaussdb=# DROP RESOURCE LABEL mask_lb3;

-- Drop a table.
gaussdb=# DROP TABLE tb_for_masking;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Helpful Links

ALTER MASKING POLICY and **CREATE MASKING POLICY**

1.13.10.21 DROP MATERIALIZED VIEW

Description

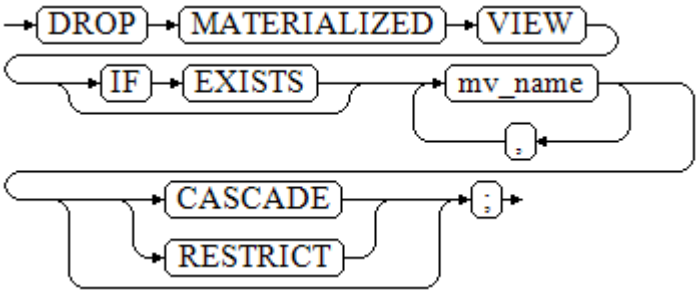
Drops an existing materialized view from the database.

Precautions

The owner of a materialized view, owner of the schema where the materialized view resides, users with the DROP MATERIALIZED VIEW permission, or users with the DROP ANY TABLE permission can perform this operation. System administrators have this permission by default.

Syntax

```
DROP MATERIALIZED VIEW [ IF EXISTS ] mv_name [, ...] [ CASCADE | RESTRICT ];
```



Parameters

- **IF EXISTS**

  Checks whether a specified materialized view exists.

  - If the materialized view exists, it will be dropped successfully.
  - If the materialized view does not exist, the DROP operation will not be performed. Only a NOTICE message will be generated, indicating that the materialized view does not exist.

- **mv_name**

  Specifies the name of the materialized view to be dropped.

- **CASCADE | RESTRICT**

  (Optional) Specifies whether to drop objects that depend on the materialized view when dropping the materialized view itself. If this parameter is not specified, the default value is **RESTRICT**.

  - **CASCADE**: The database cascadingly drops the objects that depend on the materialized view.
  - **RESTRICT**: The database refuses to drop the materialized view if any objects depend on it.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Examples

```
-- Create a table.
gaussdb=# CREATE TABLE my_table (c1 int, c2 int)
WITH(STORAGE_TYPE=ASTORE);

-- Create a materialized view named my_mv.
gaussdb=# CREATE MATERIALIZED VIEW my_mv AS SELECT * FROM my_table;

-- Drop the materialized view named my_mv.
gaussdb=# DROP MATERIALIZED VIEW my_mv;

-- Drop a table.
gaussdb=# DROP TABLE my_table;
```

Helpful Links

1.13.10.22 DROP MODEL

Description

Drops a model object that has been trained and saved.

Precautions

This syntax is not supported currently.

1.13.10.23 DROP NODE

Description

Drops nodes from a cluster.

Precautions

DROP NODE is an API of the cluster management tool and is used to manage clusters. Only administrators have the permission to use this API. Do not use this API directly. Otherwise, the cluster status may be affected and the database may be unavailable.

Syntax

```
DROP NODE [ IF EXISTS ] nodename [WITH ( cnnodename [, ... ] )] (nodetype);
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameters

- **IF EXISTS**

  Reports a notice instead of an error if the specified node does not exist.

- **nodename**

  Specifies the name of the node to be dropped.

  Value range: an existing node name.

- **cnnodename**

  Specifies the CN name. If this parameter is defined, the cluster nodes under the currently connected CN and the defined CN are dropped.

  Value range: an existing CN name.

- **nodetype**

  Type of the node to be changed, which is the value of **node_type** in the pgxc_node system catalog.

  Value range: **"C"** (CN)

NOTE

If there are multiple CNs, cluster nodes are created only on the currently connected CNs and will not be synchronized to other CNs. You need to create cluster nodes on all CNs. To drop a cluster node, you only need to connect to one CN. If cluster nodes are created on only one CN, you need to define the current CN name and drop the cluster node on the CN.

Examples

```
-- Create cluster nodes on all CNs.
gaussdb=# CREATE NODE datanode1 WITH(
   TYPE = datanode,
   PREFERRED = false
);

-- Connect to only one CN to drop cluster nodes.
gaussdb=# DROP NODE datanode1;
```

Helpful Links

CREATE NODE and **ALTER NODE**

1.13.10.24 DROP NODE GROUP

Description

Drops a node group.

Precautions

- DROP NODE GROUP is an API of the cluster management tool.
- Only system administrators or users with the DROP permission on node groups can perform this operation.

Syntax

```
DROP NODE GROUP groupname;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameters

groupname

Specifies the name of the node group to be dropped.

Value range: names of existing node groups.

Examples

```
-- Query the initial cluster DN status.
gaussdb=# SELECT node_name, nodeis_preferred FROM pgxc_node WHERE node_type = 'D' ORDER BY 1;
 node_name | nodeis_preferred
-----------+------------------
 dn_6001_6002_6003 | f
 dn_6004_6005_6006 | f
 dn_6007_6008_6009 | f
(3 rows)

-- Create a node group and replace dn_6001_6002_6003 with the actual node name obtained in the previous step.
gaussdb=# CREATE NODE GROUP test_group WITH ( dn_6001_6002_6003 );

-- Drop the node group.
gaussdb=# DROP NODE GROUP test_group;
```

Helpful Links

ALTER NODE GROUP and **CREATE NODE GROUP**

1.13.10.25 DROP OWNED

Description

Deletes the database objects owned by a database role.

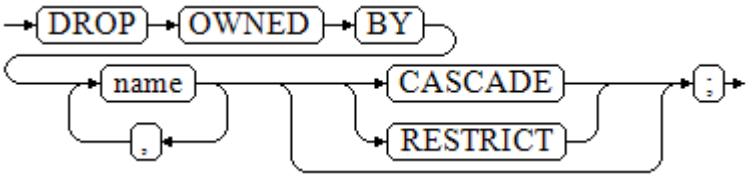
Precautions

- The role's permissions on all objects in the current database and shared objects (databases and tablespaces) will be revoked.
- DROP OWNED is usually considered as a preparation for removing one or more roles and affects only the objects in the current database. You need to run this statement in each database that contains the objects owned by the role to be removed.
- Using the **CASCADE** option may recursively delete objects owned by other users. Exercise caution when using this option.
- The databases and tablespaces owned by the role will not be removed.
- Private database links owned by a role can be dropped only after the **CASCADE** option is added.

Syntax

```
DROP OWNED BY name [, ...] [ CASCADE | RESTRICT ];
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.



Parameters

- **name**

  Specifies the role name.

- **CASCADE | RESTRICT**

  (Optional) Specifies whether to delete objects that depend on the role in cascading mode. The default value is **RESTRICT**.

  – **CASCADE**: cascadingly drops the objects that depend on the objects to be dropped.

  – **RESTRICT**: refuses to delete the role that has dependent objects.

Examples

```
-- Create user jim.
gaussdb=# CREATE USER jim PASSWORD '********';

-- Revoke user jim's permissions on all objects in the current database and on shared objects (databases and tablespaces).
gaussdb=# DROP OWNED BY jim;

-- Delete user jim.
gaussdb=# DROP USER jim;
```

Helpful Links

REASSIGN OWNED

1.13.10.26 DROP PACKAGE

Description

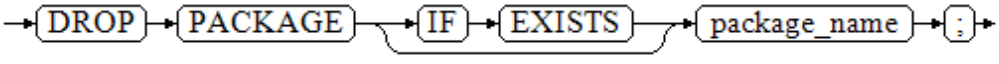
Drops an existing package or package body.

Precautions

- After a package body is dropped, the stored procedures and functions in the package become invalid.
- Only the initial user has the permission to perform the DROP operation on the packages of the initial user.

Syntax

```
DROP PACKAGE [ IF EXISTS ] package_name;
```



```
DROP PACKAGE BODY [ IF EXISTS ] package_name;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameters

- **IF EXISTS**

  Checks whether a specified package or package body exists.

  - If the package or package body exists, it will be dropped successfully.
  - If the package or package body does not exist, the DROP operation will not be performed. Only a NOTICE message will be generated, indicating that the package or package body does not exist.

- **package_name**

  Specifies the name of the package to be dropped.

  Value range: names of existing packages.

Examples

```
-- Create an ORA-compatible database.
gaussdb=# CREATE DATABASE ora_compat_db DBCOMPATIBILITY 'ORA';
CREATE DATABASE
gaussdb=# \c ora_compat_db

-- Create a package.
ora_compat_db=# CREATE OR REPLACE PACKAGE emp_bonus IS
var1 INT:=1;-- Public variable
var2 INT:=2;
PROCEDURE testpro1(var3 INT);-- Public stored procedure, which can be called by external systems.
END emp_bonus;
/

-- Drop a package.
ora_compat_db=# DROP PACKAGE emp_bonus;

-- Switch back to the initial database and drop the ORA-compatible database. Replace postgres with the actual database name.
ora_compat_db=# \c postgres
gaussdb=# DROP DATABASE ora_compat_db;
```

Helpful Links

ALTER PACKAGE and **CREATE PACKAGE**

1.13.10.27 DROP PROCEDURE

Description

Drops a stored procedure.

Precautions

Only the initial user has the permission to perform the DROP operation on the stored procedures of the initial user.

Syntax

```
DROP PROCEDURE [ IF EXISTS ] procedure_name;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameters

- **IF EXISTS**

  Checks whether a specified stored procedure exists.
  - If the stored procedure exists, it will be dropped successfully.
  - If the stored procedure does not exist, the DROP operation will not be performed. Only a NOTICE message will be generated, indicating that the stored procedure does not exist.
- **procedure_name**

  Specifies the name of the stored procedure to be dropped.

  Value range: names of existing stored procedures.

Examples

For details, see **CREATE PROCEDURE** in **Examples**.

Helpful Links

ALTER PROCEDURE and **CREATE PROCEDURE**

1.13.10.28 DROP RESOURCE LABEL

Description

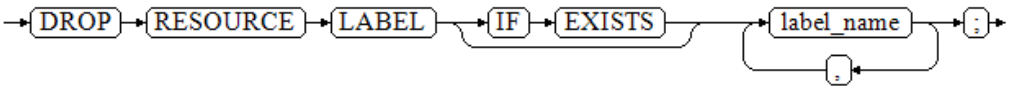
Drops a resource label.

Precautions

Only users with the POLADMIN or SYSADMIN permission, or the initial user, can perform this operation.

Syntax

```
DROP RESOURCE LABEL [IF EXISTS] label_name [, ...];
```



Parameters

label_name

Specifies the name of the resource label to be dropped.

Value range: character strings complying with **Identifier Naming Conventions**.

Examples

```
-- Create table tb_for_label.
gaussdb=# CREATE TABLE tb_for_label(col1 text, col2 text, col3 text);
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
-- Create a resource label based on a table.
gaussdb=# CREATE RESOURCE LABEL IF NOT EXISTS table_label add TABLE(public.tb_for_label);

-- Create an existing table resource label again and compare the differences between adding IF NOT EXISTS and not adding IF NOT EXISTS.
gaussdb=# CREATE RESOURCE LABEL IF NOT EXISTS table_label add TABLE(public.tb_for_label);
NOTICE:  table_label label already defined, skipping
CREATE RESOURCE LABEL
gaussdb=# CREATE RESOURCE LABEL table_label add TABLE(public.tb_for_label);
ERROR:  table_label label already defined

-- Create a resource label based on columns.
gaussdb=# CREATE RESOURCE LABEL IF NOT EXISTS column_label add COLUMN(public.tb_for_label.col1);

-- Create schema schema_for_label.
gaussdb=# CREATE SCHEMA schema_for_label;

-- Create a resource label based on a schema.
gaussdb=# CREATE RESOURCE LABEL IF NOT EXISTS schema_label add SCHEMA(schema_for_label);

-- Create view view_for_label.
gaussdb=# CREATE VIEW view_for_label AS SELECT 1;

-- Create a resource label based on a view.
gaussdb=# CREATE RESOURCE LABEL IF NOT EXISTS view_label add VIEW(view_for_label);

-- Create function func_for_label.
gaussdb=# CREATE FUNCTION func_for_label RETURNS TEXT AS $$ SELECT col1 FROM tb_for_label; $$ LANGUAGE SQL;

-- Create a resource label based on a function.
gaussdb=# CREATE RESOURCE LABEL IF NOT EXISTS func_label add FUNCTION(func_for_label);

-- Drop the table resource label table_label.
gaussdb=# DROP RESOURCE LABEL IF EXISTS table_label;

-- Drop the column resource label column_label.
gaussdb=# DROP RESOURCE LABEL IF EXISTS column_label;

-- Drop the function resource label func_for_label.
gaussdb=# DROP FUNCTION func_for_label;

-- Drop the view resource label view_for_label.
gaussdb=# DROP VIEW view_for_label;

-- Drop the schema resource label schema_for_label.
gaussdb=# DROP SCHEMA schema_for_label;

-- Drop the tb_for_label table.
gaussdb=# DROP TABLE tb_for_label;
```

Helpful Links

ALTER RESOURCE LABEL and **CREATE RESOURCE LABEL**

1.13.10.29 DROP RESOURCE POOL

Description

Drops a resource pool.

NOTE

The resource pool cannot be dropped if it is associated with a role.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Precautions

- Only users with the SYSADMIN permission or the initial user can perform this operation.
- This syntax is not supported during upgrade.

Syntax

```
DROP RESOURCE POOL [ IF EXISTS ] pool_name;
```

Parameters

- **IF EXISTS**

  Checks whether the specified resource pool exists.

  - If the specified resource pool exists, the deletion is successful.
  - If the specified resource pool does not exist, the deletion is not performed. Only a NOTICE message is generated, indicating that the specified resource pool does not exist.

- **pool_name**

  Specifies the name of a created resource pool.

  Value range: character strings complying with **Identifier Naming Conventions**.

NOTE

In a multi-tenant scenario, dropping a group resource pool also drops the related service resource pools. A resource pool can be dropped only when it is not associated with any users.

Examples

For details, see **CREATE RESOURCE POOL** in **Examples**.

Helpful Links

ALTER RESOURCE POOL and **CREATE RESOURCE POOL**

1.13.10.30 DROP ROLE

Description

Drops a role.

Syntax

```
DROP ROLE [ IF EXISTS ] role_name [, ...];
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameters

- **IF EXISTS**

  Checks whether a specified role exists.

  - If the role exists, it will be dropped successfully.
  - If the role does not exist, the DROP operation will not be performed. Only a NOTICE message will be generated, indicating that the role does not exist.

- **role_name**

  Specifies the name of the role to be dropped.

  Value range: names of existing roles.

Examples

```
-- Create role role11.
gaussdb=# CREATE ROLE role11  PASSWORD '********';
CREATE ROLE

-- Drop role role11.
gaussdb=# DROP ROLE IF EXISTS role11;
DROP ROLE

-- Drop role role12 that does not exist.
gaussdb=# DROP ROLE IF EXISTS role12;
NOTICE:  role "role12" does not exist, skipping
DROP ROLE
```

Helpful Links

CREATE ROLE, **ALTER ROLE**, and **SET ROLE**

1.13.10.31 DROP ROW LEVEL SECURITY POLICY

Description

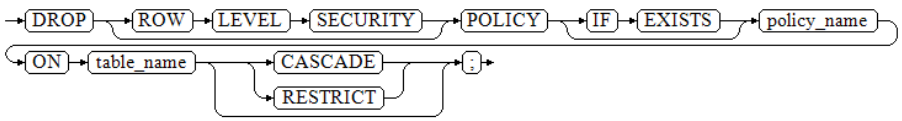
Drops a row-level security policy from a table.

Precautions

Only the table owner or administrators can drop a row-level security policy from the table.

Syntax

```
DROP [ ROW LEVEL SECURITY ] POLICY [ IF EXISTS ] policy_name ON table_name [ CASCADE | RESTRICT ];
```



Parameters

- **IF EXISTS**

  Checks whether a specified row-level security policy exists.

  - If the row-level security policy exists, it will be dropped successfully.
  - If the row-level security policy does not exist, the DROP operation will not be performed. Only a NOTICE message will be generated, indicating that the row-level security policy does not exist.
- **policy_name**

  Specifies the name of the row-level security policy to be dropped.
- **table_name**

  Specifies the name of the table containing the row-level security policy.
- **CASCADE | RESTRICT**

  Currently, no objects depend on row-level security policies. Therefore, CASCADE is equivalent to RESTRICT, and they are reserved to ensure backward compatibility.

Examples

```
-- Create the data table all_data.
gaussdb=# CREATE TABLE all_data(id int, role varchar(100), data varchar(100));

-- Create a row-level security policy.
gaussdb=# CREATE ROW LEVEL SECURITY POLICY all_data_rls ON all_data USING(role = CURRENT_USER);

-- Drop the row-level security policy.
gaussdb=# DROP ROW LEVEL SECURITY POLICY all_data_rls ON all_data;

-- Drop the all_data table.
gaussdb=# DROP TABLE all_data;
```

Helpful Links

ALTER ROW LEVEL SECURITY POLICY and **CREATE ROW LEVEL SECURITY POLICY**

1.13.10.32 DROP SCHEMA

Description

Drops a specified schema from the current database.

Precautions

- Only the schema owner or users with the DROP permission on the schema can execute the **DROP SCHEMA** command. When separation of duties is disabled, system administrators have this permission by default.
- You are not allowed to drop DBE_PLDEVELOPER when **allow_system_table_mods** is disabled.
- Only the initial user can perform the DROP operation on system schemas, except public schemas.

Syntax

```
DROP SCHEMA [ IF EXISTS ] schema_name [, ...] [ CASCADE | RESTRICT ];
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameters

- **IF EXISTS**

  Checks whether the specified schema exists. This parameter can be used to avoid errors.

  - If the specified schema exists, you can perform DROP directly.
  - If the specified schema does not exist, a notice will be issued instead of an error.

- **schema_name**

  Specifies a schema name.

  Value range: existing schema names.

- **CASCADE | RESTRICT**

  (Optional) Specifies whether to drop objects that depend on the schema when dropping the schema itself. If not specified, the default is **RESTRICT**.

  - **CASCADE**: automatically drops all the objects contained in the schema.
  - **RESTRICT**: If the schema contains any objects, the schema will fail to be dropped.

NOTICE

- Do not drop schemas starting with pg_temp or pg_toast_temp. Such schemas are for internal use only, and dropping them may result in unexpected results.
- Do not directly drop the current schema. You can switch to another schema and then drop the current schema.

Examples

```
-- Create role role2.
gaussdb=# CREATE ROLE role2 IDENTIFIED BY '********';

-- Create a schema based on the name.
gaussdb=# CREATE SCHEMA schema1 AUTHORIZATION role2;
CREATE SCHEMA

-- Drop the schema.
gaussdb=# DROP SCHEMA schema1 CASCADE;

-- Drop a user.
gaussdb=# DROP USER role2 CASCADE;
```

Helpful Links

ALTER SCHEMA and **CREATE SCHEMA**

1.13.10.33 DROP SECURITY LABEL

Description

Drops a security label from the current database.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Precautions

The initial user, a user with the SYSADMIN permission, or a user who inherits permissions of the built-in role gs_role_seclabel can drop security labels.

Syntax

```
DROP SECURITY LABEL label_name;
```

Parameters

label_name

Specifies the name of the security label to be dropped. The security label must exist in the database.

Examples

```
-- Create a security label sec_label.
gaussdb=# CREATE SECURITY LABEL sec_label 'L1:G4';

-- Drop the security label sec_label2 that does not exist.
gaussdb=# DROP SECURITY LABEL sec_label2;
ERROR:  security label "sec_label2" does not exist

-- Drop the existing security label sec_label.
gaussdb=# DROP SECURITY LABEL sec_label;
```

Helpful Links

CREATE SECURITY LABEL and **SECURITY LABEL ON**

1.13.10.34 DROP SEQUENCE

Description

Drops a sequence from the current database.

Precautions

Only the owner of a sequence, the owner of the schema to which the sequence belongs, or users with the DROP permission on a sequence or users with the DROP ANY SEQUENCE permission can perform this operation. When separation of duties is disabled, system administrators have this permission by default.

Syntax

```
DROP [LARGE] SEQUENCE [ IF EXISTS ] { [schema.] sequence_name } [ , ... ] [ CASCADE | RESTRICT ];
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameters

- **LARGE**

  Specifies a LARGE flag. If a LARGE flag is used when the sequence is created, the LARGE flag must be specified when the sequence is dropped.

- **IF EXISTS**

  Checks whether a specified sequence exists.

  - If the sequence exists, it will be dropped successfully.
  - If the sequence does not exist, the DROP operation will not be performed. Only a NOTICE message will be generated, indicating that the sequence does not exist.

- **sequence_name**

  Specifies a sequence name.

- **CASCADE | RESTRICT**

  (Optional) Specifies whether to drop objects that depend on the sequence when dropping the sequence itself. If this parameter is not specified, the default value is **RESTRICT**.

  - **CASCADE**: The database cascadingly drops the objects that depend on the sequence.
  - **RESTRICT**: The database refuses to drop the sequence if any objects depend on it.

Examples

```
-- Create an ascending sequence named serial, starting from 101.
gaussdb=# CREATE SEQUENCE serial START 101;

-- Drop the sequence.
gaussdb=# DROP SEQUENCE serial;
```

Helpful Links

ALTER SEQUENCE and **DROP SEQUENCE**

1.13.10.35 DROP SERVER

Description

Drops an existing data server.

Precautions

Only the server owner or users with the DROP permission can perform this operation. System administrators have this permission by default.

Syntax

```
DROP SERVER [ IF EXISTS ] server_name [ CASCADE | RESTRICT ];
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameters

- **IF EXISTS**

  Checks whether a specified data server exists.

  - If the data server exists, it will be dropped successfully.
  - If the data server does not exist, the DROP operation will not be performed. Only a NOTICE message will be generated, indicating that the data server does not exist.

- **server_name**

  Specifies the name of the data server to be dropped.

- **CASCADE | RESTRICT**

  (Optional) Specifies whether to drop objects that depend on the data server when dropping the server itself. If this parameter is not specified, the default value is **RESTRICT**.

  - **CASCADE**: The database cascadingly drops the objects that depend on the data server.
  - **RESTRICT**: The database refuses to drop the data server if any objects depend on it.

Examples

```
-- Create a server.
gaussdb=# CREATE SERVER my_server FOREIGN DATA WRAPPER log_fdw;
CREATE SERVER

-- Drop a server.
gaussdb=# DROP SERVER my_server;
DROP SERVER
```

Helpful Links

ALTER SERVER and **CREATE SERVER**

1.13.10.36 DROP SYNONYM

Description

Drops a synonym.

Precautions

Only the synonym owner or users with the DROP ANY SYNONYM permission can perform this operation. System administrators have this permission by default.

Syntax

```
DROP [PUBLIC] SYNONYM [ IF EXISTS ] synonym_name [ CASCADE | RESTRICT ];
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameters

- **PUBLIC**

  (Optional) Drops PUBLIC synonyms.

- **IF EXISTS**

  Checks whether a specified synonym exists.

  - If the synonym exists, it will be dropped successfully.
  - If the synonym does not exist, the DROP operation will not be performed. Only a NOTICE message will be generated, indicating that the synonym does not exist.

- **synonym_name**

  Specifies the synonym name (using a schema optionally).

- **CASCADE | RESTRICT**

  (Optional) Specifies whether to drop objects that depend on the synonym when dropping the synonym itself. If this parameter is not specified, the default value is **RESTRICT**.

  - **CASCADE**: The database cascadingly drops the objects (such as views) that depend on the synonym.
  - **RESTRICT**: The database refuses to drop the synonym if any objects depend on it.

Examples

```
-- Create a synonym.
gaussdb=# CREATE OR REPLACE SYNONYM test_tbl1 FOR test_tbl1;
-- Drop a synonym.
gaussdb=# DROP SYNONYM test_tbl1;
```

Helpful Links

ALTER SYNONYM and **CREATE SYNONYM**

1.13.10.37 DROP TABLE

Description

Drops a table.

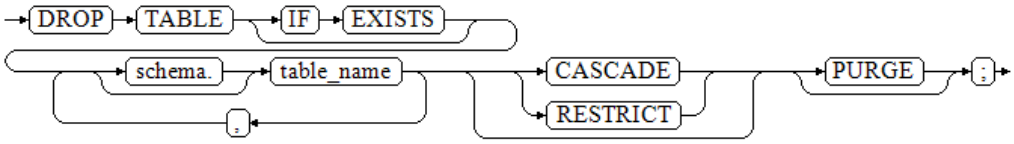
Precautions

- After the table is dropped, the indexes depending on the table are dropped, and the functions and stored procedures that need to use this table cannot be executed. Deleting a partitioned table also deletes all partitions in the table.
- Only the owner of a table, the owner of the schema of the table, users with the DROP permission on the table, or users with the DROP ANY TABLE permission can perform this operation. When separation of duties is disabled, system administrators have the permission by default.

Syntax

```
DROP TABLE [ IF EXISTS ]
   { [schema.]table_name } [, ...] [ CASCADE | RESTRICT ] [ PURGE ];
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.



Parameters

- **IF EXISTS**

  Checks whether a specified table exists.

  - If the table exists, it will be dropped successfully.
  - If the table does not exist, the DROP operation will not be performed. Only a NOTICE message will be generated, indicating that the table does not exist.

- **schema**

  Specifies a schema name. The parameter is optional. It is used to specify restrictions for a table.

- **table_name**

  Table name.

- **CASCADE | RESTRICT**

  (Optional) Specifies whether to drop objects that depend on the table when dropping the table itself. If this parameter is not specified, the default value is **RESTRICT**.

  - **CASCADE**: The database cascadingly drops the objects that depend on the table, such as views, triggers, and indexes. Note that joined table objects cannot be dropped cascadingly.
  - **RESTRICT**: The database refuses to drop the table if any objects depend on it.

- **PURGE**

  Specifies that even if the recycle bin function is enabled, the table is physically dropped instead of being moved to the recycle bin when you use DROP TABLE to drop tables.

Examples

```
-- Create the test table.
gaussdb=# CREATE TABLE test(c1 int, c2 int);
-- Drop the test table.
gaussdb=# DROP TABLE IF EXISTS test;

-- Create the test1 table.
gaussdb=# CREATE TABLE test1(c1 int, c2 int);
-- Create the v_test1 view.
gaussdb=# CREATE VIEW v_test1 AS SELECT * FROM test1 WHERE c1 < 20;
-- An error is reported when the table is dropped.
gaussdb=# DROP TABLE test1;
ERROR:  table test1 cannot be dropped because other objects depend on it.
DETAIL:  view v_test1 depends on table test1
HINT:  Use DROP ... CASCADE to drop the dependent objects.

-- Use the CASCADE parameter to drop the test1 table, which will cascadingly drop the views.
gaussdb=# DROP TABLE test1 CASCADE;
NOTICE:  drop cascades to view v_test1
DROP TABLE
```

ALTER TABLE and **CREATE TABLE**

1.13.10.38 DROP TABLESPACE

Description

Drops a tablespace.

Precautions

- Only the tablespace owner or users with the DROP TABLESPACE permission can perform this operation. System administrators have this permission by default.
- The tablespace to be dropped should not contain any database objects. Otherwise, an error will be reported.
- After a tablespace is dropped, rollback is not supported. Therefore, the tablespace cannot be dropped within a transaction block.
- When you drop a tablespace, if another session is running **\db** for a query, the query may fail due to the tablespace transaction. In this case, run **\db** again.
- If DROP TABLESPACE fails to be executed, execute DROP TABLESPACE IF EXISTS.

Syntax

```
DROP TABLESPACE [ IF EXISTS ] tablespace_name;
```

Parameters

- **IF EXISTS**

  Checks whether a specified tablespace exists.

  - If the tablespace exists, it will be dropped successfully.
  - If the tablespace does not exist, the DROP operation will not be performed. Only a NOTICE message will be generated, indicating that the tablespace does not exist.

- **tablespace_name**

  Specifies the tablespace name.

  Value range: names of existing tablespaces.

Examples

```
-- Create a tablespace.
gaussdb=# CREATE TABLESPACE tbs_location1 RELATIVE LOCATION 'test_tablespace/test_tablespace_1';

-- Drop the tablespace.
gaussdb=# DROP TABLESPACE tbs_location1;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Helpful Links

ALTER TABLESPACE and **CREATE TABLESPACE**

1.13.10.39 DROP TEXT SEARCH CONFIGURATION

NOTICE

This function is for internal use only. You are advised not to use it.

Description

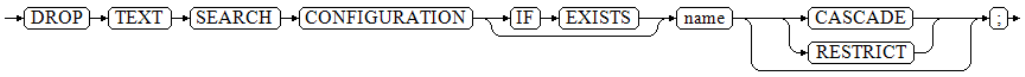
Drops an existing text search configuration.

Precautions

Only the owner of the text search configuration can perform this operation.

Syntax

```
DROP TEXT SEARCH CONFIGURATION [ IF EXISTS ] name [ CASCADE | RESTRICT ];
```



Parameters

- **IF EXISTS**

  Checks whether a specified text search configuration exists.
  - If the text search configuration exists, it will be dropped successfully.
  - If the text search configuration does not exist, the DROP operation will not be performed. Only a NOTICE message will be generated, indicating that the text search configuration does not exist.
- **name**

  Specifies the name of the text search configuration to be dropped. You can use a pattern to specify the name.
- **CASCADE | RESTRICT**

  (Optional) Specifies whether to drop objects that depend on the text search configuration when dropping the text search configuration itself. If this parameter is not specified, the default value is **RESTRICT**.
  - **CASCADE**: The database cascadingly drops the objects that depend on the text search configuration.
  - **RESTRICT**: The database refuses to drop the text search configuration if any objects depend on it.

Examples

For details, see **CREATE TEXT SEARCH CONFIGURATION** in **Examples**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

1.13.10.40 DROP TEXT SEARCH DICTIONARY

NOTICE

This function is for internal use only. You are advised not to use it.

Description

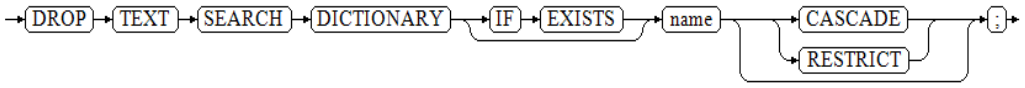
Drops an existing full-text search dictionary.

Precautions

- Predefined dictionary templates do not support the DROP operation.
- Only the owner of a dictionary or a system administrator has the permission to perform this operation.
- Exercise caution when specifying **CASCADE** explicitly with DROP. This operation will cascadingly drop the text search configuration that uses the dictionary.

Syntax

```
DROP TEXT SEARCH DICTIONARY [ IF EXISTS ] name [ CASCADE | RESTRICT ];
```



Parameters

- **IF EXISTS**

  Checks whether a specified full-text search dictionary exists.
  - If the full-text search dictionary exists, it will be dropped successfully.
  - If the full-text search dictionary does not exist, the DROP operation will not be performed. Only a NOTICE message will be generated, indicating that the full-text search dictionary does not exist.
- **name**

  Specifies the name (optionally schema-qualified) of the full-text search dictionary to be dropped. (If you do not specify a schema name, the dictionary will be dropped in the current schema by default.)

  Value range: names of existing dictionaries.
- **CASCADE** | **RESTRICT**

  (Optional) Specifies whether to drop objects that depend on the dictionary when dropping the dictionary itself. If this parameter is not specified, the default value is **RESTRICT**.
  - **CASCADE**: The database cascadingly drops the objects that depend on the full-text search dictionary and other objects that depend on these objects.
  - **RESTRICT**: The database refuses to drop the dictionary if any objects depend on it.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Examples

```
-- Create the dictionary english.
gaussdb=# CREATE TEXT SEARCH DICTIONARY english (
    TEMPLATE = simple
);

-- Drop the english dictionary.
gaussdb=# DROP TEXT SEARCH DICTIONARY english;
```

Helpful Links

CREATE TEXT SEARCH DICTIONARY

1.13.10.41 DROP TRIGGER

Description

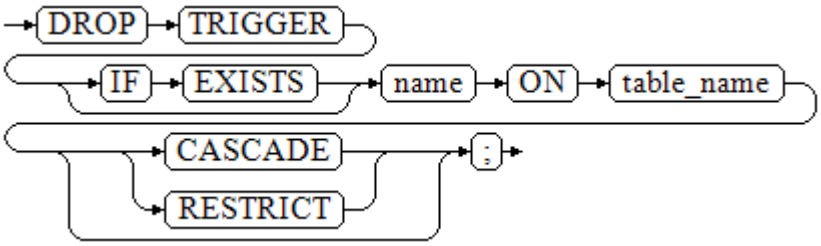
Drops a trigger.

Precautions

Only the trigger owner or users with the DROP ANY TRIGGER permission can perform this operation. System administrators have this permission by default.

Syntax

```
DROP TRIGGER [ IF EXISTS ] name ON table_name [ CASCADE | RESTRICT ];
```



Parameters

- **IF EXISTS**

  Checks whether a specified trigger exists.

  - If the trigger exists, it will be dropped successfully.
  - If the trigger does not exist, the DROP operation will not be performed. Only a NOTICE message will be generated, indicating that the trigger does not exist.

- **trigger_name**

  Specifies the name of the trigger to be deleted.

  Value range: an existing trigger name

- **table_name**

  Specifies the name of the table containing the trigger.

  Value range: name of the table containing the trigger

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **CASCADE | RESTRICT**

  (Optional) Specifies whether to drop objects that depend on the trigger when dropping the trigger itself. If this parameter is not specified, the default value is **RESTRICT**.

  – **CASCADE**: The database cascadingly drops the objects that depend on the trigger.

  – **RESTRICT**: The database refuses to drop the trigger if any objects depend on it.

Examples

```
-- Create a source table and a target table.
gaussdb=# CREATE TABLE test_trigger_src_tbl(id1 INT, id2 INT, id3 INT);
gaussdb=# CREATE TABLE test_trigger_des_tbl(id1 INT, id2 INT, id3 INT);
```

Use the INSERT trigger.

```
-- Create an INSERT trigger function.
gaussdb=# CREATE OR REPLACE FUNCTION tri_insert_func() RETURNS TRIGGER AS
        $$
        DECLARE
        BEGIN
                INSERT INTO test_trigger_des_tbl VALUES(NEW.id1, NEW.id2, NEW.id3);
                RETURN NEW;
        END
        $$ LANGUAGE plpgsql;

-- Create an INSERT trigger.
gaussdb=# CREATE TRIGGER insert_trigger
        BEFORE INSERT ON test_trigger_src_tbl
        FOR EACH ROW
        EXECUTE PROCEDURE tri_insert_func();

-- Execute the INSERT event and check the trigger results.
gaussdb=# INSERT INTO test_trigger_src_tbl VALUES(100,200,300);

gaussdb=# SELECT * FROM test_trigger_src_tbl;
 id1 | id2 | id3
-----+-----+-----
 100 | 200 | 300
(1 row)

gaussdb=# SELECT * FROM test_trigger_des_tbl;  // Check whether the trigger operation takes effect.
 id1 | id2 | id3
-----+-----+-----
 100 | 200 | 300
(1 row)
```

Use the UPDATE trigger.

```
-- Create an UPDATE trigger function.
gaussdb=# CREATE OR REPLACE FUNCTION tri_update_func() RETURNS TRIGGER AS
$$
DECLARE
BEGIN
UPDATE test_trigger_des_tbl SET id3 = NEW.id3 WHERE id1=OLD.id1;
RETURN OLD;
END
$$ LANGUAGE plpgsql;

-- Create an UPDATE trigger.
gaussdb=# CREATE TRIGGER update_trigger
        AFTER UPDATE ON test_trigger_src_tbl
        FOR EACH ROW
        EXECUTE PROCEDURE tri_update_func();
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
-- Execute the UPDATE event and check the trigger results.
gaussdb=# UPDATE test_trigger_src_tbl SET id3=400 WHERE id1=100;

gaussdb=# SELECT * FROM test_trigger_src_tbl;
 id1 | id2 | id3
-----+-----+-----
 100 | 200 | 400
(1 row)

gaussdb=# SELECT * FROM test_trigger_des_tbl;  // Check whether the trigger operation takes effect.
 id1 | id2 | id3
-----+-----+-----
 100 | 200 | 400
(1 row)
```

Use the DELETE trigger.

```
-- Create a DELETE trigger function.
gaussdb=# CREATE OR REPLACE FUNCTION TRI_DELETE_FUNC() RETURNS TRIGGER AS
        $$
        DECLARE
        BEGIN
                DELETE FROM test_trigger_des_tbl WHERE id1=OLD.id1;
                RETURN OLD;
        END
        $$ LANGUAGE plpgsql;

-- Create a DELETE trigger.
gaussdb=# CREATE TRIGGER delete_trigger BEFORE DELETE ON test_trigger_src_tbl FOR EACH ROW
EXECUTE PROCEDURE tri_delete_func();

-- Execute the DELETE event and check the trigger results.
gaussdb=# DELETE FROM test_trigger_src_tbl WHERE id1=100;

gaussdb=# SELECT * FROM test_trigger_src_tbl;
 id1 | id2 | id3
-----+-----+-----
(0 rows)

gaussdb=# SELECT * FROM test_trigger_des_tbl;  // Check whether the trigger operation takes effect.
 id1 | id2 | id3
-----+-----+-----
(0 rows)
```

Rename a trigger.

```
-- Rename a trigger.
gaussdb=# ALTER TRIGGER delete_trigger ON test_trigger_src_tbl RENAME TO delete_trigger_renamed;
```

Disable a trigger.

```
-- Disable insert_trigger.
gaussdb=# ALTER TABLE test_trigger_src_tbl DISABLE TRIGGER insert_trigger;

gaussdb=# INSERT INTO test_trigger_src_tbl VALUES(100,200,300);

gaussdb=# SELECT * FROM test_trigger_src_tbl;
 id1 | id2 | id3
-----+-----+-----
 100 | 200 | 300
(1 row)

gaussdb=# SELECT * FROM test_trigger_des_tbl; // The trigger does not take effect.
 id1 | id2 | id3
-----+-----+-----
(0 rows)

-- Disable all triggers on the current table.
gaussdb=# ALTER TABLE test_trigger_src_tbl DISABLE TRIGGER ALL;
```

Deleting a trigger

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gaussdb=# DROP TRIGGER insert_trigger ON test_trigger_src_tbl;

gaussdb=# DROP TRIGGER update_trigger ON test_trigger_src_tbl;

gaussdb=# DROP TRIGGER delete_trigger_renamed ON test_trigger_src_tbl;
```

Deleting a function

```
gaussdb=# DROP FUNCTION tri_insert_func;

gaussdb=# DROP FUNCTION tri_update_func;

gaussdb=# DROP FUNCTION tri_delete_func;
-- Drop the source table and destination table.
gaussdb=# DROP TABLE test_trigger_src_tbl;
gaussdb=# DROP TABLE test_trigger_des_tbl;
```

Helpful Links

CREATE TRIGGER, **ALTER TRIGGER**, and **ALTER TABLE**

1.13.10.42 DROP TYPE

Description

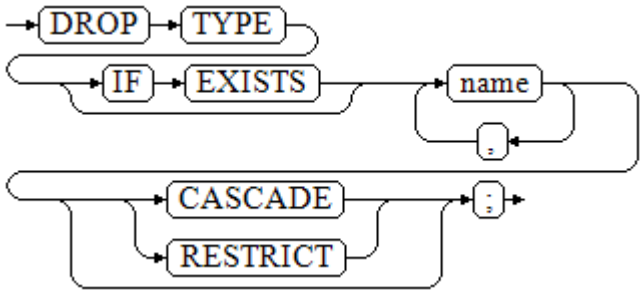
Drops a user-defined data type.

Precautions

Only the owner of a type, users with the DROP TYPE permission, or users with the DROP ANY TYPE permission can perform this operation. When separation of duties is disabled, system administrators have this permission by default.

Syntax

```
DROP TYPE [ IF EXISTS ] name [, ...] [ CASCADE | RESTRICT ];
```



Parameters

- **IF EXISTS**

  Checks whether a specified type exists.

  - If the type exists, it will be dropped successfully.
  - If the type does not exist, the DROP operation will not be performed. Only a NOTICE message will be generated, indicating that the type does not exist.

- **name**

Specifies the name of the type to be dropped. You can use a schema to specify the name.

- **CASCADE | RESTRICT**

  (Optional) Specifies whether to drop objects that depend on the type when dropping the type itself. If this parameter is not specified, the default value is **RESTRICT**.

  - **CASCADE**: The database cascadingly drops the objects (such as columns, functions, and operators) that depend on the type.
  - **RESTRICT**: The database refuses to drop the type if any objects depend on it.

Examples

For details, see **CREATE TYPE** in **Examples**.

Helpful Links

CREATE TYPE and **ALTER TYPE**

1.13.10.43 DROP USER

Description

Drops a specified user.

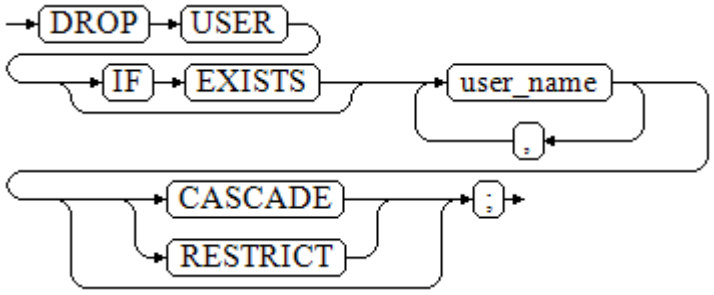
Precautions

- The DROP USER operation can be performed only when you have the permission to create a user. After a user is dropped, the schema with the same name is also dropped.
- Specifying CASCADE explicitly cannot drop locked objects that depend on a user when dropping the user itself unless the objects are unlocked or the threads locking the objects are terminated.
- If the dependent objects are other databases or reside in other databases, manually drop them before dropping the user from the current database. That is, DROP USER cannot drop objects across databases.
- Before dropping a user across databases, you must first drop the schema—which has the same name as the user—created by that user in the database where the user resides.
- Before dropping a user, you need to drop all the objects owned by the user and revoke the user's permissions on other objects. Alternatively, specify **CASCADE** to drop these objects and permissions.
- In multi-tenant scenarios, service users will also be dropped when you drop group users. If you specify CASCADE to drop group users, you also need to specify CASCADE explicitly when dropping service users.
- If the user has an error table that is specified during the creation of a GDS foreign table, the user cannot be dropped by specifying the CASCADE keyword in the DROP USER statement.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Syntax

```
DROP USER [ IF EXISTS ] user_name [, ...] [ CASCADE | RESTRICT ];
```



Parameters

- **IF EXISTS**

  Checks whether a specified user exists.

  - If the user exists, the user is dropped successfully.
  - If the user does not exist, the DROP operation will not be performed. Only a NOTICE message will be generated, indicating that the user does not exist.

- **user_name**

  Specifies the name of the user to be dropped.

  Value range: existing usernames in the database.

- **CASCADE | RESTRICT**

  (Optional) Specifies whether to drop objects that depend on the user when dropping the user itself. If this parameter is not specified, the default value is **RESTRICT**.

  - **CASCADE**: automatically drops the objects that depend on the user and revokes permissions from the user.
  - **RESTRICT**: The database refuses to drop the user if any objects depend on it or if the user has been granted permissions on other objects.

  NOTE

  In GaussDB, configuring the **enable_kill_query** parameter in the **gaussdb.conf** file affects the cascading dropping of user objects.

  - If **enable_kill_query** is **on** and **CASCADE** is used, the statement automatically ends the threads locking dependent objects and directly drops the specified user.
  - When **enable_kill_query** is **off** and **CASCADE** is used, the statement waits until the threads locking the dependent objects end and then drops the specified user.

Examples

```
-- Create user jim whose login password is ********.
gaussdb=# CREATE USER jim PASSWORD '********';

-- Drop user tom that does not exist.
gaussdb=# DROP USER IF EXISTS tom;
NOTICE:  role "tom" does not exist, skipping
DROP ROLE

-- Drop the user.
gaussdb=# DROP USER jim CASCADE;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Helpful Links

ALTER USER and **CREATE USER**

1.13.10.44 DROP VIEW

Description

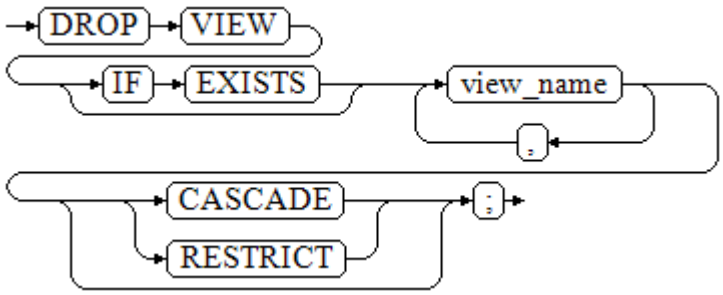
Drops a view from the database.

Precautions

Only the owner of a view, the owner of the schema of the view, users with the DROP permission on the view, or users with the DROP ANY TABLE permission can run this command. When separation of duties is disabled, system administrators have the permission by default.

Syntax

```
DROP VIEW [ IF EXISTS ] view_name [, ...] [ CASCADE | RESTRICT ];
```



Parameters

- **IF EXISTS**

  Checks whether a specified view exists.

  - If the view exists, it will be dropped successfully.
  - If the view does not exist, the DROP operation will not be performed. Only a NOTICE message will be generated, indicating that the view does not exist.

- **view_name**

  Specifies the name of the view to be dropped.

  Value range: existing view names.

- **CASCADE | RESTRICT**

  (Optional) Specifies whether to drop dependent objects along with the view. If not specified, **RESTRICT** is the default.

  - **CASCADE**: automatically drops the objects (such as other views) that depend on the view.
  - **RESTRICT**: refuses to drop the view if any objects depend on it.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Examples

```
-- Create the test_tb1 table and insert 100 data records into the table.
gaussdb=# CREATE TABLE test_tb1(col1 int, col2 int);
gaussdb=# INSERT INTO test_tb1 VALUES (generate_series(1,100),generate_series(1,100));

-- Create a view whose value of col1 is less than 3.
gaussdb=# CREATE VIEW test_v1 AS SELECT * FROM test_tb1 WHERE col1 < 3;

-- Query the view.
gaussdb=# SELECT * FROM test_v1;
 col1 | col2
------+------
    1 |    1
    2 |    2
(2 rows)

-- Drop the table and the view.
gaussdb=# DROP VIEW test_v1;
gaussdb=# DROP TABLE test_tb1;
```

Helpful Links

ALTER VIEW and **CREATE VIEW**

1.13.10.45 DROP WEAK PASSWORD DICTIONARY

Description

Clears the weak password dictionary.

Precautions

- Only the initial user, system administrators, and security administrators can perform this operation.
- Users can use this statement to clear all weak passwords in the gs_global_config system catalog.

Syntax

```
DROP WEAK PASSWORD DICTIONARY;
```

Examples

```
-- Insert a single weak password into the gs_global_config system catalog.
gaussdb=# CREATE WEAK PASSWORD DICTIONARY WITH VALUES ('********');

-- Check weak passwords in the gs_global_config system catalog.
gaussdb=# SELECT * FROM gs_global_config WHERE NAME LIKE 'weak_password';
      name       |    value
-----------------+--------------
 weak_password   | ********
(1 rows)

-- Clear all weak passwords in the gs_global_config system catalog.
gaussdb=# DROP WEAK PASSWORD DICTIONARY;

-- View existing weak passwords.
gaussdb=# SELECT * FROM gs_global_config WHERE NAME LIKE 'weak_password';
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
 name | value

CREATE WEAK PASSWORD DICTIONARY

1.13.11 E

1.13.11.1 EXECUTE

Description

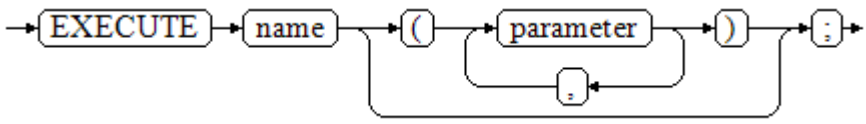
Executes a prepared statement. Because a prepared statement exists only in the lifetime of the session, the prepared statement must be created earlier in the current session by using the PREPARE statement.

Precautions

- If the PREPARE statement declares some parameters when the prepared statement is created, the parameter set passed to the EXECUTE statement must be compatible. Otherwise, an error occurs. If no parameter is defined in the prepared statement declaration, any valid parameter binding passed in subsequent EXECUTE statements will be silently ignored by the system.
- If the table definition on which the prepared statement depends changes (for example, a column definition is added, deleted, or modified), the expected result definition in the cached plan may not match the actual table definition. As a result, an unexpected result is returned when the statement is executed.

Syntax

```
EXECUTE name [ ( parameter [, ...] ) ];
```



Parameters

- **name**

  Specifies the name of the prepared statement to be executed.

- **parameter**

  Specifies a parameter of the prepared statement. It must be an expression that generates a value compatible with the data type of the parameter specified when the prepared statement was created. **ROWNUM** cannot be used as a parameter.

Examples

```
-- Create the reason table.
gaussdb=# CREATE TABLE reason (
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
    CD_DEMO_SK          int NOT NULL,
    CD_GENDER           varchar(10),
    CD_MARITAL_STATUS   varchar(10)
);

-- Create a prepared statement for an INSERT statement and execute the prepared statement.
gaussdb=# PREPARE insert_reason(int,varchar(10),varchar(10)) AS INSERT INTO reason VALUES($1,$2,$3);
gaussdb=# EXECUTE insert_reason(52, 'AAAAAAAADD', 'reason 52');

-- Query data.
gaussdb=# SELECT * FROM reason;
 cd_demo_sk | cd_gender  | cd_marital_status
------------+------------+--------------------
         52 | AAAAAAAADD | reason 52
(1 row)

-- Drop the reason table.
gaussdb=# DROP TABLE reason;
```

Helpful Links

PREPARE and **DEALLOCATE**

1.13.11.2 EXECUTE DIRECT

Description

Executes an SQL statement on a specified node. Generally, the cluster automatically allocates an SQL statement to proper nodes. EXECUTE DIRECT is mainly used for database maintenance and testing.

Precautions

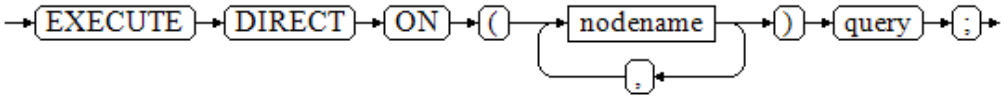
- When **enable_nonsysadmin_execute_direct** is **off**, only the SYSADMIN or MONADMIN has the EXECUTE DIRECT permission.
- When **enable_udf_execute_direct** is **off**, EXECUTE DIRECT cannot be used to execute user-defined functions, functions in the advanced packages DBE_SQL, PKG_SERVICE, and DBE_XMLGE, as well as DBE_UTILITY.EXEC_DDL_STATEMENT.
- To ensure data consistency across nodes, only the SELECT statement can be used. Transaction statements, DDL, and DML cannot be used.
- When the stddev aggregation calculation is performed on the specified DN using such statements, the result set is returned in triplet. For example, {3, 8, 30} indicates that the count result is 3, the sum result is 8, and the sum of squares is 30. When the AVG aggregation calculation is performed on the specified DN using such statements, the result set is returned in a binary tuple, for example, {4,2}. The result of count is 4, and that of sum is 2.
- When multiple nodes are specified, aggregate functions are not supported. If the query contains an aggregate function, the message "EXECUTE DIRECT on multinode not support agg functions." is returned.
- CN nodes do not store user table data. Therefore, do not execute SELECT for querying user tables on a CN.
- If the SQL statement to be executed is also EXECUTE DIRECT, do not nest it into EXECUTE DIRECT; instead, directly execute the inner EXECUTE DIRECT.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

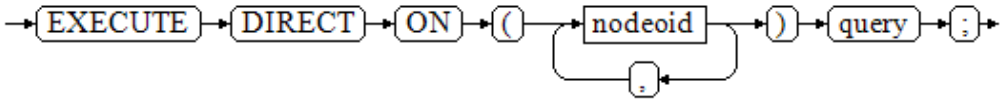
- The query result of the aggregate function is inconsistent with that on the CN. Multiple pieces of information are returned. The array_avg function is not supported.
- If the **nodeoid** or **nodeoid list** parameter is specified, this parameter takes effect only when the **enable_direct_standby_datanodes** parameter is successfully set in distributed mode. To query data on a specified DN, invalid or duplicate **nodeoid** values are not supported, and **nodeoid** and **nodename** cannot be used together.

Syntax

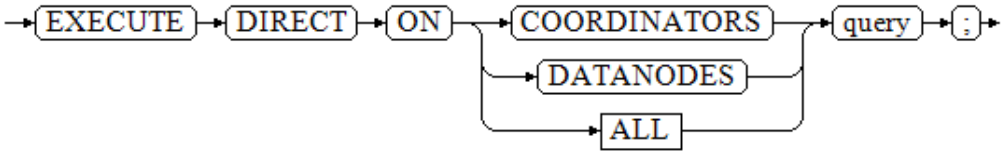
```
EXECUTE DIRECT ON ( nodename [, ... ] ) query ;
```



```
EXECUTE DIRECT ON ( nodeoid [, ... ] ) query;
```



```
EXECUTE DIRECT ON { COORDINATORS | DATANODES | ALL } query;
```



Parameters

- **nodename**

  Node name.

  Value range: an existing node name
- **nodeoid**

  Node OID.

  Value range: an existing DN OID, which can be obtained from the **PGXC_NODE** system catalog.
- **query**

  Specifies the query statement to be executed.
- **COORDINATORS**

  Runs the query statement on all CNs.
- **DATANODES**

  Runs the query statement on all DNs.
- **ALL**

  Runs the query statement on all CNs and DNs.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Examples

```
-- Query the name of the current node in the cluster.
gaussdb=# SELECT node_name,oid FROM pgxc_node WHERE node_type IN ('C','D') ORDER BY 1;
     node_name     |  oid
-------------------+-------
 cn_5001           | 15517
 cn_5002           | 16387
 cn_5003           | 16391
 dn_6001_6002_6003 | 16384
 dn_6004_6005_6006 | 16388
 dn_6007_6008_6009 | 16392
(6 rows)

-- Create a range-distributed table and insert data into the table.
gaussdb=# CREATE TABLE tbl_range(
  id       INT,
  name     VARCHAR(20),
  province VARCHAR(60),                       -- Province

                                       (300,'Jordan','Beijing','China');

-- Query the table data distributed on the dn_6007_6008_6009 node.
gaussdb=# EXECUTE DIRECT ON(dn_6007_6008_6009) 'SELECT * FROM tbl_range';
 id  |  name  | province | country
-----+--------+----------+---------
 300 | Jordan | Beijing  | China
(1 row)

-- Delete the tbl_range table.
gaussdb=# DROP TABLE tbl_range;
```

1.13.11.3 EXPDP DATABASE

Description

Exports all physical files in a database.

Syntax

```
EXPDP DATABASE db_name LOCATION = 'directory';
```

Parameters

- **db_name**

  Name of the database to be exported.

- **directory**

  Directory for storing exported files.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Examples

```
-- The EXPDP DATABASE syntax is used for fine-grained backup and restoration and is called by the backup and restoration tool. If a user calls it directly, the error message "ERROR: Only auxdb is allowed to execute expdp cmd." is displayed.
gaussdb=# EXPDP DATABASE test LOCATION = '/data1/expdp/database';
```

1.13.11.4 EXPDP TABLE

Description

Exports all table-related index, sequence, partition, TOAST, and TOAST index files.

Syntax

```
EXPDP TABLE table_name LOCATION = 'directory';
```

Parameters

- **table_name**

  Name of the table to be exported.
- **directory**

  Directory for storing exported files.

Examples

```
-- The EXPDP TABLE syntax is used for fine-grained backup and restoration and is called by the backup and restoration tool. If a user calls it directly, the error message "ERROR: Only auxdb is allowed to execute expdp cmd." is displayed.
gaussdb=# EXPDP TABLE test_t LOCATION = '/data1/expdp/table0';
```

1.13.11.5 EXPLAIN

Description

Shows the execution plan of an SQL statement, including:

- How the tables referenced by the SQL statement will be scanned, for example, by plain sequential scan or index scan.
- How the tables referenced by the SQL statement will be joined.

Precautions

- The most critical part of the display is the estimated statement execution cost, which is the plan generator's guess at how long it will take to run the statement.
- If the **ANALYZE** option is specified, the SQL statement will be executed and show actual run times and other statistics. This is useful for determining whether the plan generator's estimates are close to reality. The statistics include the total elapsed time expended within each plan node (in milliseconds) and the total number of rows it actually returned.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- The statement is actually executed when the **ANALYZE** option is used. If you want to use EXPLAIN ANALYZE on an INSERT, UPDATE, DELETE, CREATE TABLE AS, or EXECUTE statement without letting the statement affect your data, use this approach:

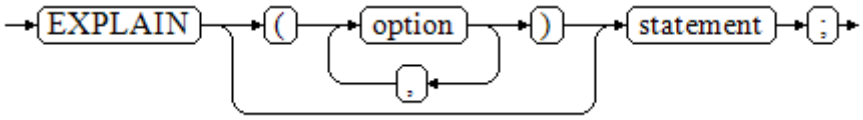
```
START TRANSACTION;
EXPLAIN ANALYZE ...;
ROLLBACK;
```

- When you use EXPLAIN to view an execution plan, the audit type recorded in the audit log depends on the specific SQL statement being analyzed.

Syntax

- Display the execution plan of an SQL statement, which supports multiple options and has no requirements for the order of options.

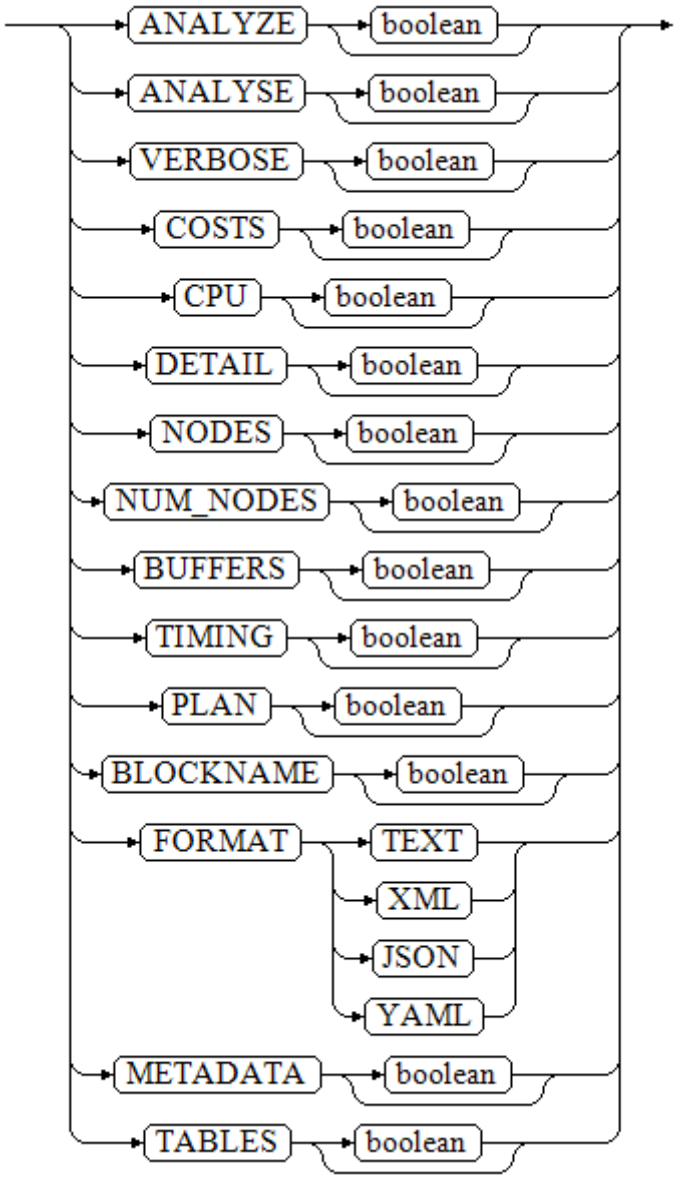
```
EXPLAIN [ ( option [, ...] ) ] statement;
```



option can be as follows:

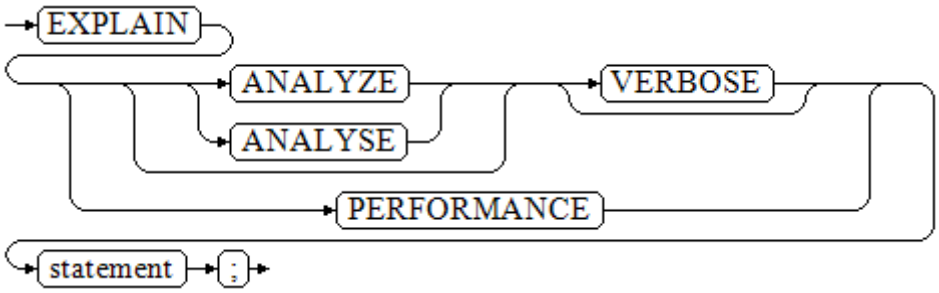
```
{
    ANALYZE [ boolean ] |
    ANALYSE [ boolean ] |
    VERBOSE [ boolean ] |
    COSTS [ boolean ] |
    CPU [ boolean ] |
    DETAIL [ boolean ] |
    NODES [ boolean ] |
    NUM_NODES [ boolean ] |
    BUFFERS [ boolean ] |
    TIMING [ boolean ] |
    PLAN [ boolean ] |
    BLOCKNAME [ boolean ] |
    FORMAT { TEXT | XML | JSON | YAML } |
    METADATA [ boolean ] |
    TABLES [ boolean ]
}
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.



- Display the execution plan of an SQL statement, where options are in order.

```
EXPLAIN { [ ANALYZE | ANALYSE ] [ VERBOSE ] | PERFORMANCE } statement;
```



Parameters

- **statement**

  Specifies the SQL statement to explain.

- **ANALYZE boolean | ANALYSE boolean**

  Specifies whether to display actual run times and other statistics. When two parameters are used at the same time, the latter one in **option** takes effect.

  Value range:

  – **TRUE** (default): displayed.

  – **FALSE**: not displayed.

- **VERBOSE boolean**

  Specifies whether to display additional information regarding the plan.

  Value range:

  – **TRUE** (default): displayed.

  – **FALSE**: not displayed.

- **COSTS boolean**

  Specifies whether to display the estimated total cost of each plan node, estimated number of rows, estimated width of each row.

  Value range:

  – **TRUE** (default): displayed.

  – **FALSE**: not displayed.

- **CPU boolean**

  Specifies whether to display CPU usage. This parameter must be used together with ANALYZE or ANALYSE.

  Value range:

  – **TRUE** (default): displayed.

  – **FALSE**: not displayed.

- **DETAIL boolean**

  Specifies whether to display DN information. This parameter must be used together with ANALYZE or ANALYSE.

  Value range:

  – **TRUE** (default): displays it.

  – **FALSE**: not printed.

- **NODES boolean**

  Specifies whether to display information about the nodes executed by query.

  Value range:

  – **TRUE** (default): displays it.

  – **FALSE**: not printed.

- **NUM_NODES boolean**

  Specifies whether to display the number of executing nodes.

  Value range:

  – **TRUE** (default): displays it.

  – **FALSE**: not printed.

- **BUFFERS boolean**

  Specifies whether to display buffer usage. This parameter must be used together with ANALYZE or ANALYSE.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Value range:

- **TRUE**: displayed.
- **FALSE** (default): not displayed.

- **TIMING boolean**

  Specifies whether to display the actual startup time and time spent on the output node. This parameter must be used together with ANALYZE or ANALYSE.

  Value range:

  - **TRUE** (default): displayed.
  - **FALSE**: not displayed.

- **PLAN boolean**

  Specifies whether to store the execution plan in **PLAN_TABLE**. If this parameter is set to **on**, the execution plan is stored in **PLAN_TABLE** and is not displayed on the screen. Therefore, this parameter cannot be used together with other parameters when it is set to **on**.

  Value range:

  - **TRUE** (default): The execution plan is stored in **PLAN_TABLE** and not displayed on the screen. If the plan is stored successfully, "EXPLAIN SUCCESS" is returned.
  - **FALSE**: The execution plan is not stored but is printed on the screen.

- **BLOCKNAME boolean**

  Specifies whether to display the query block where each operation of the plan is located. When this option is enabled, each name of the query block where each operation is performed is displayed in the **Query Block** column. This helps users obtain the query block name and use hints to modify the execution plan.

  - **TRUE** (default value): The name of the query block where each operation is located is displayed in the **Query Block** column. This option must be used in the pretty mode. For details, see "Hint-based Optimization > Hints for Specifying the Query Block Where the Hint Is Located" in *SQL Optimization Guide*.
  - **FALSE**: The plan display is not affected.

- **FORMAT**

  Specifies the output format.

  Value range: **TEXT**, **XML**, **JSON**, and **YAML**.

  Default value: **TEXT**.

- **PERFORMANCE**

  Prints all relevant information in execution. Some information is described as follows:

  - **ex c/r**: indicates the average number of CPU cycles used by each row, which is equal to **(ex cyc) / (ex row)**.
  - **ex row**: indicates the number of executed rows.
  - **ex cyc**: indicates the number of used CPU cycles.
  - **inc cyc**: indicates the total number of CPU cycles used by subnodes.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

  - **shared hit**: indicates the shared buffer hits of the operator.
  - **loops**: indicates the number of operator loop execution times.
  - **total_calls**: indicates the total number of generated elements.
  - **remote query poll time stream gather**: indicates the operator used to listen to the network poll time when data on each DN reaches the CN.
  - **deserialize time**: indicates the time required for deserialization.
  - **estimated time**: indicates the estimated time.
  - **Network Poll Time**: indicates the duration for the libcomm receiver to wait for data during distributed stream network communication.
  - **Stream Send time**: indicates the time consumed by libcomm or libpq to send data during distributed stream network communication.
  - **OS Kernel Send time**: indicates the time required for the OS layer to send data during distributed stream network communication. This parameter is displayed only when the value is greater than **0**.
  - **Wait Quota time**: indicates the duration for libcomm to wait for the peer end to send the quota traffic control size during distributed stream network communication. This parameter is displayed only when the value is greater than **0**.
  - **Data Serialize time**: indicates the data serialization time during distributed stream network communication.
  - **Data Copy time**: indicates the data replication time during distributed stream network communication. This parameter is displayed only when the value is greater than **0**.

- **METADATA boolean**

  Specifies whether to display the statement metadata. If **boolean** is not specified, **TRUE** is used by default. This part is displayed only when the statement uses a stream plan. The following describes the output information:

  - Defined objects, including tables, indexes, views, functions, and operators referenced in statements.
  - Statistics, which are classified into table-level and column-level statistics. Their common fields are as follows:

    - **nspname**: schema name, corresponding to **pg_namespace.nspname**.
    - **relname**: table name, corresponding to the **pg_class.relname** of a table or index.
    - **partname**: partition name, corresponding to the **pg_partition.relname** of a partition.
    - **subpartname**: subpartition name, corresponding to the **pg_partition.relname** of a subpartition.

    Other table-level statistics include:

    - **reltuples**: total number of rows in the table, corresponding to **pg_class/pg_partition.reltuples**.
    - **relpages**: total number of pages in the table, corresponding to **pg_class/pg_partition.relpages**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **analyze_time**: timestamp when the table or index was last analyzed, which corresponds to the return value of pg_stat_get_last_analyze_time or gs_stat_get_partition_last_analyze_time.
- **rows_changed**: number of rows changed in the table or index since the last ANALYZE operation, which corresponds to the return value of pg_stat_get_tuples_changed or pg_stat_get_partition_tuples_changed.
- **rows_inserted**: number of rows inserted into the table or index since the last ANALYZE operation. The value is null.

Other column-level statistics (including single-column and multi-column statistics) are as follows:

- **colnames**: column name. For a single column, the value is the same as that of **pg_stats.attname**. For multiple columns, the value is the set of column names represented by the column numbers in **pg_ext_stats.attname**.
- **nullfrac**: null fraction, which corresponds to **pg_stats/ pg_ext_stats.nullfrac**.
- **avgwidth**: average row width, which corresponds to **pg_stats/ pg_ext_stats.avgwidth**.
- **distinct**: number of distinct values, which corresponds to **pg_stats/ pg_ext_stats.n_distinct**.
- **dndistinct**: number of distinct values on a DN, which corresponds to **pg_stats/pg_ext_stats.n_dndistinct**.
- **mcvs_top5**: top 5 most frequent values, which corresponds to **pg_stats/pg_ext_stats.most_common_vals**.
- **mcfs_top5**: frequencies of the top 5 most frequent values, which correspond to **pg_stats/pg_ext_stats.most_common_freqs**.
- **hist_qrtl**: histogram bucket value. For a single column, the value is the same as that of **pg_stats.histogram_bounds**. Only five values on the quartile boundary are used. For multiple columns, the value is empty.
- **correlation**: correlation. For a single column, the value is the same as that of **pg_stats.correlation**. For multiple columns, the value is **0**.

– In **Query Others**, the following information is included:

- **current time**: current timestamp, which is used to compare with **analyze_time**.
- **use_hints: Yes,** *<string>*: If hints are effective for a statement, the hints are printed in a list.

Value range:

– **TRUE** (default value): The statement metadata is displayed. This option must be used in pretty mode.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

  - **FALSE**: not displayed.

- **TABLES boolean**

  Specifies whether to display the information of table objects on which the SQL statement depends, including tables and materialized views. If **boolean** is not specified, **TRUE** is used by default. This part is displayed only when the statement uses a stream plan.

  - **TRUE** (default value): The information about the table objects on which the statement depends is displayed. This option must be used in pretty mode.
  - **FALSE**: not displayed.

Example 1

```
-- Create a schema.
gaussdb=# CREATE SCHEMA tpcds;

-- Create the tpcds.customer_address table.
gaussdb=# CREATE TABLE tpcds.customer_address
(
ca_address_sk         INTEGER           NOT NULL,
ca_address_id         CHARACTER(16)     NOT NULL
);

-- Insert multiple records into the table.
gaussdb=# INSERT INTO tpcds.customer_address VALUES (5000, 'AAAAAAAABAAAAAAA'),(10000,
'AAAAAAAACAAAAAAA');

-- Create the tpcds.customer_address_p1 table.
gaussdb=# CREATE TABLE tpcds.customer_address_p1 AS TABLE tpcds.customer_address;

-- Change the value of explain_perf_mode to normal.
gaussdb=# SET explain_perf_mode=normal;

-- Display an execution plan for simple queries in the table.
gaussdb=# EXPLAIN SELECT * FROM tpcds.customer_address_p1;
QUERY PLAN
--------------------------------------------------
Data Node Scan  (cost=0.00..0.00 rows=0 width=0)
Node/s: All datanodes
(2 rows)

-- Use the ANALYZE option to add runtime statistics to the output.
gaussdb=# EXPLAIN ANALYZE SELECT * FROM tpcds.customer_address_p1;
                                  QUERY PLAN

ANALYZE | ANALYSE

1.13.11.6 EXPLAIN PLAN

Description

EXPLAIN PLAN saves information about an execution plan into the **PLAN_TABLE** table. Different from the EXPLAIN statement, EXPLAIN PLAN only saves plan information and does not print information on the screen.

Precautions

- EXPLAIN PLAN cannot be executed on a DN.
- Plan information cannot be collected for SQL statements that failed to be executed.
- Data in **PLAN_TABLE** is in a session-level lifecycle. Sessions are isolated from users, and therefore users can only view the data of the current session and current user.
- **PLAN_TABLE** cannot be joined with GDS foreign tables.
- For a query that cannot be pushed down, only such information as **REMOTE_QUERY** and **CTE** can be collected from **PLAN_TABLE** after **EXPLAIN PLAN** is executed. For details, see **Example 2**.
- **PLAN**: saves plan information into **PLAN_TABLE**. If information is stored successfully, "EXPLAIN SUCCESS" is returned.
- **STATEMENT_ID**: tags each query. The tag information will be stored in **PLAN_TABLE**.
- After the EXPLAIN PLAN statement is executed, plan information is automatically stored in **PLAN_TABLE**. INSERT, UPDATE, and ANALYZE cannot be performed on **PLAN_TABLE**. For details about **PLAN_TABLE**, see **PLAN_TABLE**.

Syntax

```
EXPLAIN PLAN [ SET STATEMENT_ID = name ] FOR statement ;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameters

- **name**

  Specifies a query tag.

  Value range: a string.

  > NOTE
  >
  > If **STATEMENT_ID** is not set when the EXPLAIN PLAN statement is executed, **STATEMENT_ID** is left empty by default. In addition, the value of **STATEMENT_ID** cannot exceed 30 bytes. Otherwise, an error will be reported.

- **statement**

  Specifies the SQL statement to explain.

Example 1

```
-- Create tables foo1 and foo2.
gaussdb=# CREATE TABLE foo1(f1 int, f2 text, f3 text[]);
gaussdb=# CREATE TABLE foo2(f1 int, f2 text, f3 text[]);

-- Run EXPLAIN PLAN.
gaussdb=# EXPLAIN PLAN SET STATEMENT_ID = 'TPCH-Q4' FOR SELECT f1, count(*) FROM foo1 WHERE f1
> 1 AND f1 < 3 AND EXISTS (SELECT * FROM foo2) GROUP BY f1;

-- Query PLAN_TABLE.
gaussdb=# SELECT * FROM plan_table;

-- Delete data from the PLAN_TABLE table and delete tables foo1 and foo2.
gaussdb=# DELETE FROM plan_table WHERE STATEMENT_ID = 'TPCH-Q4';
gaussdb=# DROP TABLE foo1;
gaussdb=# DROP TABLE foo2;
```

Example 2

```
-- Disable enable_stream_recursive so that associated WITH RECURSIVE queries cannot be pushed down.
gaussdb=# SET enable_stream_recursive = off;

-- Create the chinamap table.
gaussdb=# CREATE TABLE chinamap
(
  id integer,
  pid integer,
  name text
) DISTRIBUTE BY hash(id);

-- Plan collected by plan_table.
gaussdb=# EXPLAIN PLAN SET statement_id = 'cte can not be push down'
FOR
WITH RECURSIVE rq AS
(
  SELECT id, name FROM chinamap WHERE id = 11
  UNION ALL
  SELECT origin.id, rq.name || ' > ' || origin.name
  FROM rq JOIN chinamap origin ON origin.pid = rq.id
)
SELECT id, name FROM rq ORDER BY 1;

-- Query PLAN_TABLE.
gaussdb=# SELECT * FROM plan_table;

-- Delete the chinamap table.
gaussdb=# DROP TABLE chinamap;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

1.13.11.7 EXPLAIN AUTOHINT

Description

EXPLAIN AUTOHINT stores the query execution plan information and execution result in the AUTOHINT memory context while the **EXPLAIN** command is executed, facilitating hint exploration and recommendation of the AUTOHINT feature.

Precautions

- This statement can be automatically called by the kernel only when the AUTOHINT task is running. If a user calls it, no effect will be produced or an AUTOHINT error will be reported for blocking the task.
- The data stored in the AUTOHINT memory context has the session-level lifecycle and is isolated by session and user. The AUTOHINT called in the current session allows you to access and call only the data of the current session and user.

Syntax

```
EXPLAIN AUTOHINT cache_id exec_type argument
FOR statement ;
```

Parameters

- **statement**

  SQL statement to be stored for the plan and execution result of the current AUTOHINT task. (Only the SELECT statement is supported.)

- **cache_id**

  ID of the current AUTOHINT task. The value is of the int type.

- **exec_type**

  Type of the result stored by the current statement.

  Value range:

  – **PLAN**: stores plan information.

  – **EXECUTE**: stores execution result information.

- **argument**

  Parameter required for executing the current statement. The value is in JSON format.

  If **exec_type** is set to **PLAN**, the value is the hint applied to the current statement.

  If **exec_type** is set to **EXECUTE**, the value is the hash value of the execution plan corresponding to the current statement.

Example 1

```
-- AUTOHINT executes the corresponding SQL statement to store the plan information.
gaussdb=# EXPLAIN AUTOHINT 2 PLAN
        '{"hints":[{"type": 0, "name": "enable_seqscan", "value": "true"},
         {"type": 0, "name": "enable_mergejoin", "value": "false"}]}' FOR
            SELECT * FROM t1, t2 WHERE t1.id = t2.id and t1.a > 100 and t2.b < 200;
-- The user directly executes the statement, which does not take effect.
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
 QUERY PLAN
------------
(0 rows)
-- The user directly executes the statement, which is blocked with an error reported.
gaussdb=# ERROR:  Can not get exploration cache for cache id: 2.
```

Example 2

```
-- AUTOHINT executes the corresponding SQL statement to store the execution information.
gaussdb=# EXPLAIN AUTOHINT 2 EXECUTE '{"topology": 740798663, "cards": [18936500, 10592, 9308,
9308]}' FOR
            SELECT * FROM t1, t2 WHERE t1.id = t2.id and t1.a > 100 and t2.b < 200;
-- The user directly executes the statement, which does not take effect.
 QUERY PLAN
------------
(0 rows)
-- The user directly executes the statement, which is blocked with an error reported.
gaussdb=# ERROR:  Can not get exploration cache for cache id: 2.
```

1.13.12 F

1.13.12.1 FETCH

Description

FETCH retrieves rows using a previously created cursor.

A cursor has an associated position, which is used by FETCH. The cursor position can be before the first row of the query result, on any particular row of the result, or after the last row of the result.

- When created, a cursor is positioned before the first row.
- After fetching some rows, the cursor is positioned on the row most recently retrieved.
- If FETCH runs off the end of the available rows then the cursor is left positioned after the last row, or before the first row if fetching backward.
- FETCH ALL or FETCH BACKWARD ALL will always leave the cursor positioned after the last row or before the first row.

Precautions

- If the cursor is declared with **NO SCROLL**, backward fetches like FETCH BACKWARD are not allowed.
- The forms **NEXT**, **PRIOR**, **FIRST**, **LAST**, **ABSOLUTE**, and **RELATIVE** fetch a single row after moving the cursor appropriately. If there is no such row, an empty result is returned, and the cursor is left positioned before the first row (backward fetch) or after the last row (forward fetch) as appropriate.
- The forms using **FORWARD** and **BACKWARD** retrieve the indicated number of rows moving in the forward or backward direction, leaving the cursor positioned on the last-returned row or after (backward fetch)/before (forward fetch) all rows if the **count** exceeds the number of rows available.
- **RELATIVE 0**, **FORWARD 0**, and **BACKWARD 0** all request fetching the current row without moving the cursor, that is, re-fetching the most recently fetched row. This action will succeed unless the cursor is positioned before the first

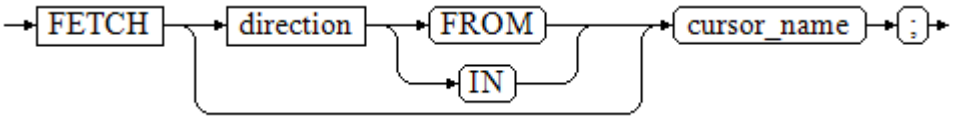
 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

row or after the last row. If the cursor is positioned before the first row or after the last row, no row is returned.

- If the cursor of FETCH involves a non-system catalog, backward fetches like **BACKWARD**, **PRIOR**, and **FIRST** are not allowed.

Syntax

```
FETCH [ direction { FROM | IN } ] cursor_name;
```



The **direction** clause specifies optional parameters.

```
{ NEXT
  | PRIOR
  | FIRST
  | LAST
  | ABSOLUTE count
  | RELATIVE count
  | count
  | ALL
  | FORWARD
  | FORWARD count
  | FORWARD ALL
  | BACKWARD
  | BACKWARD count
  | BACKWARD ALL }
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameters

- **direction**

  Defines the fetch direction.

  Value range:

  - NEXT (default value)

    Fetches the next row.
  - PRIOR

    Fetches the prior row.
  - FIRST

    Fetches the first row of the query (same as **ABSOLUTE 1**).
  - LAST

    Fetches the last row of the query (same as **ABSOLUTE –1**).
  - ABSOLUTE count

    Fetches the *count*th row of the query.

    ABSOLUTE fetches are not any faster than navigating to the desired row with a relative move: the underlying implementation must traverse all the intermediate rows anyway.

    Value range: a possibly-signed integer

    - If *count* is positive, the *count*th row of the query will be fetched. If *count* is less than the current cursor position, rewind is required, which is currently not supported.
    - If *count* is negative or 0, backward scan is required, which is currently not supported.
  - RELATIVE count

    Fetches the *count*th succeeding row or the *count*th prior row.

    Value range: signed integer

    - If *count* is a positive integer, the *count*th succeeding row will be fetched.
    - If *count* is a negative integer or 0, backward scan is required, which is currently not supported.
    - If the current row contains no data, **RELATIVE 0** returns null.
  - count

    Fetches the next *count* rows (same as **FORWARD** *count*).
  - ALL

    Fetches all remaining rows (same as **FORWARD ALL**).
  - FORWARD

    Fetches the next row (same as **NEXT**).
  - FORWARD count

    Fetches the next or prior *count* rows (same as **RELATIVE** *count*).
  - FORWARD ALL

    Fetches all remaining rows.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

  - BACKWARD

    Fetches the prior row (same as **PRIOR**).
  - BACKWARD count

    Fetches the prior *count* rows (scanning backwards).

    Value range: signed integer

    - If *count* is a positive integer, the *count*th prior row will be fetched.
    - If *count* is a negative integer, the *abs(count)*th succeeding row will be fetched.
    - **BACKWARD 0** re-fetches the current row, if any.
  - BACKWARD ALL

    Fetches all prior rows (scanning backwards).
- **{ FROM | IN } cursor_name**

  Specifies the cursor name using the keyword **FROM** or **IN**.

  Value range: an existing cursor name

Examples

```
-- Create the test table and insert 20 data records into the table.
gaussdb=# CREATE TABLE test(c1 int, c2 int);
gaussdb=# INSERT INTO test VALUES (generate_series(1,20),generate_series(1,20));

-- Start a transaction and create a cursor named cursor1.
gaussdb=# START TRANSACTION;
gaussdb=# CURSOR cursor1 FOR SELECT * FROM test ORDER BY 1;

-- The cursor retrieves three rows of data from the associated position.
gaussdb=# FETCH FORWARD 3 FROM cursor1;
 c1 | c2
----+----
  1 |  1
  2 |  2
  3 |  3
(3 rows)

-- Close the cursor and commit the transaction.
gaussdb=# CLOSE cursor1;
gaussdb=# END;

-- Drop the table.
gaussdb=# DROP TABLE test;
```

Helpful Links

CLOSE, **MOVE**, and **CURSOR**

1.13.13 G

1.13.13.1 GENERATED UPDATE SYSTEM OBJECT

Description

Generates an upgrade rollback script for system objects. OM will call this script during upgrade rollback. This is an internal syntax; its use is therefore discouraged.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Precautions

- This statement is called exclusively by OM during upgrades. Specifically, it can be executed only when the GUC parameter **upgrade_mode** is not **0** and **application_name** is set to **OM**.
- Only the initial user has permission to execute this statement.

Syntax

```
GENERATED UPDATE SYSTEM OBJECT;
```

1.13.13.2 GRANT

Description

Grants permissions to roles and users.

GRANT is used in the following scenarios:

- **Granting system permissions to roles or users**

  System permissions are also called user attributes, including SYSADMIN, CREATEDB, CREATEROLE, AUDITADMIN, MONADMIN, OPRADMIN, POLADMIN, INHERIT, REPLICATION, and LOGIN.

  They can be specified only by the CREATE ROLE or ALTER ROLE statement. The SYSADMIN permissions can be granted and revoked using GRANT ALL PRIVILEGE and REVOKE ALL PRIVILEGE, respectively. System permissions cannot be inherited by roles or users, nor can they be granted to **PUBLIC**.

- **Granting database object permissions to roles or users**

  Grant permissions on a database object (table, view, column, database, function, schema, or tablespace) to a role or user.

  GRANT gives specific permissions on a database object to one or more roles. These permissions are added to those already granted, if any.

  PUBLIC indicates that the permissions are to be granted to all roles, including those that might be created later. **PUBLIC** can be thought of as an implicitly defined group that always includes all roles. Any particular role will have the sum of permissions granted directly to it, permissions granted to any role it is presently a member of, and permissions granted to **PUBLIC**.

  If **WITH GRANT OPTION** is specified, the recipient of the permission can in turn grant it to others. Without a grant option, the recipient cannot do that. This option cannot be granted to PUBLIC, which is a unique GaussDB attribute.

  GaussDB grants the permissions on certain types of objects to PUBLIC. By default, permissions on tables, columns, sequences, foreign data sources, foreign servers, schemas, and tablespaces are not granted to PUBLIC, but the following permissions are granted to PUBLIC: CONNECT and CREATE TEMP TABLE permissions on databases, EXECUTE permission on functions, and USAGE permission on languages and data types. An object owner can revoke the default permissions granted to **PUBLIC** and grant permissions to other users as needed. For security purposes, you are advised to create an object

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

and set its permissions in the same transaction so that other users do not have time windows to use the object. These default permissions can be modified by running the **ALTER DEFAULT PRIVILEGES** command.

By default, an object owner has all permissions on the object. For security purposes, the owner can discard some permissions. However, the ALTER, DROP, COMMENT, INDEX, VACUUM, and re-grantable permissions of the object are inherent permissions implicitly owned by the owner.

- **Granting the permissions of one role or user to others**

  The permissions of one role or user can be granted to others. In this case, every role or user can be regarded as a set of one or more database permissions.

  If **WITH ADMIN OPTION** is specified, the recipients can in turn grant the permissions to or revoke them from others. If the grantors' permissions are changed or revoked later, the grantees' permissions will also change.

  When separation of duties is disabled, a system administrator can grant or revoke the permissions of any non-permanent user or O&M administrator. Security administrators can grant or revoke permissions of any non-system administrator, built-in role, permanent user or O&M administrator.

- **Granting ANY permissions to roles or users**

  The ANY permissions can be granted to specific roles or users. See the "Syntax" section for the scope of ANY permissions. If **WITH ADMIN OPTION** is specified, the recipients can in turn grant the ANY permissions to others or revoke them from others. The ANY permissions can be inherited by a role but cannot be granted to **PUBLIC**. The initial user and system administrators (when separation of duties is disabled) can grant the ANY permissions to or revoke them from any roles or users.

  Currently, the following ANY permissions are supported: CREATE ANY TABLE, ALTER ANY TABLE, DROP ANY TABLE, SELECT ANY TABLE, INSERT ANY TABLE, UPDATE ANY TABLE, DELETE ANY TABLE, TRUNCATE ANY TABLE, CREATE ANY SEQUENCE, CREATE ANY INDEX, CREATE ANY FUNCTION, EXECUTE ANY FUNCTION, CREATE ANY PACKAGE, EXECUTE ANY PACKAGE, CREATE ANY TYPE, ALTER ANY TYPE, DROP ANY TYPE, ALTER ANY SEQUENCE, DROP ANY SEQUENCE, SELECT ANY SEQUENCE, ALTER ANY INDEX, DROP ANY INDEX, CREATE ANY SYNONYM, DROP ANY SYNONYM, CREATE ANY TRIGGER, ALTER ANY TRIGGER, and DROP ANY TRIGGER. For details about the ANY permission scope, see **Table 1-402**.

Precautions

- The ANY permissions cannot be granted to **PUBLIC**, nor can they be revoked from **PUBLIC**.
- The ANY permissions are database-specific and apply only to objects within the granting database. For example, SELECT ANY TABLE allows users to view data from all user tables in the current database, but does not grant access to user tables in other databases.
- The ANY permissions operate independently of existing permissions.
- If a user is granted the CREATE ANY TABLE permission, the owner of a table created in a schema with the same name as the user is the creator of the schema. When the user performs other operations on the table, the user needs to be granted the corresponding operation permission. Similarly, if a

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

user is granted the CREATE ANY FUNCTION, CREATE ANY PACKAGE, CREATE ANY TYPE, CREATE ANY SEQUENCE, or CREATE ANY INDEX permission, the owner of an object created in a schema with the same name is the owner of the schema. If a user is granted the CREATE ANY TRIGGER or CREATE ANY SYNONYM permission, the owner of an object created in a schema with the same name is the creator.

- Exercise caution when granting the CREATE ANY FUNCTION or CREATE ANY PACKAGE permission to users to prevent other users from using DEFINER functions or PACKAGE for privilege escalation.
- When GRANT is used to grant a user the permission to use a table, if the permission is not properly used, ALTER may be used to add expressions to the default values and constraints of the table, or indexes may be created to add expressions to INDEX. In this case, the permission may be exploited.
- When GRANT is used to grant the TRIGGER permission, if the permission is not properly used, the WHEN condition may be used to create expressions. When the trigger is triggered, the permission may be exploited.
- When granting permissions to users, pay special attention to the definer permission on functions/packages. The definer permission is executed as the owner of the functions/packages. If the permission is not properly granted (including GRANT ROLE TO ROLE), the permission may be exploited.
- Do not grant object permissions to too many users. You can use roles or PUBLIC based on service requirements.

Syntax

- Grant the table or view access permission to a user or role.

```
GRANT { { SELECT | INSERT | UPDATE | DELETE | TRUNCATE | REFERENCES | TRIGGER | ALTER | DROP
| COMMENT | INDEX | VACUUM } [, ...]
    | ALL [ PRIVILEGES ] }
  ON { [ TABLE ] table_name [, ...]
    | ALL TABLES IN SCHEMA schema_name [, ...] }
  TO { [ GROUP ] role_name | PUBLIC } [, ...]
  [ WITH GRANT OPTION ];
```

- Grant the column access permission to a user or role.

```
GRANT { {{ SELECT | INSERT | UPDATE | REFERENCES | COMMENT } ( column_name [, ...] )} [, ...]
    | ALL [ PRIVILEGES ] ( column_name [, ...] ) }
  ON [ TABLE ] table_name [, ...]
  TO { [ GROUP ] role_name | PUBLIC } [, ...]
  [ WITH GRANT OPTION ];
```

  NOTE

  If you have permission to access a table, you automatically have permission to access all columns within that table by default. To grant access only to a specific column in a table, you must revoke the table-level access permission first.

- Grant the sequence access permission to a specified user or role.

```
GRANT { { SELECT | UPDATE | USAGE | ALTER | DROP | COMMENT } [, ...]
    | ALL [ PRIVILEGES ] }
  ON { [ SEQUENCE ] sequence_name [, ...]
    | ALL SEQUENCES IN SCHEMA schema_name [, ...] }
  TO { [ GROUP ] role_name | PUBLIC } [, ...]
  [ WITH GRANT OPTION ];
```

- Grant the database access permission to a user or role.

```
GRANT { { CREATE | CONNECT | TEMPORARY | TEMP | ALTER | DROP | COMMENT } [, ...]
    | ALL [ PRIVILEGES ] }
  ON DATABASE database_name [, ...]
  TO { [ GROUP ] role_name | PUBLIC } [, ...]
  [ WITH GRANT OPTION ];
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- Grant the CMK access permission to a specified user or role.

```
GRANT { { USAGE | DROP } [, ...] | ALL [ PRIVILEGES ] }
    ON CLIENT_MASTER_KEY client_master_key
    TO { [ GROUP ] role_name | PUBLIC } [, ...]
    [ WITH GRANT OPTION ];
```

- Grant the column encryption key (CEK) access permission to a specified user or role.

```
GRANT { { USAGE | DROP } [, ...] | ALL [ PRIVILEGES ] }
    ON COLUMN_ENCRYPTION_KEY column_encryption_key
    TO { [ GROUP ] role_name | PUBLIC } [, ...]
    [ WITH GRANT OPTION ];
```

- Grant the foreign data source access permission to a user or role.

```
GRANT { USAGE | ALL [ PRIVILEGES ] }
    ON FOREIGN DATA WRAPPER fdw_name [, ...]
    TO { [ GROUP ] role_name | PUBLIC } [, ...]
    [ WITH GRANT OPTION ];
```

- Grant the foreign server access permission to a user or role.

```
GRANT { { USAGE | ALTER | DROP | COMMENT } [, ...] | ALL [ PRIVILEGES ] }
    ON FOREIGN SERVER server_name [, ...]
    TO { [ GROUP ] role_name | PUBLIC } [, ...]
    [ WITH GRANT OPTION ];
```

- Grant the function access permission to a user or role.

```
GRANT { { EXECUTE | ALTER | DROP | COMMENT } [, ...] | ALL [ PRIVILEGES ] }
    ON { FUNCTION {function_name ( [ {[ argmode ] [ arg_name ] arg_type} [, ...] ] )} [, ...]
      | ALL FUNCTIONS IN SCHEMA schema_name [, ...] }
    TO { [ GROUP ] role_name | PUBLIC } [, ...]
    [ WITH GRANT OPTION ];
```

- Grant the procedural procedure access permission to a user or role.

```
GRANT { { EXECUTE | ALTER | DROP | COMMENT } [, ...] | ALL [ PRIVILEGES ] }
    ON PROCEDURE {proc_name ( [ {[ argmode ] [ arg_name ] arg_type} [, ...] ] )} [, ...]
    TO { [ GROUP ] role_name | PUBLIC } [, ...]
    [ WITH GRANT OPTION ];
```

- Grant the procedural language access permission to a user or role.

```
GRANT { USAGE | ALL [ PRIVILEGES ] }
    ON LANGUAGE lang_name [, ...]
    TO { [ GROUP ] role_name | PUBLIC } [, ...]
    [ WITH GRANT OPTION ];
```

NOTE

In the current version, all users can create C functions, whereas only users with the SYSADMIN permission can create Java and internal functions.

- When a user with the SYSADMIN permission grants the permission for creating C functions to others, the user must specify a recipient and cannot use GRANT USAGE ON LANGUAGE c TO PUBLIC.
- When a user with the SYSADMIN permission grants the permission for creating C functions to others, the user cannot specify WITH GRANT OPTION.

- Grant the sub-cluster access permission to a user or role.

```
GRANT { { CREATE | USAGE | COMPUTE | ALTER | DROP } [, ...] | ALL [ PRIVILEGES ] }
    ON NODE GROUP group_name [, ...]
    TO { [ GROUP ] role_name | PUBLIC } [, ...]
    [ WITH GRANT OPTION ];
```

NOTE

When the CREATE permission of a sub-cluster is granted to a specified user or role, the USAGE and COMPUTE permissions are granted to the specified user or role by default.

- Grant the schema access permission to a user or role.

```
GRANT { { CREATE | USAGE | ALTER | DROP | COMMENT } [, ...] | ALL [ PRIVILEGES ] }
    ON SCHEMA schema_name [, ...]
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
  TO { [ GROUP ] role_name | PUBLIC } [, ...]
  [ WITH GRANT OPTION ];
```

NOTE

When granting permissions on tables or views within a schema to other users, you also need to grant the USAGE permission on the schema containing those objects. Without the USAGE permission, grantees can only see the object names but cannot actually access them.

- Grant the tablespace access permission to a user or role.

```
GRANT { { CREATE | ALTER | DROP | COMMENT } [, ...] | ALL [ PRIVILEGES ] }
  ON TABLESPACE tablespace_name [, ...]
  TO { [ GROUP ] role_name | PUBLIC } [, ...]
  [ WITH GRANT OPTION ];
```

- Grant the type access permission to a user or role.

```
GRANT { { USAGE | ALTER | DROP | COMMENT } [, ...] | ALL [ PRIVILEGES ] }
  ON TYPE type_name [, ...]
  TO { [ GROUP ] role_name | PUBLIC } [, ...]
  [ WITH GRANT OPTION ];
```

NOTE

In the current version, the type access permission cannot be granted.

- Grant the DIRECTORY permission to a role.

```
GRANT { { READ | WRITE | ALTER | DROP } [, ...] | ALL [PRIVILEGES] }
  ON DIRECTORY directory_name [, ...]
  TO { [GROUP] role_name | PUBLIC } [, ...]
  [WITH GRANT OPTION];
```

- Grant the PACKAGE permission to a role.

```
GRANT { { EXECUTE | ALTER | DROP | COMMENT } [, ...] | ALL [PRIVILEGES] }
  ON PACKAGE package_name [, ...]
  TO { [GROUP] role_name | PUBLIC } [, ...]
  [WITH GRANT OPTION];
```

- Grant a role's permissions to other users or roles.

```
GRANT role_name [, ...]
  TO role_name [, ...]
  [ WITH ADMIN OPTION ];
```

NOTE

After the execution of **GRANT role1 to role2**, role2 does not inherit system permissions from role1. However, as role2 acquires all object permissions from role1, there is a potential risk of exploiting role1's system permissions. Exercise caution when granting a role with system permissions to other users or roles.

- Grant the SYSADMIN permission to a role.

```
GRANT ALL { PRIVILEGES | PRIVILEGE }
  TO role_name;
```

- Grant the ANY permissions to a user or role.

```
GRANT { CREATE ANY TABLE | ALTER ANY TABLE | DROP ANY TABLE | SELECT ANY TABLE |
INSERT ANY TABLE | UPDATE ANY TABLE | DELETE ANY TABLE | TRUNCATE ANY TABLE | CREATE ANY
SEQUENCE |
CREATE ANY INDEX | CREATE ANY FUNCTION | EXECUTE ANY FUNCTION | CREATE ANY PACKAGE |
EXECUTE ANY PACKAGE | CREATE ANY TYPE | ALTER ANY TYPE | DROP ANY TYPE |
ALTER ANY SEQUENCE | DROP ANY SEQUENCE | SELECT ANY SEQUENCE | ALTER ANY INDEX |
DROP ANY INDEX | CREATE ANY SYNONYM | DROP ANY SYNONYM | CREATE ANY TRIGGER | ALTER
ANY TRIGGER |
  DROP ANY TRIGGER } [, ...]
  TO [ GROUP ] role_name [, ...]
  [ WITH ADMIN OPTION ];
```

- Grant the database link object permission to a specified user.

```
GRANT { CREATE | ALTER | DROP } [PUBLIC] DATABASE LINK TO role_name;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- **PUBLIC**: creates a public database link visible to all users. If this clause is omitted, the database link is private and used only as a compatible API. The data that can be accessed on the remote database depends on the identity used by the database link during connection.
- When the permission to create a database link is granted to a user, the user can remotely access a database by using the IP address of the remote database. Exercise caution when granting this permission to users.
- In addition to the statement for directly granting the database link permission, you can also obtain the database link permission by inheriting permission and granting permission to an administrator.
- For details about database links, see "Feature Usage Guidelines > Database Links" in *Developer Guide*.

- Grant the permission to create PUBLIC synonyms to a specified user.

```
GRANT { CREATE | DROP } PUBLIC SYNONYM TO role_name [ WITH ADMIN OPTION ];
```

  Built-in roles (gs_role_public_synonym_create and gs_role_public_synonym_drop) can also be used to grant users the permission to create and delete PUBLIC synonyms.

  – Grant the permission to create PUBLIC synonyms to a user.

```
GRANT gs_role_public_synonym_create TO role_name;
```

  – Grant the permission to delete PUBLIC synonyms to a user.

```
GRANT gs_role_public_synonym_drop TO role_name;
```

Parameters

In GRANT, permissions are classified as follows:

- **SELECT**

  Allows SELECT from any table, view, or sequence. The SELECT permission on the corresponding column is also required for UPDATE or DELETE.

- **INSERT**

  Allows INSERT of a new row into a table.

- **UPDATE**

  Allows you to execute the UPDATE statement on any column in the specified table. The UPDATE statement also requires the SELECT permission to query which rows need to be updated. In addition to the SELECT permission, SELECT ... FOR UPDATE and SELECT ... FOR SHARE require the UPDATE permission.

- **DELETE**

  Allows DELETE of a row from a table. DELETE also requires the SELECT permission to query which rows need to be deleted.

- TRUNCATE

  Allows TRUNCATE on a table.

- **REFERENCES**

  Allows to create a foreign key constraint referencing a table. This permission is required on both referencing and referenced tables. This function is not supported in distributed mode.

- **TRIGGER**

  Allows the creation of a trigger on the specified table.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **CREATE**
  - For databases, allows new schemas to be created within the database.
  - Allows users to create objects within a schema. To rename an existing object, they must own the object and have the CREATE permission on the schema containing that object.
  - Allows users to create tables within a tablespace. When creating a database or schema, they can specify the tablespace as the default tablespace.
  - For sub-clusters, allows tables to be created within the sub-cluster.
- **CONNECT**

  Allows the grantee to connect to the database.
- **TEMPORARY**

  Allows users to create temporary tables in the database.
- **READ**

  Allows users to read a specified directory.
- **WRITE**

  Allows users to write data to a specified directory.
- **EXECUTE**

  Allows calling a function, including use of any operators that are implemented on top of the function.
- **USAGE**
  - For procedural languages, allows use of the language for the creation of functions in that language.
  - Allows users to access objects within a schema. Without the USAGE permission, users can only see the object names.
  - Allows the use of the nextval function for sequences.
  - For sub-clusters, allows users who can access objects contained in the schema to access tables in the sub-cluster.
  - For a key object, USAGE is the permission to use the key.
- **COMPUTE**

  For computing sub-clusters, allows users to perform elastic computing in the sub-cluster that they have the compute permission on.
- **ALTER**

  Allows users to modify the attributes of an object, excluding the object owner and schema.
- **DROP**

  Allows users to drop an object.
- **COMMENT**

  Allows users to define or modify the comment of an object.
- **INDEX**

  Allows users to create indexes on specified tables, manage indexes on the tables, and perform REINDEX and CLUSTER operations on the tables.
- **VACUUM**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Allows users to analyze and vacuum a table.

- **ALL PRIVILEGES**

  Grants all available permissions to a user or role at a time. Only system administrators can execute GRANT ALL PRIVILEGES.

GRANT parameters are as follows:

- **role_name**

  Specifies an existing username.
- **table_name**

  Specifies an existing table name.
- **column_name**

  Specifies an existing column name.
- **schema_name**

  Specifies an existing schema name.
- **database_name**

  Specifies the database name.
- **function_name**

  Specifies the function name.
- **sequence_name**

  Specifies an existing sequence name.
- **fdw_name**

  Specifies the foreign data wrapper name.
- **lang_name**

  Specifies the language name.
- **type_name**

  Specifies an existing type name.
- **group_name**

  Specifies the sub-cluster name.
- **argmode**

  Specifies the parameter mode.

  Value range: character strings complying with **Identifier Naming Conventions**.
- **arg_name**

  Specifies the parameter name.

  Value range: character strings complying with **Identifier Naming Conventions**.
- **arg_type**

  Specifies the parameter type.

  Value range: character strings complying with **Identifier Naming Conventions**.
- **tablespace_name**

  Specifies the tablespace name.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **client_master_key**

  Name of the CMK.

  Value range: character strings complying with **Identifier Naming Conventions**.

- **column_encryption_key**

  Name of the column encryption key.

  Value range: character strings complying with **Identifier Naming Conventions**.

- **directory_name**

  Specifies the directory name.

  Value range: character strings complying with **Identifier Naming Conventions**.

- **WITH GRANT OPTION**

  If **WITH GRANT OPTION** is specified, the recipient of the permission can in turn grant it to others. Without a grant option, the recipient cannot do that. Grant options cannot be granted to **PUBLIC**.

When a non-owner of an object attempts to grant permissions on the object:

- The statement will fail outright if the user has no permissions whatsoever on the object.
- As long as some permission is available, the statement will proceed, but it will grant only those permissions for which the user has grant options.
- The GRANT ALL PRIVILEGES forms will issue a warning message if no grant options are held, while the other forms will issue a warning if grant options for any of the permissions specifically named in the statement are not held.

NOTE

When separation of duties is disabled, database administrators can access all objects, regardless of object permission settings. It is unwise to operate as a system administrator except when necessary.

- **WITH ADMIN OPTION**

  When **WITH ADMIN OPTION** is specified for granting a role, the recipients can in turn grant the role to or revoke it from others.

  When **WITH ADMIN OPTION** is specified for granting ANY permissions, the recipients can in turn grant the permissions to or revoke them from others.

Table 1-402 ANY permissions

Permission	Description
CREATE ANY TABLE	This permission allows users to create tables or views in the schemas of user **PUBLIC** and other common users. The users must be granted the permission to create sequences to create a table that contains serial columns.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Permission	Description
ALTER ANY TABLE	This permission allows users to alter tables or views in the schemas of user **PUBLIC** and other common users. To add PRIMARY KEY or UNIQUE constraints to the table by modifying the table's unique index, the users must also be granted the index permission on the table.
DROP ANY TABLE	This permission allows users to drop tables or views in the schemas of user **PUBLIC** and other common users.
SELECT ANY TABLE	Users' SELECT permission on tables or views in the public and user schemas, which is still subject to row-level security.
UPDATE ANY TABLE	Users' UPDATE permission on tables or views in the public and user schemas, which is still subject to row-level security.
INSERT ANY TABLE	This permission allows users to insert data into tables or views in the schemas of user **PUBLIC** and other common users.
DELETE ANY TABLE	Users' DELETE permission on tables or views in the public and user schemas, which is still subject to row-level security.
TRUNCATE ANY TABLE	This permission allows users to truncate tables or views in the schemas of user **PUBLIC** and other common users.
CREATE ANY FUNCTION	Users can create functions or stored procedures in the user schemas.
EXECUTE ANY FUNCTION	Users' EXECUTE permission on functions or stored procedures in the public and user schemas.
CREATE ANY PACKAGE	Users' permission to create packages in the public and user schemas.
EXECUTE ANY PACKAGE	Users' EXECUTE permission on packages in the public and user schemas.
CREATE ANY TYPE	Users can create types in the public and user schemas.
CREATE ANY SEQUENCE	This permission allows users to create sequences in the schemas of user **PUBLIC** and other common users.
CREATE ANY INDEX	This permission allows users to create indexes in the schemas of user **PUBLIC** and other common users. To create a partitioned table index in a tablespace, the users must also be granted the CREATE permission on that tablespace.
ALTER ANY TYPE	Users have the ALTER permission on types in public and user schemas, excluding modifying the owner of a type or modifying the schema of a type.
DROP ANY TYPE	Users' DROP permission on types in the public and user schemas.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Permission	Description
ALTER ANY SEQUENCE	This permission allows users to alter sequences (excluding sequence owners) in the schemas of user **PUBLIC** and other common users.
DROP ANY SEQUENCE	This permission allows users to drop sequences in the schemas of user **PUBLIC** and other common users.
SELECT ANY SEQUENCE	This permission allows users to select, use, and update sequences in the schemas of user **PUBLIC** and other common users.
ALTER ANY INDEX	This permission allows users to alter indexes in the schemas of user **PUBLIC** and other common users. To rename an index, the users must also have permission to create objects in the schema containing that index. If tablespace operations are involved, the corresponding tablespace permissions are required as well. To set an index as **UNUSABLE**, they still require the DROP ANY INDEX permission.
DROP ANY INDEX	This permission allows users to drop indexes in the schemas of user **PUBLIC** and other common users.
CREATE ANY TRIGGER	Users can create triggers in the public and user schemas.
ALTER ANY TRIGGER	Users' ALTER permission on triggers in the public and user schemas.
DROP ANY TRIGGER	Users' DROP permission on triggers in the public and user schemas.
CREATE ANY SYNONYM	Users can create synonyms in user schema.
DROP ANY SYNONYM	Users' DROP permission on synonyms in the public and user schemas.

NOTE

If a user is granted any ANY permission, the user has the USAGE permission on the public and user schemas but does not have the USAGE permission on the system schemas except public listed in **Table 8-1**.

Examples

Example 1: Grant system permissions to a user or role.

Create user **joe** and grant the SYSADMIN permission to it.

```
gaussdb=# CREATE USER joe PASSWORD 'xxxxxxxxxx';
gaussdb=# GRANT ALL PRIVILEGES TO joe;
```

On success, **joe** gains the SYSADMIN permission.

Example 2: Grant object permissions to a user or role.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

1. Revoke the SYSADMIN permission from the **joe** user. Grant the usage permission of the **tpcds** schema and all permissions on the **tpcds.reason** table to **joe**.

```
gaussdb=# CREATE SCHEMA tpcds;
gaussdb=# CREATE TABLE tpcds.reason (
r_reason_sk         INTEGER      NOT NULL,
r_reason_id         CHAR(16)     NOT NULL,
r_reason_desc       VARCHAR(20)
);
gaussdb=# REVOKE ALL PRIVILEGES FROM joe;
gaussdb=# GRANT USAGE ON SCHEMA tpcds TO joe;
gaussdb=# GRANT ALL PRIVILEGES ON tpcds.reason TO joe;
```

   Then **joe** has all permissions on the **tpcds.reason** table, including create, retrieve, update, and delete.

2. Grant the retrieve permission of **r_reason_sk**, **r_reason_id**, and **r_reason_desc** columns and the update permission of the **r_reason_desc** column in the **tpcds.reason** table to **joe**.

```
gaussdb=# GRANT select (r_reason_sk,r_reason_id,r_reason_desc),update (r_reason_desc) ON
tpcds.reason TO joe;
```

   Then **joe** has the retrieve permission on the **r_reason_sk**, **r_reason_id**, and **r_reason_desc** columns in the **tpcds.reason** table. To enable **joe** to grant these permissions to other users, execute the following statement:

```
gaussdb=# GRANT select (r_reason_sk, r_reason_id) ON tpcds.reason TO joe WITH GRANT OPTION;
```

   Grant the connection and schema creation permissions of the **testdb** database to **joe**, and allow **joe** to grant these permissions to other users.

```
gaussdb=# CREATE DATABASE testdb;
gaussdb=# GRANT create,connect on database testdb TO joe WITH GRANT OPTION;
```

   Create the **tpcds_manager** role, grant the access and object creation permissions of the tpcds schema to **tpcds_manager**, but do not allow **tpcds_manager** to grant these permissions to others.

```
gaussdb=# CREATE ROLE tpcds_manager PASSWORD 'xxxxxxxxxx';
gaussdb=# GRANT USAGE,CREATE ON SCHEMA tpcds TO tpcds_manager;
```

   Grant all permissions on the **tpcds_tbspc** tablespace to **joe**, but do not allow **joe** to grant these permissions to others.

```
gaussdb=# CREATE TABLESPACE tpcds_tbspc RELATIVE LOCATION 'tablespace/tablespace_1';
gaussdb=# GRANT ALL ON TABLESPACE tpcds_tbspc TO joe;
```

   Grant the PUBLIC synonym permission on creating the **tpcds.reason** table to **joe** using the built-in role (**gs_role_public_synonym_create**).

```
gaussdb=# CREATE OR REPLACE SYNONYM t1 FOR tpcds.reason;
gaussdb=# GRANT gs_role_public_synonym_create TO joe;
```

3. Create the fun1 function in the tpcds schema, and grants the ALTER permission of the fun1 function to **joe**.

```
gaussdb=# CREATE or replace FUNCTION tpcds.fun1() RETURN boolean AS
BEGIN
SELECT current_user;
RETURN true;
END;
/
gaussdb=# GRANT ALTER ON FUNCTION tpcds.fun1() TO joe;
```

Example 3: Grant a user's or role's permissions to other users or roles.

1. Create the **manager** role, grant **joe**'s permissions to **manager**, and allow **manager** to grant these permissions to others.

```
gaussdb=# CREATE ROLE manager PASSWORD 'xxxxxxxxxx';
gaussdb=# GRANT joe TO manager WITH ADMIN OPTION;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

2. Create user **senior_manager** and grant **manager**'s permissions to it.

```
gaussdb=# CREATE ROLE senior_manager PASSWORD 'xxxxxxxxxx';
gaussdb=# GRANT manager TO senior_manager;
```

3. Revoke permissions and drop the user.

```
gaussdb=# REVOKE joe FROM manager;
gaussdb=# REVOKE manager FROM senior_manager;
gaussdb=# DROP USER manager;
gaussdb=# DROP DATABASE testdb;
```

Example 4: Grant the CMK or CEK permission to other users or roles.

1. Connect to an encrypted database.

```
-- Use the -C parameter to enable the encrypted database function.
gsql -p 57101 postgres -r -C
gaussdb=#  CREATE CLIENT MASTER KEY MyCMK1 WITH ( KEY_STORE = xxx , KEY_PATH = xxx ,
ALGORITHM = AES_256_CBC);
CREATE CLIENT MASTER KEY
gaussdb=# CREATE COLUMN ENCRYPTION KEY MyCEK1 WITH VALUES (CLIENT_MASTER_KEY =
MyCMK1, ALGORITHM = AEAD_AES_256_CBC_HMAC_SHA256);
CREATE COLUMN ENCRYPTION KEY
```

2. Create a role **newuser** and grant the key permission to **newuser**.

```
gaussdb=# CREATE USER newuser PASSWORD 'xxxxxxxxx';
CREATE ROLE
gaussdb=# GRANT ALL ON SCHEMA public TO newuser;
GRANT
gaussdb=# GRANT USAGE ON COLUMN_ENCRYPTION_KEY MyCEK1 to newuser;
GRANT
gaussdb=# GRANT USAGE ON CLIENT_MASTER_KEY MyCMK1 to newuser;
GRANT
```

3. Set the user to connect to a database and use a CEK to create an encrypted table.

```
gaussdb=# SET ROLE newuser PASSWORD 'xxxxxxxxx';
gaussdb=>  CREATE TABLE acltest1 (x int, x2 varchar(50) ENCRYPTED WITH
(COLUMN_ENCRYPTION_KEY = MyCEK1, ENCRYPTION_TYPE = DETERMINISTIC));
NOTICE:  The 'DISTRIBUTE BY' clause is not specified. Using 'x' as the distribution column by default.
HINT:  Please use 'DISTRIBUTE BY' clause to specify suitable data distribution column.
CREATE TABLE
gaussdb=> SELECT has_cek_privilege('newuser', 'MyCEK1', 'USAGE');
 has_cek_privilege
-------------------
 t
(1 row)
```

4. Revoke permissions and drop the user.

```
gaussdb=> RESET ROLE;
gaussdb=# REVOKE USAGE ON COLUMN_ENCRYPTION_KEY MyCEK1 FROM newuser;
gaussdb=# REVOKE USAGE ON CLIENT_MASTER_KEY MyCMK1 FROM newuser;
gaussdb=# DROP TABLE newuser.acltest1;
gaussdb=# DROP COLUMN ENCRYPTION KEY MyCEK1;
gaussdb=# DROP CLIENT MASTER KEY MyCMK1;
gaussdb=# DROP SCHEMA IF EXISTS newuser CASCADE;
gaussdb=# REVOKE ALL ON SCHEMA public FROM newuser;
gaussdb=# DROP ROLE IF EXISTS newuser;
```

Example 5: Revoke permissions and delete roles and users.

```
gaussdb=# REVOKE gs_role_public_synonym_create FROM joe;
gaussdb=# REVOKE ALTER ON FUNCTION tpcds.fun1() FROM joe;
gaussdb=# REVOKE ALL PRIVILEGES ON tpcds.reason FROM joe;
gaussdb=# REVOKE ALL PRIVILEGES ON SCHEMA tpcds FROM joe;
gaussdb=# REVOKE ALL ON TABLESPACE tpcds_tbspc FROM joe;
gaussdb=# DROP TABLESPACE tpcds_tbspc;
gaussdb=# REVOKE USAGE,CREATE ON SCHEMA tpcds FROM tpcds_manager;
gaussdb=# DROP ROLE tpcds_manager;
gaussdb=# DROP ROLE senior_manager;
gaussdb=# DROP USER joe CASCADE;
gaussdb=# DROP TABLE tpcds.reason;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gaussdb=# DROP SYNONYM t1;
gaussdb=# DROP FUNCTION tpcds.fun1();
gaussdb=# DROP SCHEMA tpcds CASCADE;
```

REVOKE and **ALTER DEFAULT PRIVILEGES**

1.13.14 I

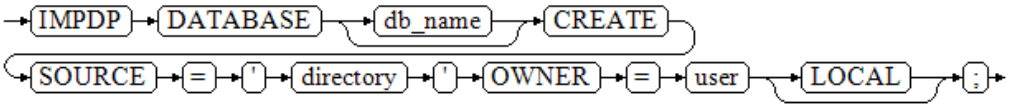
1.13.14.1 IMPDP DATABASE CREATE

Description

Specifies the preparation phase for importing a database.

Syntax

```
IMPDP DATABASE [db_name] CREATE SOURCE = 'directory' OWNER = user [LOCAL];
```



Parameters

- **db_name**

  Name of the new database after the import. If it is not specified, the original database name is retained after the import.
- **directory**

  Data source directory of the imported database.
- **user**

  Owner of the imported database.
- **LOCAL**

  If it is specified, data is imported to the original cluster. Otherwise, data is imported to a new cluster.

Examples

```
-- The IMPDP DATABASE CREATE syntax is used for fine-grained backup and restoration and is called by the backup and restoration tool. If you directly call the syntax, an error message may be displayed, indicating that the directory does not exist. Therefore, you are advised not to directly call the syntax.
gaussdb=# IMPDP DATABASE test CREATE SOURCE = '/data1/impdp/database' OWNER = admin;
```

1.13.14.2 IMPDP RECOVER

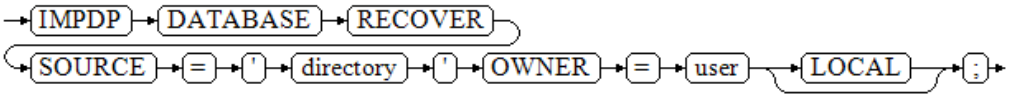
Description

Specifies the execution phase of importing a database.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Syntax

```
IMPDP DATABASE RECOVER SOURCE = 'directory' OWNER = user [LOCAL];
```



Parameters

- **directory**

  Data source directory of the imported database.
- **user**

  Owner of the imported database.
- **LOCAL**

  If it is specified, data is imported to the original cluster. Otherwise, data is imported to a new cluster.

Examples

```
-- The IMPDP DATABASE RECOVER syntax is used for fine-grained backup and restoration and is called by the backup and restoration tool. If you directly call the syntax, an error message may be displayed, indicating that the directory does not exist. Therefore, you are advised not to directly call the syntax.
gaussdb=# IMPDP DATABASE RECOVER SOURCE = '/data1/impdp/database' OWNER=admin;
```

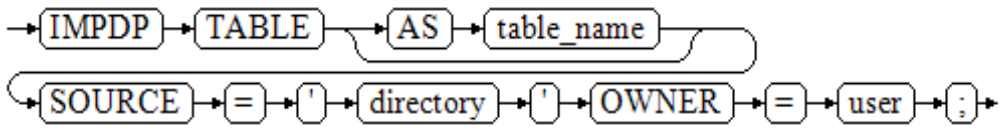
1.13.14.3 IMPDP TABLE

Description

Specifies the execution phase of importing a table.

Syntax

```
IMPDP TABLE [AS table_name] SOURCE = 'directory' OWNER = user;
```



Parameters

- **table_name**

  Name of the new table after the import. If it is not specified, the original table name is retained after the import.
- **directory**

  Data source directory of the imported table.
- **user**

  Owner of the imported table.

Examples

```
-- The IMPDP TABLE syntax is used for fine-grained backup and restoration and is called by the backup and restoration tool. If you directly call the syntax, an error message may be displayed, indicating that the
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
directory does not exist. Therefore, you are advised not to directly call the syntax.
gaussdb=# IMPDP TABLE SOURCE = '/data1/impdp/table0' OWNER=admin;
```

1.13.14.4 IMPDP TABLE PREPARE

Description

Specifies the preparation phase for importing a table.

Syntax

```
IMPDP TABLE PREPARE SOURCE = 'directory' OWNER = user;
```

Parameters

- **directory**

  Data source directory of the imported table.
- **user**

  Owner of the imported table.

Examples

```
-- The IMPDP TABLE PREPARE syntax is used for fine-grained backup and restoration and is called by the backup and restoration tool. If you directly call the syntax, an error message may be displayed, indicating that the directory does not exist. Therefore, you are advised not to directly call the syntax.
gaussdb=# IMPDP TABLE PREPARE SOURCE = '/data1/impdp/table0' OWNER=admin;
```

1.13.14.5 INSERT

Description

Inserts one or more rows of data into a table.

Precautions

- The owner of a table, users with the INSERT permission on the table, or users with the INSERT ANY TABLE permission can insert data into the table. System administrators have the permission to insert data into the table by default when separation of duties is disabled.
- Use of the RETURNING clause requires the SELECT permission on all columns mentioned in RETURNING.
- If ON DUPLICATE KEY UPDATE is used, you must have the INSERT and UPDATE permissions on the table and the SELECT permission on the columns of the UPDATE clause.
- If you use the query clause to insert rows from a query, you need to have the SELECT permission on any table or column used in the query.
- If you use the query clause to insert data from the dynamic data anonymization column, the inserted result is the anonymized value and cannot be restored.
- When you connect to a TD-compatible database and **td_compatible_truncation** is **on**, long strings will be automatically truncated.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

If later INSERT statements (not involving foreign tables) insert long strings into columns of CHAR- and VARCHAR-typed columns in the target table, the system will truncate the long strings to ensure no strings exceed the maximum length defined in the target table.

NOTE

If multi-byte character data (such as Chinese characters) is inserted into a database with the character set byte encoding (such as SQL_ASCII and LATIN1), and the character data crosses the truncation position, the string is truncated based on its bytes instead of characters. Unexpected result will occur in tail after the truncation. If you want correct truncation result, you are advised to adopt encoding set such as UTF8, which has no character data crossing the truncation position.

Syntax

```
[ WITH [ RECURSIVE ] with_query [, ...] ]
INSERT [/*+ plan_hint */] [ IGNORE ] INTO table_name [ { [alias_name] [ ( column_name [, ...] ) ] } |
{ [partition_clause] [ AS alias ] [ ( column_name [, ...] ) ] } ]
   { DEFAULT VALUES
   | { VALUES | VALUE } {( { expression | DEFAULT } [, ...] ) }[, ...]
   | query }
   [ { ON DUPLICATE KEY UPDATE { NOTHING | { column_name = { expression | DEFAULT } } [, ...]
[ WHERE condition ] } }
   | { [ ON CONFLICT [ conflict_target ] conflict_action ] } ]
   [ RETURNING {* | {output_expression [ [ AS ] output_name ] }[, ...]} ];
```

Insert subqueries and views.

```
[ WITH [ RECURSIVE ] with_query [, ...] ]
INSERT [/*+ plan_hint */] INTO {subquery | view_name} [ AS alias ] [ ( column_name [, ...] ) ]
   { DEFAULT VALUES
   | { VALUES | VALUE } {( { expression | DEFAULT } [, ...] ) }[, ...]
   | query }
   [ RETURNING {* | {output_expression [ [ AS ] output_name ] }[, ...]} ];
```

- Detailed information of **subquery**:

  ```
  [ WITH [ RECURSIVE ] with_query [, ...] ]
  SELECT [/*+ plan_hint */] [ ALL ]
  { * | {expression [ [ AS ] output_name ]} [, ...] }
  [ into_option ]
  [ FROM from_item [, ...] ]
  [ WHERE condition ]
  [ [ START WITH condition ] CONNECT BY [NOCYCLE] condition [ ORDER SIBLINGS BY expression ] ]
  [ ORDER BY {expression [ [ ASC | DESC | USING operator ] | nlssort_expression_clause ] [ NULLS
  { FIRST | LAST } ]} [, ...] ]
  [ FETCH { FIRST | NEXT } [ count ] { ROW | ROWS } ONLY ]
  [ into_option ];
  ```

- The specified subquery source **from_item** is as follows:

  ```
  {[ ONLY ] {table_name | view_name} [ * ] [ partition_clause ] [ [ AS ] alias [ ( column_alias [, ...] ) ] ]
  |( select ) [ AS ] alias [ ( column_alias [, ...] ) ]
  |with_query_name [ [ AS ] alias [ ( column_alias [, ...] ) ] ]
  |from_item [ NATURAL ] join_type from_item [ ON join_condition | USING ( join_column [, ...] ) ]}
  ```

- Detailed information of **with_query**:

  ```
  with_query_name [ ( column_name [, ...] ) ] AS [ [ NOT ] MATERIALIZED ]
  ( {SELECT | VALUES | INSERT | UPDATE | DELETE} )
  ```

- Detailed information of partition_clause:

  ```
  PARTITION { ( partition_name ) | FOR ( partition_value [, ...] ) }
  ```

- Detailed information of **conflict_target**:

  ```
  ( { index_column_name | ( index_expression ) } [, ...] ) [ WHERE index_predicate ]
  ```

- Detailed information of **conflict_action**:

  ```
  DO NOTHING |
  DO UPDATE SET { column_name = { expression | DEFAULT } | ( column_name [, ...] ) = ( { expression |
  DEFAULT } [, ...] ) } [, ...] [ WHERE condition ]
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameters

- **WITH [RECURSIVE] with_query [, ...]**

  Specifies one or more subqueries that can be referenced by name in the main query, which is equivalent to a temporary table.

  If **RECURSIVE** is specified, a SELECT subquery can be referenced by name.

  with_query:

  – **with_query_name** specifies the name of the result set generated by a subquery. Such names can be used to access the result sets of subqueries in a query.

  – **column_name** specifies the column name displayed in the subquery result set.

  - Each subquery can be a SELECT, VALUES, INSERT, UPDATE, or DELETE statement.

  NOTICE

  If a subquery is a DML statement with a RETURNING statement, the number of command output records of the INSERT statement is determined by the subquery. Assume that table **T1** exists. Run the following statement:

  ```
  WITH CTE AS (INSERT INTO T1 VALUES(1,2) RETURNING *) INSERT INTO T1 SELECT * FROM CTE;
  ```

  The number of command output records of the preceding statement is determined by the following part instead of the entire statement. That is, the command output is "INSERT 0 1" instead of "INSERT 0 2".

  ```
  INSERT INTO T1 VALUES(1,2) RETURNING *
  ```

  – You can use MATERIALIZED or NOT MATERIALIZED to modify the CTE.

  – If **MATERIALIZED** is specified, the WITH query will be materialized, and a copy of the subquery result set is generated. The copy is directly queried at the reference point. Therefore, the WITH subquery cannot be jointly optimized with the SELECT statement trunk (for example, predicate pushdown and equivalence class transfer). In this scenario, you can use **NOT MATERIALIZED** for modification. If the WITH query can be executed as a subquery inline, the preceding optimization can be performed.

  – If the user does not explicitly declare the materialized attribute, comply with the following rules: If the CTE is referenced only once in the trunk statement to which it belongs and semantically supports inline execution, it will be rewritten as subquery inline execution. Otherwise, the materialized execution will be performed in CTE Scan mode.

  NOTE

  INSERT ON DUPLICATE KEY UPDATE does not support the WITH or WITH RECURSIVE clauses.

- **plan_hint** clause

  Follows the INSERT keyword in the /*+ */ format. It is used to optimize the plan of a INSERT statement block using hints. For details, see "Hint-based Optimization" in *SQL Optimization Guide*. In each statement, only the first **/*+** *plan_hint* ***/** comment block takes effect as a hint. Multiple hints can be written.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **IGNORE**

  When the INSERT statement uses the IGNORE keyword, some ERROR-level errors can be degraded to WARNING-level errors, and invalid values can be adjusted to the closest values based on error scenarios. GaussDB supports the following error codes for error downgrade:

  - Damage to the NOT NULL constraint
  - UNIQUE KEY conflict
  - No partition found for the inserted value
  - Unmatch between the inserted data and the specified partition
  - Multiple rows returned for a subquery
  - Oversized data
  - Time function overflow
  - Division by 0
  - Incorrect value

  NOTE

  1. INSERT IGNORE is supported only when **sql_compatibility** is set to **'MYSQL'**, **b_format_version** set to **'5.7'**, and **b_format_dev_version** set to **'s1'**.
  2. INSERT IGNORE does not support encrypted tables and foreign tables.
  3. INSERT IGNORE does not support PRIMARY KEY constraints or UNIQUE constraints that take effect with a delay.
  4. INSERT IGNORE allows **NULL** values to damage NOT NULL constraints in terms of some data types, whose OIDs are TIMESTAMPOID, TIMESTAMPTZOID, TIMEOID, TIMETZOID, RELTIMEOID, INTERVALOID, TINTERVALOOID, SMALLDATETIMEOID, DATEOID, NAMEOID, POINTOID, PATHOID, POLYGONOID, CIRCLEOID, LSEGOID, BOXOID, JSONOID, JSONBOID, XMLOID, XMLTYPEOID, VARBITOID, NUMERICOID, CIDROID, INETOID, MACADDROID, NUMRANGEOID, INT8RANGEOID, INT4RANGEOID, TSRANGEOID, TSTZRANGEOID, DATERANGEOID, ABSTIMEOID, BOOLOID, INT8OID, INT4OID, INT2OID, INT1OID, FLOAT4OID, FLOAT8OID, CASHOID, UINT1OID, UINT2OID, UINT4OID, UINT8OID, BPCHAROID, VARCHAROID, NVARCHAR2OID, CHAROID, BYTEAOID, RAWOID, BLOBOID, CLOBOID, TEXTOID, and YEAROID. **Table 1-403** lists the zero values of each data type.
  5. When the default zero value is used for calculation, exercise caution when using IGNORE to ignore the NOT NULL constraint.
  6. INSERT IGNORE does not support tables with global secondary indexes.
  7. An error generated on a CN is degraded to the warning information while an error generated on a DN is not degraded to the warning information.

Table 1-403 Default zero values for the data type

OID of Each Data Type	Default Zero Value
INT8OID, INT4OID, INT2OID, INT1OID, UINT1OID, UINT2OID, UINT4OID, UINT8OID, FLOAT4OID, FLOAT8OID, NUMERICOID	0 or 0.00 (The number of 0s after the decimal point is specified by a parameter.)

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

OID of Each Data Type	Default Zero Value
BPCHAROID, VARCHAROID, CHAROID, BYTEAOID, RAWOID, BLOBOID, NVARCHAR2OID, CLOBOID, TEXTOID, VARBITOID, NAMEOID	Empty string
NUMRANGEOID, INT8RANGEOID, INT4RANGEOID, TSRANGEOID, TSTZRANGEOID, DATERANGEOID	empty
TIMEOID	time '00:00:00'
TIMETZOID	timetz '00:00:00'
INTERVALOID	interval '00:00:00'
TINTERVALOOID	tinterval(abstime '1970-01-01 00:00:00', abstime '1970-01-01 00:00:00')
SMALLDATETIMEOID	smalldatetime '1970-01-01 00:00:00'
ABSTIMEOID	abstime '1970-01-01 00:00:00'
RELTIMEOID	reltime '00:00:00'
TIMESTAMPOID, TIMESTAMPTZOID	1970-01-01 00:00:00
DATEOID	1970-01-01
YEAROID	0000
POINTOID	(0,0)
PATHOID, POLYGONOID	((0,0))
CIRCLEOID	<(0,0),0>
LSEGOID	[(0,0),(0,0)]
BOXOID	(0,0),(0,0)
JSONOID, JSONBOID, XMLOID	'null'
XMLTYPEOID	'<null/>'
CIDROID	0.0.0.0/32
INETOID	0.0.0.0
MACADDROID	00:00:00:00:00:00
BOOLOID	f
CASHOID	$0.00

- **table_name**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Specifies the name of the target table where data will be inserted.

Value range: existing table names.

NOTE

You can use database links to perform operations on remote tables. For details, see "Feature Usage Guidelines > Database Links" in *Developer Guide*.

- **subquery**

  The inserted object can be a subquery. When a subquery is inserted, the subquery is regarded as a temporary view. The **CHECK OPTION** option can be added to the end of the subquery.

  If a subquery contains only one table, data is inserted into the table. If a subquery contains multiple tables or has nested relationships, check whether a key-preserved table exists to determine whether data can be inserted. For details about key-preserved tables and **WITH CHECK OPTION**, see **CREATE VIEW**.

- **view_name**

  Specifies the target view to be inserted.

  NOTE

  The restrictions on inserting views and subqueries are as follows:

  - The INSERT operation can be performed only on columns that directly reference user columns in the base table.
  - A subquery or view must contain at least one updatable column. For details about updatable columns, see **CREATE VIEW**.
  - The view or subquery must not contain the DISTINCT, GROUP BY, HAVING, LIMIT, or OFFSET clause at the top layer.
  - Views and subqueries that contain set operations (UNION, INTERSECT, EXCEPT, and MINUS) at the top layer are not supported.
  - Views and subqueries whose target lists contain aggregate functions, window functions, or return set functions (such as array_agg, json_agg, and generate_series) are not supported.
  - Views with BEFORE or AFTER triggers but without INSTEAD OF triggers or INSTEAD rules are not supported.
  - ON DUPLICATE KEY UPDATE is not supported.
  - Table types supported in views and subqueries include ordinary tables, temporary tables, global temporary tables, partitioned tables, subpartitioned tables, Ustore tables, and Astore tables.
  - For a multi-table join view or subquery, only one base table can be inserted at a time.
  - When INSERT joins a view or subquery, explicitly specified columns to be inserted or implicitly specified columns (columns specified during view or subquery creation) cannot reference columns of non-key-preserved tables; if the WITH CHECK OPTION clause is used, INSERT operations cannot be performed on join columns in join views or subqueries. For details about key-preserved tables, see **CREATE VIEW**.
  - The INSERT operation cannot be performed on the system view.

- **alias_name**

  Specifies the table alias when the INSERT statement is used without AS alias.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

1. When the INSERT statement is used without AS alias, the table alias cannot be a keyword (such as SELECT and VALUE) or an expression. The alias must comply with the identifier naming rule.
2. When the INSERT statement is used without AS alias, data cannot be inserted into the specified partition.

- **partition_clause**

  Inserts data to a specified partition.

  For details about the keywords, see **SELECT**.

  If the value of the VALUE clause is inconsistent with that of the specified partition, an exception is displayed.

- **column_name**

  Specifies the name of a column in a table.

  - The column name can be qualified with a subcolumn name or array index, if needed.
  - Each column not present in the column list will be filled with a default value, either its declared default value or **NULL** if there is none. Inserting data into only some columns of a composite type leaves the other columns **NULL**.
  - The target column names **column_name** can be listed in any order. If no list of column names is given at all, the default is all the columns of the table in their declared order.
  - The target columns are the first *N* column names, if there are only *N* columns supplied by the VALUE clause or query.
  - The values supplied by the VALUE clause or query are joined with the columns left-to-right.
  - Data can be inserted in the format of **table alias.column name**.

  Value range: existing column names.

- **expression**

  Specifies an expression or a value to assign to the corresponding column.

  - In the INSERT ON DUPLICATE KEY UPDATE statement, expression can be **VALUES(***column_name***)** or **EXCLUDED.***column_name*, indicating that the value of **column_name** corresponding to the conflict row is referenced. **VALUES(***column_name***)** can be nested in a compound expression, for example, **VALUES(***column_name***)+1**, **VALUES(***column_name***) +VALUES(***column_name***)**, and **function_name(VALUES(***column_name***))**.

    NOTE

    - **VALUES(***column_name***)** can be used only in the ON DUPLICATE KEY UPDATE clause.
    - **VALUES(***column_name***)** cannot be used in the IN or NOT IN expressions.
  - If single quotation marks (') are inserted into a column, they must be escaped by using an additional pair of single quotation marks.
  - If the expression for any column is not of the correct data type, automatic type conversion will be attempted. If the attempt fails, data insertion fails, and the system returns an error message.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **DEFAULT**

  Specifies the default value of a column. The value is **NULL** if there is no default value.

- **query**

  Specifies a query statement (SELECT statement) that uses the query result as the inserted data.

- **RETURNING**

  Returns the inserted rows. The syntax of the RETURNING list is identical to that of the output list of SELECT.

- **output_expression**

  Specifies an expression used to calculate the output result of the INSERT statement after each row is inserted.

  Value range: The expression can use any column in the table. You can use the asterisk (*) to return all columns of the inserted row.

- **output_name**

  Specifies a name to use for a returned column.

  Value range: character strings complying with **Identifier Naming Conventions**.

- **ON DUPLICATE KEY UPDATE**

  For a table with a UNIQUE constraint (UNIQUE INDEX or PRIMARY KEY), if the inserted data violates the UNIQUE constraint, the UPDATE clause is executed to update the conflicting rows. If **NOTHING** is specified for the UPDATE clause, no operation will be performed. You can use **EXCLUDED.** or **VALUES()** to select the column corresponding to the source data.

  For a table without a unique constraint, only insert is performed.

  - The INSERT ... ON DUPLICATE KEY UPDATE statement supports STATEMENT triggers but does not support ROW triggers. Triggers are determined by the executed statement:
    - Executing **UPDATE NOTHING** will trigger the BEFORE INSERT and AFTER INSERT triggers.
    - Executing **UPDATE** will trigger the BEFORE INSERT, AFTER INSERT, BEFORE UPDATE, and AFTER UPDATE triggers.
  - Deferrable UNIQUE constraints or primary keys are not supported.
  - If a table has multiple unique constraints and the inserted data violates multiple unique constraints, only the first row that has a conflict is updated. (The check sequence is closely related to index maintenance. Generally, the conflict check is performed on the index that is created first.)
  - Primary keys and unique index columns cannot be updated.
  - Foreign tables are not supported.
  - The WHERE clause and expression of UPDATE cannot contain sublinks.

- **ON CONFLICT [conflict_target] conflict_action**

  Specifies whether to continue an INSERT operation when a unique or exclusive constraint conflict occurs during the operation. If no conflict occurs, the INSERT operation is performed. When a conflict occurs, if **ON CONFLICT**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

is followed by **DO NOTHING**, the current INSERT operation is abandoned; if **ON CONFLICT** is followed by **DO UPDATE SET**, the UPDATE operation is performed.

- **conflict_target**
  - **index_column_name**: Name of the index column.
  - **index_expression**: Similar to **index_column_name**, it is an expression index based on one or more columns of the table and can be used for fast access to a variation of the basic data.
  - **index_predicate**: condition expression that specifies the range of a partially unique index.
- **conflict_action**
  - **expression**: expression or value to be assigned to the corresponding column.
  - **DEFAULT**: The corresponding column will be filled with the default value.

NOTE

The INSERT... ON CONFLICT syntax has the following restrictions:

- Only PG compatibility is supported.
- The [COLLATE collation] [opclass] syntax is not supported.
- The ON CONSTRAINT constraint_name syntax is not supported.
- Users must have the UPDATE permission before using DO UPDATE SET.
- Nesting in the conflict_target, UPDATE SET, or UPDATE SET clause is not supported.
- Column-format tables, foreign tables, STREAM objects, and CONTVIEW objects are not supported.
- Distribution keys cannot be updated.
- In distributed mode, if the execution plan is **stream**, **light proxy**, or **fqs**, multiple data records with the same unique key cannot be inserted into the same statement at a time. If the execution plan is **PGXC**, the preceding operation is allowed.
- GSIs are not supported.
- Database links are not supported.
- Subqueries cannot be inserted.
- Only STATEMENT triggers are supported. ROW triggers are not supported.

Examples

- **Insert a data record.**

  Example:

```
-- Create a table.
gaussdb=# CREATE TABLE test_t1(col1 INT,col2 VARCHAR);

-- Insert data.
gaussdb=# INSERT INTO test_t1 (col1, col2) VALUES (1,'AB');

-- Add values to some columns of the table.
gaussdb=# INSERT INTO test_t1 (col1) VALUES (2);

-- There is no parenthesis on the left of the VALUES keyword. Values must be added to all fields in the parenthesis on the right according to the table definition sequence.
gaussdb=# INSERT INTO test_t1 VALUES (3,'AC');
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
-- Query the table.
gaussdb=# SELECT * FROM test_t1;
 col1 | col2
------+------
    1 | AB
    2 |
    3 | AC
(3 rows)
-- Drop.
gaussdb=# DROP TABLE test_t1;
```

- **Insert multiple data records.**

  Example:

```
-- Create a table.
gaussdb=# CREATE TABLE test_t2(col1 INT,col2 VARCHAR);
gaussdb=# CREATE TABLE test_t3(col1 INT,col2 VARCHAR);

-- Insert multiple data records.
gaussdb=# INSERT INTO test_t2 (col1, col2) VALUES (10,'AA'),(20,'BB'),(30,'CC');

-- Query.
gaussdb=# SELECT * FROM test_t2;
 col1 | col2
------+------
   10 | AA
   20 | BB
   30 | CC
(3 rows)

-- Insert data in test_t2 into test_t3.
gaussdb=# INSERT INTO test_t3 SELECT * FROM test_t2;

-- Query.
gaussdb=# SELECT * FROM test_t3;
 col1 | col2
------+------
   10 | AA
   20 | BB
   30 | CC
(3 rows)

-- Drop.
gaussdb=# DROP TABLE test_t2;
DROP TABLE test_t3;
```

- **ON DUPLICATE KEY UPDATE**

  Example:

```
-- Create a table.
gaussdb=# CREATE TABLE test_t4 (id INT PRIMARY KEY, info VARCHAR(10));
gaussdb=# INSERT INTO test_t4 VALUES (1, 'AA'), (2,'BB'), (3, 'CC');

-- Use the ON DUPLICATE KEY UPDATE keyword.
gaussdb=# INSERT INTO test_t4 VALUES (3, 'DD'), (4, 'EE') ON DUPLICATE KEY UPDATE info =
VALUES(info);

-- Query.
gaussdb=# SELECT * FROM test_t4;
 id | info
----+------
  1 | AA
  2 | BB
  4 | EE
  3 | DD

-- Drop.
gaussdb=# DROP TABLE test_t4;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **ON CONFLICT**

  Example:

```
-- Create a PG-compatible database and a data table.
gaussdb=# CREATE DATABASE pg_db dbcompatibility = 'PG';
gaussdb=# \c pg_db
pg_db=# CREATE TABLE insert_onconflict_tb1(id INT, a INT PRIMARY KEY, b INT, c VARCHAR2(20));
pg_db=# INSERT INTO insert_onconflict_tb1 VALUES (1, 1, 2, 'aaa'), (2, 2, 0, 'zzz');

-- Query table information.
pg_db=# SELECT * FROM insert_onconflict_tb1;
 id | a | b |  c
----+---+---+-----
  1 | 1 | 2 | aaa
  2 | 2 | 0 | zzz
(2 rows)

-- Use the ON CONFLICT keyword.
pg_db=# INSERT INTO insert_onconflict_tb1 VALUES (1, 1, 5, 'ddd'), (2, 2, 1, 'yyy') ON CONFLICT (a)
DO UPDATE SET b=excluded.b, c=excluded.c;
pg_db=# INSERT INTO insert_onconflict_tb1 VALUES (1, 1, 4, 'ccc'), (2, 2, 3, 'zzz') ON CONFLICT (a)
DO NOTHING;

-- Query table information.
pg_db=# SELECT * FROM insert_onconflict_tb1;
 id | a | b |  c
----+---+---+-----
  1 | 1 | 5 | ddd
  2 | 2 | 1 | yyy
(2 rows)

-- Drop the data table and the PG-compatible database.
pg_db=# DROP TABLE insert_onconflict_tb1;
pg_db=# \c postgres
gaussdb=# DROP DATABASE pg_db;
```

- **INSERT IGNORE**

  Example 1: Damage to the NOT NULL constraint

```
-- Create a table.
gaussdb=# CREATE TABLE test_t5(f1 INT NOT NULL);
NOTICE:  The 'DISTRIBUTE BY' clause is not specified. Using 'f1' as the distribution column by default.
HINT:  Please use 'DISTRIBUTE BY' clause to specify suitable data distribution column.
CREATE TABLE

-- Use the IGNORE keyword.
gaussdb=# INSERT IGNORE INTO test_t5 VALUES(NULL);
WARNING:  The null value in column "f1" violates the not-null constraint
DETAIL:  Failing row contains (null).
INSERT 0 1

-- Query the table.
gaussdb=# SELECT * FROM test_t5;
 f1
----
  0
(1 row)

-- Drop the table.
gaussdb=# DROP TABLE test_t5;
DROP TABLE
```

  Example 2: UNIQUE KEY conflict

```
-- Create a table.
gaussdb=# CREATE TABLE test_t6(f1 INT PRIMARY KEY);
NOTICE:  CREATE TABLE / PRIMARY KEY will create implicit index "test_t6_pkey" for table "test_t6"
CREATE TABLE

-- Insert data.
gaussdb=# INSERT INTO test_t6 VALUES(1);
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
INSERT 0 1

-- Use the IGNORE keyword.
gaussdb=# INSERT IGNORE INTO test_t6 VALUES(1);
INSERT 0 0

-- Query the table.
gaussdb=# SELECT * FROM test_t6;
 f1
----
  1
(1 row)

-- Drop the table.
gaussdb=# DROP TABLE test_t6;
DROP TABLE
```

Example 3: No partition found for the inserted value

```
-- Create a table.
gaussdb=# CREATE TABLE test_t7(f1 INT, f2 INT) PARTITION BY LIST(f1) (PARTITION p0 VALUES(1, 4,
7), PARTITION p1 VALUES (2, 5, 8));
NOTICE:  The 'DISTRIBUTE BY' clause is not specified. Using 'f1' as the distribution column by default.
HINT:  Please use 'DISTRIBUTE BY' clause to specify suitable data distribution column.
CREATE TABLE

-- Use the IGNORE keyword.
gaussdb=# INSERT IGNORE INTO test_t7 VALUES(3, 5);
INSERT 0 0

-- Query the table.
gaussdb=# SELECT * FROM test_t7;
 f1 | f2
----+----
(0 rows)

-- Drop the table.
gaussdb=# DROP TABLE test_t7;
DROP TABLE
```

Example 4: Unmatch between the inserted data and the specified partition

```
-- Create a table.
gaussdb=# CREATE TABLE test_t8(f1 INT NOT NULL, f2 TEXT, f3 INT) PARTITION BY RANGE(f1)
(PARTITION p0 VALUES LESS THAN(5), PARTITION p1 VALUES LESS THAN(10), PARTITION p2
VALUES LESS THAN(15), PARTITION p3 VALUES LESS THAN(MAXVALUE));
NOTICE:  The 'DISTRIBUTE BY' clause is not specified. Using 'f1' as the distribution column by default.
HINT:  Please use 'DISTRIBUTE BY' clause to specify suitable data distribution column.
CREATE TABLE

-- Use the IGNORE keyword.
gaussdb=# INSERT IGNORE INTO test_t8 PARTITION(p2) VALUES(20, 'Jan', 1);
INSERT 0 0

-- Query the table.
gaussdb=# SELECT * FROM test_t8;
 f1 | f2 | f3
----+----+----
(0 rows)

-- Drop the table.
gaussdb=# DROP TABLE test_t8;
DROP TABLE
```

Example 5: Multiple rows returned for a subquery

```
-- Create a table.
gaussdb=# CREATE TABLE test_t9(f1 INT, f2 INT);
NOTICE:  The 'DISTRIBUTE BY' clause is not specified. Using 'f1' as the distribution column by default.
HINT:  Please use 'DISTRIBUTE BY' clause to specify suitable data distribution column.
CREATE TABLE
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
-- Insert data.
gaussdb=# INSERT INTO test_t9 VALUES(1, 1), (2, 2), (3, 3);
INSERT 0 3

-- Use the IGNORE keyword.
gaussdb=# INSERT IGNORE INTO test_t9 VALUES((SELECT f1 FROM test_t9), 0);
WARNING:  more than one row returned by a subquery used as an expression
CONTEXT:  referenced column: f1
INSERT 0 1

-- Query the table.
gaussdb=# SELECT * FROM test_t9 WHERE f2 = 0;
 f1 | f2
----+----
    |  0
(1 row)

-- Drop the table.
gaussdb=# DROP TABLE test_t9;
DROP TABLE
```

Example 6: Oversized data

```
-- Create a table.
gaussdb=# CREATE TABLE test_t10(f1 VARCHAR(5));
NOTICE:  The 'DISTRIBUTE BY' clause is not specified. Using 'f1' as the distribution column by default.
HINT:  Please use 'DISTRIBUTE BY' clause to specify suitable data distribution column.
CREATE TABLE

-- Use the IGNORE keyword.
gaussdb=# INSERT IGNORE INTO test_t10 VALUES('aaaaaaaaa');
WARNING:  value too long for type character varying(5)
CONTEXT:  referenced column: f1
INSERT 0 1

-- Query the table.
gaussdb=# SELECT * FROM test_t10;
  f1
-------
 aaaaa
(1 row)

-- Drop the table.
gaussdb=# DROP TABLE test_t10;
DROP TABLE
```

Example 7: Time function overflow

```
-- Create a table.
gaussdb=# CREATE TABLE test_t11(f1 DATETIME);
NOTICE:  The 'DISTRIBUTE BY' clause is not specified. Using 'f1' as the distribution column by default.
HINT:  Please use 'DISTRIBUTE BY' clause to specify suitable data distribution column.
CREATE TABLE

-- Use the IGNORE keyword.
gaussdb=# INSERT IGNORE INTO test_t11 VALUES(date_sub('2000-01-01', INTERVAL 2001 YEAR));
WARNING:  Datetime function: datetime field overflow
CONTEXT:  referenced column: f1
INSERT 0 1

-- Query the table.
gaussdb=# SELECT * FROM test_t11;
 f1
----

(1 row)

-- Drop the table.
gaussdb=# DROP TABLE test_t11;
DROP TABLE
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Example 8: Division by 0

```
-- Create a table.
gaussdb=# CREATE TABLE test_t12(f1 INT);
CREATE TABLE

-- Use the IGNORE keyword.
gaussdb=# INSERT IGNORE INTO test_t12 VALUES(1/0);
WARNING:  division by zero
CONTEXT:  referenced column: f1
INSERT 0 1

-- Query the table.
gaussdb=# SELECT * FROM test_t12;
 f1
----

(1 row)

-- Drop the table.
gaussdb=# DROP TABLE test_t12;
DROP TABLE
```

Example 9: Incorrect value

```
-- Create a table.
gaussdb=# CREATE TABLE test_t13(f0 INT, f1 FLOAT);
NOTICE:  The 'DISTRIBUTE BY' clause is not specified. Using 'f0' as the distribution column by default.
HINT:  Please use 'DISTRIBUTE BY' clause to specify suitable data distribution column.
CREATE TABLE

-- Use the IGNORE keyword.
gaussdb=# INSERT IGNORE INTO test_t13 VALUES(1, '1.11aaa');
WARNING:  invalid input syntax for type real: "1.11aaa"
LINE 1: INSERT IGNORE INTO test_t13 VALUES(1, '1.11aaa');
                                              ^
CONTEXT:  referenced column: f1
INSERT 0 1

-- Query the table.
gaussdb=# SELECT * FROM  test_t13;
 f0 |  f1
----+------
  1 | 1.11
(1 row)

-- Drop the table.
gaussdb=# DROP TABLE test_t13;
DROP TABLE
```

Example 10: Insert a data record using a table alias.

```
-- Create a table.
gaussdb=# create table tb1 (va int , vb int);
NOTICE:  The 'DISTRIBUTE BY' clause is not specified. Using 'va' as the distribution column by default.
HINT:  Please use 'DISTRIBUTE BY' clause to specify suitable data distribution column.
CREATE TABLE

 -- Use a table alias.
gaussdb=# insert into tb1 as tt(tt.va, tt.vb) values (1,2);
INSERT 0 1
gaussdb=# insert into tb1 tt(tt.va, tt.vb) values (3,4);
INSERT 0 1

-- Query the table.
gaussdb=# select * from tb1;
 va | vb
----+----
  1 |  2
  3 |  4
(2 rows)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
-- Drop the table.
gaussdb=# DROP TABLE tb1;
DROP TABLE
```

- **WITH [RECURSIVE] with_query [, ...]**

  Example:

```
-- Grade table.
gaussdb=# CREATE TABLE grade (
    sid INT,
    course VARCHAR(20),
    score FLOAT
);
-- Student table.
gaussdb=# CREATE TABLE student(
    sid INT PRIMARY KEY,
    class INT,
    name  VARCHAR(50),
    gender INT CHECK (gender = 0 or gender = 1)
);

-- Insert data.
gaussdb=# WITH student_sid AS ( INSERT INTO student ( sid, CLASS, NAME, gender ) VALUES ( 1, 1,
'scott', 1 ) RETURNING sid )
    INSERT INTO grade ( sid, course, score )
    VALUE ( ( SELECT sid FROM student_sid ), 'Mathematics', '96' ),
      ( ( SELECT sid FROM student_sid ), 'Chinese', '82' ),
      ( ( SELECT sid FROM student_sid ), 'English', '86' );

-- Query data.
gaussdb=# SELECT * FROM student;
 sid | class | name  | gender
-----+-------+-------+-----
   1 |     1 | scott |   1
(1 row)

gaussdb=# SELECT * FROM grade;
 sid | course  | score
-----+---------+-------
   1 | Mathematics    |    96
   1 | Chinese    |    82
   1 | English    |    86
(3 rows)

-- Drop.
gaussdb=# DROP TABLE student;
gaussdb=# DROP TABLE grade;
```

- **Insert data into a view or subquery.**

  Example 1: Insert a subquery.

```
-- Create a schema.
gaussdb=# CREATE SCHEMA ins_subqry;
CREATE SCHEMA
gaussdb=# SET CURRENT_SCHEMA = 'ins_subqry';
SET

-- Create tables.
gaussdb=# CREATE TABLE t1 (x1 int, y1 int);
NOTICE:  The 'DISTRIBUTE BY' clause is not specified. Using 'x1' as the distribution column by default.
HINT:  Please use 'DISTRIBUTE BY' clause to specify suitable data distribution column.
CREATE TABLE
gaussdb=# CREATE TABLE t2 (x2 int PRIMARY KEY, y2 int);
NOTICE:  CREATE TABLE / PRIMARY KEY will create implicit index "t2_pkey" for table "t2"
CREATE TABLE

-- Insert data into t1 through a subquery.
gaussdb=# INSERT INTO (SELECT * FROM t1) VALUES (1, 1);
INSERT 0 1
gaussdb=# INSERT INTO (SELECT * FROM t1 WHERE y1 < 3) VALUES (5, 5);
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
INSERT 0 1

-- Insert a subquery with CHECK OPTION specified.
gaussdb=# INSERT INTO (SELECT * FROM t1 WHERE y1 < 3 WITH CHECK OPTION) VALUES (5, 5);
ERROR:  New row violates WITH CHECK OPTION for view "__unnamed_subquery__"
DETAIL:  Failing row contains (5, 5).

-- Insert a subquery with READONLY specified.
gaussdb=# INSERT INTO (SELECT * FROM t1 WITH READ ONLY) VALUES (5, 5);
ERROR:  DML operation cannot be performed on a read-only view.

-- Insert a multi-table join subquery.
gaussdb=# INSERT INTO (SELECT * FROM t1, t2 WHERE x1 = x2) (x1, y1) VALUES (2, 2);
INSERT 0 1

-- Drop a schema.
gaussdb=# RESET CURRENT_SCHEMA;
RESET
gaussdb=# DROP SCHEMA ins_subqry CASCADE;
NOTICE:  drop cascades to 2 other objects
DETAIL:  drop cascades to table ins_subqry.t1
drop cascades to table ins_subqry.t2
DROP SCHEMA
```

Example 2: Insert a view.

```
-- Create a schema.
gaussdb=# CREATE SCHEMA ins_view;
CREATE SCHEMA
gaussdb=# SET CURRENT_SCHEMA = 'ins_view';
SET

-- Create tables.
gaussdb=# CREATE TABLE t1 (x1 int, y1 int);
NOTICE:  The 'DISTRIBUTE BY' clause is not specified. Using 'x1' as the distribution column by default.
HINT:  Please use 'DISTRIBUTE BY' clause to specify suitable data distribution column.
CREATE TABLE
gaussdb=# CREATE TABLE t2 (x2 int PRIMARY KEY, y2 int);
NOTICE:  CREATE TABLE / PRIMARY KEY will create implicit index "t2_pkey" for table "t2"
CREATE TABLE

-- Create a single table view.
gaussdb=# CREATE VIEW v_ins1 AS SELECT * FROM t1;
CREATE VIEW
gaussdb=# CREATE VIEW v_ins2 AS SELECT * FROM t1 WHERE y1 < 3;
CREATE VIEW
gaussdb=# CREATE VIEW v_ins2_wco AS SELECT * FROM t1 WHERE y1 < 3 WITH CHECK OPTION;
CREATE VIEW
gaussdb=# CREATE VIEW v_ins_read AS SELECT * FROM t1 WITH READ ONLY;
CREATE VIEW

-- Insert data into t1 through a view.
gaussdb=# INSERT INTO v_ins1 VALUES (1, 1);
INSERT 0 1
gaussdb=# INSERT INTO v_ins2 VALUES (5, 5);
INSERT 0 1
gaussdb=# INSERT INTO v_ins2_wco VALUES (5, 5);
ERROR:  new row violates WITH CHECK OPTION for view "v_ins2_wco"
DETAIL:  Failing row contains (5, 5).

gaussdb=# INSERT INTO v_ins_read VALUES (5, 5);
ERROR:  DML operation cannot be performed on a read-only view.

-- Create a multi-table view.
gaussdb=# CREATE VIEW vv_ins AS SELECT * FROM t1, t2 WHERE x1 = x2;
CREATE VIEW

-- Insert data into t1 through a view.
gaussdb=# INSERT INTO vv_ins (x1, y1) VALUES (2, 2);
INSERT 0 1
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
-- Drop a schema.
gaussdb=# RESET CURRENT_SCHEMA;
RESET
gaussdb=# DROP SCHEMA ins_view CASCADE;
NOTICE:  drop cascades to 7 other objects
DETAIL:  drop cascades to table ins_view.t1
drop cascades to table ins_view.t2
drop cascades to view ins_view.v_ins1
drop cascades to view ins_view.v_ins2
drop cascades to view ins_view.v_ins2_wco
drop cascades to view ins_view.v_ins_read
drop cascades to view ins_view.vv_ins
DROP SCHEMA
```

Suggestions

- VALUES

  When you run the INSERT statement to insert data in batches, you are advised to combine multiple records into one statement to improve data loading performance.

  Example:

  ```
  INSERT INTO sections VALUES (30, 'Administration', 31, 1900),(40, 'Development', 35, 2000), (50, 'Development' , 60 , 2001);
  ```

  If values of an INSERT statement are distributed on a DN, GaussDB can push the statement down to the corresponding DN for execution. Currently, VALUES only supports constants, simple expressions, and pushdown functions (**provolatile** in pg_proc is set to **'i'**). If a column in the table has a default value, the value must be a constant or a simple expression. Neither a single-value statement nor a multi-value statement can be pushed down to a single DN.

- Batch insertion index performance optimization

  If any of the following scenarios meet all the restriction conditions, you are advised to enable the GUC parameter **batch_insert_index_types** and set it to **"rcr_ubtree"** to improve the performance of inserting indexes in batches:

  Scenario 1: Use JDBC to connect to the database and use the Java batch data insertion API executeBatch to insert indexes in batches.

  Scenario 2: Run the **insert into t1 select * from t2** statement, where tables **t1** and **t2** have the same schema, and **t1** contains indexes. This statement can be used to insert indexes in batches to the **t1** table. In this scenario, the stream plan must be enabled (the **enable_fast_query_shipping** parameter is set to **off**). Indexes are inserted in batches only when table data is inserted in batches. (You can run the **explain verbose** command to check whether table data is inserted in batches. **Streaming** indicates that data is inserted in batches.) If these prerequisites are met, enable the batch index insertion function to insert indexes in batches.

  Scenario 3: Run the **COPY FROM** statement (for example, **COPY t1 FROM 'file.csv' delimiter ',' csv header**), where **t1** and **file.csv** have the same schema, and **t1** contains indexes. This statement can be used to insert indexes in batches to the **t1** table.

  Restriction 1: The inserted index is a UB-tree RCR index.

  Restriction 2: The inserted data does not increase. (If the inserted data increases, the cache is used, that is, the last page is used. In this case, the performance of batch index insertion is not improved.)

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Restriction 3: **enable_stream_operator** is set to **on**.

Restriction 4: Batch index insertion is not performed in an SMP environment.

NOTE

This feature affects performance in the following scenarios:

1. If the data to be inserted in batches increases (violating restriction 2), after batch insertion is disabled, the performance is good. In this scenario, enabling the batch insertion function will slightly deteriorate the performance.

2. During continuous batch insertion, the index gradually increases. As a result, the batch insertion performance deteriorates.

3. If the cache page hit ratio is too low or the running memory is too small due to scattered data inserted in batches, enabling the batch insertion function will greatly deteriorate the performance.

If the performance deteriorates greatly, you are advised to set the GUC parameter **batch_insert_index_types** to **""** to disable the function. Then, the performance deterioration problem can be resolved.

If technical support needs to locate the cause, you can set the GUC parameter **logging_module** to **'on(BIINDEX)'** to enable the log printing function for batch index insertion. Perform batch insertion for several minutes until the **BIINDEX** character string is displayed in the log.

1.13.14.6 INSERT ALL

Description

Inserts one or multiple data records into multiple tables.

Precautions

- You must have the INSERT permission on a table to insert data into it. If a user is granted the INSERT ANY TABLE permission, the user has the USAGE permission on all schemas except system schemas and the INSERT permission on tables in these schemas.
- If you use the query clause to insert rows from a query, you need to have the SELECT permission on any table or column used in the query.
- Data cannot be written directly to a generated column. In the INSERT statement, values cannot be specified for generated columns, but the keyword DEFAULT can be specified.
- This syntax can be executed only in the ORA-compatible mode.

Syntax

```
INSERT [/*+ plan_hint */] [ ALL | FIRST ]
   { [ WHEN condition THEN ]
   { INTO table_name
   [ { [alias_name] [ ( column_name [, ...] ) ] } | { [partition_clause] [ AS alias ]
   [ ( column_name [, ...] ) ] } ]
   [ VALUES {( { expression | DEFAULT } [, ...] ) } ] }[, ...] }[, ...]
   { subquery };
```

Detailed information of **subquery**:

```
[ WITH [ RECURSIVE ] with_query [, ...] ]
SELECT [/*+ plan_hint */] [ ALL ]
{ * | {expression [ [ AS ] output_name ]} [, ...] }
[ into_option ]
[ FROM from_item [, ...] ]
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
[ WHERE condition ]
[ ORDER BY {expression [ [ ASC | DESC | USING operator ] | nlssort_expression_clause ] [ NULLS { FIRST | LAST } ]} [, ...] ]
[ FETCH { FIRST | NEXT } [ count ] { ROW | ROWS } ONLY ]
[ into_option ];
```

- Detailed information of **with_query**:

  ```
  with_query_name [ ( column_name [, ...] ) ] AS [ [ NOT ] MATERIALIZED ]
  ( {select | values | insert | update | delete} )
  ```

- The specified subquery source **from_item** is as follows:

  ```
  {[ ONLY ] {table_name | view_name} [ * ] [ partition_clause ] [ [ AS ] alias [ ( column_alias [, ...] ) ] ]
  |( select ) [ AS ] alias [ ( column_alias [, ...] ) ]
  |with_query_name [ [ AS ] alias [ ( column_alias [, ...] ) ] ]
  |from_item [ NATURAL ] join_type from_item [ ON join_condition | USING ( join_column [, ...] ) ]}
  ```

  Detailed information of partition_clause:

  ```
  PARTITION { ( partition_name ) | FOR ( partition_value [, ...] ) } |
  SUBPARTITION { ( subpartition_name ) | FOR ( subpartition_value [, ...] ) }
  ```

Parameters

- plan_hint clause

  Follows the INSERT keyword in the **/*+ */** format. Only the syntax format is adapted, and specific functions are not supported.

- **ALL/FIRST**

  The keyword cannot be omitted and can only be **ALL**, if a conditional clause (WHEN condition THEN) is not used. The keyword can be omitted and is **ALL** by default if a conditional clause is used. In this case, the meanings of **ALL** and **FIRST** are as follows:

  - **ALL**: Run through all branches of matching conditions and insert data into the corresponding table as long as the conditions are met.
  - **FIRST**: After finding the first branch that meets the conditions, insert the data into the table corresponding to the branch, and the check for remaining branches stops.

- **WHEN condition THEN**

  Specifies the condition judgment when inserting data into a table. The insertion is performed only when the condition is met. For conditions, refer to the columns in the subquery.

  Subqueries are not supported in the condition.

- **table_name**

  Specifies the name of the target table where data will be inserted.

  Value range: an existing table name.

- **alias_name**

  Specifies the table alias when the INSERT statement is used without AS alias.

  NOTE

  1. When the INTO clause is used without AS alias, the table alias cannot be a keyword (such as SELECT and VALUE) or an expression. The alias must comply with **Identifier Naming Conventions**.
  2. When the INTO clause is used without AS alias, the table alias cannot be in the INTO table_name alias_name(alias_name.col1, ...,alias_name.coln) VALUES(xxx); format.
  3. When the INTO clause is used without AS alias, data cannot be inserted into the specified partition.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **partition_clause**

  Inserts data to a specified partition.

  ```
  PARTITION { ( partition_name ) | FOR ( partition_value [, ...] ) } |
  SUBPARTITION { ( subpartition_name ) | FOR ( subpartition_value [, ...] ) }
  ```

  For details about the keywords, see **SELECT**.

  If the value of the VALUE clause is inconsistent with that of the specified partition, an exception is displayed.

- **column_name**

  Specifies the name of a column in a table.

  - The column name can be qualified with a subcolumn name or array index, if needed.
  - Each column not present in the column list will be filled with a default value, either its declared default value or **NULL** if there is none. Inserting data into only some columns of a composite type leaves the other columns **NULL**.
  - The target column names **column_name** can be listed in any order. If no list of column names is given at all, the default is all the columns of the table in their declared order.
  - The target columns are the first *N* column names, if there are only *N* columns provided by the VALUE clause and QUERY.
  - The values provided by the VALUE clause and QUERY are joined with the corresponding columns from left to right in the table.

  Value range: name of an existing column.

- **VALUES**

  It cannot be followed by multiple rows.

  Subqueries are not supported.

- **expression**

  Specifies an expression or a value to assign to the corresponding column.

  - If single-quotation marks **(')** are inserted into a column, the single-quotation marks need to be used for escape.
  - If the expression for any column is not of the correct data type, automatic type conversion will be attempted. If the attempt fails, data insertion fails, and the system returns an error message.
  - Aggregate functions are not supported.
  - Subqueries are not supported.

- **DEFAULT**

  Specifies the default value of a column. The value is **NULL** if there is no default value.

- **subquery**

  Specifies a query statement (SELECT statement) that uses query results as the inserted data and cannot be omitted. If there are no subqueries, use SELECT * FROM DUAL.

  If a subquery contains a table alias, the alias cannot be referenced in the CONDITION and INTO clauses.

  For details, see **SELECT**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Examples

- **Inserting data to multiple tables without conditions**

  Example:

```
-- Create an ORA-compatible database.
gaussdb=# CREATE DATABASE insertall_test_db DBCOMPATIBILITY 'ORA';

-- Switch to the ORA-compatible database.
gaussdb=# \c insertall_test_db;

-- Create tables.
insertall_test_db=# CREATE TABLE insert_all_test0(c1 INT, c2 VARCHAR2(20));
insertall_test_db=# CREATE TABLE insert_all_test1(c1 INT, c2 VARCHAR2(20));
insertall_test_db=# CREATE TABLE insert_all_test2(c1 INT, c2 VARCHAR2(20));
insertall_test_db=# CREATE TABLE insert_all_test3(c1 INT, c2 VARCHAR2(20));

-- Construct data.
insertall_test_db=# INSERT INTO insert_all_test0 VALUES(1,'a'),(2,'b'),(3,'c'),(4,'d'),(5,'e');

-- Insert data to the tables.
insertall_test_db=# INSERT ALL
INTO insert_all_test1
INTO insert_all_test1 VALUES(1,'a')
INTO insert_all_test1(c1,c2)
INTO insert_all_test1(c1) VALUES(1)
INTO insert_all_test1(c2) VALUES('aaa')
INTO insert_all_test2(c2) VALUES(c2)
INTO insert_all_test2(c2) VALUES(c2||'*')
INTO insert_all_test3(c1,c2) VALUES(1,'a')
INTO insert_all_test3(c1,c2) VALUES(1,c2)
INTO insert_all_test3(c1,c2) VALUES(c1,c2)
INTO insert_all_test3(c2,c1) VALUES('***',666)
SELECT * FROM insert_all_test0;

-- Query data.
insertall_test_db=# SELECT * FROM insert_all_test1 ORDER BY c1,c2;

1.13.15 L

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

1.13.15.1 LOAD DATA

Description

Imports data from a file to a specified table in the database.

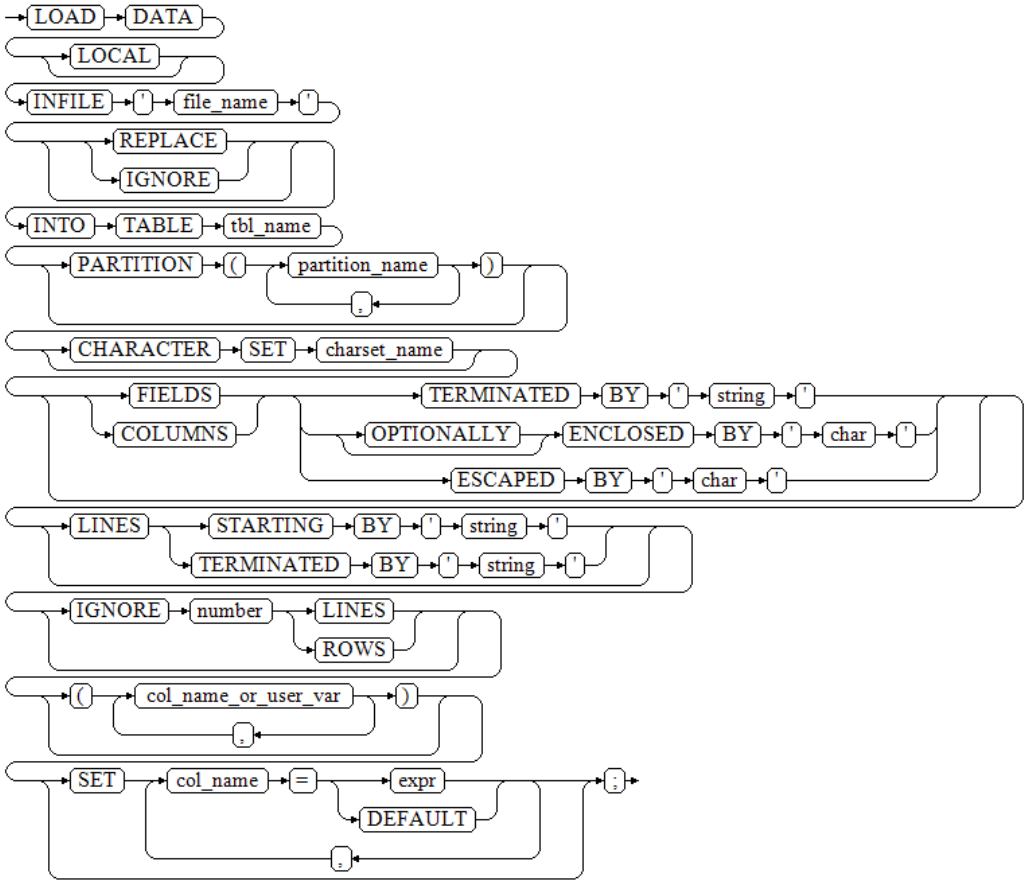
Precautions

- This syntax can be used only in the MySQL-compatible mode (**sql_compatibility = 'MYSQL'**) where **b_format_version** is **'5.7'** and **b_format_dev_version** is **'s2'**.
- In other compatibility modes or when the compatibility parameters (**b_format_version='5.7'** and **b_format_dev_version='s2'**) are not set, several statements will be returned. These statements are mainly used internally by gs_loader.
- **Native Syntax** is internally called only by gs_loader. You are advised to use it based on **Recommended Syntax** instead of using it directly.
- The GUC parameters related to the LOAD DATA syntax are the same as those of the COPY FROM syntax. For details, see **Precautions**.
- The LOAD DATA syntax requires the INSERT and DELETE permissions on tables.
- If the data written to a table by running **LOAD DATA** cannot be converted to the data type of the table, the import fails.
- LOAD DATA applies only to tables but not views.

Recommended Syntax

```
LOAD DATA [LOCAL] INFILE 'file_name'
    [REPLACE | IGNORE]
    INTO TABLE tbl_name
    [PARTITION (partition_name [, ...])]
    [CHARACTER SET charset_name]
    [{FIELDS | COLUMNS} {TERMINATED BY 'string' | [OPTIONALLY] ENCLOSED BY 'char' | ESCAPED BY
'char'}]
    [LINES {STARTING BY 'string' | TERMINATED BY 'string'}]
    [IGNORE number {LINES | ROWS}]
    [(col_name_or_user_var [, ...])]
    [SET {col_name={expr | DEFAULT}} [, ...]];
```

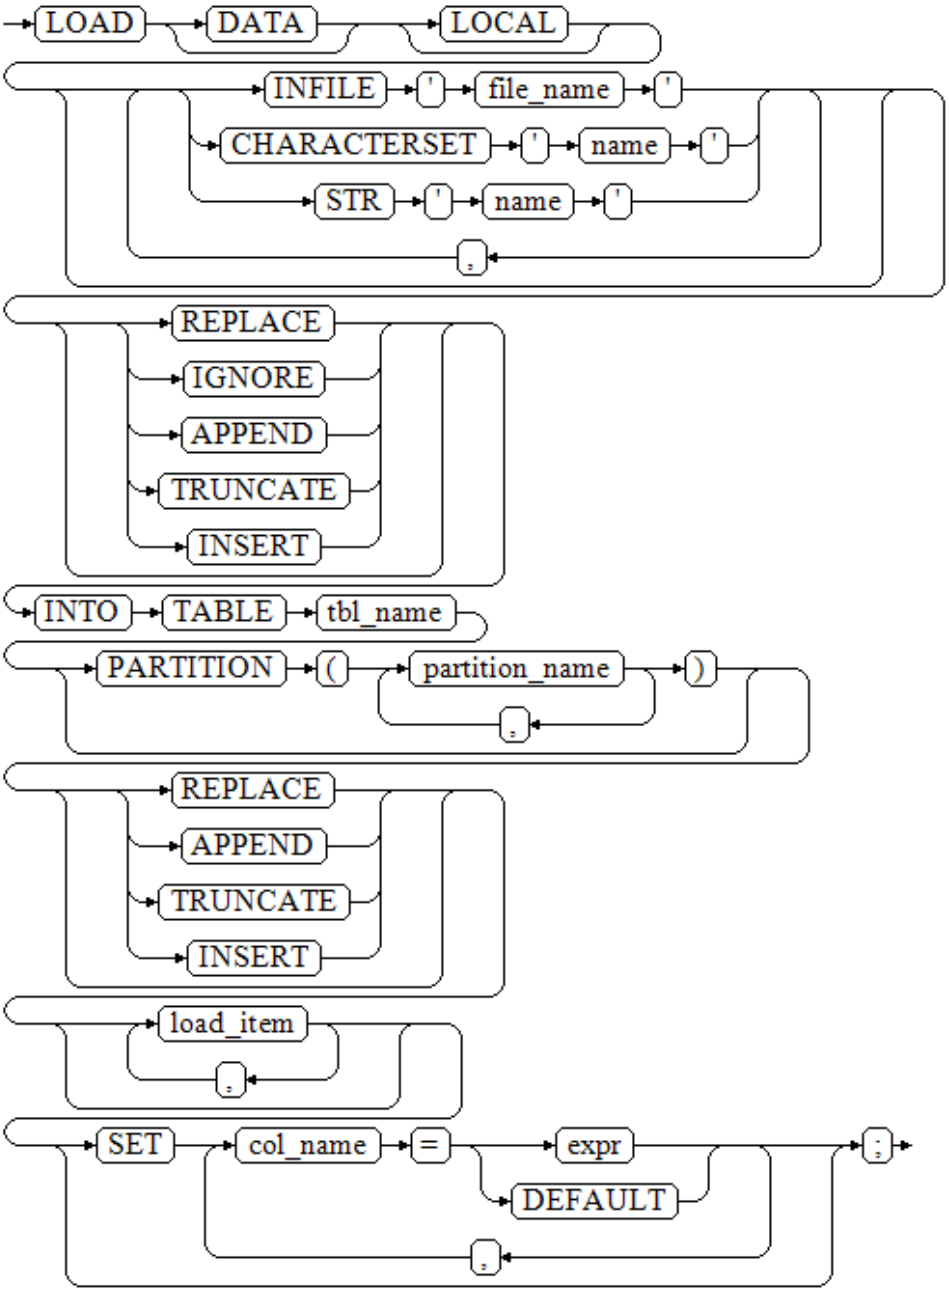
 Copyright © Huawei Cloud Computing Technologies Co., Ltd.



Native Syntax

```
LOAD [DATA] [LOCAL]
   [{INFILE 'file_name' | CHARACTERSET 'name' | STR 'name' } [,...]]
   [REPLACE | IGNORE | APPEND | TRUNCATE | INSERT ]
   INTO TABLE tbl_name
   [PARTITION (partition_name [, ...])]
 [REPLACE | APPEND | TRUNCATE | INSERT ]
   [load_item [,...]]
   [SET {col_name={expr | DEFAULT}} [,...]];
```

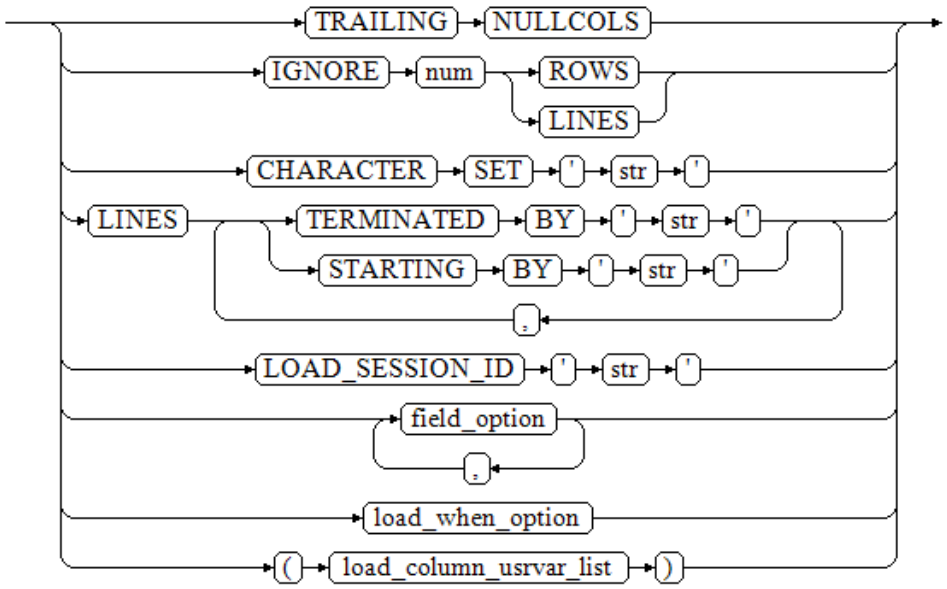
 Copyright © Huawei Cloud Computing Technologies Co., Ltd.



- **load_item** specifies the options for importing a file. The syntax is as follows:

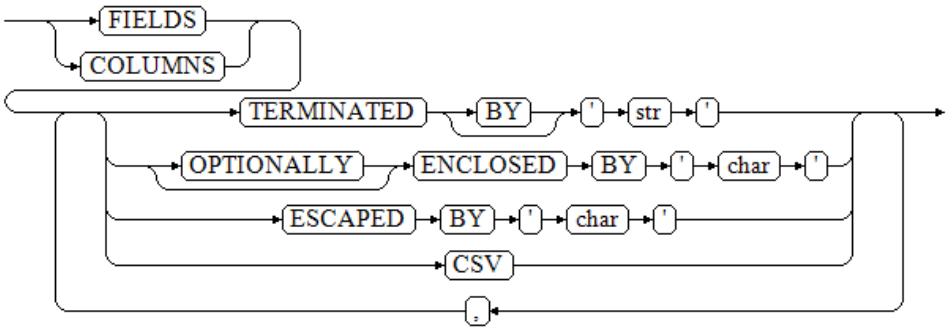
```
{
  TRAILING NULLCOLS | IGNORE num {ROWS | LINES} | CHARACTER SET 'str'|
   LINES {{TERMINATED BY 'str' | STARTING BY 'str'} [, ...]} |
   LOAD_SESSION_ID 'str' |
   {field_option [,...]} |
   load_when_option |
   ( load_column_usrvar_list )
}
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.



- **filed_option** is an option related to the format of the imported file. The syntax format is as follows:

```
{
 {FIELDS | COLUMNS}
 {{TERMINATED [BY] 'str' | [OPTIONALLY] ENCLOSED BY 'char' | ESCAPED BY 'char' | CSV } [, ...]}
}
```



- **load_when_option** indicates the specific filtering option used for importing files. The syntax format is as follows:

```
{
 WHEN
 {{{( start - end ) | (start) | col_name } cmp_op 'str' }[AND ...]}
}
```
