Contents

- 1 Database System Overview..... 1**
 - 1.1 Database Logical Architecture..... 1
 - 1.2 Query Request Handling Process..... 3
 - 1.3 Managing Transactions..... 3
 - 1.4 Concepts..... 5
- 2 Database Security Management.....6**
 - 2.1 Users and Permissions..... 6
 - 2.1.1 Default Permission Mechanism..... 6
 - 2.1.2 Administrator..... 7
 - 2.1.3 Separation of Duties..... 9
 - 2.1.4 Users..... 11
 - 2.1.5 Roles..... 12
 - 2.1.6 Schemas..... 14
 - 2.1.7 Setting User Permissions..... 15
 - 2.1.8 Row-Level Security Policy..... 16
 - 2.2 Database Audit..... 18
- 3 Database Quick Start..... 20**
 - 3.1 Connecting to a Database..... 20
 - 3.1.1 Using gsql to Connect to a Database..... 20
 - 3.1.2 APIs..... 22
 - 3.2 Operating a Database..... 22
 - 3.2.1 Creating a Database Account..... 22
 - 3.2.2 Creating and Managing Databases..... 23
 - 3.2.3 Creating and Managing Tablespaces..... 25
 - 3.2.4 Creating and Managing Tables..... 28
 - 3.2.4.1 Creating Tables..... 28
 - 3.2.4.2 Inserting Data to Tables..... 28
 - 3.2.4.3 Updating Data in a Table..... 30
 - 3.2.4.4 Viewing Data..... 31
 - 3.2.4.5 Deleting Data from a Table..... 32
 - 3.2.5 Querying a System Catalog..... 32
 - 3.2.6 Other Operations..... 34

3.2.6.1 Creating and Managing Schemas.....	34
3.2.6.2 Creating and Managing Partitioned Tables.....	37
3.2.6.3 Creating and Managing Indexes.....	41
3.2.6.4 Creating and Managing Views.....	45
3.2.6.5 Creating and Managing Sequences.....	46
3.2.6.6 Creating and Managing Scheduled Jobs.....	47
4 Development and Design Proposal.....	51
4.1 Overview.....	51
4.2 Database Design Specifications.....	52
4.2.1 General Specifications.....	52
4.2.2 Deployment Specifications.....	54
4.2.3 Database Object Naming Specifications.....	54
4.2.4 Database and Schema Design Specifications.....	56
4.2.5 Permission Design Specifications.....	58
4.2.6 Character Set Design Specifications.....	59
4.2.7 Table Design Specifications.....	59
4.2.8 Column Design Specifications.....	61
4.2.9 Index Design Specifications.....	65
4.2.10 Function/Stored Procedure Design Specifications.....	66
4.2.11 Constraint Design.....	66
4.2.12 View and Joined Table Design.....	67
4.3 Database Design Specifications.....	67
4.3.1 GUC Parameter Programming Specifications.....	67
4.3.2 Object Access Programming Specifications.....	68
4.3.3 WHERE.....	68
4.3.4 SELECT.....	70
4.3.5 INSERT.....	70
4.3.6 UPDATE.....	71
4.3.7 DELETE.....	71
4.3.8 Join Query.....	72
4.3.9 Subquery.....	72
4.3.10 Transaction.....	73
4.3.11 SQL Compilation.....	74
4.4 Client Programming Specifications.....	78
4.4.1 JDBC.....	78
5 Application Development Guide.....	81
5.1 GaussDB Application Development Guide.....	81
5.2 Development Specifications.....	84
5.3 Development Based on JDBC.....	85
5.3.1 Development Process.....	85
5.3.2 Development Process.....	85
5.3.2.1 Obtaining the Driver JAR Package and Configuring JDK 1.8.....	86

5.3.2.2 Connecting to a Database.....	87
5.3.2.2.1 Connection Methods.....	87
5.3.2.2.2 Connection Parameter Reference.....	89
5.3.2.2.3 Connecting to a Database in Non-Encrypted Mode.....	110
5.3.2.2.4 Connecting to a Database in SSL Mode.....	113
5.3.2.2.5 Connecting to a Database in UDS Mode.....	115
5.3.2.3 Running SQL Statements.....	116
5.3.2.4 Processing Data in a Result Set.....	121
5.3.2.5 Closing a Database Connection.....	124
5.3.3 Typical Application Development Examples.....	124
5.3.3.1 Configuring Connection Parameters in Different Scenarios.....	124
5.3.3.2 Creating and Calling a Stored Procedure.....	126
5.3.3.3 Obtaining the Return Value of a Function.....	128
5.3.3.4 Batch Query.....	130
5.3.3.5 SQL Retry at an Application Layer.....	132
5.3.3.6 Importing and Exporting Data Through Local Files.....	135
5.3.3.7 Migrating Data from a MySQL Database.....	137
5.3.3.8 Logical Replication.....	139
5.3.4 JDBC API Reference.....	145
5.3.4.1 java.sql.Connection.....	145
5.3.4.2 java.sql.CallableStatement.....	147
5.3.4.3 java.sql.DatabaseMetaData.....	149
5.3.4.4 java.sql.Driver.....	158
5.3.4.5 java.sql.PreparedStatement.....	159
5.3.4.6 java.sql.ResultSet.....	163
5.3.4.7 java.sql.ResultSetMetaData.....	170
5.3.4.8 java.sql.Statement.....	171
5.3.4.9 javax.sql.ConnectionPoolDataSource.....	173
5.3.4.10 javax.sql.DataSource.....	174
5.3.4.11 javax.sql.PooledConnection.....	174
5.3.4.12 javax.naming.Context.....	175
5.3.4.13 javax.naming.spi.InitialContextFactory.....	175
5.3.4.14 CopyManager.....	175
5.3.4.15 PGReplicationConnection.....	177
5.3.4.16 PGReplicationStream.....	177
5.3.4.17 ChainedStreamBuilder.....	179
5.3.4.18 ChainedCommonStreamBuilder.....	179
5.4 Development Based on ODBC.....	180
5.4.1 Development Process.....	180
5.4.2 Development Procedure.....	181
5.4.2.1 Obtaining a Source Code Package, ODBC Packages, and Dependent Libraries.....	181
5.4.2.2 Connecting to a Database.....	182

5.4.2.2.1 Configuring a Data Source in the Linux OS.....	182
5.4.2.2.2 Configuring a Data Source in the Windows OS.....	191
5.4.2.2.3 APIs for Connecting to a Database.....	195
5.4.2.3 Executing SQL Statements.....	196
5.4.2.4 Processing Data in a Result Set.....	197
5.4.2.5 Closing a Connection.....	198
5.4.3 Typical Application Development Examples.....	198
5.4.3.1 Typical Application Scenarios and Configurations.....	198
5.4.3.2 Obtaining and Processing Data in a Database.....	199
5.4.3.3 Batch Binding.....	201
5.4.3.4 High-Performance Binding.....	207
5.4.4 ODBC Interface Reference.....	214
5.4.4.1 SQLAllocEnv.....	214
5.4.4.2 SQLAllocConnect.....	214
5.4.4.3 SQLAllocHandle.....	214
5.4.4.4 SQLAllocStmt.....	216
5.4.4.5 SQLBindCol.....	216
5.4.4.6 SQLBindParameter.....	217
5.4.4.7 SQLColAttribute.....	218
5.4.4.8 SQLConnect.....	220
5.4.4.9 SQLDisconnect.....	221
5.4.4.10 SQLExecDirect.....	222
5.4.4.11 SQLExecute.....	223
5.4.4.12 SQLFetch.....	224
5.4.4.13 SQLFreeStmt.....	225
5.4.4.14 SQLFreeConnect.....	225
5.4.4.15 SQLFreeHandle.....	225
5.4.4.16 SQLFreeEnv.....	226
5.4.4.17 SQLPrepare.....	226
5.4.4.18 SQLGetData.....	227
5.4.4.19 SQLGetDiagRec.....	228
5.4.4.20 SQLSetConnectAttr.....	231
5.4.4.21 SQLSetEnvAttr.....	232
5.4.4.22 SQLSetStmtAttr.....	233
5.5 Development Based on libpq.....	234
5.5.1 Development Process.....	234
5.5.2 Development Procedure.....	234
5.5.2.1 Obtaining a Driver Package, a Dependency Library, and Header Files.....	234
5.5.2.2 Connecting to a Database.....	235
5.5.2.3 Executing SQL Statements.....	236
5.5.2.4 Processing Data in a Result Set.....	236
5.5.2.5 Closing a Connection.....	237

5.5.3 Typical Application Development Examples.....	237
5.5.3.1 Establishing a Database Connection, Executing SQL Statements, and Returning Results.....	237
5.5.3.2 Executing Prepared Statements.....	240
5.5.3.3 Binding Parameters and Returning a Binary Result.....	241
5.5.4 libpq API Reference.....	244
5.5.4.1 Database Connection Control Functions.....	244
5.5.4.1.1 PQconnectdbParams.....	245
5.5.4.1.2 PQconnectdb.....	245
5.5.4.1.3 PQconninfoParse.....	246
5.5.4.1.4 PQconnectStart.....	247
5.5.4.1.5 PQerrorMessage.....	247
5.5.4.1.6 PQsetdbLogin.....	248
5.5.4.1.7 PQfinish.....	249
5.5.4.1.8 PQreset.....	249
5.5.4.1.9 PQstatus.....	250
5.5.4.2 Database Statement Execution Functions.....	251
5.5.4.2.1 PQclear.....	251
5.5.4.2.2 PQexec.....	252
5.5.4.2.3 PQexecParams.....	253
5.5.4.2.4 PQexecParamsBatch.....	253
5.5.4.2.5 PQexecPrepared.....	254
5.5.4.2.6 PQexecPreparedBatch.....	255
5.5.4.2.7 PQprepare.....	256
5.5.4.3 Asynchronous Command Processing Functions.....	257
5.5.4.3.1 PQsendQuery.....	258
5.5.4.3.2 PQsendQueryParams.....	258
5.5.4.3.3 PQsendPrepare.....	259
5.5.4.3.4 PQsendQueryPrepared.....	260
5.5.4.3.5 PQflush.....	261
5.5.4.4 Functions for Canceling Query Processing.....	262
5.5.4.4.1 PQgetCancel.....	262
5.5.4.4.2 PQfreeCancel.....	263
5.5.4.4.3 PQcancel.....	263
5.5.4.5 Functions for Processing Database Result.....	264
5.5.4.5.1 PQgetvalue.....	264
5.5.4.5.2 PQfname.....	265
5.5.4.5.3 PQnfields.....	265
5.5.4.5.4 PQntuples.....	266
5.5.4.5.5 PQresultStatus.....	266
5.6 Psycopg-based Development.....	267
5.6.1 Development Process.....	269
5.6.2 Psycopg Package.....	269

5.6.3 Example: Common Operations.....	272
5.6.4 Psycpg API Reference.....	274
5.6.4.1 psycpg2.connect().....	274
5.6.4.2 connection.cursor().....	276
5.6.4.3 cursor.execute(query,vars_list).....	276
5.6.4.4 cursor.executemany(query,vars_list).....	277
5.6.4.5 connection.commit().....	278
5.6.4.6 connection.rollback().....	278
5.6.4.7 cursor.fetchone().....	279
5.6.4.8 cursor.fetchall().....	279
5.6.4.9 cursor.close().....	280
5.6.4.10 connection.close().....	280
5.7 Development Based on the Go Driver.....	281
5.7.1 Go Driver Package, Environment Class, and Driver Class.....	281
5.7.2 Development Process.....	282
5.7.3 Connecting to the Database.....	284
5.7.4 Connecting to the Database (Using SSL).....	291
5.7.5 Go API Reference.....	292
5.7.5.1 sql.Open.....	292
5.7.5.2 type DB.....	293
5.7.5.3 type Stmt.....	295
5.7.5.4 type Tx.....	296
5.7.5.5 type Rows.....	298
5.7.5.6 type Row.....	299
5.7.5.7 type ColumnType.....	299
5.7.5.8 type Result.....	300
5.8 Appendix.....	300
5.8.1 JDBC.....	300
5.8.1.1 Data Type Mapping.....	300
5.8.1.2 Log Management.....	301
5.8.1.3 Troubleshooting.....	306
5.8.1.3.1 Incorrect batchSize Settings.....	306
5.8.1.3.2 Error Is Reported or Connection Is Blocked in SSL Mode.....	306
5.8.2 libpq.....	307
5.8.2.1 Connection Parameters.....	308
5.8.3 Parameters Related to Log Output.....	313
6 SQL Optimization.....	318
6.1 Query Execution Process.....	318
6.2 Introduction to the SQL Execution Plan.....	321
6.2.1 Overview.....	321
6.2.2 Description.....	322
6.3 Tuning Process.....	329

6.4 Updating Statistics.....	330
6.5 Reviewing and Modifying a Table Definition.....	330
6.5.1 Overview.....	330
6.5.2 Selecting a Storage Model.....	331
6.5.3 Using Partitioned Tables.....	331
6.5.4 Selecting a Data Type.....	332
6.6 Typical SQL Optimization Methods.....	332
6.6.1 Optimizing SQL Self-Diagnosis.....	332
6.6.2 Optimizing Subqueries.....	333
6.6.3 Optimizing Statistics.....	341
6.6.4 Optimizing Operators.....	343
6.7 Experience in Rewriting SQL Statements.....	344
6.8 Configuring Key Parameters for SQL Optimization.....	346
6.9 Hint-based Tuning.....	348
6.9.1 Plan Hint Optimization.....	348
6.9.2 Join Order Hints.....	353
6.9.3 Join Operation Hints.....	354
6.9.4 Rows Hints.....	355
6.9.5 Scan Operation Hints.....	356
6.9.6 Sublink Name Hints.....	357
6.9.7 Hint Errors, Conflicts, and Other Warnings.....	358
6.9.8 Optimizer GUC Parameter Hints.....	359
6.9.9 Hint for Selecting the Custom Plan or Generic Plan.....	360
6.9.10 Hint Specifying Not to Expand Subqueries.....	361
6.9.11 Hint Specifying Not to Use Global Plan Cache.....	362
6.9.12 Hint of Parameterized Paths at the Same Level.....	362
6.9.13 Hint for Materializing a Sub-plan Result.....	363
6.10 Tuning with SQL PATCH.....	364
6.11 Optimization Cases.....	367
6.11.1 Case: Modifying the GUC Parameter rewrite_rule.....	367
6.11.2 Case: Creating an Appropriate Index.....	370
6.11.3 Case: Adding NOT NULL for the JOIN Columns.....	371
6.11.4 Case: Modifying a Partitioned Table.....	372
6.11.5 Case: Rewriting SQL Statements to Eliminate Subqueries.....	372
6.11.6 Case: Rewriting SQL Statements and Deleting in-clause.....	373
7 SQL Reference.....	376
7.1 GaussDB SQL.....	376
7.2 Keywords.....	377
7.3 Data Type.....	412
7.3.1 Numeric Types.....	413
7.3.2 Monetary Types.....	419
7.3.3 Boolean Types.....	420

7.3.4 Character Types.....	421
7.3.5 Binary Types.....	423
7.3.6 Date/Time Types.....	425
7.3.7 Geometric.....	434
7.3.8 Network Address Types.....	437
7.3.9 Bit String Types.....	440
7.3.10 UUID.....	441
7.3.11 JSON/JSONB Types.....	442
7.3.12 HLL.....	446
7.3.13 Range Types.....	450
7.3.14 OID Types.....	455
7.3.15 Pseudo-Types.....	457
7.3.16 ACLItem.....	458
7.4 Constant and Macro.....	459
7.5 Functions and Operators.....	460
7.5.1 Logical Operators.....	460
7.5.2 Comparison Operators.....	461
7.5.3 Character Processing Functions and Operators.....	462
7.5.4 Binary String Functions and Operators.....	480
7.5.5 Bit String Functions and Operators.....	483
7.5.6 Pattern Matching Operators.....	486
7.5.7 Mathematical Functions and Operators.....	490
7.5.8 Date and Time Processing Functions and Operators.....	505
7.5.9 Type Conversion Functions.....	528
7.5.10 Geometric Functions and Operators.....	545
7.5.11 Network Address Functions and Operators.....	556
7.5.12 JSON/JSONB Functions and Operators.....	561
7.5.13 HLL Functions and Operators.....	573
7.5.14 SEQUENCE Functions.....	586
7.5.15 Array Functions and Operators.....	588
7.5.16 Range Functions and Operators.....	596
7.5.17 Aggregate Functions.....	601
7.5.18 Window Functions.....	614
7.5.19 Security Functions.....	619
7.5.20 Set Returning Functions.....	624
7.5.21 Conditional Expression Functions.....	626
7.5.22 System Information Functions.....	628
7.5.23 System Administration Functions.....	657
7.5.23.1 Configuration Settings Functions.....	657
7.5.23.2 Universal File Access Functions.....	657
7.5.23.3 Server Signal Functions.....	659
7.5.23.4 Backup and Restoration Control Functions.....	661

7.5.23.5 DR Control Functions for Dual Database Instances.....	667
7.5.23.6 DR Query Functions for Dual-Database Instances.....	669
7.5.23.7 Snapshot Synchronization Functions.....	673
7.5.23.8 Database Object Functions.....	673
7.5.23.9 Advisory Lock Functions.....	679
7.5.23.10 Logical Replication Functions.....	682
7.5.23.11 Segment-Page Storage Functions.....	692
7.5.23.12 Other Functions.....	695
7.5.23.13 Undo System Functions.....	716
7.5.24 Statistics Information Functions.....	730
7.5.25 Trigger Functions.....	774
7.5.26 Hash Function.....	775
7.5.27 Prompt Message Function.....	778
7.5.28 Global Temporary Table Functions.....	778
7.5.29 Fault Injection System Function.....	781
7.5.30 AI Feature Functions.....	781
7.5.31 Dynamic Data Masking Functions.....	783
7.5.32 Hierarchical Recursion Query Functions.....	784
7.5.33 Internal Functions.....	785
7.5.34 Global SysCache Feature Functions.....	791
7.5.35 Data Damage Detection and Repair Functions.....	793
7.5.36 Other System Functions.....	799
7.5.37 Obsolete Functions.....	821
7.6 Expressions.....	822
7.6.1 Simple Expressions.....	822
7.6.2 Condition Expressions.....	824
7.6.3 Subquery Expressions.....	828
7.6.4 Array Expressions.....	831
7.6.5 Row Expressions.....	832
7.7 Type Conversion.....	834
7.7.1 Overview.....	834
7.7.2 Operators.....	836
7.7.3 Functions.....	838
7.7.4 Value Storage.....	840
7.7.5 UNION, CASE, and Related Constructs.....	841
7.8 System Operation.....	845
7.9 Controlling Transactions.....	846
7.10 DDL Syntax Overview.....	847
7.11 DML Syntax Overview.....	852
7.12 DCL Syntax Overview.....	853
7.13 SQL Syntax.....	854
7.13.1 ABORT.....	854

7.13.2 ALTER AGGREGATE.....	855
7.13.3 ALTER AUDIT POLICY.....	856
7.13.4 ALTER DATABASE.....	858
7.13.5 ALTER DEFAULT PRIVILEGES.....	860
7.13.6 ALTER DIRECTORY.....	862
7.13.7 ALTER FUNCTION.....	863
7.13.8 ALTER GLOBAL CONFIGURATION.....	866
7.13.9 ALTER GROUP.....	867
7.13.10 ALTER INDEX.....	868
7.13.11 ALTER LANGUAGE.....	870

1 Database System Overview

1.1 Database Logical Architecture

Data nodes (DNs) in GaussDB store data on disks. This section describes the objects on each DN from the logical view and the relationship between these objects. [Figure 1-1](#) shows the database logical structure.

Figure 1-1 Database logical architecture

NOTE

- A tablespace is a directory storing physical files of one or more databases. An instance may contain multiple tablespaces.
- Database: A database manages various data objects and is isolated from each other. Objects managed by a database can be distributed to multiple tablespaces.
- Datafile Segment: Data file, each of which stores data of only one table. A table containing more than 1 GB of data is stored in multiple datafile segments.
- One table belongs to only one database and one tablespace. The datafile segments storing the data of the same table must be in the same tablespace.
- Block: Basic unit of database management. Its default size is 8 KB.

1.2 Query Request Handling Process

Figure 1-2 GaussDB service response process

1.3 Managing Transactions

A transaction is a customized sequence of database operations, which form an integral unit of work. In GaussDB, you can start, set, commit, and roll back transactions. A GaussDB database supports the following transaction isolation levels: READ COMMITTED, READ UNCOMMITTED (not recommended), REPEATABLE READ, and SERIALIZABLE. SERIALIZABLE is equivalent to REPEATABLE READ.

Controlling Transactions

The following describes transaction operations supported by the database:

- Starting transactions

You can use the **START TRANSACTION** or **BEGIN** syntax to start a transaction. For details, see [START TRANSACTION](#) and [BEGIN](#).

- Setting transactions

You can use the **SET TRANSACTION** or **SET LOCAL TRANSACTION** syntax to set transactions. For details, see [SET TRANSACTION](#).

- **Committing transactions**
You can commit all operations of a transaction using **COMMIT** or **END**. For details, see [COMMIT | END](#).
- **Rolling back transactions**
Rollback indicates that the system cancels all changes that a transaction has made to a database if the transaction fails to be executed due to a fault. For details, see [ROLLBACK](#).

Transaction Isolation Levels

A transaction isolation level specifies how concurrent transactions process the same object.

NOTE

The isolation level cannot be changed after data is modified using **SELECT**, **INSERT**, **DELETE**, **UPDATE**, **FETCH**, or **COPY** in the transaction.

- **READ COMMITTED:** At this level, a transaction can access only committed data. This is the default level.

The **SELECT** statement accesses the snapshot of the database taken when the query begins. The **SELECT** statement can also access the data modifications in its transaction, regardless of whether they have been committed. Note that different database snapshots may be available to two consecutive **SELECT** statements for the same transaction, because data may be committed for other transactions while the first **SELECT** statement is executed.

At the **READ COMMITTED** level, the execution of each statement begins with a new snapshot, which contains all the transactions that have been committed by the execution time. Therefore, during a transaction, a statement can access the result of other committed transactions. Note whether a single statement always accesses absolutely consistent data in a database.

Transaction isolation at this level meets the requirements of many applications, and is fast and easy to use. However, applications performing complicated queries and updates may require data that is more consistent than this level can provide.
- **READ UNCOMMITTED:** This level is not recommended, because it may result in data inconsistency. You are advised not to use it to write transactions, as this may lead to data inconsistency. However, you can use it to read transactions in emergency cases.
- **REPEATABLE READ:** At this level, a transaction can only read data committed before it starts. Uncommitted data or data committed in other concurrent transactions cannot be read. However, a query can read earlier data modifications in its transaction, regardless of whether they have been committed. **READ COMMITTED** differs from this level in that a transaction reads the snapshot taken at the start of the transaction, not at the beginning of the current query within the transaction. Therefore, the **SELECT** statement within a transaction always reads the same data, and cannot read data committed by other concurrent transactions after the transaction starts. Applications at this level must be able to retry transactions, because serialization failures may occur.
- **SERIALIZABLE:** Currently, GaussDB does not support this isolation level. Setting this isolation level is equivalent to **REPEATABLE READ**.

1.4 Concepts

Database

Databases manage various data objects and are isolated from each other. While creating a database, you can specify a tablespace. If you do not specify it, the object will be saved to the **PG_DEFAULT** tablespace by default. Objects managed by a database can be distributed to multiple tablespaces.

Tablespace

In GaussDB, a tablespace is a directory storing physical files of databases. An instance may contain multiple tablespaces. Files are physically isolated using tablespaces and managed by a file system.

Schema

GaussDB schemas logically separate databases. All database objects are created under certain schemas. In GaussDB, schemas and users are loosely bound. When you create a user, a schema with the same name as the user will be created automatically. You can also create a schema or specify another schema.

User and Role

GaussDB uses users and roles to control the access to databases. A role can be a database user or a group of database users, depending on role settings. In GaussDB, the difference between roles and users is that a role does not have the **LOGIN** permission by default. In GaussDB, one user can have only one role, but you can put a user's role under a parent role to grant multiple permissions to the user.

Transaction

In GaussDB, transactions are managed by multi-version concurrency control (MVCC) and two-phase locking (2PL). It enables smooth data reads and writes. In GaussDB, Astore stores various versions of historical data together with the current tuple version. In GaussDB, Astore uses a VACUUM thread instead of rollback segments to periodically delete historical data. Generally, you do not need to pay special attention to the VACUUM thread unless you need to optimize the performance. In GaussDB, Ustore stores various versions of historical data to the undo rollback segments. The thread for purging undo deletes various versions of historical data in a unified manner. In addition, GaussDB automatically commits transactions for single-statement queries (without using statements such as BEGIN to explicitly start a transaction block).

2 Database Security Management

2.1 Users and Permissions

2.1.1 Default Permission Mechanism

A user who creates an object is the owner of this object. By default, [separation of duties](#) is disabled after database installation. A database system administrator has the same permissions as object owners. After an object is created, only the object owner or system administrator can query, modify, and delete the object, and grant permissions for the object to other users through [GRANT](#) by default.

To enable another user to use the object, grant required permissions to the user or the role that contains the user.

GaussDB supports the following permissions: SELECT, INSERT, UPDATE, DELETE, TRUNCATE, REFERENCES, CREATE, CONNECT, EXECUTE, USAGE, ALTER, DROP, COMMENT, INDEX, and VACUUM. Permission types are associated with object types. For permission details, see [GRANT](#).

To revoke permissions, run [REVOKE](#). Object owners have implicit permissions (such as ALTER, DROP, COMMENT, INDEX, VACUUM, GRANT, and REVOKE) on objects. That is, once becoming the owner of an object, the owner is immediately granted the implicit permissions on the object. Object owners can remove their own common permissions, for example, making tables read-only to themselves or others, except the system administrator.

System catalogs and views are visible to either system administrators or all users. System catalogs and views that require system administrator permissions can be queried only by system administrators. For details, see [System Catalogs and System Views](#).

The database provides the object isolation feature. If this feature is enabled, users can view only the objects (tables, views, columns, and functions) that they have the permission to access. System administrators are not affected by this feature. For details, see [ALTER DATABASE](#).

You are advised not to modify the permissions on system catalogs or system views.

2.1.2 Administrator

Initial User

The account automatically generated during database installation is called an initial user. The initial user has the highest-level permissions in the system, including SYSADMIN, CREATEROLE, AUDITADMIN, MONADMIN, OPRADMIN, and POLADMIN, and can perform all operations. If the initial username is not specified during installation, the username is the same as the name of the OS user who installs the database. If the password of the initial user is not specified during the installation, the password is empty after the installation. In this case, you need to change the password of the initial user on the GSQL client before performing other operations. If the initial user password is empty, you cannot perform any SQL operations, such as upgrade, scaling, and node replacement, except changing the password.

The initial user bypasses all permission checks. You are advised to use the initial user as a database administrator only for database management other than service running.

System Administrator

A system administrator is an account with the SYSADMIN attribute. By default, a system administrator has the same permissions as the object owner but does not have the object permissions in the dbf_perf schema or the permission to use Roach to perform backup and restoration.

To create a database administrator, connect to the database as an administrator and run the **CREATE USER** or **ALTER USER** statement with **SYSADMIN** specified.

```
openGauss=# CREATE USER sysadmin WITH SYSADMIN password '*****';
```

or

```
openGauss=# ALTER USER joe SYSADMIN;
```

To run the **ALTER USER** statement, the user must exist.

Security Administrator

A security administrator is an account with the CREATEROLE attribute. It has the permission to create, modify, and delete users or roles, and grant or revoke the permission of any non-system administrator, built-in role, permanent user, or O&M administrator.

If you want to create a security administrator when separation of duties is disabled, connect to the database as a system administrator or security administrator. When separation of duties is enabled, connect to the database as a security administrator and use the **CREATE USER** or **ALTER USER** statement with the **CREATEROLE** option.

```
openGauss=# CREATE USER createrole WITH CREATEROLE password '*****';
```

or

```
openGauss=# ALTER USER joe CREATEROLE;
```

To run the **ALTER USER** statement, the user must exist.

Audit Administrator

An audit administrator is an account with the AUDITADMIN attribute, which has the permission to view and delete audit logs.

If you want to create an audit administrator when separation of duties is disabled, connect to the database as a system administrator or security administrator. When separation of duties is enabled, connect to the database only as the initial user and use the **CREATE USER** or **ALTER USER** statement with the **AUDITADMIN** option.

```
openGauss=# CREATE USER auditadmin WITH AUDITADMIN password '*****';
```

or

```
openGauss=# ALTER USER joe AUDITADMIN;
```

To run the **ALTER USER** statement, the user must exist.

Monitor Administrator

A monitor administrator is an account with the MONADMIN attribute and has the permission to view views and functions in the db_perf schema. The monitor administrator can also grant or revoke object permissions in the db_perf schema.

To create a monitor administrator, connect to the database as a system administrator and run the **CREATE USER** or **ALTER USER** statement with **MONADMIN** specified.

```
openGauss=# CREATE USER monadmin WITH MONADMIN password '*****';
```

Alternatively,

```
openGauss=# ALTER USER joe MONADMIN;
```

To run the **ALTER USER** statement, the user must exist.

O&M Administrator

An O&M administrator is an account with the OPRADMIN attribute and has the permission to use Roach to perform backup and restoration.

To create an O&M administrator, connect to the database as an initial user and run the **CREATE USER** or **ALTER USER** statement with **OPRADMIN** specified.

```
openGauss=# CREATE USER opradmin WITH OPRADMIN password '*****';
```

Alternatively,

```
openGauss=# ALTER USER joe OPRADMIN;
```

To run the **ALTER USER** statement, the user must exist.

Security Policy Administrator

A security policy administrator is an account with the POLADMIN attribute and has the permission to create resource tags, masking policies, and unified audit policies.

To create a security policy administrator, connect to the database as an administrator and run the **CREATE USER** or **ALTER USER** statement with **POLADMIN** specified.

```
openGauss=# CREATE USER poladmin WITH POLADMIN password '*****';
```

Alternatively,

```
openGauss=# ALTER USER joe POLADMIN;
```

To run the **ALTER USER** statement, the user must exist.

2.1.3 Separation of Duties

Descriptions in **Default Permission Mechanism** and **Administrator** are about the initial situation after the database system is created. By default, a system administrator with the SYSADMIN attribute has the highest-level permissions.

To avoid risks caused by centralized permissions, you can enable separation of duties to assign the system administrator's user creation permission to security administrators and audit management permission to audit administrators.

After separation of duties, the system administrator does not have the CREATEROLE attribute (security administrator) or the AUDITADMIN attribute (audit administrator). That is, the system administrator can neither create roles or users, nor view or maintain database audit logs. For details about the CREATEROLE and AUDITADMIN attributes, see **CREATE ROLE**.

Separation of duties does not take effect for an initial user. Therefore, you are advised to use an initial user as a database administrator only for database management other than service running.

To enable separation of duties, set GUC parameter **enableSeparationOfDuty** to **on**.

If you need to use the separation of duties model, specify it during database initialization. You are advised not to switch the permission management model back and forth. In particular, if you want to switch from a non-separation-of-duties permission management model to the separation-of-duties permission management model, you need to review the permission set of existing users. If a user has the system administrator permission and audit administrator permission, the permissions need to be tailored.

After separation of duties, the system administrator does not have permissions for non-system schemas of other users. Therefore, the system administrator cannot access the objects in other users' schemas before being granted the permissions. For details about permission changes before and after enabling separation of duties, see **Table 2-1** and **Table 2-2**.

Table 2-1 Default user permissions

Object Name	Initial User (ID: 10)	System Administrator	Security Administrator	Audit Administrator	Common User
Tablespaces	Has all permissions.	Can create, modify, delete, access, or grant permissions for tablespaces.	Cannot create, modify, delete, or grant permissions for tablespaces and can access tablespaces if the access permission is granted.		
Schemas		Has all permissions for all schemas except dbperf .	Has all permissions for their own schemas, but does not have permissions for non-system schemas of other users.		
User-defined functions		Has all permissions for all user-defined functions.	Has all permissions for their own functions, and has only the call permission for other users' functions.		
User-defined tables or views		Has all permissions for all user-defined tables or views.	Has all permissions for their own tables or views, but does not have permissions for other users' tables or views.		

Table 2-2 Changes in permissions after separation of duties

Object Name	Initial User (ID: 10)	System Administrator	Security Administrator	Audit Administrator	Common User
Tablespaces	N/A Has all permissions.	N/A	N/A		
Schemas		Permissions reduced Has all permissions for their own schemas, but does not have permissions for non-system schemas of other users.	N/A		
User-defined functions		Cannot access functions in non-system schemas of other users before being granted the permissions.	N/A		

Object Name	Initial User (ID: 10)	System Administrator	Security Administrator	Audit Administrator	Common User
User-defined tables or views		Cannot access tables or views in non-system schemas of other users before being granted the permissions.	N/A		

NOTICE

PG_STATISTIC and **PG_STATISTIC_EXT** store sensitive information about statistical objects, such as high-frequency MCVs. After separation of duties is enabled, a system administrator can still access the two system catalogs to obtain sensitive information in statistics.

2.1.4 Users

You can use **CREATE USER** and **ALTER USER** to create and manage database users, respectively. A database system contains one or more databases. Users and roles are shared within the entire database system, but their data is not shared. That is, a user can connect to any database, but after the connection is successful, any user can access only the database declared in the connection request.

In non-**Separation of Duties** scenarios, GaussDB user accounts can be created and deleted only by a system administrator or a security administrator with the **CREATEROLE** attribute. In separation-of-duties scenarios, a user account can be created only by an initial user or a security administrator.

When a user logs in, GaussDB authenticates the user. A user can own databases and database objects (such as tables), and grant permissions on these objects to other users and roles. In addition to system administrators, users with the **CREATEDB** attribute can create databases and grant permissions on these databases.

Adding, Modifying, and Deleting Users

- To create a user, use the SQL statement **CREATE USER**.
For example, create a user **joe** and set the **CREATEDB** attribute for the user.

```
openGauss=# CREATE USER joe WITH CREATEDB PASSWORD '*****';  
CREATE ROLE
```
- To create a system administrator, use the **CREATE USER** statement with the **SYSADMIN** parameter.
- To delete an existing user, use **DROP USER**.
- To change a user account (for example, rename the user or change the password), use **ALTER USER**.

- To view the user list, query the view **PG_USER**:
`openGauss=# SELECT * FROM pg_user;`
- To view user attributes, query the system catalog **PG_AUTHID**.
`openGauss=# SELECT * FROM pg_authid;`

Permanent User

GaussDB provides the permanent user solution. That is, create a permanent user with the **PERSISTENCE** attribute.

```
openGauss=# CREATE USER user_persistence WITH PERSISTENCE IDENTIFIED BY "*****";
```

Only the initial user is allowed to create, modify, and delete permanent users with the **PERSISTENCE** attribute.

2.1.5 Roles

After a role is granted to a user through **GRANT**, the user will have all the permissions of the role. It is recommended that roles be used to efficiently grant permissions. For example, you can create different roles of design, development, and maintenance personnel, grant the roles to users, and then grant specific data permissions required by different users. When permissions are granted or revoked at the role level, these changes take effect on all members of the role.

GaussDB provides an implicitly defined group **PUBLIC** that contains all roles. By default, all new users and roles have the permissions of **PUBLIC**. For details about the default permissions of **PUBLIC**, see **GRANT**. To revoke permissions of **PUBLIC** from a user or role, or re-grant these permissions to them, add the **PUBLIC** keyword in the **REVOKE** or **GRANT** statement.

To view all roles, query the system catalog **PG_ROLES**.

```
SELECT * FROM PG_ROLES;
```

Adding, Modifying, and Deleting Roles

In scenarios other than separation of duties, a role can be created, modified, and deleted only by a system administrator or a user with the **CREATEROLE** attribute. In **separation-of-duties** scenarios, a role can be created, modified, and deleted only by the initial user or a user with the **CREATEROLE** attribute.

- To create a role, use **CREATE ROLE**.
- To add or delete users in an existing role, use **ALTER ROLE**.
- To delete a role, use **DROP ROLE**. **DROP ROLE** deletes only a role, rather than role members.

Built-in Roles

GaussDB provides a group of default roles whose names start with "gs_role_". These roles are provided to access to specific, typically high-privileged operations. You can grant these roles to other users or roles within the database so that they can use specific functions. These roles should be given with great care to ensure that they are used where they are needed. **Table 2-3** describes the permissions of built-in roles.

Table 2-3 Permission description of built-in roles

Roles	Permission
gs_role_copy_files	Permission to run the copy... to/from filename command. However, the GUC parameter enable_copy_server_files must be set first to enable the function of copying server files.
gs_role_signal_backend	Permission to call the pg_cancel_backend , pg_terminate_backend , and pg_terminate_session functions to cancel or terminate other sessions. However, this role cannot perform operations on sessions of the initial user or PERSISTENCE user.
gs_role_tablespace	Permission to create a tablespace.
gs_role_replication	Permission to call logical replication functions, such as kill_snapshot , pg_create_logical_replication_slot , pg_create_physical_replication_slot , pg_drop_replication_slot , pg_replication_slot_advance , pg_create_physical_replication_slot_extern , pg_logical_slot_get_changes , pg_logical_slot_peek_changes , pg_logical_slot_get_binary_changes , and pg_logical_slot_peek_binary_changes .
gs_role_account_lock	Permission to lock and unlock users. However, this role cannot lock or unlock the initial user or users with the PERSISTENCE attribute.
gs_role_pldebugger	Permission to debug functions in db_pldebugger .
gs_role_directory_create	Permission to create directory objects. However, this role needs to enable the GUC parameter enable_access_server_directory first.
gs_role_directory_drop	Permission to delete directory objects. However, this role needs to enable the GUC parameter enable_access_server_directory first.

The restrictions on built-in roles are as follows:

- The role names starting with "gs_role_" are reserved for built-in roles in the database. Do not create users or roles starting with "gs_role_" or rename existing users or roles to names starting with "gs_role_".
- Do not perform the ALTER or DROP operation on built-in roles.
- By default, built-in roles do not have the LOGIN permission and do not have preset passwords.
- The gsql meta-commands **\du** and **\dg** do not display information about built-in roles. However, if *pattern* is specified as a specific built-in role, the information is displayed.
- When separation-of-duties is disabled, the initial user, users with the SYSADMIN permission, and users with the ADMIN OPTION built-in role

permission have the permission to perform GRANT and REVOKE operations on built-in roles. When separation of duties is enabled, the initial user and users with the ADMIN OPTION built-in role permission have the permission to perform GRANT and REVOKE operations on built-in roles. Example:

```
GRANT gs_role_signal_backend TO user1;  
REVOKE gs_role_signal_backend FROM user1;
```

2.1.6 Schemas

Schemas function as models. Schema management allows multiple users to use the same database without mutual impacts, to organize database objects as manageable logical groups, and to add third-party applications to the same schema without causing conflicts.

Each database has one or more schemas. Each schema contains tables and other types of objects. When a database is created, a public schema named **public** is created by default, and all users have the **USAGE** permission on this schema. In addition, each database has a **pg_catalog** schema, which contains system catalogs and all built-in data types, functions, and operators. Only system administrators and the initial user can create common functions, aggregate functions, stored procedures, and synonym objects in public and pg_catalog schemas. Only the initial user can create operators in public and pg_catalog schemas. Other users cannot create the preceding five types of objects even if they are granted the CREATE permission on the public and pg_catalog schemas. You can group database objects by schema. A schema is similar to an OS directory but cannot be nested. By default, only the initial user can create objects in **pg_catalog**.

The same database object name can be used in different schemas of the same database without causing conflicts. For example, both **a_schema** and **b_schema** can contain a table named **mytable**. Users with required permissions can access objects across multiple schemas of the same database.

When you run the **CREATE USER** command to create a user, the system creates a schema with the same name as the user in the database where the command is executed.

Database objects are generally created in the first schema in a database search path. For details about the first schema and how to change the schema order, see [Search Path](#).

Creating, Modifying, and Deleting Schemas

- To create a schema, use **CREATE SCHEMA**. By default, the initial user and system administrators can create schemas. Other users can create schemas in the database only when they have the CREATE permission on the database. For details about how to grant the permission, see the syntax in [GRANT](#).
- To change the name or owner of a schema, use **ALTER SCHEMA**. The schema owner can change the schema.
- To delete a schema and its objects, use **DROP SCHEMA**. Schema owners can delete schemas.
- To create a table in a schema, use the *schema_name.table_name* format to specify the table. If *schema_name* is not specified, the table will be created in the first schema in [search path](#).

- To view the owner of a schema, perform the following join query on the system catalogs **PG_NAMESPACE** and **PG_USER**. Replace *schema_name* in the statement with the name of the schema to be queried.

```
openGauss=# SELECT s.nspname,u.username AS nspowner FROM pg_namespace s, pg_user u WHERE  
nspname='schema_name' AND s.nspowner = u.usesysid;
```
- To view a list of all schemas, query the system catalog **PG_NAMESPACE**.

```
openGauss=# SELECT * FROM pg_namespace;
```
- To view a list of tables in a schema, query the system catalog **PG_TABLES**. For example, the following query will return a table list from **PG_CATALOG** in the schema.

```
openGauss=# SELECT distinct(tablename),schemaname from pg_tables where schemaname =  
'pg_catalog';
```

Search Path

A search path is defined in the **search_path** parameter. The parameter value is a list of schema names separated by commas (,). If no target schema is specified during object creation, the object will be added to the first schema listed in the search path. If there are objects with the same name across different schemas and no schema is specified for an object query, the object will be returned from the first schema containing the object in the search path.

- To view the current search path, use **SHOW**.

```
openGauss=# SHOW SEARCH_PATH;  
search_path  
-----  
"$user",public  
(1 row)
```

The default value of **search_path** is **"\$user",public**. *\$user* indicates the name of the schema with the same name as the current session user. If the schema does not exist, *\$user* will be ignored. By default, after a user connects to a database that has schemas with the same name, objects will be added to all the schemas. If there are no such schemas, objects will be added only to the **public** schema.

- To change the default schema of the current session, run the **SET** statement.

Run the following command to set the search path to **myschema,public** (**myschema** will be searched before **public**):

```
openGauss=# SET SEARCH_PATH TO myschema, public;  
SET
```

2.1.7 Setting User Permissions

- To grant permissions for an object to a user, use **GRANT**.

When permissions for a table or view in a schema are granted to a user or role, the **USAGE** permission of the schema must be granted together. Otherwise, the user or role can only see these objects but cannot access them.

In the following example, permissions for the schema **tpcds** are first granted to user **joe**, and then the **SELECT** permission for the **tpcds.web_returns** table is also granted.

```
openGauss=# GRANT USAGE ON SCHEMA tpcds TO joe;  
openGauss=# GRANT SELECT ON TABLE tpcds.web_returns to joe;
```

- Grant a role to a user to allow the user to inherit the object permissions of the role.

- a. Create a role.

Create a role **lily** and grant the system permission **CREATEDB** to the role.

```
openGauss=# CREATE ROLE lily WITH CREATEDB PASSWORD '*****!';
```

- b. Grant object permissions to the role by using **GRANT**.

For example, first grant permissions for the schema **tpcds** to the role **lily**, and then grant the **SELECT** permission of the **tpcds.web_returns** table to **lily**.

```
openGauss=# GRANT USAGE ON SCHEMA tpcds TO lily;
openGauss=# GRANT SELECT ON TABLE tpcds.web_returns TO lily;
```

- c. Grant the role permissions to a user.

```
openGauss=# GRANT lily TO joe;
```

NOTE

When the permissions of a role are granted to a user, the attributes of the role are not transferred together.

- To revoke user permissions, use **REVOKE**.

2.1.8 Row-Level Security Policy

The row-level security feature enables database access control to be accurate to each row of data tables. In this way, the same SQL query may return different results for different users.

You can create a row-level security policy for a data table. The policy defines an expression that takes effect only for specific database users and SQL operations. When a database user accesses the data table, if a SQL statement meets the specified row-level security policies of the data table, the expressions that meet the specified condition will be combined by using **AND** or **OR** based on the attribute type (**PERMISSIVE** | **RESTRICTIVE**) and applied to the execution plan in the query optimization phase.

Row-level security policy is used to control the visibility of row-level data in tables. By predefining filters for data tables, the expressions that meet the specified condition can be applied to execution plans in the query optimization phase, which will affect the final execution result. Currently, the SQL statements that can be affected include **SELECT**, **UPDATE**, and **DELETE**.

Scenario 1: A table summarizes the data of different users. Users can view only their own data.

```
-- Create users alice, bob, and peter.
openGauss=# CREATE USER alice PASSWORD '*****!';
openGauss=# CREATE USER bob PASSWORD '*****!';
openGauss=# CREATE USER peter PASSWORD '*****!';

-- Create the all_data table that contains user information.
openGauss=# CREATE TABLE all_data(id int, role varchar(100), data varchar(100));

-- Insert data into the data table.
openGauss=# INSERT INTO all_data VALUES(1, 'alice', 'alice data');
openGauss=# INSERT INTO all_data VALUES(2, 'bob', 'bob data');
openGauss=# INSERT INTO all_data VALUES(3, 'peter', 'peter data');

-- Grant the read permission for the all_data table to users alice, bob, and peter.
openGauss=# GRANT SELECT ON all_data TO alice, bob, peter;

-- Enable the row-level security policy.
openGauss=# ALTER TABLE all_data ENABLE ROW LEVEL SECURITY;
```

```
-- Create a row-level security policy to specify that the current user can view only their own data.
openGauss=# CREATE ROW LEVEL SECURITY POLICY all_data_rls ON all_data USING(role =
CURRENT_USER);

-- View table details.
openGauss=# \d+ all_data
Table "public.all_data"
Column |      Type      | Modifiers | Storage | Stats target | Description
-----+-----+-----+-----+-----+-----
id      | integer         |           |         |              |
role    | character varying(100) |         | extended |              |
data    | character varying(100) |         | extended |              |
Row Level Security Policies:
  POLICY "all_data_rls"
    USING (((role)::name = "current_user"()))
Has OIDs: no
Location Nodes: ALL DATANODES
Options: orientation=row, compression=no, enable_rowsecurity=true

-- Switch to user alice and run SELECT * FROM public.all_data.
openGauss=# SELECT * FROM public.all_data;
id | role | data
---+---+---
1  | alice | alice data
(1 row)

openGauss=# EXPLAIN(COSTS OFF) SELECT * FROM public.all_data;
QUERY PLAN
-----
Streaming (type: GATHER)
Node/s: All datanodes
-> Seq Scan on all_data
   Filter: ((role)::name = 'alice'::name)
Notice: This query is influenced by row level security feature
(5 rows)

-- Switch to user peter and run SELECT * FROM public.all_data.
openGauss=# SELECT * FROM public.all_data;
id | role | data
---+---+---
3  | peter | peter data
(1 row)

openGauss=# EXPLAIN(COSTS OFF) SELECT * FROM public.all_data;

Streaming (type: GATHER)
Node/s: All datanodes
-> Seq Scan on all_data
   Filter: ((role)::name = 'peter'::name)
Notice: This query is influenced by row level security feature
(5 rows)
```

NOTICE

PG_STATISTIC and **PG_STATISTIC_EXT** store sensitive information about statistical objects, such as high-frequency MCVs. If the permission to query the two system catalogs is granted to a common user after the row-level security policy is created, the common user can still access the two system catalogs to obtain the information in the statistical objects.

2.2 Database Audit

Context

Database security is critical to the database system. GaussDB writes all user operations on the database into audit logs. Database security administrators can use the audit logs to reproduce a series of events that cause faults in the database and identify unauthorized users, unauthorized operations, and the time when these operations are performed.

You need to know the following about the audit function:

- The overall audit parameter **audit_enabled** supports dynamic loading. If you change the value of this configuration when the database is running, the change takes effect immediately and you do not need to restart the database. The default value is **on**, indicating that the audit function is enabled.
- In addition to the overall audit configuration, each audit item can be independently configured. The function of each audit item takes effect only after the configuration is enabled.
- The configuration of each audit item supports dynamic loading. After changing the audit switch status when the database is running, the modification takes effect immediately without restarting the database.

Table 2-4 describes the audit items supported by GaussDB.

Table 2-4 Audit items

Parameter	Description
User login and logout audit	Parameter: audit_login_logout Its default value is 7 , which indicates that the function of user login and logout audit is enabled. 0 indicates that the function of user login and logout audit is disabled. Other values are not recommended.
Database startup, stop, recovery, and switchover audit	Parameter: audit_database_process Its default value is 1 , which indicates that the audit of database startup, stop, recovery, and switchover is enabled.
User locking and unlocking audit	Parameter: audit_user_locked Its default value is 1 , which indicates that the audit of user locking and unlocking is enabled.
Unauthorized access audit	Parameter: audit_user_violation Its default value is 0 , which indicates that the audit of unauthorized access is disabled.
Permission granting and revoking audit	Parameter: audit_grant_revoke Its default value is 1 , which indicates that the audit of permission granting and revoking is enabled.

Parameter	Description
Audit of CREATE, ALTER, and DROP operations on database objects	Parameter: audit_system_object Its default value is 67121159 , only the CREATE, ALTER, and DROP operations on databases, schemas, users, data sources, and SQL patches are audited.
Audit of INSERT, UPDATE, and DELETE operations on a specific table	Parameter: audit_dml_state Its default value is 0 , which indicates that the audit of DML operations (except SELECT) on a specific table is disabled.
SELECT operation audit	Parameter: audit_dml_state_select Its default value is 0 , which indicates that the audit of the SELECT operation is disabled.
COPY operation audit	Parameter: audit_copy_exec Its default value is 1 , which indicates that the audit of COPY operations is enabled.
Stored procedure and user-defined function execution audit	Parameter: audit_function_exec The default value is 0 , which indicates that no execution audit logs of stored procedures and user-defined functions are recorded.
SET operation audit	Parameter: audit_set_parameter Its default value is 0 , which indicates that the audit of the SET operation is disabled.
Transaction ID record	Parameter: audit_xid_info Its default value is 0 , which indicates that the function of recording transaction IDs in audit logs is disabled.

3 Database Quick Start

3.1 Connecting to a Database

Client tools used for connecting to a database include **gsql** and APIs (such as **ODBC** and **JDBC**).

- **gsql** is a client tool provided by GaussDB. As described in [Using gsql to Connect to a Database](#), **psql** is used to enter, edit, and run SQL statements in an interactive manner.
- As described in [APIs](#), standard databases, such as **ODBC** and **JDBC**, can be used to develop GaussDB-based applications.

3.1.1 Using gsql to Connect to a Database

gsql provided by GaussDB is a database connection tool running in the CLI. **gsql** provides basic and advanced functions of databases to facilitate user operations. This section describes how to use **gsql** to connect to a database. For details about how to use **gsql**, see "Client Tools > gsql" in *Tool Reference*.

Precautions

By default, when a client has been idle for the period specified by **session_timeout** after connecting to a database, the client automatically disconnects from the database. To disable the timeout setting, set **session_timeout** to 0.

Prerequisites

You have contacted the administrator for connection information.

Remotely Connecting to a Database

- Step 1** Contact an administrator to configure the remote connection.
- Step 2** On the host, upload the client tool package and configure environment variables for the **gsql** client. The openEuler environment is used as an example.

1. Log in to the client.
2. Run the following command to create the **/tmp/tools** directory:
`mkdir /tmp/tools`
3. Obtain **GaussDB-Kernel_VxxxRxxxCxx-XXXXX-64bit-gsql.tar.gz** from the software installation package and upload it to the **/tmp/tools** directory.

NOTE

- The software package is located where you put it before installation. Set it based on actual situation.
 - The tool package name may vary in different OSs. Select the tool package suitable for your OS.
4. Run the following commands to decompress the package:
`cd /tmp/tools`
`tar -zxvf GaussDB-Kernel_VxxxRxxxCxx-XXXXX-64bit-gsql.tar.gz`
 5. Log in to the server where the primary database node is located, and copy the **bin** directory in the database installation directory to **/tmp/tools** on the client host.
`scp -r /opt/huawei/install/app/bin root@10.10.0.30:/tmp/tools`
In the preceding command, **/opt/huawei/install/app** indicates the *{gaussdbAppPath}* path configured in the **clusterconfig.xml** file, and **10.10.0.30** indicates the IP address of the client host.
 6. Log in to the host where the client is installed and set environment variables.
Run the following command to open the **~/.bashrc** file:
`vi ~/.bashrc`
Enter the following content and run **:wq!** to save and exit:
`export PATH=/tmp/tools/bin:$PATH`
`export LD_LIBRARY_PATH=/tmp/tools/lib:$LD_LIBRARY_PATH`
 7. Run the following command to make the environment variables take effect:
`source ~/.bashrc`

Step 3 Connect to a database.

After the database is installed, a database named **postgres** is generated by default. When connecting to a database for the first time, you can connect to this database.

```
gsql -d postgres -h 10.10.0.11 -U jack -p 8000
Password for user jack:
```

postgres is the name of the database, **10.10.0.11** is the IP address of the server where the primary node of the database resides, **jack** is the user for connecting to the database, and **8000** is the port number of the primary database node.

In a centralized database instance, when you need to connect to the primary node and the IP addresses of three nodes in the database instance are 10.10.0.11, 10.10.0.12, and 10.10.0.13, you can use the **gsql -d postgres -h 10.10.0.11,10.10.0.12,10.10.0.13 -U jack -p 8000** command. **gsql** connects to the three IP addresses in sequence. If the current IP address is not the IP address of the primary node, **gsql** disconnects from the current IP address and attempts to connect to the next IP address, until the primary node is found.

 NOTE

- If a machine connected to GaussDB is not in the same network segment as GaussDB, the IP address specified by **-h** should be the value of **coo.cooListenIp2** (application access IP address) set in Manager.
- By default, the initial user of the database is not allowed to remotely connect to the database. If Kerberos authentication is enabled in an instance, the initial user is allowed to remotely connect to the database in the instance.

----End

3.1.2 APIs

You can use standard database APIs, such as **ODBC** and **JDBC**, to develop GaussDB-based applications.

Supported APIs

Each application is an independent GaussDB development project. APIs alleviate applications from directly operating in databases, and enhance the database portability, extensibility, and maintainability. [Table 3-1](#) lists the APIs supported by GaussDB and the download addresses.

Table 3-1 Database APIs

API	How to Obtain
ODBC	• Linux: Driver: GaussDB-Kernel_VxxxRxxxCxx-xxxxx-64bit-Odbc.tar.gz unixODBC source code package: https://sourceforge.net/projects/unixodbc/files/unixODBC/2.3.7/ • Windows: Driver: GaussDB-Kernel_VxxxRxxxCxx-Windows-Odbc.tar.gz
JDBC	• Driver: GaussDB-Kernel_VxxxRxxxCxx-xxxxx-64bit-Jdbc.tar.gz • Driver: com.huawei.opengauss.jdbc.Driver

The JDBC and ODBC APIs are used to connect to the database remotely. Therefore, you need to configure a remote connection in GaussDB. Contact an administrator for related operations.

For details about more APIs, see [Application Development Guide](#).

3.2 Operating a Database

This section explains how to use databases, including creating database accounts, databases, and tables, inserting data to tables, and querying data in tables.

3.2.1 Creating a Database Account

Only administrators that are created during database installation can access the initial database by default. You can also create other database accounts.

```
openGauss=# CREATE USER joe WITH PASSWORD 'xxxxxxxxx';
```

If the following information is displayed, the creation is successful:

```
CREATE ROLE
```

In this case, you have created a user account named **joe**, and the user password is **xxxxxxxxx**.

Run the following command to set user **joe** as the system administrator:

```
openGauss=# GRANT ALL PRIVILEGES TO joe;
```

Run the **GRANT** command to set related permissions. For details, see [GRANT](#).

NOTE

Note: For details about how to create database accounts, see [Users and Permissions](#).

3.2.2 Creating and Managing Databases

Prerequisites

Only the database system administrators or users granted with database creation permissions can create a database. For details about how to grant database creation permissions to a user, see [Users and Permissions](#).

Context

- GaussDB has two default template databases **template0** and **template1** and a default user database **postgres**. The default compatible database type of Postgres is O (that is, **DBCOMPATIBILITY** is set to **A**). In this compatible type, empty strings are processed as null values.
- CREATE DATABASE** creates a database by copying a template database (**template0** by default). Do not use a client or any other tools to connect to or to perform operations on the template databases.

NOTE

- The template database does not contain any user table. You can view the attributes of the template database in the **PG_DATABASE** system catalog.
- The **template0** template does not allow user connections. Only the initial user and system administrators can connect to **template1**.
- A maximum of 128 databases can be created in GaussDB.
- A database system consists of multiple databases. A client can connect to only one database at a time. Users cannot query data across databases. If one GaussDB contains multiple databases, set the **-d** parameter to specify the database instance to be connected.

Precautions

Assume that the database encoding is SQL_ASCII. (You can run the **show server_encoding;** command to query the encoding used for storing data in the current database.) If the database object name contains multi-byte characters (such as Chinese) or if the object name length exceeds the allowed maximum (63 bytes), the database truncates the last byte (not the last character) of the object name. In this case, half characters may appear.

To resolve this problem, you need to:

- Ensure that the name of the data object does not exceed the maximum length.
- Change the default database storage code set (**server_encoding**) to UTF-8.
- Exclude multi-byte characters from object names.
- Ensure that no more than 128 databases are created (recommended).
- If you fail to delete an object by specifying its name after truncation, specify its original name to delete it, or manually delete it from the system catalogs on each node.

Procedure

Step 1 Run the following command to create a database named **db_tpcc**:

```
openGauss=# CREATE DATABASE db_tpcc;  
CREATE DATABASE
```

NOTE

- Database names must comply with the general naming convention rules of SQL identifiers. The current role automatically becomes the owner of this new database.
- If a database system is used to support independent users and projects, store them in different databases.
- If the projects or users are associated with each other and share resources, store them in one database. However, you can divide them into different schemas. A schema is a logical structure, and the access permission for a schema is controlled by the permission system module.
- A database name contains a maximum of 63 bytes and the excessive bytes at the end of the name will be truncated by the server. You are advised to specify a database name no longer than 63 bytes when you create a database.

- New databases are created in the **pg_default** tablespace by default. To specify another tablespace, run the following statement:

```
openGauss=# CREATE DATABASE db_tpcc WITH TABLESPACE = hr_local;  
CREATE DATABASE
```

hr_local indicates the tablespace name. For details about how to create a tablespace, see [Creating and Managing Tablespace](#).

- After creating the **db_tpcc** database, you can perform other operations in the default **postgres** database. Alternatively, you can perform the following operations to exit the **postgres** database, connect to the **db_tpcc** database as a new user, and perform operations such as creating tables.

```
openGauss=# \q  
gsqll -d db_tpcc -p 8000 -U joe  
Password for user joe:  
gsqll ((GaussDB Kernel 503.1.XXX build f521c606) compiled at 2021-09-16 14:55:22 commit 2935  
last mr 6385 release)  
Non-SSL connection (SSL connection is recommended when requiring high-security)  
Type "help" for help.  
db_tpcc=>
```

Step 2 View databases.

- Run the **\l** meta-command to view the database list of the database system.
openGauss=# \l
- Run the following command to query the database list in the **pg_database** system catalog:

```
openGauss=# SELECT datname FROM pg_database;
```

Step 3 Modify the database.

You can modify database configuration such as the database owner, name, and default settings.

- Run the following command to set the default search path for the database:

```
openGauss=# ALTER DATABASE db_tpcc SET search_path TO pa_catalog,public;  
ALTER DATABASE
```
- Run the following command to rename the database:

```
openGauss=# ALTER DATABASE db_tpcc RENAME TO human_tpcds;  
ALTER DATABASE
```

Step 4 Delete the database.

You can run the **DROP DATABASE** command to delete a database. This command deletes the system catalog of the database and the database directory on the disk. Only the database owner or system administrators can delete a database. A database accessed by users cannot be deleted. You need to connect to another database before deleting this database.

Run the following command to delete the database:

```
openGauss=# DROP DATABASE human_tpcds;  
DROP DATABASE
```

----End

3.2.3 Creating and Managing Tablespaces

Background

The administrator can use tablespaces to control the layout of disks where a database is installed. This has the following advantages:

- If the disk partition or tablespace initially allocated to the database is full and the space cannot be logically extended, you can create and use tablespaces in other partitions until the system space is reconfigured.
- Tablespaces allow the administrator to distribute data based on the schema of database objects, improving system performance.
 - A frequently used index can be placed in a disk having stable performance and high computing speed, such as a solid device.
 - A table that stores archived data and is rarely used or has low performance requirements can be placed in a disk with a slow computing speed.
- The administrator can use tablespaces to set the maximum available disk space. In this way, when a partition is shared with other data, tablespaces will not occupy excessive space in the partition.
- You can use tablespaces to control the disk space occupied by data in a database. If the usage of a disk where a tablespace resides reaches 90%, the database switches to the read-only mode. It switches back to read/write mode when the disk usage becomes less than 90%.

You are advised to use the background monitoring program or Database Manager to monitor the disk space usage when using the database to prevent the database from switching to the read-only mode.

- Each tablespace corresponds to a file system directory. If *data directory / pg_location/mount1/path1* is an empty directory for which users have read

and write permissions, an absolute path tablespace can be created in this directory.

If the tablespace quota management is used, the performance may deteriorate by about 30%. **MAXSIZE** specifies the maximum quota for each database node. The deviation must be within 500 MB. Determine whether to set a tablespace to its maximum size as required.

GaussDB provides two tablespaces: **pg_default** and **pg_global**.

- Default tablespace **pg_default**: stores non-shared system tables, user tables, user table indexes, temporary tables, temporary table indexes, and internal temporary tables. The corresponding storage directory is the base directory in the instance data directory.
- Shared tablespace **pg_global**: stores shared system tables. The corresponding storage directory is the base directory in the global data directory.

Precautions

You are not advised to use user-defined tablespaces. This is because user-defined tablespaces are usually used with storage media other than the main storage (storage device where the default tablespace is located, such as a disk) to isolate I/O resources that can be used by different services. Storage devices use standard configurations and do not have other available storage media. If the user-defined tablespace is not properly used, the system cannot run stably for a long time and the overall performance is affected. Therefore, you are advised to use the default tablespace.

Procedure

- Create a tablespace.
 - a. Run the following command to create user **jack** and set the password to **XXXXXXXX**:
openGauss=# **CREATE USER jack IDENTIFIED BY 'XXXXXXXX';**
If the following information is displayed, the creation is successful:
CREATE ROLE
 - b. Run the following command to create a tablespace:
openGauss=# **CREATE TABLESPACE fastspace RELATIVE LOCATION 'tablespace/tablespace_1';**
If the following information is displayed, the creation is successful:
CREATE TABLESPACE
fastspace is the new tablespace, and *Database node data directory/pg_location/tablespace/tablespace_1* is an empty directory for which users have read and write permissions.
 - c. A database system administrator can run the following command to grant the permission of accessing the **fastspace** tablespace to user **jack**:
openGauss=# **GRANT CREATE ON TABLESPACE fastspace TO jack;**
If the following information is displayed, the grant operation is successful:
GRANT
- Create an object in a tablespace.

If you have the CREATE permission on the tablespace, you can create database objects in the tablespace, such as tables and indexes.

Take creating a table as an example:

- Method 1: Run the following command to create a table in a specified tablespace:

```
openGauss=# CREATE TABLE foo(i int) TABLESPACE fastspace;
```

If the following information is displayed, the creation is successful:

```
CREATE TABLE
```

- Method 2: Use **set default_tablespace** to set the default tablespace and then create a table:

```
openGauss=# SET default_tablespace = 'fastspace';
```

```
SET
```

```
openGauss=# CREATE TABLE foo2(i int);
```

```
CREATE TABLE
```

In this example, **fastspace** is the default tablespace, and **foo2** is the created table.

- Use one of the following methods to query a tablespace:

- Method 1: Check the **pg_tablespace** system catalog. Run the following command to view all the tablespaces defined by the system and users:

```
openGauss=# SELECT spcname FROM pg_tablespace;
```

- Method 2: Run the following meta-command of the **gsql** program to query the tablespaces:

```
openGauss=# \db
```

- Query the tablespace usage.

- a. Query the current usage of the tablespace.

```
openGauss=# SELECT PG_TABLESPACE_SIZE('example');
```

The following information is displayed:

```
pg_tablespace_size
-----
                2146304
(1 row)
```

2146304 is the size of the tablespace, and its unit is byte.

- b. Calculate the tablespace usage.

Tablespace usage rate = **PG_TABLESPACE_SIZE**/Size of the disk where the tablespace resides

- Modify a tablespace.

Run the following command to rename tablespace **fastspace** to **fspace**:

```
openGauss=# ALTER TABLESPACE fastspace RENAME TO fspace;
```

```
ALTER TABLESPACE
```

- Delete a tablespace and related data.

- Run the following command to delete user **jack**:

```
openGauss=# DROP USER jack CASCADE;
```

```
DROP ROLE
```

- Run the following commands to delete tables **foo** and **foo2**:

```
openGauss=# DROP TABLE foo;
```

```
openGauss=# DROP TABLE foo2;
```

If the following information is displayed, the deletion is successful:

```
DROP TABLE
```

- Run the following command to delete tablespace **fspace**:

```
openGauss=# DROP TABLESPACE fspace;
```

```
DROP TABLESPACE
```

NOTE

Only the tablespace owner or system administrator can delete a tablespace.

3.2.4 Creating and Managing Tables

3.2.4.1 Creating Tables

Context

A table is created in a database and can be saved in different databases. Tables under different schemas in a database can have the same name.

Procedure

Run the following statement to create a table:

```
openGauss=# CREATE TABLE customer_t1
(
  c_customer_sk      integer,
  c_customer_id      char(5),
  c_first_name       char(6),
  c_last_name        char(8)
);
```

If the following information is displayed, the creation is successful:

```
CREATE TABLE
```

c_customer_sk, **c_customer_id**, **c_first_name**, and **c_last_name** are the column names of the table. **integer**, **char(5)**, **char(6)**, and **char(8)** are column name types.

NOTE

- By default, new database objects, such as the **mytable** table, are created in the **\$user** schema. For more details about schemas, see [Creating and Managing Schemas](#).
- In addition to the created tables, a database contains many system catalogs. These system catalogs contain database installation information and information about various queries and processes in GaussDB. You can collect information about the database by querying system catalogs. For details, see [Querying a System Catalog](#).

3.2.4.2 Inserting Data to Tables

A new table contains no data. You need to insert data to the table before using it. This section describes how to insert a row or multiple rows of data by running the **INSERT** command and to insert data from a specified table. Contact an administrator if a large amount of data needs to be imported.

Context

The length of a character on the server and client may vary by the character sets they use. A string entered on the client will be processed based on the server's character set, so the result may differ from expected.

Table 3-2 Comparison of character set output between the client and server

Procedure	Server and Client Use Same Encoding	Server and Client Use Different Encoding
No operations are performed to the string while it is saved and read.	Your expected result is returned.	If the encoding for input and output on the client is the same, your expected result is returned.
Operations (such as executing string functions) are performed to the string while it is saved and read.	Your expected result is returned.	The result may differ from expected, depending on the operations performed to the string.
A long string is truncated while it is saved.	Your expected result is returned.	If the character sets used on the client and server have different character length, the result may differ from expected.

More than one of the preceding operations can be performed to a string. For example, if the character sets of the client and server are different, a string may be processed and then truncated. In this case, the result will also be unexpected.

NOTE

Long strings are truncated only if **DBCOMPATIBILITY** is set to **TD** (compatible with Teradata) and **td_compatible_truncation** is set to **on**.

Procedure

You need to create a table before inserting data to it. For details about how to create a table, see [Creating and Managing Tables](#).

- Insert a row to table **customer_t1**.

Data values are arranged in the same order as the columns in the table and are separated by commas (,). Generally, column values are text values (constants). But column values can also be scalar expressions.

```
openGauss=# INSERT INTO customer_t1(c_customer_sk, c_customer_id, c_first_name) VALUES (3769, 'hello', 'Grace');
```

If you know the sequence of the columns in the table, you can obtain the same result without listing these columns. For example, the following command generates the same result as the preceding command:

```
openGauss=# INSERT INTO customer_t1 VALUES (3769, 'hello', 'Grace');
```

If you do not know some of the column values, you can omit them. In the INSERT statement, if the column name of the specified target table is not displayed, the values to be inserted in the VALUES clause correspond to the columns of the target table based on the column number. That is, the first value in the VALUES clause corresponds to the first column of the target table, the second value of the VALUES clause corresponds to the second

column of the target table, and so on. Columns that do not have corresponding values in the VALUES clause are automatically filled with default values or NULL. Example:

```
openGauss=# INSERT INTO customer_t1 (c_customer_sk, c_first_name) VALUES (3769, 'Grace');
```

```
openGauss=# INSERT INTO customer_t1 VALUES (3769, 'hello');
```

You can also specify the default value of a column or row:

```
openGauss=# INSERT INTO customer_t1 (c_customer_sk, c_customer_id, c_first_name) VALUES (3769, 'hello', DEFAULT);
```

```
openGauss=# INSERT INTO customer_t1 DEFAULT VALUES;
```

- To insert multiple rows to a table, run the following command:

```
openGauss=# INSERT INTO customer_t1 (c_customer_sk, c_customer_id, c_first_name) VALUES (6885, 'maps', 'Joes'), (4321, 'tpcds', 'Lily'), (9527, 'world', 'James');
```

You can also insert multiple rows by running the command for inserting one row for multiple times. However, you are advised to run this command to improve efficiency.

- Assume that you have created a backup table **customer_t2** for table **customer_t1**. To insert data from **customer_t1** to **customer_t2**, run the following statements:

```
openGauss=# CREATE TABLE customer_t2 (
  c_customer_sk      integer,
  c_customer_id      char(5),
  c_first_name       char(6),
  c_last_name        char(8)
);
```

```
openGauss=# INSERT INTO customer_t2 SELECT * FROM customer_t1;
```

NOTE

If implicit conversion is not implemented between the column data types of the specified table and those of the current table, the two tables must have the same column data types when data is inserted from the specified table to the current table.

- To delete a backup table, run the following command:

```
openGauss=# DROP TABLE customer_t2 CASCADE;
```

NOTE

If the table to be deleted is in dependent relationship with other tables, you need to delete its dependent tables first.

3.2.4.3 Updating Data in a Table

Existing data in a database can be updated. You can update one row, all rows, or specified rows of data, or update data in a single column without affecting the data in the other columns.

The following types of information are required when the **UPDATE** statement is used to update a row:

- Table name and column name of the data to be updated
- New column value
- Rows of the data to be updated

Generally, the SQL language does not provide a unique ID for a row of data. Therefore, it is impossible to directly specify the rows of the data to be updated.

However, you can specify the rows by declaring the conditions that must be met by the updated row. If a table contains primary keys, you can specify a row using the primary keys.

For details about how to create a table and insert data to it, see [Creating Tables](#) and [Inserting Data to Tables](#).

c_customer_sk in the table **customer_t1** must be changed from **9527** to **9876**:

```
openGauss=# UPDATE customer_t1 SET c_customer_sk = 9876 WHERE c_customer_sk = 9527;
```

You can use a schema to modify the table name. If no such modifier is specified, the table is located based on the default schema path. In the statement, **SET** is followed by the target column and the new column value. The new value can be a constant or an expression.

For example, run the following statement to increase all the values in the **c_customer_sk** column by 100:

```
openGauss=# UPDATE customer_t1 SET c_customer_sk = c_customer_sk + 100;
```

This statement does not include the **WHERE** clause, so all rows are updated. If the statement includes the **WHERE** clause, only the rows matching the clause are updated.

In the **SET** clause, the equal sign (=) indicates value setting. In the **WHERE** clause, the equal sign indicates comparison. **WHERE** may not represent an equation and can be replaced by other operators.

You can run an **UPDATE** statement to update multiple columns by specifying multiple values in the **SET** clause. For example:

```
openGauss=# UPDATE customer_t1 SET c_customer_id = 'Admin', c_first_name = 'Local' WHERE c_customer_sk = 4421;
```

After data has been updated or deleted in batches, a large number of deletion markers are generated in the data file. During query, data with these deletion markers needs to be scanned as well. In this case, a large amount of data with deletion marks can greatly affect the query performance after batch updates or deletions. If data needs to be updated or deleted in batches frequently, you are advised to periodically run the **VACUUM FULL** statement to maintain the query performance.

3.2.4.4 Viewing Data

- Run the following command to query information about all tables in a database in the system catalog **pg_tables**:

```
openGauss=# SELECT * FROM pg_tables;
```
- Run the **\d+** command of the **gsql** tool to query table attributes:

```
openGauss=# \d+ customer_t1;
```
- Run the following command to query the data volume of table **customer_t1**:

```
openGauss=# SELECT count(*) FROM customer_t1;
```
- Run the following command to query all data in the table **customer_t1**:

```
openGauss=# SELECT * FROM customer_t1;
```
- Run the following command to query only the data in the column **c_customer_sk**:

```
openGauss=# SELECT c_customer_sk FROM customer_t1;
```
- Run the following command to filter repeated data in the column **c_customer_sk**:

```
openGauss=# SELECT DISTINCT( c_customer_sk ) FROM customer_t1;
```

- Run the following command to query all data whose column **c_customer_sk** is **3869**:

```
openGauss=# SELECT * FROM customer_t1 WHERE c_customer_sk = 3869;
```

- Run the following command to collate data based on the column **c_customer_sk**:

```
openGauss=# SELECT * FROM customer_t1 ORDER BY c_customer_sk;
```

3.2.4.5 Deleting Data from a Table

Outdated data may need to be deleted when tables are used. Data can be deleted from tables only by row.

SQL statements can only access and delete an independent row by declaring conditions that match the row. If a table has a primary key, you can use it to specify a row. You can delete several rows that match the specified condition or delete all the rows from a table.

For example, to delete all the rows whose **c_customer_sk** column is **3869** from the table **customer_t1**, run the following command:

```
openGauss=# DELETE FROM customer_t1 WHERE c_customer_sk = 3869;
```

To delete all rows from the table, run either of the following commands:

```
openGauss=# DELETE FROM customer_t1;
```

Or

```
openGauss=# TRUNCATE TABLE customer_t1;
```

NOTE

If you need to delete an entire table, you are advised to use the **TRUNCATE** statement rather than **DELETE**.

To delete a table, run the following command:

```
openGauss=# DROP TABLE customer_t1;
```

3.2.5 Querying a System Catalog

In addition to the created tables, a database contains many system catalogs. These system catalogs contain database installation information and information about various queries and processes in GaussDB. You can collect information about the database by querying system catalogs.

In [System Catalogs and System Views](#), the description about each table specifies whether the table is visible to all users or only the initial user. To query tables that are visible only to the initial user, log in as the user.

GaussDB provides the following types of system catalogs and system views:

- PG-compatible system catalogs and views
These system catalogs and views have the prefix **PG**.
- New system catalogs and system views of GaussDB
These system catalogs and views have the prefix **GS**.

Querying Database Tables

Create the following tables in the public schema:

```
openGauss=# CREATE TABLE public.search_table_t1(a int);
CREATE TABLE
openGauss=# CREATE TABLE public.search_table_t2(b int);
CREATE TABLE
openGauss=# CREATE TABLE public.search_table_t3(c int);
CREATE TABLE
openGauss=# CREATE TABLE public.search_table_t4(d int);
CREATE TABLE
openGauss=# CREATE TABLE public.search_table_t5(e int);
CREATE TABLE
```

In the PG_TABLES system catalog, view the tables prefixed with search_table in the public schema.

```
openGauss=# SELECT distinct(tablename) FROM pg_tables WHERE SCHEMANAME = 'public' AND
TABLENAME LIKE 'search_table%';
```

Information similar to the following is displayed:

```
tablename
-----
search_table_t1
search_table_t2
search_table_t3
search_table_t4
search_table_t5
(5 rows)
```

Viewing Database Users

You can run the **PG_USER** command to view the list of all users in the database, and view the user ID (**USESYSID**) and permissions.

```
SELECT * FROM pg_user;
username | usesysid | usecreatedb | usesuper | usecatupd | userepl | passwd | valbegin | valuntil |
respool  | parent  | spacelimit | useconfig | no        | degroup | tempspacelimit | spillspacelimit | usemonitoradmin | useoperatoradmin | usepolicyadmin
-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----
omm      | 10      | t          | t        | t        | t       | ***** |               |               | default_pool | 0
|         |          |          |          |          |          |          |               |               |               |
|         |          |          | t        | t        | t       |          |               |               |               |
```

Viewing and Stopping the Running Query Statements

You can view the running query statements in the **PG_STAT_ACTIVITY** view. You can use the following methods:

Step 1 Set the parameter **track_activities** to **on**.

```
SET track_activities = on;
```

The database collects the running information about active queries only if the parameter is set to **on**.

Step 2 View the running query statements. Run the following command to view the database names, users performing queries, query status, and the corresponding PIDs which are connected to the running query statements:

```
SELECT datname, username, state, pid FROM pg_stat_activity;
datname | username | state | pid
-----+-----+-----+-----
testdb  | Ruby    | active | 140298793514752
```

```
testdb | Ruby | active | 140298718004992
testdb | Ruby | idle | 140298650908416
testdb | Ruby | idle | 140298625742592
testdb | omm | active | 140298575406848
(5 rows)
```

If the **state** column is **idle**, the connection is idle and requires a user to enter a command.

To identify only active query statements, run the following command:

```
SELECT datname, username, state, pid FROM pg_stat_activity WHERE state != 'idle';
```

Step 3 To cancel queries that have been running for a long time, use the **PG_TERMINATE_BACKEND** function to end sessions based on the thread ID.

```
SELECT PG_TERMINATE_BACKEND(139834759993104);
```

If information similar to the following is displayed, the session is successfully terminated:

```
PG_TERMINATE_BACKEND
-----
t
(1 row)
```

If information similar to the following is displayed, a user has terminated the current session:

```
FATAL: terminating connection due to administrator command
FATAL: terminating connection due to administrator command
```

NOTE

If the **PG_TERMINATE_BACKEND** function is used to terminate the backend threads of the current session, the **gsql** client will be reconnected automatically rather than be logged out. The message "The connection to the server was lost. Attempting reset: Succeeded." is returned.

```
FATAL: terminating connection due to administrator command
FATAL: terminating connection due to administrator command
The connection to the server was lost. Attempting reset: Succeeded.
```

----End

3.2.6 Other Operations

3.2.6.1 Creating and Managing Schemas

Context

Schemas function as models. Schema management allows multiple users to use the same database without mutual impacts, to organize database objects as manageable logical groups, and to add third-party applications to the same schema without causing conflicts. Schema management involves creating a schema, using a schema, deleting a schema, setting a search path for a schema, and setting schema permissions.

Precautions

- GaussDB contains one or more named databases. Users and user groups are shared within the database, but their data is not shared. Any user who has

connected to a server can access only the database specified in the connection request.

- A database can have one or more schemas, and a schema can contain tables and other data objects, such as data types, functions, and operators. One object name can be used in different schemas. For example, both **schema1** and **schema2** can have a table named **mytable**.
- Different from databases, schemas are not isolated. You can access the objects in a schema of the connected database if you have schema permissions. To manage schema permissions, you need to have knowledge about database permissions.
- A schema named with the **PG_** prefix cannot be created because this type of schema is reserved for the database system.
- Each time a new user is created, the system creates a schema with the same name for the new user in the current database. In other databases, such a schema needs to be manually created.
- To reference a table that is not modified with a schema name, the system uses **search_path** to find the schema that the table belongs to. **pg_temp** and **pg_catalog** are always the first two schemas to be searched no matter whether or how they are specified in **search_path**. **search_path** is a schema name list, and the first table detected in it is the target table. If no target table is found, an error will be reported. (If a table exists but the schema it belongs to is not listed in **search_path**, the search fails as well.) The first schema in **search_path** is called "current schema". This schema is the first one to be searched. If no schema name is declared, newly created database objects are saved in this schema by default.
- Each database has a **pg_catalog** schema, which contains system catalogs and all embedded data types, functions, and operators. **pg_catalog** is a part of the search path and has the second highest search priority. It is searched after the schema of temporary tables and before other schemas specified in **search_path**. This search order ensures that database built-in objects can be found. To use a custom object that has the same name as a built-in object, you can specify the schema of the custom object.

Procedure

- Create a management user and permission schema.
 - Run the following command to create a schema:

```
openGauss=# CREATE SCHEMA myschema;
```

If the following information is displayed, the schema named **myschema** is successfully created:

```
CREATE SCHEMA
```

To create or access an object in the schema, the object name in the command should consist of the schema name and the object name, which are separated by a dot (.), for example, **myschema.table**.
 - Run the following command to create a schema and specify the owner:

```
openGauss=# CREATE SCHEMA myschema AUTHORIZATION omm;
```

If the following information is displayed, the **myschema** schema that belongs to **omm** is created successfully:

```
CREATE SCHEMA
```
- Use a schema.

If you want to create or access an object in a specified schema, the object name must contain the schema name. To be specific, the name consists of a schema name and an object name, which are separated by a dot (.).

- Run the following command to create the **mytable** table in **myschema**:

```
openGauss=# CREATE TABLE myschema.mytable(id int, name varchar(20));
CREATE TABLE
```

To specify the location of an object, the object name must contain the schema name.

- Run the following command to query all data of the **mytable** table in **myschema**:

```
openGauss=# SELECT * FROM myschema.mytable;
id | name
----+-----
(0 rows)
```

- View the search path of a schema.

You can set **search_path** to specify the sequence of schemas in which objects are searched. The first schema listed in the search path will become the default schema. If no schema is specified during object creation, the object will be created in the default schema.

- Run the following command to view the search path:

```
openGauss=# SHOW SEARCH_PATH;
search_path
-----
"$user",public
(1 row)
```

- Run the following command to set the search path to **myschema,public** (**myschema** will be searched before **public**):

```
openGauss=# SET SEARCH_PATH TO myschema, public;
SET
```

- Set permissions for a schema.

By default, a user can only access database objects in their own schema. Only after a user is granted with the usage permission for a schema by the schema owner, the user can access the objects in the schema.

By granting the **CREATE** permission for a schema to a user, the user can create objects in this schema. By default, all roles have the **USAGE** permission in the **public** schema, but common users do not have the **CREATE** permission in the **public** schema. It is insecure for a common user to connect to a specified database and create objects in its **public** schema. If the common user has the **CREATE** permission on the **public** schema, it is advised to:

- Run the following command to revoke **PUBLIC**'s permission to create objects in the **public** schema. **public** indicates the schema and **PUBLIC** indicates all roles.

```
openGauss=# REVOKE CREATE ON SCHEMA public FROM PUBLIC;
REVOKE
```

- Run the following command to view the current schema:

```
openGauss=# SELECT current_schema();
current_schema
-----
myschema
(1 row)
```

- Run the following commands to create user **jack** and grant the **usage** permission for **myschema** to the user:

```
openGauss=# CREATE USER jack IDENTIFIED BY '*****';
CREATE ROLE
```

```
openGauss=# GRANT USAGE ON schema myschema TO jack;  
GRANT
```

- Run the following command to revoke the usage permission for **myschema** from **jack**:

```
openGauss=# REVOKE USAGE ON schema myschema FROM jack;  
REVOKE
```

- Delete a schema.

- If a schema is empty, that is, it contains no database objects, you can execute the **DROP SCHEMA** command to delete it. For example, run the following command to delete an empty schema named **nullschema**:

```
openGauss=# DROP SCHEMA IF EXISTS nullschema;  
DROP SCHEMA
```

- To delete a schema that is not null, use the keyword **CASCADE** to delete it and all its objects. For example, run the following command to delete **myschema** and all its objects in it:

```
openGauss=# DROP SCHEMA myschema CASCADE;  
DROP SCHEMA
```

- Run the following command to delete user **jack**:

```
openGauss=# DROP USER jack;  
DROP ROLE
```

3.2.6.2 Creating and Managing Partitioned Tables

Context

GaussDB supports range partitioned tables, interval partitioned tables, list partitioned tables, and hash partitioned tables.

- Range partitioned table: Data within a certain range is mapped to each partition. The range is determined by the partition key specified when the partitioned table is created. This partitioning mode is most commonly used. The partition key is usually a date. For example, sales data is partitioned by month.
- Interval partitioned table: A special type of range partitioned tables. Compared with range partitioned tables, interval value definition is added. When no matching partition can be found for an inserted record, a partition can be automatically created based on the interval value.
- List partitioned table: Key values contained in the data are stored in different partitions, and the data is mapped to each partition in sequence. The key values contained in the partitions are specified when the partitioned table is created.
- Hash partitioned table: Data is mapped to each partition based on the internal hash algorithm. The number of partitions is specified when the partitioned table is created.

A partitioned table has the following advantages over an ordinary table:

- High query performance: You can specify partitions when querying partitioned tables, improving query efficiency.
- High availability: If a certain partition in a partitioned table is faulty, data in the other partitions is still available.
- Easy maintenance: To fix a partitioned table having a faulty partition, you only need to fix the partition.

To convert an ordinary table to a partitioned table, you need to create a partitioned table and import data to it from the ordinary table. When you design tables, plan whether to use partitioned tables based on service requirements.

Procedure

Example 1: using the default tablespace

- Create a partitioned table (assuming that the **tpcds** schema has been created).

```
openGauss=# CREATE TABLE tpcds.customer_address
(
  ca_address_sk      integer          NOT NULL ,
  ca_address_id      character(16)    NOT NULL ,
  ca_street_number   character(10)    ,
  ca_street_name     character varying(60) ,
  ca_street_type     character(15)    ,
  ca_suite_number    character(10)    ,
  ca_city            character varying(60) ,
  ca_county          character varying(30) ,
  ca_state           character(2)     ,
  ca_zip            character(10)     ,
  ca_country         character varying(20) ,
  ca_gmt_offset      numeric(5,2)    ,
  ca_location_type   character(20)
)
PARTITION BY RANGE (ca_address_sk)
(
  PARTITION P1 VALUES LESS THAN(5000),
  PARTITION P2 VALUES LESS THAN(10000),
  PARTITION P3 VALUES LESS THAN(15000),
  PARTITION P4 VALUES LESS THAN(20000),
  PARTITION P5 VALUES LESS THAN(25000),
  PARTITION P6 VALUES LESS THAN(30000),
  PARTITION P7 VALUES LESS THAN(40000),
  PARTITION P8 VALUES LESS THAN(MAXVALUE)
)
ENABLE ROW MOVEMENT;
```

If the following information is displayed, the creation is successful:

```
CREATE TABLE
```

- Insert data.

Insert data from the **tpcds.customer_address** table to the **tpcds.web_returns_p2** table.

Suppose the backup table **tpcds.web_returns_p2** of the **tpcds.customer_address** table has been created in the database. You can run the following command to insert the data of the **tpcds.customer_address** table into the backup table **tpcds.web_returns_p2**:

```
openGauss=# CREATE TABLE tpcds.web_returns_p2
(
  ca_address_sk      integer          NOT NULL ,
  ca_address_id      character(16)    NOT NULL ,
  ca_street_number   character(10)    ,
  ca_street_name     character varying(60) ,
  ca_street_type     character(15)    ,
  ca_suite_number    character(10)    ,
  ca_city            character varying(60) ,
  ca_county          character varying(30) ,
  ca_state           character(2)     ,
  ca_zip            character(10)     ,
  ca_country         character varying(20) ,
  ca_gmt_offset      numeric(5,2)    ,
  ca_location_type   character(20)
)
```

```
)  
  
PARTITION BY RANGE (ca_address_sk)  
(  
    PARTITION P1 VALUES LESS THAN(5000),  
    PARTITION P2 VALUES LESS THAN(10000),  
    PARTITION P3 VALUES LESS THAN(15000),  
    PARTITION P4 VALUES LESS THAN(20000),  
    PARTITION P5 VALUES LESS THAN(25000),  
    PARTITION P6 VALUES LESS THAN(30000),  
    PARTITION P7 VALUES LESS THAN(40000),  
    PARTITION P8 VALUES LESS THAN(MAXVALUE)  
)  
  
ENABLE ROW MOVEMENT;  
CREATE TABLE  
openGauss=# INSERT INTO tpcds.web_returns_p2 SELECT * FROM tpcds.customer_address,  
INSERT 0 0
```

- Modify the row movement attributes of the partitioned table.

```
openGauss=# ALTER TABLE tpcds.web_returns_p2 DISABLE ROW MOVEMENT;  
ALTER TABLE
```

- Delete a partition.

Delete partition **P8**.

```
openGauss=# ALTER TABLE tpcds.web_returns_p2 DROP PARTITION P8;  
ALTER TABLE
```

- Add a partition.

Add partition **P8** and set its range to [40000,MAXVALUE].

```
openGauss=# ALTER TABLE tpcds.web_returns_p2 ADD PARTITION P8 VALUES LESS THAN  
(MAXVALUE);  
ALTER TABLE
```

- Rename a partition.

- Rename partition **P8** to **P_9**.

```
openGauss=# ALTER TABLE tpcds.web_returns_p2 RENAME PARTITION P8 TO P_9;  
ALTER TABLE
```

- Rename partition **P_9** to **P8**.

```
openGauss=# ALTER TABLE tpcds.web_returns_p2 RENAME PARTITION FOR (40000) TO P8;  
ALTER TABLE
```

- Query a partition.

Query partition **P6**.

```
openGauss=# SELECT * FROM tpcds.web_returns_p2 PARTITION (P6);  
openGauss=# SELECT * FROM tpcds.web_returns_p2 PARTITION FOR (35888);
```

- Delete a partitioned table and its tablespaces.

```
openGauss=# DROP TABLE tpcds.customer_address;  
DROP TABLE  
openGauss=# DROP TABLE tpcds.web_returns_p2;  
DROP TABLE
```

Example 2: using a user-defined tablespace

Perform the following operations on range partitioned tables.

- Creating tablespaces

```
openGauss=# CREATE TABLESPACE example1 RELATIVE LOCATION 'tablespace1/tablespace_1';  
openGauss=# CREATE TABLESPACE example2 RELATIVE LOCATION 'tablespace2/tablespace_2';  
openGauss=# CREATE TABLESPACE example3 RELATIVE LOCATION 'tablespace3/tablespace_3';  
openGauss=# CREATE TABLESPACE example4 RELATIVE LOCATION 'tablespace4/tablespace_4';
```

If the following information is displayed, the creation is successful:

```
CREATE TABLESPACE
```

- Create a partitioned table.

```
openGauss=# CREATE TABLE tpcds.customer_address  
(
```

```
ca_address_sk integer NOT NULL ,
ca_address_id character(16) NOT NULL ,
ca_street_number character(10) ,
ca_street_name character varying(60) ,
ca_street_type character(15) ,
ca_suite_number character(10) ,
ca_city character varying(60) ,
ca_county character varying(30) ,
ca_state character(2) ,
ca_zip character(10) ,
ca_country character varying(20) ,
ca_gmt_offset numeric(5,2) ,
ca_location_type character(20)
)
TABLESPACE example1
PARTITION BY RANGE (ca_address_sk)
(
PARTITION P1 VALUES LESS THAN(5000),
PARTITION P2 VALUES LESS THAN(10000),
PARTITION P3 VALUES LESS THAN(15000),
PARTITION P4 VALUES LESS THAN(20000),
PARTITION P5 VALUES LESS THAN(25000),
PARTITION P6 VALUES LESS THAN(30000),
PARTITION P7 VALUES LESS THAN(40000),
PARTITION P8 VALUES LESS THAN(MAXVALUE) TABLESPACE example2
)
ENABLE ROW MOVEMENT;
```

If the following information is displayed, the creation is successful:

```
CREATE TABLE
```

- Insert data.

Insert data from the **tpcds.customer_address** table to the **tpcds.web_returns_p2** table.

Suppose the backup table **tpcds.web_returns_p2** of the **tpcds.customer_address** table has been created in the database. You can run the following command to insert the data of the **tpcds.customer_address** table into the backup table **tpcds.web_returns_p2**:

```
openGauss=# CREATE TABLE tpcds.web_returns_p2
(
ca_address_sk integer NOT NULL ,
ca_address_id character(16) NOT NULL ,
ca_street_number character(10) ,
ca_street_name character varying(60) ,
ca_street_type character(15) ,
ca_suite_number character(10) ,
ca_city character varying(60) ,
ca_county character varying(30) ,
ca_state character(2) ,
ca_zip character(10) ,
ca_country character varying(20) ,
ca_gmt_offset numeric(5,2) ,
ca_location_type character(20)
)
TABLESPACE example1
PARTITION BY RANGE (ca_address_sk)
(
PARTITION P1 VALUES LESS THAN(5000),
PARTITION P2 VALUES LESS THAN(10000),
PARTITION P3 VALUES LESS THAN(15000),
PARTITION P4 VALUES LESS THAN(20000),
PARTITION P5 VALUES LESS THAN(25000),
PARTITION P6 VALUES LESS THAN(30000),
PARTITION P7 VALUES LESS THAN(40000),
PARTITION P8 VALUES LESS THAN(MAXVALUE) TABLESPACE example2
)
```

ENABLE ROW MOVEMENT;

```
CREATE TABLE  
openGauss=# INSERT INTO tpcds.web_returns_p2 SELECT * FROM tpcds.customer_address;  
INSERT 0 0
```

- Modify the row movement attributes of the partitioned table.

```
openGauss=# ALTER TABLE tpcds.web_returns_p2 DISABLE ROW MOVEMENT;  
ALTER TABLE
```

- Delete a partition.

Delete partition **P8**.

```
openGauss=# ALTER TABLE tpcds.web_returns_p2 DROP PARTITION P8;  
ALTER TABLE
```

- Add a partition.

Add partition **P8** and set its range to [40000,MAXVALUE].

```
openGauss=# ALTER TABLE tpcds.web_returns_p2 ADD PARTITION P8 VALUES LESS THAN  
(MAXVALUE);  
ALTER TABLE
```

- Rename a partition.

- Rename partition **P8** to **P_9**.

```
openGauss=# ALTER TABLE tpcds.web_returns_p2 RENAME PARTITION P8 TO P_9;  
ALTER TABLE
```

- Rename partition **P_9** to **P8**.

```
openGauss=# ALTER TABLE tpcds.web_returns_p2 RENAME PARTITION FOR (40000) TO P8;  
ALTER TABLE
```

- Modify the tablespace of a partition.

- Change the tablespace of partition **P6** to **example3**.

```
openGauss=# ALTER TABLE tpcds.web_returns_p2 MOVE PARTITION P6 TABLESPACE  
example3;  
ALTER TABLE
```

- Change the tablespace of partition **P4** to **example4**:

```
openGauss=# ALTER TABLE tpcds.web_returns_p2 MOVE PARTITION P4 TABLESPACE  
example4;  
ALTER TABLE
```

- Query a partition.

Query partition **P6**.

```
openGauss=# SELECT * FROM tpcds.web_returns_p2 PARTITION (P6);  
openGauss=# SELECT * FROM tpcds.web_returns_p2 PARTITION FOR (35888);
```

- Delete a partitioned table and its tablespaces.

```
openGauss=# DROP TABLE tpcds.web_returns_p2;  
DROP TABLE  
openGauss=# DROP TABLESPACE example1;  
openGauss=# DROP TABLESPACE example2;  
openGauss=# DROP TABLESPACE example3;  
openGauss=# DROP TABLESPACE example4;  
DROP TABLESPACE
```

3.2.6.3 Creating and Managing Indexes

Background

Indexes accelerate data access but increase the processing time of insertion, update, and deletion operations. Therefore, before creating an index, consider whether it is necessary and select the columns where indexes are to be created. You can determine whether to create an index for a table by analyzing the service processing and data use of applications, as well as columns that are frequently used as search criteria or need to be collated.

Indexes are created based on columns in database tables. Therefore, you must correctly identify which columns require indexes. You are advised to create indexes for any of the following columns:

- Columns that are often searched and queried. This speeds up searches.
- Columns that function as primary keys. This enforces the uniqueness of the columns and the data collation structures in organized tables.
- Columns that are often searched by range. The index helps collate data, and therefore the specified ranges are contiguous.
- Columns that often need to be collated. The index helps collate data, reducing the time for a collation query.
- Columns where the **WHERE** clause is executed frequently. This speeds up condition judgment.
- Columns that often appear after the keywords **ORDER BY**, **GROUP BY**, and **DISTINCT**.

NOTE

- After an index is created, the system automatically determines when to reference it. If the system determines that indexing is faster than sequential scan, the index will be used.
- After an index is created, it must be synchronized with the associated table to ensure that new data can be accurately located, which increases the data operation load. Therefore, delete unnecessary indexes periodically.
- Partitioned table indexes are classified into local indexes and global indexes. A local index corresponds to a specific partition, and a global index corresponds to the entire partitioned table.
- When logical replication is enabled, if you need to create a primary key index that contains system columns, you must set the **REPLICA IDENTITY** attribute of the table to **FULL** or use USING INDEX to specify a unique, non-local, non-deferrable index that does not contain system columns and contains only columns marked **NOT NULL**.

Procedure

For details about how to create a partitioned table, see [Creating and Managing Partitioned Tables](#).

- Create an index.
 - Create the local index **tpcds_web_returns_p2_index1** without specifying the partition name.

```
openGauss=# CREATE INDEX tpcds_web_returns_p2_index1 ON tpcds.web_returns_p2
(ca_address_id) LOCAL;
```

If the following information is displayed, the creation is successful:

```
CREATE INDEX
```

- Create the local index **tpcds_web_returns_p2_index2** with the partition name specified.

```
openGauss=# CREATE INDEX tpcds_web_returns_p2_index2 ON tpcds.web_returns_p2
(ca_address_sk) LOCAL
```

```
(
```

```
  PARTITION web_returns_p2_P1_index,
  PARTITION web_returns_p2_P2_index TABLESPACE example3,
  PARTITION web_returns_p2_P3_index TABLESPACE example4,
  PARTITION web_returns_p2_P4_index,
```

```
PARTITION web_returns_p2_P5_index,  
PARTITION web_returns_p2_P6_index,  
PARTITION web_returns_p2_P7_index,  
PARTITION web_returns_p2_P8_index  
) TABLESPACE example2;
```

If the following information is displayed, the creation is successful:

```
CREATE INDEX
```

- Create the global index **tpcds_web_returns_p2_global_index** for a partitioned table.

```
CREATE INDEX tpcds_web_returns_p2_global_index ON tpcds.web_returns_p2  
(ca_street_number) GLOBAL;
```

- Modify the tablespace of an index partition.

- Change the tablespace of index partition **web_returns_p2_P2_index** to **example1**.

```
openGauss=# ALTER INDEX tpcds.tpcds_web_returns_p2_index2 MOVE PARTITION  
web_returns_p2_P2_index TABLESPACE example1;
```

If the following information is displayed, the modification is successful:

```
ALTER INDEX
```

- Change the tablespace of index partition **web_returns_p2_P3_index** to **example2**.

```
openGauss=# ALTER INDEX tpcds.tpcds_web_returns_p2_index2 MOVE PARTITION  
web_returns_p2_P3_index TABLESPACE example2;
```

If the following information is displayed, the modification is successful:

```
ALTER INDEX
```

- Rename an index partition.

Rename the name of index partition **web_returns_p2_P8_index** to **web_returns_p2_P8_index_new**.

```
openGauss=# ALTER INDEX tpcds.tpcds_web_returns_p2_index2 RENAME PARTITION  
web_returns_p2_P8_index TO web_returns_p2_P8_index_new;
```

If the following information is displayed, the rename operation is successful:

```
ALTER INDEX
```

- Query indexes.

- Run the following command to query all indexes defined by the system and users:

```
openGauss=# SELECT RELNAME FROM PG_CLASS WHERE RELKIND='i' or RELKIND='I';
```

- Run the following command to query information about a specified index:

```
openGauss=# \di+ tpcds.tpcds_web_returns_p2_index2
```

- Delete indexes.

```
openGauss=# DROP INDEX tpcds.tpcds_web_returns_p2_index1;  
openGauss=# DROP INDEX tpcds.tpcds_web_returns_p2_index2;
```

If the following information is displayed, the deletion is successful:

```
DROP INDEX
```

GaussDB supports four methods for creating indexes. For details, see [Table 3-3](#).

NOTE

- After an index is created, the system automatically determines when to reference it. If the system determines that indexing is faster than sequential scan, the index will be used.
- After an index is successfully created, it must be synchronized with the associated table to ensure new data can be accurately located, which increases the data operation load. Therefore, delete unnecessary indexes periodically.

Table 3-3 Indexing method

Indexing Method	Description
Unique index	An index that requires the uniqueness of an index attribute or an attribute group. If a table declares unique constraints or primary keys, GaussDB automatically creates unique indexes (or composite indexes) for columns that form the primary keys or unique constraints. Currently, unique indexes can be created only for the B-tree and UB-tree in GaussDB.
Composite index	An index that can be defined for multiple attributes of a table. Currently, the B-tree in GaussDB supports composite indexes.
Partial index	An index that can be created for subsets of a table. This indexing method contains only tuples that meet condition expressions.
Expression index	An index that is built on a function or expression calculated based on one or more attributes of a table. An expression index works only when the queried expression is the same as the created expression.

- Create an ordinary table.

```
openGauss=# CREATE TABLE tpcds.customer_address_bak AS TABLE tpcds.customer_address;  
INSERT 0 0
```

- Create an ordinary index.

For the **tpcds.customer_address_bak** table, you need to perform the following operations frequently:

```
openGauss=# SELECT ca_address_sk FROM tpcds.customer_address_bak WHERE  
ca_address_sk=14888;
```

Generally, the database system needs to scan the **tpcds.customer_address_bak** table row by row to find all matched tuples. If the size of the **tpcds.customer_address_bak** table is large but only a few (possibly zero or one) of the **WHERE** conditions are met, the performance of this sequential scan is poor. If the database system uses an index to maintain the **ca_address_sk** attribute, the database system only needs to search a few tree layers for the matched tuples. This greatly improves data query performance. Furthermore, indexes can improve the update and deletion operation performance in the database.

Run the following command to create an index:

```
openGauss=# CREATE INDEX index_wr_returned_date_sk ON tpcds.customer_address_bak  
(ca_address_sk);  
CREATE INDEX
```

- Create a unique index.

Create a unique index on the **SM_SHIP_MODE_SK** column in the **tpcds.ship_mode_t1** table.

```
openGauss=# CREATE UNIQUE INDEX ds_ship_mode_t1_index1 ON  
tpcds.ship_mode_t1(SM_SHIP_MODE_SK);
```

- Create a composite index.

Assume you need to frequently query records with **ca_address_sk** being **5050** and **ca_street_number** smaller than **1000** in the

tpcds.customer_address_bak table. Run the following commands:

```
openGauss=# SELECT ca_address_sk,ca_address_id FROM tpcds.customer_address_bak WHERE  
ca_address_sk = 5050 AND ca_street_number < 1000;
```

Run the following command to define a composite index on **ca_address_sk** and **ca_street_number** columns:

```
openGauss=# CREATE INDEX more_column_index ON  
tpcds.customer_address_bak(ca_address_sk ,ca_street_number);  
CREATE INDEX
```

- Create a partial index.

If you only want to find records whose **ca_address_sk** is **5050**, you can create a partial index to facilitate your query.

```
openGauss=# CREATE INDEX part_index ON tpcds.customer_address_bak(ca_address_sk) WHERE  
ca_address_sk = 5050;  
CREATE INDEX
```

- Create an expression index.

Assume that you need to frequently query records with **ca_street_number** smaller than **1000**, run the following command:

```
openGauss=# SELECT * FROM tpcds.customer_address_bak WHERE trunc(ca_street_number) < 1000;
```

The following expression index can be created for this query task:

```
openGauss=# CREATE INDEX para_index ON tpcds.customer_address_bak (trunc(ca_street_number));  
CREATE INDEX
```

- Delete the **tpcds.customer_address_bak** table.

```
openGauss=# DROP TABLE tpcds.customer_address_bak;  
DROP TABLE
```

3.2.6.4 Creating and Managing Views

Context

If some columns in one or more tables in a database are frequently searched for, an administrator can define a view for these columns, and then users can directly access these columns in the view without entering search criteria.

A view is different from a base table. It is only a virtual object rather than a physical one. Only view definition is stored in the database and view data is not. The data is stored in a base table. If data in the base table changes, the data in the view changes accordingly. In this sense, a view is like a window through which users can know their interested data and data changes in the database. A view is triggered every time it is referenced.

Managing Views

- Create a view.

Create the **MyView** view. In the command, **tpcds.web_returns** indicates the created user table that contains the **wr_refunded_cash** integer column.

```
openGauss=# CREATE OR REPLACE VIEW MyView AS SELECT * FROM tpcds.web_returns WHERE  
trunc(wr_refunded_cash) > 10000;  
CREATE VIEW
```

NOTE

The **OR REPLACE** parameter in this command is optional. It indicates that if the view exists, the new view will replace the existing view.

- Query a view.

Run the following command to query **MyView**:

```
openGauss=# SELECT * FROM MyView;
```

- View details about a specified view.

Run the following command to view details about **MyView**:

```
openGauss=# \d+ MyView
```

```
View "PG_CATALOG.MyView"
Column |      Type      | Modifiers | Storage | Description
-----+-----+-----+-----+-----
USERNAME | CHARACTER VARYING(64) |          | extended |
View definition:
SELECT PG_AUTHID.ROLNAME::CHARACTER VARYING(64) AS USERNAME
FROM PG_AUTHID;
```

- Delete a view.

Run the following command to delete **MyView**:

```
openGauss=# DROP VIEW MyView;
DROP VIEW
```

3.2.6.5 Creating and Managing Sequences

Background

A sequence is a database object that generates unique integers. Sequence numbers are generated according to a certain rule. Sequences are unique because they increase automatically. This is why they are often used as primary keys.

You can create a sequence for a column in either of the following methods:

- Set the data type of a column to **sequence integer**. A sequence will be automatically created by the database for this column.
- Run the **CREATE SEQUENCE** statement to create a sequence. Set the initial value of the **nextval('sequence_name')** function to the default value of a column.

Procedure

Method 1: Set the data type of a column to a sequence integer. For example:

```
openGauss=# CREATE TABLE T1
(
    id serial,
    name text
);
```

If the following information is displayed, the creation is successful:

```
CREATE TABLE
```

Method 2: Create a sequence and set the initial value of the **nextval('sequence_name')** function to the default value of a column.

1. Create a sequence.

```
openGauss=# CREATE SEQUENCE seq1 cache 100;
```

If the following information is displayed, the creation is successful:

```
CREATE SEQUENCE
```

2. Set the default value of a column so that the column has a unique identification attribute.

```
openGauss=# CREATE TABLE T2
(
```

```
id int not null default nextval('seq1'),  
name text  
);
```

If the following information is displayed, the default value has been specified:

```
CREATE TABLE
```

3. Associate the sequence with a column.

Associates a sequence with a specified column included in a table. In this way, the sequence will be deleted when you delete its associated column or the table where the column belongs to.

```
openGauss=# ALTER SEQUENCE seq1 OWNED BY T2.id;
```

If the following information is displayed, the configuration is successful:

```
ALTER SEQUENCE
```

NOTE

The preceding methods are similar, except that the second method specifies cache for the sequence. A sequence having cache defined has inconsecutive values (such as 1, 4, and 5) and cannot maintain the order of its values. After the dependent column of a sequence has been specified, once the sequence is deleted, the sequence of the dependent will be deleted. A sequence shared by multiple columns is not forbidden in a database, but you are not advised to do that.

In the current version, you can specify the auto-increment column or set the default value of a column to **nextval('seqname')** when defining a table. You cannot add an auto-increment column or a column whose default value is **nextval('seqname')** to an existing table.

3.2.6.6 Creating and Managing Scheduled Jobs

Context

Time-consuming jobs, such as summarizing statistics or synchronizing data from another database, affect service performance if they are performed during the daytime and incur overtime hours if performed at night. To solve this problem, GaussDB Kernel is compatible with the scheduled job function in the A database. You can create scheduled jobs that are automatically triggered to reduce O&M workload.

This function calls APIs provided by the DBE_TASK package to create scheduled jobs, execute jobs automatically, delete jobs, modify job attributes (including job ID, the enabled/disabled status of a job, job triggering time, triggering interval, and job content), and implement other functions.

Managing Scheduled Jobs

Step 1 Create a test table.

```
openGauss=# CREATE TABLE test(id int, time date);
```

If the following information is displayed, the creation is successful:

```
CREATE TABLE
```

Step 2 Create a user-defined stored procedure.

```
openGauss=# CREATE OR REPLACE PROCEDURE PRC_JOB_1()  
AS  
N_NUM integer :=1;  
BEGIN
```

```
FOR I IN 1..1000 LOOP
INSERT INTO test VALUES(I,SYSDATE);
END LOOP;
END;
/
```

If the following information is displayed, the creation is successful:

```
CREATE PROCEDURE
```

Step 3 Create a job.

- Create a job with unspecified **job_id** and execute the **PRC_JOB_1** stored procedure every minute.

```
openGauss=# call db_task.submit('call public.prc_job_1(); ', sysdate, 'interval "1 minute"', :a);
id
-----
1
(1 row)
```

- Specify **job_id** to create a job. The value of **job_id** ranges from 1 to 32767.

```
openGauss=# call db_task.id_submit(1,'call public.prc_job_1(); ', sysdate, 'interval "1 minute"');
id_submit
-----
(1 row)
```

Step 4 View details of jobs created by the current user.

```
openGauss=# select job,dbname,start_date,last_date,this_date,next_date,broken,status,interval,failures,what
from my_jobs;
 job | dbname | start_date | last_date | this_date | next_date | broken | status | interval | failures | what
-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----
1 | testdb | 2017-07-18 11:38:03 | 2017-07-18 13:53:03.607838 | 2017-07-18 13:53:03.607838 | 2017-07-18 13:54:03 | n | s | interval '1 minute' | 0 | call public.prc_job_1();
(1 row)
```

Step 5 Stop the job.

```
openGauss=# call db_task.finish(1,true);
finish
-----
(1 row)
```

Step 6 Start a job.

```
openGauss=# call db_task.finish(1,false);
finish
-----
(1 row)
```

Step 7 Modify job attributes.

- Modify the **next_time** parameter information about the job.

-- Set **next_time** of **Job1** to 1 hour so that **Job1** will be executed in one hour.

```
openGauss=# call db_task.next_time(1, sysdate+1.0/24);
next_time
-----
(1 row)
```

- Modify the **Interval** parameter of the job.

-- Set **Interval** of **Job1** to 1 hour so that **Job1** will be executed every one hour.

```
openGauss=# call db_task.interval(1,'sysdate + 1.0/24');
interval
-----
(1 row)
```

- Modify the **What** parameter of the job.
-- Set **What** to **insert into public.test values(333, sysdate+5);** for **Job1**.
openGauss=# call db_task.content(1,'insert into public.test values(333, sysdate+5);');
content

(1 row)
- Modify **Next_date**, **Interval**, and **What** parameters of the job.
openGauss=# call db_task.update(1, 'call public.prc_job_1();', sysdate, 'interval "1 minute"');
update

(1 row)

Step 8 Remove the job.

```
openGauss=# call db_task.cancel(1);
cancel
-----
(1 row)
```

Step 9 View the job execution status.

If a job fails to be automatically executed (that is, the value of **job_status** is 'f'), contact the administrator to view the gs_log run log to view the failure information of the job.

From **detail error msg**, you can see the failure causes.

```
LOG: Execute Job Detail:
     job_id: 1
    what: call public.test();
 start_date: 2017-07-19 23:30:47.401818
 job_status: failed
detail error msg: relation "test" does not exist
 end_date: 2017-07-19 23:30:47.401818
next_run_date: 2017-07-19 23:30:56.855827
```

Step 10 Set job permissions.

- During the creation of a job, the job is bound to the user and database that created the job. Accordingly, the user and database are added to **dbname** and **log_user** columns in the pg_job system catalog, respectively.
- If the current user is a database administrator, system administrator, or the user (**log_user** in pg_job) who created the job, the user has permissions to delete or modify job parameters using the **remove**, **change**, **next_data**, **what**, or **interval** parameter. Otherwise, the system displays a message indicating that the user has no permissions to perform operations on this job.
- If the current database is the one that created a job (that is, **dbname** in pg_job), you can delete or modify parameter settings of the job using the **cancel**, **update**, **next_data**, **content**, or **interval** parameter.
- When deleting the database that created a job (that is, **dbname** in pg_job), the system automatically deletes the job records of the database.
- When deleting the user who created a job (that is, **log_user** in pg_job), the system automatically deletes the job records of the user.

Step 11 Manage job concurrency.

You can configure the GUC parameter **job_queue_processes** to adjust the number of jobs running at the same time.

- Setting **job_queue_processes** to **0** indicates that the scheduled job function is disabled and no job will be executed.
- Setting **job_queue_processes** to a value that is greater than 0 indicates that the scheduled job function is enabled and this value is the maximum number of jobs that can be concurrently executed.

Too many concurrent jobs consume many system resources, so you need to set the number of concurrent jobs to be processed. If the current number of concurrent jobs reaches the value of **job_queue_processes** and some of them expire, these jobs will be postponed to the next polling period. Therefore, you are advised to set the polling interval (the **Interval** parameter of the submit API) based on the execution duration of each job to avoid the problem that jobs in the next polling period cannot be properly processed because of overlong job execution time.

Note: For database instances that do not use jobs, set **job_queue_processes** to **0** to disable the job function to reduce the resource consumption.

----End

4 Development and Design Proposal

4.1 Overview

Introduction

This document describes the database-related design and development specifications in the product design and development process based on the product lifecycle.

This document aims to improve the readability and code quality, and emphasizes the practicability and operability. It specifies the issues that may occur during the database development. The specifications are as follows:

Design specifications in terms of database and performance

Programming specifications in terms of typesetting, naming, comments, syntax, scripts, database programming, installation and deployment, and security

In addition, detailed rules and specific examples are provided for some specifications if necessary.

The development specifications are for reference only. The specific specifications should be comprehensively evaluated and implemented by database users based on the application technical architecture and planning.

Terms

This document uses the following terms for description:

- **Specification:** database specification, which must be complied with during programming and design. Otherwise, the database reports an error.
- **Rule:** a convention that must be followed during programming and design.
- **Recommendation:** a convention that must be considered during programming and design.
- **Description:** explanation of the rule or recommendation in question.
- **Example:** a positive or negative example of the rule or recommendation.

Applicability

This document is intended for designers, developers, development database administrators (DBAs), operation and maintenance (O&M) DBAs, and O&M personnel.

4.2 Database Design Specifications

4.2.1 General Specifications

- [Rule] Database valuable features

Table 4-1 Recommended database valuable features

Category	Feature List	Description
Table type	Partitioned table	Data partitioning.
Storage engine	Row store	Stores tables by row, which is recommended in the point query and a scenario with many add, delete, and alter operations.
Transaction	Transaction block	Explicitly starts a transaction.
	Single-statement transaction	Does not explicitly start a transaction. A single statement is a transaction.
Deployment	One primary and multiple standby DN	One primary DN and multiple standby DNs, ensuring data backup and disaster recovery.
Security	Transparent data encryption	Supports database-level storage encryption. Upper-layer services are unaware of the encryption.
Data type	Integer	TINYINT, SMALLINT, INTEGER, and BIGINT
	Arbitrary-precision	NUMERIC/DECIMAL
	Floating-point	REAL/FLOAT4, DOUBLE PRECISION/FLOAT8, and FLOAT
	Boolean	Boolean
	Fixed-length character	CHAR(n)
	Variable-length character	VARCHAR(n), NVARCHAR2(n), and TEXT
	Time	DATE, TIME, TIMETZ, TIMESTAMP, TIMESTAMPTZ, SMALLDATETIME, INTERVAL, and REALTIME

Category	Feature List	Description
	Binary	BYTEA (variable-length binary)
	Bit string	BIT(n) and VARBIT(n)
Function	String function	String data type processing function.
	Binary string function	Binary string type processing function.
	Numeric operation function	Numeric type processing function.
	Time and date processing function	Time and date type processing function.
Index	Primary key or unique index	Single-column or multi-column primary key or unique index.
	B-tree index	Index type.

- [Rule] Recommended best practices for database usage

Table 4-2 Recommended best practices for database usage

No.	Item	Recommended Value
1	Optimal number of long connections to the database	For details, see the default configuration of GUC parameter max_connections in the corresponding hardware specifications.
2	Maximum data volume on a single physical node	16 TB (Determine the capacity based on the backup and restoration specifications.)
3	Number of active databases	1
4	Total number of database tables and indexes	10000 (It is recommended that the number of tables in a single schema be less than or equal to 200.) NOTE The value is only a recommended value. You need to plan the value based on the disk capacity and customer services. Theoretically, the maximum value is 2^{32} .

No.	Item	Recommended Value
5	Optimal number of columns in a single table	< 50
6	Optimal number of indexes in a table	< 5
7	Optimal number of composite indexes in a table	< 3
8	Optimal number of columns in a single composite index	< 5
9	Optimal width of a single row	< 2000
10	Optimal capacity of a single column	< 10 MB
11	Optimal SQL statement length	< 5000
12	Percentage of available disk space	85% (If the disk capacity is greater than 24 TB, 90% is recommended.)

4.2.2 Deployment Specifications

[Rule] After a database is installed, DBA must configure the database GUC parameters properly based on the environment features.

4.2.3 Database Object Naming Specifications

- [Specification] Do not use reserved or non-reserved keywords to name database objects.

You can run the following command to query the database keyword, or view it in the [Keywords](#) section:

```
SELECT * FROM pg_get_keywords();
```

- [Specification] The database object name contains a maximum of 63 bytes.

Table 4-3 Restriction on the length of database object names

Object Type	Length Restriction (Unit: Byte)	Remarks
Database name	≤ 63	-
Table name	≤ 63	-
Table object	≤ 63	If the length of a table name exceeds this value, the kernel truncates the table name. As a result, the actual name is inconsistent with the configured value. In addition, characters may be truncated in different character sets and unexpected characters may appear.
Temporary table not used by services	≤ 63	For example, an intermediate table used by operation personnel for temporary backup or data collection. Naming rule: tmp_Table name abbreviation_Creator account abbreviation_Creation date , for example, tmp_user_ytw_160505 .
Table column	≤ 63	Meaningful English words or abbreviations are used to name the column. For example, a column of the bool type is named in the format of is_Description . A column whose member status is enabled in the member table is named is_enabled .
View name and column name	≤ 63	-
Function name and parameter name	≤ 63	-

- [Rule] Do not use a string enclosed in double quotation marks (") to define the database object name, unless you must specify its capitalization.
 - By default, GaussDB is case-insensitive for object names in SQL statements. If two different tables (**t_Table** and **t_table**) exist in the same database, use double quotation marks ("). Otherwise, avoid using double quotation marks (").
 - Case sensitivity of database object names makes fault locating difficult.
- [Rule] Identifiers must meet the following requirements:
 - An identifier starts with a letter or underscore (_) and can contain letters, digits, underscores (_), dollar signs (\$), and number signs (#).

- If an identifier is enclosed in backquotes (``) in B-compatible mode or double quotation marks (""), any combination of valid characters can be used, for example, "123gs_column".
 - Identifiers are case-insensitive. They are case-sensitive only when they are enclosed in backquotes (``) in B-compatible mode or double quotation marks ("").
- [Recommendation] Do not use a string enclosed in double quotation marks (") to define the database object name, unless you need to specify its capitalization. Case sensitivity of database object names makes fault locating difficult.
- [Recommendation] Use the same naming style for database objects.
 - In a system undergoing incremental development or service migration, you are advised to comply with its historical naming conventions.
 - You are advised to use multiple words separated with underscores (_).
 - You are advised to use intelligible names and common acronyms or abbreviations for database objects. For example, you can use English words or Chinese pinyin indicating actual business terms. The naming format should be consistent within a database instance.
 - A variable name must be descriptive and meaningful. It must have a prefix indicating its type.
- [Recommendation] The name of a table object should indicate its main characteristics, for example, whether it is an ordinary, temporary, or unlogged table.
 - An ordinary table name should indicate the business relevant to a data set.
 - Temporary tables are named in the format of **tmp_Suffix**.
 - Unlogged tables are named in the format of **ul_Suffix**.
 - Do not create database objects whose names start with **redis_**.
 - Do not create database objects whose names start with **mlog_** or **matviewmap_**.

4.2.4 Database and Schema Design Specifications

- [Description] When you create a database, exercise caution when you set **ENCODING** and **DBCOMPATIBILITY** configuration items. GaussDB supports the A, B, C, and PG compatibility modes, which are compatible with the syntax of Oracle Database, MySQL, Teradata, and Postgres, respectively. The syntax behavior varies according to the compatibility mode. By default, the A compatibility mode is used.
- [Description] By default, a database owner has all permissions for all objects in the database, including the deletion permission. Exercise caution when deleting a permission.
- [Description] To let a user access an object in a schema, assign the usage permission and the permissions for the object to the user, unless the user has the SYSADMIN permission or is the schema owner.
- [Description] To let a user create an object in the schema, grant the CREATE permission for the schema to the user.

- [Description] By default, a schema owner has all permissions for all objects in the schema, including the deletion permission. Exercise caution when deleting a permission.
- [Specification] The database name must be specified when the JDBC client is used to connect to the database. The format is as follows:
`jdbc:postgresql://ip:port/database_name`

NOTICE

Once a JDBC instance is created, the database cannot be switched.

-
- [Specification] The database does not support case-insensitive collation.
 - [Rule] Before using services, a system administrator must create databases, schemas, and users for services, and then grant object permissions to corresponding users.
 - [Rule] Create a service database before using a service. Do not use the Postgres database created by default after the database is installed to store service data. You are advised to create your own database based on service requirements.
 - [Rule] When creating a database, you must set the character set to **UTF8** and must select the character set that is the same as that of the client.

To meet globalization requirements, database encoding should store and identify most characters. Therefore, UTF8 is recommended. The UTF-8 character set is equivalent to the utf8mb4 character set in MySQL databases and supports emoji.

If the encoding mode of the client is different from that of the database, transcoding is required, affecting performance. In addition, kernel optimization for the same encoding cannot be triggered, affecting the query efficiency.

To change the character set of the client, perform the following steps:

- Set client connection parameters. Take JDBC as an example. Add the parameters **characterEncoding** and **allowEncodingChanges** to the URL.
`jdbc:postgresql://ip:port/database_name?characterEncoding=utf8&allowEncodingChanges=true`
- Modify the database GUC parameter.
`SET client_encoding = 'UTF8';`

Set the database encoding when executing **CREATE DATABASE**.

`CREATE DATABASE tester WITH ENCODING = 'UTF8';`

NOTICE

The character set cannot be changed once the database is created.

-
- [Recommendation] In a database instance, it is recommended that the number of user-defined databases be 3 and no more than 10. If there are too many user-defined databases, O&M operations, such as upgrade and backup, will be inefficient.
 - [Recommendation] It is recommended that the number of schemas in the actual user environment be no more than 100. If there are too many schemas

in a database, operations that depend on the number of schemas, such as `gs_dump`, becomes slow.

- [Recommendation] You are advised to use schemas to isolate services for convenience and resource sharing.

Both database and schema can be used to isolate services . Differences are as follows:

- Databases share few resources. Connections to and permissions on them are also isolated. However, the databases cannot access each other. The database must be specified during JDBC connection establishment. After the connection is established, the database cannot be switched.
 - Schemas share more resources than databases do. User permissions on schemas and subordinate objects can be controlled over the GRANT and REVOKE syntax.
- [Recommendation] You are advised to specify **LC_CTYPE** and **LC_COLLATE** when creating a database. These parameters will affect the data collation sequence.

Example:

```
CREATE DATABASE SAMPLE_DB WITH LC_CTYPE = 'zh_CN.gbk' LC_COLLATE = 'zh_CN.gbk';
```

4.2.5 Permission Design Specifications

- [Rule] The initial database user can only connect and access a database for DBA management. Services are not allowed to directly log in as this user to connect to and access the database.

NOTE

Initial database user, that is, the database installation user, which has the same name as the OS user to which the database belongs.

- [Rule] The initial database user creates a database and users for services. Services use the created users to log in to and access the database.

- [Rule] Assign permissions to roles and users based on the least privilege principle.

- [Recommendation] Manage permissions by roles instead of users.

Use roles to manage permissions, that is, configure permissions for roles and grant the roles to users.

Roles facilitate permission management in scenarios such as multiple users and user changes. Example:

- Roles and users are in many-to-many relationship. A role can be granted to multiple users. If permissions of a role are modified, the permissions of the granted users can be updated at the same time.
 - Deleting a user does not affect the role.
 - A new user can quickly obtain required permissions by granting a role to the user.
- [Recommendation] When deleting a specified database, revoke the CONNECT permission of users on the database to prevent deletion failures caused by active database connections.

4.2.6 Character Set Design Specifications

- [Specification] Currently, character sets can be defined only for databases.
- [Recommendation] The database and client use the same UTF-8 character set.
 - Clients include ODBC, JDBC, and GSQL.
 - For reasons, see [Database and Schema Design Specifications](#).

4.2.7 Table Design Specifications

- [Rule] View nesting is not recommended.
 - On the one hand, if a wildcard is used when a view is written, an error occurs in the view when a column is added to or deleted from the called view.
 - On the other hand, view nesting may be inefficient because indexes cannot be used. You are advised to use base tables with indexes instead of performing join operations on views.
- [Recommendation] Try to avoid collation operations when defining a view. ORDER BY is invalid in the top-level view. If you must collate the output data, use ORDER BY in a called view.
- [Recommendation] Minimize random I/Os. Through clustering, you can sequentially store hot data, converting random I/O to sequential I/O to reduce the cost of I/O scanning.

Selecting a Storage Model

[Recommendation] Selecting a storage model is the first step in defining a table. The storage model mainly depends on the customer's service type. For details, see [Table 4-4](#).

Table 4-4 Table storage models and scenarios

Storage Model	Application Scenario
Row store	• Point queries (simple index-based queries that only return a few records). • Scenarios requiring frequent addition, deletion, and modification

Selecting a Partitioning Mode

Comply with the following rules to partition a table containing a large amount of data:

- [Rule] Select a proper partition scheme for large data tables.
Currently, RANGE PARTITION, LIST PARTITION, and HASH PARTITION partitioning methods are provided. Note the following principles during partitioning:

- You are advised to use interval columns, such as date and area, for partitioning.
- The upper boundary value of a range partition must be set to **MAXVALUE** to prevent data overflow.
- The partition name must reflect the data features of the partition. For example, the partition name can be in the format of *keyword+interval feature*.
- [Recommendation] It is recommended that the number of partitions be less than or equal to 100, the data volume of a single partition be less than or equal to 50 million, and the data capacity of a single partition be less than or equal to 50 GB.
- [Description] Reduce the amount of data to be scanned. You can use the pruning mechanism of a partitioned table.
- [Recommendation] Create partitions on columns that indicate certain ranges, such as dates and regions.
- [Recommendation] A partition name should show the data characteristics of a partition. For example, its format can be *Keyword+Range* characteristics.
- [Recommendation] Set the upper limit of a partition to **MAXVALUE** to prevent data overflow.

Table 4-5 Table partitioning modes and scenarios

Partitioning Mode	Description
Range	Table data is partitioned by range.
Interval	Table data is partitioned by range. If the data exceeds the range, a new partition is automatically created based on the interval.
List	Table data is partitioned by a specified column based on a specific value.
Hash	Table data is partitioned by hash.

The example of defining a partitioned table is as follows:

```
-- Create a range partitioned table.
CREATE TABLE staffS_p1
(
  staff_ID    NUMBER(6) not null,
  FIRST_NAME  VARCHAR2(20),
  LAST_NAME   VARCHAR2(25),
  EMAIL       VARCHAR2(25),
  PHONE_NUMBER VARCHAR2(20),
  HIRE_DATE   DATE,
  employment_ID VARCHAR2(10),
  SALARY      NUMBER(8,2),
  COMMISSION_PCT NUMBER(4,2),
  MANAGER_ID  NUMBER(6),
  section_ID  NUMBER(4)
)
PARTITION BY RANGE (HIRE_DATE)
(
  PARTITION HIRE_19950501 VALUES LESS THAN ('1995-05-01 00:00:00'),
  PARTITION HIRE_19950502 VALUES LESS THAN ('1995-05-02 00:00:00'),
```

```
PARTITION HIRE_maxvalue VALUES LESS THAN (MAXVALUE)
);

-- Create an interval partitioned table. The table has two initial partitions. When data that is not in
the partition range is inserted, another partition is automatically added.
CREATE TABLE sales
(prod_id NUMBER(6),
 cust_id NUMBER,
 time_id DATE,
 channel_id CHAR(1),
 promo_id NUMBER(6),
 quantity_sold NUMBER(3),
 amount_sold NUMBER(10,2)
)
PARTITION BY RANGE (time_id)
INTERVAL('1 day')
( PARTITION p1 VALUES LESS THAN ('2019-02-01 00:00:00'),
  PARTITION p2 VALUES LESS THAN ('2019-02-02 00:00:00')
);

-- Create a list partitioned table.
CREATE TABLE test_list (col1 int, col2 int)
partition by list(col1)
(
 partition p1 values (2000),
 partition p2 values (3000),
 partition p3 values (4000),
 partition p4 values (5000)
);

-- Create a hash partitioned table.
CREATE TABLE test_hash (col1 int, col2 int)
partition by hash(col1)
(
 partition p1,
 partition p2
);
```

For details about the table partition syntax, see [CREATE TABLE PARTITION](#).

4.2.8 Column Design Specifications

- [Rule] Use recommended data types for column design.
Recommended data types must be used for column design. If you want to use prohibited or unrecommended data types, contact database experts for evaluation. Some data types are not recommended because they apply to limited service scenarios and are not used on a large scale for commercial purposes.

Table 4-6 Best practices for database data types

Data Type	Description	Recommended or Not
UUID	Different databases may generate the same UUID.	Prohibited
Serial integer	Auto-increment column, including SMALLSERIAL, SERIAL, and BIGSERIAL.	Prohibited
Integer	TINYINT, SMALLINT, INTEGER, and BIGINT	Recommended

Data Type	Description	Recommended or Not
Arbitrary-precision	NUMERIC/DECIMAL	Recommended
Floating-point	REAL/FLOAT4, DOUBLE PRECISION/FLOAT8, and FLOAT	Recommended
Boolean	Boolean	Recommended
Fixed-length character	CHAR(<i>n</i>)	Recommended
Variable-length character	VARCHAR(<i>n</i>) and NVARCHAR2(<i>n</i>)	Recommended
	TEXT and CLOB (character large object)	Not recommended
Time	DATE, TIME, TIMESTAMP, SMALLDATETIME, INTERVAL, and REALTIME	Recommended
	TIMETZ and TIMESTAMPTZ	Not recommended
Binary	BYTEA (variable-length binary)	Recommended
	BLOB (binary large object), and RAW (variable-length hexadecimal string)	Not recommended
Bit string	BIT(<i>n</i>) and VARBIT(<i>n</i>)	Recommended
Special character	NAME and "CHAR" are usually used within the database system.	Not recommended
JSON	JSON data does not support operators.	Not recommended
User-defined	Defines enumerated types.	Not recommended
HLL	You are advised to use the HLL functions to reduce the impact on performance.	Not recommended
Currency	The MONEY type stores a currency amount with fixed fractional precision.	Not recommended
Geometric	POINT, LSEG, BOX, PATH, POLYGON, and CIRCLE	Not recommended

Data Type	Description	Recommended or Not
Network address	Stores IPv4 and MAC addresses.	Not recommended

- [Rule] Use the most specific numeric data types. If all of the following numeric types provide the required service precision, they are recommended in descending order of priority: integer, floating-point number, and numeric.
- [Rule] Properly set the data type of a numeric column based on the value range, and use the NUMERIC or DECIMAL type as less as possible. NUMERIC and DECIMAL are equivalent. NUMERIC or DECIMAL data operations consume great CPU resources.

Table 4-7 Storage space and value range of numeric data types

Type	Storage Size (Unit: Byte)	Minimum Value	Maximum Value
TINYINT	1	0	255
SMALLINT	2	-32768	32767
INTEGER	4	-2147483648	2147483647
BIGINT	8	-9223372036854775808	9223372036854775807
REAL/FLOAT4	4	6-bit decimal digits	
DOUBLE PRECISION/FLOAT8	8	15-bit decimal digits	

- [Rule] Select a proper string type. If the value of a column must be a fixed-length character, use fixed-length character types or automatically add spaces. Otherwise, use the variable-length character type VARCHAR.
For a typical fixed-length column, for example, **gender**, you can enter only **f** or **m** that occupies a byte. You are advised to use the fixed-length data type (for example, CHAR(*n*)) for this type of columns.
If such requirement does not exist or longer characters may be required for future expansion, use variable-length character types (such as VARCHAR and TEXT) preferentially. You are advised not to specify the length of variable-length characters.
The reasons are as follows:
 - For fixed-length columns, the input data that is shorter than the fixed length will be padded with space characters and then be saved to the database. This wastes the storage space in the database.

- For fixed-length character types, the entire table needs to be scanned and rewritten if the length needs to be extended later. This causes high performance overhead and affects online services.
- For a variable-length column with a fixed length, the system checks whether the length exceeds the limit each time upon data insertion. This causes performance overhead.
- [Rule] Do not store data of the numeric type in columns of the character type.
If numeric calculation or comparison (for example, adding a filter condition) is performed on data stored in columns of the character type, unnecessary overhead will be caused due to data type conversion, and the column indexes may become invalid, affecting query performance.
- [Rule] Do not store data of the time or date type in columns of the character type.
If calculation or comparison (for example, adding a filter condition) with data of the time or date type is performed on data stored in columns of the character type, unnecessary overhead will be caused by data type conversion, and the column indexes may become invalid, affecting query performance.
- [Rule] Add NOT NULL constraints to columns that never have NULL values.
In certain scenarios, the optimizer may specially optimize non-**NULL** columns to improve query performance.
- [Rule] Use the same data type for joined columns.
If the column types are inconsistent during a join operation, overhead will be caused by data type conversion.
- [Recommendation] In tables that are logically related, columns having the same meaning should use the same data type.
- [Recommendation] For string data, you are advised to use variable-length strings and specify the maximum length. To avoid truncation, ensure that the specified maximum length is greater than the maximum number of characters to be stored. You are advised not to use CHAR(n), BPCHAR(n), NCHAR(n), or CHARACTER(n), unless you know that the string length is fixed.
- [Rule] The number of long columns, such as VARCHAR(1000) and VARCHAR(4000), does not exceed 8.
- [Recommendation] When defining a column, you are advised to create a comment for the column to facilitate subsequent maintenance.
For details about the description, value range, and usage of different types of fields, see [Data Type](#).
- [Recommendation] Add NOT NULL constraints to columns that are used for WHERE filtering and join operations.
In certain scenarios, the optimizer may specially optimize non-**NULL** columns to greatly improve query performance.
- [Recommendation] Do not reserve columns for a table. In most cases, you can quickly add or delete table columns, or change the default values of columns.
An added column must meet the following requirements. Otherwise, the entire table is updated, leading to additional overheads and affecting online services.

- The data type is BOOL, BYTEA, SMALLINT, BIGINT, SMALLINT, INTEGER, NUMERIC, FLOAT, DOUBLE PRECISION, CHAR, VARCHAR, TEXT, TIMESTAMPTZ, TIMESTAMP, DATE, TIME, TIMETZ, or INTERVAL.
- The length of the default value cannot exceed 128 bytes.
- The default value of the added column does not contain the volatile function.
- The default value is required and cannot be **NULL**.

If you are not sure whether the third condition is met, contact GaussDB technical support for evaluation.

4.2.9 Index Design Specifications

- [Specification] Use the index types in the recommended database index practices.

NOTE

Recommended types must be used for index design. If you need to use prohibited, unrecommended, or restricted index types, contact database experts for advice.

Table 4-8 Recommended database index practices

Index Type	Description	Recommended or Not
Primary key or unique index	Single-column or multi-column primary key or unique index.	Recommended
Global index	Index organization method.	Recommended for some data types
Expression index	An index column is a function or scalar expression calculated from one or multiple columns in a table.	Restricted
B-tree index	Index building type.	Recommended for some data types

- [Rule] Properly design composite indexes to avoid redundancy.
For example, if an index has been created for **(a, b, c)**, you shall not create an index for **(a)**, **(b)**, **(c)**, **(a, b)**, or **(b, c)** independently. If only the filtering condition of the **a** column is used for a query, composite indexes are used for the query as well.
- [Rule] A composite index contains a maximum of 5 columns.
- [Rule] A composite index contains a maximum of 200 characters.
- [Rule] Index (including single-column and composite indexes) columns must be **NOT NULL**.
- [Rule] Do not create multiple unique indexes for a single table.

Maintaining multiple unique indexes at the same time generates more overheads than maintaining a multi-column unique index. If multiple unique indexes are equivalent to a multi-column unique index in service logic, a multi-column unique index shall be preferred.

- [Recommendation] The efficiency of maintaining indexes created for the same column is different. Columns of the number type are better than those of the character type and other data types. Therefore, it is recommended that columns such as IDs and time for creating indexes be stored as data of the number type.
- [Recommendation] Create indexes on joined columns.

Hash join is supported, whereas nested loop join may be used for join operations if the rescan cost is low (for example, the inner table is small). If the **NESTLOOP JOIN** plan can be viewed by executing **EXPLAIN**, you can create indexes on joined columns to improve the efficiency of executing **NESTLOOP JOIN**.

4.2.10 Function/Stored Procedure Design Specifications

- [Rule] Do not use stored procedures or triggers to implement service logic. Instead, process the logic on the service server to prevent logical dependency on the database.
- [Rule] Do not use stored procedures to implement the upgrade logic in the database upgrade scripts of a service.
- [Rule] Create functions that have fixed return values for fixed input parameters and set the function type to **IMMUTABLE** or **SHIPPABLE**.

Currently, the database supports three types of functions: **IMMUTABLE**, **STABLE**, and **VOLATILE**.

If the attribute of an **IMMUTABLE** function is set to **SHIPPABLE**, the function can be executed on DNs. In most scenarios, such functions perform efficiently. However, such functions require fixed return values for fixed input parameters to ensure that the functions are correctly executed on DNs. If the function execution result depends on the table scan result (for example, maximum value of a column in the table) or scan time (for example, current time), set the function type to **STABLE** or **VOLATILE**, and set the function attribute to **NOT SHIPPABLE** to ensure that the function is correctly executed.

4.2.11 Constraint Design

DEFAULT and NULL Constraints

- [Recommendation] If all the column values can be obtained from services, you are advised not to use the **DEFAULT** constraint. Otherwise, unexpected results will be generated during data loading.
- [Recommendation] Add **NOT NULL** constraints to columns that never have **NULL** values. The optimizer automatically optimizes the columns in certain scenarios.
- [Recommendation] Explicitly name all constraints excluding **NOT NULL** and **DEFAULT**.

Unique Constraints

- [Description] Row-store tables support UNIQUE constraints.
- [Recommendation] The constraint name should indicate that it is a unique constraint, for example, **UNI***Included columns*.

Primary Key Constraints

- [Description] Row-store tables support PRIMARY KEY constraints.
- [Recommendation] The constraint name should indicate that it is a primary key constraint, for example, **PK***Column name*.

Check Constraints

- [Description] Row-store tables support CHECK constraints.
- [Recommendation] The constraint name should indicate that it is a check constraint, for example, **CK***Column name*.

4.2.12 View and Joined Table Design

View Design

- [Proposal] Do not nest views unless they have strong dependency on each other.
- [Proposal] Try to avoid collation operations in a view definition.

Joined Table Design

- [Proposal] Minimize joined columns across tables.
- [Proposal] Use the same data type for joined columns.
- [Proposal] The names of joined columns should indicate their relationship. For example, they can use the same name.

4.3 Database Design Specifications

4.3.1 GUC Parameter Programming Specifications

- [Rule] Clients (such as JDBC) should use default parameters for query. If session-level GUC parameters need to be modified, exercise caution when performing this operation.

When modifying GUC parameters through ODBC or JDBC, note that the GUC parameters take effect only in the current connection. Especially in the connection pool scenario, problems may occur and cause difficulty in locating problems.

If the GUC parameters must be set in a connection, you must use the following statements before releasing the connection to the connection pool:

```
SET SESSION AUTHORIZATION DEFAULT;  
RESET ALL;
```

Clear the connection status.

4.3.2 Object Access Programming Specifications

- [Rule] When operating an object, a user should have the operation permission on the object.

For details about the permission description, see [Users and Permissions](#) and comply with [Permission Design Specifications](#).

- [Rule] Use *schemaname.tablename* to access objects (such as tables and functions).

If the schema name prefix is not added, the system searches all tablespaces in the current **search_path** until a matched table is found, which causes unnecessary performance overhead.

4.3.3 WHERE

- [Rule] Do not compare the same table columns in WHERE conditions.

For example, the following statement does not meet specifications:

```
SELECT * FROM t1 WHERE col1 = col1;
```

The following modification should be considered:

```
SELECT * FROM t1 WHERE col1 IS NOT NULL;
```

- [Rule] Do not include implicit data type conversion in WHERE conditions.

After implicit conversion is performed in the database, the created index may fail to be used.

You are advised to enable the GUC parameter **check_implicit_conversions** and disable **enable_fast_query_shipping** during development to check whether query statements contain implicit data types that may affect performance.

```
SET enable_fast_query_shipping = off;  
SET check_implicit_conversions = true;
```

Implicit data type conversion check requires extra overhead. After the query statement is developed, disable the **check_implicit_conversions** parameter and reset **enable_fast_query_shipping**.

Example:

- The following lines of code do not meet specifications:

```
-- The phonenumber column in the t_tablename table is of the VARCHAR type instead of the numeric type.
```

```
SELECT column1  
  INTO i_l_variable1  
  FROM t_tablename  
 WHERE phonenumber = 13512345678;
```

- The following modification should be considered:

```
-- The phonenumber column in the t_tablename table is of the VARCHAR type instead of the numeric type.
```

```
SELECT column1  
  INTO i_l_variable1  
  FROM t_tablename  
 WHERE phonenumber = '13512345678';
```

- [Rule] Do not use expressions or functions in WHERE condition columns.

When expressions or functions are used in condition columns, indexes become invalid, and each row of data is calculated, causing unnecessary performance consumption.

Example:

- The following lines of code do not meet specifications:

```
SELECT income FROM table WHERE abs(income) > ?;
SELECT income FROM table WHERE income * 10 > ?;
SELECT create_time
FROM table
WHERE date_format(create_time, '%Y%m%d %H:%i:%s') = '20090101 00:00:0';
```

- The following modification should be considered:

```
SELECT income FROM table WHERE income > ? OR income < (-1) * ?;
SELECT income FROM table WHERE income > ?/10;
SELECT create_time
FROM table
WHERE create_time = str_to_date('20090101 00:00:0', '%Y%m%d %H:%i:%s');
```

- [Rule] Do not use comparison operator (!=) when comparing with NULL in query conditions. Instead, use IS NULL or IS NOT NULL.
- [Rule] Do not use comparison operator (!=) in the index columns of the query condition to avoid invalid indexes.
- [Rule] Do not compare the index columns of the query condition with NULL (IS NULL and IS NOT NULL instead).
- [Rule] Do not use NOT in the index columns of the query condition.
- [Rule] Do not use NOT IN in the index columns of the query condition.
- [Rule] Do not place % at the beginning of the LIKE statement for fuzzy query. If % is placed at the beginning of the LIKE statement, the index cannot be used and the entire table will be scanned.
- [Recommendation] The number of IN clauses in the WHERE statement shall be less than or equal to 500.
 - During the query, the values of all the IN clauses will be compared to check whether they are equal, which increases the overhead.
 - If the included values are relatively fixed, consider creating a temporary table, writing the clause data into the table, and then using INNER JOIN to implement the inclusion query.
- [Recommendation] If the IN clause in the WHERE condition is not a constant but a column in the table, you are advised to change it to a subquery. In this case, it is actually an unequal JOIN, which is executed through the nestloop plan. If the table is too large, the execution efficiency is low. You are advised to change the query to a subquery of the JOIN type.

Example:

- The following code does not meet specifications:

```
SELECT col1, COALESCE(max(col2 - 1), 0)
FROM t1, t2
WHERE t1.col1 = ANY(VALUES(id1), (id2))
GROUP BY col1;
```

- The following modification should be considered:

```
SELECT col1, COALESCE(max(tmp), 0) FROM
(
  (
    SELECT col1, (col2-1) AS tmp
    FROM t1, t2
    WHERE t1.col1 = t2.id1 AND t1.col1 != t2.id2
  ) UNION ALL (
    SELECT col1, (col2-1) AS tmp
    FROM t1, t2
    WHERE t1.col1 = t2.id2
  )
) GROUP BY col1;
```

- [Recommendation] Use equal operators, instead of not equal operators.
If a not equal operator (IN, BETWEEN, <, <=, >, or >=) is used in the WHERE condition, no index can be used in the following conditions because two range conditions cannot be used at the same time.

4.3.4 SELECT

- [Rule] Do not use the wildcard character (*) in the SELECT statement.

If the table structure is changed due to service or database upgrade when a wildcard column is used to query a table, the table structure may be incompatible with service statements. Therefore, the service must specify the name of the table column to be queried and avoid using the wildcard character.

- [Rule] Do not perform operations that may cause sorting, such as ORDER BY, DISTINCT, GROUP BY, and UNION, on large columns (such as VARCHAR(2000)).

These operations consume a large number of CPU and memory resources, resulting in low execution efficiency.

- [Rule] Do not use the LOCK TABLE statement to lock a table. Instead, use the SELECT .. FOR UPDATE statement.

LOCK TABLE provides multiple levels of locks. However, if you do not fully understand the database principles and services, misuse of table locks may trigger deadlocks, causing the database to be unavailable.

- [Recommendation] Use UNION ALL instead of UNION. Consider data deduplication if necessary.

UNION ALL does not deduplicate data and does not require sorting operations. Therefore, UNION ALL is faster than UNION. If deduplication is not required, UNION ALL is preferred.

- [Recommendation] Do not frequently use count() to obtain the number of rows in a large table. This operation consumes a large number of resources and affects the execution efficiency of parallel jobs.

If you do not need the real-time row statistics, run the following statement to obtain the number of rows in the table:

```
SELECT reltuples FROM pg_class WHERE relname = 'tablename';
```

The number of rows recorded in pg_class is updated only after ANALYZE is executed on the table.

Currently, ANALYZE is triggered in either of the following conditions:

- The service sends an ANALYZE statement. For example:

```
-- Analyze all tables in the connection library.
ANALYZE;
-- Analyze the specified table.
ANALYZE tablename;
```
- This event is triggered when the number of rows added or deleted at a specified interval or in a table reaches a specified value by using the AUTO VACUUM mechanism. The interval and addition/deletion ratio can be set through the GUC parameters.

4.3.5 INSERT

- [Specification] INSERT ON DUPLICATE KEY UPDATE does not support UPDATE on columns with PRIMARY KEY or UNIQUE constraints.

The semantics of **INSERT ON DUPLICATE KEY UPDATE** is to update the rows that have **UNIQUE** constraint conflicts. In this process, the value of the constraint should not be updated.

- [Rule] Do not run **INSERT ON DUPLICATE KEY UPDATE** on a table that has multiple **UNIQUE** constraints.

A table may have multiple unique indexes, or both primary keys and unique indexes. When multiple **UNIQUE** constraints exist, the system checks all the **UNIQUE** constraints by default. If any constraint conflicts, the system updates the conflicting rows. That is, multiple records may be updated, which does not meet the service expectation. More specific conditions for inserting and updating data shall be added.

- [Recommendation] In the case of batch insertion, you are advised to use `executeBatch` to execute **INSERT INTO VALUES (?)**. The execution efficiency is higher than that of executing multiple **INSERT INTO VALUES()** or **INSERT INTO VALUES(?), ..., (?)** statements.

4.3.6 UPDATE

- [Specification] **LIMIT** cannot be directly used in the **UPDATE** statement. The **WHERE** condition must be used to specify the target row to be updated.

- [Specification] Multi-table update is not supported.

Multi-table update is to update multiple tables in a single SQL statement.

- [Rule] The **UPDATE** statement must contain the **WHERE** clause to avoid full table scan.

- [Rule] Do not use the updated columns as the update source when the **UPDATE** clause updates multiple columns simultaneously.

Even if multiple columns are updated simultaneously from the same source, the behavior varies depending on the database. To avoid compatibility issues, avoid the preceding operations at the service layer.

Example:

```
UPDATE table SET col1 = col2, col3 = col1 WHERE col1 = 1;
```

In , the value of **col3** is the original value of **col1**. In database B, the value of **col3** is the value of **col2** (because the value of **col2** is assigned to **col1**).

- [Rule] Do not use **ORDER BY** or **GROUP BY** in the **UPDATE** statement to avoid unnecessary sorting.
- [Recommendation] If a table has a primary key or index, the **WHERE** condition must be used together with the primary key or index during update.

4.3.7 DELETE

- [Specification] **LIMIT** cannot be used in the **DELETE** statement. The **WHERE** condition should be used to specify the target row to be deleted.

- [Specification] Multi-table deletion is not supported.

Multi-table deletion indicates that multiple tables are deleted in a single SQL statement.

- [Rule] The **DELETE** statement must contain the **WHERE** clause to avoid full table scan.

- [Rule] Do not use **ORDER BY** or **GROUP BY** in the **DELETE** statement to avoid unnecessary sorting.

- [Rule] Use TRUNCATE instead of DELETE to clear a table.
TRUNCATE creates a new physical file and physically deletes the original file when the transaction ends to clear the disk space. However, the DELETE statement marks data in the table and does not clear the disk space until the VACUUM FULL phase.
- [Recommendation] If **DELETE** is executed on a table that has a primary key or index, the WHERE condition must be used together with the primary key or index to improve execution efficiency.

4.3.8 Join Query

- [Rule] The nesting depth of multi-table join must be less than 8.
If the join nesting is too deep, slow SQL statements may be generated. You need to optimize the join nesting at the service layer.
- [Rule] Specify the join condition (ON) of each table to avoid Cartesian product.
For example, in B database, JOIN is equivalent to CROSS JOIN and INNER JOIN. However, in the SQL standards, JOIN is equivalent to INNER JOIN only and must be used together with the ON condition.
- [Rule] Specify the JOIN mode based on the SQL standards during join. Do not use the JOIN keyword directly. Instead, use CROSS JOIN, INNER JOIN, LEFT JOIN, or RIGHT JOIN.
- [Rule] When multiple tables are joined for query, aliases must be added to the tables to ensure that the statement logic is clear and easy to maintain.
- [Recommendation] Different columns have different comparison overheads. Use a column type with high efficiency for joined columns.
 - The comparison efficiency of the numeric type is much higher than that of the string type.
 - The comparison efficiency of integers is much higher than that of numeric and floating-point types.
- [Recommendation] The joined columns must be of the same data type to avoid the impact of implicit type conversion on the execution efficiency.
- [Recommendation] Do not use nested subqueries. Use table join if possible because subqueries will generate temporary tables, which greatly affects SQL performance.
- [Recommendation] If a large number of NULL values exist in the joined columns, you are advised to add the IS NOT NULL condition to the WHERE condition to improve the execution efficiency.

4.3.9 Subquery

- [Rule] Do not use repeated subquery statements in an SQL statement.
- [Recommendation] Do not use scalar subqueries.

A scalar subquery is a subquery whose result is one value and whose condition expression uses an equal operator.

Example:

The following statement does not meet specifications:

```
SELECT * FROM t1 WHERE id = (SELECT id FROM t2 LIMIT 1);
```

You are advised to split the preceding statement into two SQL statements and execute the subquery first.

- [Recommendation] Do not use subqueries in the SELECT target columns. Otherwise, the plan cannot be pushed down, affecting the execution performance.
- [Recommendation] The nesting depth of a subquery cannot exceed 2. Subqueries cause temporary table overhead. Therefore, complex queries must be optimized based on service logic.

4.3.10 Transaction

- [Specification] Large object operations do not support transactions. Large object operations include creating and deleting DATABASE, ANALYZE, and VACUUM jobs.
- [Rule] When accessing the database through the JDBC client, disable the **autocommit** parameter and explicitly execute the transaction COMMIT.
 - On the one hand, enabling the **autocommit** parameter will cause some parameters (such as **fetchsize**) to become invalid.
 - On the other hand, the service should clarify the service logic and reduce the dependence on the database.
- [Rule] Do not combine multiple SQL statements into one statement when accessing the database through JDBC.

When multiple statements are combined into one statement that contains object operations, if the intermediate object operation fails, a new transaction is started to execute subsequent statements.

Example:

- The following statement does not meet specifications:

```
Connection conn = ....
try {
    Statement stmt = null;
    try {
        stmt = conn.createStatement();
        stmt.executeUpdate("CREATE TABLE t1 (a int); DROP TABLE t1");
    } finally {
        stmt.close();
    }
    conn.commit();
} catch (Exception e) {
    conn.rollback();
} finally {
    conn.close();
}
```

In the preceding statement, if

```
CREATE TABLE t1;
```

The creation fails, and a new transaction will be started.

```
DROP TABLE t1;
```

The execution fails.

- You are advised to split the statement into two statements and send them separately:

```
Connection conn = ....
try {
    Statement stmt = null;
    try {
```

```
stmt = conn.createStatement();
stmt.executeUpdate("CREATE TABLE t1 (a int)");
stmt.executeUpdate("DROP TABLE t1");
} finally {
    stmt.close();
}
conn.commit();
} catch(Exception e) {
    conn.rollback();
} finally {
    conn.close();
}
```

4.3.11 SQL Compilation

DDL

- [Recommendation] In GaussDB, you are advised to perform DDL operations (such as CREATE TABLE and COMMENT) in a unified manner. Avoid DDL operations in batch processing. to avoid performance deterioration caused by many concurrent transactions.
- [Recommendation] Perform the TRUNCATE operation immediately after an unlogged table is used, because GaussDB cannot ensure the security of unlogged tables in abnormal scenarios.
- [Recommendation] Suggestions on the storage model of temporary and unlogged tables are the same as those on base tables. If the base table is a row-store table, you are advised to create temporary tables and unlogged tables as row-store tables.
- [Recommendation] The total length of an index column cannot exceed 50 bytes. Otherwise, the index size will increase greatly, resulting in large storage cost and low index performance.
- [Recommendation] Do not delete objects using DROP...CASCADE, unless the dependency between objects is specified. Otherwise, the objects may be deleted by mistake.

Data Loading and Unloading

- [Recommendation] Explicitly provide the inserted column list in the INSERT statement. Example:

```
INSERT INTO task(name,id,comment) VALUES ('task1','100','100th task');
```
- [Recommendation] After data is imported to the database in batches or the data increment reaches the threshold, you are advised to analyze tables to prevent the execution plan from being degraded due to inaccurate statistics.
- [Recommendation] To clear all data in a table, you are advised to use TRUNCATE TABLE instead of DELETE TABLE. DELETE TABLE is not efficient and cannot release disk space occupied by the deleted data.

Type Conversion

- [Recommendation] Convert data types explicitly. If you perform implicit conversion, the result may differ from expected.
- [Recommendation] During data query, explicitly specify the data type for constants, and do not attempt to perform any implicit data type conversion.

- [Description] If **sql_compatibility** is set to **A**, null strings will be automatically converted to NULL during data import. If null strings need to be retained, set **sql_compatibility** to **C**.

Query Operation

- [Recommendation] Do not return a large number of result sets to a client except the ETL program. If a large result set is returned, consider modifying your service design.
- [Recommendation] Perform DDL and DML operations encapsulated in transactions. For example, operations such as TRUNCATE TABLE, UPDATE TABLE, DELETE TABLE, and DROP TABLE cannot be revoked once they are committed. You are advised to encapsulate such operations in transactions so that you can roll back the operations if necessary.
- [Recommendation] During query compilation, you are advised to list all columns to be queried and avoid using **SELECT ***. Doing so reduces output lines, improves query performance, and avoids the impact of adding or deleting columns on front-end service compatibility.
- [Recommendation] During table object access, add the schema prefix to the table object to avoid accessing an unexpected table due to schema switchover.
- [Recommendation] The cost of joining more than three tables or views, especially FULL JOIN, is difficult to be estimated. You are advised to use the WITH TABLE AS statement to create interim tables to improve the readability of SQL statements.
- [Recommendation] Avoid using a Cartesian product or FULL JOIN. Cartesian products and full joins will result in a sharp expansion of result sets and poor performance.
- [Description] Only IS NULL and IS NOT NULL can be used to determine NULL value comparison results. If any other method is used, NULL is returned. For example, NULL instead of expected Boolean values is returned for NULL<>NULL, NULL=NULL, and NULL<>1.
- [Description] Do not use count(col) instead of count(*) to count the total number of records in a table. count(*) counts the NULL value (actual rows) while count(col) does not.
- [Description] While executing count(col), the number of NULL record rows is counted as 0. While executing sum(col), NULL is returned if all records are NULL. If not all the records are NULL, the number of NULL record rows is counted as 0.
- [Description] To count multiple columns using count(), column names must be enclosed in parentheses. For example, count ((col1, col2, col3)). Note: When multiple columns are used to count the number of NULL record rows, a row is counted even if all the selected columns are NULL. The result is the same as that when count(*) is executed.
- [Description] Null records are not counted when count(distinct col) is used to calculate the number of non-NULL columns that are not repeated.
- [Description] If all statistical columns are NULL when count(distinct (col1,col2,...)) is used to count the number of unique values in multiple columns, null records are also counted, and the records are considered the same.

- [Recommendation] Use the connection operator || to replace the **concat** function for string connection, because the concat function needs to query type tables and function tables, which slows down the basic performance. In addition, because the concat output is related to the data type, the execution plan generated by the concat function cannot calculate results in advance. As a result, the query performance severely deteriorates.
- [Recommendation] Use the following time-related macros to replace the now function and obtain the current time, because the execution plan generated by the now function cannot be pushed down to disks. As a result, the query performance deteriorates severely.

Table 4-9 Time-related macros

Macro Name	Description	Example
CURRENT_DATE	Obtains the current date, excluding the hour, minute, and second details.	openGauss=# SELECT CURRENT_DATE; date ----- 2018-02-02 (1 row)
CURRENT_TIME	Obtains the current time, excluding the year, month, and day.	openGauss=# SELECT CURRENT_TIME; timetz ----- 00:39:34.633938+08 (1 row)
CURRENT_TIMESTAMP(n)	Obtains the current date and time, including year, month, day, hour, minute, and second. NOTE n indicates the number of digits after the decimal point in the time string.	openGauss=# SELECT CURRENT_TIMESTAMP(6); timestampz ----- 2018-02-02 00:39:55.231689+08 (1 row)

- [Recommendation] Do not use scalar subquery statements. A scalar subquery appears in the output list of a SELECT statement. In the following example, the underlined part is a scalar subquery statement:

```
SELECT id, (SELECT COUNT(*) FROM films f WHERE f.did = s.id) FROM staffs_p1 s;
```

Scalar subqueries often result in query performance deterioration. During application development, scalar subqueries need to be converted into equivalent table joins based on the service logic.

- [Recommendation] In WHERE clauses, the filter conditions should be collated. The condition that few records are selected for reading (the number of filtered records is small) is listed at the beginning.
- [Recommendation] Filter conditions in WHERE clauses should comply with unilateral rules, that is, to place the column name on one side of a comparison operator. In this way, the optimizer automatically performs pruning optimization in some scenarios. The format is *col op expression*, where *col* indicates a table column, *op* indicates a comparison operator, such

as = and >, and *expression* indicates an expression that does not contain a column name. Example:

```
SELECT id, from_image_id, from_person_id, from_video_id FROM face_data WHERE  
current_timestamp(6) - time < '1 days'::interval;
```

The modification is as follows:

```
SELECT id, from_image_id, from_person_id, from_video_id FROM face_data where time >  
current_timestamp(6) - '1 days'::interval;
```

- [Recommendation] Do not perform unnecessary collation operations. Collation requires a large amount of memory and CPU. If service logic permits, ORDER BY and LIMIT can be combined to reduce resource overhead. By default, GaussDB performs collation by ASC & NULL LAST.
- [Recommendation] When the ORDER BY clause is used for collation, specify collation modes (ASC or DESC), and use NULL FIRST or NULL LAST for NULL record sorting.
- [Recommendation] Do not rely on only the LIMIT clause to return the result set displayed in a specific sequence. Combine ORDER BY and LIMIT clauses for some specific result sets and use OFFSET to skip specific results if necessary.
- [Recommendation] If the service logic is accurate, you are advised to use UNION ALL instead of UNION.
- [Recommendation] If a filter condition contains only an OR expression, convert the OR expression to UNION ALL to improve performance. SQL statements that use **OR** expressions cannot be optimized, resulting in slow execution. Example:

```
SELECT * FROM scdc.pub_menu  
WHERE (cdp= 300 AND inline=301) OR (cdp= 301 AND inline=302) OR (cdp= 302 AND inline=301);
```

Convert the statement to the following:

```
SELECT * FROM scdc.pub_menu  
WHERE (cdp= 300 AND inline=301)  
union all  
SELECT * FROM scdc.pub_menu  
WHERE (cdp= 301 AND inline=302)  
union all  
SELECT * FROM tablename  
WHERE (cdp= 302 AND inline=301)
```

- [Recommendation] If an IN(val1, val2, val3...) expression contains a large number of columns, you are advised to replace it with the IN (VALUES (val1), (val2), (val3)...) statement. The optimizer will automatically convert the IN constraint into a non-correlated subquery to improve the query performance.
- [Recommendation] Replace (NOT) IN with (NOT) EXIST when joined columns do not contain **NULL** values. For example, in the following query statement, if the **T1.C1** column does not contain any **NULL** value, add the NOT NULL constraint to the **T1.C1** column, and then rewrite the statements.

```
SELECT * FROM T1 WHERE T1.C1 NOT IN (SELECT T2.C2 FROM T2);
```

Rewrite the statement as follows:

```
SELECT * FROM T1 WHERE NOT EXISTS (SELECT * FROM T2 WHERE T1.C1=T2.C2);
```

NOTE

- If the value of the T1.C1 column is not **NOT NULL**, the preceding rewriting cannot be performed.
- If the **T1.C1** column is the output of a subquery, check whether the output is **NOT NULL** based on the service logic.
- [Recommendation] Use cursors instead of the LIMIT OFFSET syntax to perform pagination queries to avoid resource overheads caused by multiple

executions. A cursor must be used in a transaction, and you must disable the cursor and commit the transaction once the query is finished.

4.4 Client Programming Specifications

4.4.1 JDBC

- [Specification] A database must be specified for each JDBC instance. Once the instance is created, it cannot switch to another database.
- [Specification] The length of a single SQL statement cannot exceed 2 GB bytes. Considering the communications cost, it is recommended that the length of a single SQL statement be less than or equal to 5 KB.
- [Specification] Currently, only the DEFAULT value of the columns in CREATE/ALTER TABLE can be set through parameters. Other DDL statements do not support parameter settings using the Prepare Execute method.
- [Rule] Each PreparedStatement of JDBC can contain a maximum of 32767 parameters.
- [Specification] The connection parameter **fetchsize** must be used when **autocommit** is disabled. Otherwise, the **fetchsize** configuration is invalid.
- [Rule] Use the default GUC parameters and avoid sending SET requests through JDBC to modify GUC parameters. For details, see [GUC Parameter Programming Specifications](#).
- [Recommendation] Use Prepare Execute method to execute query statements to improve execution efficiency.
- [Rule] Execute SQL statements one by one in the same transaction. Do not combine multiple SQL statements and send them as one statement.

For details, see [\[Rule\] Do not combine multiple SQL statements into one statement when accessing the database through JDBC](#).

- [Rule] The time zone of the host where the JDBC client is located, the time zone of the host where the database is located, and the time zone during database configuration must be the same.
- [Rule] If a temporary table is created in a connection, delete the temporary table before releasing the connection to the connection pool to avoid service errors.
- [Description] When a third-party tool connects to GaussDB through JDBC, JDBC sends a connection request to GaussDB. By default, the following parameters are added. For details, see the implementation of the ConnectionFactoryImpl JDBC code.

```
params = {  
  { "user", user },  
  { "database", database },  
  { "client_encoding", "UTF8" },  
  { "DateStyle", "ISO" },  
  { "extra_float_digits", "3" },  
  { "TimeZone", createPostgresTimeZone() },  
};
```

These parameters may cause the JDBC and gsql clients to display inconsistent data, for example, date data display mode, floating point precision representation, and timezone.

If the result is not as expected, you are advised to explicitly set these parameters in the Java connection setting.

When the database is connected through JDBC, **extra_float_digits** is set to **3**. When the database is connected using gsql, **extra_float_digits** is set to **0**. As a result, the precision of the same data displayed in JDBC clients may be different from that displayed in gsql clients.

In precision-sensitive scenarios, the numeric type is recommended.

- [Recommendation] When connecting to the database through JDBC, ensure that the following three time zones are the same:
 - Time zone of the host where the JDBC client is located
 - Time zone of the host where the GaussDB database instance is located.
 - Time zone used during GaussDB database instance configuration.

NOTE

For details about how to set the time zone, contact the administrator.

- [Recommendation] Enable **autocommit** in the code for connecting to GaussDB by the JDBC. If **autocommit** needs to be disabled to improve performance or for other purposes, applications need to ensure that transactions are committed. For example, explicitly commit transactions after specifying service SQL statements. Particularly, ensure that all transactions are committed before the client exits.
- [Recommendation] You are advised to use connection pools to limit the number of connections from applications. You are advised not to connect to a database each time an SQL statement is executed.
- [Recommendation] After an application completes its jobs, disconnect it from GaussDB to release occupied resources. You are advised to set the session timeout interval in the jobs.
- [Recommendation] Reset the session environment before releasing connections to the JDBC connection tool. Otherwise, historical session information may cause object conflicts.
 - If GUC parameters are set in the connection, run **SET SESSION AUTHORIZATION DEFAULT;RESET ALL;** to clear the connection status before you return the connection to the connection pool.
 - If a temporary table is used, delete the temporary table before you return the connection to the connection pool.
- [Recommendation] In the scenario where the ETL tool is not used and real-time data import is required, it is recommended that you use the CopyManager API driven by the GaussDB JDBC to import data in micro-batches during application development.
- [Recommendation] Set **prepareThreshold** to a proper value. If the query statement is fixed, set it to **1**.
- [Recommendation] You are advised to set **batchMode** to **on** to use the batch connection mode to improve the execution performance.
- [Recommendation] Set a proper JDBC connection timeout interval based on the upper-layer request timeout of the service to prevent the job from always occupying database resources.

Timeout parameters include **loginTimeout**, **connectTimeout**, and **socketTimeout**.

- **loginTimeout**: integer type. Specifies the waiting time for establishing the database connection, in seconds. The default value is **0**, indicating that the timeout mechanism is disabled.
- **connectTimeout**: integer type. This parameter specifies the timeout interval for connecting to a server. If the time taken to connect to a server exceeds the value specified, the connection is interrupted. The unit of the timeout interval is second. The default value **0** indicates that the timeout mechanism is disabled.
- **socketTimeout**: integer type. This parameter indicates the timeout interval for a socket read operation. If the time taken to read data from a server exceeds the value specified, the connection is closed. The unit of the timeout interval is second. The default value **0** indicates that the timeout mechanism is disabled.
- **cancelSignalTimeout**: integer type. A cancel message may cause a block. This attribute controls "connect timeout" and "socket timeout" in a cancel command. The default value is **10**.
- **tcpKeepAlive**: Boolean type. This parameter is used to enable or disable TCP keepalive detection. The default value is **false**.

5 Application Development Guide

5.1 GaussDB Application Development Guide

You can connect to and perform operations on a database through APIs such as JDBC, ODBC, libpq, Psycopg, Go, and ecpg.

JDBC

Java Database Connectivity (JDBC) is a Java API for running SQL statements. It provides unified access APIs for different relational databases. It allows Java applications to use SQL statements to perform database operations, such as querying, inserting, updating, and deleting data.

Some key features and usage of JDBC are as follows:

1. Database connection management: JDBC allows applications to establish connections to databases and manages the lifecycle of these connections.
2. SQL execution: JDBC can be used to query, update, and delete SQL statements. This is achieved by constructing SQL statements in Java code and sending them to the database.
3. Transaction management: JDBC APIs can be used to start, commit, or roll back transactions to ensure the consistency and integrity of database operations.
4. Exception handling: JDBC defines a group of exception classes to handle various exceptions that may occur during database operations. Developers can use the try-catch block to capture and handle these exceptions.
5. Batch processing: JDBC provides the batch processing function, which allows multiple SQL statements to be executed concurrently, improving the efficiency of database operations.
6. Metadata access: JDBC can be used to obtain the metadata information of the database, such as the table structure, column name, and data type. Developers then can dynamically construct SQL query statements or perform operations based on the database structure.

In conclusion, JDBC provides a flexible and powerful bridge that enables Java applications to interact with various databases and to implement data persistence

and management. GaussDB supports JDBC 4.0 and requires JDK 1.8 for code compiling. It does not support JDBC-ODBC bridging.

For details about JDBC-based development, see [Development Based on JDBC](#).

ODBC

Open Database Connectivity (ODBC) is a Microsoft API for accessing databases in C/C++ based on the X/OPEN CLI. It provides a unified method for applications to access various database management systems (DBMSs) without considering specific database types or OS platforms. ODBC allows applications to use SQL to query, insert, update, and delete data in a database. Applications interact with the database through the APIs provided by ODBC, which enhances their portability, scalability, and maintainability.

The ODBC architecture consists of three main components: application, ODBC driver manager, and ODBC driver. Applications use ODBC APIs to communicate with the ODBC driver manager which loads and manages ODBC drivers. The ODBC drivers are responsible for communicating with a specific database, executing SQL queries, and returning results. [Figure 5-1](#) shows the system structure of ODBC.

In conclusion, ODBC provides a flexible and cross-platform method that allows users to easily connect applications to various databases without worrying about the details of a specific database system.

For details about ODBC-based development, see [Development Based on ODBC](#).

Figure 5-1 ODBC system structure

GaussDB supports ODBC in the following environments.

Table 5-1 Platforms supported by ODBC

OS	Platform
CentOS 6.4/6.5/6.6/6.7/6.8/6.9/7.0/7.1/7.2/7.3/7.4	x86_64
CentOS 7.6	Arm64
EulerOS 2.0 SP2/SP3	x86_64
EulerOS 2.0 SP8	Arm64
Kylin V10	x86_64
Kylin V10	Arm64

The ODBC Driver Manager running on Unix or Linux can be unixODBC or iODBC. unixODBC-2.3.7 is used as the component for connecting to the database.

Windows has a native ODBC Driver Manager. You can locate **Data Sources (ODBC)** by choosing **Control Panel > Administrative Tools**.

NOTE

The current database ODBC driver is based on an open-source version and may be incompatible with data types tinyint, smalldatetime, nvarchar, and nvarchar2.

ODBC limitations:

- ODBC does not support read on standby.
- ODBC does not support user-defined types and does not support user-defined parameters in stored procedures.
- ODBC does not support DR failover.
- When the **proc_outparam_override** parameter is enabled for the database, ODBC cannot properly call the stored procedure that contains the **out** parameter.

libpq

libpq is a GaussDB C API. libpq contains a set of library functions that allow client programs to send query requests to the GaussDB servers and obtain query results. It is also the underlying engine of other GaussDB APIs, such as ODBC.

For details about libpq-based development, see [Development Based on libpq](#).

5.2 Development Specifications

If the connection pool mechanism is used during application development, comply with the following specifications:

- If GUC parameters are set in the connection, run **SET SESSION AUTHORIZATION DEFAULT;RESET ALL;** to clear the connection status before you return the connection to the connection pool.
- If a temporary table is used, delete the temporary table before you return the connection to the connection pool.

If you do not do so, the connection in the connection pool will be stateful, which affects subsequent operations on the connection pool.

[Table 5-2](#) describes the compatibility of application development drivers.

Table 5-2 Compatibility

Driver	Compatibility
JDBC, Go, ODBC, libpq, Psycopg, and ecpg	The drivers are compatible with the earlier database version. However, to use the new features added to the drivers and database, you must upgrade the database.

NOTICE

Setting **behavior_compat_options** to '**proc_outparam_override**' is applicable only in A-compatible mode.

If the driver is used in a multi-thread environment:

The JDBC driver is not thread-safe and does not guarantee that the connection methods are synchronized. The caller synchronizes the calls to the driver.

5.3 Development Based on JDBC

5.3.1 Development Process

Application development based on JDBC covers obtaining the driver JAR package and configuring JDK 1.8, connecting to a database, running SQL statements, processing result sets, and closing the connection.

Figure 5-2 Application development process based on JDBC

5.3.2 Development Process

5.3.2.1 Obtaining the Driver JAR Package and Configuring JDK 1.8

Environment preparation includes obtaining the driver JAR package and configuring JDK 1.8.

Obtaining the Driver JAR Package

Decompress the obtained driver package, find the JDBC driver package **GaussDB-Kernel_Database version number_OS_64bit_Jdbc.tar.gz**, and decompress it. After the decompression, you will obtain the following driver packages in JAR format:

- **gsjdbc4.jar**: The main class name is **org.postgresql.Driver**, and the URL prefix of the database connection is **jdbc:postgresql**. This driver package applies to the scenario where services are migrated from PG. The driver class and loading path are the same as those before the migration, but the supported APIs are different. The APIs that are not supported need to be adjusted on the service side.
- **opengaussjdbc.jar**: The main class name is **com.huawei.opengauss.jdbc.Driver**. The URL prefix of the database connection is **jdbc:opengauss**. This driver package is recommended. This driver package is used when both PG and GaussDB are accessed in a JVM process.

NOTICE

- The loading paths and URL prefixes of driver classes vary in different driver packages, but their functions are the same.
 - **gsjdbc200.jar**: This driver package applies to the scenario where services are migrated from Gauss200. The driver class and loading path are the same as those before the migration, but the supported APIs are different. The APIs that are not supported need to be adjusted on the service side.
 - The **gsjdbc4.jar** driver package cannot be used to operate the PG database. Although the connection can be successfully established in some versions, some API behaviors are different from those of PG JDBC, which may cause unknown errors.
 - The PG driver package cannot be used to operate the GaussDB database. Although the connection can be successfully established in some versions, some API behaviors are different from those of GaussDB JDBC, which may cause unknown errors.
-

Configuring JDK 1.8

JDK 1.8 must be configured on the client. JDK supports multiple platforms such as Windows and Linux. The following uses Windows as an example to describe the configuration method:

- Step 1** Enter the following command in the MS-DOS window (command prompt in Windows) to check the JDK version:

```
java -version
```

Ensure that the JDK version is JDK 1.8. If JDK is not installed, download the installation package from the [official website](#) and install it.

Step 2 Configure system environment variables.

1. Right-click **My computer** and choose **Properties**.
2. In the **System** window, click **Advanced system settings** in the navigation pane.
3. In the **System Properties** dialog box, click **Environment Variables** on the **Advanced** tab page.
4. In the **System variables** area of the **Environment Variables** dialog box, click **New** or **Edit** to configure system variables. For details, see [Table 5-3](#).

Table 5-3 Variables

Variable	Operation	Variable Value
JAVA_HOME	– If the variable exists, click Edit. – If the variable does not exist, click New.	Specifies the Java installation directory. Example: C:\Program Files\Java\jdk1.8.0_131
Path	Click Edit .	– If <i>JAVA_HOME</i> is configured, add %JAVA_HOME%\bin before the variable value. – If <i>JAVA_HOME</i> is not configured, add the full Java installation path before the variable value: C:\Program Files\Java\jdk1.8.0_131\bin
CLASSPATH	Click New .	.;%JAVA_HOME%\lib;%JAVA_HOME%\lib\tools.jar

----End

5.3.2.2 Connecting to a Database

After you have obtained the driver JAR package and configured JDK 1.8, GaussDB allows you to connect to a database in three methods. This section describes how to connect to a database in the three methods.

5.3.2.2.1 Connection Methods

The database connection method is usually selected based on factors such as security, performance, scalability, and implementation complexity. The following lists advantages, disadvantages, and selection principles of three database connection methods.

Table 5-4 Advantages, disadvantages, and selection principles of different methods

Connection Method	Advantage	Disadvantage	Selection Principle
Non-encrypted	- This method is easy to implement and does not require additional encryption and decryption operations. - It features high performance because no encryption or decryption operation is required, which reduces the overhead of data transmission.	- It provides low security and data is easily intercepted or tampered with during transmission. - It is not suitable for sensitive data transmission and may violate privacy protection laws and regulations.	It applies only to internal networks or environments that have low security requirements.
SSL	- It provides encrypted transmission. Data is protected during transmission, ensuring high security. - It supports client/server identity authentication, which enhances security.	- It is complex in configuration and management, and certificates need to be issued and updated. - Some performance overhead may be added, especially when it is used for encrypting and decrypting large amounts of data.	It applies to environments that require high data transmission security, such as finance and healthcare industries.

Conn ectio n Met hod	Advantage	Disadvantage	Selection Principle
UDS	- It applies to local communication without passing through the network, featuring a high transmission speed. - No extra network overhead is required, and it is not vulnerable to network attacks.	It is used only for the communication between processes on the same host but cannot be used for remote connections.	It applies to local communication scenarios, for example, data exchange between local services and applications.

5.3.2.2.2 Connection Parameter Reference

All connection properties of the **info** parameter are case-sensitive. [Table 5-5](#) describes the common properties.

Table 5-5 Connection properties of the info parameter

Property	Description	Value
PGDBNAME	Specifies the database name. You do not need to set this parameter in the URL because the database name is automatically parsed from the .properties file.	Property type: string
PGHOST	Specifies the host IP address.	Property type: string
PGPORT	Specifies the host port number.	Property type: integer
user	Specifies the database user who creates the connection.	Property type: string
password	Specifies the password of the database user.	Property type: string

Property	Description	Value
driverInfo Mode	Controls the output mode of the driver description information.	Property type: string Value range: postgresql and gaussdb. • postgresql: The driver description related to PG is displayed. • gaussdb: The driver description related to GaussDB is displayed. Default value: postgresql
loggerLevel	Specifies the logging level.	Property type: string Value range: The following logging levels are supported: OFF, INFO, DEBUG, and TRACE. • OFF: The logging function is disabled. • INFO, DEBUG, and TRACE logs record information of different levels. Default value: No default value is provided. If this property is not set, the value INFO is used.
loggerFile	Specifies the log output path (directory and file name). This parameter has been deprecated and does not take effect. To specify the log output path, you can configure the java.util.logging property file or system property.	Property type: string
logger	Specifies the log output framework used by the JDBC driver. The JDBC driver supports the log output framework used for interconnecting with user applications.	Property type: string Value range: Slf4JLogger • If it is left empty, JDK LOGGER is used. • Currently, only the Slf4j-API-based third-party log output framework is supported. For details, see Log Management.

Property	Description	Value
allowEncodingChanges	If this parameter is set to true , the character set type can be changed. This parameter is used together with characterEncoding to set the character set. The two parameters are separated by ampersands (&). The value of characterEncoding can be UTF8 , GBK , LATIN1 , or GB18030 . Example: allowEncodingChanges=true&characterEncoding=UTF8 .	Property type: Boolean Value range: true: The character set type can be changed. false: The character set type cannot be changed. Default value: false
currentSchema	Specifies the schema of the current connection. You need to specify a schema in search-path . If the schema name contains special characters except letters, digits, and underscores (_), you are advised to enclose the schema name in quotation marks. Note that the schema name is case-sensitive after quotation marks are added. If multiple schemas need to be configured, separate them with commas (,). Schemas containing special characters also need to be enclosed in quotation marks. Example: currentSchema=schema_a,"schema-b","schema/c"	Property type: string Default value: If this parameter is not set, the default schema is the username used for the connection.
hostRecheckSeconds	After JDBC attempts to connect to a host, the host status is saved: connection success or connection failure. This status is trusted within the period specified by hostRecheckSeconds . After the period expires, the status becomes invalid.	Property type: integer Unit: s Value range: 0 to 2147483647. Default value: 10

Property	Description	Value
ssl	Specifies that the database is connected in SSL mode. When ssl is set to true, the NonValidatingFactory channel and certificate mode are supported. 1. For the NonValidatingFactory channel, configure the username and password and set SSL to true. 2. In certification mode, configure the client certificate, key, and root certificate, and set SSL to true.	Property type: Boolean Value range: • true: The database is connected in SSL mode. • false: The database is not connected in SSL mode. Default value: No default value is provided. If this property is not set, the value false is used.

Property	Description	Value
sslmode	This parameter specifies the SSL authentication mode.	Property type: string Value range: disable, allow, prefer, require, verify-ca, and verify-full. • disable: SSL connection is disabled. • allow: If the database server requires SSL connection, SSL connection can be enabled. However, authenticity of the database server will not be verified. • prefer: If the database supports SSL connection, SSL connection is preferred. However, authenticity of the database server will not be verified. • require: The system attempts to set up an SSL connection. If there is a CA file, the system performs verification as if the parameter was set to verify-ca. • verify-ca: The system attempts to set up an SSL connection and checks whether the server certificate is issued by a trusted CA. • verify-full: The system attempts to set up an SSL connection, checks whether the server certificate is issued by a trusted CA, and checks whether the host name of the server is the same as that in the certificate. Default value: No default value is provided. If this property is not set, the value require is used.

Property	Description	Value
sslcert	Specifies the complete path of the certificate file. The certificate type is End Entity .	Property type: string Default value: No default value is provided. If this property is not set, the root directory of the user is read.
sslkey	Specifies the complete path of the key file. You need to convert the key to the DER format before using it. <code>openssl pkcs8 -topk8 -outform DER -in client.key -out client.key.pk8 -nocrypt</code>	Property type: string Default value: No default value is provided. If this property is not set, the root directory of the user is read.
sslrootcert	Specifies the name of the SSL root certificate. The root certificate type is CA .	Property type: string Default value: No default value is provided. If this property is not set, the root directory of the user is read.
sslpassword	Specifies the SSL password, which is provided for ConsoleCallbackHandler.	Property type: string
sslpasswordcallback	Specifies the class name of the SSL password provider.	Property type: string Default value: No default value is provided.
sslfactory	Specifies the class name used by SSLSocketFactory to establish an SSL connection.	Property type: string Default value: No default value is provided.
sslprivatekeyfactory	This parameter specifies the fully qualified name of the implementation class of the org.postgresql.ssl.PrivateKeyFactory API that implements the private key decryption method. If this parameter is not specified, try the default JDK private key decryption algorithm. If the decryption fails, use org.postgresql.ssl.BouncyCastlePrivateKeyFactory. You need to provide the bcpkix-jdk15on.jar package. The recommended version is 1.65 or later.	Property type: string Default value: No default value is provided.
sslfactoryarg	Specifies the optional parameter of the constructor function of the sslfactory class. (This parameter is not recommended.)	Property type: string Default value: No default value is provided.

Property	Description	Value
sslhostnamerverifier	Specifies the class name of the host name verifier. The API must implement javax.net.ssl.HostnameVerifier. The default value is com.huawei.opengauss.jdbc.ssl.PGjdbcHostnameVerifier .	Property type: string Default value: No default value is provided. If this property is not set, com.huawei.opengauss.jdbc.ssl.PGjdbcHostnameVerifier is used.

Property	Description	Value
loginTimeout	Specifies the waiting time for establishing the database connection. When multiple IP addresses are configured in the URL, if the time for obtaining the connection exceeds the value of this parameter, the connection fails and the subsequent IP addresses are not tried. The value of loginTimeout is related to connectTimeout and socketTimeoutInConnecting. The calculation formula is as follows: loginTimeout = (connectTimeout + Connection authentication time + Initialization statement execution time) x Number of nodes.	Property type: integer Unit: s Value range: 0 to 2147483647. The value 0 indicates that the timeout mechanism does not take effect. Default value: 0 Suggestion: After this parameter is set, an asynchronous thread is started each time a connection is established. If there are a large number of connections, the pressure on the client may increase. If this parameter needs to be set in a centralized environment, you are advised to set it as follows: $\max(\text{connectTimeout}, \text{socketTimeoutInConnecting}) \times \text{Number of nodes}$. This prevents connection failures when the network is abnormal and the nth IP address is the IP address of the primary node.

Property	Description	Value
	NOTICE • This parameter sets the time for attempting to connect to all IP addresses in a list. If this parameter is set to a small value, the subsequent IP addresses in the list may fail to be connected. For example, if three IP addresses are set, loginTimeout is set to 5s, and it takes 5s to connect to the first two IP addresses, the third IP address cannot be connected. In a centralized environment, the last IP address is the IP address of the primary node. As a result, the automatic search for the primary node may fail. • When any of the CPU, memory, and I/O load approaches 100%, the connection is slow, which may cause connection timeout. You can locate the fault as follows: 1. Log in to a physical machine with slow connections or use a management tool to query the resource load. You can run the top command to check the CPU usage, run the free command to check the memory usage, and run the iostat command to check the I/O load. In addition, you can check the monitoring logs in the CM Agent and the monitoring records on the database O&M platform. 2. For peak load scenarios caused by a large number of slow queries in a short period of time, you can use the port specified by <i>[Port number of the database server + 1]</i> to query the pg_stat_activity view. For slow queries, you can use the system function pg_terminate_backend(pid int) to kill sessions. 3. If service overloading exists for a long time (that is, there is no obvious slow query, or new queries still become slow after slow queries are killed), reduce the service load and increase database resources.	

Property	Description	Value
connectTimeout	Specifies the timeout interval for connecting to a server OS. If the time taken to connect to a server OS exceeds the value specified, the connection is interrupted. When multiple IP addresses are configured in the URL, this parameter indicates the timeout interval for connecting to a single IP address.	Property type: integer Unit: s Value range: 0 to 2147483647. The value 0 indicates that the timeout mechanism does not take effect. Default value: 0
socketTimeout	Specifies the timeout period for a socket read operation. If the time taken to read data streams from a server exceeds the value specified, the connection is closed. If this parameter is not set, the client waits for a long time when the database process is abnormal. You are advised to set this parameter based on the SQL execution time acceptable to services. NOTE When the timeout is triggered on the JDBC side and the connection is closed, the running services delivered by the JDBC to the database are forcibly terminated. The capability of forcibly terminating a service is controlled by the GUC parameter check_disconnect_query . If this parameter is set to on , the capability is supported. If this parameter is set to off , the capability is not supported.	Property type: integer Unit: s Value range: 0 to 2147483647. The value 0 indicates that the timeout mechanism does not take effect. Default value: 0
socketTimeoutInConnecting	Specifies the timeout interval for a socket read operation during the connection establishment. If the time of reading data streams from the server exceeds the threshold, it attempts to search for the next node for connection.	Property type: integer Unit: s Value range: 0 to 2147483647. Default value: 5

Property	Description	Value
cancelSignalTimeout	Controls "connect timeout" and "socket timeout" of a cancel command, which may cause blocking. If the cancel command does not respond within the specified time, the connection is interrupted to reduce the occupation of client resources.	Property type: integer Unit: s Value range: 0 to 2147483647. Default value: 10
tcpKeepAlive	Specifies whether to enable TCP keepalive detection.	Property type: Boolean Value range: • true: TCP keepalive detection is enabled. • false: TCP keepalive detection is disabled. Default value: false
logUnclosedConnections	The client may leak a connection object because it does not call the close() method to close the connection object. Such object will be recycled and finalized using the finalize() method.	Property type: Boolean Value range: • true: If the close() method is not called, the finalize() method will be used to close the corresponding connection object. • false: If the close() method is not called, the corresponding connection object will not be closed. Default value: false
assumeMinServerVersion (Deprecated)	Specifies the version of the server to be connected. If the value of assumeMinServerVersion is greater than or equal to 9.0 , the number of packets to be sent are reduced during connection establishment. The client does not send a request to set the floating point to 3 (that is, retain the original floating point 2).	Property type: string Default value: No default value is provided.

Property	Description	Value
ApplicationName	Specifies the name of the JDBC driver that is being connected. You can query the pg_stat_activity table on the primary database node to view information about the client that is being connected. The JDBC driver name is displayed in the application_name column.	Property type: string Default value: PostgreSQL JDBC Driver
connectionExtraInfo	Specifies whether the driver reports the driver deployment path, process owner, and URL connection configuration information to the database.	Property type: Boolean Value range: • true: The JDBC driver reports the driver deployment path, process owner, and URL connection configuration information to the database and displays the information in the connection_info parameter. In this case, you can query the information from PG_STAT_ACTIVITY. • false: The driver does not report the driver deployment path, process owner, and URL connection configuration information to the database. Default value: false
autosave	Specifies the action that the driver should perform upon a query failure.	Property type: string Value range: always , never , and conservative . • always: The JDBC driver sets a savepoint before each query and rolls back to the savepoint if the query fails. • never: There is no savepoint. • conservative: A savepoint is set for each query. However, the system rolls back and retries only when there is an invalid statement. Default value: never

Property	Description	Value
protocolVersion	Specifies the connection protocol version.	Property type: integer Value range: 1 and 3. - If it is set to 1, only the V1 server is connected. - If it is set to 3, only the V5 server is connected. Default value: No default value is provided. If this property is not set, the value 3 is used.
prepareThreshold	Specifies the number of times that the PreparedStatement object is executed before the parsed statement on the server is used. NOTE You are advised not to use JDBC and prepareStatement to execute password-related statements (for example, CREATE USER user_name WITH PASSWORD '*****'). This is because when the number of execution times reaches the value specified by prepareThreshold, the database caches SQL statements but does not cache the passwords for security purposes. When the prepareStatement is executed again, error message "Password must contain at least 8 characters." will be displayed.	Property type: integer Value range: 0 to 2147483647. Default value: 5. The default value indicates that when the same PreparedStatement object is executed for five or more times, the parse message is not sent to the server to parse the statement. Instead, the statement that has been parsed on the server is used.
preparedStatementCacheQueries	Specifies the maximum number of queries generated by caching preparedStatement objects in each connection.	Property type: integer Value range: 0 to 2147483647. The value 0 indicates that the cache function is disabled. Default value: 256. If more than 256 different queries are used in the prepareStatement() call, the least recently used query cache will be discarded. Suggestion: Set the value based on service requirements. This parameter is used together with prepareThreshold.

Property	Description	Value
preparedStatementCacheSizeMiB	Specifies the maximum size of queries generated by caching preparedStatement objects in each connection.	Property type: integer Unit: MB Value range: 0 to 2147483647. The value 0 indicates that the cache function is disabled. Default value: 5 . If the size of the cached queries exceeds 5 MB, the least recently used query cache will be discarded.
databaseMetadataCacheFields	Specifies the maximum number of columns that can be cached in each connection.	Property type: integer Value range: 0 to 2147483647. The value 0 indicates that the cache function is disabled. Default value: 65536
databaseMetadataCacheFieldsMiB	Specifies the maximum size of columns that can be cached in each connection.	Property type: integer Unit: MB Value range: 0 to 2147483647. The value 0 indicates that the cache function is disabled. Default value: 5
stringtype	Specifies the type of the parameter passed to the database when the java.sql.PreparedStatement#setString method is called.	Property type: string Value range: unspecified and varchar . • varchar: Parameters are sent to the server as varchar parameters. • unspecified: Parameters are sent to the server without their types specified, and the server will attempt to infer the appropriate types. Default value: varchar

Property	Description	Value
batchMode	Specifies whether to use the batch mode. NOTE If batchMode is set to on, the data type of each column is the same as that specified by the first data record. If the data types are mixed, an error may be reported or the inserted data may be abnormal.	Property type: string Value range: • on: The batch mode is enabled to improve the batch update performance. If batchMode is set to on, the returned result is [count, 0, 0...0]. The first element in the array is the total number of records affected in batches. • off: The batch mode is disabled. If batchMode is set to off, the returned result is [1, 1, 1...1]. Each element in the array corresponds to the number of affected records in a single modification. Default value: on
fetchsize	Specifies the default fetchsize for statements in the created connection. Specifies the number of rows fetched from ResultSet each time. It has the same function as defaultRowFetchSize. If fetchsize and defaultRowFetchSize are set at the same time, fetchsize prevails.	Property type: integer Value range: 0 to 2147483647. Default value: 0 It indicates that all results are obtained from the database at a time. Suggestion: You are advised to set this parameter based on the amount of data queried by services and the memory of the client. When setting fetchsize, disable automatic commit (set autocommit to false). Otherwise, the setting of fetchsize does not take effect.
defaultRowFetchSize	Specifies the number of rows fetched from ResultSet each time. Limiting the number of rows read each time in a database access request can avoid unnecessary memory consumption, thereby avoiding the out of memory exception.	Property type: integer Value range: 0 to 2147483647. Default value: 0. It indicates that all results are obtained from the database at a time.

Property	Description	Value
rewriteBatchInserts	Specifies whether to rewrite SQL statements during batch insertion. When this parameter is used, batchMode must be set to off .	Property type: Boolean Value range: • true: <i>N</i> insert statements can be combined into one: insert into TABLE_NAME values(values1, ..., valuesN), ..., (values1, ..., valuesN) • false: SQL statements are not rewritten during batch insertion. Default value: false
unknownLength	Specifies the length of some GaussDB types (such as TEXT) whose length is unknown and not defined when they are returned by functions such as ResultSetMetaData.getColumnDisplaySize and ResultSetMetaData.getPrecision.	Property type: integer Value range: 0 to 2147483647 Default value: Integer.MAX_VALUE
uppercaseAttributeName	Converts the query result of the API for obtaining metadata to uppercase letters. The application scenario is as follows: All metadata stored in the database is in lowercase, but they must be used as the input and output parameters in uppercase. For details about the involved APIs, see java.sql.DatabaseMetaData and java.sql.ResultSetMetaData. NOTE After the uppercaseAttributeName parameter is enabled, if the database contains metadata with a mixture of uppercase and lowercase letters, only the metadata in lowercase letters can be queried and output in uppercase letters. Before using the metadata, ensure that the metadata is stored in lowercase letters to prevent data errors.	Property type: string Value range: • true: Metadata is converted to uppercase letters. • false: GUC parameter configuration is used. Default value: false

Property	Description	Value
binaryTransfer	Specifies whether data is sent and received in binary format.	Property type: Boolean Value range: true: enabled. false: disabled. Default value: false
binaryTransferEnable	Specifies types for which binary transmission is enabled. Types are separated by commas (,), for example, binaryTransferEnable=Integer4_ARRAY,Integer8_ARRAY . You can select either the OID or name. For example, if the name is BLOB and the OID is 88, set binaryTransferEnable to BLOB or 88 .	Property type: string Default value: No default value is provided.
binaryTransferDisable	Specifies types for which binary transmission is disabled. Types are separated by commas (,). You can select either the OID or name. If binaryTransferDisable and binaryTransferEnable have the same value, the disabling function is used.	Property type: string Default value: No default value is provided.
blobMode	Sets the setBinaryStream() method to assign values to different types of data. You are advised to set this parameter to on for systems migrated from database A or B and to off for systems migrated from database PG.	Property type: string Value range: on: Values are assigned to BLOB data. off: Values are assigned to bytea data. Default value: on
socketFactory	Specifies the name of the class used to create a socket connection with the server. This class must implement the javax.net.SocketFactory API and define a constructor with no parameter or a single string parameter.	Property type: string
socketFactoryArg	The value is an optional parameter of the constructor function of the socketFactory class and is not recommended.	Property type: string

Property	Description	Value
receiveBufferSize	Sets SO_RCVBUF on a connection stream.	Property type: integer Unit: byte Value range: -1 to 2147483647 Default value: -1 . It indicates that the buffer size is not set.
sendBufferSize	Sets SO_SNDBUF on a connection stream.	Property type: integer Unit: byte Value range: -1 to 2147483647 Default value: -1 . It indicates that the buffer size is not set.
preferQueryMode	Specifies the query mode.	Property type: string Value range: simple , extended , extendedForPrepared , and extendedCacheEverything . - In simple mode, the query is executed without parsing or binding. - In extended mode, the query is executed and bound. - The extendedForPrepared mode is used for prepared statement extension. - In extendedCacheEverything mode, each statement is cached. Default value: extended

Property	Description	Value
targetServerType	Identifies the primary DN and standby DN by querying whether a DN allows the write operation in the URL connection string.	Property type: string Value range: any, master, slave, preferSlave, and clusterMainNode. • master: The system attempts to connect to the IP addresses configured in the URL connection string in sequence until the primary DN in the database instance is connected. If the primary DN cannot be found, an exception is thrown. • slave: The system attempts to connect to the IP addresses configured in the URL connection string in sequence until a standby DN in the database instance is connected. If no standby DN can be found, an exception is thrown. • preferSlave: The system prefers to connect to a standby DN (if available) in the URL connection string; if no standby DN can be found, it connects to the primary DN. • any: The system attempts to connect to any DN in the URL connection string. • clusterMainNode: The system attempts to connect to the primary DN or main standby DN in the URL string. If the primary DN or main standby DN cannot be found, an exception is thrown. Default value: any Query statement: select local_role, db_state from pg_stat_get_stream_replications(); Suggestion: You are advised to set this parameter to master for services with write

Property	Description	Value
		operations to ensure that the primary DN can be properly connected after a switchover. However, if the standby DN is not completely promoted to primary during the switchover, the connection cannot be established. As a result, service statements cannot be executed.
priorityServers	Specifies the first n nodes configured in the URL as the primary database instance to be connected preferentially. It is used in streaming DR scenarios. Example: jdbc:opengauss://host1:port1,host2:port2,host3:port3,host4:port4/database?priorityServers=2 . That is, host1 and host2 are primary database instance nodes, and host3 and host4 are standby database instance nodes for DR.	Property type: integer Value range: a number greater than 0 and less than the number of DNs configured in the URL. Default value: NULL
forceTargetServerSlave	Specifies whether to enable the function of forcibly connecting to the standby node and forbid the existing connections to the standby node that is promoted to primary after a switchover of the database instance.	Property type: Boolean Value range: • false: The function of forcibly connecting to the standby node is disabled. • true: The function of forcibly connecting to the standby node is enabled. Default value: false
tracerInterfaceClass	Specifies the fully qualified name of the implementation class of the com.huawei.opengauss.jdbc.log.Tracer API that implements the method for obtaining traceld .	Property type: string Default value: NULL
use_boolean	Sets the OID type bound to the setBoolean() method in extended mode.	Property type: Boolean Value range: • false: The int2 type is bound. • true: The Boolean type is bound. Default value: false

Property	Description	Value
allowRead Only	Specifies whether to enable the read-only mode for a connection.	Property type: Boolean Value range: • true: The read-only mode is enabled. • false: The read-only mode is disabled. In this case, calling connection.setReadOnly(true) does not take effect, and data can still be modified. Default value: true
TLS_CIPHERS	Specifies the supported TLS cipher suite.	Property type: string Default value: TLS_DHE_RSA_WITH_AES_128_GCM_SHA256,TLS_DHE_RSA_WITH_AES_256_GCM_SHA384,TLS_ECDHE_RSA_WITH_AES_128_GCM_SHA256,TLS_ECDHE_RSA_WITH_AES_256_GCM_SHA384,TLS_ECDHE_ECDSA_WITH_AES_128_GCM_SHA256,TLS_ECDHE_ECDSA_WITH_AES_256_GCM_SHA384
stripTrailingZeros	Specifies whether trailing 0s of the numeric type are removed. It is valid only for ResultSet.getObject(int columnIndex).	Property type: Boolean Value range: • true: Trailing 0s of the numeric type are removed. • false: Trailing 0s of the numeric type are not removed. Default value: false
enableTimeZone	Specifies whether to enable the time zone setting on the client.	Property type: Boolean Value range: • true: The time zone setting on the client is enabled. The JVM time zone is obtained to specify the database time zone. • false: The time zone setting on the client is disabled. Instead, the database time zone is used. Default value: true

Property	Description	Value
loadBalanceHosts	Specifies whether to enable the load balancing function. In a centralized environment, ensure that no write operation is in services when using this parameter.	Property type: Boolean Value range: • true: The shuffle algorithm is used to randomly select a host from the candidates to establish a connection. • false: Multiple hosts specified in the URL are connected in sequence. Default value: false

5.3.2.2.3 Connecting to a Database in Non-Encrypted Mode

To connect to a database in non-encrypted mode, you need to load a driver and then establish a database connection. This section describes methods of loading drivers, APIs for creating database connections, and APIs for non-encrypted connections.

Methods of Loading Drivers

You can load drivers in the following ways:

- Implicitly load a driver at any position in code before creating a connection.
`Class.forName("com.huawei.opengauss.jdbc.Driver");`
- Pass parameters when a JVM is started. **jdbctest** is the name of the test case program.
`java -Djdbc.drivers=com.huawei.opengauss.jdbc.Driver jdbctest`

NOTE

1. GaussDB is compatible with PG in the use of JDBC. Therefore, when two JDBC drivers are used in the same process, class names may conflict.
2. Compared with the PG driver, the GaussDB JDBC driver has the following enhanced features:
 1. SHA-256 is supported for encrypted login.
 2. The third-party log framework that implements the sf4j API can be connected.
 3. DR failover is supported.

APIs for Creating Database Connections

JDBC provides three APIs for creating database connections. For details about the **url**, **info**, **user**, and **password** parameters, see [Table 5-6](#).

API 1: `DriverManager.getConnection(String url)`. You need to write a database username and password in a URL, which is insecure and not recommended.

API 2: `DriverManager.getConnection(String url, String user, String password)`. For details, see [Connecting to a Database Using API 2](#).

API 3: `DriverManager.getConnection(String url, Properties info)`. For details, see [Connecting to a Database Using API 3](#).

Table 5-6 Database connection parameters

Parameter	Description
url	Database connection descriptor when opengaussjdbc.jar is used. The format is as follows: • jdbc:opengauss:database • jdbc:opengauss://host/database • jdbc:opengauss://host:port/database • jdbc:opengauss://host:port/database?param1=value1&param2=value2 • jdbc:opengauss://host1:port1,host2:port2/database?param1=value1&param2=value2 NOTE • database indicates the name of the database to connect. • host indicates the name or IP address of the database server. For security purposes, the primary database node forbids access from other nodes in the database without authentication. To access the primary database node from inside the database, deploy the JDBC program on the host where the primary database node is located and set host to 127.0.0.1. Otherwise, the error message "FATAL: Forbid remote connection with trust method!" may be displayed. It is recommended that the service system be deployed outside the database. If it is deployed inside, database performance may be affected. By default, the localhost is used to connect to the server. • port indicates the port number of the database server. By default, the database on port 5431 of the localhost is connected. • param indicates a database connection attribute. The parameter can be configured in the URL. The URL starts with a question mark (?), uses an equal sign (=) to assign a value to the parameter, and uses an ampersand (&) to separate parameters. • value indicates the database connection attribute values. • The connectTimeout and socketTimeout parameters must be set for connection. If they are not set, the default value 0 is used, indicating that the connection will not time out. When the network between a DN and the client is faulty, the client cannot receive the ACK packet from the DN and retries transmission repeatedly. A timeout error is reported only when the number of retransmission times reaches 15 (the default value). As a result, the RTO is high. • You are advised to ensure the validity of the URL when using the standard JDBC API to establish a connection. An invalid URL may cause an exception, and the exception contains the original URL character string, which may cause sensitive information leakage.
info	Database connection property. For details about all parameters, see Connection Parameter Reference .
user	Database user.
password	Password of the database user.

Connecting to a Database Using API 2

Use the `DriverManager.getConnection(String url, String user, String password)` API to establish a database connection. The commands are as follows:

Step 1 Import `java.sql.Connection` and `java.sql.DriverManager`.

`java.sql.Connection` is a database connection API. The `getConnection()` method of `java.sql.DriverManager` is used to connect applications to a database. In addition, you need to import other APIs and classes based on the actual application scenario. For details, see [JDBC API Reference](#).

```
import java.sql.Connection;
import java.sql.DriverManager;
```

Step 2 Specify the database **sourceURL** (change *\$ip*, *\$port*, and *database* as required), username, and password.

Writing the username and password to code has great security risks. You are advised to store the username and password in environment variables.

```
String sourceURL = "jdbc:opengauss://$ip:$port/database";
String userName = System.getenv("EXAMPLE_USERNAME_ENV");
String password = System.getenv("EXAMPLE_PASSWORD_ENV");
```

Step 3 Load the driver.

1. Add the **opengaussjdbc.jar** package to the code running tool (such as IDE).
2. Load the database driver **com.huawei.opengauss.jdbc.Driver** as follows:

```
String driver = "com.huawei.opengauss.jdbc.Driver";
Class.forName(driver);
```

Step 4 Establish a database connection.

Call `DriverManager.getConnection(String url, String user, String password)` to connect to the database.

```
Connection conn = DriverManager.getConnection(sourceURL, userName, password);
```

----End

Connecting to a Database Using API 3

Use the `DriverManager.getConnection(String url, Properties info)` API to establish a database connection. The commands are as follows:

Step 1 Import `java.sql.Connection`, `java.sql.DriverManager`, and `java.util.Properties`.

The `setProperty()` method of `java.util.Properties` is used to set property values of a `Properties` object. In addition, you need to import other APIs and classes based on the actual application scenario. For details, see [JDBC API Reference](#).

```
import java.sql.Connection;
import java.sql.DriverManager;
import java.util.Properties;
```

Step 2 Specify the database **sourceURL** (change *\$ip*, *\$port*, and *database* as required), username, and password.

Writing the username and password to code has great security risks. You are advised to store the username and password in environment variables.

```
String sourceURL = "jdbc:opengauss://$ip:$port/database";
String userName = System.getenv("EXAMPLE_USERNAME_ENV");
String password = System.getenv("EXAMPLE_PASSWORD_ENV");
```

Step 3 Create a Properties object and set **userName** and **password** as the property values of the object.

```
Properties info = new Properties();  
info.setProperty("user", userName);  
info.setProperty("password", password);
```

Step 4 Load the driver.

1. Add the **opengaussjdbc.jar** package to the code running tool (such as IDE).
2. Load the database driver **com.huawei.opengauss.jdbc.Driver** as follows:

```
String driver = "com.huawei.opengauss.jdbc.Driver";  
Class.forName(driver);
```

Step 5 Establish a database connection.

Call `DriverManager.getConnection(String url, Properties info)` to connect to the database.

```
Connection conn = DriverManager.getConnection(sourceURL, info);
```

----End

5.3.2.2.4 Connecting to a Database in SSL Mode

When establishing connections to the GaussDB server using JDBC, you can enable SSL connections to encrypt client and server communications for security of sensitive data transmission on the Internet. You can connect to a database in SSL mode using the **NonValidatingFactory** channel or certificate-based authentication. In certificate-based authentication mode, a client and a server authenticate each other. In this section, the `DriverManager.getConnection(String url, Properties info)` API is used to connect to a database.

Method 1: NonValidatingFactory Channel

Prerequisites: You have obtained the certificates and private key file required by the server and configured the server. For details about how to generate and obtain the certificates and configure the server, contact an administrator or refer to related OpenSSL documents and commands.

Connect to a database through the **NonValidatingFactory** channel as follows:

Step 1 Import `java.sql.Connection`, `java.sql.DriverManager`, and `java.util.Properties`.

In addition, you need to import other APIs and classes based on the actual application scenario. For details, see [JDBC API Reference](#).

```
import java.sql.Connection;  
import java.sql.DriverManager;  
import java.util.Properties;
```

Step 2 Specify the database **sourceURL** (change *\$ip*, *\$port*, and *database* as required), username, and password.

Writing the username and password to code has great security risks. You are advised to store the username and password in environment variables.

```
String sourceURL = "jdbc:opengauss://$ip:$port/database";  
Properties urlProps = new Properties();  
urlProps.setProperty("user", System.getenv("EXAMPLE_USERNAME_ENV"));  
urlProps.setProperty("password", System.getenv("EXAMPLE_PASSWORD_ENV"));
```

Step 3 Set the SSL property to **true** to use the **NonValidatingFactory** channel.

```
urlProps.setProperty("ssl", "true");  
urlProps.setProperty("sslfactory", "com.huawei.opengauss.jdbc.ssl.NonValidatingFactory");
```

Step 4 Load the driver.

1. Add the **opengaussjdbc.jar** package to the code running tool (such as IDE).
2. Load the database driver **com.huawei.opengauss.jdbc.Driver** as follows:

```
Class.forName("com.huawei.opengauss.jdbc.Driver");
```

Step 5 Establish a database connection.

Call `DriverManager.getConnection(String url, Properties info)` to connect to the database.

```
Connection conn = DriverManager.getConnection(sourceURL, urlProps);
```

----End

Method 2: Certificate-based Authentication

Prerequisites: You have obtained the certificates and private key file required by the server and configured the server. You have obtained the **client.crt** client certificate, **cacert.pem** root certificate, and **client.key.pk8** client private key file required by the client. [Step 3](#) describes how to configure the certificates and private key file on the client. For details about how to generate and obtain the certificates and configure the server, contact an administrator or refer to related OpenSSL documents and commands.

Configure certificates on the client to connect to a database as follows:

Step 1 Import `java.sql.Connection`, `java.sql.DriverManager`, and `java.util.Properties`.

In addition, you need to import other APIs and classes based on the actual application scenario. For details, see [JDBC API Reference](#).

```
import java.sql.Connection;  
import java.sql.DriverManager;  
import java.util.Properties;
```

Step 2 Specify the database **sourceURL** (change *\$ip*, *\$port*, and *database* as required), username, and password.

Writing the username and password to code has great security risks. You are advised to store the username and password in environment variables.

```
String sourceURL = "jdbc:opengauss://$ip.$port/database";  
Properties urlProps = new Properties();  
urlProps.setProperty("user", System.getenv("EXAMPLE_USERNAME_ENV"));  
urlProps.setProperty("password", System.getenv("EXAMPLE_PASSWORD_ENV"));
```

Step 3 Set the SSL property to **true** and configure the **client.crt** client certificate, **cacert.pem** root certificate, and **client.key.pk8** client private key on the client.

```
urlProps.setProperty("ssl", "true");  
urlProps.setProperty("sslcert", "client.crt");  
urlProps.setProperty("sslrootcert", "cacert.pem");  
urlProps.setProperty("sslkey", "client.key.pk8");
```

 NOTE

Before using the client private key file, convert **client.key** to **client.key.pk8**.

```
/**
 * openssl pkcs8 -topk8 -outform DER -in client.key -out client.key.pk8 -nocrypt
 * openssl pkcs8 -topk8 -inform PEM -in client.key -outform DER -out client.key.der -v1 PBE-MD5-DES
 * openssl pkcs8 -topk8 -inform PEM -in client.key -outform DER -out client.key.der -v1 PBE-SHA1-3DES
 * The preceding algorithms are not recommended due to their low security.
 * If the customer needs to use a higher-level private key encryption algorithm, the following private
 * key encryption algorithms can be used after the BouncyCastle or a third-party private key is used to
 * decrypt the password package:
 * openssl pkcs8 -in client.key -topk8 -outform DER -out client.key.der -v2 AES128
 * openssl pkcs8 -in client.key -topk8 -outform DER -out client.key.der -v2 aes-256-cbc -iter 1000000
 * openssl pkcs8 -in client.key -topk8 -out client.key.der -outform Der -v2 aes-256-cbc -v2prf
 * hmacWithSHA512
 * Enable BouncyCastle: Introduce the bcpkix-jdk15on.jar package for projects that use JDBC. The
 * recommended version is 1.65 or later.
 */
```

Step 4 Configure **sslmode**.

Set **sslmode** to **require**, **verify-ca**, or **verify-full**. For details about the parameters, see [sslmode](#). You can select one of them based on the application scenario.

```
/* Set sslmode to require. */
urlProps.setProperty("sslmode", "require");
/* Set sslmode to verify-ca. */
urlProps.setProperty("sslmode", "verify-ca");
/* Set sslmode to verify-full (verification in Linux). */
urlProps.setProperty("sslmode", "verify-full");
```

Step 5 Load the driver.

1. Add the **opengaussjdbc.jar** package to the code running tool (such as IDE).
2. Load the database driver **com.huawei.opengauss.jdbc.Driver** as follows:

```
Class.forName("com.huawei.opengauss.jdbc.Driver");
```

Step 6 Establish a database connection.

Call `DriverManager.getConnection(String url, Properties info)` to connect to the database.

```
Connection conn = DriverManager.getConnection(sourceURL,urlProps);
```

----End

5.3.2.2.5 Connecting to a Database in UDS Mode

The UDS is used for data exchange between different processes on the same host. You can add **unixsocket** to obtain the socket factory.

Prerequisites: You have referenced **unixsocket-core-XXX.jar**, **unixsocket-common-XXX.jar**, and **unixsocket-native-common-XXX.jar**. XXX indicates the version number. The version numbers of the referenced JAR packages must be consistent.

To connect to a database in UDS mode, perform the following steps:

Step 1 Import `java.sql.Connection`, `java.sql.DriverManager`, and `java.util.Properties`.

In addition, you need to import other APIs and classes based on the actual application scenario. For details, see [JDBC API Reference](#).

```
import java.sql.Connection;
import java.sql.DriverManager;
import java.util.Properties;
```

Step 2 Specify the username and password of the database.

Writing the username and password to code has great security risks. You are advised to store the username and password in environment variables. Set the username and password to the property values of the Properties object.

```
String userName = System.getenv("EXAMPLE_USERNAME_ENV");
String password = System.getenv("EXAMPLE_PASSWORD_ENV");
Properties properties = new Properties();
properties.setProperty("user", userName);
properties.setProperty("password", password);
```

Step 3 Load the driver.

1. Add the **opengaussjdbc.jar** package to the code running tool (such as IDE).
2. Load the database driver **com.huawei.opengauss.jdbc.Driver** as follows:

```
String driver = "com.huawei.opengauss.jdbc.Driver";
Class.forName(driver);
```

Step 4 Specify the database *\$ip*, *\$port*, *database*, **socketFactory**, and **socketFactoryArg**.

Change *\$ip*, *\$port* as required. Set *database* to **localhost**, **socketFactory** to **org.newsclub.net.unix.AFUNIXSocketFactory\$FactoryArg**, and **socketFactoryArg** to *[path-to-the-unix-socket]* to connect to the database in UDS mode. For details about the **socketFactory** and **socketFactoryArg** parameters, see [socketFactory](#) and [socketFactoryArg](#).

 NOTE

Set the **socketFactoryArg** parameter based on the actual path. The value must be the same as that of the GUC parameter **unix_socket_directory**.

```
Connection conn = DriverManager.getConnection("jdbc:opengauss://$ip:$port/database?
socketFactory=org.newsclub.net.unix" +
".AFUNIXSocketFactory$FactoryArg&socketFactoryArg=[path-to-the-unix-socket]",properties);
System.out.println("Connection Successful!");
```

----End

5.3.2.3 Running SQL Statements

In this section, you can [execute basic SQL statements](#) to create the **customer_t1** table, [execute a prepared statement](#) to insert data in batches, [execute a prepared statement](#) to update data, and [create and call stored procedures](#).

Running a Common SQL Statement

SQL statements are run on applications to operate a database. Operations such as SELECT, UPDATE, INSERT, and DELETE can be performed on XML data.

The prerequisite is that you have connected to the database using the connection object **conn**. Execute basic SQL statements to create the **customer_t1** table as follows:

Step 1 Create a statement object by calling the `createStatement` method of the Connection API.

```
Statement stmt = conn.createStatement();
```

Step 2 Run the SQL statement by calling the `executeUpdate` method of the Statement API.

```
int rc = stmt.executeUpdate("CREATE TABLE customer_t1(c_customer_sk INTEGER, c_customer_name  
VARCHAR(32));");
```

Step 3 Close the statement object **stmt** by calling the close method of the Statement API.

```
stmt.close();
```

----End

NOTE

- If an execution request (not in a transaction block) received in the database contains multiple statements, the request is packed into a transaction. **VACUUM** is not supported in a transaction block. If one of the statements fails, the entire request will be rolled back.
- Use semicolons (;) to separate statements. Stored procedures, functions, and anonymous blocks do not support multi-statement execution. When **preferQueryMode** is set to **simple**, the statement does not execute the parsing logic, and the semicolons (;) cannot be used to separate statements in this scenario.
- The slash (/) can be used as the terminator for creating a single stored procedure, function, anonymous block, or package body. When **preferQueryMode** is set to **simple**, the statement does not execute the parsing logic, and the slash (/) cannot be used as the terminator in this scenario.
- JDBC caches SQL statements in PreparedStatement, which may cause memory bloat. If the JVM memory is small, you are advised to adjust **preparedStatementCacheSizeMiB** or **preparedStatementCacheQueries**.

Executing a Prepared Statement for Insertion

When a prepared statement processes multiple pieces of similar data, the database creates only one execution plan. This improves compilation and optimization efficiency.

The prerequisite is that the **customer_t1** table has been created by executing the preceding basic SQL statements. Execute the prepared statement to insert data in batches as follows:

Step 1 Create the prepared statement object **pst** by calling the prepareStatement method of the Connection API.

```
PreparedStatement pst = conn.prepareStatement("INSERT INTO customer_t1 VALUES (?,?)");
```

Step 2 Call the corresponding API to set parameters for each piece of data and call addBatch to add SQL statements to the batch processing.

```
for (int i = 0; i < 3; i++) {  
    pst.setInt(1, i);  
    pst.setString(2, "data " + i);  
    pst.addBatch();  
}
```

Step 3 Perform batch processing by calling the executeBatch method of the PreparedStatement API.

```
pst.executeBatch();
```

Step 4 Close the prepared statement object **pst** by calling the close method of the PreparedStatement API.

```
pst.close();
```

----End

 NOTE

Do not terminate a batch processing action when it is ongoing; otherwise, database performance will deteriorate. Therefore, disable automatic commit during batch processing. Manually commit several lines at a time. The statement for disabling automatic commit is as follows:

```
conn.setAutoCommit(false);
```

Running a Prepared SQL Statement

Prepared statements are compiled and optimized once but can be used in different scenarios by assigning different values. Using prepared statements improves execution efficiency. If you want to run a statement for several times, use a prepared statement.

The prerequisite is that the preceding prepared statement has been executed and data has been inserted into the **customer_t1** table in batches. Execute the prepared SQL statement to update data as follows:

- Step 1** Create the prepared statement object **pstmt** by calling the `prepareStatement` method of the Connection API.

```
PreparedStatement pstmt = conn.prepareStatement("UPDATE customer_t1 SET c_customer_name = ?  
WHERE c_customer_sk = 1");
```

- Step 2** Set parameters by calling the `setString` method of the PreparedStatement API.

```
pstmt.setString(1, "new Data");
```

- Step 3** Execute the prepared statement by calling the `executeUpdate` method of the PreparedStatement API.

```
int rowcount = pstmt.executeUpdate();
```

- Step 4** Close the prepared statement object **pstmt** by calling the `close` method of the PreparedStatement API.

```
pstmt.close();
```

----End

NOTICE

After binding parameters are set in `PreparedStatement`, a B packet or U packet is constructed and sent to the server when the SQL statement is executed. However, the maximum length of a B packet or U packet cannot exceed 1023 MB. If the data bound at a time is too large, an exception may occur because the packet is too long. Therefore, when setting binding parameters in `PreparedStatement`, you need to evaluate and control the size of the bound data to avoid exceeding the upper limit of the packet.

Creating and Calling a Stored Procedure

GaussDB can call stored procedures through JDBC. The prerequisite is that the database connection is established using the connection object `conn`.

Create the **testproc** stored procedure as follows:

```
// Create the stored procedure (containing the out parameter) in the database as follows:  
create or replace procedure testproc
```

```
(
    psv_in1 in integer,
    psv_in2 in integer,
    psv_inout inout integer
)
as
begin
    psv_inout := psv_in1 + psv_in2 + psv_inout;
end;
/
```

Call the **testproc** stored procedure as follows:

Step 1 Create a call statement object **cstmt** by calling the `prepareCall` method of `Connection`.

```
CallableStatement cstmt = conn.prepareCall("{? = CALL TESTPROC(?,?,?)}");
```

Step 2 Set parameters by calling the `setInt` method of `CallableStatement`.

```
cstmt.setInt(2, 50);
cstmt.setInt(1, 20);
cstmt.setInt(3, 90);
```

Step 3 Register an output parameter by calling the **registerOutParameter** method in **CallableStatement**.

```
cstmt.registerOutParameter(4, Types.INTEGER); // Register an OUT parameter of the integer type.
```

Step 4 Execute SQL statements by calling the `execute` method of `CallableStatement`.

```
cstmt.execute();
```

Step 5 Obtain the out parameter by calling the `getInt` method of `CallableStatement`.

```
int out = cstmt.getInt(4);
```

Step 6 Close the call statement object **cstmt** by calling the `close` method of `CallableStatement`.

```
cstmt.close();
```

----End

NOTICE

- If JDBC is used to call a stored procedure whose returned value is a cursor, the returned cursor cannot be used.
- A stored procedure and a basic SQL statement must be run separately.
- Output parameters must be registered for parameters of the `inout` type in the stored procedure.

 NOTE

- Many database classes such as Connection, Statement, and ResultSet have a close() method. Close these classes after using their objects. Closing Connection objects is to close all the related Statement objects, and closing a Statement object is to close its ResultSet object.
- Some JDBC drivers support named parameters, which can be used to set parameters by name rather than sequence. If a parameter has the default value, you do not need to specify any parameter value but can use the default value directly. Even though the parameter sequence changes during a stored procedure, the application does not need to be modified. Currently, the GaussDB JDBC driver does not support this method.
- GaussDB does not support functions containing OUT parameters, or stored procedures and function parameters containing default values.
- When you bind parameters in `conn.prepareStatement("{? = CALL TESTPROC(?,?,?)})"` during a stored procedure calling, you can bind parameters and register the first parameter as the output parameter according to the placeholder sequence or the fourth parameter as the output parameter according to the parameter sequence in the stored procedure. The preceding example registers the fourth parameter.

Creating and Calling a Stored Procedure (Input Parameters of the Composite Data Type)

The following shows how to create and call a stored procedure whose input parameters are of the composite data type in A-compatible mode. The prerequisite is that the database connection is established using the connection object `conn`.

Create the **test_proc** stored procedure as follows:

```
// Create a composite data type in the database.
CREATE TYPE compfoo AS (f1 int, f3 text);
// Create the following stored procedure (containing the out parameter) in the database:
create or replace procedure test_proc
(
    psv_in in compfoo,
    psv_out out compfoo
)
as
begin
    psv_out := psv_in;
end;
/
```

Call the **test_proc** stored procedure as follows:

Step 1 After setting **behavior_compat_options** to '**proc_outparam_override**', create the call statement object **cs** by calling the `prepareCall` method of Connection.

```
Statement statement = conn.createStatement();
statement.execute("set behavior_compat_options='proc_outparam_override'");
CallableStatement cs = conn.prepareCall("{ CALL TEST_PROC(?,?) }");
```

Step 2 Set parameters by calling the `set` method of CallableStatement.

```
PObject pObject = new PObject();
pObject.setType("public.compfoo"); // Set the composite type name. The format is "schema.typename".
pObject.setValue("1,demo"); // Bind the value of the composite type. The format is "(value1,value2)".
cs.setObject(1, pObject);
```

Step 3 Register an output parameter by calling the **registerOutParameter** method in CallableStatement.

```
//Register an out parameter of the composite type. The format is "schema.typename".
cs.registerOutParameter(2, Types.STRUCT, "public.compfoo");
```

Step 4 Execute SQL statements by calling the execute method of CallableStatement.

```
cs.execute();
```

Step 5 Obtain the output parameter by calling the **getObject** method in **CallableStatement**.

```
PObject result = (PObject)cs.getObject(2); // Obtain the out parameter.  
result.getValue(); // Obtain the string value of the composite type.  
result.getArrayValue(); // Obtain the array values of the composite type and sort the values according to  
the sequence of columns of the composite type.  
result.getStruct(); // Obtain the subtype names of the composite type and sort them according to the  
creation sequence.
```

Step 6 Close the call statement object **cs** by calling the close method of CallableStatement.

```
cs.close();
```

----End

NOTE

- After the A-compatible mode is enabled, you must use the {call proc_name(?,?) format to call a stored procedure and use the {? = call func_name(?,?) format to call a function. The question mark (?) on the left of the equal mark is the placeholder for the return value of the function and is used to register the return value of the function.
- After setting **behavior_compat_options** to 'proc_outparam_override', re-establish the connection. Otherwise, the stored procedures and functions cannot be correctly called.
- If a function or stored procedure contains a composite type, bind and register parameters in the schema.typename format.

5.3.2.4 Processing Data in a Result Set

After running SQL statements, you need to process the result set. This section describes how to set the result set type, locate the result set, obtain the cursor position from a result set, and obtain data from the result set.

Setting a Result Set Type

Different types of result sets apply to different application scenarios. Applications select proper types of result sets based on requirements. Before running an SQL statement, you must create a statement object. Some methods of creating statement objects can set the type of a result set. [Table 5-7](#) lists result set parameters. The related Connection methods are as follows:

```
// Create a Statement object. This object will generate a ResultSet object with a specified type and  
concurrency.  
createStatement(int resultSetType, int resultSetConcurrency);  
  
// Create a PreparedStatement object. This object will generate a ResultSet object with a specified type and  
concurrency.  
prepareStatement(String sql, int resultSetType, int resultSetConcurrency);  
  
// Create a CallableStatement object. This object will generate a ResultSet object with a specified type and  
concurrency.  
prepareCall(String sql, int resultSetType, int resultSetConcurrency);
```

Table 5-7 Result set types

Parameter	Description
resultSetType	Type of a result set. There are three types of result sets: • ResultSet.TYPE_FORWARD_ONLY: The ResultSet object can only be navigated forward. It is the default value. • ResultSet.TYPE_SCROLL_SENSITIVE: You can view the modified result by scrolling to the modified row. • ResultSet.TYPE_SCROLL_INSENSITIVE: The ResultSet object is insensitive to changes in the underlying data source. NOTE After a result set has obtained data from the database, the result set is insensitive to data changes made by other transactions, even if the result set type is ResultSet.TYPE_SCROLL_SENSITIVE. To obtain up-to-date data of the record pointed by the cursor from the database, call the <code>refreshRow()</code> method in a ResultSet object.
resultSetConcurrency	Concurrency type of a result set. There are two types of concurrency. • ResultSet.CONCUR_READ_ONLY: Data in a result set cannot be updated except that an updated statement has been created in the result set data. • ResultSet.CONCUR_UPDATEABLE: changeable result set. The concurrency type for a result set object can be updated if the result set is scrollable.

Positioning a Cursor in a Result Set

ResultSet objects include a cursor pointing to the current data row. The cursor is initially positioned before the first row. The `next` method moves the cursor to the next row from its current position. When a ResultSet object does not have a next row, a call to the `next` method returns **false**. Therefore, this method is used in the while loop for result set iteration. However, the JDBC driver provides more cursor positioning methods for scrollable result sets, which allows positioning cursor in the specified row. [Table 5-8](#) describes these methods.

Table 5-8 Methods for positioning a cursor in a result set

Method	Description
<code>next()</code>	Moves cursor to the next row from its current position.
<code>previous()</code>	Moves cursor to the previous row from its current position.
<code>beforeFirst()</code>	Places cursor before the first row.

Method	Description
afterLast()	Places cursor after the last row.
first()	Places cursor to the first row.
last()	Places cursor to the last row.
absolute(int row)	Places cursor to a specified row.
relative(int rows)	Moves the result set downwards by the number of rows specified by rows when rows is set to a positive number, or moves the result set upwards by the number of rows specified by rows when rows is set to a negative number.

Obtaining the Cursor Position from a Result Set

This cursor positioning method will be used to change the cursor position for a scrollable result set. The JDBC driver provides a method to obtain the cursor position in a result set. [Table 5-9](#) describes these methods.

Table 5-9 Methods for obtaining a cursor position in a result set

Method	Description
isFirst()	Checks whether it is in the first row.
isLast()	Checks whether it is in the last row.
isBeforeFirst()	Checks whether it is before the first row.
isAfterLast()	Checks whether it is after the last row.
getRow()	Obtains its current row number.

Obtaining Data from a Result Set

ResultSet objects provide a variety of methods to obtain data from a result set. [Table 5-10](#) describes the common methods for obtaining data. If you want to know more about other methods, see JDK official documents.

Table 5-10 Common methods for obtaining data from a result set

Method	Description
<code>getInt(int columnIndex)</code>	Retrieves the value of the column designated by a column index in the current row as an integer.
<code>getInt(String columnLabel)</code>	Retrieves the value of the column designated by a column label in the current row as an integer.
<code>getString(int columnIndex)</code>	Retrieves the value of the column designated by a column index in the current row as a string.
<code>getString(String columnLabel)</code>	Retrieves the value of the column designated by a column label in the current row as a string.
<code>getDate(int columnIndex)</code>	Retrieves the value of the column designated by a column index in the current row as a date.
<code>getDate(String columnLabel)</code>	Retrieves the value of the column designated by a column name in the current row as a date.

5.3.2.5 Closing a Database Connection

After you complete required data operations in the database, close the database connection.

You can call the close method to close the connection.

```
conn.close();
```

5.3.3 Typical Application Development Examples

5.3.3.1 Configuring Connection Parameters in Different Scenarios

NOTE

In the following example, **host:port** represents a node, where **host** indicates the name or IP address of the server where the database resides, and **port** indicates the port number of the server where the database resides.

DR

A customer has two database instances. Database instance A is the production database instance, and database instance B is the DR database instance. When the customer performs a DR failover, database instance A is demoted to the DR database instance, and database instance B is promoted the production database instance. In this case, to avoid application restart or re-release caused by

modifications on the configuration file, the customer can write database instances A and B to the connection string when initializing the configuration file. If the primary database instance cannot be connected, the driver attempts to connect to the DR database instance. For example, database instance A consists of *node1*, *node2*, and *node3*, and database instance B consists of *node4*, *node5*, and *node6*.

The URL can be configured as follows:

```
jdbc:opengauss://node1,node2,node3,node4,node5,node6/database?priorityServers=3
```

If you want to connect to both the primary database instance and hosts in the primary database instance, set **targetServerType** to **master**. The URL can be configured as follows:

```
jdbc:opengauss://node1,node2,node3,node4,node5,node6/database?  
priorityServers=3&targetServerType=master
```

Load Balancing

A customer has a centralized database instance that consists of one primary node and two standby nodes {*node1*, *node2*, *node3*}. **node1** is the primary node, and **node2** and **node3** are standby nodes.

If the customer wants to evenly distribute the connections established on the same application to three nodes, the URL can be configured as follows:

```
jdbc:opengauss://node1,node2,node3/database?loadBalanceHosts=true
```

CAUTION

When **loadBalanceHosts** is used, if the connection is established on the standby DN, write operations cannot be performed. If read and write operations are required, do not set this parameter.

Automatic Selection of the Primary Node

A customer has a centralized database instance that consists of one primary node and two standby nodes {*node1*, *node2*, *node3*}. **node1** is the primary node, and **node2** and **node3** are standby nodes.

If the customer requires that the application connection be established on the primary DN and a new primary node be automatically selected to establish the connection during the primary/standby switchover, configure the URL as follows:

```
jdbc:opengauss://node1,node2,node3/database?targetServerType=master
```

Log Diagnosis Scenario

If a customer encounters slow data import or some errors that are difficult to analyze, the trace log function can be enabled for diagnosis. The URL can be configured as follows:

```
jdbc:opengauss://node1/database?loggerLevel=trace
```

High Performance

A customer may execute the same SQL statement for multiple times with different input parameters. To improve the execution efficiency, the **prepareThreshold**

parameter can be enabled to avoid repeatedly generating execution plans. The URL can be configured as follows:

```
jdbc:opengauss://node1/database?prepareThreshold=5
```

A customer queries 10 million data records at a time. To prevent memory overflow caused by simultaneous return of the data records, the **defaultRowFetchSize** parameter can be used. The URL can be configured as follows:

```
jdbc:opengauss://node1/database?defaultRowFetchSize=50000
```

A customer needs to insert 10 million data records in batches. To improve efficiency, the **batchMode** parameter can be used. The URL can be configured as follows:

```
jdbc:opengauss://node1/database?batchMode=on
```

Case Conversion

In GaussDB, metadata is stored in lowercase letters by default. If metadata is migrated from a database where metadata is stored in uppercase letters by default to GaussDB, the metadata in uppercase letters changes to lowercase letters. If the original service involves the processing of uppercase metadata, you can enable **uppercaseAttributeName**. However, you are advised to modify the service code instead of using this method to solve the problem. If you have to use this function, ensure that the metadata in the current database is in lowercase to avoid problems.

```
jdbc:opengauss://node1/database?uppercaseAttributeName=true
```

The APIs involved in DatabaseMetaData can be directly called based on input parameters. The methods of using the APIs involved in ResultSetMetaData are as follows:

```
Statement stmt = conn.createStatement();
ResultSet rs = stmt.executeQuery("select * from test_supplier");
ResultSetMetaData rsmd = rs.getMetaData();
for (int i = 1; i <= rsmd.getColumnCount(); i++) {
    System.out.println(rsmd.getColumnLabel(i) + " " + rsmd.getColumnName(i));
}
```

5.3.3.2 Creating and Calling a Stored Procedure

The following illustrates how to develop applications based on GaussDB JDBC APIs. It also demonstrates how to connect to a database and create and call stored procedures.

Prerequisites for code running: Add the **opengaussjdbc.jar** package as required. For example, if you use an IDE to run code, you need to add the **opengaussjdbc.jar** package to the local IDE.

```
// There will be security risks if the username and password used for authentication are directly written into code. It is recommended that the username and password be stored in the configuration file or environment variables (the password must be stored in ciphertext and decrypted when being used) to ensure security.
```

```
// In this example, the username and password are stored in environment variables. Before running this example, set environment variables EXAMPLE_USERNAME_ENV and EXAMPLE_PASSWORD_ENV in the local environment (set the environment variable names based on the actual situation).
```

```
// You need to change the values of $ip, $port, and database.
```

```
import java.sql.Connection;
import java.sql.DriverManager;
```

```
import java.sql.PreparedStatement;
import java.sql.SQLException;
import java.sql.Statement;
import java.sql.CallableStatement;
import java.sql.Types;

public class DBTest {

    // Establish a database connection in non-encrypted mode.
    public static Connection GetConnection(String username, String passwd) {
        String driver = "com.huawei.opengauss.jdbc.Driver";
        String sourceURL = "jdbc:opengauss://$p:$port/database";
        Connection conn = null;
        try {
            // Load the database driver.
            Class.forName(driver).newInstance();
        } catch (Exception e) {
            e.printStackTrace();
            return null;
        }

        try {
            // Create a database connection.
            conn = DriverManager.getConnection(sourceURL, username, passwd);
            System.out.println("Connection succeed!");
        } catch (Exception e) {
            e.printStackTrace();
            return null;
        }

        return conn;
    };

    // Create a stored procedure.
    public static void CreateCallable(Connection conn) {
        Statement stmt = null;
        try {
            stmt = conn.createStatement();
            // Create a stored procedure and return the sum of the three input values.
            stmt.execute("create or replace procedure testproc \n" +
                "\n" +
                "    psv_in1 in integer,\n" +
                "    psv_in2 in integer,\n" +
                "    psv_inout inout integer\n" +
                ")\n" +
                "as\n" +
                "begin\n" +
                "    psv_inout := psv_in1 + psv_in2 + psv_inout;\n" +
                "end;\n" +
                "/");
        } catch (SQLException e) {
            throw new RuntimeException(e);
        } finally {
            if (stmt != null) {
                try {
                    stmt.close();
                } catch (SQLException e) {
                    throw new RuntimeException(e);
                }
            }
        }
    }

    -- Call the stored procedure.
    public static void ExecCallableSQL(Connection conn) {
        CallableStatement cstmt = null;
        try {
            cstmt=conn.prepareCall("{? = CALL TESTPROC(?,?,?)");
        }
```

```
cstmt.setInt(2, 50);
cstmt.setInt(1, 20);
cstmt.setInt(3, 90);
cstmt.registerOutParameter(4, Types.INTEGER); // Register an OUT parameter of the integer type.
cstmt.execute();
int out = cstmt.getInt(4); // Obtain the OUT parameter.
System.out.println("The CallableStatement TESTPROC returns:"+out);
cstmt.close();
} catch (SQLException e) {
    if (cstmt != null) {
        try {
            cstmt.close();
        } catch (SQLException e1) {
            e1.printStackTrace();
        }
    }
    e.printStackTrace();
}
}
```

```
/**
 * Main process. Call static methods one by one.
 * @param args
 */
public static void main(String[] args) {
    // Create a database connection.
    String userName = System.getenv("EXAMPLE_USERNAME_ENV");
    String password = System.getenv("EXAMPLE_PASSWORD_ENV");
    Connection conn = GetConnection(userName, password);

    // Create a stored procedure.
    CreateCallable(conn);

    // Run the stored procedure.
    ExecCallableSQL(conn);

    // Close the connection to the database.
    try {
        conn.close();
    } catch (SQLException e) {
        e.printStackTrace();
    }
}
```

The execution result of the preceding example is as follows:

```
Connection succeed!
The CallableStatement TESTPROC returns:160
```

5.3.3.3 Obtaining the Return Value of a Function

JDBC obtains the return value when calling a function. The following example shows the return values of the bit and float8 types. For other data types, refer to this example.

Prerequisites for code running: Add the **opengaussjdbc.jar** package as required. For example, if you use an IDE to run code, you need to add the **opengaussjdbc.jar** package to the local IDE.

```
// There will be security risks if the username and password used for authentication are directly written into
code. It is recommended that the username and password be stored in the configuration file or
environment variables (the password must be stored in ciphertext and decrypted when being used) to
ensure security.
```

```
// In this example, the username and password are stored in environment variables. Before running this
// example, set environment variables EXAMPLE_USERNAME_ENV and EXAMPLE_PASSWORD_ENV in the local
// environment (set the environment variable names based on the actual situation).
// You need to change the values of $ip, $port, and database.

import java.sql.Connection;
import java.sql.DriverManager;
import java.sql.Statement;
import java.sql.CallableStatement;
import java.sql.SQLException;
import java.sql.PreparedStatement;
import java.sql.Types;

public class Type {
    public static void main(String[] args) throws SQLException {
        String driver = "com.huawei.opengauss.jdbc.Driver";
        String username = System.getenv("EXAMPLE_USERNAME_ENV");
        String passwd = System.getenv("EXAMPLE_PASSWORD_ENV");
        String sourceURL = "jdbc:opengauss://$ip:$port/database";
        Connection conn = null;

        try {
            // Load the database driver.
            Class.forName(driver).newInstance();
        } catch (Exception e) {
            e.printStackTrace();
        }

        try {
            // Establish a database connection in non-encrypted mode.
            conn = DriverManager.getConnection(sourceURL, username, passwd);
            System.out.println("Connection succeed!");
        } catch (Exception e) {
            e.printStackTrace();
        }

        // Create a table.
        String createsql = "create table if not exists t_bit(col_bit bit)";
        Statement stmt = conn.createStatement();
        stmt.execute(createsql);
        stmt.close();
        // Example of using the bit type. Note that the value range of the bit type is [0,1].
        Statement st = conn.createStatement();
        String sqlstr = "create or replace function fun_1()\n" + "returns bit AS $$\n"
            + "select col_bit from t_bit limit 1;\n" + "$$\n" + "LANGUAGE SQL;";
        st.execute(sqlstr);
        CallableStatement c = conn.prepareCall("{ ? = call fun_1() }");
        // Register the output type, which is a bit string.
        c.registerOutParameter(1, Types.BIT);
        c.execute();
        // Use the Boolean type to obtain the result.
        System.out.println(c.getBoolean(1));

        // Example of using the float8 type.
        st.execute("create table if not exists t_float(col1 float8)");
        PreparedStatement pstmt = conn.prepareStatement("insert into t_float values(?)");
        pstmt.setDouble(1, 123456.123);
        pstmt.execute();
        pstmt.close();

        // Example of using the function whose return value is of the float8 type.
        st.execute(
            "create or replace function func_float() " + "return float8 " + "as declare " + "var1 float8; " + "begin
"
            + " select col1 into var1 from t_float limit 1; " + " return var1; " + "end;");
        CallableStatement cs = conn.prepareCall("{ ? = call func_float() }");
        cs.registerOutParameter(1, Types.DOUBLE);
        cs.execute();
        System.out.println(cs.getDouble(1));
    }
}
```

```
st.close();

// Close the connection to the database.
try {
    conn.close();
} catch (SQLException e) {
    e.printStackTrace();
}
}
```

The execution result of the preceding example is as follows:

```
Connection succeed!
false
123456.123
```

 CAUTION

Currently, JDBC cannot call stored procedures and functions whose return data type is money.

5.3.3.4 Batch Query

In this example, `setFetchSize` adjusts the memory usage of the client by using the database cursor to obtain server data in batches. It may increase network interaction and affect performance to some extent. The cursor is valid within a transaction. Therefore, disable automatic transaction commit and then manually commit the transaction.

Prerequisites for code running: Add the **opengaussjdbc.jar** package as required. For example, if you use an IDE to run code, you need to add the **opengaussjdbc.jar** package to the local IDE.

```
// There will be security risks if the username and password used for authentication are directly written into
// code. It is recommended that the username and password be stored in the configuration file or
// environment variables (the password must be stored in ciphertext and decrypted when being used) to
// ensure security.
// In this example, the username and password are stored in environment variables. Before running this
// example, set environment variables EXAMPLE_USERNAME_ENV and EXAMPLE_PASSWORD_ENV in the local
// environment (set the environment variable names based on the actual situation).
// You need to change the values of $ip, $port, and database.
```

```
import java.sql.Connection;
import java.sql.DriverManager;
import java.sql.Statement;
import java.sql.ResultSet;
import java.sql.SQLException;
import java.sql.PreparedStatement;

public class Batch {
    public static void main(String[] args) throws SQLException {
        String driver = "com.huawei.opengauss.jdbc.Driver";
        String username = System.getenv("EXAMPLE_USERNAME_ENV");
        String passwd = System.getenv("EXAMPLE_PASSWORD_ENV");
        String sourceURL = "jdbc:opengauss://$ip:$port/database";
        Connection conn = null;

        try {
            // Load the database driver.
            Class.forName(driver).newInstance();
        } catch (Exception e) {
            e.printStackTrace();
        }
    }
}
```

```
}

try {
    // Establish a database connection in non-encrypted mode.
    conn = DriverManager.getConnection(sourceURL, username, passwd);
    System.out.println("Connection succeed!");
} catch (Exception e) {
    e.printStackTrace();
}

// Disable automatic commit.
conn.setAutoCommit(false);

// Create a table.
Statement st = conn.createStatement();
st.execute("create table mytable (cal1 int);");

// Insert 200 rows of data into the table.
PreparedStatement pstmt = conn.prepareStatement("insert into mytable values (?)");
for (int i = 0; i < 200; i++) {
    pstmt.setInt(1, i + 1);
    pstmt.addBatch();
}
pstmt.executeBatch();
conn.commit();
pstmt.close();

// Open the cursor and obtain 50 rows of data each time.
st.setFetchSize(50);
int fetchCount = 0;
ResultSet rs = st.executeQuery("SELECT * FROM mytable");
while (rs.next()) {
    fetchCount++;
}
System.out.println(fetchCount == 200);
conn.commit();
rs.close();

// Disable the server cursor.
st.setFetchSize(0);
fetchCount = 0;
rs = st.executeQuery("SELECT * FROM mytable");
while (rs.next()) {
    fetchCount++;
}
System.out.println(fetchCount == 200);
conn.commit();
rs.close();

// Close the statement object and database connection.
st.close();
conn.close();

}
}
```

The execution result of the preceding example is as follows:

```
Connection succeed!
true
true
```

Enable automatic commit.

```
conn.setAutoCommit(true);
```

5.3.3.5 SQL Retry at an Application Layer

If the primary database node is faulty and cannot be restored within 10s, GaussDB automatically switches the standby database node to the active state to ensure the normal running of the database. Jobs running during the failover will fail and those started after the failover will not be affected. To prevent upper-layer services from being affected by the failover, refer to the following example to construct an SQL retry mechanism at the service layer.

Prerequisites for code running: Add the **opengaussjdbc.jar** package as required. For example, if you use an IDE to run code, you need to add the **opengaussjdbc.jar** package to the local IDE.

```
// There will be security risks if the username and password used for authentication are directly written into
// code. It is recommended that the username and password be stored in the configuration file or
// environment variables (the password must be stored in ciphertext and decrypted when being used) to
// ensure security.
// In this example, the username and password are stored in environment variables. Before running this
// example, set environment variables EXAMPLE_USERNAME_ENV and EXAMPLE_PASSWORD_ENV in the local
// environment (set the environment variable names based on the actual situation).
// You need to change the values of $ip, $port, and database.
```

```
import java.sql.Connection;
import java.sql.DriverManager;
import java.sql.PreparedStatement;
import java.sql.ResultSet;
import java.sql.SQLException;
import java.sql.Statement;

class ExitHandler extends Thread {
    private Statement cancel_stmt = null;

    public ExitHandler(Statement stmt) {
        super("Exit Handler");
        this.cancel_stmt = stmt;
    }

    public void run() {
        System.out.println("exit handle");
        try {
            this.cancel_stmt.cancel();
        } catch (SQLException e) {
            System.out.println("cancel query failed.");
            e.printStackTrace();
        }
    }
}

public class SQLRetry {
    // Establish a database connection in non-encrypted mode.
    public static Connection GetConnection(String username, String passwd) {
        String driver = "com.huawei.opengauss.jdbc.Driver";
        String sourceURL = "jdbc:opengauss://$ip:$port/database";
        Connection conn = null;
        try {
            // Load the database driver.
            Class.forName(driver).newInstance();
        } catch (Exception e) {
            e.printStackTrace();
            return null;
        }

        try {
            // Create a database connection.
            conn = DriverManager.getConnection(sourceURL, username, passwd);
            System.out.println("Connection succeed!");
        } catch (Exception e) {
            e.printStackTrace();
        }
    }
}
```

```
        return null;
    }

    return conn;
}

// Run a common SQL statement to create the jdbc_test1 table.
public static void CreateTable(Connection conn) {
    Statement stmt = null;
    try {
        stmt = conn.createStatement();

finesh.....  
time:10  
col1 = 10  
finesh.....  
exit handle
```

5.3.3.6 Importing and Exporting Data Through Local Files

When Java is used for secondary development based on GaussDB, you can use the CopyManager API to export data from the database to a local file or import a local file to the database by streaming. The file can be in CSV or TEXT format.

Prerequisites for code running:

1. The **opengaussjdbc.jar** package is added as required. For example, if you use an IDE to run code, you need to add the **opengaussjdbc.jar** package to the local IDE.
2. Tables **migration_table** and **migration_table_1** have been created in the database, and data has been inserted into the **migration_table** table.

```
// There will be security risks if the username and password used for authentication are directly written into  
// code. It is recommended that the username and password be stored in the configuration file or  
// environment variables (the password must be stored in ciphertext and decrypted when being used) to  
// ensure security.  
// In this example, the username and password are stored in environment variables. Before running this
```

example, set environment variables *EXAMPLE_USERNAME_ENV* and *EXAMPLE_PASSWORD_ENV* in the local environment (set the environment variable names based on the actual situation).
// You need to change the values of *\$ip*, *\$port*, and *database*.

```
import java.sql.Connection;
import java.sql.DriverManager;
import java.io.IOException;
import java.io.FileInputStream;
import java.io.FileOutputStream;
import java.sql.SQLException;
import com.huawei.opengauss.jdbc.copy.CopyManager;
import com.huawei.opengauss.jdbc.core.BaseConnection;

public class Copy{

    public static void main(String[] args)
    {
        String urls = new String("jdbc:opengauss://$ip:$port/database"); // Database URL
        String username = System.getenv("EXAMPLE_USERNAME_ENV"); // Username
        String password = System.getenv("EXAMPLE_PASSWORD_ENV"); // Password
        String tablename = new String("migration_table"); // Table information
        String tablename1 = new String("migration_table_1"); // Table information
        String driver = "com.huawei.opengauss.jdbc.Driver";
        Connection conn = null;

        try {
            Class.forName(driver);
            conn = DriverManager.getConnection(urls, username, password);
        } catch (ClassNotFoundException e) {
            e.printStackTrace(System.out);
        } catch (SQLException e) {
            e.printStackTrace(System.out);

        CopyManager copyManager = new CopyManager((BaseConnection)connection);
        fileOutputStream = new FileOutputStream(filePath);
        copyManager.copyOut("COPY " + tableOrQuery + " TO STDOUT", fileOutputStream);
    } finally {
        if (fileOutputStream != null) {
            try {
                fileOutputStream.close();
            } catch (IOException e) {
                e.printStackTrace();
            }
        }
    }
}
```

Execution result of the preceding example: The data in the **data.txt** and **data1.txt** files in local drive D, and in the database tables **migration_table_1** and **migration_table** is the same.

5.3.3.7 Migrating Data from a MySQL Database

The following example shows how to use CopyManager to migrate data from MY to GaussDB.

Prerequisites for code running:

1. The **opengaussjdbc.jar** package is added as required. For example, if you use an IDE to run code, you need to add the **opengaussjdbc.jar** package to the local IDE.
2. The **migration_table** table has been created in MySQL and GaussDB databases. Data has been inserted into the **migration_table** table in the MySQL database in advance.

// There will be security risks if the username and password used for authentication are directly written into code. It is recommended that the username and password be stored in the configuration file or environment variables (the password must be stored in ciphertext and decrypted when being used) to ensure security.

// In this example, the username and password are stored in environment variables. Before running this example, set environment variables *EXAMPLE_USERNAME_ENV* and *EXAMPLE_PASSWORD_ENV* in the local environment (set the environment variable names based on the actual situation).

// You need to change the values of *\$ip*, *\$port*, and *database*.

```
import java.io.StringReader;
import java.sql.Connection;
import java.sql.DriverManager;
import java.sql.ResultSet;
import java.sql.SQLException;
import java.sql.Statement;

import com.huawei.opengauss.jdbc.copy.CopyManager;
import com.huawei.opengauss.jdbc.core.BaseConnection;

public class Migration{

    public static void main(String[] args) {
        String url = new String("jdbc.opengauss://$ip:$port/database"); // Database URL
        String user = System.getenv("EXAMPLE_USERNAME_ENV");           // GaussDB username
        String pass = System.getenv("EXAMPLE_PASSWORD_ENV");           // GaussDB password
        String tablename = new String("migration_table"); // Table information
        String delimiter = new String("|"); // Delimiter
        String encoding = new String("UTF8"); // Character set
        String driver = "com.huawei.opengauss.jdbc.Driver";
        StringBuffer buffer = new StringBuffer(); // Buffer to store formatted data

        try {
            // Obtain the query result set of the source database.
            ResultSet rs = getDataSet();

            // Traverse the result set and obtain records row by row.
            // The values of columns in each record are separated by the specified delimiter and end with a
            //linefeed, forming strings.
            // Add the strings to the buffer.
            while (rs.next()) {
                buffer.append(rs.getString(1) + delimiter
                    + rs.getString(2) + delimiter
                    + rs.getString(3) + delimiter
                    + rs.getString(4)
                    + "\n");
            }
            rs.close();

            try {
                // Connect to the database in non-encrypted mode.
                Class.forName(driver);
                Connection conn = DriverManager.getConnection(url, user, pass);
                BaseConnection baseConn = (BaseConnection) conn;
                baseConn.setAutoCommit(false);

                // Initialize the table.
                String sql = "Copy " + tablename + " from STDIN DELIMITER " + "'" + delimiter + "'" + "
ENCODING " + "'" + encoding + "'";

                // Commit data in the buffer.
                CopyManager cp = new CopyManager(baseConn);
                StringReader reader = new StringReader(buffer.toString());
                cp.copyIn(sql, reader);
                baseConn.commit();
                reader.close();
                baseConn.close();
            } catch (ClassNotFoundException e) {
                e.printStackTrace(System.out);
            } catch (SQLException e) {
                e.printStackTrace(System.out);
            }

            } catch (Exception e) {
                e.printStackTrace();
            }
        }
    }
}
```

```

//*****
// Return the query result set from the source database.
//*****
private static ResultSet getDataSet() {
    ResultSet rs = null;
    try {
        Class.forName("com.mysql.jdbc.Driver").newInstance();
        String userName = System.getenv("EXAMPLE_USERNAME_ENV");
        String password = System.getenv("EXAMPLE_PASSWORD_ENV");
        Connection conn = DriverManager.getConnection("jdbc:mysql://$ip:$port/database?
useSSL=false&allowPublicKeyRetrieval=true", userName, password);
        Statement stmt = conn.createStatement();
        rs = stmt.executeQuery("select * from migration_table");
    } catch (SQLException e) {
        e.printStackTrace();
    } catch (Exception e) {
        e.printStackTrace();
    }
    return rs;
}
}

```

Execution result of the preceding example: After the migration, data in the **migration_table** table of GaussDB is consistent with that of MySQL.

5.3.3.8 Logical Replication

The following example demonstrates how to use the logical replication function through the JDBC APIs.

For logical replication, in addition to the configuration items described in [Logical Decoding](#), the following configuration items are added for JDBC streaming decoding:

1. Decoding thread concurrency

Set **parallel-decode-num** to specify the number of decoder threads for parallel decoding. The value is an integer ranging from 1 to 20. The value **1** indicates that decoding is performed based on the original serial logic. Other values indicate that parallel decoding is enabled. The default value is **1**. When this parameter is set to **1**, do not configure the following options: **decode-style**, **sending-batch**, and **parallel-queue-size**.

2. Decoding format

Configure **decode-style** to specify the decoding format. The value can be 'j', 't' or 'b' of the char type, indicating the JSON, text, or binary format, respectively. This option is set only when parallel decoding is allowed and binary decoding is supported only in the parallel decoding scenario. For the JSON and TEXT formats, in the decoding result sent in batches, the uint32 consisting of the first four bytes of each decoding statement indicates the total number of bytes of the statement (the four bytes occupied by the uint32 are excluded, and **0** indicates that the decoding of this batch ends). The 8-byte uint64 indicates the corresponding LSN (**begin** corresponds to **first_lsn**, **commit** corresponds to **end_lsn**, and other values correspond to the LSN of the statement).

 NOTE

The binary encoding rules are as follows:

1. The first four bytes represent the total number of bytes of the decoding result of statements following the statement-level delimiter letter P (excluded) or the batch end character F (excluded). If the value is **0**, the decoding of this batch ends.
2. The next eight bytes (uint64) indicate the corresponding LSN (**begin** corresponds to **first_lsn**, **commit** corresponds to **end_lsn**, and other values correspond to the LSN of the statement).
3. The following 1-byte letter can be **B**, **C**, **I**, **U**, or **D**, representing BEGIN, COMMIT, INSERT, UPDATE, or DELETE.
4. When the one-byte letter in step 3 is **B**:
 1. The following eight bytes (uint64) indicate the CSN.
 2. The next eight bytes (uint64) indicate **first_lsn**.
 3. (Optional) If the next 1-byte letter is **T**, the following four bytes (uint32) indicate the timestamp length for committing the transaction. The following characters with the same length are the timestamp character string.
 4. (Optional) If the next one-byte letter is **N**, the following four bytes (uint32) indicate the length of the transaction username. The following characters with the same length are the transaction username.
 5. Because there may still be a decoding statement subsequently, a 1-byte letter **P** or **F** is used as a separator between statements. **P** indicates that there are still decoded statements in this batch, and **F** indicates that this batch is completed.
5. When the one-byte letter in step 3 is **C**:
 1. (Optional) If the next 1-byte letter is **X**, the following eight bytes (uint64) indicate XID.
 2. (Optional) If the next 1-byte letter is **T**, the following four bytes (uint32) indicate the timestamp length. The following characters with the same length are the timestamp character string.
 3. When logs are sent in batches, decoding results of other transactions may still exist after a COMMIT log is decoded. If the next 1-byte letter is **P**, the batch still needs to be decoded. If the letter is **F**, the batch decoding ends.
6. When the one-byte letter in step 3 is **I**, **U**, or **D**:
 1. The following two bytes (uint16) indicate the length of the schema name.
 2. The schema name is read based on the preceding length.
 3. The following two bytes (uint16) indicate the length of the table name.
 4. The table name is read based on the preceding length.
 5. (Optional) If the next 1-byte letter is **N**, it indicates a new tuple. If the letter is **O**, it indicates an old tuple. In this case, the new tuple is sent first.
 1. The following two bytes (uint16) indicate the number of columns to be decoded for the tuple, which is recorded as **attrnum**.
 2. The following procedure is repeated for *attrnum* times.
 1. The next two bytes (uint16) indicate the length of the column name.
 2. The column name is read based on the preceding length.
 3. The following four bytes (uint32) indicate the OID of the current column type.
 4. The next four bytes (uint32) indicate the length of the value (stored in the character string format) in the current column. If the value is **0xFFFFFFFF**, it indicates null. If the value is **0**, it indicates a character string whose length is 0.
 5. The column value is read based on the preceding length.

6. Because there may still be a decoding statement after, if the next one-byte letter is **P**, it indicates that the batch still needs to be decoded, and if the next one-byte letter is **F**, it indicates that decoding of the batch ends.
3. Decoding only on the standby node
Configure the **standby-connection** option to specify whether to perform decoding only on the standby node. The value is of the Boolean type (**0** or **1**). The value **true** (or **1**) indicates that only the standby node can be connected for decoding. When the primary node is connected for decoding, an error is reported and the system exits. The value **false** (or **0**) indicates that there is no restriction. The default value is **false (0)**.
4. Batch sending
Configure **sending-batch** to specify whether to send results in batches. The value is an integer ranging from 0 to 1. The value **0** indicates that decoding results are sent one by one. The value **1** indicates that decoding results are sent in batches when the accumulated size of decoding results reaches 1 MB. The default value is **0**. This parameter can be set only during parallel decoding. In the scenario where batch sending is enabled, if the decoding format is 'j' or 't', before each original decoding statement, a uint32 type is added indicating the length of the decoding result (excluding the current uint32 type), and a uint64 type is added, indicating the LSN corresponding to the current decoding result.
5. Length of the parallel decoding queue
Configure **parallel-queue-size** to specify the length of the queue for interaction among parallel logical decoding threads. The value ranges from 2 to 1024 and must be a power of 2. The default value is **128**. The queue length is positively correlated with the memory usage during decoding.
6. Memory threshold for logical decoding
The **max-txn-in-memory** configuration item specifies the memory threshold for caching the intermediate decoding result of a single transaction, in MB. The value ranges from 0 to 100. The default value is **0**, indicating that the memory usage is not controlled. The **max-reorderbuffer-in-memory** configuration item specifies the memory threshold for caching intermediate decoding results of all transactions, in GB. The value ranges from 0 to 100. The default value is **0**, indicating that the memory usage is not controlled. When the memory usage exceeds the threshold, intermediate decoding results are written into a temporary file during decoding, affecting the logical decoding performance.
7. Logical decoding sending timeout threshold
The **sender-timeout** configuration item specifies the heartbeat timeout threshold between the kernel and client. If no message is received from the client within the period, the logical decoding stops and disconnects from the client. The unit is ms, and the value range is [0,2147483647]. The default value depends on the value of **logical_sender_timeout**.
8. User blacklist options for logical decoding
Use the user blacklist for logical decoding. The transaction operations of blacklisted users are filtered from the logical decoding result. The options are as follows:
 - a. **exclude-userids**: specifies the OIDs of blacklisted users. Multiple OIDs are separated by commas (,). The system does not check whether the user OIDs exist.

- b. **exclude-users**: specifies blacklisted usernames. Multiple usernames are separated by commas (,). **dynamic-resolution** specifies whether to dynamically parse and identify usernames. If the decoding is interrupted because the user does not exist and the corresponding blacklisted user does not exist at the time when logs are generated, you can set **dynamic-resolution** to **true** or delete the username from the blacklist to start decoding and continue to obtain logical logs.
 - c. **dynamic-resolution**: specifies whether to dynamically parse blacklisted usernames. The default value is **true**. If the parameter is set to **false**, an error is reported and the logical decoding exits when the decoding detects that the user does not exist in blacklist **exclude-users**. If the parameter is set to **true**, decoding continues when it detects that the user does not exist in blacklist **exclude-users**.
9. Output options for transaction logic logs
- a. **include-xids**: specifies whether the BEGIN logical log of a transaction outputs the transaction ID. The default value is **true**.
 - b. **include-timestamp**: specifies whether the BEGIN logical log of a transaction outputs the time when the transaction is committed. The default value is **false**.
 - c. **include-user**: specifies whether the BEGIN logical log of a transaction outputs the username of the transaction. The default value is **false**. The username of a transaction refers to the authorized user, that is, the login user who executes the session corresponding to the transaction. The username does not change during the execution of the transaction.
10. By default, **socketTimeout** of the logical decoding connection is set to **10s**. When the primary node is overloaded during decoding on the standby node, the connection may be closed due to timeout. You can set **withStatusInterval(10000,TimeUnit.MILLISECONDS)** to adjust the timeout interval.

The decoding performance (Xlog consumption) is greater than or equal to 100 Mbps in the following standard parallel decoding scenario: 16-core CPU, 128 GB memory, network bandwidth > 200 Mbps, 10 to 100 columns in a table, 0.1 KB to 1 KB data in a single row, INSERT as main DML operations, less than 4096 statements in a single transaction, **parallel-decode-num** set to **8**, decoding format as **'b'**, and batch sending function enabled. To ensure that the decoding performance meets the requirements and minimize the impact on services, you are advised to set up only one parallel decoding connection on a standby node to ensure that the CPU, memory, and bandwidth resources are sufficient.

 CAUTION

The logical replication class PGReplicationStream is a non-thread-safe class. Concurrent calls may cause data exceptions.

Prerequisites for code running:

1. The **opengaussjdbc.jar** package is added as required. For example, if you use an IDE to run code, you need to add the **opengaussjdbc.jar** package to the local IDE.

2. Add the IP address (for example, 10.11.12.34) of the JDBC user to the whitelist of the data replication permission. The command is as follows:
`gs_guc reload -Z datanode -N all -I all -h 'host replication all 10.11.12.34/32 sha256'`
3. Set **wal_level** to **logical**. For details, contact the administrator.
4. Create tables **t1** and **t2** and perform DDL or DML operations on the tables.

// There will be security risks if the username and password used for authentication are directly written into code. It is recommended that the username and password be stored in the configuration file or environment variables (the password must be stored in ciphertext and decrypted when being used) to ensure security.

// In this example, the username and password are stored in environment variables. Before running this example, set environment variables *EXAMPLE_USERNAME_ENV* and *EXAMPLE_PASSWORD_ENV* in the local environment (set the environment variable names based on the actual situation).

// You need to change the values of *\$ip*, *\$port*, and *database*.

    .start();
    while (true) {
        ByteBuffer byteBuffer = stream.readPending();

        if (byteBuffer == null) {
            TimeUnit.MILLISECONDS.sleep(10L);
            continue;
        }

        int offset = byteBuffer.arrayOffset();
        byte[] source = byteBuffer.array();
        int length = source.length - offset;
        System.out.println(new String(source, offset, length));

        // If the LSN needs to be flushed, call the following APIs based on the service requirements:
        // LogSequenceNumber lastRecv = stream.getLastReceiveLSN();
        // stream.setFlushedLSN(lastRecv);
        // stream.forceUpdateStatus();

    }
} else if (testMode == TEST_MODE_DROP_SLOT) {
    conn.getReplicationAPI()
        .dropReplicationSlot("replication_slot");
}
} catch (Exception e) {
    e.printStackTrace();
    return;
}
}
```

The following is an example of the decoding result in the text format (that is, the 't' format):

```
BEGIN CSN: 2014 first_lsn: 0/2816A28 username: xxx
table public t1 INSERT: a[integer]:1 b[integer]:2 c[text]:'hello'
```

```
commit xid: 15504
BEGIN CSN: 2015 first_lsn: 0/2816C20 username: xxx
table public t1 UPDATE: old-key: a[integer]:1 new-tuple: a[integer]:1 b[integer]:5 c[text]:'hello'
commit xid: 15505
BEGIN CSN: 2016 first_lsn: 0/2816D60 username: xxx
table public t1 DELETE: a[integer]:1
commit xid: 15506
```

5.3.4 JDBC API Reference

This section describes common JDBC APIs. For more APIs, check JDK 1.8 (software package) and JDBC 4.0.

5.3.4.1 java.sql.Connection

java.sql.Connection is an API for connecting to a database.

Table 5-11 Support status for java.sql.Connection

Method	Return Type	JDBC 4 Supported or Not
abort(Executor executor)	void	Yes
clearWarnings()	void	Yes
close()	void	Yes
commit()	void	Yes
createArrayOf(String typeName, Object[] elements)	Array	Yes
createBlob()	Blob	Yes
createClob()	Clob	Yes
createSQLXML()	SQLXML	Yes
createStatement()	Statement	Yes
createStatement(int resultSetType, int resultSetConcurrency)	Statement	Yes
createStatement(int resultSetType, int resultSetConcurrency, int resultSetHoldability)	Statement	Yes
getAutoCommit()	boolean	Yes
getCatalog()	String	Yes
getClientInfo()	Properties	Yes
getClientInfo(String name)	String	Yes

Method	Return Type	JDBC 4 Supported or Not
getHoldability()	int	Yes
getMetaData()	DatabaseMetaData	Yes
getNetworkTimeout()	int	Yes
getSchema()	String	Yes
getTransactionIsolation()	int	Yes
getTypeMap()	Map<String,Class<?>>	Yes
getWarnings()	SQLWarning	Yes
isClosed()	boolean	Yes
isReadOnly()	boolean	Yes
isValid(int timeout)	Boolean	Yes
nativeSQL(String sql)	String	Yes
prepareCall(String sql)	CallableStatement	Yes
prepareCall(String sql, int resultSetType, int resultSetConcurrency)	CallableStatement	Yes
prepareCall(String sql, int resultSetType, int resultSetConcurrency, int resultSetHoldability)	CallableStatement	Yes
prepareStatement(String sql)	PreparedStatement	Yes
prepareStatement(String sql, int autoGeneratedKeys)	PreparedStatement	Yes
prepareStatement(String sql, int[] columnIndexes)	PreparedStatement	Yes
prepareStatement(String sql, int resultSetType, int resultSetConcurrency)	PreparedStatement	Yes
prepareStatement(String sql, int resultSetType, int resultSetConcurrency, int resultSetHoldability)	PreparedStatement	Yes
prepareStatement(String sql, String[] columnNames)	PreparedStatement	Yes
releaseSavepoint(Savepoint savepoint)	void	Yes

Method	Return Type	JDBC 4 Supported or Not
rollback()	void	Yes
rollback(Savepoint savepoint)	void	Yes
setAutoCommit(boolean autoCommit)	void	Yes
setClientInfo(Properties properties)	void	Yes
setClientInfo(String name,String value)	void	Yes
setHoldability(int holdability)	void	Yes
setNetworkTimeout(Executor executor, int milliseconds)	void	Yes
setReadOnly(boolean readOnly)	void	Yes
setSavepoint()	Savepoint	Yes
setSavepoint(String name)	Savepoint	Yes
setSchema(String schema)	void	Yes
setTransactionIsolation(int level)	void	Yes
setTypeMap(Map<String,Class<?>> map)	void	Yes

NOTICE

The AutoCommit mode is used by default within the API. If you disable it by running **setAutoCommit(false)**, all the statements executed later will be packaged in explicit transactions, and you cannot execute statements that cannot be executed within transactions.

5.3.4.2 java.sql.CallableStatement

This section describes java.sql.CallableStatement, the API for executing the stored procedure.

Table 5-12 Support status for java.sql.CallableStatement

Method Name	Return Type	JDBC 4 Is Supported Or Not
getArray(int parameterIndex)	Array	Yes
getBigDecimal(int parameterIndex)	BigDecimal	Yes
getBlob(int parameterIndex)	Blob	Yes
getBoolean(int parameterIndex)	Boolean	Yes
getByte(int parameterIndex)	byte	Yes
getBytes(int parameterIndex)	byte[]	Yes
getClob(int parameterIndex)	Clob	Yes
getDate(int parameterIndex)	Date	Yes
getDate(int parameterIndex, Calendar cal)	Date	Yes
getDouble(int parameterIndex)	double	Yes
getFloat(int parameterIndex)	float	Yes
getInt(int parameterIndex)	int	Yes
getLong(int parameterIndex)	long	Yes
getObject(int parameterIndex)	Object	Yes
getObject(int parameterIndex, Class<T> type)	Object	Yes
getShort(int parameterIndex)	short	Yes
getSQLXML(int parameterIndex)	SQLXML	Yes
getString(int parameterIndex)	String	Yes
getNString(int parameterIndex)	String	Yes
getTime(int parameterIndex)	Time	Yes
getTime(int parameterIndex, Calendar cal)	Time	Yes
getTimestamp(int parameterIndex)	Timestamp	Yes

Method Name	Return Type	JDBC 4 Is Supported Or Not
getTimestamp(int parameterIndex, Calendar cal)	Timestamp	Yes
registerOutParameter(int parameterIndex, int type)	void	Yes
registerOutParameter(int parameterIndex, int sqlType, int type)	void	Yes
wasNull()	boolean	Yes

 NOTE

- The batch operation of statements containing OUT parameter is not allowed.
- The following methods are inherited from **java.sql.Statement**: **close**, **execute**, **executeQuery**, **executeUpdate**, **getConnection**, **getResultSet**, **getUpdateCount**, **isClosed**, **setMaxRows**, and **setFetchSize**.
- The following methods are inherited from **java.sql.PreparedStatement**: **addBatch**, **clearParameters**, **execute**, **executeQuery**, **executeUpdate**, **getMetaData**, **setBigDecimal**, **setBoolean**, **setByte**, **setBytes**, **setDate**, **setDouble**, **setFloat**, **setInt**, **setLong**, **setNull**, **setObject**, **setString**, **setTime**, and **setTimestamp**.
- The **registerOutParameter(int parameterIndex, int sqlType, int type)** method is used only to register the composite data type.

5.3.4.3 java.sql.DatabaseMetaData

This section describes **java.sql.DatabaseMetaData**, the API for defining database objects.

Table 5-13 Support status for **java.sql.DatabaseMetaData**

Method Name	Return Type	JDBC 4 Is Supported Or Not
allProceduresAreCallable()	Boolean	Yes
allTablesAreSelectable()	Boolean	Yes
autoCommitFailureClosesAllResultSets()	Boolean	Yes
dataDefinitionCausesTransactionCommit()	Boolean	Yes
dataDefinitionIgnoredInTransactions()	Boolean	Yes
deletesAreDetected(int type)	Boolean	Yes

Method Name	Return Type	JDBC 4 Is Supported Or Not
doesMaxRowSizeIncludeBlobs()	Boolean	Yes
generatedKeyAlwaysReturned()	Boolean	Yes
getBestRowIdentifier(String catalog, String schema, String table, int scope, boolean nullable)	ResultSet	Yes
getCatalogs()	ResultSet	Yes
getCatalogSeparator()	String	Yes
getCatalogTerm()	String	Yes
getClientInfoProperties()	ResultSet	Yes
getColumnPrivileges(String catalog, String schema, String table, String columnNamePattern)	ResultSet	Yes
getConnection()	Connection	Yes
getCrossReference(String parentCatalog, String parentSchema, String parentTable, String foreignCatalog, String foreignSchema, String foreignTable)	ResultSet	Yes
getDefaultTransactionIsolation()	int	Yes
getExportedKeys(String catalog, String schema, String table)	ResultSet	Yes
getExtraNameCharacters()	String	Yes
getFunctionColumns(String catalog, String schemaPattern, String functionNamePattern, String columnNamePattern)	ResultSet	Yes
getFunctions(String catalog, String schemaPattern, String functionNamePattern)	ResultSet	Yes
getIdentifierQuoteString()	String	Yes

Method Name	Return Type	JDBC 4 Is Supported Or Not
getImportedKeys(String catalog, String schema, String table)	ResultSet	Yes
getIndexInfo(String catalog, String schema, String table, boolean unique, boolean approximate)	ResultSet	Yes
getMaxBinaryLiteralLength()	int	Yes
getMaxCatalogNameLength()	int	Yes
getMaxCharLiteralLength()	int	Yes
getMaxColumnNameLength()	int	Yes
getMaxColumnsInGroupBy()	int	Yes
getMaxColumnsInIndex()	int	Yes
getMaxColumnsInOrderBy()	int	Yes
getMaxColumnsInSelect()	int	Yes
getMaxColumnsInTable()	int	Yes
getMaxConnections()	int	Yes
getMaxCursorNameLength()	int	Yes
getMaxIndexLength()	int	Yes
getMaxLogicalLobSize()	default long	Yes
getMaxProcedureNameLength()	int	Yes
getMaxRowSize()	int	Yes
getMaxSchemaNameLength()	int	Yes
getMaxStatementLength()	int	Yes
getMaxStatements()	int	Yes
getMaxTableNameLength()	int	Yes
getMaxTablesInSelect()	int	Yes
getMaxUserNameLength()	int	Yes
getNumericFunctions()	String	Yes

Method Name	Return Type	JDBC 4 Is Supported Or Not
getPrimaryKeys(String catalog, String schema, String table)	ResultSet	Yes
getPartitionTablePrimaryKeys(String catalog, String schema, String table)	ResultSet	Yes
getProcedureColumns(String catalog, String schemaPattern, String procedureNamePattern, String columnNamePattern)	ResultSet	Yes
getProcedures(String catalog, String schemaPattern, String procedureNamePattern)	ResultSet	Yes
getProcedureTerm()	String	Yes
getSchemas()	ResultSet	Yes
getSchemas(String catalog, String schemaPattern)	ResultSet	Yes
getSchemaTerm()	String	Yes
getSearchStringEscape()	String	Yes
getSQLKeywords()	String	Yes
getSQLStateType()	int	Yes
getStringFunctions()	String	Yes
getSystemFunctions()	String	Yes
getTablePrivileges(String catalog, String schemaPattern, String tableNamePattern)	ResultSet	Yes
getTimeDateFunctions()	String	Yes
getTypeInfo()	ResultSet	Yes
getUDTs(String catalog, String schemaPattern, String typeNamePattern, int[] types)	ResultSet	Yes
getURL()	String	Yes

Method Name	Return Type	JDBC 4 Is Supported Or Not
getVersionColumns(String catalog, String schema, String table)	ResultSet	Yes
insertsAreDetected(int type)	Boolean	Yes
locatorsUpdateCopy()	Boolean	Yes
othersDeletesAreVisible(int type)	Boolean	Yes
othersInsertsAreVisible(int type)	Boolean	Yes
othersUpdatesAreVisible(int type)	Boolean	Yes
ownDeletesAreVisible(int type)	Boolean	Yes
ownInsertsAreVisible(int type)	Boolean	Yes
ownUpdatesAreVisible(int type)	Boolean	Yes
storesLowerCaseIdentifiers()	Boolean	Yes
storesMixedCaseIdentifiers()	Boolean	Yes
storesUpperCaseIdentifiers()	Boolean	Yes
supportsBatchUpdates()	Boolean	Yes
supportsCatalogsInDataManipulation()	Boolean	Yes
supportsCatalogsInIndexDefinitions()	Boolean	Yes
supportsCatalogsInPrivilegeDefinitions()	Boolean	Yes
supportsCatalogsInProcedureCalls()	Boolean	Yes
supportsCatalogsInTableDefinitions()	Boolean	Yes
supportsCorrelatedSubqueries()	Boolean	Yes
supportsDataDefinitionAndDataManipulationTransactions()	Boolean	Yes

Method Name	Return Type	JDBC 4 Is Supported Or Not
supportsDataManipulation-TransactionsOnly()	Boolean	Yes
supportsGetGeneratedKeys()	Boolean	Yes
supportsMixedCaseIdentifiers()	Boolean	Yes
supportsMultipleOpenResults()	Boolean	Yes
supportsNamedParameters()	Boolean	Yes
supportsOpenCursorsAcrossCommit()	Boolean	Yes
supportsOpenCursorsAcrossRollback()	Boolean	Yes
supportsOpenStatementsAcrossCommit()	Boolean	Yes
supportsOpenStatementsAcrossRollback()	Boolean	Yes
supportsPositionedDelete()	Boolean	Yes
supportsPositionedUpdate()	Boolean	Yes
supportsRefCursors()	Boolean	Yes
supportsResultSetConcurrency(int type, int concurrency)	Boolean	Yes
supportsResultSetType(int type)	Boolean	Yes
supportsSchemasInIndexDefinitions()	Boolean	Yes
supportsSchemasInPrivilegeDefinitions()	Boolean	Yes
supportsSchemasInProcedureCalls()	Boolean	Yes
supportsSchemasInTableDefinitions()	Boolean	Yes
supportsSelectForUpdate()	Boolean	Yes
supportsStatementPooling()	Boolean	Yes
supportsStoredFunctionsUsingCallSyntax()	Boolean	Yes

Method Name	Return Type	JDBC 4 Is Supported Or Not
supportsStoredProcedures()	Boolean	Yes
supportsSubqueriesInComparisons()	Boolean	Yes
supportsSubqueriesInExists()	Boolean	Yes
supportsSubqueriesInIns()	Boolean	Yes
supportsSubqueriesInQuantifieds()	Boolean	Yes
supportsTransactionIsolationLevel(int level)	Boolean	Yes
supportsTransactions()	Boolean	Yes
supportsUnion()	Boolean	Yes
supportsUnionAll()	Boolean	Yes
updatesAreDetected(int type)	Boolean	Yes
getTables(String catalog, String schemaPattern, String tableNamePattern, String[] types)	ResultSet	Yes
getColumns(String catalog, String schemaPattern, String tableNamePattern, String columnNamePattern)	ResultSet	Yes
getTableTypes()	ResultSet	Yes
getUserName()	String	Yes
isReadOnly()	Boolean	Yes
nullsAreSortedHigh()	Boolean	Yes
nullsAreSortedLow()	Boolean	Yes
nullsAreSortedAtStart()	Boolean	Yes
nullsAreSortedAtEnd()	Boolean	Yes
getDatabaseProductName()	String	Yes
getDatabaseProductVersion()	String	Yes
getDriverName()	String	Yes
getDriverVersion()	String	Yes

Method Name	Return Type	JDBC 4 Is Supported Or Not
getDriverMajorVersion()	int	Yes
getDriverMinorVersion()	int	Yes
usesLocalFiles()	Boolean	Yes
usesLocalFilePerTable()	Boolean	Yes
supportsMixedCaseIdentifiers()	Boolean	Yes
storesUpperCaseIdentifiers()	Boolean	Yes
storesLowerCaseIdentifiers()	Boolean	Yes
supportsMixedCaseQuotedIdentifiers()	Boolean	Yes
storesUpperCaseQuotedIdentifiers()	Boolean	Yes
storesLowerCaseQuotedIdentifiers()	Boolean	Yes
storesMixedCaseQuotedIdentifiers()	Boolean	Yes
supportsAlterTableWithAddColumn()	Boolean	Yes
supportsAlterTableWithDropColumn()	Boolean	Yes
supportsColumnAliasing()	Boolean	Yes
nullPlusNonNullIsNull()	Boolean	Yes
supportsConvert()	Boolean	Yes
supportsConvert(int fromType, int toType)	Boolean	Yes
supportsTableCorrelationNames()	Boolean	Yes
supportsDifferentTableCorrelationNames()	Boolean	Yes
supportsExpressionsInOrderBy()	Boolean	Yes
supportsOrderByUnrelated()	Boolean	Yes
supportsGroupBy()	Boolean	Yes
supportsGroupByUnrelated()	Boolean	Yes

Method Name	Return Type	JDBC 4 Is Supported Or Not
supportsGroupByBeyondSelect()	Boolean	Yes
supportsLikeEscapeClause()	Boolean	Yes
supportsMultipleResultSets()	Boolean	Yes
supportsMultipleTransactions()	Boolean	Yes
supportsNonNullableColumns()	Boolean	Yes
supportsMinimumSQLGrammar()	Boolean	Yes
supportsCoreSQLGrammar()	Boolean	Yes
supportsExtendedSQLGrammar()	Boolean	Yes
supportsANSI92EntryLevelSQL()	Boolean	Yes
supportsANSI92IntermediateSQL()	Boolean	Yes
supportsANSI92FullSQL()	Boolean	Yes
supportsIntegrityEnhancementFacility()	Boolean	Yes
supportsOuterJoins()	Boolean	Yes
supportsFullOuterJoins()	Boolean	Yes
supportsLimitedOuterJoins()	Boolean	Yes
isCatalogAtStart()	Boolean	Yes
supportsSchemasInDataManipulation()	Boolean	Yes
supportsSavepoints()	Boolean	Yes
supportsResultSetHoldability(int holdability)	Boolean	Yes
getResultSetHoldability()	int	Yes
getDatabaseMajorVersion()	int	Yes
getDatabaseMinorVersion()	int	Yes
getJDBCMajorVersion()	int	Yes

Method Name	Return Type	JDBC 4 Is Supported Or Not
getJDBCMajorVersion()	int	Yes

 NOTE

If the value of **uppercaseAttributeName** is **true**, the following APIs convert the query result to uppercase letters. The conversion range is the same as that of the **toUpperCase** method in Java.

- `public ResultSet getProcedures(String catalog, String schemaPattern, String procedureNamePattern)`
- `public ResultSet getProcedureColumns(String catalog, String schemaPattern, String procedureNamePattern, String columnNamePattern)`
- `public ResultSet getTables(String catalog, String schemaPattern, String tableNamePattern, String[] types)`
- `public ResultSet getSchemas(String catalog, String schemaPattern)`
- `public ResultSet getColumns(String catalog, String schemaPattern, String tableNamePattern, String columnNamePattern)`
- `public ResultSet getColumnPrivileges(String catalog, String schema, String table, String columnNamePattern)`
- `public ResultSet getTablePrivileges(String catalog, String schemaPattern, String tableNamePattern)`
- `public ResultSet getBestRowIdentifier(String catalog, String schema, String table, int scope, boolean nullable)`
- `public ResultSet getPrimaryKeys(String catalog, String schema, String table)`
- `protected ResultSet getImportedExportedKeys(String primaryCatalog, String primarySchema, String primaryTable, String foreignCatalog, String foreignSchema, String foreignTable)`
- `public ResultSet getIndexInfo(String catalog, String schema, String tableName, boolean unique, boolean approximate)`
- `public ResultSet getUDTs(String catalog, String schemaPattern, String typeNamePattern, int[] types)`
- `public ResultSet getFunctions(String catalog, String schemaPattern, String functionNamePattern)`

 CAUTION

The `getPartitionTablePrimaryKeys(String catalog, String schema, String table)` API is used to obtain the primary key column of a partitioned table that contains global indexes. An example is as follows:

```
PgDatabaseMetaData dbmd = (PgDatabaseMetaData)conn.getMetaData();  
dbmd.getPartitionTablePrimaryKeys("catalogName", "schemaName", "tableName");
```

5.3.4.4 java.sql.Driver

`java.sql.Driver` is a database driver API.

Table 5-14 Support status for java.sql.Driver

Method	Return Type	JDBC 4 Supported or Not
acceptsURL(String url)	boolean	Yes
connect(String url, Properties info)	Connection	Yes
jdbcCompliant()	boolean	Yes
getMajorVersion()	int	Yes
getMinorVersion()	int	Yes
getParentLogger()	Logger	Yes
getPropertyInfo(String url, Properties info)	DriverPropertyInfo[]	Yes

5.3.4.5 java.sql.PreparedStatement

java.sql.PreparedStatement is a prepared statement API.

Table 5-15 Support status for java.sql.PreparedStatement

Method	Return Type	JDBC 4 Supported or Not
clearParameters()	void	Yes
execute()	boolean	Yes
executeQuery()	ResultSet	Yes
excuteUpdate()	int	Yes
executeLargeUpdate()	long	No
getMetaData()	ResultSetMetaData	Yes
getParameterMetaData()	ParameterMetaData	Yes
setArray(int parameterIndex, Array x)	void	Yes
setAsciiStream(int parameterIndex, InputStream x, int length)	void	Yes
setBinaryStream(int parameterIndex, InputStream x)	void	Yes

Method	Return Type	JDBC 4 Supported or Not
setBinaryStream(int parameterIndex, InputStream x, int length)	void	Yes
setBinaryStream(int parameterIndex, InputStream x, long length)	void	Yes
setBlob(int parameterIndex, InputStream inputStream)	void	Yes
setBlob(int parameterIndex, InputStream inputStream, long length)	void	Yes
setBlob(int parameterIndex, Blob x)	void	Yes
setCharacterStream(int parameterIndex, Reader reader)	void	Yes
setCharacterStream(int parameterIndex, Reader reader, int length)	void	Yes
setClob(int parameterIndex, Reader reader)	void	Yes
setClob(int parameterIndex, Reader reader, long length)	void	Yes
setClob(int parameterIndex, Clob x)	void	Yes
setDate(int parameterIndex, Date x, Calendar cal)	void	Yes
setNull(int parameterIndex, int sqlType)	void	Yes

Method	Return Type	JDBC 4 Supported or Not
setNull(int parameterIndex, int sqlType, String typeName)	void	Yes
setObject(int parameterIndex, Object x)	void	Yes
setObject(int parameterIndex, Object x, int targetSqlType)	void	Yes
setObject(int parameterIndex, Object x, int targetSqlType, int scaleOrLength)	void	Yes
setSQLXML(int parameterIndex, SQLXML xmlObject)	void	Yes
setTime(int parameterIndex, Time x)	void	Yes
setTime(int parameterIndex, Time x, Calendar cal)	void	Yes
setTimestamp(int parameterIndex, Timestamp x)	void	Yes
setTimestamp(int parameterIndex, Timestamp x, Calendar cal)	void	Yes
setUnicodeStream(int parameterIndex, InputStream x, int length)	void	Yes
setURL(int parameterIndex, URL x)	void	Yes
setBoolean(int parameterIndex, boolean x)	void	Yes
setBigDecimal(int parameterIndex, BigDecimal x)	void	Yes

Method	Return Type	JDBC 4 Supported or Not
setByte(int parameterIndex, byte x)	void	Yes
setBytes(int parameterIndex, byte[] x)	void	Yes
setDate(int parameterIndex, Date x)	void	Yes
setDouble(int parameterIndex, double x)	void	Yes
setFloat(int parameterIndex, float x)	void	Yes
setInt(int parameterIndex, int x)	void	Yes
setLong(int parameterIndex, long x)	void	Yes
setShort(int parameterIndex, short x)	void	Yes
setString(int parameterIndex, String x)	void	Yes
setNString(int parameterIndex, String x)	void	Yes
addBatch()	void	Yes
executeBatch()	int[]	Yes

 NOTE

- Execute **addBatch()** and **execute()** only after running **clearBatch()**.
- Batch is not cleared by calling **executeBatch()**. Clear batch by explicitly calling **clearBatch()**.
- After bound variables of a batch are added, if you want to reuse these values, you do not need to use **set*()** again. Instead, add a batch.
- The following methods are inherited from **java.sql.Statement**: **close**, **execute**, **executeQuery**, **executeUpdate**, **getConnection**, **getResultSet**, **getUpdateCount**, **isClosed**, **setMaxRows**, and **setFetchSize**.
- The **executeLargeUpdate()** method can only be used in JDBC 4.2 or later.

5.3.4.6 java.sql.ResultSet

This section describes java.sql.ResultSet, the API for execution result sets.

Table 5-16 Support status for java.sql.ResultSet

Method Name	Return Type	JDBC 4 Is Supported Or Not
absolute(int row)	boolean	Yes
afterLast()	void	Yes
beforeFirst()	void	Yes
cancelRowUpdates()	void	Yes
clearWarnings()	void	Yes
close()	void	Yes
deleteRow()	void	Yes
findColumn(String columnLabel)	int	Yes
first()	boolean	Yes
getArray(int columnIndex)	Array	Yes
getArray(String columnLabel)	Array	Yes
getAsciiStream(int columnIndex)	InputStream	Yes
getAsciiStream(String columnLabel)	InputStream	Yes
getBigDecimal(int columnIndex)	BigDecimal	Yes
getBigDecimal(String columnLabel)	BigDecimal	Yes
getBinaryStream(int columnIndex)	InputStream	Yes
getBinaryStream(String columnLabel)	InputStream	Yes
getBlob(int columnIndex)	Blob	Yes
getBlob(String columnLabel)	Blob	Yes
getBoolean(int columnIndex)	boolean	Yes

Method Name	Return Type	JDBC 4 Is Supported Or Not
getBoolean(String columnLabel)	boolean	Yes
getByte(int columnIndex)	byte	Yes
getBytes(int columnIndex)	byte[]	Yes
getByte(String columnLabel)	byte	Yes
getBytes(String columnLabel)	byte[]	Yes
getCharacterStream(int columnIndex)	Reader	Yes
getCharacterStream(String columnLabel)	Reader	Yes
getClob(int columnIndex)	Clob	Yes
getClob(String columnLabel)	Clob	Yes
getConcurrency()	int	Yes
getCursorName()	String	Yes
getDate(int columnIndex)	Date	Yes
getDate(int columnIndex, Calendar cal)	Date	Yes
getDate(String columnLabel)	Date	Yes
getDate(String columnLabel, Calendar cal)	Date	Yes
getDouble(int columnIndex)	double	Yes
getDouble(String columnLabel)	double	Yes
getFetchDirection()	int	Yes
getFetchSize()	int	Yes
getFloat(int columnIndex)	float	Yes
getFloat(String columnLabel)	float	Yes

Method Name	Return Type	JDBC 4 Is Supported Or Not
getInt(int columnIndex)	int	Yes
getInt(String columnLabel)	int	Yes
getLong(int columnIndex)	long	Yes
getLong(String columnLabel)	long	Yes
getMetaData()	ResultSetMetaData	Yes
getObject(int columnIndex)	Object	Yes
getObject(int columnIndex, Class<T> type)	<T> T	Yes
getObject(int columnIndex, Map<String,Class<?>> map)	Object	Yes
getObject(String columnLabel)	Object	Yes
getObject(String columnLabel, Class<T> type)	<T> T	Yes
getObject(String columnLabel, Map<String,Class<?>> map)	Object	Yes
getRow()	int	Yes
getShort(int columnIndex)	short	Yes
getShort(String columnLabel)	short	Yes
getSQLXML(int columnIndex)	SQLXML	Yes
getSQLXML(String columnLabel)	SQLXML	Yes
getStatement()	Statement	Yes
getString(int columnIndex)	String	Yes

Method Name	Return Type	JDBC 4 Is Supported Or Not
getString(String columnLabel)	String	Yes
getString(int columnIndex)	String	Yes
getString(String columnLabel)	String	Yes
getTime(int columnIndex)	Time	Yes
getTime(int columnIndex, Calendar cal)	Time	Yes
getTime(String columnLabel)	Time	Yes
getTime(String columnLabel, Calendar cal)	Time	Yes
getTimestamp(int columnIndex)	Timestamp	Yes
getTimestamp(int columnIndex, Calendar cal)	Timestamp	Yes
getTimestamp(String columnLabel)	Timestamp	Yes
getTimestamp(String columnLabel, Calendar cal)	Timestamp	Yes
getType()	int	Yes
getWarnings()	SQLWarning	Yes
insertRow()	void	Yes
isAfterLast()	boolean	Yes
isBeforeFirst()	boolean	Yes
isClosed()	boolean	Yes
isFirst()	boolean	Yes
isLast()	boolean	Yes
last()	boolean	Yes
moveToCurrentRow()	void	Yes
moveToInsertRow()	void	Yes

Method Name	Return Type	JDBC 4 Is Supported Or Not
next()	boolean	Yes
previous()	boolean	Yes
refreshRow()	void	Yes
relative(int rows)	boolean	Yes
rowDeleted()	boolean	Yes
rowInserted()	boolean	Yes
rowUpdated()	boolean	Yes
setFetchDirection(int direction)	void	Yes
setFetchSize(int rows)	void	Yes
updateArray(int columnIndex, Array x)	void	Yes
updateArray(String columnLabel, Array x)	void	Yes
updateAsciiStream(int columnIndex, InputStream x, int length)	void	Yes
updateAsciiStream(String columnLabel, InputStream x, int length)	void	Yes
updateBigDecimal(int columnIndex, BigDecimal x)	void	Yes
updateBigDecimal(String columnLabel, BigDecimal x)	void	Yes
updateBinaryStream(int columnIndex, InputStream x, int length)	void	Yes
updateBinaryStream(String columnLabel, InputStream x, int length)	void	Yes
updateBoolean(int columnIndex, boolean x)	void	Yes
updateBoolean(String columnLabel, boolean x)	void	Yes

Method Name	Return Type	JDBC 4 Is Supported Or Not
updateByte(int columnIndex, byte x)	void	Yes
updateByte(String columnLabel, byte x)	void	Yes
updateBytes(int columnIndex, byte[] x)	void	Yes
updateBytes(String columnLabel, byte[] x)	void	Yes
updateCharacter-Stream(int columnIndex, Reader x, int length)	void	Yes
updateCharacter-Stream(String columnLabel, Reader reader, int length)	void	Yes
updateDate(int columnIndex, Date x)	void	Yes
updateDate(String columnLabel, Date x)	void	Yes
updateDouble(int columnIndex, double x)	void	Yes
updateDouble(String columnLabel, double x)	void	Yes
updateFloat(int columnIndex, float x)	void	Yes
updateFloat(String columnLabel, float x)	void	Yes
updateInt(int columnIndex, int x)	void	Yes
updateInt(String columnLabel, int x)	void	Yes
updateLong(int columnIndex, long x)	void	Yes
updateLong(String columnLabel, long x)	void	Yes
updateNull(int columnIndex)	void	Yes

Method Name	Return Type	JDBC 4 Is Supported Or Not
updateNull(String columnLabel)	void	Yes
updateObject(int columnIndex, Object x)	void	Yes
updateObject(int columnIndex, Object x, int scaleOrLength)	void	Yes
updateObject(String columnLabel, Object x)	void	Yes
updateObject(String columnLabel, Object x, int scaleOrLength)	void	Yes
updateRow()	void	Yes
updateShort(int columnIndex, short x)	void	Yes
updateShort(String columnLabel, short x)	void	Yes
updateSQLXML(int columnIndex, SQLXML xmlObject)	void	Yes
updateSQLXML(String columnLabel, SQLXML xmlObject)	void	Yes
updateString(int columnIndex, String x)	void	Yes
updateString(String columnLabel, String x)	void	Yes
updateTime(int columnIndex, Time x)	void	Yes
updateTime(String columnLabel, Time x)	void	Yes
updateTimestamp(int columnIndex, Timestamp x)	void	Yes
updateTimestamp(String columnLabel, Timestamp x)	void	Yes
wasNull()	boolean	Yes

 NOTE

- One statement cannot have multiple open ResultSets.
- The cursor that is used for traversing the ResultSet cannot be open after being committed.

5.3.4.7 java.sql.ResultSetMetaData

java.sql.ResultSetMetaData describes the information about ResultSet objects.

Table 5-17 Support status for java.sql.ResultSetMetaData

Method	Return Type	JDBC 4 Is Supported Or Not
getCatalogName(int column)	String	Yes
getColumnClassName(int column)	String	Yes
getColumnCount()	int	Yes
getColumnDisplaySize(int column)	int	Yes
getColumnLabel(int column)	String	Yes
getColumnName(int column)	String	Yes
getColumnType(int column)	int	Yes
getColumnTypeName(int column)	String	Yes
getPrecision(int column)	int	Yes
getScale(int column)	int	Yes
getSchemaName(int column)	String	Yes
getTableName(int column)	String	Yes
isAutoIncrement(int column)	Boolean	Yes
isCaseSensitive(int column)	Boolean	Yes
isCurrency(int column)	Boolean	Yes
isDefinitelyWritable(int column)	Boolean	Yes
isNullable(int column)	int	Yes

Method	Return Type	JDBC 4 Is Supported Or Not
isReadOnly(int column)	Boolean	Yes
isSearchable(int column)	Boolean	Yes
isSigned(int column)	Boolean	Yes
isWritable(int column)	Boolean	Yes

 NOTE

When **uppercaseAttributeName** is set to **true**, the following APIs convert the query result to uppercase letters. The conversion range is 26 English letters.

- public String getColumnName(int column)
- public String getColumnLabel(int column)

5.3.4.8 java.sql.Statement

This section describes java.sql.Statement, the API for executing SQL statements.

Table 5-18 Support status for java.sql.Statement

Method Name	Return Type	JDBC 4 Is Supported Or Not
addBatch(String sql)	void	Yes
clearBatch()	void	Yes
clearWarnings()	void	Yes
close()	void	Yes
closeOnCompletion()	void	Yes
execute(String sql)	boolean	Yes
execute(String sql, int autoGeneratedKeys)	boolean	Yes
execute(String sql, int[] columnIndexes)	boolean	Yes
execute(String sql, String[] columnNames)	boolean	Yes
executeBatch()	boolean	Yes
executeQuery(String sql)	ResultSet	Yes
executeUpdate(String sql)	int	Yes

Method Name	Return Type	JDBC 4 Is Supported Or Not
executeUpdate(String sql, int autoGeneratedKeys)	int	Yes
executeUpdate(String sql, int[] columnIndexes)	int	Yes
executeUpdate(String sql, String[] columnNames)	int	Yes
getConnection()	Connection	Yes
getFetchDirection()	int	Yes
getFetchSize()	int	Yes
getGeneratedKeys()	ResultSet	Yes
getMaxFieldSize()	int	Yes
getMaxRows()	int	Yes
getMoreResults()	boolean	Yes
getMoreResults(int current)	boolean	Yes
getResultSet()	ResultSet	Yes
getResultSetConcurrency()	int	Yes
getResultSetHoldability()	int	Yes
getResultSetType()	int	Yes
getQueryTimeout()	int	Yes
getUpdateCount()	int	Yes
getWarnings()	SQLWarning	Yes
isClosed()	boolean	Yes
isCloseOnCompletion()	boolean	Yes
isPoolable()	boolean	Yes
setCursorName(String name)	void	Yes
setEscapeProcessing(boolean enable)	void	Yes

Method Name	Return Type	JDBC 4 Is Supported Or Not
setFetchDirection(int direction)	void	Yes
setMaxFieldSize(int max)	void	Yes
setMaxRows(int max)	void	Yes
setPoolable(boolean poolable)	void	Yes
setQueryTimeout(int seconds)	void	Yes
setFetchSize(int rows)	void	Yes
cancel()	void	Yes
executeLargeUpdate(String sql)	long	No
getLargeUpdateCount()	long	No
executeLargeBatch()	long	No
executeLargeUpdate(String sql, int autoGeneratedKeys)	long	No
executeLargeUpdate(String sql, int[] columnIndexes)	long	No
executeLargeUpdate(String sql, String[] columnNames)	long	No

 NOTE

- Using setFetchSize can reduce the memory occupied by result sets on the client. Result sets are packaged into cursors and segmented for processing, which will increase the communication traffic between the database and the client, affecting performance.
- Database cursors are valid only within their transactions. If **setFetchSize** is set, set **setAutoCommit(false)** and commit transactions on the connection to flush service data to a database.
- The LargeUpdate method can only be used in JDBC 4.2 or later.

5.3.4.9 javax.sql.ConnectionPoolDataSource

This section describes **javax.sql.ConnectionPoolDataSource**, the API for data source connection pools.

Table 5-19 Support status for javax.sql.ConnectionPoolDataSource

Method Name	Return Type	JDBC 4 Is Supported Or Not
getPooledConnection()	PooledConnection	Yes
getPooledConnection(String user,String password)	PooledConnection	Yes

5.3.4.10 javax.sql.DataSource

This section describes **javax.sql.DataSource**, the interface for data sources.

Table 5-20 Support status for javax.sql.DataSource

Method Name	Return Type	Support JDBC 4
getConnection()	Connection	Yes
getConnection(String username,String password)	Connection	Yes
getLoginTimeout()	int	Yes
getLogWriter()	PrintWriter	Yes
setLoginTimeout(int seconds)	void	Yes
setLogWriter(PrintWriter out)	void	Yes

5.3.4.11 javax.sql.PooledConnection

This section describes **javax.sql.PooledConnection**, the connection API created by a connection pool.

Table 5-21 Support status for javax.sql.PooledConnection

Method Name	Return Type	JDBC 4 Is Supported Or Not
addConnectionEventListener(ConnectionEventListener listener)	void	Yes
close()	void	Yes
getConnection()	Connection	Yes
removeConnectionEventListener(ConnectionEventListener listener)	void	Yes

5.3.4.12 javax.naming.Context

javax.naming.Context is the context API for connection configuration.

Table 5-22 Support status for javax.naming.Context

Method	Return Type	Support JDBC 4
bind(Name name, Object obj)	void	Yes
bind(String name, Object obj)	void	Yes
lookup(Name name)	Object	Yes
lookup(String name)	Object	Yes
rebind(Name name, Object obj)	void	Yes
rebind(String name, Object obj)	void	Yes
rename(Name oldName, Name newName)	void	Yes
rename(String oldName, String newName)	void	Yes
unbind(Name name)	void	Yes
unbind(String name)	void	Yes

5.3.4.13 javax.naming.spi.InitialContextFactory

This section describes **javax.naming.spi.InitialContextFactory**, the initial context factory interface.

Table 5-23 Support status for javax.naming.spi.InitialContextFactory

Method Name	Return Type	Support JDBC 4
getInitialContext(Hashtable<?,?> environment)	Context	Yes

5.3.4.14 CopyManager

CopyManager is an API class provided by the JDBC driver in GaussDB. It is used to import data to GaussDB in batches.

Inheritance Relationship of CopyManager

The CopyManager class is in the **com.huawei.opengauss.jdbc.copy** package and inherits the java.lang.Object class. The declaration of the class is as follows:

```
public class CopyManager  
extends Object
```

Construction Method

```
public CopyManager(BaseConnection connection)  
  
throws SQLException
```

Common Methods

Table 5-24 Common methods of CopyManager

Method	Return Type	Description	throws
copyIn(String sql)	CopyIn	-	SQLException
copyIn(String sql, InputStream from)	long	Uses COPY FROM STDIN to quickly load data to tables in the database from InputStream.	SQLException,IOException
copyIn(String sql, InputStream from, int bufferSize)	long	Uses COPY FROM STDIN to quickly load data of a specified length to tables in the database from InputStream.	SQLException,IOException
copyIn(String sql, Reader from)	long	Uses COPY FROM STDIN to quickly load data to tables in the database from Reader.	SQLException,IOException
copyIn(String sql, Reader from, int bufferSize)	long	Uses COPY FROM STDIN to quickly load data of a specified length to tables in the database from Reader.	SQLException,IOException
copyOut(String sql)	CopyOut	-	SQLException
copyOut(String sql, OutputStream to)	long	Sends the result set of COPY TO STDOUT from the database to the OutputStream class.	SQLException,IOException

Method	Return Type	Description	throws
copyOut(String sql, Writer to)	long	Sends the result set of COPY TO STDOUT from the database to the Writer class.	SQLException,IOException

5.3.4.15 PGReplicationConnection

PGReplicationConnection is an API class provided by the JDBC driver in GaussDB. It is used to implement functions related to logical replication.

Inheritance Relationship of PGReplicationConnection

PGReplicationConnection is a logical replication API. Its implementation class is PGReplicationConnectionImpl, which is in the **com.huawei.opengauss.jdbc.replication** package. The declaration of the class is as follows:

```
public class PGReplicationConnection implements PGReplicationConnection
```

Constructor

```
public PGReplicationConnection(BaseConnection connection)
```

Common Methods

Table 5-25 Common methods of PGReplicationConnection

Method	Return Type	Description	Throws
createReplicationSlot()	ChainedCreateReplicationSlotBuilder	Creates a logical replication slot.	-
dropReplicationSlot(String slotName)	void	Drops a logical replication slot.	SQLException,IOException
replicationStream()	ChainedStreamBuilder	Enables logical replication.	-

5.3.4.16 PGReplicationStream

PGReplicationStream is an API class provided by the GaussDB JDBC driver. It is used to operate logical replication streams.

Inheritance Relationship of PGReplicationStream

PGReplicationStream is a logical replication API. Its implementation class is V3PGReplicationStream, which is in the **com.huawei.opengauss.jdbc.core.v3.replication** package. The declaration of the class is as follows:

```
public class V3PGReplicationStream implements PGReplicationStream
```

Constructor

```
public V3PGReplicationStream(CopyDual copyDual, LogSequenceNumber  
startLSN, long updateIntervalMs, ReplicationType replicationType)
```

Common Methods

Table 5-26 Common methods of PGReplicationConnection

Method Name	Return Type	Description	throws
close()	void	Ends the logical replication and releases resources.	SQLException
forceUpdateStatus()	void	Forcibly sends the LSN status received, flushed, and applied last time to the backend.	SQLException
getLastAppliedLSN()	LogSequenceNumber	Obtains the LSN when the primary node replays logs last time.	-
getLastFlushedLSN()	LogSequenceNumber	Obtains the LSN flushed by the primary node last time, that is, the LSN pushed by the current logical decoding.	-
getLastReceivedLSN()	LogSequenceNumber	Obtains the LSN received last time.	-
isClosed()	boolean	Determines whether the replication stream is disabled.	-
read()	ByteBuffer	Reads the next WAL record from the backend. If the data cannot be read, this method blocks the I/O read.	SQLException
readPending()	ByteBuffer	Reads the next WAL record from the backend. If the data cannot be read, this method does not block the I/O read.	SQLException

Method Name	Return Type	Description	throws
setAppliedLSN(LogSequenceNumber applied)	void	Sets the applied LSN.	-
setFlushedLSN(LogSequenceNumber flushed)	void	Sets the flushed LSN, which is sent to the backend at the next update to push the LSN on the server.	-

5.3.4.17 ChainedStreamBuilder

ChainedStreamBuilder is an API class provided by the GaussDB JDBC driver. It is used to build replication streams.

Inheritance Relationship of ChainedStreamBuilder

ChainedStreamBuilder is a logical replication API. Its implementation class is ReplicationStreamBuilder, which is in the **com.huawei.opengauss.jdbc.replication.fluent** package. The declaration of the class is as follows:

```
public class ReplicationStreamBuilder implements ChainedStreamBuilder
```

Constructor

```
public ReplicationStreamBuilder(final BaseConnection connection)
```

Common Methods

Table 5-27 Common methods of ReplicationStreamBuilder

Method Name	Return Type	Description	throws
logical()	ChainedLogicalStreamBuilder	Creates a logical replication stream.	-
physical()	ChainedPhysicalStreamBuilder	Creates a physical replication stream.	-

5.3.4.18 ChainedCommonStreamBuilder

ChainedCommonStreamBuilder is an API class provided by the GaussDB JDBC driver. It is used to specify common parameters for logical and physical replication.

Inheritance Relationship of ChainedCommonStreamBuilder

ChainedCommonStreamBuilder is an API for logical replication. The implementation abstract class is AbstractCreateSlotBuilder. The inheritance class is LogicalCreateSlotBuilder which is in the **com.huawei.opengauss.jdbc.replication.fluent.logical** package. The declaration of this class is as follows:

```
public class LogicalCreateSlotBuilder
    extends AbstractCreateSlotBuilder<ChainedLogicalCreateSlotBuilder>
    implements ChainedLogicalCreateSlotBuilder
```

Constructor

```
public LogicalCreateSlotBuilder(BaseConnection connection)
```

Common Methods

Table 5-28 Common methods of LogicalCreateSlotBuilder

Method	Return Type	Description	throws
withSlotName(String slotName)	T	Specifies the name of a replication slot.	-
withOutputPlugin(String outputPlugin)	ChainedLogicalCreateSlotBuilder	Plug-in name. Currently, mppdb_decoding is supported.	-
make()	void	Creates a slot with the specified parameters in the database.	SQLException
self()	ChainedLogicalCreateSlotBuilder	-	-

5.4 Development Based on ODBC

5.4.1 Development Process

Figure 5-3 shows the ODBC-based development process.

Figure 5-3 ODBC development process

5.4.2 Development Procedure

5.4.2.1 Obtaining a Source Code Package, ODBC Packages, and Dependent Libraries

You need to obtain the unixODBC source code package, ODBC packages, and dependency libraries for ODBC-based development.

Obtaining the Source Code Package

- To obtain the unixODBC source code package, visit <https://www.unixodbc.org/unixODBC-2.3.7.tar.gz>.
- To obtain the MD5 file, visit <https://www.unixodbc.org/unixODBC-2.3.7.tar.gz.md5>.

Use the MD5 file to verify the integrity of the unixODBC source code package. (Check whether the MD5 value is the same as that in the source code package.)

Obtaining ODBC Packages and Dependency Libraries

ODBC packages and dependency libraries support both Linux and Windows systems. Obtain the required files based on the OS you use.

- For Linux:

Obtain the package **GaussDB-Kernel-Database version number-OS information-64bit-Odbc.tar.gz** from the driver package. In the Linux OS, unixODBC header files (including **sql.h** and **sqlext.h**) and the library **libodbc.so** are required in application development.

The header files and the library can be obtained from the unixODBC-2.3.7 source code package.

- For Windows:

Obtain the package **GaussDB-Kernel_Database version number_Windows_X86_Odbc.tar.gz** (32-bit) or **GaussDB-Kernel-Database version number-Windows-X64-Odbc.tar.gz** (64-bit) from the driver package.

In the Windows OS, the required header files and library files are system-resident.

5.4.2.2 Connecting to a Database

5.4.2.2.1 Configuring a Data Source in the Linux OS

Before using ODBC to connect to a database, you need to prepare the required resources. To connect to a database, you need to configure the ODBC data source or use the ODBC APIs or the driver to implement the communication and interaction between an application and a database. This section describes how to configure a data source and connect to a database in the Linux OS.

Procedure

- Step 1** Install unixODBC. (By default, the unixODBC source code package has been obtained during environment preparation.) It does not matter if unixODBC of another version has been installed.

For example, to install unixODBC-2.3.7, run the commands below.

```
tar zxvf unixODBC-2.3.7.tar.gz
cd unixODBC-2.3.7
```

```
./configure --enable-gui=no # To perform compilation on an Arm server, add the configure parameter --  
build=aarch64-unknown-linux-gnu.  
make  
# The installation may require root permissions.  
make install
```

NOTE

- Currently, unixODBC-2.2.1 is not supported.
- By default, it is installed in the **/usr/local** directory. The data source file is generated in the **/usr/local/etc** directory, and the library file is generated in the **/usr/local/lib** directory.
- You can compile unixODBC with the **--enable-fastvalidate=yes** option to achieve higher performance. However, this option may cause an application that passes an invalid handle to the ODBC API to fail instead of returning an SQL_INVALID_HANDLE error.

Step 2 Replace the GaussDB client driver.

Decompress **GaussDB-Kernel-Database version number-OS information-64bit-Odbc.tar.gz**. After the decompression, the **lib** and **odbc** folders are generated. The **odbc** folder contains another **lib** folder. Copy all dynamic libraries in the **/lib** and **/odbc/lib** folders to the **/usr/local/lib** directory.

Step 3 Configure a data source.

1. Configure the ODBC driver file.

Add the following content to the **/usr/local/etc/odbcinst.ini** file:

```
[GaussMPP]
Driver64=/usr/local/lib/psqlodbcw.so
setup=/usr/local/lib/psqlodbcw.so
```

For descriptions of the parameters in the **odbcinst.ini** file, see [Table 5-29](#).

Table 5-29 odbcinst.ini configuration parameters

Parameter	Description	Example
[DriverName]	Driver name, corresponding to the driver in DSN.	[GaussMPP]
Driver64	Path of the dynamic driver library.	Driver64=/usr/local/lib/psqlodbcw.so
setup	Driver installation path, which is the same as the dynamic library path in Driver64.	setup=/usr/local/lib/psqlodbcw.so

2. Configure the data source file.

Add the following content to the **/usr/local/etc/odbc.ini** file:

```
[gaussdb]
Driver=GaussMPP
Servername=127.0.0.1 # Database server IP address
Database=postgres # Database name
Username=omm # Database username
Password= # Database user password
Port=8000 # Database listening port
Sslmode = allow
```

For descriptions of the parameters in the **odbc.ini** file, see [Table 5-30](#).

Table 5-30 odbc.ini configuration parameters

Parameter	Description	Example
[DSN]	Data source name.	[gaussdb]
Driver	Driver name, corresponding to DriverName in odbcinst.ini .	Driver=GaussMPP
Servername	Server IP address. Multiple IP addresses can be configured.	Servername=127.0.0.1

Parameter	Description	Example
Database	Name of the database to connect to.	Database=postgres
Username	Database username.	Username=omm
Password	Database user password. NOTE After a user establishes a connection, the ODBC driver automatically clears their password stored in memory. However, if this parameter is configured, unixODBC will cache data source files, which may cause the password to be stored in the memory for a long time. When you connect to an application, you are advised to send your password through an API instead of writing it in a data source configuration file. After the connection has been established, immediately clear the memory segment where your password is stored. NOTICE The password in the configuration file must comply with the following HTTP rules: 1. Characters must comply with the URL encoding specifications. For example, the exclamation mark (!) must be written as %21, and the percent sign (%) must be written as %25. Therefore, pay attention to the handling of the percent sign (%). 2. A plus sign (+) will be replaced by a space.	Password=*****
Port	Port number of the server.	Port=8000
Sslmode	Specifies whether to enable SSL. NOTE For details about the values of the Sslmode option, see Table 5-31.	Sslmode=allow
Debug	Specifies whether to enable the debugging mode. Value range: 0 to <i>INT_MAX</i>. – If this parameter is set to 0, the function is disabled. – If this parameter is set to a value greater than 0, the mylog file of the psqLODBC driver will be printed. The directory generated for storing logs is /tmp/. The default value is 0.	Debug=1

Parameter	Description	Example
UseServerSidePrepare	Specifies whether to enable the extended query protocol for the database. Value range: 0 and 1 – If this parameter is set to 0, the function is disabled. – If this parameter is set to 1, the function is enabled. The default value is 1.	UseServerSidePrepare=1
UseBatchProtocol	Specifies whether to enable the batch query protocol. If it is enabled, DML performance can be improved. Value range: 0 and 1 – If this parameter is set to 0, the batch query protocol is disabled (mainly for communication with earlier database versions). – If this parameter is set to 1 and support_batch_bind is set to on, the batch query protocol is enabled. The default value is 1.	UseBatchProtocol=1
ForExtensionConnector	Specifies whether the savepoint is sent. Value range: 0 and 1 – If this parameter is set to 0, the savepoint is sent. – If this parameter is set to 1, the savepoint is not sent. The default value is 1.	ForExtensionConnector=1

Parameter	Description	Example
ConnectionExtraInfo	Specifies whether to display the driver deployment path and process owner in the connection_info GUC parameter. Value range: 0 and 1 – If this parameter is set to 0, the information is not displayed. – If this parameter is set to 1, the information is displayed. The default value is 0. NOTE The default value is 0. If this parameter is set to 1, the ODBC driver reports the driver deployment path and process owner to the database and displays the information in the connection_info parameter. In this case, you can query the information from PG_STAT_ACTIVITY.	ConnectionExtraInfo=1
BoolsAsChar	Specifies whether to process Boolean values as characters. Value range: 0 and 1 – If this parameter is set to 0, the Boolean values are mapped to the SQL_BIT type. – If this parameter is set to 1, the Boolean values are mapped to the SQL_CHAR type. The default value is 1.	BoolsAsChar = 1
RowVersioning	Specifies whether to allow the application to check whether a row of data is modified by another user when the row of data is updated. Value range: 0 and 1 – If this parameter is set to 0, application detection is not allowed. – If this parameter is set to 1, application detection is allowed. The default value is 0.	RowVersioning=1

Parameter	Description	Example
ShowSystemTables	Specifies whether to regard the system catalog as a common SQL table by default. Value range: 0 and 1 – If this parameter is set to 0, the driver does not regard the system catalog as a common SQL table by default. – If this parameter is set to 1, the driver regards the system catalog as a common SQL table by default. The default value is 0.	ShowSystemTables=1
TcpUserTimeout	Specifies the maximum duration for which transmitted data can remain unacknowledged before the TCP connection is forcibly closed on an OS that supports the TCP_USER_TIMEOUT socket option. Value range: 0 to <i>INT_MAX</i>. The default value is 0. NOTE 0 indicates that the default value is used. Ignore this parameter for UDS connections. The unit is millisecond.	TcpUserTimeout=5000

The valid values of **Sslmode** are described in the following table.

Table 5-31 Sslmode options

Sslmode	Enable SSL Encryption	Description
disable	No	SSL connection is not enabled.
allow	Possible	If the database server requires SSL connection, SSL connection can be enabled. However, authenticity of the database server will not be verified.
prefer	Possible	If the database supports SSL connection, SSL connection is recommended. However, authenticity of the database server will not be verified.

Sslmode	Enable SSL Encryption	Description
require	Yes	SSL connection is required and data is encrypted. However, authenticity of the database server will not be verified.
verify-ca	Yes	SSL connection is required and whether the database has a trusted certificate will be verified.
verify-full	Yes	SSL connection is required. In addition to the check scope specified by verify-ca , the system checks whether the name of the host where the database resides is the same as that in the certificate. GaussDB does not support this mode.

 NOTE

When establishing connections to the GaussDB server using ODBC, you can enable SSL connections to encrypt client and server communications. To enable SSL connection, you must have the server certificate, client certificate, and private key files. For details on how to obtain these files, see related documents and commands of OpenSSL.

Step 4 Configure the environment variables on the client.

```
vim ~/.bashrc
```

Add the following information to the configuration file:

```
export LD_LIBRARY_PATH=/usr/local/lib/:$LD_LIBRARY_PATH
export ODBC_SYSINI=/usr/local/etc
export ODBCINI=/usr/local/etc/odbc.ini
```

Step 5 Run the following command to validate the addition:

```
source ~/.bashrc
```

Step 6 Test the connection.

After the installation, the generated binary file is stored in the **/usr/bin** directory. You can run the **isql -v gaussdb** command (*gaussdb* is the data source name).

- If the following information is displayed, the configuration is correct and the connection succeeds:

```
+-----+
| Connected!          |
|                    |
| sql-statement       |
| help [tablename]    |
| quit                |
|                    |
+-----+
```

- If error information is displayed, the configuration is incorrect. Check whether the preceding configuration steps are correctly performed.

NOTE

When ODBC is used to connect to a database, the kernel parameters are set as follows:

```
SET extra_float_digits = 2;  
SET DateStyle = 'ISO';
```

These parameters may cause the ODBC and gsql clients to display inconsistent data, for example, date data display mode and floating-point precision representation. If the result is not as expected, you are advised to explicitly set these parameters in the ODBC application code.

----End

Troubleshooting

- [UnixODBC][Driver Manager]Can't open lib 'xxx/xxx/psqlodbcw.so' : file not found.
Possible causes:
 - The path configured in the **odbcinst.ini** file is incorrect.
Run **ls** to check the path in the error information, ensuring that the **psqlodbcw.so** file exists and you have execution permissions on it.
 - The dependent library of **psqlodbcw.so** does not exist or is not in system environment variables.
Run **ldd** to check the path in the error information. If **libodbc.so.1** or other unixODBC libraries do not exist, configure unixODBC again following the procedure provided in this section, and add the **lib** directory under its installation directory to **LD_LIBRARY_PATH**. If other libraries do not exist, add the **lib** directory under the ODBC driver package to **LD_LIBRARY_PATH**. If other standard libraries are missing, install them.
- [UnixODBC]connect to server failed: no such file or directory
Possible causes:
 - An incorrect or unreachable database IP address or port was configured.
Check the **Servename** and **Port** configuration items in data sources.
 - Server monitoring is improper.
If **Servename** and **Port** are correctly configured, ensure the proper NIC and port are monitored by following the database server configurations in the procedure in this section.
 - Firewall and network gatekeeper settings are improper.
Check firewall settings, and ensure that the database communication port is trusted.
Check to ensure network gatekeeper settings are proper (if any).
- [unixODBC]The password-stored method is not supported.
Possible causes:
The **sslmode** configuration item is not configured in the data sources.
Solution:
Set the configuration item to **allow** or a higher level. For details, see [Table 5-31](#).
- Server common name "xxxx" does not match host name "xxxxx"
Possible causes:

When **verify-full** is used for SSL encryption, the driver checks whether the host name in certificates is the same as the actual one.

Solution:

To solve this problem, use **verify-ca** to stop checking host names, or generate a set of CA certificates containing the actual host names.

- Driver's SQLAllocHandle on SQL_HANDLE_DBC failed

Possible causes:

The executable file (such as the **isql** tool of unixODBC) and the database driver (**psqlodbcw.so**) depend on different library versions of ODBC, such as **libodbc.so.1** and **libodbc.so.2**. You can verify this problem by using the following method:

```
ldd `which isql` | grep odbc  
ldd psqlodbcw.so | grep odbc
```

If the suffix digits of the outputs **libodbc.so** are different or indicate different physical disk files, this problem exists. Both **isql** and **psqlodbcw.so** require **libodbc.so** to be loaded. If they load different physical files, two sets of function lists with the same name are generated in a visible domain (the **libodbc.so.*** function export lists of unixODBC are the same). This results in conflicts and the database driver cannot be loaded.

Solution:

Uninstall the unnecessary unixODBC, such as **libodbc.so.2**, and create a soft link with the same name and the **.so.2** suffix for the remaining **libodbc.so.1** library.

- FATAL: Forbid remote connection with trust method!

For security reasons, the primary database node prevents unauthorized access from other nodes within the database.

To access the primary database node from inside the database, deploy the ODBC program on the host where the primary database node is located and set the server address to **127.0.0.1**. It is recommended that the service system be deployed outside the database. Otherwise, the database performance may be affected.

- [unixODBC][Driver Manager]Invalid attribute value

The unixODBC version may not be the recommended one. You are advised to run the **odbcinst --version** command to check the unixODBC version in the environment.

- authentication method 10 not supported.

If this error occurs on an open-source client, the cause may be:

The database stores only the SHA-256 hash of the password, but the open-source client supports only MD5 hashes.

NOTE

- The database stores the hashes of user passwords instead of actual passwords.
- If a password is updated or a user is created, both types of hashes will be stored, compatible with open-source authentication protocols.
- An MD5 hash can only be generated using the original password, but the password cannot be obtained by reversing its SHA-256 hash. Passwords in the source version will only have SHA-256 hashes and not support MD5 authentication.
- MD5 has lower security and poses security risks. Therefore, you are advised to use a more secure cryptographic algorithm.

To solve this problem, you can update the user password (see [ALTER USER](#)) or create a user (see [CREATE USER](#)) having the same permissions as the faulty user.

- unsupported frontend protocol 3.51: server supports 1.0 to 3.0

The database version is too early or the database is an open-source database. Use the driver of the required version to connect to the database.

- FATAL: GSS authentication method is not allowed because XXXX user password is not disabled.

In **pg_hba.conf** of the target primary database node, the authentication mode is set to **gss** for authenticating the IP address of the current client. However, this authentication algorithm cannot authenticate clients. Change the authentication algorithm to **sha256** and try again.

- isql: error while loading shared libraries:xxx

The dynamic library does not exist in the environment. You need to install the corresponding library.

5.4.2.2.2 Configuring a Data Source in the Windows OS

Configure an ODBC data source using the ODBC data source manager preinstalled in the Windows OS.

Procedure

Step 1 Replace the GaussDB client driver.

Decompress **GaussDB-Kernel-Database version number-Windows-Odbc.tar.gz** and click **psqlodbc.exe** (32-bit) to install the driver.

Step 2 Open the driver manager.

Use the ODBC Driver Manager for the 32-bit OS to configure the data source. (Currently, only the ODBC Driver Manager for the 32-bit OS is supported. The following description assumes that the OS is installed on drive C. If the OS is installed on another drive, change the path accordingly.)

- If you want to use 32-bit ODBC driver manager in a 64-bit OS, open **C:\Windows\SysWOW64\odbcad32.exe**. Do not choose **Control Panel > Administrative Tools > Data Sources (ODBC)**.

NOTE

WoW64 is short for Windows 32-bit on Windows 64-bit. **C:\Windows\SysWOW64** stores the 32-bit environment on a 64-bit system. **C:\Windows\System32** stores the environment consistent with the current OS. For technical details, see Windows technical documents.

- For a 32-bit OS, open **C:\Windows\System32\odbcad32.exe** or choose **Computer > Control Panel > Administrative Tools > Data Sources (ODBC)** to open Driver Manager.

Step 3 Configure a data source.

On the **User DSN** tab, click **Add** and choose **PostgreSQL Unicode** for setup.

The screenshot shows the 'PostgreSQL ANSI ODBC Driver (psqlODBC) Setup' window. It contains the following fields and controls:

- Data Source:** Text box with 'gaussdb1'.
- Description:** Text box.
- Database:** Text box with 'postgres'.
- SSL Mode:** Dropdown menu with 'disable' selected.
- Server:** Text box with '10.145.130.27'.
- Port:** Text box with '25308'.
- User Name:** Text box with 'xxxx'.
- Password:** Password field with 12 dots.
- AutoBalance:** Text box with '1'.
- Refresh Time:** Text box with '1'.
- Priority:** Text box.
- Options:** A group box containing three buttons: 'Datasource', 'Global', and 'Manage DSN'.
- Action Buttons:** 'Test', 'Save', and 'Cancel' buttons at the bottom right.

NOTICE

The entered username and password will be recorded in the Windows registry and you do not need to enter them again when connecting to the database next time. For security purposes, you are advised to delete sensitive information before clicking **Save** and enter the required username and password again when using ODBC APIs to connect to the database.

Step 4 Enable the SSL mode.

Change the value of **SSL Mode** in [Step 3](#) to **require**.

Table 5-32 sslmode options

sslmode	Whether SSL Encryption Is Enabled	Description
disable	No	SSL connection is not enabled.
allow	Possible	If the database server requires SSL connection, SSL connection can be enabled. However, authenticity of the database server will not be verified.
prefer	Possible	If the database supports SSL connection, SSL connection is preferred. However, authenticity of the database server will not be verified.
require	Yes	SSL connection is required and data is encrypted. However, authenticity of the database server will not be verified.

sslmode	Whether SSL Encryption Is Enabled	Description
verify-ca	Yes	SSL connection is required and whether the database has a trusted certificate will be verified. Currently, Windows ODBC does not support the cert authentication.
verify-full	Yes	SSL connection is required. In addition to the check scope specified by verify-ca , the system checks whether the name of the host where the database resides is the same as that in the certificate. Currently, Windows ODBC does not support the cert authentication.

NOTE

When establishing connections to the GaussDB server using ODBC, you can enable SSL connections to encrypt client and server communications. To enable SSL connections, you must have the server certificate, client certificate, and private key files. For details on how to obtain these files, see related documents and commands of OpenSSL.

Step 5 Test the connection.

Click **Test**.

- If the following information is displayed, the configuration is correct and the connection succeeds.

- If error information is displayed, the configuration is incorrect. Check the configuration.

 NOTE

When ODBC is used to connect to a database, the kernel parameters are set as follows:

```
SET extra_float_digits = 2;  
SET DateStyle = 'ISO';
```

These parameters may cause the ODBC and gsql clients to display inconsistent data, for example, date data display mode and floating-point precision representation. If the result is not as expected, you are advised to explicitly set these parameters in the ODBC application code.

----End

FAQ

- connect to server failed: no such file or directory
Possible causes:
 - An incorrect or unreachable database IP address or port was configured.
Check the **Server** and **Port** configuration items in data sources.
 - Server monitoring is improper.
If **Server** and **Port** are correctly configured, ensure the proper NIC and port are monitored by following the database server configurations in the procedure in this section.
 - Firewall and network gatekeeper settings are improper.
Check firewall settings, and ensure that the database communication port is trusted.
Check to ensure network gatekeeper settings are proper (if any).
- The password-stored method is not supported.
Possible causes:
sslmode is not configured for the data source. Set this configuration item to **allow** or a higher level to enable SSL connections. For details on **sslmode**, see [Table 5-32](#).
- authentication method 10 not supported.
If this error occurs on an open-source client, the cause may be:
The database stores only the SHA-256 hash of the password, but the open-source client supports only MD5 hashes.

 NOTE

- The database stores the hashes of user passwords instead of actual passwords.
 - If a password is updated or a user is created, both types of hashes will be stored, compatible with open-source authentication protocols.
 - An MD5 hash can only be generated using the original password, but the password cannot be obtained by reversing its SHA-256 hash. Passwords in the source version will only have SHA-256 hashes and not support MD5 authentication.
 - The MD5 encryption algorithm has lower security and poses security risks.
Therefore, you are advised to use a more secure encryption algorithm.
- To solve this problem, you can update the user password (see [ALTER USER](#)) or create a user (see [CREATE USER](#)) having the same permissions as the faulty user.
- unsupported frontend protocol 3.51: server supports 1.0 to 3.0

The database version is too early or the database is an open-source database. Use the driver of the required version to connect to the database.

- FATAL: GSS authentication method is not allowed because XXXX user password is not disabled.

In **pg_hba.conf** of the target DN, the authentication mode is set to **gss** for authenticating the IP address of the current client. However, this authentication algorithm cannot authenticate clients. Change the authentication algorithm to **sha256** and try again.

5.4.2.2.3 APIs for Connecting to a Database

After the database connection test is successful, the ODBC APIs provide a group of functions to connect to the database, as shown in [Table 5-33](#).

Table 5-33 API description

Function	API
Allocate a handle.	SQLAllocHandle is a generic function for allocating a handle. It can replace the following functions: • SQLAllocEnv: allocates an environment handle. • SQLAllocConnect: allocates a connection handle. • SQLAllocStmt: allocates a statement handle.
Set environment attributes.	SQLSetEnvAttr
Set connection attributes.	SQLSetConnectAttr
Connect to a database.	SQLConnect

The following uses the development source program **DBtest.c** as an example (for details about the complete example, see [Obtaining and Processing Data in a Database](#)).

```
// DBtest.c (compile with: libodbc.so)
// For details about program header files and global variables, see the complete example.

// Allocate an environment handle.
V_OD_erg = SQLAllocHandle(SQL_HANDLE_ENV,SQL_NULL_HANDLE,&V_OD_Env);
if ((V_OD_erg != SQL_SUCCESS) && (V_OD_erg != SQL_SUCCESS_WITH_INFO))
{
    printf("Error AllocHandle\n");
    exit(0);
}

// Set the version information (environment attributes).
SQLSetEnvAttr(V_OD_Env, SQL_ATTR_ODBC_VERSION, (void*)SQL_OV_ODBC3, 0);

// Allocate a connection handle.
V_OD_erg = SQLAllocHandle(SQL_HANDLE_DBC, V_OD_Env, &V_OD_hdbc);
if ((V_OD_erg != SQL_SUCCESS) && (V_OD_erg != SQL_SUCCESS_WITH_INFO))
{
```

```
SQLFreeHandle(SQL_HANDLE_ENV, V_OD_Env);
exit(0);
}

//Obtain the username and password.
char *userName;
userName = getenv("EXAMPLE_USERNAME_ENV");
char *password;
password = getenv("EXAMPLE_PASSWORD_ENV");

// Set connection attributes.
SQLSetConnectAttr(V_OD_hdbc, SQL_ATTR_AUTOCOMMIT,(SQLPOINTER *)SQL_AUTOCOMMIT_ON, 0);

// Connect to the database. userName and password indicate the username and password for connecting
to the database respectively.
// If the username and password have been set in the odbc.ini file, you can retain "". However, you are
advised not to do so because the username and password will be disclosed if the permission for odbc.ini is
abused.
V_OD_erg = SQLConnect(V_OD_hdbc, (SQLCHAR*) "gaussdb", SQL_NTS,
(SQLCHAR*) userName, SQL_NTS, (SQLCHAR*) password, SQL_NTS);
if ((V_OD_erg != SQL_SUCCESS) && (V_OD_erg != SQL_SUCCESS_WITH_INFO))
{
    printf("Error SQLConnect %d\n",V_OD_erg);
    SQLFreeHandle(SQL_HANDLE_ENV, V_OD_Env);
    exit(0);
}
printf("Connected !\n");
```

5.4.2.3 Executing SQL Statements

To help users interact with the database, the ODBC provides APIs for executing SQL statements, as shown in [Table 5-34](#).

Table 5-34 API description

Function	API
Set statement attributes.	SQLSetStmtAttr
Prepare an SQL statement for execution.	SQLPrepare
Run a prepared SQL statement.	SQLExecute
Bind the parameter marker of an SQL statement to a buffer.	SQLBindParameter
Run an SQL statement directly.	SQLExecDirect

NOTE

- ODBC connects applications to the database and delivers the SQL statements sent by an application to the database. It does not parse the SQL syntax. Therefore, when confidential information (such as a plaintext password) is written into the SQL statement sent by an application, the confidential information is exposed in the driver log.
- If an execution request (not in a transaction block) received in the database contains multiple statements, the request is packed into a transaction. If one of the statements fails, the entire request will be rolled back.

The following is an example (for details about the complete example, see [Obtaining and Processing Data in a Database](#)):

```
// Set statement attributes.
SQLSetStmtAttr(V_OD_hstmt, SQL_ATTR_QUERY_TIMEOUT, (SQLPOINTER *)3, 0);

// Allocate a statement handle.
SQLAllocHandle(SQL_HANDLE_STMT, V_OD_hdbc, &V_OD_hstmt);

// Run an SQL statement directly.
SQLExecDirect(V_OD_hstmt, "drop table IF EXISTS customer_t1", SQL_NTS);
SQLExecDirect(V_OD_hstmt, "CREATE TABLE customer_t1(c_customer_sk INTEGER, c_customer_name
VARCHAR(32));", SQL_NTS);
SQLExecDirect(V_OD_hstmt, "insert into customer_t1 values(25, 'li')", SQL_NTS);

// Prepare for execution.
SQLPrepare(V_OD_hstmt, "insert into customer_t1 values(?)", SQL_NTS);

// Bind parameters.
SQLBindParameter(V_OD_hstmt,1, SQL_PARAM_INPUT, SQL_C_SLONG, SQL_INTEGER, 0, 0,
&value, 0, NULL);

// Run the prepared statement.
SQLExecute(V_OD_hstmt);    SQLExecDirect(V_OD_hstmt, "select c_customer_sk from customer_t1",
SQL_NTS);
```

5.4.2.4 Processing Data in a Result Set

The ODBC obtains data from the database and provides the data to the application program for processing. Functions of ODBC processing include but are not limited to: retrieving data, displaying data, processing data, transmitting data, and implementing service logic.

The ODBC provides APIs for processing data in a result set, as shown in [Table 5-35](#).

Table 5-35 API description

Function	API
Bind a buffer to a column in the result set.	SQLBindCol
Fetch the next row (or rows) from the result set.	SQLFetch
Return data in a column of the result set.	SQLGetData
Get the column information from the result set.	SQLColAttribute
Return the error message of the last operation.	SQLGetDiagRec

The following is an example (for details about the complete example, see [Obtaining and Processing Data in a Database](#)):

```
// After the SQL statement is executed, obtain the attributes of a column in the result set.
SQLColAttribute(V_OD_hstmt,1,SQL_DESC_TYPE,typename,100,NULL,NULL);
```

```
printf("SQLColAttribute %s\n",typename);

// Bind the result set.
SQLBindCol(V_OD_hstmt,1,SQL_C_SLONG, (SQLPOINTER*)&V_OD_buffer,150,
           (SQLLEN *)&V_OD_err);

// Use SQLFetch to obtain data from the result set.
V_OD_erg=SQLFetch(V_OD_hstmt);

// Use SQLGetData to obtain and return data.
while(V_OD_erg != SQL_NO_DATA)
{
    SQLGetData(V_OD_hstmt,1,SQL_C_SLONG,(SQLPOINTER*)&V_OD_id,0,NULL);
    printf("SQLGetData ----ID = %d\n",V_OD_id);
    V_OD_erg=SQLFetch(V_OD_hstmt);
};
printf("Done !\n");
```

5.4.2.5 Closing a Connection

The ODBC provides APIs for disconnecting from a database and releasing resources, as shown in [Table 5-36](#).

Table 5-36 API description

Function	API
Disconnect from a data source.	SQLDisconnect
Release a handle.	SQLFreeHandle is a generic function for releasing a handle. It can replace the following functions: • SQLFreeEnv: releases an environment handle. • SQLFreeConnect: releases a connection handle. • SQLFreeStmt: releases a statement handle.

The following is an example (for details about the complete example, see [Obtaining and Processing Data in a Database](#)):

```
// Disconnect from the data source and release handles.
SQLFreeHandle(SQL_HANDLE_STMT,V_OD_hstmt);
SQLDisconnect(V_OD_hdbc);
SQLFreeHandle(SQL_HANDLE_DBC,V_OD_hdbc);
SQLFreeHandle(SQL_HANDLE_ENV, V_OD_Env);
```

5.4.3 Typical Application Development Examples

5.4.3.1 Typical Application Scenarios and Configurations

Log Diagnosis Scenario

ODBC logs are classified into unixODBC driver manager logs and psqLODBC driver logs. The former is used to trace whether the application API is successfully

executed, and the latter is used to locate problems based on DFX logs generated during underlying implementation.

The unixODBC log needs to be configured in the **odbcinst.ini** file:

```
[ODBC]
Trace=Yes
TraceFile=/path/to/odbctrace.log

[GaussMPP]
Driver64=/usr/local/lib/psqlodbcw.so
setup=/usr/local/lib/psqlodbcw.so
```

You only need to add the following information to the **odbc.ini** file:

```
[gaussdb]
Driver=GaussMPP
Servername=10.10.0.13 (database server IP address)
...
Debug=1 (Enable the debug log function of the driver.)
```

NOTE

The unixODBC logs are generated in the path configured by **TraceFile**. The psqlODBC generates the **mylog_XXX.log** file in the **/tmp/** directory.

Automatic Primary/Standby Switchover

Example Scenario

If a database instance is configured with one primary DN and multiple standby DNs, write the IP addresses of all DNs into the configuration file. ODBC automatically searches for the primary DN and establishes a connection with it. When a primary/standby switchover occurs, ODBC can also connect to the new primary DN.

5.4.3.2 Obtaining and Processing Data in a Database

NOTE

- In Windows, ODBC application code can be compiled using the Minimalist GNU for Windows (MinGW) compiler. The compilation command is as follows:

```
gcc odbctest.c -o odbctest -lodb32
```

Run the following command:

```
./odbctest.exe
```

- In Linux, ODBC application code can be compiled using the GNU Compiler Collection (GCC). The compilation command is as follows:

```
gcc odbctest.c -o odbctest -lodb
```

Run the following command:

```
./odbctest
```

If **sql.h** or API cannot be found during compilation, manually connect to the header file and dynamic library of unixODBC.

```
gcc -I /home/omm/unixodbc/include -L /home/omm/unixodbc/lib odbctest.c -o odbctest -lodb
```

This example illustrates how to obtain and process data in GaussDB through ODBC.

Prerequisite: The data source has been configured successfully. For Linux OS, see [Configuring a Data Source in the Linux OS](#). For Windows OS, see [Configuring a Data Source in the Windows OS](#).

```
// DBtest.c (compile with: libodbc.so)
// In this example, the username and password are stored in environment variables. Before running this
// example, set the environment variables EXAMPLE_USERNAME_ENV and EXAMPLE_PASSWORD_ENV in the
// local environment.
#ifdef WIN32
#include <windows.h>
#else
#include <stdio.h>
#include <stdlib.h>
#include <sql.h>
#include <sqlext.h>
SQLHENV    V_OD_Env;    // Handle ODBC environment
SQLHSTMT    V_OD_hstmt; // Handle statement
SQLHDBC    V_OD_hdbc;   // Handle connection
char        typename[100];
SQLINTEGER  value = 100;
SQLINTEGER  V_OD_erg,V_OD_buffer,V_OD_err,V_OD_id;
int main(int argc,char *argv[])
{
    // 1. Allocate an environment handle.
    V_OD_erg = SQLAllocHandle(SQL_HANDLE_ENV,SQL_NULL_HANDLE,&V_OD_Env);
    if ((V_OD_erg != SQL_SUCCESS) && (V_OD_erg != SQL_SUCCESS_WITH_INFO))
    {
        printf("Error AllocHandle\n");
        exit(0);
    }

    // 2. Set the version information (environment attributes).
    SQLSetEnvAttr(V_OD_Env, SQL_ATTR_ODBC_VERSION, (void*)SQL_OV_ODBC3, 0);

    // 3. Allocate a connection handle.
    V_OD_erg = SQLAllocHandle(SQL_HANDLE_DBC, V_OD_Env, &V_OD_hdbc);
    if ((V_OD_erg != SQL_SUCCESS) && (V_OD_erg != SQL_SUCCESS_WITH_INFO))
    {
        SQLFreeHandle(SQL_HANDLE_ENV, V_OD_Env);
        exit(0);
    }

    // Obtain the username and password.
    char *userName;
    userName = getenv("EXAMPLE_USERNAME_ENV");
    char *password;
    password = getenv("EXAMPLE_PASSWORD_ENV");

    // 4. Set connection attributes.
    SQLSetConnectAttr(V_OD_hdbc, SQL_ATTR_AUTOCOMMIT,(SQLPOINTER *)SQL_AUTOCOMMIT_ON, 0);

    // 5. Connect to the database. userName and password indicate the username and password for
    // connecting to the database, respectively.
    // If the username and password have been set in the odbc.ini file, you can retain "". However, you are
    // advised not to do so because the username and password will be disclosed if the permission for odbc.ini is
    // abused.
    V_OD_erg = SQLConnect(V_OD_hdbc, (SQLCHAR*) "gaussdb", SQL_NTS,
        (SQLCHAR*) userName, SQL_NTS, (SQLCHAR*) password, SQL_NTS);
    if ((V_OD_erg != SQL_SUCCESS) && (V_OD_erg != SQL_SUCCESS_WITH_INFO))
    {
        printf("Error SQLConnect %d\n",V_OD_erg);
        SQLFreeHandle(SQL_HANDLE_ENV, V_OD_Env);
        exit(0);
    }
    printf("Connected !\n");

    // 6. Set statement attributes.
    SQLSetStmtAttr(V_OD_hstmt, SQL_ATTR_QUERY_TIMEOUT, (SQLPOINTER *)3,0);

    // 7. Allocate a statement handle.
    SQLAllocHandle(SQL_HANDLE_STMT, V_OD_hdbc, &V_OD_hstmt);

    // 8. Run SQL statements.
```

```
SQLExecDirect(V_OD_hstmt, "drop table IF EXISTS customer_t1", SQL_NTS);
SQLExecDirect(V_OD_hstmt, "CREATE TABLE customer_t1(c_customer_sk INTEGER, c_customer_name
VARCHAR(32));", SQL_NTS);
SQLExecDirect(V_OD_hstmt, "insert into customer_t1 values(25,'li')", SQL_NTS);

// 9. Prepare for execution.
SQLPrepare(V_OD_hstmt, "insert into customer_t1 values(?)", SQL_NTS);

// 10. Bind parameters.
SQLBindParameter(V_OD_hstmt, 1, SQL_PARAM_INPUT, SQL_C_SLONG, SQL_INTEGER, 0, 0,
&value, 0, NULL);

// 11. Run prepared statements.
SQLExecute(V_OD_hstmt);
SQLExecDirect(V_OD_hstmt, "select c_customer_sk from customer_t1", SQL_NTS);

// 12. Obtain attributes of a specific column in the result set.
SQLColAttribute(V_OD_hstmt, 1, SQL_DESC_TYPE, typename, 100, NULL, NULL);
printf("SQLColAttribute %s\n", typename);

// 13. Bind the result set.
SQLBindCol(V_OD_hstmt, 1, SQL_C_SLONG, (SQLPOINTER)&V_OD_buffer, 150,
(SQLLEN *)&V_OD_err);

// 14. Obtain data in the result set by executing SQLFetch.
V_OD_erg=SQLFetch(V_OD_hstmt);

// 15. Obtain and return data by executing SQLGetData.
while(V_OD_erg != SQL_NO_DATA)
{
    SQLGetData(V_OD_hstmt, 1, SQL_C_SLONG, (SQLPOINTER)&V_OD_id, 0, NULL);
    printf("SQLGetData ----ID = %d\n", V_OD_id);
    V_OD_erg=SQLFetch(V_OD_hstmt);
};
printf("Done !\n");

// 16. Disconnect data source connections and release handles.
SQLFreeHandle(SQL_HANDLE_STMT, V_OD_hstmt);
SQLDisconnect(V_OD_hdbc);
SQLFreeHandle(SQL_HANDLE_DBC, V_OD_hdbc);
SQLFreeHandle(SQL_HANDLE_ENV, V_OD_Env);
return(0);
}
```

The running result is as follows:

```
Connected !
SQLColAttribute
SQLGetData ----ID = 25
SQLGetData ----ID = 100
Done!
```

5.4.3.3 Batch Binding

Prerequisite: The data source has been configured successfully. For Linux OS, see [Configuring a Data Source in the Linux OS](#). For Windows OS, see [Configuring a Data Source in the Windows OS](#).

```
/*
*****
* Enable UseBatchProtocol in the data source and set the database parameter support_batch_bind to on.
* The CHECK_ERROR command is used to check and print error information.
* This example is used to interactively obtain the DSN, data volume to be processed, and volume of ignored
data from users, and insert required data into the test_odbc_batch_insert table.
*****
*/
#ifdef WIN32
#include <windows.h>
#endif
#include <stdio.h>
```

```
#include <stdlib.h>
#include <sql.h>
#include <sqlext.h>
#include <string.h>
void Exec(SQLHDBC hdbc, SQLCHAR* sql)
{
    SQLRETURN retcode;          // Return status
    SQLHSTMT hstmt = SQL_NULL_HSTMT; // Statement handle

The running result is as follows:

Complete.

Part of database query result is as follows:

id	col
0	column test value 0
1	column test value 1
2	column test value 2
3	column test value 3
4	column test value 4
5	column test value 5
6	column test value 6
7	column test value 7
8	column test value 8
.....	

5.4.3.4 High-Performance Binding

If a large amount of data needs to be inserted, you are advised to perform the following operations:

- You need to set **UseBatchProtocol** to **1** in the **odbc.ini** file and **support_batch_bind** to **on** in the database.
- The ODBC program binding type must be the same as that in the database.
- The character set of the client is the same as that of the database.
- The transaction is committed manually.

odbc.ini configuration file:

```
[gaussdb]
Driver=GaussMPP
Servername=10.10.0.13 # Database server IP address
...
UseBatchProtocol=1 # Enabled by default
ConnSettings=set client_encoding=UTF8 # Set the character code on the client to be the same as that on the server.
```

The binding type example is as follows:

Prerequisite: The data source has been configured successfully. For Linux OS, see [Configuring a Data Source in the Linux OS](#). For Windows OS, see [Configuring a Data Source in the Windows OS](#).

```
#ifdef WIN32
#include <windows.h>

    { "1234.5678", "1234.57"},
    { "1234.5677", "1234.57"},
    { "1234.5678", "1234.57"},
    { "-1", "12345"},
    { "18446744073709551615", "12345"},
    { "-1", "12345"},
    { "4294967295", "12345"},
    { "-1", "-1"},
    { "65535", "65535"},
    { "-1", "-1"},
    { "255", "255"},
    };

RETURN_IF_NOT_SUCCESS(execute_cmd(sql_select));
while ( SQL_NO_DATA != SQLFetch(h_stmt))
{
    RETURN_IF_NOT_SUCCESS_I(i, SQLGetData(h_stmt, 1, SQL_C_CHAR, &getValue[0],
```

```
MESSAGE_BUFFER_LEN, NULL));  
    RETURN_IF_NOT_SUCCESS_I(i, SQLGetData(h_stmt, 2, SQL_C_CHAR, &getValue[1],  
MESSAGE_BUFFER_LEN, NULL));  
    i++;  
}  
printf("\nComplete!\n");  
RETURN_IF_NOT_SUCCESS(SQLRowCount(h_stmt, &RowCount));  
RETURN_IF_NOT(i, RowCount);  
SQLCloseCursor(h_stmt);  
/* Final step. Delete the table and restore the environment. */  
RETURN_IF_NOT_SUCCESS(execute_cmd(sql_drop));  
RETURN_IF_NOT_SUCCESS(commit_exec());  
end_unit_test();  
}
```

NOTE

In the preceding example, the **number** column is defined. When the SQLBindParameter API is called, the performance of binding SQL_NUMERIC is higher than that of SQL_LONG. If char is used, the data type needs to be converted when data is inserted to the database server, causing a performance bottleneck.

The running result is as follows:

```
Complete!
```

5.4.4 ODBC Interface Reference

The ODBC interface is a set of API functions provided to users. This chapter describes its common interfaces. For details on other interfaces, see "ODBC Programmer's Reference" at MSDN ([https://msdn.microsoft.com/en-us/library/windows/desktop/ms714177\(v=vs.85\).aspx](https://msdn.microsoft.com/en-us/library/windows/desktop/ms714177(v=vs.85).aspx)).

5.4.4.1 SQLAllocEnv

In ODBC 3.x, SQLAllocEnv (an ODBC 2.x function) was deprecated and replaced by SQLAllocHandle. For details, see [SQLAllocHandle](#).

5.4.4.2 SQLAllocConnect

In ODBC 3.x, SQLAllocConnect (a function in ODBC 2.x) was deprecated and replaced by SQLAllocHandle. For details, see [SQLAllocHandle](#).

5.4.4.3 SQLAllocHandle

Description

Allocates environment, connection, statement, or descriptor handles. This function replaces the deprecated ODBC 2.x functions SQLAllocEnv, SQLAllocConnect, and SQLAllocStmt.

Prototype

```
SQLRETURN SQLAllocHandle(SQLSMALLINT HandleType,  
                          SQLHANDLE InputHandle,  
                          SQLHANDLE *OutputHandlePtr);
```

Parameter

Table 5-37 SQLAllocHandle parameters

Keyword	Description
HandleType	Type of handle to be allocated by SQLAllocHandle. The value must be one of the following: • SQL_HANDLE_ENV (environment handle) • SQL_HANDLE_DBC (connection handle) • SQL_HANDLE_STMT (statement handle) • SQL_HANDLE_DESC (descriptor handle) The handle application sequence is: SQL_HANDLE_ENV > SQL_HANDLE_DBC > SQL_HANDLE_STMT . The handle applied later depends on the handle applied prior to it.
InputHandle	Existing handle to use as a context for the new handle being allocated. • If HandleType is set to SQL_HANDLE_ENV, this parameter is set to SQL_NULL_HANDLE. • If HandleType is set to SQL_HANDLE_DBC, this parameter value must be an environment handle. • If HandleType is set to SQL_HANDLE_STMT or SQL_HANDLE_DESC, this parameter value must be a connection handle.
OutputHandlePtr	Output parameter: Pointer to a buffer that stores the returned handle in the newly allocated data structure.

Return Value

- **SQL_SUCCESS** indicates that the call succeeded.
- **SQL_SUCCESS_WITH_INFO** indicates that some warning information is displayed.
- **SQL_ERROR** indicates major errors, such as memory allocation and connection failures.
- **SQL_INVALID_HANDLE** indicates that invalid handles were called. This value may also be returned by other APIs.

Precautions

If SQLAllocHandle returns **SQL_ERROR** when it is used to allocate a non-environment handle, it sets **OutputHandlePtr** to **SQL_NULL_HDBC**, **SQL_NULL_HSTMT**, or **SQL_NULL_HDESC**. The application can then call [SQLGetDiagRec](#), with **HandleType** and **Handle** set to the value of **InputHandle**, to obtain the **SQLSTATE** value. The **SQLSTATE** value provides the detailed function calling information.

Examples

For details, see [Typical Application Development Examples](#).

5.4.4.4 SQLAllocStmt

In ODBC 3.x, SQLAllocStmt (a function in ODBC 2.x) was deprecated and replaced by SQLAllocHandle. For details, see [SQLAllocHandle](#).

5.4.4.5 SQLBindCol

Description

Binds application data buffers to columns in a result set.

Prototype

```
SQLRETURN SQLBindCol(SQLHSTMT StatementHandle,  
SQLUSMALLINT ColumnNumber,  
SQLSMALLINT TargetType,  
SQLPOINTER TargetValuePtr,  
SQLLEN BufferLength,  
SQLLEN *StrLen_or_IndPtr);
```

Parameters

Table 5-38 SQLBindCol parameters

Keyword	Description
StatementHandle	Statement handle.
ColumnNumber	Number of the column to be bound. The column number starts with 0 and increases in ascending order. Column 0 is the bookmark column. If no bookmark column is set, column numbers start with 1.
TargetType	C data type in the buffer.
TargetValuePtr	Output parameter: pointer to the buffer bound with the column. The SQLFetch function returns data in the buffer. If this parameter is a null pointer, StrLen_or_IndPtr is a valid value.
BufferLength	Length of the TargetValuePtr buffer in bytes.
StrLen_or_IndPtr	Output parameter: pointer to the length or indicator of the buffer. If the value is null, no length or indicator is used.

Return Value

- **SQL_SUCCESS** indicates that the call succeeded.

- **SQL_SUCCESS_WITH_INFO** indicates that some warning information is displayed.
- **SQL_ERROR** indicates major errors, such as memory allocation and connection failures.
- **SQL_INVALID_HANDLE** indicates that invalid handles were called. This value may also be returned by other APIs.

Precautions

If SQLBindCol returns **SQL_ERROR** or **SQL_SUCCESS_WITH_INFO**, the application can call [SQLGetDiagRec](#), with **HandleType** and **Handle** set to **SQL_HANDLE_STMT** and **StatementHandle**, respectively, to obtain the **SQLSTATE** value. The **SQLSTATE** value provides the detailed function calling information.

Examples

For details, see [Typical Application Development Examples](#).

5.4.4.6 SQLBindParameter

Description

Binds parameter markers in an SQL statement to a buffer.

Prototype

```
SQLRETURN SQLBindParameter(SQLHSTMT StatementHandle,  
    SQLUSMALLINT ParameterNumber,  
    SQLSMALLINT InputOutputType,  
    SQLSMALLINT ValueType,  
    SQLSMALLINT ParameterType,  
    SQLULEN ColumnSize,  
    SQLSMALLINT DecimalDigits,  
    SQLPOINTER ParameterValuePtr,  
    SQLLEN BufferLength,  
    SQLLEN *StrLen_or_IndPtr);
```

Parameters

Table 5-39 SQLBindParameter

Keyword	Description
StatementHandle	Statement handle.
ParameterNumber	Parameter marker number, starting with 1 and increasing in ascending order.
InputOutputType	Input/output type of the parameter.
ValueType	C data type of the parameter.
ParameterType	SQL data type of the parameter.

Keyword	Description
ColumnSize	Size of the column or expression of the corresponding parameter marker.
DecimalDigits	Decimal digit of the column or the expression of the corresponding parameter marker.
ParameterValuePtr	Pointer to the storage parameter buffer.
BufferLength	Length of the ParameterValuePtr buffer in bytes.
StrLen_or_IndPtr	Pointer to the length or indicator of the buffer. If the value is null, no length or indicator is used.

Return Value

- **SQL_SUCCESS** indicates that the call succeeded.
- **SQL_SUCCESS_WITH_INFO** indicates that some warning information is displayed.
- **SQL_ERROR** indicates major errors, such as memory allocation and connection failures.
- **SQL_INVALID_HANDLE** indicates that invalid handles were called. This value may also be returned by other APIs.

Precautions

If `SQLBindParameter` returns **SQL_ERROR** or **SQL_SUCCESS_WITH_INFO**, the application can call [SQLGetDiagRec](#), with **HandleType** and **Handle** set to **SQL_HANDLE_STMT** and **StatementHandle**, respectively, to obtain the **SQLSTATE** value. The **SQLSTATE** value provides the detailed function calling information.

Examples

For details, see [Typical Application Development Examples](#).

5.4.4.7 SQLColAttribute

Description

Returns the descriptor information about a column in the result set.

Prototype

```
SQLRETURN SQLColAttribute(SQLHSTMT StatementHandle,
                           SQLUSMALLINT ColumnNumber,
                           SQLUSMALLINT FieldIdentifier,
                           SQLPOINTER CharacterAttributePtr,
                           SQLSMALLINT BufferLength,
                           SQLSMALLINT *StringLengthPtr,
                           SQLLEN *NumericAttributePtr);
```

Parameters

Table 5-40 SQLColAttribute parameters

Keyword	Description
StatementHandle	Statement handle.
ColumnNumber	Column number of the field to be queried, starting with 1 and increasing in ascending order.
FieldIdentifier	Field identifier of ColumnNumber in IRD.
CharacterAttributePtr	Output parameter: pointer to the buffer that returns the FieldIdentifier value.
BufferLength	- This parameter indicates the length of the buffer if FieldIdentifier is an ODBC-defined field and CharacterAttributePtr points to a string or a binary buffer. - Ignore this parameter if FieldIdentifier is an ODBC-defined field and CharacterAttributePtr points to an integer.
StringLengthPtr	Output parameter: pointer to a buffer in which the total number of valid bytes (for string data) is stored in *CharacterAttributePtr . Ignore the value of BufferLength if the data is not a string.
NumericAttributePtr	Output parameter: pointer to an integer buffer in which the value of FieldIdentifier in the ColumnNumber row of the IRD is returned.

Return Value

- SQL_SUCCESS** indicates that the call succeeded.
- SQL_SUCCESS_WITH_INFO** indicates that some warning information is displayed.
- SQL_ERROR** indicates major errors, such as memory allocation and connection failures.
- SQL_INVALID_HANDLE** indicates that invalid handles were called. This value may also be returned by other APIs.

Precautions

If SQLColAttribute returns **SQL_ERROR** or **SQL_SUCCESS_WITH_INFO**, the application can call [SQLGetDiagRec](#), with **HandleType** and **Handle** set to **SQL_HANDLE_STMT** and **StatementHandle**, respectively, to obtain the **SQLSTATE** value. The **SQLSTATE** value provides the detailed function calling information.

Examples

For details, see [Typical Application Development Examples](#).

5.4.4.8 SQLConnect

Description

Establishes a connection between a driver and a data source. After the connection is established, the connection handle can be used to access all information about the data source, including its application operating status, transaction processing status, and error information.

Prototype

```
SQLRETURN SQLConnect(SQLHDBC ConnectionHandle,  
    SQLCHAR *ServerName,  
    SQLSMALLINT NameLength1,  
    SQLCHAR *UserName,  
    SQLSMALLINT NameLength2,  
    SQLCHAR *Authentication,  
    SQLSMALLINT NameLength3);
```

Parameters

Table 5-41 SQLConnect parameters

Keyword	Description
ConnectionHandle	Connection handle, obtained from SQLAllocHandle.
ServerName	Name of the data source to connect.
NameLength1	Length of ServerName .
UserName	Username of the database in the data source.
NameLength2	Length of UserName .
Authentication	User password of the database in the data source.
NameLength3	Length of Authentication .

Return Value

- **SQL_SUCCESS** indicates that the call succeeded.
- **SQL_SUCCESS_WITH_INFO** indicates that some warning information is displayed.
- **SQL_ERROR** indicates major errors, such as memory allocation and connection failures.
- **SQL_INVALID_HANDLE** indicates that invalid handles were called. This value may also be returned by other APIs.

- **SQL_STILL_EXECUTING** indicates that the statement is being executed.

Precautions

If SQLConnect returns **SQL_ERROR** or **SQL_SUCCESS_WITH_INFO**, the application can call [SQLGetDiagRec](#), with **HandleType** and **Handle** set to **SQL_HANDLE_DBC** and **ConnectionHandle**, respectively, to obtain the **SQLSTATE** value. The **SQLSTATE** value provides the detailed function calling information.

Examples

For details, see [Typical Application Development Examples](#).

5.4.4.9 SQLDisconnect

Description

Closes the connection associated with a database connection handle.

Prototype

```
SQLRETURN SQLDisconnect(SQLHDBC ConnectionHandle);
```

Parameter

Table 5-42 SQLDisconnect parameters

Keyword	Description
ConnectionHandle	Connection handle, obtained from SQLAllocHandle.

Return Value

- **SQL_SUCCESS** indicates that the call succeeded.
- **SQL_SUCCESS_WITH_INFO** indicates that some warning information is displayed.
- **SQL_ERROR** indicates major errors, such as memory allocation and connection failures.
- **SQL_INVALID_HANDLE** indicates that invalid handles were called. This value may also be returned by other APIs.

Precautions

If SQLDisconnect returns **SQL_ERROR** or **SQL_SUCCESS_WITH_INFO**, the application can call [SQLGetDiagRec](#), with **HandleType** and **Handle** set to **SQL_HANDLE_DBC** and **ConnectionHandle**, respectively, to obtain the **SQLSTATE** value. The **SQLSTATE** value provides the detailed function calling information.

Examples

For details, see [Typical Application Development Examples](#).

5.4.4.10 SQLExecDirect

Description

Executes a prepared statement specified in this parameter. SQLExecDirect is the fastest method for executing only one SQL statement at a time.

Prototype

```
SQLRETURN SQLExecDirect(SQLHSTMT StatementHandle,  
                        SQLCHAR *StatementText,  
                        SQLINTEGER TextLength);
```

Parameter

Table 5-43 SQLExecDirect parameters

Keyword	Description
StatementHandle	Statement handle, obtained from SQLAllocHandle.
StatementText	SQL statement to be executed. Multiple statements cannot be executed at a time.
TextLength	Length of StatementText .

Return Value

- **SQL_SUCCESS** indicates that the call succeeded.
- **SQL_SUCCESS_WITH_INFO** indicates that some warning information is displayed.
- **SQL_NEED_DATA** indicates that parameters provided before executing the SQL statement are insufficient.
- **SQL_ERROR** indicates major errors, such as memory allocation and connection failures.
- **SQL_INVALID_HANDLE** indicates that invalid handles were called. This value may also be returned by other APIs.
- **SQL_STILL_EXECUTING** indicates that the statement is being executed.
- **SQL_NO_DATA** indicates that the SQL statement does not return a result set.

Precautions

If SQLExecDirect returns **SQL_ERROR** or **SQL_SUCCESS_WITH_INFO**, the application can call [SQLGetDiagRec](#), with **HandleType** and **Handle** set to **SQL_HANDLE_STMT** and **StatementHandle**, respectively, to obtain the

SQLSTATE value. The **SQLSTATE** value provides the detailed function calling information.

Examples

For details, see [Typical Application Development Examples](#).

5.4.4.11 SQLExecute

Description

If a statement contains a parameter marker, the SQLExecute function uses the current value of the parameter marker to execute a prepared SQL statement.

Prototype

```
SQLRETURN SQLExecute(SQLHSTMT StatementHandle);
```

Parameter

Table 5-44 SQLExecute parameter

Keyword	Description
StatementHandle	Statement handle to be executed.

Return Value

- **SQL_SUCCESS** indicates that the call succeeded.
- **SQL_SUCCESS_WITH_INFO** indicates that some warning information is displayed.
- **SQL_NEED_DATA** indicates that parameters provided before executing the SQL statement are insufficient.
- **SQL_ERROR** indicates major errors, such as memory allocation and connection failures.
- **SQL_NO_DATA** indicates that the SQL statement does not return a result set.
- **SQL_INVALID_HANDLE** indicates that invalid handles were called. This value may also be returned by other APIs.
- **SQL_STILL_EXECUTING** indicates that the statement is being executed.

Precautions

If SQLExecute returns **SQL_ERROR** or **SQL_SUCCESS_WITH_INFO**, the application can call [SQLGetDiagRec](#), with **HandleType** and **Handle** set to **SQL_HANDLE_STMT** and **StatementHandle**, respectively, to obtain the **SQLSTATE** value. The **SQLSTATE** value provides the detailed function calling information.

Examples

For details, see [Typical Application Development Examples](#).

5.4.4.12 SQLFetch

Description

Advances the cursor to the next row of the result set and retrieves any bound columns.

Prototype

```
SQLRETURN SQLFetch(SQLHSTMT StatementHandle);
```

Parameter

Table 5-45 SQLFetch parameters

Keyword	Description
StatementHandle	Statement handle, obtained from SQLAllocHandle.

Return Value

- **SQL_SUCCESS** indicates that the call succeeded.
- **SQL_SUCCESS_WITH_INFO** indicates that some warning information is displayed.
- **SQL_ERROR** indicates major errors, such as memory allocation and connection failures.
- **SQL_NO_DATA** indicates that the SQL statement does not return a result set.
- **SQL_INVALID_HANDLE** indicates that invalid handles were called. This value may also be returned by other APIs.
- **SQL_STILL_EXECUTING** indicates that the statement is being executed.

Precautions

If SQLFetch returns **SQL_ERROR** or **SQL_SUCCESS_WITH_INFO**, the application can call [SQLGetDiagRec](#), with **HandleType** and **Handle** set to **SQL_HANDLE_STMT** and **StatementHandle**, respectively, to obtain the **SQLSTATE** value. The **SQLSTATE** value provides the detailed function calling information.

Examples

For details, see [Typical Application Development Examples](#).

5.4.4.13 SQLFreeStmt

In ODBC 3.x, SQLFreeStmt (a function in ODBC 2.x) was deprecated and replaced with SQLFreeHandle. For details, see [SQLFreeHandle](#).

5.4.4.14 SQLFreeConnect

In ODBC 3.x, SQLFreeConnect (an ODBC 2.x function) was deprecated and replaced by SQLFreeHandle. For details, see [SQLFreeHandle](#).

5.4.4.15 SQLFreeHandle

Description

SQLFreeHandle is used to release resources associated with a specific environment, connection, or statement handle. It replaces the ODBC 2.x functions: SQLFreeEnv, SQLFreeConnect, and SQLFreeStmt.

Prototype

```
SQLRETURN SQLFreeHandle(SQLSMALLINT HandleType,  
                        SQLHANDLE Handle);
```

Parameter

Table 5-46 SQLFreeHandle parameters

Keyword	Description
HandleType	Type of handle to be freed by SQLFreeHandle. The value must be one of the following: • SQL_HANDLE_ENV • SQL_HANDLE_DBC • SQL_HANDLE_STMT • SQL_HANDLE_DESC If HandleType is not one of the preceding values, SQLFreeHandle returns SQL_INVALID_HANDLE .
Handle	Name of the handle to be freed.

Return Value

- **SQL_SUCCESS** indicates that the call succeeded.
- **SQL_SUCCESS_WITH_INFO** indicates that some warning information is displayed.
- **SQL_ERROR** indicates major errors, such as memory allocation and connection failures.
- **SQL_INVALID_HANDLE** indicates that invalid handles were called. This value may also be returned by other APIs.

Precautions

If SQLFreeHandle returns **SQL_ERROR**, the handle is still valid.

Examples

For details, see [Typical Application Development Examples](#).

5.4.4.16 SQLFreeEnv

In ODBC 3.x, SQLFreeEnv (an ODBC 2.x function) was deprecated and replaced by SQLFreeHandle. For details, see [SQLFreeHandle](#).

5.4.4.17 SQLPrepare

Description

Prepares an SQL statement to be executed.

Note that ODBC does not support the kernel reuse plan when sending prepared statements. As a result, a new plan needs to be generated for each execution, causing high CPU usage. If services have requirements on plan reuse, you are advised to use the JDBC client.

Prototype

```
SQLRETURN SQLPrepare(SQLHSTMT StatementHandle,  
                      SQLCHAR *StatementText,  
                      SQLINTEGER TextLength);
```

Parameter

Table 5-47 SQLPrepare parameters

Keyword	Description
StatementHandle	Statement handle.
StatementText	SQL text string.
TextLength	Length of StatementText .

Return Value

- **SQL_SUCCESS** indicates that the call succeeded.
- **SQL_SUCCESS_WITH_INFO** indicates that some warning information is displayed.
- **SQL_ERROR** indicates major errors, such as memory allocation and connection failures.
- **SQL_INVALID_HANDLE** indicates that invalid handles were called. This value may also be returned by other APIs.

- **SQL_STILL_EXECUTING** indicates that the statement is being executed.

Precautions

If SQLPrepare returns **SQL_ERROR** or **SQL_SUCCESS_WITH_INFO**, the application can call [SQLGetDiagRec](#), with **HandleType** and **Handle** set to **SQL_HANDLE_STMT** and **StatementHandle**, respectively, to obtain the **SQLSTATE** value. The **SQLSTATE** value provides the detailed function calling information.

Examples

For details, see [Typical Application Development Examples](#).

5.4.4.18 SQLGetData

Description

SQLGetData is used to retrieve data for a single column in the result set. It can be called for many times to retrieve data of variable lengths.

Prototype

```
SQLRETURN SQLGetData(SQLHSTMT StatementHandle,  
SQLUSMALLINT Col_or_Param_Num,  
SQLSMALLINT TargetType,  
SQLPOINTER TargetValuePtr,  
SQLLEN BufferLength,  
SQLLEN *StrLen_or_IndPtr);
```

Parameter

Table 5-48 SQLGetData parameters

Keyword	Description
StatementHandle	Statement handle, obtained from SQLAllocHandle.
Col_or_Param_Num	Column number for which the data retrieval is requested. The column number starts with 1 and increases in ascending order. The number of the bookmark column is 0.
TargetType	C data type in the TargetValuePtr buffer. If TargetType is SQL_ARD_TYPE , the driver uses the data type of the SQL_DESC_CONCISE_TYPE field in ARD. If it is SQL_C_DEFAULT , the driver selects a default data type according to the source SQL data type.
TargetValuePtr	Output parameter: pointer to the pointer that points to the buffer where the data is located.
BufferLength	Size of the buffer pointed to by TargetValuePtr .

Keyword	Description
StrLen_or_IndPtr	Output parameter: pointer to the buffer where the length or identifier value is returned.

Return Value

- **SQL_SUCCESS** indicates that the call succeeded.
- **SQL_SUCCESS_WITH_INFO** indicates that some warning information is displayed.
- **SQL_ERROR** indicates major errors, such as memory allocation and connection failures.
- **SQL_NO_DATA** indicates that the SQL statement does not return a result set.
- **SQL_INVALID_HANDLE** indicates that invalid handles were called. This value may also be returned by other APIs.
- **SQL_STILL_EXECUTING** indicates that the statement is being executed.

Precautions

If `SQLGetData` returns **SQL_ERROR** or **SQL_SUCCESS_WITH_INFO**, the application can call [SQLGetDiagRec](#), with **HandleType** and **Handle** set to **SQL_HANDLE_STMT** and **StatementHandle**, respectively, to obtain the **SQLSTATE** value. The **SQLSTATE** value provides the detailed function calling information.

Examples

For details, see [Typical Application Development Examples](#).

5.4.4.19 SQLGetDiagRec

Description

Returns the current values of multiple columns in a diagnostic record that contains error, warning, and status information.

Prototype

```
SQLRETURN SQLGetDiagRec(SQLSMALLINT  HandleType,  
                        SQLHANDLE      Handle,  
                        SQLSMALLINT     RecNumber,  
                        SQLCHAR         *SQLState,  
                        SQLINTEGER       *NativeErrorPtr,  
                        SQLCHAR         *MessageText,  
                        SQLSMALLINT     BufferLength  
                        SQLSMALLINT     *TextLengthPtr);
```

Parameters

Table 5-49 SQLGetDiagRec parameters

Keyword	Description
HandleType	Handle-type identifier that describes the type of handle for which diagnostics are desired. The value must be one of the following: • SQL_HANDLE_ENV • SQL_HANDLE_DBC • SQL_HANDLE_STMT • SQL_HANDLE_DESC
Handle	Handle for the diagnostic data structure. Its type is indicated by HandleType . If HandleType is set to SQL_HANDLE_ENV , Handle may indicate a shared or non-shared environment handle.
RecNumber	Status record from which the application seeks information. Status records are numbered from 1.
SQLState	Output parameter: pointer to a buffer that saves the 5-character SQLSTATE code pertaining to RecNumber .
NativeErrorPtr	Output parameter: pointer to a buffer that saves the native error code.
MessageText	Pointer to a buffer that saves text strings of diagnostic information.
BufferLength	Length of MessageText .
TextLengthPtr	Output parameter: pointer to the buffer, the total number of bytes in the returned MessageText . If the number of bytes available to return is greater than BufferLength , then the diagnostics information text in MessageText is truncated to BufferLength minus the length of the null termination character.

Return Value

- **SQL_SUCCESS** indicates that the call succeeded.
- **SQL_SUCCESS_WITH_INFO** indicates that some warning information is displayed.
- **SQL_ERROR** indicates major errors, such as memory allocation and connection failures.
- **SQL_INVALID_HANDLE** indicates that invalid handles were called. This value may also be returned by other APIs.

Precautions

SQLGetDiagRec does not release diagnostic records for itself. It uses the following return values to report execution results:

- **SQL_SUCCESS** indicates that the function successfully returns diagnostic information.
- **SQL_SUCCESS_WITH_INFO** indicates that the **MessageText** buffer is too small to hold the requested diagnostic information. No diagnostic records are generated.
- **SQL_INVALID_HANDLE** indicates that the handle indicated by **HandType** and **Handle** is an invalid handle.
- **SQL_ERROR** indicates that the value of **RecNumber** is less than or equal to 0 or the value of **BufferLength** is less than 0.

If an ODBC function returns **SQL_ERROR** or **SQL_SUCCESS_WITH_INFO**, the application can call SQLGetDiagRec to obtain the **SQLSTATE** value. The possible **SQLSTATE** values are listed as follows:

Table 5-50 SQLSTATE values

SQLSATATE	Error	Description
HY000	General error.	An error occurred for which there is no specific SQLSTATE.
HY001	Memory allocation error.	The driver is unable to allocate memory required to support execution or completion of the function.
HY008	Operation canceled.	SQLCancel is called to terminate the statement execution, but the StatementHandle function is still called.
HY010	Function sequence error.	The function is called prior to sending data to data parameters or columns being executed.
HY013	Memory management error.	The function fails to be called. The error may be caused by low memory conditions.
HYT01	Connection timeout.	The timeout period expired before the application was able to connect to the data source.
IM001	Function not supported by the driver.	The called function is not supported by the StatementHandle driver.

Examples

For details, see [Typical Application Development Examples](#).

5.4.4.20 SQLSetConnectAttr

Description

Sets connection attributes.

Prototype

```
SQLRETURN SQLSetConnectAttr(SQLHDBC ConnectionHandle,  
                             SQLINTEGER Attribute,  
                             SQLPOINTER ValuePtr,  
                             SQLINTEGER StringLength);
```

Parameters

Table 5-51 SQLSetConnectAttr parameters

Keyword	Description
ConnectionHandle	Connection handle.
Attribute	Attribute to set.
ValuePtr	Pointer to the Attribute value. ValuePtr depends on the Attribute value, and can be a 32-bit unsigned integer value or a null-terminated string. If the ValuePtr parameter is a driver-specific value, it may be a signed integer.
StringLength	If ValuePtr points to a string or a binary buffer, StringLength is the length of *ValuePtr . If ValuePtr points to an integer, StringLength is ignored.

Return Value

- **SQL_SUCCESS** indicates that the call succeeded.
- **SQL_SUCCESS_WITH_INFO** indicates that some warning information is displayed.
- **SQL_ERROR** indicates major errors, such as memory allocation and connection failures.
- **SQL_INVALID_HANDLE** indicates that invalid handles were called. This value may also be returned by other APIs.

Precautions

If SQLSetConnectAttr returns **SQL_ERROR** or **SQL_SUCCESS_WITH_INFO**, the application can call [SQLGetDiagRec](#), with **HandleType** and **Handle** set to **SQL_HANDLE_DBC** and **ConnectionHandle**, respectively, to obtain the **SQLSTATE** value. The **SQLSTATE** value provides the detailed function calling information.

Examples

For details, see [Typical Application Development Examples](#).

5.4.4.21 SQLSetEnvAttr

Description

SQLSetEnvAttr is used to set environment attributes.

Prototype

```
SQLRETURN SQLSetEnvAttr(SQLHENV EnvironmentHandle,  
                        SQLINTEGER Attribute,  
                        SQLPOINTER ValuePtr,  
                        SQLINTEGER StringLength);
```

Parameter

Table 5-52 SQLSetEnvAttr parameters

Keyword	Description
EnvironmentHandle	Environment handle.
Attribute	Environment attribute to be set. The value must be one of the following: • SQL_ATTR_ODBC_VERSION: ODBC version • SQL_CONNECTION_POOLING: connection pool attribute • SQL_OUTPUT_NTS: string type returned by the driver
ValuePtr	Pointer to the Attribute value. ValuePtr depends on the Attribute value, and can be a 32-bit integer value or a null-terminated string.
StringLength	If ValuePtr points to a string or a binary buffer, StringLength is the length of *ValuePtr . If ValuePtr points to an integer, StringLength is ignored.

Return Value

- **SQL_SUCCESS** indicates that the call succeeded.
- **SQL_SUCCESS_WITH_INFO** indicates that some warning information is displayed.
- **SQL_ERROR** indicates major errors, such as memory allocation and connection failures.
- **SQL_INVALID_HANDLE** indicates that invalid handles were called. This value may also be returned by other APIs.

Precautions

If SQLSetEnvAttr returns **SQL_ERROR** or **SQL_SUCCESS_WITH_INFO**, the application can call [SQLGetDiagRec](#), set **HandleType** and **Handle** to **SQL_HANDLE_ENV** and **EnvironmentHandle**, and obtain the **SQLSTATE** value. The **SQLSTATE** value provides the detailed function calling information.

Examples

For details, see [Typical Application Development Examples](#).

5.4.4.22 SQLSetStmtAttr

Description

Sets attributes related to a statement.

Prototype

```
SQLRETURN SQLSetStmtAttr(SQLHSTMT StatementHandle,  
                           SQLINTEGER Attribute,  
                           SQLPOINTER ValuePtr,  
                           SQLINTEGER StringLength);
```

Parameters

Table 5-53 SQLSetStmtAttr parameters

Keyword	Description
StatementHandle	Statement handle.
Attribute	Attribute to set.
ValuePtr	Pointer to the Attribute value. ValuePtr depends on the Attribute value, and can be a 32-bit unsigned integer value or a pointer to a null-terminated string, a binary buffer, or a driver-specified value. If the ValuePtr parameter is a driver-specific value, it may be a signed integer.
StringLength	If ValuePtr points to a string or a binary buffer, StringLength is the length of *ValuePtr . If ValuePtr points to an integer, StringLength is ignored.

Return Value

- **SQL_SUCCESS** indicates that the call succeeded.
- **SQL_SUCCESS_WITH_INFO** indicates that some warning information is displayed.
- **SQL_ERROR** indicates major errors, such as memory allocation and connection failures.
- **SQL_INVALID_HANDLE** indicates that invalid handles were called. This value may also be returned by other APIs.

Precautions

If SQLSetStmtAttr returns **SQL_ERROR** or **SQL_SUCCESS_WITH_INFO**, the application can call [SQLGetDiagRec](#), with **HandleType** and **Handle** set to

SQL_HANDLE_STMT and **StatementHandle**, respectively, to obtain the **SQLSTATE** value. The **SQLSTATE** value provides the detailed function calling information.

Examples

For details, see [Typical Application Development Examples](#).

5.5 Development Based on libpq

5.5.1 Development Process

[Figure 5-4](#) shows the libpq-based development process.

Figure 5-4 libpq-based development process

5.5.2 Development Procedure

5.5.2.1 Obtaining a Driver Package, a Dependency Library, and Header Files

Obtain the library and header files of libpq from **GaussDB-Kernel-Database version number-OS information-64bit-Libpq.tar.gz** in the driver package. The

required header file is stored in the **include** folder, and the **lib** folder contains the required libpq library file. Programs that use libpq must include the header file **libpq-fe.h** and must connect to the libpq library.

NOTE

In addition to **libpq-fe.h**, the **include** folder contains the header files **postgres_ext.h**, **gs_thread.h**, and **gs_threadlocal.h** by default. These three header files are the dependency files of **libpq-fe.h**.

5.5.2.2 Connecting to a Database

Connecting to a database is the first step in developing an application using libpq. In this case, you can use functions, such as **PQconnectdb** and **PQsetdbLogin**, to connect to the database server. These functions return a connection object. You need to save the connection object for subsequent database operations.

The following uses the development source program **testlibpq.c** as an example (for details about the complete example, see [Establishing a Database Connection, Executing SQL Statements, and Returning Results](#)).

```
/*
 * Note: The source program testlibpq.c provides basic and common application scenarios of libpq.
 * The PQconnectdb, PQexec, PQntuples, and PQfinish APIs provided by libpq are used to establish database
 * connections, execute SQL statements, obtain returned results, and clear resources.
 * Header file. For details about user-defined functions, see the complete example.
 */

/* The values of variables such as user and passwd must be read from environment variables or
 * configuration files. Environment variables need to be configured as required. If no environment variable is
 * used, a character string can be directly assigned. */
const char conninfo[1024];
PGconn *conn;
PGresult *res;
int nFields;
int i,j;
char *passwd = getenv("EXAMPLE_PASSWD_ENV");
char *port = getenv("EXAMPLE_PORT_ENV");
char *host = getenv("EXAMPLE_HOST_ENV");
char *username = getenv("EXAMPLE_USERNAME_ENV");
char *dbname = getenv("EXAMPLE_DBNAME_ENV");

/*
 * This value is used when the user provides the value of the conninfo character string in the command line.
 * Otherwise, the environment variables or all other connection parameters
 * use the default values.
 */
if (argc > 1)
    strcpy(conninfo, argv[1]);
else
    sprintf(conninfo,
        "dbname=%s port=%s host=%s application_name=test connect_timeout=5 sslmode=allow user=%s"
        "password=%s",
        dbname, port, host, username, passwd);

/* Connect to the database. */
conn = PQconnectdb(conninfo);

/* Check whether the backend connection has been successfully established. */
if (PQstatus(conn) != CONNECTION_OK)
{
    fprintf(stderr, "Connection to database failed: %s",
        PQerrorMessage(conn));
    exit_nicely(conn);
}
```

5.5.2.3 Executing SQL Statements

You can use the function **PQexec** to execute SQL query statements through the connection object. This includes querying data (SELECT), inserting data, updating data, and deleting data. If multiple SQL statements are executed concurrently as a transaction, use the transaction control function. For example, run SQL statements such as BEGIN, COMMIT, and ROLLBACK to control the start, committing, and rollback of a transaction. Handle the errors after executing the SQL query statements.

The following is an example (for details about the complete example, see [Establishing a Database Connection, Executing SQL Statements, and Returning Results](#)).

```
/*
 * After the connection is successful
 * Since a cursor is used in the test case, a transaction block is required.
 * Put all data in one "select * from pg_database".
 * PQexec() is too simple and is not recommended.
 */

/* Start a transaction block. */
res = PQexec(conn, "BEGIN");
if (PQresultStatus(res) != PGRES_COMMAND_OK)
{
    fprintf(stderr, "BEGIN command failed: %s", PQerrorMessage(conn));
    PQclear(res);
    exit_nicely(conn);
}

/*
 * PQclear PGresult should be executed when it is no longer needed, to avoid memory leakage.
 */
PQclear(res);

/*
 * Fetch data from the pg_database system catalog.
 */
res = PQexec(conn, "DECLARE myportal CURSOR FOR select * from pg_database");
if (PQresultStatus(res) != PGRES_COMMAND_OK)
{
    fprintf(stderr, "DECLARE CURSOR failed: %s", PQerrorMessage(conn));
    PQclear(res);
    exit_nicely(conn);
}
PQclear(res);

res = PQexec(conn, "FETCH ALL in myportal");
if (PQresultStatus(res) != PGRES_TUPLES_OK)
{
    fprintf(stderr, "FETCH ALL failed: %s", PQerrorMessage(conn));
    PQclear(res);
    exit_nicely(conn);
}
```

5.5.2.4 Processing Data in a Result Set

libpq provides functions, such as **PQntuples**, **PQnfields**, and **PQfname**, to help you properly parse and process the results of SELECT queries.

The following is an example (for details about the complete example, see [Establishing a Database Connection, Executing SQL Statements, and Returning Results](#)).

```
/* First, print out the attribute name. */
nFields = PQnfields(res);
for (i = 0; i < nFields; i++)
    printf("%-15s", PQfname(res, i));
printf("\n\n");

/* Print lines. */
for (i = 0; i < PQntuples(res); i++)
{
    for (j = 0; j < nFields; j++)
        printf("%-15s", PQgetvalue(res, i, j));
    printf("\n");
}

/* Release the memory of the result object to avoid memory leakage. */
PQclear(res);
```

5.5.2.5 Closing a Connection

libpq usually uses the function **PQfinish** to close the connection to the database. If your application has established multiple connections, make sure that each connection is closed correctly.

The following is an example (for details about the complete example, see [Establishing a Database Connection, Executing SQL Statements, and Returning Results](#)).

```
/* Close the portal. We do not need to check for errors. */
res = PQexec(conn, "CLOSE myportal");
PQclear(res);

/* End the transaction. */
res = PQexec(conn, "END");
PQclear(res);

/* Close the database connection and clean up the database. */
PQfinish(conn);
```

5.5.3 Typical Application Development Examples

5.5.3.1 Establishing a Database Connection, Executing SQL Statements, and Returning Results

NOTE

To compile the libpq source program by running **gcc**, use the **-I** *directory* option to provide the installation location of header files. (Sometimes the compiler looks for the default directory, so this option can be ignored.) Example:

```
gcc -I (Directory where header files are located) -L (Directory where the libpq library is located) -o
testlibpq testlibpq.c -lpq
```

Run the following command:

```
./testlibpq.c
```

If a makefile is used, add the following options to variables **CPPFLAGS**, **LDFLAGS**, and **LIBS**:

```
CPPFLAGS += -I (Directory of header files)
```

```
LDFLAGS += -L (Directory of the libpq library)
```

```
LIBS += -lpq
```

Example:

```
CPPFLAGS += -I$(GAUSSHOME)/include/libpq
```

```
LDFLAGS += -L$(GAUSSHOME)/lib
```

```
/*
 * testlibpq.c
```

```
* Note: testlibpq.c source program provides basic and common application scenarios of libpq.
* The PQconnectdb, PQexec, PQntuples, and PQfinish APIs provided by libpq are used to establish database
connections, execute SQL statements, obtain returned results, and clear resources.
*/
#include <stdio.h>
#include <stdlib.h>
#include <libpq-fe.h>
#include <string.h>

static void
exit_nicely(PGconn *conn)
{
    PQfinish(conn);
    exit(1);
}

int main(int argc, char **argv)
{
    /* The values of variables such as user and passwd must be read from environment variables or
configuration files. Environment variables need to be configured as required. If no environment variable is
used, a character string can be directly assigned. */
    const char conninfo[1024];
    PGconn *conn;
    PGresult *res;
    int nFields;
    int i,j;
    char *passwd = getenv("EXAMPLE_PASSWD_ENV");
    char *port = getenv("EXAMPLE_PORT_ENV");
    char *host = getenv("EXAMPLE_HOST_ENV");
    char *username = getenv("EXAMPLE_USERNAME_ENV");
    char *dbname = getenv("EXAMPLE_DBNAME_ENV");

    /*
    * This value is used when the user provides the value of the conninfo character string in the command
line.
    * Otherwise, the environment variables or the default values
    * are used for all other connection parameters.
    */
    if (argc > 1)
        strcpy(conninfo, argv[1]);
    else
        sprintf(conninfo,
            "dbname=%s port=%s host=%s application_name=test connect_timeout=5 sslmode=allow user=%s
password=%s",
            dbname, port, host, username, passwd);

    /* Connect to the database. */
    conn = PQconnectdb(conninfo);

    /* Check whether the backend connection has been successfully established. */
    if (PQstatus(conn) != CONNECTION_OK)
    {
        fprintf(stderr, "Connection to database failed: %s",
            PQerrorMessage(conn));
        exit_nicely(conn);
    }

    /*
    * After the connection is successful
    * Since a cursor is used in the test case, a transaction block is required.
    * Put all data in one "select * from pg_database".
    * PQexec() is too simple and is not recommended.
    */

    /* Start a transaction block. */
    res = PQexec(conn, "BEGIN");
    if (PQresultStatus(res) != PGRES_COMMAND_OK)
    {
        fprintf(stderr, "BEGIN command failed: %s", PQerrorMessage(conn));
```

```
PQclear(res);
exit_nicely(conn);
}

/*
 * PQclear PGresult should be executed when it is no longer needed, to avoid memory leakage.
 */
PQclear(res);

/*
 * Fetch data from the pg_database system catalog.
 */
res = PQexec(conn, "DECLARE myportal CURSOR FOR select * from pg_database");
if (PQresultStatus(res) != PGRES_COMMAND_OK)
{
    fprintf(stderr, "DECLARE CURSOR failed: %s", PQerrorMessage(conn));
    PQclear(res);
    exit_nicely(conn);
}
PQclear(res);

res = PQexec(conn, "FETCH ALL in myportal");
if (PQresultStatus(res) != PGRES_TUPLES_OK)
{
    fprintf(stderr, "FETCH ALL failed: %s", PQerrorMessage(conn));
    PQclear(res);
    exit_nicely(conn);
}

/* First, print out the attribute name. */
nFields = PQnfields(res);
for (i = 0; i < nFields; i++)
    printf("%-15s", PQfname(res, i));
printf("\n\n");

/* Print lines. */
for (i = 0; i < PQntuples(res); i++)
{
    for (j = 0; j < nFields; j++)
        printf("%-15s", PQgetvalue(res, i, j));
    printf("\n");
}

/* Release the memory of the result object to avoid memory leakage. */
PQclear(res);

/* Close the portal. We do not need to check for errors. */
res = PQexec(conn, "CLOSE myportal");
PQclear(res);

/* End the transaction. */
res = PQexec(conn, "END");
PQclear(res);

/* Close the database connection and clean up the database. */
PQfinish(conn);

return 0;
}
```

In the following command output, **user_name** indicates the username of a database administrator, which varies according to the actual environment:

5.5.3.2 Executing Prepared Statements

```

/*
 * testlibpq2.c Test PQprepare
 * PQprepare creates a prepared statement with specified parameters for PQexecPrepared to execute the
 * prepared statement.
 */
#include <stdio.h>
#include <stdlib.h>
#include <libpq-fe.h>
#include <string.h>
int main(int argc, char * argv[])
{
    /* The values of variables such as user and passwd must be read from environment variables or
    configuration files. Environment variables need to be configured as required. If no environment variable is
    used, a character string can be directly assigned. */
    PGconn *conn;
    PGresult * res;
    ConnStatusType pgstatus;
    char connstr[1024];
    char cmd_sql[2048];
    int nParams = 0;
    int paramLengths[5];
    int paramFormats[5];
    Oid paramTypes[5];
    char * paramValues[5];
    int i, cnt;
    char cid[32];
    int k;
    char *passwd = getenv("EXAMPLE_PASSWD_ENV");
    char *port = getenv("EXAMPLE_PORT_ENV");
    char *hostaddr = getenv("EXAMPLE_HOST_ENV");
    char *username = getenv("EXAMPLE_USERNAME_ENV");
    char *dbname = getenv("EXAMPLE_DBNAME_ENV");

    /* Use PQconnectdb to connect to the database. connstr indicates the detailed connection information.*/
    sprintf(connstr,
            "hostaddr=%s dbname=%s port=%s user=%s password=%s",
            hostaddr, dbname, port, username, passwd);
    conn = PQconnectdb(connstr);
    pgstatus = PQstatus(conn);
    if (pgstatus == CONNECTION_OK)
    {
        printf("Connect database success!\n");
    }
    else
    {
        printf("Connect database fail:%s\n",PQerrorMessage(conn));
        return -1;
    }

    /* Create table t01. */
    res = PQexec(conn, "DROP TABLE IF EXISTS t01;CREATE TABLE t01(a int, b int);INSERT INTO t01
    values(1, 23);");
    if (PQresultStatus(res) != PGRES_COMMAND_OK)

```

```
{
    printf("Command failed: %s.\n", PQerrorMessage(conn));
    PQfinish(conn);
    return -1;
}

/* cmd_sql query */
sprintf(cmd_sql, "SELECT b FROM t01 WHERE a = $1");
/*Parameter corresponding to $1 in cmd_sql*/
paramTypes[0] = 23;
/* PQprepare creates a prepared statement with given parameters. */
res = PQprepare(conn,
                "pre_name",
                cmd_sql,
                1,
                paramTypes);
if( PQresultStatus(res) != PGRES_COMMAND_OK )
{
    printf("Failed to prepare SQL : %s\n: %s\n",cmd_sql, PQerrorMessage(conn));
    PQfinish(conn);
    return -1;
}
PQclear(res);
paramValues[0] = cid;
for (k=0; k<2; k++)
{
    sprintf(cid, "%d", 1);
    paramLengths[0] = 6;
    paramFormats[0] = 0;
    /*Execute the prepared statement.*/
    res = PQexecPrepared(conn,
                        "pre_name",
                        1,
                        paramValues,
                        paramLengths,
                        paramFormats,
                        0);

    if( (PQresultStatus(res) != PGRES_COMMAND_OK ) && (PQresultStatus(res) != PGRES_TUPLES_OK))
    {
        printf("%s\n",PQerrorMessage(conn));
        PQclear(res);
        PQfinish(conn);
        return -1;
    }
    cnt = PQntuples(res);
    printf("return %d rows\n", cnt);
    for (i=0; i<cnt; i++)
    {
        printf("row %d: %s\n", i, PQgetvalue(res, i, 0));
    }
    PQclear(res);
}
/* The execution is complete. Close the connection. */
PQfinish(conn);
return 0;
}
```

The command output is as follows:

```
Connect database success!
NOTICE: table "t01" does not exist, skipping
return 1 rows
row 0: 23
return 1 rows
row 0: 23
```

5.5.3.3 Binding Parameters and Returning a Binary Result

```
/*
 * testlibpq3.c
```

```
* Test PQexecParams.
* PQexecParams executes a command with parameters and requests the query result in binary format.
* Before running this example, run the following command to populate a database:
*
*
* CREATE TABLE test1 (i int4, t text);
*
* INSERT INTO test1 values (2, 'ho there');
*
* The expected output is as follows:
*
*
* tuple 0: got
* i = (4 bytes) 2
* t = (8 bytes) 'ho there'
*
*/
#include <stdio.h>
#include <stdlib.h>
#include <string.h>
#include <sys/types.h>
#include <libpq-fe.h>

/* for ntohl/htonl */
#include <netinet/in.h>
#include <arpa/inet.h>

static void
exit_nicely(PGconn *conn)
{
    PQfinish(conn);
    exit(1);
}

/*
* This function is used to print out the query results. The results are in binary format
* and fetched from the table created in the comment above.
*/
static void
show_binary_results(PGresult *res)
{
    int    i;
    int    i_fnum,
           t_fnum;

    /* Use PQfnumber to avoid assumptions about field order in the result. */
    i_fnum = PQfnumber(res, "i");
    t_fnum = PQfnumber(res, "t");

    for (i = 0; i < PQntuples(res); i++)
    {
        char    *iptr;
        char    *tptr;
        int      ival;

        /* Obtain the field value. (Ignore the possibility that they may be null.) */
        iptr = PQgetvalue(res, i, i_fnum);
        tptr = PQgetvalue(res, i, t_fnum);

        /*
        * The binary representation of INT4 is the network byte order,
        * which is better to be replaced with the local byte order.
        */
        ival = ntohl(*(uint32_t *) iptr);

        /*
        * The binary representation of TEXT is text. Since libpq can append a zero byte to it,
        * and think of it as a C string.
        */
    }
}
```

```
    */
    printf("tuple %d: got\n", i);
    printf(" i = (%d bytes) %d\n",
        PQgetlength(res, i, i_fnum), ival);
    printf(" t = (%d bytes) '%s'\n",
        PQgetlength(res, i, t_fnum), tptr);
    printf("\n\n");
}
}

int
main(int argc, char **argv)

    else
        sprintf(conninfo,
            "dbname=%s port=%s host=%s application_name=test connect_timeout=5 sslmode=allow user=%s",
            dbname, port, hostaddr, username, passwd);

    /* Connect to the database. */
    conn = PQconnectdb(conninfo);

    /* Check whether the connection to the server was successfully established. */
    if (PQstatus(conn) != CONNECTION_OK)
    {
        fprintf(stderr, "Connection to database failed: %s",
            PQerrorMessage(conn));
        exit_nicely(conn);
    }

    res = PQexec(conn, "drop table if exists test1;CREATE TABLE test1 (i int4, t text);");
    if (PQresultStatus(res) != PGRES_COMMAND_OK)
    {
        fprintf(stderr, "command failed: %s", PQerrorMessage(conn));
        PQclear(res);
        exit_nicely(conn);
    }

    PQclear(res);

    res = PQexec(conn, "INSERT INTO test1 values (2, 'ho there');");
    if (PQresultStatus(res) != PGRES_COMMAND_OK)
    {
        fprintf(stderr, "command failed: %s", PQerrorMessage(conn));
        PQclear(res);
    }
}
```

```
    exit_nicely(conn);
}

PQclear(res);

/* Convert the integer value "2" to the network byte order. */
binaryIntVal = htonl((uint32_t) 2);

/* Set the parameter array for PQexecParams. */
paramValues[0] = (char *) &binaryIntVal;
paramLengths[0] = sizeof(binaryIntVal);
paramFormats[0] = 1; /* Binary */

/* PQexecParams executes a command with parameters. */
res = PQexecParams(conn,
    "SELECT * FROM test1 WHERE i = $1::int4",
    1, /* One parameter */
    NULL, /* Enable the backend to deduce the parameter type. */
    paramValues,
    paramLengths,
    paramFormats,
    1); /* Binary result is required. */

if (PQresultStatus(res) != PGRES_TUPLES_OK)
{
    fprintf(stderr, "SELECT failed: %s", PQerrorMessage(conn));
    PQclear(res);
    exit_nicely(conn);
}
/* Output the binary result.*/
show_binary_results(res);

PQclear(res);

/* Close the database connection and clean up the database. */
PQfinish(conn);

return 0;
}
```

The command output is as follows:

```
tuple 0: got
i = (4 bytes) 2
t = (8 bytes) 'ho there'
```

5.5.4 libpq API Reference

5.5.4.1 Database Connection Control Functions

Database connection control functions control the connections to database servers. An application can connect to multiple servers at a time. For example, a client connects to multiple databases. Each connection is represented by a `PGconn` object, which is obtained from the function `PQconnectdb`, `PQconnectdbParams`, or `PQsetdbLogin`. Note that these functions will always return a non-null object pointer, unless memory allocation fails. In that case, a null pointer will be returned. The interface for establishing a connection is stored in the `PGconn` object. The `PQstatus` function can be called to check the return value for a successful connection.

5.5.4.1.1 PQconnectdbParams

Description

Establishes a new connection with the database server.

Prototype

```
PGconn *PQconnectdbParams(const char * const *keywords,  
                           const char * const *values,  
                           int expand_dbname);
```

Parameter

Table 5-54 PQconnectdbParams parameters

Keyword	Description
keywords	An array of strings, each of which is a keyword.
values	Value assigned to each keyword.
expand_dbname	When expand_dbname is non-zero, the dbname keyword value can be recognized as a connection string. Only dbname that first appears is expanded in this way, and any subsequent dbname value is treated as a database name.

Return Value

PGconn * points to the object pointer that contains a connection. The memory is applied for by the function internally.

Precautions

This function establishes a new database connection using the parameters taken from two NULL-terminated arrays. Unlike PQsetdbLogin, the parameter set can be extended without changing the function signature. Therefore, use of this function (or its non-blocking analogs PQconnectStartParams and PQconnectPoll) is preferred for new application programming.

5.5.4.1.2 PQconnectdb

Description

Establishes a new connection with the database server.

Prototype

```
PGconn *PQconnectdb(const char *conninfo);
```

Parameter

Table 5-55 PQconnectdb parameter

Keyword	Description
conninfo	Connection string. For details about the fields in the string, see Connection Parameters .

Return Value

PGconn * points to the object pointer that contains a connection. The memory is applied for by the function internally.

Precautions

- This function opens a new connection with the parameters specified by **conninfo**.
- The input parameter can be empty, indicating that all default parameters can be used. It can also contain one or more parameters separated by spaces or it can contain a URL.

Example

For details, see [Typical Application Development Examples](#).

5.5.4.1.3 PQconninfoParse

Function

PQconninfoParse is used to return parsed connection options based on the connection.

Prototype

```
PQconninfoOption* PQconninfoParse(const char* conninfo, char** errmsg);
```

Parameters

Table 5-56

Keyword	Parameter Description
conninfo	Passed string. This parameter can be left empty. In this case, the default value is used. It can contain one or more values separated by spaces or contain a URL.
errmsg	Error information.

Return Value

PQconninfoOption pointers

5.5.4.1.4 PQconnectStart

Description

Establishes a non-blocking connection with the database server.

Prototype

```
PGconn* PQconnectStart(const char* conninfo);
```

Parameters

Table 5-57

Keyword	Description
conninfo	String of connection information. This parameter can be left empty. In this case, the default value is used. It can contain one or more values separated by spaces or contain a URI.

Return Value

PGconn pointers

5.5.4.1.5 PQerrorMessage

Function

PQerrorMessage is used to return error information on a connection.

Prototype

```
char* PQerrorMessage(const PGconn* conn);
```

Parameter

Table 5-58

Keyword	Parameter Description
conn	Connection handle.

Return Value

char pointers

Example

For details, see [Typical Application Development Examples](#).

5.5.4.1.6 PQsetdbLogin

Description

Establishes a new connection with the database server.

Prototype

```
PGconn *PQsetdbLogin(const char *pghost,  
                    const char *pgport,  
                    const char *pgoptions,  
                    const char *pgtty,  
                    const char *dbName,  
                    const char *login,  
                    const char *pwd);
```

Parameters

Table 5-59 PQsetdbLogin parameters

Keyword	Description
pghost	Name of the host to be connected. For details, see the host field described in Connection Parameters .
pgport	Port number of the host server. For details, see the port field described in Connection Parameters .
pgoptions	Command-line options to be sent to the server during running. For details, see the options field described in Connection Parameters .
pgtty	Ignored. (This option declares the output direction of server logs.)
dbName	Name of the database to be connected. For details, see the dbname field described in Connection Parameters .
login	Username for connection. For details, see the user field described in Connection Parameters .
pwd	Password used for authentication during connection. For details, see the password field described in Connection Parameters .

Return Value

PGconn * points to the object pointer that contains a connection. The memory is applied for by the function internally.

Precautions

- This function is the predecessor of PQconnectdb with a fixed set of parameters. When an undefined parameter is called, its default value is used. Write NULL or an empty string for any one of the fixed parameters that is to be defaulted.
- If the **dbName** value contains an equal sign (=) or a valid prefix in the connection URL, it is taken as a conninfo string and passed to PQconnectdb, and the remaining parameters are consistent with PQconnectdbParams parameters.

Example

For details, see [Typical Application Development Examples](#).

5.5.4.1.7 PQfinish

Function

Closes the connection to the server and releases the memory used by the PGconn object.

Prototype

```
void PQfinish(PGconn *conn);
```

Parameter

Table 5-60 PQfinish parameter

Keyword	Parameter Description
conn	Points to the object pointer that contains the connection information.

Precautions

If the server connection attempt fails (as indicated by PQstatus), the application should call PQfinish to release the memory used by the PGconn object. The PGconn pointer must not be used again after PQfinish has been called.

Example

For details, see [Typical Application Development Examples](#).

5.5.4.1.8 PQreset

Description

Resets the communication port to the server.

Prototype

```
void PQreset(PGconn *conn);
```

Parameter

Table 5-61 PQreset parameter

Keyword	Description
conn	Points to the object pointer that contains the connection information.

Precautions

This function will close the connection to the server and attempt to establish a new connection to the same server by using all the parameters previously used. This function is applicable to fault recovery after a connection exception occurs.

5.5.4.1.9 PQstatus

Description

Returns the connection status.

Prototype

```
ConnStatusType PQstatus(const PGconn *conn);
```

Parameter

Table 5-62 PQ status parameter

Keyword	Description
conn	Points to the object pointer that contains the connection information.

Return Value

ConnStatusType indicates the connection status. The enumerated values are as follows:

```
CONNECTION_STARTED  
Waiting for the connection to be established.  
  
CONNECTION_MADE  
Connection succeeded; waiting to send  
  
CONNECTION_AWAITING_RESPONSE  
Waiting for a response from the server.  
  
CONNECTION_AUTH_OK
```

Authentication received; waiting for backend startup to complete.

CONNECTION_SSL_STARTUP
Negotiating SSL encryption.

CONNECTION_SETENV
Negotiating environment-driven parameter settings.

CONNECTION_OK
Normal connection.

CONNECTION_BAD
Failed connection.

Precautions

The connection status can be one of the preceding values. After the asynchronous connection procedure is complete, only two of them, **CONNECTION_OK** and **CONNECTION_BAD**, can return. **CONNECTION_OK** indicates that the connection to the database is normal. **CONNECTION_BAD** indicates that the connection attempt fails. Generally, the normal state remains until PQfinish is called. However, a communication failure may cause the connection status to become to **CONNECTION_BAD** before the connection procedure is complete. In this case, the application can attempt to call PQreset to restore the communication.

Example

For details, see [Typical Application Development Examples](#).

5.5.4.2 Database Statement Execution Functions

After the connection to the database server is successfully established, you can use the functions described in this section to execute SQL queries and commands.

5.5.4.2.1 PQclear

Function

PQclear is used to release the storage associated with PGresult. Any query result should be released by PQclear when it is no longer needed.

Prototype

```
void PQclear(PGresult *res);
```

Parameters

Table 5-63 PQclear parameter

Keyword	Parameter Description
res	Object pointer that contains the query result.

Precautions

PGresult is not automatically released. That is, it does not disappear when a new query is submitted or even if you close the connection. To delete it, you must call PQclear. Otherwise, memory leakage occurs.

Example

For details, see [Typical Application Development Examples](#).

5.5.4.2.2 PQexec

Description

Commits a command to the server and waits for the result.

Prototype

```
PGresult *PQexec(PGconn *conn, const char *command);
```

Parameter

Table 5-64 PQexec parameters

Keyword	Description
conn	Points to the object pointer that contains the connection information.
command	Query string to be executed.

Return Value

PGresult indicates the object pointer that contains the query result.

Precautions

The PQresultStatus function should be called to check the return value for any errors (including the value of a null pointer, in which **PGRES_FATAL_ERROR** will be returned). The PQerrorMessage function can be called to obtain more information about such errors.

NOTICE

The command string can contain multiple SQL commands separated by semicolons (;). Multiple queries sent in a PQexec call are processed in one transaction, unless there are specific BEGIN/COMMIT commands in the query string to divide the string into multiple transactions. Note that the returned PGresult structure describes only the result of the last command executed from the string. If a command fails, the string processing stops and the returned PGresult describes the error condition.

Example

For details, see [Typical Application Development Examples](#).

5.5.4.2.3 PQexecParams

Description

Runs a command to bind parameters.

Prototype

```
PGresult* PQexecParams(PGconn* conn,
    const char* command,
    int nParams,
    const Oid* paramTypes,
    const char* const* paramValues,
    const int* paramLengths,
    const int* paramFormats,
    int resultFormat);
```

Parameter

Table 5-65 PQexecParams parameters

Keyword	Description
conn	Connection handle.
command	SQL text string.
nParams	Number of parameters to be bound.
paramTypes	Types of parameters to be bound.
paramValues	Values of parameters to be bound.
paramLengths	Parameter lengths.
paramFormats	Parameter formats (text or binary).
resultFormat	Result format (text or binary).

Return Value

PGresult pointers

5.5.4.2.4 PQexecParamsBatch

Description

Runs a command to bind batches of parameters.

Prototype

```
PGresult* PQexecParamsBatch(PGconn* conn,
    const char* command,
```

```
int nParams,  
int nBatch,  
const Oid* paramTypes,  
const char* const* paramValues,  
const int* paramLengths,  
const int* paramFormats,  
int resultFormat);
```

Parameters

Table 5-66 PQexecParamsBatch parameters

Keyword	Description
conn	Connection handle.
command	SQL text string.
nParams	Number of parameters to be bound.
nBatch	Number of batch operations.
paramTypes	Types of parameters to be bound.
paramValues	Values of parameters to be bound.
paramLengths	Parameter lengths.
paramFormats	Parameter formats (text or binary).
resultFormat	Result format (text or binary).

Return Value

PGresult pointers.

5.5.4.2.5 PQexecPrepared

Function

PQexecPrepared is used to send a request to execute a prepared statement with given parameters and wait for the result.

Prototype

```
PGresult* PQexecPrepared(PGconn* conn,  
const char* stmtName,  
int nParams,  
const char* const* paramValues,  
const int* paramLengths,  
const int* paramFormats,  
int resultFormat);
```

Parameter

Table 5-67 PQexecPrepared parameters

Keyword	Parameter Description
conn	Connection handle.
stmtName	<i>stmt</i> name, which can be set to "" or NULL to reference an unnamed statement. Otherwise, it must be the name of an existing prepared statement.
nParams	Parameter quantity.
paramValues	Actual values of parameters.
paramLengths	Actual data lengths of parameters.
paramFormats	Parameter formats (text or binary).
resultFormat	Return result format (text or binary).

Return Value

PGresult pointers

5.5.4.2.6 PQexecPreparedBatch

Description

Sends a request to execute a prepared statement with batches of given parameters and waits for the result.

Prototype

```
PGresult* PQexecPreparedBatch(PGconn* conn,  
                              const char* stmtName,  
                              int nParams,  
                              int nBatchCount,  
                              const char* const* paramValues,  
                              const int* paramLengths,  
                              const int* paramFormats,  
                              int resultFormat);
```

Parameter

Table 5-68 PQexecPreparedBatch parameters

Keyword	Description
conn	Connection handle.
stmtName	<i>stmt</i> name, which can be set to "" or NULL to reference an unnamed statement. Otherwise, it must be the name of an existing prepared statement.

Keyword	Description
nParams	Parameter quantity.
nBatchCount	Number of batches.
paramValues	Actual values of parameters.
paramLengths	Actual data lengths of parameters.
paramFormats	Parameter formats (text or binary).
resultFormat	Return result format (text or binary).

Return Value

PGresult pointers

5.5.4.2.7 PQprepare

Description

Commits a request to create a prepared statement with given parameters and waits for completion.

Prototype

```
PGresult *PQprepare(PGconn *conn,  
    const char *stmtName,  
    const char *query,  
    int nParams,  
    const Oid *paramTypes);
```

Parameters

Table 5-69 PQprepare parameters

Keyword	Description
conn	Points to the object pointer that contains the connection information.
stmtName	Name of stmt to be executed.
query	Query string to be executed.
nParams	Parameter quantity.
paramTypes	Array of the parameter type.

Return Value

PGresult indicates the object pointer that contains the query result.

Precautions

- PQprepare creates a prepared statement for later execution with PQexecPrepared. This function allows commands to be repeatedly executed, without being parsed and planned each time they are executed. PQprepare is supported only in protocol 3.0 or later. It will fail when protocol 2.0 is used.
- This function creates a prepared statement named **stmtName** from the query string, which must contain an SQL command. **stmtName** can be "" to create an unnamed statement. In this case, any pre-existing unnamed statement will be automatically replaced. Otherwise, this is an error if the statement name has been defined in the current session. If any parameters are used, they are referred to in the query as \$1, \$2, and so on. **nParams** is the number of parameters for which types are pre-specified in the array paramTypes[]. (The array pointer can be **NULL** when **nParams** is 0.) paramTypes[] specifies the data types to be assigned to the parameter symbols by OID. If **paramTypes** is **NULL**, or any element in the array is 0, the server assigns a data type to the parameter symbol in the same way as it does for an untyped literal string. In addition, the query can use parameter symbols whose numbers are greater than **nParams**. Data types of these symbols will also be inferred.

NOTICE

You can also execute the **SQLPREPARE** statement to create a prepared statement that is used with PQexecPrepared. Although there is no libpq function of deleting a prepared statement, the **SQL DEALLOCATE** statement can be used for this purpose.

Examples

For details, see [Typical Application Development Examples](#).

5.5.4.3 Asynchronous Command Processing Functions

The PQexec function is adequate for committing commands in common, synchronous applications. However, it has several defects, which may be important to some users:

- PQexec waits for the end of the command, but the application may have other work to do (for example, maintaining a user interface). In this case, PQexec would not want to be blocked to wait for the response.
- As the client application is suspended while waiting for the result, it is difficult for the application to determine whether to cancel the ongoing command.
- PQexec can return only one PGresult structure. If the committed command string contains multiple SQL commands, all the PGresult structures except the last PGresult are discarded by PQexec.
- PQexec always collects the entire result of the command and caches it in a PGresult. Although this mode simplifies the error handling logic for applications, it is impractical for results that contain multiple rows.

Applications that do not want to be restricted by these limitations can use the following functions that PQexec is built from: PQsendQuery and PQgetResult. The

functions PQsendQueryParams, PQsendPrepare, and PQsendQueryPrepared can also be used with PQgetResult.

5.5.4.3.1 PQsendQuery

Description

Commits a command to the server without waiting for the result. If the query is successful, **1** is returned. Otherwise, **0** is returned.

Prototype

```
int PQsendQuery(PGconn *conn, const char *command);
```

Parameter

Table 5-70 PQsendQuery parameters

Keyword	Description
conn	Points to the object pointer that contains the connection information.
command	Query string to be executed.

Return Value

int indicates the execution result. **1** indicates successful execution and **0** indicates an execution failure. The failure cause is stored in **conn->errorMessage**.

Precautions

After PQsendQuery is successfully called, call PQgetResult one or more times to obtain the results. PQsendQuery cannot be called again (on the same connection) until PQgetResult returns a null pointer, indicating that the command execution is complete.

5.5.4.3.2 PQsendQueryParams

Description

Sends a command with separated parameters to the server without waiting for the result.

Prototype

```
int PQsendQueryParams(PGconn *conn,  
                      const char *command,  
                      int nParams,  
                      const Oid *paramTypes,  
                      const char * const *paramValues,  
                      const int *paramLengths,  
                      const int *paramFormats,  
                      int resultFormat);
```

Parameter

Table 5-71 PQsendQueryParams parameters

Keyword	Description
conn	Points to the object pointer that contains the connection information.
command	Query string to be executed.
nParams	Parameter quantity.
paramTypes	Parameter type.
paramValues	Parameter value.
paramLengths	Parameter length.
paramFormats	Parameter format.
resultFormat	Result format.

Return Value

int indicates the execution result. **1** indicates successful execution and **0** indicates an execution failure. The failure cause is stored in **conn->errorMessage**.

Precautions

This function is equivalent to PQsendQuery. The only difference is that query parameters can be specified separately from the query string. The parameter processing of this function is similar to that of PQexecParams. It cannot work on connections using protocol v2.0, and it allows only one command to appear in the query string.

5.5.4.3 PQsendPrepare

Description

PQsendPrepare is used to send a request to create a prepared statement with given parameters, without waiting for completion.

Prototype

```
int PQsendPrepare(PGconn *conn,  
                 const char *stmtName,  
                 const char *query,  
                 int nParams,  
                 const Oid *paramTypes);
```

Parameters

Table 5-72 PQsendPrepare parameters

Keyword	Description
conn	Points to the object pointer that contains the connection information.
stmtName	Name of prepare to be executed.
query	Query string to be executed.
nParams	Parameter quantity.
paramTypes	Array of the parameter type.

Return Value

int indicates the execution result. **1** indicates successful execution and **0** indicates an execution failure. The failure cause is stored in **conn->errorMessage**.

Precautions

PQsendPrepare is an asynchronous version of PQprepare. If it can dispatch a request, **1** is returned. Otherwise, **0** is returned. After a successful calling, call PQgetResult to check whether the server successfully created the prepared statement. PQsendPrepare parameters are handled in the same way as PQprepare parameters. Like PQprepare, it cannot work on connections using protocol v2.0.

5.5.4.3.4 PQsendQueryPrepared

Description

Sends a request to execute a prepared statement with given parameters, without waiting for the result.

Prototype

```
int PQsendQueryPrepared(PGconn *conn,  
                        const char *stmtName,  
                        int nParams,  
                        const char * const *paramValues,  
                        const int *paramLengths,  
                        const int *paramFormats,  
                        int resultFormat);
```

Parameters

Table 5-73 PQsendQueryPrepared parameters

Keyword	Description
conn	Points to the object pointer that contains the connection information.
stmtName	Name of prepare to be executed.
nParams	Parameter quantity.
paramValues	Parameter value.
paramLengths	Parameter length.
paramFormats	Parameter format.
resultFormat	Result format.

Return Value

int indicates the execution result. **1** indicates successful execution and **0** indicates an execution failure. The failure cause is stored in **conn->errorMessage**.

Precautions

This function is similar to PQsendQueryParams, but the command to be executed is specified by naming a previously-prepared statement, instead of providing a query string. The parameters of this function are processed in the same way as PQexecPrepared. Like PQexecPrepared, it cannot work on connections using protocol v2.0.

5.5.4.3.5 PQflush

Description

Tries to flush any queued output data to the server.

Prototype

```
int PQflush(PGconn *conn);
```

Parameter

Table 5-74 PQflush parameter

Keyword	Description
conn	Points to the object pointer that contains the connection information.

Return Value

int indicates the execution result. If the operation is successful (or the send queue is empty), **0** is returned. If the operation fails, **-1** is returned. If all data in the send queue fails to be sent, **1** is returned. (This case occurs only when the connection is non-blocking.) The failure cause is stored in **conn->errorMessage**.

Precautions

Call PQflush after sending any command or data over a non-blocking connection. If **1** is returned, wait for the socket to become read- or write-ready. If the socket becomes write-ready, call PQflush again. If the socket becomes read-ready, call PQconsumeInput and then call PQflush again. Repeat the operation until the value **0** is returned for PQflush. It is necessary to check read-ready and use PQconsumeInput to exhaust input because the server may prevent attempts to send data (such as NOTICE messages) to the client and does not read the client's data until the client reads its data. Once PQflush returns **0**, wait for the socket to be read-ready and then read the response as described above.

5.5.4.4 Functions for Canceling Query Processing

A client application can use the functions described in this section to cancel a command that is still being processed by the server.

5.5.4.4.1 PQgetCancel

Description

Creates a data structure that contains the information required to cancel a command issued through a specific database connection.

Prototype

```
PGcancel *PQgetCancel(PGconn *conn);
```

Parameter

Table 5-75 PQgetCancel parameter

Keyword	Description
conn	Points to the object pointer that contains the connection information.

Return Value

PGcancel points to the object pointer that contains the cancel information.

Precautions

PQgetCancel creates a PGcancel object for a given PGconn connection object. If the given connection object (**conn**) is NULL or an invalid connection, it will return

NULL. The PGcancel object is an opaque structure that cannot be directly accessed by applications. It can be passed only to PQcancel or PQfreeCancel.

5.5.4.4.2 PQfreeCancel

Description

Releases the data structure created by PQgetCancel.

Prototype

```
void PQfreeCancel(PGcancel *cancel);
```

Parameter

Table 5-76 PQfreeCancel parameter

Keyword	Description
cancel	Points to the object pointer that contains the cancel information.

Precautions

PQfreeCancel releases a data object previously created by PQgetCancel.

5.5.4.4.3 PQcancel

Description

Requests the server to abandon processing of the current command.

Prototype

```
int PQcancel(PGcancel *cancel, char *errbuf, int errbufsize);
```

Parameter

Table 5-77 PQcancel parameters

Keyword	Description
cancel	Points to the object pointer that contains the cancel information.
errbuf	Buffer for storing error information.
errbufsize	Size of the buffer for storing error information.

Return Value

int indicates the execution result. **1** indicates successful execution and **0** indicates an execution failure. The failure cause is stored in **errbuf**.

Precautions

- Successful sending does not guarantee that the request will have any effect. If the cancellation is valid, the current command is terminated early and an error is returned. If the cancellation fails (for example, because the server has processed the command), no result is returned.
- If **errbuf** is a local variable in a signal handler, you can safely call PQcancel from the signal handler. For PQcancel, the PGcancel object is read-only, so it can also be called from a thread that is separate from the thread that is operating the PGconn object.

5.5.4.5 Functions for Processing Database Result

5.5.4.5.1 PQgetvalue

Description

Returns a single field value of one row of a PGresult. Row and column numbers start from 0. The caller should not release the result directly. The result will be released when the associated PGresult handle is passed to PQclear.

Prototype

```
char *PQgetvalue(const PGresult *res,  
                 int row_number,  
                 int column_number);
```

Parameter

Table 5-78 PQgetvalue parameters

Keyword	Description
res	Operation result handle.
row_number	Number of rows.
column_number	Number of columns.

Return Value

For data in text format, the value returned by PQgetvalue is a null-terminated string representation of the field value.

For binary data, the value is a binary representation determined by the typsend and typreceive functions of the data type.

If this field is left blank, an empty string is returned.

5.5.4.5.2 PQfname

Description

Returns the column name associated with the given column number. Column numbers start from 0. The caller should not release the result directly. The result will be released when the associated PGresult handle is passed to PQclear.

Prototype

```
char *PQfname(const PGresult *res,  
              int column_number);
```

Parameter

Table 5-79 PQfname parameters

Keyword	Description
res	Operation result handle.
column_number	Number of columns.

Return Value

char pointers

5.5.4.5.3 PQnfields

Description

Returns the number of columns (fields) in each row of the query result.

Prototype

```
int PQnfields(const PGresult *res);
```

Parameter

Table 5-80 PQnfields parameters

Keyword	Description
res	Operation result handle.

Return Value

Value of the int type

Example

For details, see [Typical Application Development Examples](#).

5.5.4.5.4 PQntuples

Function

PQntuples is used to return the number of rows (tuples) in the query result. An overflow may occur if the return value is out of the value range allowed in a 32-bit OS.

Prototype

```
int PQntuples(const PGresult *res);
```

Parameter

Table 5-81 PQntuples parameters

Keyword	Parameter Description
res	Operation result handle.

Return Value

Value of the int type

Examples

For details, see [Typical Application Development Examples](#).

5.5.4.5.5 PQresultStatus

Description

Returns the result status of a command.

Prototype

```
ExecStatusType PQresultStatus(const PGresult *res);
```

Parameter

Table 5-82 PQresultStatus parameter

Keyword	Description
res	Object pointer that contains the query result.

Return Value

PQresultStatus indicates the command execution status. The enumerated values are as follows:

PQresultStatus can return one of the following values:

PGRES_EMPTY_QUERY

The string sent to the server was empty.

PGRES_COMMAND_OK

A command that does not return data was successfully executed.

PGRES_TUPLES_OK

A query (such as SELECT or SHOW) that returns data was successfully executed.

PGRES_COPY_OUT

Copy Out (from the server) data transfer started.

PGRES_COPY_IN

Copy In (to the server) data transfer started.

PGRES_BAD_RESPONSE

The response from the server cannot be understood.

PGRES_NONFATAL_ERROR

A non-fatal error (notification or warning) occurred.

PGRES_FATAL_ERROR

A fatal error occurred.

PGRES_COPY_BOTH

Copy In/Out (to and from the server) data transfer started. This state occurs only in streaming replication.

PGRES_SINGLE_TUPLE

PQresult contains a result tuple from the current command. This state occurs in a single-row query.

Precautions

- Note that the SELECT command that happens to retrieve zero rows still returns **PGRES_TUPLES_OK**. **PGRES_COMMAND_OK** is used for commands that can never return rows (such as INSERT or UPDATE, without return clauses). The result status **PGRES_EMPTY_QUERY** might indicate a bug in the client software.
- The result status **PGRES_NONFATAL_ERROR** will never be returned directly by PQexec or other query execution functions. Instead, such results will be passed to the notice processor.

Example

For details, see [Typical Application Development Examples](#).

5.6 Psycopg-based Development

Psycopg is a Python API used to execute SQL statements and provides a unified access API for GaussDB. Applications can perform data operations based on psycopg. Psycopg2 is the encapsulation of libpq and is implemented using the C language, which is efficient and secure. It provides cursors on both clients and servers, asynchronous communication and notification, and the COPY TO and COPY FROM functions. It supports multiple types of Python out-of-the-box and

adapts to GaussDB data types. Through the flexible object adaptation system, you can extend and customize the adaptation. Psycopg2 is compatible with Unicode.

GaussDB supports the psycopg2 feature and allows psycopg2 to be connected in SSL mode.

Table 5-83 Platforms supported by Psycopg

OS	Platform	Python Version
EulerOS 2.5	Arm64 x86_64	3.8.5
EulerOS 2.9	Arm64 x86_64	3.7.4
EulerOS 2.10, Kylin v10, UnionTech20	Arm64 x86_64	3.7.9
EulerOS 2.11 and SUSE 12.5	Arm64 x86_64	3.9.11

NOTICE

During psycopg2 compilation, OpenSSL of GaussDB is linked. OpenSSL of GaussDB may be incompatible with OpenSSL of the OS. If incompatibility occurs, for example, "version 'OPENSSL_1_1_1f' not found" is displayed, use the environment variable `LD_LIBRARY_PATH` to isolate the OpenSSL provided by the OS and the OpenSSL on which GaussDB depends.

For example, when the application software **client.py** that calls psycopg2 is executed, the environment variable is explicitly assigned to the application software.

```
export LD_LIBRARY_PATH=/path/to/gaussdb/libs:$LD_LIBRARY_PATH python client.py
```

In the preceding command, **/path/to/psycopg2/lib** indicates the directory where the OpenSSL library on which the GaussDB depends is located. Change it as required.

5.6.1 Development Process

Figure 5-5 Application development process based on psycopg2

5.6.2 Psycopg Package

Connecting to a Database

Step 1 Prepare related drivers and dependency libraries. Obtain the package **GaussDB-Kernel_Database version number_OS information_64bit_Python.tar.gz** from the driver package.

After the decompression, the following folders are generated:

- **psycopg2**: **psycopg2** library file
- **lib**: **lib** library file

Step 2 Load the driver.

- Before using the driver, perform the following operations:
 - a. Decompress the driver package of the corresponding version.
`tar zxvf xxxx-Python.tar.gz`

- b. Copy **psycopg2** to the **site-packages** folder in the Python installation directory as the **root** user.

```
su root  
cp psycopg2 $(python3 -c 'import site; print(site.getsitepackages()[0])') -r
```
 - c. Change the **psycopg2** directory permission to **755**.

```
chmod 755 $(python3 -c 'import site; print(site.getsitepackages()[0])')/psycopg2 -R
```
 - d. Add the **psycopg2** directory to the environment variable **\$PYTHONPATH** and validate it.

```
export PYTHONPATH=$(python3 -c 'import site; print(site.getsitepackages()[0])'):$PYTHONPATH
```
 - e. For non-database users, configure the **lib** directory in **LD_LIBRARY_PATH** after decompression.

```
export LD_LIBRARY_PATH=path/to/lib:$LD_LIBRARY_PATH
```
- Load a database driver before creating a database connection.

```
import psycopg2
```

Step 3 Connect to a database.

Connect to the database in non-SSL mode.

1. Use the `psycopg2.connect` function to obtain the connection object.
2. Use the connection object to create a cursor object.

Connect to the database in SSL mode.

When you use `psycopy2` to connect to the GaussDB server, you can enable SSL to encrypt the communication between the client and server. To enable SSL, you must have the server certificate, client certificate, and private key files. For details on how to obtain these files, see related documents and commands of OpenSSL.

1. Use the `.ini` file (the **configparser** package of Python can parse this type of configuration file) to save the configuration information about the database connection.
2. Add SSL connection parameters **sslmode**, **sslcert**, **sslkey**, and **sslrootcert** to the connection options.
 - a. **sslmode**: For details about the options, see [Table 5-84](#).
 - b. **sslcert**: client certificate path.
 - c. **sslkey**: client key path.
 - d. **sslrootcert**: root certificate path.
3. Use the `psycopg2.connect` function to obtain the connection object.
4. Use the connection object to create a cursor object.

 CAUTION

To use SSL to connect to the database, ensure that the Python interpreter is compiled in the mode of generating a dynamic link library (.so) file. You can perform the following steps to check the connection mode of the Python interpreter:

1. Run the **import ssl** command in the Python interpreter to import SSL.
2. Run the **ps ux** command to query the PID of the Python interpreter. Assume that the PID is *********.
3. In the shell CLI, run the **pmap -p ***** | grep ssl** command and check whether the command output contains the path related to **libssl.so**. If it does, the Python interpreter is compiled in dynamic link mode.

Table 5-84 sslmode options

sslmode	Enable SSL Encryption	Description
disable	No	SSL connection is not enabled.
allow	Possible	If the database server requires SSL connection, SSL connection can be enabled. However, authenticity of the database server will not be verified.
prefer	Possible	If the database supports SSL connection, SSL connection is preferred. However, authenticity of the database server will not be verified.
require	Yes	SSL connection is required, but only data is encrypted. However, authenticity of the database server will not be verified.
verify-ca	Yes	SSL connection is required, and the validity of the server CA must be verified.
verify-full	Yes	The SSL connection must be enabled, which is not supported by GaussDB currently.

Step 4 Run SQL statements.

1. Construct an operation statement and use %s as a placeholder. During execution, psycopg2 will replace the placeholder with the parameter value. You can add the RETURNING clause to obtain the automatically generated column values.
2. Use the cursor.execute method to execute one row of SQL statement, and use the cursor.executemany method to execute multiple rows of SQL statements.

Step 5 Process the result set.

1. `cursor.fetchone()`: fetches the next row in a query result set and returns a sequence. If no data is available, null is returned.
2. `cursor.fetchall()`: fetches all remaining rows in a query result and returns a list. An empty list is returned when no rows are available.

 NOTE

For database-specific data types, such as `tinyint`, the corresponding columns in the query result are character strings.

Step 6 Close the connection.

After you complete required data operations in a database, close the database connection. Call the close method such as `connection.close()` to close the connection.

 CAUTION

This method closes the database connection and does not automatically call `commit()`. If you close the database connection without calling `commit()`, changes will be lost.

----End

5.6.3 Example: Common Operations

```
import psycopg2
import os

# Obtain the username and password from environment variables.
user = os.getenv('user')
password = os.getenv('password')

# Create a connection object.
conn=psycopg2.connect(database="database", user=user, password=password, host="localhost", port=port)
cur=conn.cursor() # Create a pointer object.

# Create a connection object (using SSL).
conn = psycopg2.connect(dbname="database", user=user, password=password, host="localhost", port=port,
                        sslmode="verify-ca", sslcert="client.crt", sslkey="client.key", sslrootcert="cacert.pem")
Note: If sslcert, sslkey, and sslrootcert are not set, the following files in the .postgresql directory of the
current user are used by default: client.crt, client.key, and root.crt.

# Create a table.
cur.execute("CREATE TABLE student(id integer,name varchar,sex varchar);")

# Insert data.
cur.execute("INSERT INTO student(id,name,sex) VALUES(%s,%s,%s)",(1,'Aspirin','M'))
cur.execute("INSERT INTO student(id,name,sex) VALUES(%s,%s,%s)",(2,'Taxol','F'))
cur.execute("INSERT INTO student(id,name,sex) VALUES(%s,%s,%s)",(3,'Dixheral','M'))

# Insert data in batches.
stus = ((4,'John','M'),(5,'Alice','F'),(6,'Peter','M'))
cur.executemany("INSERT INTO student(id,name,sex) VALUES(%s,%s,%s)",stus)

# Obtain the result.
cur.execute("SELECT * FROM student")
results=cur.fetchall()
print (results)
```

```
# Perform a commit.
conn.commit()

# Insert a data record.
cur.execute("INSERT INTO student(id,name,sex) VALUES(%s,%s,%s)",(7,'Lucy','F'))

# Perform a rollback.
conn.rollback()

# Close the connection.
cur.close()
conn.close()

Common connection modes of psycopg2
1. conn = psycopg2.connect(dbname="dbname", user=user, password=password, host="localhost",
port=port)
2. conn = psycopg2.connect(f"dbname=dbname user={user} password={password} host=localhost
port=port")
3. Using logs
import logging
import psycopg2
from psycopg2.extras import LoggingConnection
import os

# Obtain the username and password from environment variables.
user = os.getenv('user')
password = os.getenv('password')

logging.basicConfig(level=logging.DEBUG) # Log level
logger = logging.getLogger(__name__)

db_settings = {
    "user": user,
    "password": password,
    "host": "localhost",
    "database": "dbname",
    "port": port
}

# LoggingConnection records all SQL statements by default. You can filter unnecessary or sensitive SQL
statements. Example of filtering password-related SQL statements:
class SelfLoggingConnection(LoggingConnection):

    def filter(self, msg, curs):
        if db_settings['password'] in msg.decode():
            return b'queries containing the password will not be recorded'
        return msg

conn = psycopg2.connect(connection_factory=SelfLoggingConnection, **db_settings)
conn.initialize(logger)
```

CAUTION

- By default, **LoggingConnection** records all SQL information and does not anonymize sensitive information. You can use the filter function to define the output SQL content.
- The log function is an additional function provided by psycopg2 for developers to explicitly debug full SQL statements. By default, the log function is not used. This function prints SQL statements before psycopg2 executes SQL statements. However, the SQL statements can be printed only when the log level is **DEBUG**. This function is not a default function. It is used only when there are special requirements. You are advised not to use this function unless there are special requirements. For details, visit <https://www.psycopg.org/docs/extras.html?highlight=loggingconnection>.

5.6.4 Psycopg API Reference

Psycopg APIs are a set of methods provided for users. This section describes some common APIs.

5.6.4.1 psycopg2.connect()

Description

This method creates a database session and returns a new connection object.

Prototype

```
import os
conn=psycopg2.connect(dbname="test",user=os.getenv('user'),password=os.getenv('password'),host="127.0.0.1",port="5432")
```

Parameter

Table 5-85 psycopg2.connect parameters

Keyword	Description
dbname	Database name
user	Username
password	Password
host	Database IP address. The default type is Unix socket.
port	Connection port number. The default value is 5432 .
sslmode	SSL mode, which is used for SSL connection.
sslcert	Path of the client certificate, which is used for SSL connection.
sslkey	Path of the client key, which is used for SSL connection.

Keyword	Description
sslrootcert	Path of the root certificate, which is used for SSL connection.
hostaddr	IP address of the database
connect_timeout	Client connection timeout interval
client_encoding	Encoding format of the client
application_name	Value of application_name
fallback_application_name	Rollback value of application_name
keepalives	Specifies whether to enable the TCP connection on the client. The default value is 1 , indicating that the TCP connection is enabled. The value 0 indicates that the TCP connection is disabled. If the UDS connection is used, ignore this parameter.
options	Specifies the command line options sent to the server when the connection starts.
keepalives_idle	Describes inactivity before keepalive messages are sent to the server. If keepalive messages are disabled, ignore this parameter.
keepalives_interval	Specifies whether keepalive messages that are not confirmed by the server need to be resent. If keepalive messages are disabled, ignore this parameter.
keepalives_count	Specifies the number of TCP connections that may be lost before the client is disconnected from the server.
replication	Ensures that the connection uses the replication protocol instead of the common protocol.
requiressl	Supports the SSL mode.
sslcompression	Specifies the SSL compression. If this parameter is set to 1 , the data sent through the SSL connection is compressed. If this parameter is set to 0 , compression is disabled. If no SSL connection is established, ignore this parameter.
sslcrld	Specifies the path of the CRL, which is used to check whether the SSL server certificate is available.
requirepeer	Specifies the OS username of the server.

Return Value

Connection object (for connecting to a database instance)

Examples

For details, see [Example: Common Operations](#).

5.6.4.2 connection.cursor()

Function

This method returns a new cursor object.

Prototype

```
cursor(name=None, cursor_factory=None, scrollable=None, withhold=False)
```

Parameter

Table 5-86 connection.cursor parameters

Keyword	Description
name	Cursor name. The default value is None .
cursor_factory	Creates a non-standard cursor. The default value is None .
scrollable	Sets the SCROLL option. The default value is None .
withhold	Sets the HOLD option. The default value is False .

Return Value

Cursor object (used for cursors that are programmed using Python in the entire database)

Examples

For details, see [Example: Common Operations](#).

5.6.4.3 cursor.execute(query,vars_list)

Description

This method executes the parameterized SQL statements (that is, placeholders instead of SQL literals). The psycopg2 module supports placeholders marked with %s.

Prototype

```
cursor.execute(query,vars_list)
```

Parameters

Table 5-87 cursor.execute parameters

Keyword	Description
query	SQL statement to be executed.
vars_list	Variable list, which matches the %s placeholder in the query.

Return Value

None

Examples

For details, see [Example: Common Operations](#).

5.6.4.4 cursor.executemany(query,vars_list)

Description

This method executes an SQL command against all parameter sequences or mappings found in the sequence SQL.

Prototype

```
cursor.executemany(query,vars_list)
```

Parameter

Table 5-88 cursor.executemany parameters

Keyword	Description
query	SQL statement that you want to execute.
vars_list	Variable list, which matches the %s placeholder in the query.

Return Value

None

Examples

For details, see [Example: Common Operations](#).

5.6.4.5 connection.commit()

Function

This method commits the currently pending transaction to the database.

CAUTION

By default, Psycopg opens a transaction before executing the first command. If **commit()** is not called, the effect of any data operation will be lost.

Prototype

```
connection.commit()
```

Parameter

None

Return Value

None

Examples

For details, see [Example: Common Operations](#).

5.6.4.6 connection.rollback()

Function

This method rolls back the current pending transaction.

CAUTION

If you close the connection using **close()** but do not commit the change using **commit()**, an implicit rollback will be performed.

Prototype

```
connection.rollback()
```

Parameter

None

Return Value

None

Examples

For details, see [Example: Common Operations](#).

5.6.4.7 cursor.fetchone()

Description

This method extracts the next row of the query result set and returns a tuple.

Prototype

```
cursor.fetchone()
```

Parameter

None

Return Value

A single tuple is the first result in the result set. If no more data is available, **None** is returned.

Examples

For details, see [Example: Common Operations](#).

5.6.4.8 cursor.fetchall()

Function

This method obtains all the (remaining) rows of the query result and returns them as a list of tuples.

Prototype

```
cursor.fetchall()
```

Parameter

None

Return Value

Tuple list, which contains all results of the result set. An empty list is returned when no rows are available.

Examples

For details, see [Example: Common Operations](#).

5.6.4.9 cursor.close()

Function

This method closes the cursor of the current connection.

Prototype

```
cursor.close()
```

Parameter

None

Return Value

None

Examples

For details, see [Example: Common Operations](#).

5.6.4.10 connection.close()

Function

This method closes the database connection.

CAUTION

This method closes the database connection and does not automatically call **commit()**. If you just close the database connection without calling **commit()** first, changes will be lost.

Prototype

```
connection.close()
```

Parameter

None

Return Value

None

Examples

For details, see [Example: Common Operations](#).

5.7 Development Based on the Go Driver

5.7.1 Go Driver Package, Environment Class, and Driver Class

Go Driver Package

Obtain the **GaussDB-Kernel-*VxxxRxxxCxx-OS information*-64bit-Go.tar.gz** package from the driver package. Decompress the package to obtain the Go driver source code package.

NOTICE

The Go driver package provided by the database depends on Go 1.13 or later.

Environment Class

- **Configure the Go environment.**
- You need to configure the following parameters in the environment variables:
 - **GO111MODULE**: Set **GO111MODULE** to **on** when installing the Go driver by importing a file online. If you do not want to reconstruct the **go mod** project, set **GO111MODULE** to **off** and manually download the dependency package. The dependency package must be at the same level as the driver root directory and service code.
 - **GOPROXY**: When importing data online, you need to configure the path that contains the Go driver package.
 - You can configure other Go environment variables based on your scenario parameters.

Run the **go env** command to view the Go environment variable configuration result and check whether the Go version is 1.13 or later.

- **Install the Go driver.**
 - Obtain the Go driver package **GaussDB-Kernel_*Database version number_OS information*_64bit_Go.tar.gz** from the driver package and save it to the local PC. Decompress the package to obtain the Go driver source code package.
 - Go to the root path of the Go driver code and run the **go mod tidy** command to download related dependencies. You need to configure **GOPATH=\${Path for storing the Go driver dependency package}** in the environment variables.
 - If the dependencies have been downloaded to the localhost, you can add a line "Replace the Go driver package with the local Go driver package address through replace" to **go.mod**, indicating that all import Go driver packages in the code are stored in the local path and the dependencies are not downloaded from the proxy.

 CAUTION

When you run the **go mod tidy** command to download dependencies, some of them may be downloaded as an earlier version. If the earlier version has vulnerabilities, you can change the dependency version in the **go.mod** file and update the dependency to the version after the vulnerability is fixed to avoid risks.

Driver Class

When creating a database connection, you need to enter the database driver name **opengauss**.

NOTICE

- The Go driver provided by the database does not adapt to mature ORM frameworks (such as XORM) in the industry. As such, the driver name input during database connection creation must be compatible with Postgres and PostgreSQL.
 - The Go driver of the database cannot coexist with that of PostgreSQL.
-

5.7.2 Development Process

The Go driver of the database complies with the rule of the Go language third-party library. You only need to import the driver to the application program and save the driver code in the directory specified by *GOPATH*.

Figure 5-6 Application development process based on Go

5.7.3 Connecting to the Database

When you call the standard SQL API **open** of the Go language to create a database connection, a connected object is returned to transfer the driver name and description string.

Function Prototype

The Go driver provides the following method to generate a database connected object:

```
func Open(driverName, dataSourceName string) (*DB, error)
```

Parameter description:

- **driverName** indicates the driver name. The database driver name is **opengauss**, which is compatible with Postgres.
- **dataSourceName** indicates the data source to be connected. The value can be in DSN or URL format.
 - DSN format: key1 = value1 key2 = value2... Different groups of keywords are separated by space. The space on the left and right of the equal sign (=) is optional.
 - URL format: driverName://[userspec@][hostspec]/[dbname][?paramspec]

In the preceding information, **driverName** indicates the driver name. The database driver name is **opengauss**, which is compatible with Postgres and PostgreSQL.

userspec indicates user[:password]. When a URL is used for connection, the password cannot contain separators in the URL string. If the password contains separators, the DSN format is recommended.

hostspec indicates [host][:port][, ...].

dbname indicates the database name. Note: The initial user cannot be used for remote login. **paramspec** indicates name=value[&...].

NOTICE

- In the DSN format, if there are multiple IP addresses:
 - When the value of **num(ip)** is the same as that of **num(port)**, the IP address matches the port number.
 - When the value of **num(ip)** is greater than that of **num(port)**, the IP address that cannot match the port number matches the first port number. For example, the matching condition of **host = ip1, ip2, ip3 port = port1, port2** is **ip1:port1, ip2:port2, ip3:port1**.
 - When the value of **num(ip)** is smaller than that of **num(port)**, the extra port numbers are discarded. For example, the mapping result of **host = ip1, ip2, ip3 port = port1, port2, port3, port4** is **ip1:port1, ip2:port2, ip3:port3**.
- In the URL format, if there are multiple IP addresses:
 - In the URL, *ip:port* must appear in pairs, that is, the value of **num(ip)** is the same as that of **num(port)**. Use commas (,) to separate multiple pairs. Example: **opengauss://user:password@ip1:port1, ip2:port2, ip3:port3/postgres**.
 - The URL contains only multiple IP addresses. The port number is specified by the environment variable or uses the default value **5432**. For example, in the case of **opengauss://user:password@ip1, ip2, ip3/postgres**, if the environment variable is set as **PGPORT = "port1, port2"**, the mapping is **ip1:port1, ip2:port2, ip3:port1**. If the environment variable is not set, the mapping is **ip1:5432, ip2:5432, ip3:5432**.

Parameters

Table 5-89 Database connection parameters

Parameter	Parameters
host	IP address of the host server, which can also be specified by the environment variable <code>\${PGHOST}</code>
port	Port number of the host server, which can also be specified by the environment variable <code>\${PGPORT}</code>
dbname	Database name, which can also be specified by the environment variable <code>\${PGDATABASE}</code>
user	Username to be connected, which can also be specified by the environment variable <code>\${PGUSER}</code>
password	Password of the user to be connected
connect_timeout	Timeout interval for connecting to the server, which can also be specified by the environment variable <code>\${PGCONNECT_TIMEOUT}</code>

sslmode	SSL encryption mode, which can also be specified by the environment variable <code>PGSSLMODE</code> Value range: • disable: SSL connection is disabled. • allow: If the database server requires SSL connection, SSL connection can be enabled. However, authenticity of the database server will not be verified. • prefer: If the database supports SSL connection, SSL connection is preferred. However, authenticity of the database server will not be verified. • require: SSL connection is required and data is encrypted. However, authenticity of the database server will not be verified. • verify-ca: SSL connection is required, and whether the server certificate is issued by a trusted CA is verified. • verify-full: SSL connection is required, and whether the server certificate is issued by a trusted CA and whether the host name of the server is the same as that in the certificate are verified.
sslkey	Key location of the client certificate. If SSL connection is required and this parameter is not specified, you can set the environment variable <code>PGSSLKEY</code> to specify the location.
sslcert	File name of the client SSL certificate, which can also be specified by the environment variable <code>PGSSLCERT</code>
sslrootcert	Name of the file that contains the SSL CA certificate, which can also be specified by the environment variable <code>PGSSLROOTCERT</code>
sslcrll	File name of the SSL CRL. If a certificate listed in this file exists, the server certificate authentication will be rejected and the connection will fail. The value can also be specified by the environment variable <code>PGSSLCRL</code>.
sslpassword	Passphrase used to decrypt a key into plaintext. If this parameter is specified, the SSL key is an encrypted file. Currently, the SSL key supports DES encryption and AES encryption. NOTE The DES encryption algorithm has lower security and poses security risks. Therefore, you are advised to use a more secure encryption algorithm.

disable_prepared_binary_result	The value of this parameter is a string. If it is set to yes, the connection should not use the binary format when the query results are received from prepared statements. This parameter is used only for debugging. Value range: yes and no.
binary_parameters	Specifies whether []byte is always sent in binary format. The value is a string. Value range: yes and no. If this parameter is set to yes, you are advised to bind parameters based on [] byte to reduce internal type conversion.
target_session_attrs	Connection type of the database, which can also be specified by the environment variable <code>\${PGTARGETSESSIONATTRS}</code>. This parameter is used to identify the primary and standby nodes. There are six value options, namely, any, master, slave, preferSlave, read-write, and read-only. The default value is any. • any: attempts to connect to any DN in the URL connection string. • master: attempts to connect to a primary node in the URL connection string. If the primary node cannot be found, an exception is thrown. • slave: attempts to connect to a standby node in the URL connection string. If the standby node cannot be found, an exception is thrown. • preferSlave: attempts to connect to a standby DN (if available) in the URL connection string. Otherwise, it connects to the primary DN. • read-write: specifies that only the primary node can be connected. • read-only: specifies that only the standby node can be connected.
loggerLevel	Log level, which is used to print debugging information. The value can also be specified by the environment variable <code>\${PGLOGGERLEVEL}</code>. The value can be trace, debug, info, warn, error, or none, in descending order of priority.
application_name	Name of the Go driver that is being connected. The default value is go-driver. You are advised not to configure this parameter.

RuntimeParams	Value of the GUC parameter of the set type that is run by default when a session is connected. for example, search_path , application_name , or timezone . For details about the parameters, see the default settings of the client connection. You can run the SHOW command to check whether the parameters are set successfully.

Example 1:

```
// Single IP address and port (ip:port) are used as an example. In this example, the username and password
// are stored in environment variables. Before running this example, set environment variables in the local
// environment (set the environment variable name based on the actual situation).
func main() {
    hostip := os.Getenv("GOHOSTIP") // GOHOSTIP indicates the IP address written into the environment
    // variable.
    port := os.Getenv("GOPORT") // GOPORT indicates the port number written into the environment
    // variable.
    username := os.Getenv("GOUSRNAME") // GOUSRNAME indicates the username for writing environment
    // variables.
    passwd := os.Getenv("GOPASSWD") // GOPASSWD indicates the user password written into the
    // environment variable.
    str := "host=" + hostip + " port=" + port + " user=" + username + " password=" + passwd + "
    dbname=postgres sslmode=disable" // DSN connection string
    //str := "opengauss://" + username + ":" + passwd + "@" + hostip + ":" + port + "/postgres?
    //sslmode=disable" // URL connection string
    db, err := sql.Open("opengauss", str)
    if err != nil {
        log.Fatal(err)
    }
    defer db.Close()

    err = db.Ping()
    if err != nil {
        log.Fatal(err)
    }

```

```
}  
}
```

5.7.4 Connecting to the Database (Using SSL)

The Go driver supports SSL connections to the database. After the SSL mode is enabled, if the Go driver connects to the database server in SSL mode, the Go driver uses the standard TLS 1.3 protocol by default, and the TLS version must be 1.2 or later. This section describes how applications configure the client in SSL mode through Go. Contact an administrator for details about the configuration on the server. To enable SSL connections, you must have the server certificate, client certificate, and private key files. For details on how to obtain these files, see related documents and commands of OpenSSL.

NOTE

In SSL-based certificate authentication mode, you do not need to specify the user password in the connection string.

Configuring the Client

Upload the certificate files **client.key**, **client.crt**, and **ca.crt** generated on the server to the client. Contact an administrator for details about the configuration on the server.

Example 1:

```
// Mutual authentication is used as an example. In this example, the username and password are stored in  
// environment variables. Before running this example, set environment variables in the local environment (set  
// the environment variable name based on the actual situation).  
func main() {  
    hostip := os.Getenv("GOHOSTIP") // GOHOSTIP indicates the IP address written into the environment  
    // variable.  
    port := os.Getenv("GOPORT") // GOPORT indicates the port number written into the environment  
    // variable.  
    username := os.Getenv("GOUSRNAME") // GOUSRNAME indicates the username for writing environment  
    // variables.  
    passwd := os.Getenv("GOPASSWD") // GOPASSWD indicates the user password written into the  
    // environment variable.  
    sslpasswd := os.Getenv("GOSSLPASSWD") // GOSSLPASSWD indicates the passphrase written into the  
    // environment variable.  
    dsnStr := "host=" + hostip + " port=" + port + " user=" + username + " password=" + passwd + "  
    sslcert=certs/client.crt sslkey=certs/client.key sslpassword=" + sslpasswd  
    parameters := []string{  
        "sslmode=require",  
        "sslmode=verify-ca sslrootcert=certs/ca.crt",  
    }  
  
    for _, param := range parameters {  
        db, err := sql.Open("opengauss", dsnStr+param)  
        if err != nil {  
            log.Fatal(err)  
        }  
    }  
  
    var f1 int  
    err = db.QueryRow("select 1").Scan(&f1)  
    if err != nil {  
        log.Fatal(err)  
    } else {  
        fmt.Printf("RESULT: select 1: %d\n", f1)  
    }  
  
    db.Close()
```

```
}  
}
```

Example 2:

```
// For example, verify sslpassword. In this example, the username and password are stored in environment  
// variables. Before running this example, set environment variables in the local environment (set the  
// environment variable name based on the actual situation).  
func main() {  
    hostip := os.Getenv("GOHOSTIP") // GOHOSTIP indicates the IP address written into the environment  
    // variable.  
    port := os.Getenv("GOPORT") // GOPORT indicates the port number written into the environment  
    // variable.  
    username := os.Getenv("GOUSRNAME") // GOUSRNAME indicates the username for writing environment  
    // variables.  
    passwd := os.Getenv("GOPASSWD") // GOPASSWD indicates the user password written into the  
    // environment variable.  
    dsnStr := "host=" + hostip + " port=" + port + " user=" + username + " password=" + passwd + "  
    dbname=postgres"  
  
    sslpasswd := os.Getenv("GOSSLPASSWD") // GOSSLPASSWD indicates the passphrase written into the  
    // environment variable.  
    connStrs := []string{  
        " sslmode=verify-ca sslcert=certs/client_rsa.crt sslkey=certs/client_rsa.key sslpassword=" + sslpasswd + "  
    sslrootcert=certs/cacert_rsa.pem",  
        " sslmode=verify-ca sslcert=certs/client_ecdsa.crt sslkey=certs/client_ecdsa.key sslpassword=" + sslpasswd + "  
    sslrootcert=certs/cacert_ecdsa.pem",  
    }  
    for _, connStr := range connStrs {  
        db, err := sql.Open("opengauss", dsnStr+connStr)  
        if err != nil {  
            log.Fatal(err)  
        }  
        var f1 int  
        err = db.QueryRow("select 1").Scan(&f1)  
        if err != nil {  
            if !strings.HasPrefix(err.Error(), "connect failed.") {  
                log.Fatal(err)  
            }  
        }  
        db.Close()  
    }  
}
```

5.7.5 Go API Reference

5.7.5.1 sql.Open

The following table describes sql.Open.

Method	Description	Return Value
Open(driverName, dataSourceName string)	Opens a database based on a specified database driver and the dedicated data source of the driver.	*DB and error

For details about the **driverName** and **dataSourceName** parameters, see [Connecting to the Database](#).

5.7.5.2 type DB

The following table describes type DB.

Method	Description	Return Value
(db *DB)Begin()	Starts a transaction. The isolation level of the transaction is determined by the driver.	*Tx and error
(db *DB)BeginTx(ctx context.Context, opts *TxOptions)	Starts a transaction with a specified transaction isolation level. A specified context is used until the transaction is committed or rolled back. If the context is canceled, the SQL package rolls back the transaction.	*Tx and error
(db *DB)Close()	Closes the database and releases all the opened resources.	error
(db *DB)Exec(query string, args ...interface{})	Performs an operation that does not return rows of data.	Result and error
(db *DB)ExecContext(ctx context.Context, query string, args ...interface{})	Performs an operation that does not return rows of data in a specified context.	Result and error
(db *DB)Ping()	Checks whether the database connection is still valid and establishes a connection if necessary.	error
(db *DB)PingContext(ctx context.Context)	Checks whether the database connection is still valid in a specified context and establishes a connection if necessary.	error
(db *DB)Prepare(query string)	Creates a prepared statement for subsequent queries or executions.	*Stmt and error
(db *DB)PrepareContext(ctx context.Context, query string)	Creates a prepared statement for subsequent queries or executions in a specified context.	*Stmt and error
(db *DB)Query(query string, args ...interface{})	Executes a query and returns multiple rows of data.	*Rows and error
(db *DB)QueryContext(ctx context.Context, query string, args ...interface{})	Executes a query and returns multiple rows of data in a specified context.	*Rows and error

(db *DB)QueryRow(query string, args ...interface{})	Executes a query that returns only one row of data.	*Row
(db *DB)QueryRowContext(ctx context.Context, query string, args ...interface{})	Executes a query that returns only one row of data in a specified context.	*Row

Parameters

Parameter	Description
ctx	Specified context
query	Executed SQL statement
args	Parameter that needs to be bound to the executed SQL statement. Binding by location and binding by name are supported. For details, see the following example.
opts	Transaction isolation level and transaction access mode. The value of the transaction isolation level (opts.Isolation) can be sql.LevelReadUncommitted, sql.LevelReadCommitted, sql.LevelRepeatableRead, or sql.LevelSerializable. The value of the transaction access mode (opts.ReadOnly) can be true (read-only) or false (read/write).

Example:

```
// In this example, the username and password are stored in environment variables. Before running this
// example, set environment variables in the local environment (set the environment variable names based on
// the actual situation).
func main() {
    hostip := os.Getenv("GOHOSTIP") // GOHOSTIP indicates the IP address written into the environment
    // variable.
    port := os.Getenv("GOPORT") // GOPORT indicates the port number written into the environment
    // variable.
    username := os.Getenv("GOUSRNAME") // GOUSRNAME indicates the username for writing environment
    // variables.
    passwd := os.Getenv("GOPASSWD") // GOPASSWD indicates the user password written into the
    // environment variable.
    str := "host=" + hostip + " port=" + port + " user=" + username + " password=" + passwd + "
    dbname=postgres sslmode=disable"
    db, err := sql.Open("opengauss", str)
    if err != nil {
        log.Fatal(err)
    }
    defer db.Close()

    err = db.Ping()
    if err != nil {
        log.Fatal(err)
    }
}
```

```
// Binding by location
_, err = db.Exec("insert into test(id, name) values(:1, :2)", 1, "Zhang San")
if err != nil {
    log.Fatal(err)
}

// Binding by name
_, err = db.Exec("insert into test(id, name) values(:id, :name)", sql.Named("id", 1), sql.Named("name",
"Zhang San"))
if err != nil {
    log.Fatal(err)
}
}
```

5.7.5.3 type Stmt

The following table describes type Stmt.

Method	Description	Return Value
(s *Stmt)Close()	Closes a specified prepared statement.	error
(s *Stmt)Exec(args ...interface{})	Executes a prepared statement with specified parameters and returns a Result value.	Result and error
(s *Stmt)ExecContext(ctx context.Context, args ...interface{})	Executes a prepared statement with specified parameters in a specified context and returns a Result value.	Result and error
(s *Stmt)Query(args ...interface{})	Executes a prepared statement with specified parameters and returns *Rows as the query result.	*Rows and error
(s *Stmt)QueryContext(ctx context.Context, args ...interface{})	Executes a prepared statement with specified parameters in a specified context and returns *Rows as the query result.	*Rows and error
(s *Stmt)QueryRow(args ...interface{})	Executes a prepared statement with specified parameters and returns *Row as the result.	*Row
(s *Stmt)QueryRowContext (ctx context.Context, args ...interface{})	Executes a prepared statement with specified parameters in a specified context and returns *Row as the result.	*Row

Parameters

Parameter	Description
ctx	Specified context
query	Executed SQL statement
args	Parameter that needs to be bound to the executed SQL statement. Binding by location and binding by name are supported. For details, see the example in type DB.

5.7.5.4 type Tx

The following table describes type Tx.

Method	Description	Return Value
(tx *Tx)Commit()	Commits a transaction.	error
(tx *Tx)Exec(query string, args ...interface{})	Performs an operation that does not return rows of data.	Result and error
(tx *Tx)ExecContext(ctx context.Context, query string, args ...interface{})	Performs an operation that does not return rows of data in a specified context.	Result and error
(tx *Tx)Prepare(query string)	Creates a prepared statement for subsequent queries or executions. The returned statement is executed within a transaction and cannot be used when the transaction is committed or rolled back.	*Stmt and error

(tx *Tx)PrepareContext(ctx context.Context, query string)	Creates a prepared statement for subsequent queries or executions. The returned statement is executed within a transaction and cannot be used when the transaction is committed or rolled back. The specified context will be used in the preparation phase, not in the transaction execution phase. The statement returned by this method will be executed in the transaction context.	*Stmt and error
(tx *Tx)Query(query string, args ...interface{})	Executes a query that returns rows of data.	*Rows and error
(tx *Tx)QueryContext(ctx context.Context, query string, args ...interface{})	Executes a query that returns rows of data in a specified context.	*Rows and error
(tx *Tx)QueryRow(query string, args ...interface{})	Executes a query that returns only one row of data.	*Row
(tx *Tx)QueryRowContext(ctx context.Context, query string, args ...interface{})	Executes a query that returns only one row of data in a specified context.	*Row
(tx *Tx) Rollback()	Rolls back a transaction.	error
(tx *Tx)Stmt(stmt *Stmt)	Returns a transaction-specific prepared statement for an existing statement. Example: str, err := db.Prepare("insert into t1 values(:1, :2)") tx, err := db.Begin() res, err := tx.Stmt(str).Exec(1, "aaa")	*Stmt
(tx *Tx)StmtContext(ctx context.Context, stmt *Stmt)	Returns a transaction-specific prepared statement for an existing statement in a specified context.	*Stmt

Parameter Description

Parameter	Description
ctx	Specified context
query	Executed SQL statement
args	Parameter that needs to be bound to the executed SQL statement. Binding by location and binding by name are supported. For details, see the example in type DB.
stmt	Existing prepared statement, which is generally the prepared statement returned by the PREPARE statement

5.7.5.5 type Rows

The following table describes type Rows.

Method	Description	Return Value
(rs *Rows)Close()	Closes Rows to stop the iteration of the dataset.	error
(rs *Rows)ColumnTypes()	Returns column information.	[]*ColumnType and error
(rs *Rows)Columns()	Returns the name of each column.	[]string and error
(rs *Rows)Err()	Returns any errors that occur during iteration.	error
(rs *Rows)Next()	Prepares the next data row to be read with the Scan method. If there is an additional result set, true is returned. Otherwise, false is returned.	bool
(rs *Rows)Scan(dest ...interface{})	Copies the columns of the current iterated row of data to the value specified by dest .	error
(rs *Rows)NextResultSet() bool	Specifies whether there is an additional result set.	Bool

Parameter

Parameter	Description
dest	The column to be queried needs to be copied to the value specified by this parameter.

5.7.5.6 type Row

The following table describes type Row.

Method	Description	Return Value
(r *Row)Scan(dest ...interface{})	Copies the columns in the current row of data to the value specified by dest .	error
(r *Row)Err()	Returns errors that occur during execution.	error

Parameter Description

Parameter	Description
dest	The column to be queried needs to be copied to the value specified by this parameter.

5.7.5.7 type ColumnType

The following table describes type ColumnType.

Method	Description	Return Value
(ci *ColumnType)DatabaseTypeName()	Returns the name of the column-type database system. If an empty string is returned, driver-type names are not supported.	error
(ci *ColumnType)DecimalSize()	Returns the scale and precision of the decimal type. If the value of ok is false , the specified type is unavailable or not supported.	precision, scale int64, ok bool

(ci *ColumnType)Length()	Returns the length of the data column type. If the value of ok is false , the specified type does not have a length.	length int64, ok bool
(ci *ColumnType)ScanType()	Returns a Go type that can be used for scanning by using Rows.Scan.	reflect.Type
(ci *ColumnType)Name()	Returns the name of a data column.	string

5.7.5.8 type Result

The following table describes type Result.

Method	Description	Return Value
(res Result)RowsAffected()	Returns the number of rows affected by the INSERT, DELETE, UPDATE, SELECT, MOVE, FETCH, and COPY operations.	int64 and error

5.8 Appendix

5.8.1 JDBC

5.8.1.1 Data Type Mapping

The relationships among data types, Java variable types, and JDBC type indexes are as follows (A: Oracle-compatible; B: MySQL-compatible):

Table 5-90 Mapping for JDBC Data Types

Compatibility Mode	Gauss Kernel Data Type	Java Variable Type	JDBC Type Index
A/B	oid	java.lang.Long	java.sql.Types.BIGINT
A/B	numeric	java.math.BigDecimal	java.sql.Types.NUMERIC
A/B	tinyint	java.lang.Integer	java.sql.Types.TINYINT

Compatibility Mode	Gauss Kernel Data Type	Java Variable Type	JDBC Type Index

5.8.1.2 Log Management

The GaussDB JDBC driver uses log records to help solve problems when the GaussDB JDBC driver is used in applications. GaussDB JDBC supports the following log management methods:

1. Use the SLF4J log framework for interconnecting with applications.
2. Use the JdkLogger log framework for interconnecting with applications.

SLF4J and JdkLogger are mainstream frameworks for Java application log management in the industry. For details about how to use these frameworks, see the official documents (SLF4J: <http://www.slf4j.org/manual.html>; JdkLogger: <https://docs.oracle.com/javase/8/docs/technotes/guides/logging/overview.html>).

Method 1: Use the SLF4J log framework for interconnecting with applications.

When a connection is set up, **logger=Slf4JLogger** is configured in the URL.

The SLF4J may be implemented by using Log4j or Log4j2. When the Log4j is used to implement the SLF4J, the following JAR packages need to be added: **log4j-*.jar**, **slf4j-api-*.jar**, and **slf4j-log4j-*.jar** (* varies according to versions), and configuration file **log4j.properties**. In addition, the code for reading the configuration file must be added to the main program. If the Log4j2 is used to implement the SLF4J, you need to add the following JAR packages: **log4j-api-*.jar**, **log4j-core-*.jar**, **log4j-slf4j18-impl-*.jar**, and **slf4j-api-*-alpha1.jar** (* varies according to versions), and configuration file **log4j2.xml**.

This method supports log management and control. The SLF4J can implement powerful log management and control functions through related configurations in files. This method is recommended.

CAUTION

This method depends on the general SLF4J APIs, such as **org.slf4j.LoggerFactory.getLogger(String name)**, **org.slf4j.Logger.debug(String var1)**, **org.slf4j.Logger.info(String var1)**, **org.slf4j.Logger.warn(String warn)**, and **org.slf4j.Logger.warn(String warn)**. If these APIs are changed, logs cannot be recorded.

Example:

```
// Note: The path of the log4j.properties or log4j2.xml file must be specified during calling.

// Use the log4j.properties file to configure the attributes of the log recorder, such as the log level and
// output target. These properties are loaded into the application by calling the configure method of
// PropertyConfigurator and passing the path of the log4j.properties file.
//PropertyConfigurator.configure("log4j.properties");

// Create the Log4j2 configuration source, specify the path of the log4j2.xml configuration file, and
// initialize the log system.
//ConfigurationSource source = new ConfigurationSource(new FileInputStream("log4j2.xml"));
//Configurator.initialize(null, source);

public static Connection GetConnection(String username, String passwd){

    String sourceURL = "jdbc:opengauss://$ip:$port/database?logger=Slf4JLogger";
    Connection conn = null;

    try{
        // Create a connection.
        conn = DriverManager.getConnection(sourceURL,username,passwd);
        System.out.println("Connection succeed!");
    }catch (Exception e){
        e.printStackTrace();
    }
```

```
        return null;
    }
    return conn;
}
```

log4j.properties configuration file:

```
log4j.logger.com.huawei.opengauss.jdbc=ALL, log_gsjdbc

# Default file output configuration
log4j.appender.log_gsjdbc=org.apache.log4j.RollingFileAppender
log4j.appender.log_gsjdbc.Append=true
log4j.appender.log_gsjdbc.File=gsjdbc.log
log4j.appender.log_gsjdbc.Threshold=TRACE
log4j.appender.log_gsjdbc.MaxFileSize=10MB
log4j.appender.log_gsjdbc.MaxBackupIndex=5
log4j.appender.log_gsjdbc.layout=org.apache.log4j.PatternLayout
log4j.appender.log_gsjdbc.layout.ConversionPattern=%d %p %t %c - %m%n
log4j.appender.log_gsjdbc.File.Encoding = UTF-8
```

log4j2.xml configuration file:

```
<?xml version="1.0" encoding="UTF-8"?>
<configuration status="OFF">
    <appenders>
        <Console name="Console" target="SYSTEM_OUT">
            <PatternLayout pattern="%d %p %t %c - %m%n"/>
        </Console>
        <File name="FileTest" fileName="test.log">
            <PatternLayout pattern="%d %p %t %c - %m%n"/>
        </File>
        <!-- JDBC driver log file output configuration. Log rewinding is supported. When the log size exceeds
        10 MB, a new file is created. The new file is named in the format of yyyy-mm-dd-file ID. -->
        <RollingFile name="RollingFileJdbc" fileName="gsjdbc.log" filePattern="%d{yyyy-MM-dd}-%i.log">
            <PatternLayout pattern="%d %p %t %c - %m%n"/>
            <Policies>
                <SizeBasedTriggeringPolicy size="10 MB"/>
            </Policies>
        </RollingFile>
    </appenders>
    <loggers>
        <root level="all">
            <appender-ref ref="Console"/>
            <appender-ref ref="FileTest"/>
        </root>
        <!-- JDBC driver logs. The log level is all. All logs can be viewed and exported to the gsjdbc.log file. -->
        <logger name="com.huawei.opengauss.jdbc" level="all" additivity="false">
            <appender-ref ref="RollingFileJdbc"/>
        </logger>
    </loggers>
</configuration>
```

NOTICE

- In the configuration file, you can specify the configuration paths for JDBC and upper-layer services to store JDBC logs and service logs to different files.
- When multiple GaussDB data sources are configured in the same project, if **logger** is set to **Slf4JLogger** in some services, it will affect the logging configuration of each other. In this case, you are advised to configure the connection strings in a unified manner.

Method 2: Use the JdkLogger log framework for interconnecting with applications. You can use the **logging.properties** configuration file or configure the parameters in the sample code.

1. The default Java logging framework stores its configurations in a file named **logging.properties**. Java installs the global configuration file in the folder in the Java installation directory. The **logging.properties** file can also be created and stored with a single project.

logging.properties configuration file:

```
# Specify the processing program as a file.
handlers= java.util.logging.FileHandler

# Specify the default global log level.
.level= ALL

# Specify the log output control standard.
java.util.logging.FileHandler.level=ALL
java.util.logging.FileHandler.pattern = gsjdbc.log
java.util.logging.FileHandler.limit = 500000
java.util.logging.FileHandler.count = 30
java.util.logging.FileHandler.formatter = java.util.logging.SimpleFormatter
java.util.logging.FileHandler.append=false
```

2. Configure the parameters in the sample code:

```
System.setProperty("java.util.logging.FileHandler.pattern","jdbc.log");
FileHandler fileHandler = new FileHandler(System.getProperty("java.util.logging.FileHandler.pattern"));
Formatter formatter = new SimpleFormatter();
fileHandler.setFormatter(formatter);
Logger logger = Logger.getLogger("com.huawei.opengauss.jdbc");
logger.addHandler(fileHandler);
logger.setLevel(Level.ALL);
logger.setUseParentHandlers(false);
```

Link Trace Function

The GaussDB JDBC driver provides the application-to-database link trace function to associate discrete SQL statements on the database side with application requests. This function requires application developers to implement the `com.huawei.opengauss.jdbc.log.Tracer` API class and specify the full name of the API implementation class in the URL.

URL example:

```
String URL = "jdbc:opengauss://$ip:$port/database?traceInterfaceClass=xxx.xxx.xxx.OpenGaussTraceImpl";
```

The `com.huawei.opengauss.jdbc.log.Tracer` API class is defined as follows:

```
public interface Tracer {
    // Retrieves the value of traceId.
    String getTraceId();
}
```

The following is an example of the `com.huawei.opengauss.jdbc.log.Tracer` API implementation class:

```
import com.huawei.opengauss.jdbc.log.Tracer;

public class OpenGaussTraceImpl implements Tracer {
    private static MDC mdc = new MDC();

    private final String TRACE_ID_KEY = "traceId";

    public void set(String traceId) {
        mdc.put(TRACE_ID_KEY, traceId);
    }

    public void reset() {
        mdc.clear();
    }

    @Override
    public String getTraceId() {
```

```
        return mdc.get(TRACE_ID_KEY);
    }
}
```

The following is an example of context mapping which is used to store trace IDs generated for different requests:

```
import java.util.HashMap;

public class MDC {
    static final private ThreadLocal<HashMap<String, String>> threadLocal = new ThreadLocal<>();

    public void put(String key, String val) {
        if (key == null || val == null) {
            throw new IllegalArgumentException("key or val cannot be null");
        } else {
            if (threadLocal.get() == null) {
                threadLocal.set(new HashMap<>());
            }
            threadLocal.get().put(key, val);
        }
    }

    public String get(String key) {
        if (key == null) {
            throw new IllegalArgumentException("key cannot be null");
        } else if (threadLocal.get() == null) {
            return null;
        } else {
            return threadLocal.get().get(key);
        }
    }

    public void clear() {
        if (threadLocal.get() == null) {
            return;
        } else {
            threadLocal.get().clear();
        }
    }
}
```

Take the service **traceld** as an example. The prerequisite is that the table **test_trace_id (id int,name varchar(20))** is created.

```
String traceld = UUID.randomUUID().toString().replaceAll("-", "");
OpenGaussTraceImpl openGaussTrace = new OpenGaussTraceImpl();
openGaussTrace.set(traceld);
Connection con = DriverManager.getConnection(url, user, password);
pstmt = con.prepareStatement("select * from test_trace_id where id = ?");
pstmt.setInt(1, 1);
pstmt.execute();
pstmt = con.prepareStatement("insert into test_trace_id values(?,?)");
pstmt.setInt(1, 2);
pstmt.setString(2, "test");
pstmt.execute();
openGaussTrace.reset();
```

NOTE

- When the link trace function is used, the link function at the application layer is guaranteed by services.
- The application must expose the API for obtaining **traceld** to the JDBC and configure the API implementation class to the JDBC connection string.
- SQL statements of the same request must use the same **traceld**.
- The value of **traceld** transferred by the application cannot exceed 32 bytes. Otherwise, the extra bytes will be truncated.

5.8.1.3 Troubleshooting

5.8.1.3.1 Incorrect batchMode Settings

Symptom

Set the URL parameters **batchMode** to **on** and **reWriteBatchedInserts** to **true**. After JDBC is used to insert data in batches, a message is displayed, indicating that the number of binding parameters is inconsistent with the number of parameters required by the statement.

bind message supplies * parameters, but prepared statement "" requires *

Example 1:

```
// conn is a created connection object. The URL parameters for creating the connection contain
// &batchMode=on&reWriteBatchedInserts=true.
// Bind parameters in batches and then execute the statement. The number of bound parameters does not
// match the number of columns in the rewritten INSERT statement. As a result, an exception is reported.
// java.sql.BatchUpdateException: bind message supplies 3 parameters, but prepared statement "" requires 6
PreparedStatement stmt = conn.prepareStatement("insert into test_tbl values (?, ?, ?)");

stmt.setInt(1, 1);
stmt.setString(2, "aaa");
stmt.setString(3, "bbbb");
stmt.addBatch();

stmt.setInt(1, 1);
stmt.setString(2, "aaa");
stmt.setString(3, "bbbb");
stmt.addBatch();

stmt.setInt(1, 1);
stmt.setString(2, "aaa");
stmt.setString(3, "bbbb");
stmt.addBatch();

stmt.executeBatch();
```

Cause Analysis

When **reWriteBatchedInserts** is set to **true**, the batch statement combines multiple SQL statements into one. As a result, the number of reserved parameter columns in the statement changes. If **batchMode** is set to **on**, parameters are bound based on the SQL statements before combination. As a result, the number of bound parameters is inconsistent with the number of parameters required by the statement.

Solution

If **reWriteBatchedInserts** is set to **true**, **batchMode** is set to **off**.

5.8.1.3.2 Error Is Reported or Connection Is Blocked in SSL Mode

Symptom

When JDBC establishes a connection in SSL mode, a strong random number is obtained on the client. During the connection establishment, the following error information may be reported.

Scenario 1: Error report.

```
"Thread-0" #18 prio=5 os_prio=0 tid=0x00007f2ad0385000 nid=0x5429 runnable [0x00007f2aa069b000]
java.lang.Thread.State: RUNNABLE
    at java.io.FileInputStream.readBytes(Native Method)
    at java.io.FileInputStream.read(FileInputStream.java:255)
    at sun.security.provider.NativePRNG$RandomIO.readFully(NativePRNG.java:424)
    at sun.security.provider.NativePRNG$RandomIO.ensureBufferValid(NativePRNG.java:526)
    at sun.security.provider.NativePRNG$RandomIO.implNextBytes(NativePRNG.java:545)
    - locked <0x000000067273a950> (a java.lang.Object)
    at sun.security.provider.NativePRNG$RandomIO.access$400(NativePRNG.java:331)
    at sun.security.provider.NativePRNG$Blocking.engineNextBytes(NativePRNG.java:268)
    at java.security.SecureRandom.nextBytes(SecureRandom.java:468)
    at java.security.SecureRandom.next(SecureRandom.java:491)
    at java.util.Random.nextInt(Random.java:329)
    at sun.security.ssl.SSLContextImpl.engineInit(SSLContextImpl.java:106)
    at javax.net.ssl.SSLContext.init(SSLContext.java:282)
    at org.postgresql.ssl.LibPQFactory.<init>(LibPQFactory.java:175)
    at org.postgresql.core.SocketFactoryFactory.getSslSocketFactory(SocketFactoryFactory.java:62)
    at org.postgresql.ssl.MakeSSL.convert(MakeSSL.java:33)
    at org.postgresql.core.v3.ConnectionFactoryImpl.enableSSL(ConnectionFactoryImpl.java:723)
    at org.postgresql.core.v3.ConnectionFactoryImpl.tryConnect(ConnectionFactoryImpl.java:203)
    at org.postgresql.core.v3.ConnectionFactoryImpl.openConnectionImpl(ConnectionFactoryImpl.java:330)
    at org.postgresql.core.ConnectionFactory.openConnection(ConnectionFactory.java:58)
    at org.postgresql.jdbc.PgConnection.<init>(PgConnection.java:357)
```

Scenario 2: The connection is blocked. If **loginTimeout** is set in the connection string, the message "Connection attempt timed out" is displayed. If this parameter is not set, the connection is blocked.

Cause Analysis

The random number generation on the client is too slow to meet product requirements. The entropy source is insufficient. As a result, the service fails to be started. This problem exists in some Linux environments.

Solution

Solution 1: Start the haveged service on the client and increase the entropy value of the system entropy pool to improve the speed of reading random numbers. The startup command is as follows:

```
systemctl start haveged
```

Solution 2: Adjust the JDK configuration on the client.

Open the `$JAVA_PATH/jre/lib/security/java.security` file and modify the following configuration items:

```
securerandom.source=file:/dev/.urandom
securerandom.strongAlgorithms=NativePRNGNonBlocking:SUN
```

NOTICE

The essence of solution 2 is to use pseudo-random numbers instead of strong random numbers to reduce the entropy value to be consumed. All applications that use the JDK on the client are affected. Pseudo-random numbers are used to instead of strong random numbers.

5.8.2 libpq

5.8.2.1 Connection Parameters

Table 5-91 Connection parameters

Parameter	Description
host	Name of the host to connect to. If the host name starts with a slash (/), UDS communications instead of TCP/IP communications are used. The value is the directory where the socket file is stored. If host is not specified, the default behavior is to connect to the UDS in the /tmp directory (or the socket directory specified during database installation). On a machine without a UDS, the default behavior is to connect to localhost. You can specify multiple host names by using a character string separated by commas (.). Multiple host names can be specified.
hostaddr	IP address of the host to connect to. The value is in standard IPv4 address format, for example, 172.28.40.9. If the machine supports IPv6, IPv6 address can also be used. If a non-null string is specified, TCP/IP communications are used. You can specify multiple IP addresses by using a character string separated by commas (.). Multiple IP addresses can be specified. Replacing host with hostaddr can prevent applications from querying host names, which may be important for applications with time constraints. However, a host name is required for GSSAPI or SSPI authentication methods. Therefore, the following rules are used: 1. If host is specified but hostaddr is not, a query for the host name will be executed. 2. If hostaddr is specified but host is not, the value of hostaddr is the server network address. If the host name is required for authentication, the connection attempt fails. 3. If both host and hostaddr are specified, the value of hostaddr is the server network address. The value of host is ignored unless it is required by authentication, in which case it is used as the host name. NOTICE • If host is not the server name in the network address specified by hostaddr, the authentication may fail. • If neither host nor hostaddr is specified, libpq will use a local UDS for connection. If the machine does not have a UDS, it will attempt to connect to localhost.
port	Port number of the host server, or the socket file name extension for UDS connections. You can specify multiple port numbers by using a character string separated by commas (.). Multiple port numbers can be specified.
user	Name of the user to be connected. By default, the username is the same as the OS name of the user running the application.
dbname	Database name. The default value is the same as the username.

Parameter	Description
password	Password to be used if the server requires password authentication.
connect_timeout	Maximum timeout period of the connection, in seconds (written as a decimal integer string). The value 0 or null indicates infinity. You are advised not to set the connection timeout period to a value less than 2 seconds.
client_encoding	Client encoding for the connection. In addition to the values accepted by the corresponding server options, you can use auto to determine the correct encoding from the current environment in the client (the <i>LC_CTYPE</i> environment variable in the Unix system).
tty	This parameter can be ignored. (This parameter was used to specify the location to which the debugging output of the server was sent).
options	Adds command-line options to send to the server at runtime.
application_name	Current user identity.
fallback_application_name	Specifies a backup value for the application_name parameter. This value is used if no value is set for application_name through a connection parameter or the <i>PGAPPNAME</i> environment variable. In a common tool program, if you set a default name but do not want the default name to be overwritten by the user, you can specify a backup value.
keepalives	Specifies whether TCP keepalive is enabled on the client side. The default value is 1 , indicating that the function is enabled. The value 0 indicates that the function is disabled. Ignore this parameter for UDS connections.
keepalives_idle	The number of seconds of inactivity after which TCP should send a keepalive message to the server. The value 0 indicates that the default value is used. Ignore this parameter for UDS connections or if keepalive is disabled.
keepalives_interval	The number of seconds after which a TCP keepalive message that is not acknowledged by the server should be retransmitted. The value 0 indicates that the default value is used. Ignore this parameter for UDS connections or if keepalive is disabled.
keepalives_count	Controls the number of times that keepalive messages are sent through TCP. The value 0 indicates that the default value is used. Ignore this parameter for UDS connections or if keepalive is disabled.

Parameter	Description
tcp_user_timeout	Specifies the maximum duration for which transmitted data can remain unacknowledged before the TCP connection is forcibly closed on an OS that supports the TCP_USER_TIMEOUT socket option. The value 0 indicates that the default value is used. Ignore this parameter for UDS connections.
rw_timeout	Sets the read and write timeout interval of the client connection. When the timeout is triggered on the libpq and the connection is closed, the running services delivered by the libpq to the database are forcibly terminated. This capability is controlled by the GUC parameter check_disconnect_query . If this parameter is set to on , the capability is supported. If this parameter is set to off , the capability is not supported.
sslmode	Specifies whether to enable SSL encryption. • disable: SSL connection is disabled. • allow: If the database server requires SSL connection, SSL connection can be enabled. However, authenticity of the database server will not be verified. • prefer: If the database supports SSL connection, SSL connection is preferred. However, authenticity of the database server will not be verified. • require: SSL connection is required and data is encrypted. However, authenticity of the database server will not be verified. • verify-ca: SSL connection is required. Currently, Windows ODBC does not support cert authentication. • verify-full: SSL connection is required. Currently, Windows ODBC does not support cert authentication.
sslcompression	If the value is 1 (default value), the data transmitted over the SSL connection is compressed (this requires that the OpenSSL version be 0.9.8 or later). If the value is 0 , compression will be disabled (this requires OpenSSL 1.0.0 or later). If a connection without SSL is established, this parameter is ignored. If the OpenSSL version in use does not support this parameter, it will also be ignored. Compression takes up CPU time, but it increases throughput when the bottleneck is the network. If CPU performance is a limiting factor, disabling compression can improve response time and throughput.
sslcert	This parameter specifies the file name of the client SSL certificate. If no SSL connection is established, this parameter is ignored.
sslkey	This parameter specifies the location of the key used for the client certificate. It can specify a key obtained from an external "engine" (the engine is a loadable module of OpenSSL). The description of an external engine should consist of a colon-separated engine name and an engine-related key identifier. If no SSL connection is established, this parameter is ignored.

Parameter	Description
sslrootcert	This parameter specifies the name of a file that contains the SSL Certificate Authority (CA) certificate. If the file exists, the system authenticates the server certificate issued by one of these authorities.
sslcr	This parameter specifies the file name of the SSL Certificate Revocation List (CRL). If a certificate listed in this file exists, the server certificate authentication will be rejected.
requirepeer	This parameter specifies the OS user of the server, for example, requirepeer=postgres . When a UDS connection is established, if this parameter is set, the client checks whether the server process is running under the specified username at the beginning of the connection. If not, the connection will be interrupted by an error. This parameter can be used to provide server authentication similar to that of the SSL certificate on TCP/IP connections. (Note that if the UDS is in /tmp or another public writable location, any user can start a server for listening on the location. Use this parameter to ensure that you are connected to a server that is run by a trusted user.) This option is supported only on platforms that implement the peer authentication method.
krbsrvname	This parameter specifies the Kerberos service name used for GSSAPI authentication. For successful Kerberos authentication, this value must match the service name specified in the server configuration.
gsslib	This parameter specifies the GSS library used for GSSAPI authentication. It is used only in the Windows OS. If the value is gssapi , libpq is forced to use the GSSAPI library to replace the default SSPI for authentication.
service	This parameter specifies the name of the service for which the additional parameter is used. It specifies a service name in pg_service.conf that holds the additional connection parameters. This allows the application to specify only one service name so that the connection parameters can be centrally maintained.
authtype	authtype is no longer used, so it is marked as a parameter not to be displayed. It is retained in an array so as not to reject the conninfo string from old applications that might still try to set it.
remote_node_name	Specifies the name of the remote node connected to the local node.
localhost	Specifies the localhost in a connection channel.
localport	Specifies the local port in a connection channel.

Parameter	Description
fencedUdfRPCMode	Specifies whether the fenced UDF RPC protocol uses UDSs or special socket file names. The default value is 0 , indicating that the UDS mode is used and the file type is <code>.s.PGSQL.%d</code> . To use the fenced UDF mode, set this parameter to 1 . In this case, the file type is <code>.s.fencedMaster_unixdomain</code> .
replication	Specifies whether the connection should use replication protocols instead of common protocols. Protocols with this parameter configured are internal protocols used for PostgreSQL replication connections and tools such as pg_basebackup, while they can also be used by third-party applications. The following values, which are case-insensitive, are supported: • true, on, yes, and 1: Specify that the physical replication mode is connected. • database: Specifies that the logical replication mode and the database specified by dbname are connected. • false, off, no, and 0: Specify that the connection is a regular connection, which is the default behavior. In physical or logical replication mode, only simple query protocols can be used.
backend_version	Specifies the backend version to be passed to the remote end.
prototype	Sets the current protocol level. The default value is PROTO_TCP .
connection_info	The value of connection_info is a JSON character string consisting of driver_name, driver_version, driver_path, and os_user. If the value is not null, use connection_info and ignore connectionExtraInf. If the value is null, a connection information string related to libpq is generated. When connectionExtraInf is set to false, the value of connection_info consists of only driver_name and driver_version.
connectionExtraInf	Specifies whether the value of connection_info contains extension information. The default value is 0 . If the value contains other information, set this parameter to 1 .

Parameter	Description
target_session_attrs	Specifies the type of the host to be connected. The connection is successful only when the host type is the same as the configured value. The rules for setting target_session_attrs are as follows: • any (default value): All types of hosts can be connected. • read-write: The connection is set up only when the connected host is readable and writable. • read-only: Only readable hosts can be connected. • primary: Only the primary node in the primary/standby system can be connected. • standby: Only the standby node in the primary/standby system can be connected. • prefer-standby: The system first attempts to find a standby node for connection. If all hosts in the hosts list fail to be connected, try the any mode.

5.8.3 Parameters Related to Log Output

To control the output of log files and better understand the operating status of the database, modify specific configuration parameters in the **postgresql.conf** file in the instance data directory.

[Table 5-92](#) describes the adjustable configuration parameters.

Table 5-92 Configuration parameters

Parameter	Description	Value Range	Remarks
client_min_messages	Level of messages to be sent to clients.	• DEBUG5 • DEBUG4 • DEBUG3 • DEBUG2 • DEBUG1 • LOG • NOTICE • WARNING • ERROR • FATAL • PANIC Default value: NOTICE	Messages of the set level or lower will be sent to clients. The lower the level is, the fewer the messages will be sent.

Parameter	Description	Value Range	Remarks
log_min_messages	Level of messages to be recorded in server logs.	• DEBUG5 • DEBUG4 • DEBUG3 • DEBUG2 • DEBUG1 • INFO • NOTICE • WARNING • ERROR • LOG • FATAL • PANIC Default value: WARNING	Messages higher than the set level will be recorded in logs. The higher the level is, the fewer the server logs will be recorded.
log_min_error_statement	Level of SQL error statements to be recorded in server logs.	• DEBUG5 • DEBUG4 • DEBUG3 • DEBUG2 • DEBUG1 • INFO • NOTICE • WARNING • ERROR • FATAL • PANIC Default value: ERROR	SQL error statements of the set level or higher will be recorded in server logs. Only a system administrator is allowed to modify this parameter.

Parameter	Description	Value Range	Remarks
log_min_duration_statement	Minimum execution duration of a statement. If the execution duration of a statement is equal to or longer than the set milliseconds, the statement and its duration will be recorded in logs. Enabling this function can help you track the query attempts to be optimized.	INT type Default value: 30min Unit: millisecond	The value -1 indicates that the function is disabled. Only a system administrator is allowed to modify this parameter.
log_connections/ log_disconnections	Specifies whether to record a server log message when each session is connected or disconnected.	• on: The system records a log server when each session is connected or disconnected. • off: The system does not record a log server when each session is connected or disconnected. Default value: off	-
log_duration	Specifies whether to record the duration of each executed statement.	• on: The system records the duration of each executed statement. • off: The system does not record the duration of each executed statement. Default value: off	Only a system administrator is allowed to modify this parameter.

Parameter	Description	Value Range	Remarks
log_statement	SQL statements to be recorded in logs.	• none: The system does not record any SQL statements. • ddl: The system records data definition statements. • mod: The system records data definition statements and data operation statements. • all: The system records all statements. Default value: none	Only a system administrator is allowed to modify this parameter.
log_hostname	Specifies whether to record host names.	• on: The system records host names. • off: The system does not record host names. Default value: off	By default, connection logs only record the IP addresses of connected hosts. With this function, the host names will also be recorded. This parameter has an impact on viewing audit results, GS_SESSION_MEMORY_DETAIL , PG_STAT_ACTIVITY , and the parameter log_line_prefix .

[Table 5-93](#) describes the preceding parameter levels.

Table 5-93 Description of log level parameters

Level	Description
DEBUG[1-5]	Provides information that can be used by developers. Level 1 is the lowest level whereas level 5 is the highest level.
INFO	Provides information about users' hidden requests, for example, information about the VACUUM VERBOSE process.

Level	Description
NOTICE	Provides information that may be important to users, for example, truncations of long identifiers or indexes created as a part of a primary key.
WARNING	Provides warning information for users, for example, COMMIT out of transaction blocks.
ERROR	Reports an error that causes a command to terminate.
LOG	Reports information that administrators may be interested in, for example, the activity levels of check points.
FATAL	Reports the reason that causes a session to terminate.
PANIC	Reports the reason that causes all sessions to terminate.

6 SQL Optimization

The aim of SQL optimization is to maximize the utilization of resources, including CPU, memory, and disk I/O. All optimization methods are intended for resource utilization. To maximize resource utilization is to run SQL statements as efficiently as possible to achieve the highest performance at a lower cost. For example, when performing a typical point query, you can use a Seq Scan and a filter (that is, read every tuple and point query conditions for match). You can also use an Index Scan, which can be implemented at a lower cost but achieve the same effect.

You can determine a proper database deployment solution and table definition based on hardware resources and service characteristics. This is the basis of meeting performance requirements. The following performance tuning sections assume that you have finished installation based on a proper database solution in the software installation guide and performed database design based on the guide for database design and development.

6.1 Query Execution Process

The process from receiving SQL statements to the statement execution by the SQL engine is shown in [Figure 6-1](#) and described in [Table 6-1](#). The texts in red are steps where database administrators can optimize queries.

Figure 6-1 Execution process of query-related SQL statements by the SQL engine**Table 6-1** Execution process of query-related SQL statements by the SQL engine

Step	Description
1. Perform syntax and lexical parsing.	Converts the input SQL statements from the string data type to the formatted structure stmt based on the specified SQL statement rules.
2. Perform semantic parsing.	Converts the formatted structure obtained from the previous step into objects that can be recognized by the database.
3. Rewrite the query statements.	Converts the output of the previous step into the structure that optimizes the query execution.
4. Optimize the query.	Determines the execution mode of SQL statements (the execution plan) based on the result obtained from the previous step and the internal database statistics. For details about how the internal database statistics and GUC parameters affect the query optimization (execution plan), see Optimizing Queries Using Statistics and Optimizing Queries Using GUC parameters .
5. Perform the query.	Executes the SQL statements based on the execution path specified in the previous step. Selecting a proper underlying storage mode improves the query execution efficiency.

Optimizing Queries Using Statistics

The GaussDB optimizer is a typical Cost-based Optimization (CBO). By using CBO, the database calculates the number of tuples and the execution cost for each step under each execution plan based on the number of table tuples, column width, null record ratio, and characteristic values, such as distinct, MCV, and HB values, and certain cost calculation methods. The database then selects the execution plan that takes the lowest cost for the overall execution or for the return of the first tuple. These characteristic values are the statistics, which is the core for optimizing a query. Accurate statistics helps the planner select the most appropriate query plan. Generally, you can collect statistics of a table or that of some columns in a table using **ANALYZE**. You are advised to periodically execute **ANALYZE** or execute it immediately after you modified most contents in a table.

Note that DDL operations may cause statistics to change, resulting in plan changes. After DDL operations are performed on a table, check whether statistics need to be collected again.

Optimizing Queries Using GUC parameters

Optimizing queries aims to select an efficient execution mode.

Take the following SQL statement as an example:

```
select count(1)
from customer inner join store_sales on (ss_customer_sk = c_customer_sk);
```

During execution of **customer inner join store_sales**, GaussDB supports nested loop, merge join, and hash join. The optimizer estimates the result set size and the execution cost of each join mode based on the statistics on the **customer** and **store_sales** tables. It then compares the costs and selects the one costing the least.

As mentioned above, the execution cost is calculated based on certain methods and statistics. If the actual execution cost cannot be accurately estimated, you need to optimize the execution plan by setting GUC parameters. For example, the **random_page_cost** parameter indicates the optimizer's calculation of the cost of a non-sequentially-fetched disk page. The default value is **4**. When the random read speed of a machine disk (for example, an SSD) is high, you can decrease the value of this parameter. After the change, the cost of index scan is reduced, and the index scan mode is preferred when a plan is generated.

Optimizing Queries by Rewriting SQL Statements

Besides the preceding methods that improve the performance of the execution plan generated by the SQL engine, database administrators can also enhance SQL statement performance by rewriting SQL statements while retaining the original service logic based on the execution mechanism of the database and abundant practices.

This requires that database administrators know the customer services well and have professional knowledge of SQL statements. Below chapters will describe some common SQL rewriting scenarios.

6.2 Introduction to the SQL Execution Plan

6.2.1 Overview

The SQL execution plan is a node tree, which displays detailed procedure when GaussDB runs an SQL statement. A database operator indicates one step.

You can run the **EXPLAIN** command to view the execution plan generated for each query by an optimizer. The output of **EXPLAIN** has one row for each execution node, showing the basic node type and the cost estimation that the optimizer made for the execution of this node. For details, see [Figure 6-2](#).

Figure 6-2 SQL execution plan example

```
openGauss=# explain select *from t1, t2 where t1.c1=t2.c2;
               QUERY PLAN
-----
Hash Join (cost=58.35..355.67 rows=23091 width=16)
-> Seq Scan on t1 (cost=0.00..31.49 rows=2149 width=8)
-> Hash (cost=31.49..31.49 rows=2149 width=8)
    -> Seq Scan on t2 (cost=0.00..31.49 rows=2149 width=8)
(5 rows)
```

- Nodes at the bottom level are scan nodes. They scan tables and return raw rows. The types of scan nodes (sequential scans and index scans) vary depending on the table access methods. Objects scanned by the bottom layer nodes may not be row-store data (not directly read from a table), such as **VALUES** clauses and functions that return rows, which have their own types of scan nodes.
- If the query requires join, aggregation, sorting, or other operations on the raw rows, there will be other nodes above the scan nodes to perform these operations. In addition, there is more than one way to perform these operations, so different types of execution nodes may be displayed here.
- The first row (the upper-layer node) estimates the total execution cost of the execution plan. Such an estimate indicates the value that the optimizer tries to minimize.

Execution Plan Display Format

GaussDB provides four display formats: normal, pretty, summary, and run.

- normal: indicates that the default printing format is used.
- pretty: indicates that the new plan display format improved by GaussDB is used. The new format contains a plan node ID, directly and effectively analyzing performance.
- summary: indicates that the printing information analysis is added based on the pretty format.
- run: indicates that the information based on the summary format is exported as a CSV file for further analysis.

An example of an execution plan using the pretty format is as follows:

```
explain select * from t1,t2 where t1.c1=t2.c2;
id | operation | E-rows | E-width | E-costs
-----+-----+-----+-----+-----
1 | -> Hash Join (2,3) | 23091 | 16 | 58.353..355.674
2 | -> Seq Scan on t1 | 2149 | 8 | 0.000..31.490
3 | -> Hash | 2149 | 8 | 31.490..31.490
4 | -> Seq Scan on t2 | 2149 | 8 | 0.000..31.490
(4 rows)

Predicate Information (identified by plan id)
-----
1 --Hash Join (2,3)
Hash Cond: (t1.c1 = t2.c2)
(2 rows)
```

You can change the display format of execution plans by setting the GUC parameter **explain_perf_mode**. Later examples use the pretty format by default.

Execution Plan Information

In addition to setting different display formats for an execution plan, you can use different **EXPLAIN** syntax to display execution plan information in detail. The following lists the common EXPLAIN syntax. For more EXPLAIN syntax, see [EXPLAIN](#).

- **EXPLAIN *statement***: only generates an execution plan and does not execute. The *statement* indicates SQL statements.
- **EXPLAIN ANALYZE *statement***: generates and executes an execution plan, and displays the execution summary. Then actual execution time statistics are added to the display, including the total elapsed time expended within each plan node (in milliseconds) and the total number of rows it actually returned.
- **EXPLAIN PERFORMANCE *statement***: generates and executes the execution plan, and displays all execution information.

To measure the run time cost of each node in the execution plan, the current execution of EXPLAIN ANALYZE or EXPLAIN PERFORMANCE adds profiling overhead to query execution. Running **EXPLAIN ANALYZE** or **EXPLAIN PERFORMANCE** on a query sometimes takes more time than a normal query. The amount of overhead depends on the nature of the query, as well as the platform being used.

Therefore, if an SQL statement is not finished after being running for a long time, run the **EXPLAIN** statement to view the execution plan and then locate the fault. If the SQL statement has been properly executed, execute the EXPLAIN ANALYZE or EXPLAIN PERFORMANCE statement to check the execution plan and information to locate the fault.

6.2.2 Description

As described in [Overview](#), EXPLAIN displays the execution plan, but will not actually run SQL statements. **EXPLAIN ANALYZE** and **EXPLAIN PERFORMANCE** both will actually run SQL statements and return the execution information. This section describes the execution plan and execution information in detail.

Execution Plans

The following SQL statement is used as an example:

```
SELECT * FROM t1, t2 WHERE t1.c1 = t2.c2;
```

Run the **EXPLAIN** command and the output is as follows:

```
openGauss=# explain select *from t1, t2 where t1.c1=t2.c2;
               QUERY PLAN
-----
Hash Join (cost=58.35..355.67 rows=23091 width=16)
-> Seq Scan on t1 (cost=0.00..31.49 rows=2149 width=8)
-> Hash (cost=31.49..31.49 rows=2149 width=8)
    -> Seq Scan on t2 (cost=0.00..31.49 rows=2149 width=8)
(5 rows)
```

Interpretation of the execution plan level (vertical):

1. Layer 1: **Seq Scan on t2**

The table scan operator scans the table **t2** using **Seq Scan**. At this layer, data in the table **t2** is read from a buffer or disk, and then transferred to the upper-layer node for calculation.

2. Layer 2: **Hash**

Hash operator. It is used to calculate the hash value of the operator transferred from the lower layer for subsequent hash join operations.

3. Layer 3: **Seq Scan on t1**

The table scan operator scans the table **t1** using **Seq Scan**. At this layer, data in the table **t1** is read from a buffer or disk, and then transferred to the upper-layer node for hash join calculation.

4. Layer 4: **Hash Join**

Join operator. It is used to join data in the **t1** and **t2** tables using the hash join method and output the result data.

Keywords in the execution plan:

1. Table access modes

- Seq Scan

Scans all rows of the table in sequence.

- Index Scan

The optimizer uses a two-step plan: the child plan node visits an index to find the locations of rows matching the index condition, and then the upper plan node actually fetches those rows from the table itself. Fetching rows separately is much more expensive than reading them sequentially, but because not all pages of the table have to be visited, this is still cheaper than a sequential scan. The upper-layer planning node sorts index-identified rows based on their physical locations before reading them. This minimizes the independent capturing overhead.

If there are separate indexes on multiple columns referenced in **WHERE**, the optimizer might choose to use an **AND** or **OR** combination of the indexes. However, this requires the visiting of both indexes, so it is not

necessarily a win compared to using just one index and treating the other condition as a filter.

Index scans can be classified into the following types based on the index sorting mechanism:

- Bitmap index scan
Fetches data pages using a bitmap.
- Index scan using index_name
Uses simple index search, which fetches data from an index table in the sequence of index keys. This mode is commonly used when only a small amount of data needs to be fetched from a large data table or when the ORDER BY condition is used to match the index sequence to reduce the sorting time.
- Index-Only Scan
Scans the index that contains all required data, instead of referencing a table.
- Bitmap Heap Scan
Reads pages from bitmaps created by other operations and filters out the rows that do not meet the conditions. Bitmap heap scan can avoid random I/Os and accelerate read speed.
- TID Scan
Scans a table by a tuple ID.
- Index Ctid Scan
Scans a table based on the CTID index.
- CTE Scan
Specifies that CTE evaluates subquery operations and stores query results as a temporary table. The temporary table is scanned by the CTE Scan operator.
- Foreign Scan
Reads data from a remote data source.
- Function Scan
Obtains result sets returned by functions and returns them as the rows read from tables.
- Sample Scan
Queries and returns sampled data.
- Subquery Scan
Reads subquery results.
- Values Scan
Reads constants as part of the **VALUES** command.
- WorkTable Scan
Scans a work table. Data is read in the middle of an operation which is usually a recursive operation declared using WITH RECURSIVE.
- CStore Index Ctid Scan
Scans a table based on an index and returns a qualified TID set.

- CStore Index Heap Scan
Performs the intersection, difference, and union operations of TID sets, and obtains corresponding tuple based on set results.
- 2. Table connection modes
 - Nested Loop
A nested loop is used for queries that have a smaller data set connected. In a nested-loop join, the outer table drives the inner table and each row returned from the outer table should have a matching row in the inner table. The returned result set of all queries should be less than 10,000. The table that returns a smaller subset will work as an outer table, and indexes are recommended for connection columns of the inner table.
 - (Sonic) Hash Join
A hash join is used for large tables. The optimizer uses a hash join, in which rows of one table are entered into an in-memory hash table, after which the other table is scanned and the hash table is probed for matches to each row. Sonic and non-Sonic hash joins differ in their hash table structures, which do not affect the execution result set.
 - Merge Join
In most cases, the execution performance of a merge join is lower than that of a hash join. However, if the source data has been pre-sorted and no more sorting is needed during the merge join, its performance excels.
- 3. Operators
 - sort
Sorts the result set.
 - filter
The **EXPLAIN** output shows the **WHERE** clause being applied as a **Filter** condition attached to the **Seq Scan** plan node. This means that the plan node checks the condition for each row it scans, and returns only the ones that meet the condition. The estimated number of output rows has been reduced because of the **WHERE** clause. However, the scan will still have to visit all 10,000 rows, as a result, the cost is not decreased. It increases a bit (by 10,000 x **cpu_operator_cost**) to reflect the extra CPU time spent on checking the **WHERE** condition.
 - LIMIT
Limits the number of output execution results. If a **LIMIT** condition is added, not all rows are retrieved.
 - Append
Appends sub-operation results.
 - Aggregate
Aggregates the results generated from querying row. It can be an aggregation of statements such as GROUP BY, UNION, and SELECT DISTINCT.
 - BitmapAnd
Specifies the AND operation of a bitmap, which is used to form a bitmap that matches more complex conditions.
 - BitmapOr

- Specifies the OR operation of a bitmap, which is used to form a bitmap that matches more complex conditions.
- Gather
Gathers data of parallel threads.
- Group
Groups rows to perform the GROUP BY operation.
- GroupAggregate
Aggregates the pre-sorted rows of the GROUP BY operation.
- Hash
Hashes rows for the parent query. It is usually used to perform the JOIN operation.
- HashAggregate
Aggregates the result rows of GROUP BY by using a hash table.
- Merge Append
Merges subquery results in a way that preserves the sort order. It can be used to merge sorted rows in a table partition.
- Recursive Union
Performs a union operation on all steps of a recursive function.
- SetOp
Specifies a set operation, such as INTERSECT or EXCEPT.
- Unique
Removes duplicates from an ordered result set.
- HashSetOp
Specifies a strategy for set operations such as INTERSECT or EXCEPT. It uses Append to avoid pre-sorted input.
- LockRows
Locks problematic rows to prevent other queries from writing, but allows reading.
- Materialize
Stores subquery results in the memory so that the parent query can quickly access and obtain the subquery results.
- Result
Returns a value (such as a hard-coded value) without scanning.
- WindowAgg
Specifies a window aggregate function, which is triggered by the OVER statement.
- Merge
Performs a merge operation.
- StartWith Operator
Specifies the hierarchical query operator, which is used to perform recursive query operations.
- Index Cond
Specifies the index scan conditions.

- Cstore Index And
Performs the intersection operation of TID sets with CStore Index Heap Scan.
 - Cstore Index Or
Performs the union operation of TID sets with CStore Index Heap Scan.
4. Other keywords
- Partitioned
Indicates operations on a specific partition.
 - Partition Iterator
Partition iterator, which usually indicates that a subquery is an operation on a partition.
 - InitPlan
Indicates a non-related subplan.

Execution Information

The execution result of the following SQL statement in pretty mode is used as an example:

```
select sum(t2.c1) from t1,t2 where t1.c1=t2.c2 group by t1.c2;
```

The output of running EXPLAIN PERFORMANCE is as follows:

```
explain performance select sum(t2.c1) from t1,t2 where t1.c1=t2.c2 group by t1.c2;
id | operation | A-time | A-rows | E-rows | E-distinct | Peak Memory | A-width | E-width | E-costs
-----+-----+-----+-----+-----+-----+-----+-----+-----+-----
1 | -> HashAggregate | 0.574 | 0 | 200 | | 29KB | | 8 |
396.113..398.113
2 | -> Hash Join (3,4) | 0.358 | 0 | 18915 | 200, 200 | 12KB | | 8 |
53.763..301.538
3 | -> Seq Scan on public.t1 | 0.037 | 1 | 1945 | | 22KB | | 8 | 0.000..29.450
4 | -> Hash | 0.038 | 0 | 1945 | | 264KB | | 8 | 29.450..29.450
5 | -> Seq Scan on public.t2 | 0.029 | 30 | 1945 | | 22KB | | 8 | 0.000..29.450

Total runtime: 0.866 ms
(6 rows)
```

In the preceding example, the execution information consists of the following parts:

1. The plan is displayed as a table, which contains 11 columns: **id**, **operation**, **A-time**, **A-rows**, **E-rows**, **E-distinct**, **Peak Memory**, **E-memory**, **A-width**, **E-width**, and **E-costs**. The meanings of the plan-type columns (**id**, **operation**, or columns started with **E**) are the same as those when EXPLAIN is executed. For details, see [Execution Plans](#). The definition of **A-time**, **A-rows**, **E-distinct**, **Peak Memory**, and **A-width** are described as follows:
 - **A-time**: execution completion time of the current operator.
 - **A-rows**: number of actual output tuples of the operator
 - **E-distinct**: estimated distinct value of the hash join operator
 - **Peak Memory**: peak memory used by the operator during execution.
 - **A-width**: actual tuple width in each row of the current operator. This parameter is valid only for heavy memory operators, including (Vec)HashJoin, (Vec)HashAgg, (Vec)HashSetOp, (Vec)Sort, and

(Vec)Materialize. The (Vec)HashJoin calculation width is the width of its right subtree operator and will be displayed on the right subtree.

2. **Predicate Information (identified by plan id):**

This part displays the static information that does not change in the plan execution process, such as some join conditions and filter information.

3. **Memory Information (identified by plan id):**

This part displays the memory usage information printed by certain operators (mainly Hash and Sort), including **peak memory**, **control memory**, **operator memory**, **width**, **auto spread num**, and **early spilled**; and spill details, including **spill Time(s)**, **inner/outer partition spill num**, **temp file num**, spilled data volume, and **written disk IO** [*min*, *max*].

4. **Targetlist Information (identified by plan id):**

This part displays the target columns provided by each operator.

5. **DataNode Information (identified by plan id):**

The execution time, CPU, and buffer usage of each operator are printed in this part.

6. **=====
Query Summary
=====**

This part displays the total execution time and network traffic, including the maximum and minimum execution time in the initialization and end phases, available system memory when the current statement is executed, and estimated statement memory.

6.3 Tuning Process

You can analyze slow SQL statements to optimize them.

Procedure

- Step 1** Collect all table statistics associated with the SQL statements. In a database, statistics indicate the source data of a plan generated by a planner. If no statistics are available or out of date, the execution plan may seriously deteriorate, leading to low performance. According to past experience, about 10% performance problems occurred because no statistics are collected. For details, see [Updating Statistics](#).
- Step 2** View the execution plan to find out the cause. If the SQL statements have been running for a long period of time and not ended, run the **EXPLAIN** statement to view the execution plan and then locate the fault. If the SQL statement has been properly executed, run the **EXPLAIN ANALYZE** or **EXPLAIN PERFORMANCE** statement to check the execution plan and information to locate the fault. For details about the execution plan, see [Introduction to the SQL Execution Plan](#).
- Step 3** Review and modify a table definition. For details, see [Reviewing and Modifying a Table Definition](#).
- Step 4** For details about **EXPLAIN** or **EXPLAIN PERFORMANCE**, the reason why SQL statements are slowly located, and how to solve this problem, see [Typical SQL Optimization Methods](#).

Step 5 Generally, some SQL statements can be converted to its equivalent statements in all or certain scenarios by rewriting queries. SQL statements are simpler after they are rewritten. Some execution steps can be simplified to improve the performance. Query rewriting methods are universal in all databases. [Experience in Rewriting SQL Statements](#) describes several tuning methods by rewriting SQL statements.

----End

6.4 Updating Statistics

In a database, statistics indicate the source data of a plan generated by a planner. If no statistics are available or out of date, the execution plan may seriously deteriorate, leading to low performance.

Context

The **ANALYZE** statement collects statistic about table contents in databases, which will be stored in the **PG_STATISTIC** system catalog. Then, the query optimizer uses the statistics to work out the most efficient execution plan.

After executing batch insertions and deletions, you are advised to run the **ANALYZE** statement on the table or the entire library to update statistics. By default, 30,000 rows of statistics are sampled. That is, the default value of the GUC parameter **default_statistics_target** is **100**. If the total number of rows in the table exceeds 1,600,000, you are advised to set **default_statistics_target** to **-2**, indicating that 2% of the statistics are collected.

For an intermediate table generated during the execution of a batch script or stored procedure, you also need to run the **ANALYZE** statement.

Procedure

Run the following commands to update the statistics about a table or the entire database:

```
ANALYZE tablename;           -- Update statistics about a table.  
ANALYZE;                     -- Update statistics about the entire database.
```

NOTE

Use **EXPLAIN** to show the execution plan of each SQL statement. If **rows=10** (the default value, probably indicating that the table has not been analyzed) is displayed in the **SEQ SCAN** output of a table, run the **ANALYZE** statement for this table.

6.5 Reviewing and Modifying a Table Definition

6.5.1 Overview

To properly define a table, you must:

1. **Reduce the data volume scanned** by using the partition pruning mechanism.
2. **Minimize random I/Os** by using clustering or partial clustering.

The table definition is created during the database design and is reviewed and modified during the SQL statement optimization.

6.5.2 Selecting a Storage Model

During database design, some key factors about table design will greatly affect the subsequent query performance of the database. Table design affects data storage as well. Scientific table design reduces I/O operations and minimizes memory usage, improving the query performance.

Selecting a model for table storage is the first step of table definition. Select a proper storage model for your service based on the following table.

Storage Model	Application Scenario
Row store	Point queries (simple index-based queries that only return a few records) Scenarios requiring frequent addition, deletion, and modification operations

6.5.3 Using Partitioned Tables

Partitioning refers to splitting what is logically one large table into smaller physical pieces based on specific schemes. The table based on the logic is called a partitioned table, and a physical piece is called a partition. Data is stored in physical partitions not the logical table. A partitioned table has the following advantages over an ordinary table:

1. High query performance: You can specify partitions when querying partitioned tables, improving query efficiency.
2. High availability: If a certain partition in a partitioned table is faulty, data in the other partitions is still available.
3. Easy maintenance: To fix a partitioned table having a faulty partition, you only need to fix the partition.

Partitioned tables supported by the GaussDB database are level-1 and level-2 partitioned tables. Level-1 partitioned tables include range partitioned tables, interval partitioned tables, list partitioned tables, and hash partitioned tables. Level-2 partitioned tables include nine combinations of any two of range partitioned tables, list partitioned tables, and hash partitioned tables.

- Range partitioned table: Data in different ranges is mapped to different partitions. The range is determined by the partition key specified during the partitioned table creation. The partition key is usually a date. For example, sales data is partitioned by month.
- Interval partitioned table: a special type of range partitioned tables. Compared with range partitioned tables, interval value definition is added. When no matching partition can be found for an inserted record, a partition can be automatically created based on the interval value.
- List partitioned table: Key values contained in the data are stored in different partitions, and the data is mapped to each partition in sequence. The key

values contained in the partitions are specified when the partitioned table is created.

- Hash partitioned table: Data is mapped to each partition based on the internal hash algorithm. The number of partitions is specified when the partitioned table is created.
- Level-2 partitioned table: a partitioned table obtained by randomly combining range partitioning, list partitioning, and hash partitioning. Both level-1 and level-2 partitions can be defined in the preceding three ways.

6.5.4 Selecting a Data Type

Use the following principles to select efficient data types:

1. **Select data types that facilitate data calculation.**

Generally, the calculation of integers (including common comparison calculations, such as =, >, <, ≥, ≤, and ≠ and group by) is more efficient than that of strings and floating point numbers.

2. **Select data types with a short length.**

Data types with short length reduce both the data file size and the memory used for computing, improving the I/O and computing performance. For example, use **SMALLINT** instead of **INT**, and **INT** instead of **BIGINT**.

3. **Use the same data type for a join.**

You are advised to use the same data type for a join. To join columns with different data types, the database needs to convert them to the same type, which leads to additional performance overheads.

6.6 Typical SQL Optimization Methods

SQL optimization involves continuous analysis and trying. Queries are run before they are used for services to determine whether the performance meets requirements. If it does not, queries will be optimized by [checking the execution plan](#) and identifying the causes. Then, the queries will be run and optimized again until they meet the requirements.

6.6.1 Optimizing SQL Self-Diagnosis

Performance issues may occur when you query data or run the **INSERT**, **DELETE**, **UPDATE**, or **CREATE TABLE AS** statement. In this case, you can query the **warning** column in the [PG_CONTROL_GROUP_CONFIG](#) and [GS_SESSION_MEMORY_DETAIL](#) views to obtain reference for performance optimization.

Alarms that can trigger SQL self diagnosis depend on the settings of **resource_track_level**. If **resource_track_level** is set to **query**, alarms about the failures in collecting column statistics and pushing down SQL statements will trigger the diagnosis. If **resource_track_level** is set to **operator**, all alarms will trigger the diagnosis.

Whether an SQL plan will be diagnosed depends on the settings of **resource_track_cost**. An SQL plan will be diagnosed only if its execution cost is greater than **resource_track_cost**. You can use the **EXPLAIN** keyword to check the plan execution cost.

The SQL self-diagnosis function is affected by the **enable_analyze_check** parameter. Ensure that the function is enabled before using it.

If a large number of statements are executed, certain data may fail to be collected due to memory control. In this case, you can increase the value of **instr_unique_sql_count**.

Alarms

Currently, performance alarms will be reported when statistics about one or multiple columns are not collected.

An alarm will be reported if statistics of a single column are not collected. For details about the optimization, see [Updating Statistics](#) and [Optimizing Statistics](#).

Example alarms:

No statistics about a table are not collected.

```
Statistic Not Collect:  
  schema_test.t1
```

The statistics about a single column are not collected.

```
Statistic Not Collect:  
  schema_test.t2(c1,c2)
```

Restrictions

1. An alarm contains a maximum of 2048 characters. If the length of an alarm exceeds this value (for example, a large number of long table names and column names are displayed in the alarm when their statistics are not collected), a warning instead of an alarm will be reported.
WARNING, "Planner issue report is truncated, the rest of planner issues will be skipped"
2. If a query statement contains the **Limit** operator, alarms of operators lower than **Limit** will not be reported.

6.6.2 Optimizing Subqueries

Context

When an application runs an SQL statement to operate the database, a large number of subqueries are used because they are more clear than table join. Especially in complicated query statements, subqueries have more complete and independent semantics, which makes SQL statements clearer and easier to understand. Therefore, subqueries are widely used.

In GaussDB, subqueries can also be called sublinks based on the location of subqueries in SQL statements.

- Subquery: corresponds to a range table (RangeTblEntry) in the query parse tree. That is, a subquery is a **SELECT** statement following immediately after the **FROM** keyword.
- Sublink: corresponds to an expression in the query parsing tree. That is, a sublink is a statement in the **WHERE** or **ON** clause or in the target list.

In conclusion, a subquery is a range table and a sublink is an expression in the query parsing tree. A sublink can be found in constraint conditions and expressions. In GaussDB, sublinks can be classified into the following types:

- exist_sublink: corresponds to the **EXIST** and **NOT EXIST** statements.
- any_sublink: corresponds to the *op ANY(SELECT...)* statement. *op* can be the <, >, or = operator. **IN/NOT IN (SELECT...)** also belongs to this type.
- all_sublink: corresponds to the *op ALL(SELECT...)* statement. *op* can be the <, >, or = operator.
- rowcompare_sublink: corresponds to the **RECORD op (SELECT...)** statement.
- expr_sublink: corresponds to the **(SELECT with a single target list item...)** statement.
- array_sublink: corresponds to the **ARRAY(SELECT...)** statement.
- cte_sublink: corresponds to the **WITH(...)** query statement.

The exist_sublink and any_sublink are pulled up by the optimization engine of GaussDB. In addition, expr_sublink can also be pulled up. However, because of the flexible use of subqueries in SQL statements, complex subqueries may affect query performance. To disable the optimization of **expr_sublink**, set the GUC parameter **rewrite_rule**. Subqueries are classified into non-correlated subqueries and correlated subqueries.

- Non-correlated subqueries

The execution of a subquery is independent from attributes of the outer query. In this way, a subquery can be executed before outer queries.

Example:

```
openGauss=# explain select t1.c1,t1.c2
from t1
where t1.c1 in (
  select c2
  from t2
  where t2.c2 IN (2,3,4)
);
               QUERY PLAN
-----
Hash Join
Hash Cond: (t1.c1 = t2.c2)
-> Seq Scan on t1
    Filter: (c1 = ANY ('{2,3,4}'::integer[]))
-> Hash
    -> HashAggregate
        Group By Key: t2.c2
        -> Seq Scan on t2
            Filter: (c2 = ANY ('{2,3,4}'::integer[]))
(9 rows)
```

- Correlated subqueries

The execution of a subquery depends on some attributes (used as AND conditions of the subquery) of outer queries. In the following example, **t1.c1** in the **t2.c1 = t1.c1** condition is a correlated attribute. Such a subquery depends on outer queries and needs to be executed once for each outer query.

Example:

```
openGauss=# explain select t1.c1,t1.c2
from t1
where t1.c1 in (
```

```
select c2
from t2
where t2.c1 = t1.c1 AND t2.c2 in (2,3,4)
);
          QUERY PLAN
-----
Seq Scan on t1
  Filter: (SubPlan 1)
  SubPlan 1
    -> Seq Scan on t2
        Filter: ((c1 = t1.c1) AND (c2 = ANY ('{2,3,4}'::integer[])))
(5 rows)
```

Sublink Optimization on GaussDB

To optimize a sublink, a subquery is pulled up to join with tables in outer queries. You can run the **EXPLAIN** statement to check whether a sublink is converted into such a subplan.

Example:

```
openGauss=# explain SELECT t1.c1, t1.c2 FROM t1 WHERE t1.c1 IN(SELECT c2 FROM t2 WHERE t2.c1 =
t1.c1);
QUERY PLAN
-----
Seq Scan on t1
  Filter: (SubPlan 1)
  SubPlan 1
    -> Seq Scan on t2
        Filter: (c1 = t1.c1)
(5 rows)
```

- **Sublink-release scenarios supported by GaussDB**

- Non-correlated **IN** sublink
 - The subquery cannot contain columns in the outer query (columns in more outer queries are allowed).
 - The subquery cannot contain volatile functions.

Example:

Replace the execution plan on the right of the arrow with the following execution plan:

```
QUERY PLAN
-----
Hash Join
Hash Cond: (t1.c1 = t2.c2)
-> Seq Scan on t1
-> Hash
-> HashAggregate
Group By Key: t2.c2
-> Seq Scan on t2
Filter: (c1 = 1)
(8 rows)
```

– Correlated **EXISTS** sublink

The **WHERE** clause must contain a column in the outer query. Other parts of the subquery cannot contain the column. Other restrictions are as follows:

- The subquery must contain the **FROM** clause.
- The subquery cannot contain the **WITH** clause.
- The subquery cannot contain aggregate functions.
- The subquery cannot contain a **SET**, **SORT**, **LIMIT**, **WindowAgg**, or **HAVING** operation.
- The subquery cannot contain volatile functions.

Example:

Replace the execution plan on the right of the arrow with the following execution plan:

QUERY PLAN

```

Hash Join
Hash Cond: (t1.c1 = t2.c1)
-> Seq Scan on t1
-> Hash
    -> HashAggregate
        Group By Key: t2.c1
    -> Seq Scan on t2
(7 rows)

```

– Pulling up an equivalent correlated subquery containing aggregate functions

The **WHERE** condition of the subquery must contain a column from the outer query. Equality comparison must be performed between this column and related columns in tables of the subquery. These conditions must be connected using **AND**. Other parts of the subquery cannot contain the column. Other restrictions are as follows:

- The columns in the expression in the **WHERE** condition of the subquery must exist in tables.
- After the **SELECT** keyword of the subquery, there must be only one output column. The output column must be an aggregate function (for example, **MAX**), and the parameter (for example, **t2.c2**) of the aggregate function cannot be columns of a table (for example, **t1**) in outer queries. The aggregate function cannot be **COUNT**.

For example, the following subquery can be pulled up:

```

select * from t1 where c1 >(
  select max(t2.c1) from t2 where t2.c1=t1.c1
);

```

The following subquery cannot be pulled up because the subquery has no aggregate function:

```
select * from t1 where c1 >(
    select t2.c1 from t2 where t2.c1=t1.c1
);
```

The following subquery cannot be pulled up because the subquery has two output columns:

```
select * from t1 where (c1,c2) >(
    select max(t2.c1),min(t2.c2) from t2 where t2.c1=t1.c1
);
```

- The subquery must be a **FROM** clause.
- The subquery cannot contain a **GROUP BY**, **HAVING**, or **SET** operation.
- The subquery can only be an inner join.

For example, the following example cannot be pulled up:

```
select * from t1 where c1 >(
    select max(t2.c1) from t2 full join t3 on (t2.c2=t3.c2) where t2.c1=t1.c1
);
```

- The target list of the subquery cannot contain the function that returns a set.
- The **WHERE** condition of the subquery must contain a column from the outer query. Equality comparison must be performed between this column and related columns in tables of the subquery. These conditions must be connected using **AND**. Other parts of the subquery cannot contain the column. For example, the following innermost sublink can be pulled up:

```
select * from t3 where t3.c1=(
    select t1.c1
    from t1 where c1 >(
        select max(t2.c1) from t2 where t2.c1=t1.c1
    ));
```

If another condition is added to the subquery in the previous example, the subquery cannot be pulled up because the innermost subquery references to the column in the outer and outer query. Example:

```
select * from t3 where t3.c1=(
    select t1.c1
    from t1 where c1 >(
        select max(t2.c1) from t2 where t2.c1=t1.c1 and t3.c1>t2.c2
    ));
```

- Pulling up a sublink in the **OR** clause

If the **WHERE** condition contains an **EXIST** correlated sublink connected by **OR**:

Example:

```
select a, c from t1
where t1.a = (select avg(a) from t3 where t1.b = t3.b) or
exists (select * from t4 where t1.c = t4.c);
```

The process of pulling up the OR clause of the EXIST related subquery connected by the OR condition is as follows:

- i. Extract **opExpr** from the OR clause in the WHERE condition. The value is **t1.a = (select avg(a) from t3 where t1.b = t3.b)**.
- ii. The **op** contains a subquery. If the subquery can be pulled up, the subquery is rewritten as **select avg(a), t3.b from t3 group by t3.b**, generating the **NOT NULL** condition **t3.b is not null**. The **opExpr** is replaced with this **NOT NULL** condition. In this case, the SQL statement changes to:

```
select a, c
from t1 left join (select avg(a) avg, t3.b from t3 group by t3.b) as t3 on (t1.a = avg
and t1.b = t3.b)
where t3.b is not null or exists (select * from t4 where t1.c = t4.c);
```
- iii. Extract the **EXISTS** sublink **exists (select * from t4 where t1.c = t4.c)** from the **OR** clause to check whether the sublink can be pulled up. If it can be pulled up, the subquery is converted into **select t4.c from t4 group by t4.c**, generating the **NOT NULL** condition **t4.c is not null**. In this case, the SQL statement changes to:

```
select t1.a, t1.c from t1 left join (select avg(a) avg, t3.b from t3 group by t3.b) as t3 on
(t1.a = avg and t1.b = t3.b) left join (select t5.c from t5 group by t5.c) as t5 on (t1.c =
t5.c) where t3.b is not null or t5.c is not null;
```

- **Sublink-release scenarios not supported by GaussDB**

Except the sublinks described above, all the other sublinks cannot be pulled up. In this case, a correlated subquery is planned as the combination of subplans and broadcast. As a result, if inner tables have a large amount of data, query performance may be poor.

If a correlated subquery joins with two tables in outer queries, the subquery cannot be pulled up. You need to change the parent SQL statement into a **WITH** clause and then perform the join.

Example:

```
select distinct t1.a, t2.a
from t1 left join t2 on t1.a=t2.a and not exists (select a,b from test1 where test1.a=t1.a and
test1.b=t2.a);
```

The outer query is changed into:

```
with temp as
(
    select * from (select t1.a as a, t2.a as b from t1 left join t2 on t1.a=t2.a)
)
select distinct a,b
from temp
where not exists (select a,b from test1 where temp.a=test1.a and temp.b=test1.b);
```

- The correlated subquery (without **COUNT**) in the target list cannot be pulled up.

Example:

```
openGauss=# explain (costs off)
select (select c2 from t2 where t1.c1 = t2.c1) ssq, t1.c2
from t1
where t1.c2 > 10;
```

The execution plan is as follows:

```
openGauss=# explain (costs off)
select (select c2 from t2 where t1.c1 = t2.c1) ssq, t1.c2
from t1
where t1.c2 > 10;
QUERY PLAN
-----
Seq Scan on t1
  Filter: (c2 > 10)
```

```
SubPlan 1
-> Seq Scan on t2
    Filter: (t1.c1 = c1)
(5 rows)
```

The correlated subquery is displayed in the target list (query return list). Values need to be returned even if the condition **t1.c1=t2.c1** is not met. Therefore, use a right outer join to join **t2** and **t1** so that the SSQ can return padding values when the condition **t1.c1=t2.c1** is not met.

NOTE

ScalarSubQuery (SSQ) and Correlated-ScalarSubQuery (CSSQ) are described as follows:

- SSQ: a sublink that returns a scalar value of a single row with a single column
- CSSQ: an SSQ containing correlation conditions

The preceding SQL statement can be changed into:

```
with ssq as
(
    select * from t1 where t1.c2 >10
)
select t2.c2,ssq.c2 from t2 right join ssq on ssq.c1 = t2.c1;
```

The execution plan after the change is as follows:

```
QUERY PLAN
-----
Hash Right Join
Hash Cond: (t2.c1 = t1.c1)
-> Seq Scan on t2
-> Hash
    -> Seq Scan on t1
        Filter: (c2 > 10)
(6 rows)
```

In the preceding example, the SSQ in the target list is pulled up to right join, preventing poor performance caused by the plan involving subplans when the table (**t2**) in the subquery is too large.

- The subquery (with **COUNT**) in the target list cannot be pulled up.

Example:

```
select (select count(*) from t2 where t2.c1=t1.c1) cnt, t1.c1, t3.c1
from t1,t3
where t1.c1=t3.c1 order by cnt, t1.c1;
```

The execution plan is as follows:

```
QUERY PLAN
-----
Sort
Sort Key: ((SubPlan 1)), t1.c1
-> Hash Join
Hash Cond: (t1.c1 = t3.c1)
-> Seq Scan on t1
-> Hash
    -> Seq Scan on t3
SubPlan 1
-> Aggregate
    -> Seq Scan on t2
        Filter: (c1 = t1.c1)
(11 rows)
```

The correlated subquery is displayed in the target list (query return list). Values need to be returned even if the condition **t1.c1=t2.c1** is not met. Therefore, use left outer join to join **T1** and **T2** so that SSQ can return padding values when the condition **t1.c1=t2.c1** is not met. However,

COUNT is used, which requires that **0** is returned when the condition is not met. Therefore, **case-when NULL then 0 else count(*)** can be used.

The preceding SQL statement can be changed into:

```
with ssq as
(
  select count(*) cnt, c1 from t2 group by c1
)
select case when
  ssq.cnt is null then 0
  else ssq.cnt
end cnt, t1.c1, t3.c1
from t1 left join ssq on ssq.c1 = t1.c1,t3
where t1.c1 = t3.c1
order by ssq.cnt, t1.c1;
```

The execution plan after the change is as follows:

```
QUERY PLAN
-----
Sort
  Sort Key: ssq.cnt, t1.c1
  CTE ssq
    -> HashAggregate
      Group By Key: t2.c1
      -> Seq Scan on t2
    -> Hash Join
      Hash Cond: (t1.c1 = t3.c1)
      -> Hash Left Join
        Hash Cond: (t1.c1 = ssq.c1)
        -> Seq Scan on t1
        -> Hash
          -> CTE Scan on ssq
      -> Hash
        -> Seq Scan on t3
(15 rows)
```

– Non-equivalent correlated scenarios

Example:

```
select t1.c1, t1.c2
from t1
where t1.c1 = (select agg() from t2.c2 > t1.c2);
```

Non-equivalent correlated subqueries cannot be pulled up. You can perform join twice (one CorrelationKey and one rownum self-join) to rewrite the statement.

You can rewrite the statement in either of the following ways:

■ Subquery rewriting

```
select t1.c1, t1.c2
from t1, (
  select t1.rowid, agg() aggref
  from t1,t2
  where t1.c2 > t2.c2 group by t1.rowid
) dt /* derived table */
where t1.rowid = dt.rowid AND t1.c1 = dt.aggref;
```

■ CTE rewriting

```
WITH dt as
(
  select t1.rowid, agg() aggref
  from t1,t2
  where t1.c2 > t2.c2 group by t1.rowid
)
select t1.c1, t1.c2
from t1, derived_table
where t1.rowid = derived_table.rowid AND
t1.c1 = derived_table.aggref;
```

NOTICE

- If the AGG type is **COUNT(*)**, **0** is used for data padding when **CASE-WHEN** is not matched. If the type is not **COUNT(*)**, **NULL** is used.
- CTE rewriting works better by using sharescan.

More Optimization Examples

Example: Modify the SELECT statement by modifying the subquery to a join relationship between the main table and the parent query or modifying the subquery to improve the query performance. Ensure that the subquery to be used is semantically correct.

```
openGauss=# explain (costs off) select * from t1 where t1.c1 in (select t2.c1 from t2 where t1.c1 = t2.c2);
QUERY PLAN
-----
Seq Scan on t1
  Filter: (SubPlan 1)
  SubPlan 1
    -> Seq Scan on t2
        Filter: (t1.c1 = c2)
(5 rows)
```

In the preceding example, a subplan is used. To remove the subplan, you can modify the statement as follows:

```
openGauss=# explain (costs off) select * from t1 where exists (select t2.c1 from t2 where t1.c1 = t2.c2 and t1.c1 = t2.c1);
QUERY PLAN
-----
Hash Join
  Hash Cond: (t1.c1 = t2.c2)
  -> Seq Scan on t1
  -> Hash
    -> HashAggregate
      Group By Key: t2.c2, t2.c1
      -> Seq Scan on t2
          Filter: (c2 = c1)
(8 rows)
```

In this way, the subplan is replaced by the hash-join between the two tables, greatly improving the execution efficiency.

6.6.3 Optimizing Statistics

Context

GaussDB generates optimal execution plans based on the cost estimation. Optimizers need to estimate the number of data rows and the cost based on statistics collected using **ANALYZE**. Therefore, the statistics is vital for the estimation of the number of rows and cost. Global statistics are collected using **ANALYZE: relpages** and **reltuples** in the **pg_class** table; **stadistinct**, **stanullfrac**, **stanumbersN**, **stavaluesN**, and **histogram_bounds** in the **pg_statistic** table.

Example 1: Poor Query Performance Due to the Lack of Statistics

In most cases, the lack of statistics about tables or columns involved in the query greatly affects the query performance.

The table structure is as follows:

```
CREATE TABLE LINEITEM
(
  L_ORDERKEY      BIGINT      NOT NULL
, L_PARTKEY       BIGINT      NOT NULL
, L_SUPPKEY       BIGINT      NOT NULL
, L_LINENUMBER    BIGINT      NOT NULL
, L_QUANTITY       DECIMAL(15,2) NOT NULL
, L_EXTENDEDPRICE DECIMAL(15,2) NOT NULL
, L_DISCOUNT     DECIMAL(15,2) NOT NULL
, L_TAX           DECIMAL(15,2) NOT NULL
, L_RETURNFLAG    CHAR(1)     NOT NULL
, L_LINESTATUS    CHAR(1)     NOT NULL
, L_SHIPDATE      DATE        NOT NULL
, L_COMMITDATE    DATE        NOT NULL
, L_RECEIPTDATE   DATE        NOT NULL
, L_SHIPINSTRUCT  CHAR(25)    NOT NULL
, L_SHIPMODE      CHAR(10)    NOT NULL
, L_COMMENT       VARCHAR(44) NOT NULL
);

CREATE TABLE ORDERS
(
  O_ORDERKEY      BIGINT      NOT NULL
, O_CUSTKEY       BIGINT      NOT NULL
, O_ORDERSTATUS   CHAR(1)     NOT NULL
, O_TOTALPRICE    DECIMAL(15,2) NOT NULL
, O_ORDERDATE     DATE        NOT NULL
, O_ORDERPRIORITY CHAR(15)    NOT NULL
, O_CLERK         CHAR(15)    NOT NULL
, O_SHIPPRIORITY  BIGINT      NOT NULL
, O_COMMENT       VARCHAR(79) NOT NULL
);
```

The query statements are as follows:

```
explain verbose select
count(*) as numwait
from
lineitem l1,
orders
where
o_orderkey = l1.l_orderkey
and o_orderstatus = 'F'
and l1.l_receiptdate > l1.l_commitdate
and not exists (
select
*
from
lineitem l3
where
l3.l_orderkey = l1.l_orderkey
and l3.l_suppkey <> l1.l_suppkey
and l3.l_receiptdate > l3.l_commitdate
)
order by
numwait desc;
```

If such an issue occurs, you can use the following methods to check whether statistics in tables or columns has been collected using **ANALYZE**.

1. Execute **EXPLAIN VERBOSE** to analyze the execution plan and check the warning information:

```
WARNING:Statistics in some tables or columns(public.lineitem.l_receiptdate,
public.lineitem.l_commitdate, public.lineitem.l_orderkey, public.lineitem.l_suppkey,
public.orders.o_orderstatus, public.orders.o_orderkey) are not collected.
HINT:Do analyze for them in order to generate optimized plan.
```

2. Check whether the following information exists in the log file in the **pg_log** directory. If it does, the poor query performance was caused by the lack of statistics in some tables or columns.
2017-06-14 17:28:30.336 CST 140644024579856 20971684 [BACKEND] LOG:Statistics in some tables or columns(public.lineitem.l_receiptdate, public.lineitem.l_commitdate, public.lineitem.l_orderkey, public.lineitem.l_suppkey, public.orders.o_orderstatus, public.orders.o_orderkey) are not collected.
2017-06-14 17:28:30.336 CST 140644024579856 20971684 [BACKEND] HINT:Do analyze for them in order to generate optimized plan.

By using any of the preceding methods, you can identify tables or columns whose statistics have not been collected using **ANALYZE**. You can execute **ANALYZE** to warnings or tables and columns recorded in logs to resolve the problem that the query becomes slow because statistics are not collected.

6.6.4 Optimizing Operators

Context

A query statement needs to go through multiple operator procedures to generate the final result. Sometimes, the overall query performance deteriorates due to long execution time of certain operators, which are regarded as bottleneck operators. In this case, you need to execute the **EXPLAIN ANALYZE** or **EXPLAIN PERFORMANCE** command to view the bottleneck operators, and then perform optimization.

For example, in the following execution process, the execution time of the **Hashagg** operator accounts for about 66% $[(51016-13535)/56476 \approx 66\%]$ of the total execution time. Therefore, the **Hashagg** operator is the bottleneck operator for this query. Optimize this operator first.

id	operation	A-time	A-rows	E-rows	Peak Memory	E-memory	A-width	E-width	E-costs
1	-> Row Adapter	56476.397	100000000	237060	19KB			20	2093222.75
2	-> Vector Streaming (type: GATHER)	55664.220	100000000	237060	243KB			20	2093222.75
3	-> Vector Hash Aggregate	55124.685, 55132.180	100000000	237060	[29349KB, 29441KB]	10MB	[20,20]	20	20918406.50
4	-> Vector Streaming(type: REDISTRIBUTE)	[55519.784, 57709.779]	339264604	4856184	[12199KB, 32199KB]	3MB		20	10461210.85
5	-> Vector Hash Aggregate	[35675.636, 51016.424]	339264604	4856184	[732850KB, 746894KB]	16MB	[20,20]	20	10457195.65
6	-> Vector Partition Iterator	[9035.202, 13565.884]	970000000	935838097	[9KB, 9KB]	1MB		20	10195891.68
7	-> Partitioned CStore Scan on xujie_gp_day_energy_mv_1	[9015.645, 13535.346]	970000000	935838097	[845KB, 845KB]	1MB		20	10195891.68

Operator Optimization Examples

Example 1: Scan the base table. For queries requiring large volume of data filtering, such as point queries or queries that need range scanning, a full table scan using SeqScan will take a long time. To facilitate scanning, you can create indexes on the condition column and select IndexScan.

```
openGauss=# explain (analyze on, costs off) select * from store_sales where ss_sold_date_sk = 2450944;
```

id	operation	A-time	A-rows	Peak Memory	A-width
1	-> Streaming (type: GATHER)	3666.020	3360	195KB	
2	-> Seq Scan on store_sales	[3594.611, 3594.611]	3360	[34KB, 34KB]	

(2 rows)

Predicate Information (identified by plan id)

```
2 --Seq Scan on store_sales
  Filter: (ss_sold_date_sk = 2450944)
 Rows Removed by Filter: 4968936
```

```
openGauss=# create index idx on store_sales_row(ss_sold_date_sk);
```

```
CREATE INDEX
```

```
openGauss=# explain (analyze on, costs off) select * from store_sales_row where ss_sold_date_sk = 2450944;
```

id	operation	A-time	A-rows	Peak Memory	A-width

```
+-----+-----+-----+-----+
1 | -> Streaming (type: GATHER) | 81.524 | 3360 | 195KB |
2 | -> Index Scan using idx on store_sales_row | [13.352,13.352] | 3360 | [34KB, 34KB] |
(2 rows)
```

In this example, the full table scan filters much data and returns 3360 records. After an index has been created on the **ss_sold_date_sk** column, the scanning efficiency is significantly boosted from 3.6s to 13 ms by using **IndexScan**.

Example 2: If a nested-loop join is used for joining tables with a large number of rows, the join may take a long time. In the following example, the nested loop takes 181s. If **enable_mergejoin** is set to **off** to disable merge join and **enable_nestloop** is set to **off** to disable the nested loop so that the optimizer selects hash join, the join takes more than 200 ms.

```
openGauss=# explain analyze select count(*) from store_sales ss, item i where ss.ss_item_sk = i.i_item_sk;
id | operation | A-time | A-rows | E-rows | Peak Memory | E-memory | A-width | E-width | E-costs
---+-----+-----+-----+-----+-----+-----+-----+-----+
1 | -> Row Adapter | 184300.301 | 1 | 1 | 11KB | | | | 0 | 48629179.77
2 | -> Vector Aggregate | 184300.280 | 1 | 1 | 181KB | | | | 0 | 48629179.77
3 | -> Vector Streaming (type: GATHER) | 184300.186 | 4 | 4 | 188KB | | | | 0 | 48629179.77
4 | -> Vector Aggregate | [165575.384,184252.369] | 4 | 4 | [140KB, 140KB] | 1MB | | | 0 | 48629179.61
5 | -> Vector Hash Join (6,7) | [162915.848,181438.162] | 2880404 | 2880404 | [74KB, 74KB] | 1MB | | | 0 | 48627379.35
6 | -> CStore Scan on store_sales ss | [15.660,16.229] | 2880404 | 2880404 | [490KB, 490KB] | 1MB | | | 4 | 16683.10
7 | -> Vector Materialize | [118314.521,132478.454] | 12968211302 | 18000 | [869KB, 900KB] | 16MB | [8,8] | | 4 | 3890.00
8 | -> CStore Scan on item i | [0.234,0.243] | 18000 | 18000 | [476KB, 476KB] | 1MB | | | 4 | 3867.50
(8 rows)
```

```
openGauss=# set enable_nestloop=off;
SET
openGauss=# set enable_mergejoin=off;
SET
openGauss=# explain analyze select count(*) from store_sales ss, item i where ss.ss_item_sk = i.i_item_sk;
id | operation | A-time | A-rows | E-rows | Peak Memory | E-memory | A-width | E-width | E-costs
---+-----+-----+-----+-----+-----+-----+-----+-----+
1 | -> Row Adapter | 291.066 | 1 | 1 | 11KB | | | | 0 | 32308.66
2 | -> Vector Aggregate | 291.052 | 1 | 1 | 181KB | | | | 0 | 32308.66
3 | -> Vector Streaming (type: GATHER) | 290.973 | 4 | 4 | 188KB | | | | 0 | 32308.66
4 | -> Vector Aggregate | [220.792,234.532] | 4 | 4 | [140KB, 140KB] | 1MB | | | 0 | 32308.50
5 | -> Vector Hash Join (6,7) | [209.987,223.345] | 2880404 | 2880404 | [236KB, 241KB] | 16MB | [8,8] | | 0 | 30508.24
6 | -> CStore Scan on store_sales ss | [13.132,13.717] | 2880404 | 2880404 | [490KB, 490KB] | 1MB | | | 4 | 16683.10
7 | -> CStore Scan on item i | [0.214,0.246] | 18000 | 18000 | [477KB, 477KB] | 1MB | | | 4 | 3867.50
(7 rows)
```

Example 3: Generally, query performance can be improved by selecting HashAgg. If Sort and GroupAgg are used for a large result set, you need to set **enable_sort** to **off**. HashAgg consumes less time than Sort and GroupAgg.

```
openGauss=# explain analyze select count(*) from store_sales group by ss_item_sk;
id | operation | A-time | A-rows | E-rows | Peak Memory | E-memory | A-width | E-width | E-costs
---+-----+-----+-----+-----+-----+-----+-----+-----+
1 | -> Row Adapter | 1977.385 | 18000 | 17644 | 20KB | | | | 4 | 92875.24
2 | -> Vector Streaming (type: GATHER) | 1973.617 | 18000 | 17644 | 1946KB | | | | 4 | 92875.24
3 | -> Vector Sort Aggregate | [1784.800,1883.243] | 18000 | 17644 | [273KB, 273KB] | 1MB | | | 4 | 92136.02
4 | -> Vector Sort | [1752.270,1848.357] | 2880404 | 2880404 | [12846KB, 135135KB] | 16MB | [8,8] | | 4 | 88541.40
5 | -> CStore Scan on store_sales | [12.483,13.548] | 2880404 | 2880404 | [490KB, 490KB] | 1MB | | | 4 | 16683.10
(5 rows)
```

```
openGauss=# set enable_sort=off;
SET
openGauss=# explain analyze select count(*) from store_sales group by ss_item_sk;
id | operation | A-time | A-rows | E-rows | Peak Memory | E-memory | A-width | E-width | E-costs
---+-----+-----+-----+-----+-----+-----+-----+-----+
1 | -> Row Adapter | 838.215 | 18000 | 17644 | 20KB | | | | 4 | 21016.93
2 | -> Vector Streaming (type: GATHER) | 834.264 | 18000 | 17644 | 229KB | | | | 4 | 21016.93
3 | -> Vector Hash Aggregate | [585.017,758.204] | 18000 | 17644 | [262552KB, 262564KB] | 16MB | [8,8] | | 4 | 20327.72
4 | -> CStore Scan on store_sales | [12.540,13.941] | 2880404 | 2880404 | [490KB, 490KB] | 1MB | | | 4 | 16683.10
(4 rows)
```

6.7 Experience in Rewriting SQL Statements

Based on the SQL execution mechanism and a large number of practices, SQL statements can be optimized by following certain rules to enable the database to execute SQL statements more quickly and obtain correct results. You can comply with these rules to improve service query efficiency.

- Replace **UNION** with **UNION ALL**.

UNION eliminates duplicate rows while merging two result sets but **UNION ALL** merges the two result sets without deduplication. Therefore, replace **UNION** with **UNION ALL** if you are sure that the two result sets do not contain duplicate rows based on the service logic.

- Add **NOT NULL** to the join columns.

If there are many NULL values in the **JOIN** columns, you can add the filter criterion **IS NOT NULL** to filter data in advance to improve the **JOIN** efficiency.

- Convert **NOT IN** to **NOT EXISTS**.

nestloop anti join must be used to implement **NOT IN**, and **hash anti join** is required for **NOT EXISTS**. If no NULL value exists in the **JOIN** columns, **NOT IN** is equivalent to **NOT EXISTS**. Therefore, if you are sure that no NULL value exists, you can convert **NOT IN** to **NOT EXISTS** to generate **hash join** and to improve the query performance.

As shown in the following statement, if the **t2.d2** column does not contain null (the **t2.d2** column is not null in the table definition), the query can be modified as follows:

```
SELECT * FROM t1 WHERE NOT EXISTS (SELECT * FROM t2 WHERE t1.c1=t2.d2);
```

The generated execution plan is as follows:

QUERY PLAN

```
-----  
Hash Anti Join  
Hash Cond: (t1.c1 = t2.d2)  
-> Seq Scan on t1  
-> Hash  
-> Seq Scan on t2  
(5 rows)
```

- Use **hashagg**.

If a plan involving groupAgg and SORT operations generated by the **GROUP BY** statement is poor in performance, you can set **work_mem** to a larger value to generate a **hashagg** plan, which does not require sorting and improves the performance.

- Replace functions with **CASE** statements.

The GaussDB performance greatly deteriorates if a large number of functions are called. In this case, you can change the pushdown functions to **CASE** statements.

- Do not use functions or expressions for indexes.

Using functions or expressions for indexes stops indexing. Instead, it enables scanning on the full table.

- Do not use **!=** or **<>** operators, **NULL**, **OR**, or implicit parameter conversion in **WHERE** clauses.

- If the values of **>=** and **<=** are the same in **WHERE** condition, change the condition to **=** because range equivalence class derivation is not supported currently.

For example, change **SELECT * FROM t1 WHERE c1 >= 1 AND c1 <= 1** to **SELECT * FROM t1 WHERE c1 = 1**.

For range queries, the optimizer has a larger error when calculating selectivity than equivalent queries. Therefore, change range queries to equivalent queries as much as possible.

- Split complex SQL statements.

You can split an SQL statement into several ones and save the execution result to a temporary table if the SQL statement is too complex to be tuned using the solutions above, including but not limited to the following scenarios:

- The same subquery is involved in multiple SQL statements of a job and the subquery contains large amounts of data.
- Incorrect plan cost causes a small hash bucket of subquery. For example, the actual number of rows is 10 million, but only 1000 rows are in hash bucket.
- Functions such as **substr** and **to_number** cause incorrect measures for subqueries containing large amounts of data.

6.8 Configuring Key Parameters for SQL Optimization

This section describes key configuration parameters of the primary database node, which affect GaussDB SQL optimization.

Table 6-2 Parameters of the primary database node

Parameter/ Reference Value	Description
enable_nestloop=off	Specifies how the optimizer uses nested-loop join. If this parameter is set to on, the optimizer preferentially uses nested-loop join. If it is set to off, the optimizer preferentially uses other methods, if any. NOTE To temporarily change the value of this parameter for the current database connection (session), execute the following SQL statement: <pre>SET enable_nestloop to off;</pre> Disabling this parameter does not affect the index nested-loop join operator (corresponding to the enable_index_nestloop parameter). During real-world optimization, it is important to assess whether to disable this parameter based on the specific circumstances. Three types of joins are supported: nested loops, merge joins, and hash joins. Specifically, nested loops are best suited for scenarios with small data volumes or indexes, while hash joins are ideal for big data analysis.
enable_index_nestloop=on	Specifies whether to enable the index nested-loop join operator. NOTE To temporarily change the value of this parameter for the current database connection (session), execute the following SQL statement: <pre>SET enable_index_nestloop to off;</pre> Differences between enable_index_nestloop and enable_nestloop: enable_index_nestloop helps manage scenarios where the inner table undergoes index scans, and the outer table supplies index condition parameters for the inner table.

Parameter/ Reference Value	Description
enable_bitmapscan=on	Specifies whether the optimizer uses bitmap scanning. If the value is on, bitmap scanning is used. If the value is off, it is not used. NOTE To temporarily change the value of this parameter for the current database connection (session), execute the following SQL statement: SET enable_bitmapscan to off; The bitmap scanning applies only in the query condition where a > 1 and b > 1 and indexes are created on columns a and b. During optimization, if the query performance is poor and bitmapscan operators are in the execution plan, set this parameter to off and check whether the performance is improved.
enable_hashagg=on	Specifies whether to enable the optimizer's use of Hash-aggregation plan types.
enable_hashjoin=on	Specifies whether to enable the optimizer's use of Hash-join plan types.
enable_mergejoin=on	Specifies whether to enable the optimizer's use of Hash-merge plan types.
enable_indexscan=on	Specifies whether the optimizer uses index scan plans.
enable_indexonlyscan=on	Specifies whether the optimizer uses index-only scan plans.
enable_seqscan=on	Specifies whether the optimizer uses bitmap scanning. It is impossible to suppress sequential scans entirely, but setting this variable to off encourages the optimizer to choose other methods if available.
enable_sort=on	Specifies the optimizer sorts. It is impossible to fully suppress explicit sorts, but setting this variable to off allows the optimizer to preferentially choose other methods if available.
rewrite_rule	Specifies whether the optimizer enables the following rewriting rules: LAZYAGG, MAGICSET, UNIQUECHECK, INTARGETLIST, PREDPUSHNORMAL, PREDPUSHFORCE, PREDPUSH, DISABLE_PULLUP_EXPR_SUBLINK, DISABLE_PULLUP_NOT_IN_SUBLINK, and ENABLE_SUBLINK_PULLUP_ROWNUM.

Parameter/ Reference Value	Description
sql_beta_feature	Specifies whether the optimizer enables the following beta features: SEL_SEMI_POISSON, SEL_EXPR_INSTR, PARAM_PATH_GEN, RAND_COST_OPT, PARAM_PATH_OPT, PAGE_EST_OPT, CANONICAL_PATHKEY, PREDPUSH_SAME_LEVEL, PARTITION_FDW_ON, and DISABLE_BITMAP_COST_WITH_LOSSY_PAGES.

6.9 Hint-based Tuning

6.9.1 Plan Hint Optimization

In plan hints, you can specify a join order, join and scan operations, and the number of rows in a result to tune an execution plan, improving query performance.

GaussDB also provides the SQL patch function. You can create an SQL patch to make hints take effect without modifying service statements.

Description

Plan hints are specified in the following format after keywords such as SELECT, INSERT, UPDATE, DELETE, and MERGE:

```
/*+ <plan hint>*/
```

You can specify multiple hints for a query plan and separate them by spaces. A hint specified for a query plan does not apply to its subquery plans. To specify a hint for a subquery, add the hint following the **SELECT** of this subquery.

Example:

```
select /*+ <plan_hint1> <plan_hint2> */ * from t1, (select /*+ <plan_hint3> */ * from t2) where 1=1;
```

In the preceding command, *<plan_hint1>* and *<plan_hint2>* are the hints of a query, and *<plan_hint3>* is the hint of its subquery.

You can use the EXPLAIN syntax to analyze the plan hint optimization effect. You can use EXPLAIN to view the plan of the target SQL statement after the plan hint is used and check whether the plan meets the requirements to verify the plan hint effect. EXPLAIN has multiple plan display modes, which are controlled by **explain_perf_mode**. In some examples in this section, **explain_perf_mode** is set to **pretty** to display complete plan information. In some examples, **explain_perf_mode** is set to **normal** to simplify the output information.

NOTICE

If a hint is specified in the **CREATE VIEW** statement, the hint will be applied each time this view is used.

If the random plan function is enabled (**plan_mode_seed** is set to a value other than 0), the specified hint will not be used.

Scope

Currently, the following hints are supported:

- Join order hints (**leading**).
- Join operation hints, excluding the **semi join**, **anti join**, and **unique plan** hints.
- Rows hints.
- Scan operation hints, supporting only the **tablescan**, **indexscan**, and **indexonlyscan** hints.
- Sublink name hints.

Precautions

Hints do not support **Agg**, **Sort**, **Setop**, or **Subplan**.

Examples

The following is the original plan and is used for comparing with the optimized ones:

```
create table store
(
  s_store_sk          integer          not null,
  s_store_id          char(16)         not null,
  s_rec_start_date    date              ,
  s_rec_end_date      date              ,
  s_closed_date_sk    integer          ,
  s_store_name        varchar(50)      ,
  s_number_employees  integer          ,
  s_floor_space       integer          ,
  s_hours             char(20)         ,
  s_manager           varchar(40)      ,
  s_market_id         integer          ,
  s_geography_class   varchar(100)     ,
  s_market_desc       varchar(100)     ,
  s_market_manager    varchar(40)     ,
  s_division_id       integer          ,
  s_division_name     varchar(50)      ,
  s_company_id        integer          ,
  s_company_name      varchar(50)      ,
  s_street_number     varchar(10)      ,
  s_street_name       varchar(60)      ,
  s_street_type       char(15)         ,
  s_suite_number      char(10)         ,
  s_city              varchar(60)      ,
  s_county            varchar(30)      ,
  s_state             char(2)          ,
  s_zip              char(10)          ,
  s_country           varchar(20)      ,
  s_gmt_offset        decimal(5,2)     ,
```

```
s_tax_percentage    decimal(5,2)      ,
primary key (s_store_sk)
);
create table store_sales
(
  ss_sold_date_sk    integer          ,
  ss_sold_time_sk    integer          ,
  ss_item_sk         integer          not null,
  ss_customer_sk     integer          ,
  ss_cdemo_sk        integer          ,
  ss_hdemo_sk        integer          ,
  ss_addr_sk         integer          ,
  ss_store_sk        integer          ,
  ss_promo_sk        integer          ,
  ss_ticket_number    integer          not null,
  ss_quantity        integer          ,
  ss_wholesale_cost   decimal(7,2)    ,
  ss_list_price       decimal(7,2)    ,
  ss_sales_price      decimal(7,2)    ,
  ss_ext_discount_amt decimal(7,2)    ,
  ss_ext_sales_price  decimal(7,2)    ,
  ss_ext_wholesale_cost decimal(7,2)  ,
  ss_ext_list_price   decimal(7,2)    ,
  ss_ext_tax          decimal(7,2)    ,
  ss_coupon_amt       decimal(7,2)    ,
  ss_net_paid         decimal(7,2)    ,
  ss_net_paid_inc_tax decimal(7,2)    ,
  ss_net_profit       decimal(7,2)    ,
  primary key (ss_item_sk, ss_ticket_number)
);
create table store_returns
(
  sr_returned_date_sk integer          ,

6.9.2 Join Order Hints

Description

Specifies the join order and outer/inner tables.

Syntax

- Specify only the join order.

```
leading(join_table_list)
```

- Specify the join order and outer/inner tables. The outer/inner tables are specified by the outermost parentheses.

```
leading((join_table_list))
```

Parameters

join_table_list specifies the tables to be joined. The values can be table names or table aliases. If a subquery is pulled up, the value can also be the subquery alias. Separate the values with spaces. You can add parentheses to specify the join priorities of tables.

NOTICE

A table name or alias can only be a string without a schema name.

An alias (if any) is used to represent a table.

To prevent semantic errors, tables in the list must meet the following requirements:

- The tables must exist in the query or its subquery to be pulled up.
- The table names must be unique in the query or subquery to be pulled up. If they are not, their aliases must be unique.
- A table appears only once in the list.
- An alias (if any) is used to represent a table.

For example:

leading(t1 t2 t3 t4 t5): **t1**, **t2**, **t3**, **t4**, and **t5** are joined. The join order and outer/inner tables are not specified.

leading((t1 t2 t3 t4 t5)): **t1**, **t2**, **t3**, **t4**, and **t5** are joined in sequence. The table on the right is used as the inner table in each join.

leading(t1 (t2 t3 t4) t5): First, **t2**, **t3**, and **t4** are joined and the outer/inner tables are not specified. Then, the result is joined with **t1** and **t5**, and the outer/inner tables are not specified.

leading((t1 (t2 t3 t4) t5)): First, **t2**, **t3**, and **t4** are joined and the outer/inner tables are not specified. Then, the result is joined with **t1**, and **(t2 t3 t4)** is used as the inner table. Finally, the result is joined with **t5**, and **t5** is used as the inner table.

leading((t1 (t2 t3) t4 t5)) leading((t3 t2)): First, **t2** and **t3** are joined and **t2** is used as the inner table. Then, the result is joined with **t1**, and **(t2 t3)** is used as the inner table. Finally, the result is joined with **t4** and then **t5**, and the table on the right in each join is used as the inner table.

Example

Hint the query plan in [Examples](#) as follows:

explain

```
select /*+ leading((((store_sales store) promotion) item) customer) ad2) store_returns) leading((store_sales))*/ i_product_name product_name ...
```

First, **store_sales** and **store** are joined and **store_sales** is the inner table. Then, the result is joined with **promotion**, **item**, **customer**, **ad2**, and **store_returns** in sequence. The optimized plan is as follows:

```
WARNING: Duplicated or conflict hint: Leading(store_sales store), will be discarded.
QUERY PLAN
-----
HashAggregate (cost=55.24..55.25 rows=1 width=800)
  Group By Key: item.i_product_name, item.i_item_sk, store.s_store_name, store.s_zip, ad2.ca_street_number, ad2.ca_street_name, ad2.ca_city, ad2.ca_zip

              Index Cond: (ca_address_sk = customer.c_current_addr_sk)
          -> Index Only Scan using store_returns_pkey on store_returns (cost=0.00..0.41 rows=1 width=8)
              Index Cond: ((sr_item_sk = store_sales.ss_item_sk) AND (sr_ticket_number = store_sales.ss_ticket_number))
(24 rows)
```

For details about the warning at the top of the plan, see [Hint Errors, Conflicts, and Other Warnings](#).

6.9.3 Join Operation Hints

Description

Specifies the join method, which can be nested-loop join, hash join, or merge join.

Syntax

```
[no] nestloop|hashjoin|mergejoin(table_list)
```

Parameters

- no** indicates that the specified hint will not be used for a join.
- table_list** specifies the tables to be joined. The values are the same as those of [join_table_list](#) but contain no parentheses.

For example:

no nestloop(t1 t2 t3): **nestloop** is not used for joining **t1**, **t2**, and **t3**. The three tables may be joined in either of the two ways: Join **t2** and **t3**, and then **t1**; join **t1**

and **t2**, and then **t3**. This hint takes effect only for the last join. If necessary, you can hint other joins. For example, you can add **no nestloop(t2 t3)** to join **t2** and **t3** first and to forbid the use of **nestloop**.

Example

Hint the query plan in [Examples](#) as follows:

```
explain
select /*+ nestloop(store_sales store_returns item) */ i_product_name product_name ...
```

nestloop is used for the last join between **store_sales**, **store_returns**, and **item**. The optimized plan is as follows:

```
QUERY PLAN
HashAggregate (cost=23.52..23.53 rows=1 width=880)
  Group By Key: item.i_product_name, item.i_item_sk, store.s_store_name, store.s_zip, ad2.ca_street_number, ad2.ca_street_name, ad2.ca_city, ad2.ca_zip
  -> Nested Loop (cost=4.27..22.48 rows=1 width=776)
    -> Nested Loop (cost=4.27..22.80 rows=1 width=416)
      -> Nested Loop (cost=4.27..22.39 rows=1 width=420)
        -> Nested Loop (cost=4.27..21.98 rows=1 width=262)
          Join Filter: (item.i_item_sk = store_sales.ss_item_sk)
          -> Nested Loop (cost=4.27..20.78 rows=2 width=216)
            -> Seq Scan on item (cost=0.00..11.16 rows=1 width=288)
              Filters: ((i_current_price >= 35::numeric) AND (i_current_price <= 45::numeric) AND (i_current_price >= 36::numeric) AND (i_current_price <= 58::numeric) AND (i_color = ANY ({maroon,burnished,dim,steel,navajo,chocolate}::bpchar[])))
            -> Bitmap Heap Scan on store_returns (cost=4.27..9.61 rows=2 width=8)
              Recheck Cond: (sr_item_sk = item.i_item_sk)
              -> Bitmap Index Scan on store_returns_pkey (cost=0.00..4.27 rows=2 width=0)
                Index Cond: (sr_item_sk = item.i_item_sk)
          -> Index Scan using store_sales_pkey on store_sales (cost=0.00..0.38 rows=1 width=62)
            Index Cond: ((ss_item_sk = store_returns.sr_item_sk) AND (ss_ticket_number = store_returns.sr_ticket_number))
        -> Index Scan using store_pkey on store (cost=0.00..0.40 rows=1 width=168)
          Index Cond: (s_store_sk = store_sales.ss_store_sk)
      -> Index Scan using customer_pkey on customer (cost=0.00..0.40 rows=1 width=8)
        Index Cond: (c_customer_sk = store_sales.ss_customer_sk)
    -> Index Only Scan using promotion_pkey on promotion (cost=0.00..0.40 rows=1 width=4)
      Index Cond: (p_promo_sk = store_sales.ss_promo_sk)
  -> Index Scan using customer_address_pkey on customer_address ad2 (cost=0.00..0.68 rows=1 width=368)
    Index Cond: (ca_address_sk = customer.c_current_addr_sk)
```

6.9.4 Rows Hints

Description

Specifies the number of rows in an intermediate result set. Both absolute values and relative values are supported.

Syntax

```
rows(table_list #|+|-|* const)
```

Parameters

- #**, **+**, **-**, and ***** are operators used for hinting the estimation. **#** indicates that the original estimation is used without any calculation. **+**, **-**, and ***** indicate that the original estimation is calculated using these operators. The minimum calculation result is 1. **table_list** specifies the tables to be joined. The values are the same as those of **table_list** in [Join Operation Hints](#).
- const** can be any non-negative number and supports scientific notation.

Example:

rows(t1 #5): The result set of **t1** is five rows.

rows(t1 t2 t3 *1000): Multiply the result set of joined **t1**, **t2**, and **t3** by 1000.

Suggestion

- The hint using ***** for two tables is recommended. This hint will be triggered if the two tables appear on two sides of a join. For example, if the hint is **rows(t1 t2 * 3)**, the join result of **(t1 t3 t4)** and **(t2 t5 t6)** will be multiplied by 3 because **t1** and **t2** appear on both sides of the join.

- **rows** hints can be specified for the result sets of a single table, multiple tables, function tables, and subquery scan tables.

Examples

Hint the query plan in [Examples](#) as follows:

```
explain
select /*+ rows(store_sales store_returns *50) */ i_product_name product_name ...
```

Multiply the result set of joined **store_sales** and **store_returns** by 50. The optimized plan is as follows:

```
QUERY PLAN
HashAggregate (cost=23.52..23.53 rows=1 width=880)
  Group By Key: item_i_product_name, item_i_item_sk, store_s_store_name, store_s_zip, ad2_ca_street_number, ad2_ca_street_name, ad2_ca_city, ad2_ca_zip
  -> Nested Loop (cost=4.27..22.80 rows=1 width=776)
    -> Nested Loop (cost=4.27..22.80 rows=1 width=416)
      -> Nested Loop (cost=4.27..22.39 rows=1 width=420)
        -> Nested Loop (cost=4.27..21.98 rows=1 width=420)
          -> Nested Loop (cost=4.27..21.57 rows=1 width=262)

              Index Cond: ((ss_item_sk = store_returns.sr_item_sk) AND (ss_ticket_number = store_returns.sr_ticket_number))
          -> Index Scan using store_pkey on store (cost=0.00..0.40 rows=1 width=168)
            Index Cond: (s_store_sk = store_sales.ss_store_sk)
        -> Index Scan using customer_pkey on customer (cost=0.00..0.40 rows=1 width=8)
          Index Cond: (c_customer_sk = store_sales.ss_customer_sk)
      -> Index Only Scan using promotion_pkey on promotion (cost=0.00..0.40 rows=1 width=4)
        Index Cond: (p_promo_sk = store_sales.ss_promo_sk)
    -> Index Scan using customer_address_pkey on customer_address ad2 (cost=0.00..0.68 rows=1 width=368)
      Index Cond: (ca_address_sk = customer.c_current_addr_sk)
```

6.9.5 Scan Operation Hints

Description

These hints specify a scan operation, which can be **tablescan**, **indexscan**, or **indexonlyscan**.

Syntax

```
[no] tablescan|indexscan|indexonlyscan(table [index])
```

Parameters

- **no** specifies that the specified hint will not be used for scanning.
- **table** specifies the table to be scanned. You can specify only one table. Use a table alias (if any) instead of a table name.
- **index** specifies the index for **indexscan** or **indexonlyscan**. You can specify only one index.

NOTE

indexscan and **indexonlyscan** hints can be used only when the specified index belongs to the table.

Scan operation hints can be used for row-store tables, HDFS tables, and subquery tables. HDFS internal tables include base tables and delta tables. The delta tables are invisible to users. Therefore, scan operation hints are used only for base tables.

Example

To specify an index-based hint for a scan, create an index named **i** on the **i_item_sk** column of the **item** table.

```
create index i on item(i_item_sk);
```

Hint the query plan in [Examples](#) as follows:

```
explain
select /*+ indexscan(item i) */ i_product_name product_name ...
```

item is scanned based on an index. The optimized plan is as follows:

```
QUERY PLAN
-----
HashAggregate (cost=38.79..38.80 rows=1 width=880)
  Group By Key: item.i_product_name, item.i_item_sk, store.s_store_name, store.s_zip, ad2.ca_street_number, ad2.ca_street_name, ad2.ca_city, ad2.ca_zip
  -> Nested Loop (cost=18.45..38.76 rows=1 width=776)
    -> Nested Loop (cost=18.45..38.07 rows=1 width=416)
      -> Nested Loop (cost=18.45..37.66 rows=1 width=420)
        -> Nested Loop (cost=18.45..37.25 rows=1 width=420)
          -> Nested Loop (cost=18.45..36.84 rows=1 width=262)
            Join Filter: (store_sales.ss_item_sk = item.i_item_sk)
            -> Hash Join (cost=18.45..35.67 rows=1 width=42)
              Hash Cond: ((store_returns.sr_item_sk = store_sales.ss_item_sk) AND (store_returns.sr_ticket_number = store_sales.ss_ticket_number))
              -> Seq Scan on store_returns (cost=0.00..14.08 rows=408 width=8)
              -> Hash (cost=13.38..13.38 rows=338 width=42)
                -> Seq Scan on store_sales (cost=0.00..13.38 rows=338 width=42)
            -> Index Scan using i on item (cost=0.00..0.40 rows=1 width=208)
              Index Cond: (i_item_sk = store_returns.sr_item_sk)
          Filter: ((i.current_price >= 35::numeric) AND (i.current_price <= 45::numeric) AND (i.current_price >= 36::numeric) AND (i.current_price <= 50::numeric) AND (i.color = ANY (('{maroon,burnished,dia,steel,navajo,chocolate'}::bpchar))))
        -> Index Scan using store_pkey on store (cost=0.00..0.40 rows=1 width=166)
          Index Cond: (s_store_sk = store_sales.ss_store_sk)
      -> Index Scan using customer_pkey on customer (cost=0.00..0.40 rows=1 width=8)
        Index Cond: (c_customer_sk = store_sales.ss_customer_sk)
    -> Index Only Scan using promotion_pkey on promotion (cost=0.00..0.40 rows=1 width=4)
      Index Cond: (p_promo_sk = store_sales.ss_promo_sk)
  -> Index Scan using customer_address_pkey on customer_address ad2 (cost=0.00..0.68 rows=1 width=368)
    Index Cond: (ca_address_sk = customer.c_current_addr_sk)
(24 rows)
```

6.9.6 Sublink Name Hints

Function

These hints specify the name of a sublink block.

Syntax

```
blockname (table)
```

Parameter Description

- table** specifies the name you have specified for a sublink block.

NOTE

- The **blockname** hint is used by an outer query only when the corresponding sublink is not pulled up. Currently, only the **Agg** equivalent join, **IN**, and **EXISTS** sublinks can be pulled up. This hint is usually used together with the hints described in the previous sections.
- The subquery after the **FROM** keyword is hinted by using the subquery alias. In this case, **blockname** becomes invalid.
- If a sublink contains multiple tables, the tables will be joined with the outer-query tables in a random sequence after the sublink is pulled up. In this case, **blockname** also becomes invalid.

Example

```
explain select /*+nestloop(store_sales tt) */ * from store_sales where ss_item_sk in (select /*
+blockname(tt)*/ i_item_sk from item group by 1);
```

tt indicates the sublink block name. After being pulled up, the sublink is joined with the outer-query table **store_sales** by using **nestloop**. The optimized plan is as follows:

```
QUERY PLAN
-----
Nested Loop (cost=10.53..68.39 rows=169 width=212)
  -> HashAggregate (cost=10.53..10.95 rows=42 width=4)
    Group By Key: item.i_item_sk
    -> Seq Scan on item (cost=0.00..10.42 rows=42 width=4)
  -> Index Scan using store_sales_pkey on store_sales (cost=0.00..1.34 rows=2 width=212)
    Index Cond: (ss_item_sk = item.i_item_sk)
(6 rows)
```

6.9.7 Hint Errors, Conflicts, and Other Warnings

Plan hints change an execution plan. You can run **EXPLAIN** to view the changes.

Hints containing errors are invalid and do not affect statement execution. The errors will be displayed in different ways based on statement types. Hint errors in an **EXPLAIN** statement are displayed as a warning on the interface. Hint errors in other statements will be recorded in debug1-level logs containing the **PLANHINT** keyword.

Hint error types are as follows:

- Syntax errors

An error will be reported if the syntax tree fails to be reduced. The No. of the row generating an error is displayed in the error details.

For example, the hint keyword is incorrect, no table or only one table is specified in the **leading** or **join** hint, or no tables are specified in other hints. The parsing of a hint is terminated immediately after a syntax error is detected. Only the hints that have been parsed successfully are valid.

For example:

```
leading((t1 t2)) nestloop(t1) rows(t1 t2 #10)
```

The syntax of **nestloop(t1)** is wrong and its parsing is terminated. Only **leading(t1 t2)** that has been successfully parsed before **nestloop(t1)** is valid.

- Semantic errors

- An error will be reported if the specified tables do not exist, multiple tables are found based on the hint setting, or a table is used more than once in the **leading** or **join** hint.
- An error will be reported if the index specified in a scan hint does not exist.
- If multiple tables with the same name exist after a subquery is pulled up and some of them need to be hinted, add aliases for them to avoid name duplication.

- Duplicated or conflicted hints

If hint duplication or conflicts occur, only the first hint takes effect. A message will be displayed to describe the situation.

- Hint duplication indicates that a hint is used more than once in the same query, for example, **nestloop(t1 t2) nestloop(t1 t2)**.
- A hint conflict indicates that the functions of two hints with the same table list conflict with each other.

For example, if **nestloop (t1 t2) hashjoin (t1 t2)** is used, **hashjoin (t1 t2)** becomes invalid. **nestloop(t1 t2)** does not conflict with **no mergejoin(t1 t2)**.

NOTICE

The table list in the **leading** hint is disassembled. For example, **leading ((t1 t2 t3))** will be disassembled as **leading((t1 t2)) leading(((t1 t2) t3))**, which will conflict with **leading((t2 t1))** (if any). In this case, the latter **leading(t2 t1)** becomes invalid. If two hints use duplicated table lists and only one of them has the specified outer/inner table, the one without a specified outer/inner table becomes invalid.

- A hint becomes invalid after a sublink is pulled up.
In this case, a message will be displayed. Generally, such invalidation occurs when a sublink contains multiple tables to be joined. After the sublink is pulled up, the tables will not be join members.
- Hints are not used.
 - If a **hashjoin** or **mergejoin** hint is specified for non-equivalent joins, it will not be used.
 - If an **indexscan** or **indexonlyscan** hint is specified for a table that does not have an index, it will not be used.
 - If an **indexscan** or **indexonlyscan** hint is specified for a full-table scan, it will not be used. Generally, index paths are generated only when filtering conditions are used on index columns. Indexes are not used during a full table scan.
 - If an **indexonlyscan** hint is specified when the output or predicate condition column does not contain only indexes, it will not be used.
 - In equivalent joins, only the joins containing equivalence conditions are valid. Therefore, the **leading**, **join**, and **rows** hints specified for the joins without an equivalence condition will not be used. For example, **t1**, **t2**, and **t3** are to be joined, and the join between **t1** and **t3** does not contain an equivalence condition. In this case, **leading(t1 t3)** will not be used.
 - If no sublink is pulled up, the specified **blockname** hint will not be used.

6.9.8 Optimizer GUC Parameter Hints

Description

Sets GUC parameters related to query optimization that take effect during the query execution. For details about the application scenarios of hints, see the description of each GUC parameter.

Syntax

```
set(param value)
```

Parameters

- **param** indicates the parameter name.
- **value** indicates the value of a parameter.
- Currently, the following parameters can be set and take effect by using Hint:
 - Boolean

enable_bitmapscan, enable_hashagg, enable_hashjoin, enable_indexscan, enable_indexonlyscan, enable_material, enable_mergejoin, enable_nestloop, enable_index_nestloop, enable_seqscan, enable_sort, and enable_tidscan

- Integer type

query_dop

- Floating point

cost_weight_index, default_limit_rows, seq_page_cost, random_page_cost, cpu_tuple_cost, cpu_index_tuple_cost, cpu_operator_cost, and effective_cache_size

NOTE

- If you set a parameter that is not in the whitelist and the parameter value is invalid or the hint syntax is incorrect, the query execution is not affected. Run **explain(verbose on)**. An error message is displayed, indicating that hint parsing fails.
- The GUC parameter hint takes effect only in the outermost query. That is, the GUC parameter hint in the subquery does not take effect.
- The GUC parameter hint in the view definition does not take effect.
- In the **CREATE TABLE ... AS ...** statement, the outermost GUC parameter hint takes effect.

6.9.9 Hint for Selecting the Custom Plan or Generic Plan

Description

For query statements and DML statements executed in PBE mode, the optimizer generates a custom plan or generic plan based on factors such as rules, costs, and parameters. You can use the hint of **use_cplan** or **use_gplan** to specify the plan to execute.

Syntax

- To select the custom plan, run the following statement:
`use_cplan`
- To select the generic plan, run the following statement:
`use_gplan`

NOTE

- For SQL statements that are executed in non-PBE mode, setting this hint does not affect the execution mode.
- This hint has a higher priority than cost-based selection and the **plan_cache_mode** parameter. That is, this hint does not take effect for statements for which **plan_cache_mode** cannot be forcibly set to specify an execution mode.

Examples

Forcibly use the custom plan.

```
create table t (a int, b int, c int);
prepare p as select /*+ use_cplan */ * from t where a = $1;
explain execute p(1);
```

In the following plan, the filter condition is the actual value of the input parameter, that is, the plan is a custom plan.

QUERY PLAN

```
Seq Scan on t (cost=0.00..34.31 rows=10 width=12)
  Filter: (a = 1)
(2 rows)
```

Forcibly use the generic plan.

```
deallocate p;
prepare p as select /*+ use_gplan */ * from t where a = $1;
explain execute p(1);
```

In the following plan, the filter condition is the input parameter to be added. That is, the plan is a generic plan.

QUERY PLAN

```
Seq Scan on t (cost=0.00..34.31 rows=10 width=12)
  Filter: (a = $1)
(2 rows)
```

6.9.10 Hint Specifying Not to Expand Subqueries

Function

When the database optimizes the query logic, some subqueries can be promoted to the upper layer to avoid nested execution. However, for some subqueries that have a low selection rate and can use indexes to filter access pages, nested execution does not cause too much performance deterioration, while after the promotion, the query search scope is expanded, which may cause performance deterioration. In this case, you can use the **no_expand** hint for debugging. This hint is not recommended in most cases.

Syntax

```
no_expand
```

Examples

Normal query execution:

```
explain select * from t1 where t1.a in (select t2.a from t2);
```

Plan:

QUERY PLAN

```
Hash Join (cost=38.81..92.58 rows=972 width=12)
  Hash Cond: (t1.a = t2.a)
  -> Seq Scan on t1 (cost=0.00..29.45 rows=1945 width=12)
  -> Hash (cost=36.31..36.31 rows=200 width=4)
      -> HashAggregate (cost=34.31..36.31 rows=200 width=4)
          Group By Key: t2.a
          -> Seq Scan on t2 (cost=0.00..29.45 rows=1945 width=4)
(7 rows)
```

After **no_expand** is added:

```
explain select * from t1 where t1.a in (select /*+ no_expand*/ t2.a from t2);
```

Plan:

```
-----  
QUERY PLAN  
-----  
Seq Scan on t1 (cost=34.31..68.62 rows=972 width=12)  
  Filter: (hashed SubPlan 1)  
    SubPlan 1  
      -> Seq Scan on t2 (cost=0.00..29.45 rows=1945 width=4)  
(4 rows)
```

6.9.11 Hint Specifying Not to Use Global Plan Cache

Description

When global plan cache is enabled, you can use the `no_gpc` hint to force a single query statement not to share the plan cache globally. Only the plan cache within the current session lifecycle is retained.

Syntax

`no_gpc`

NOTE

This parameter takes effect only for statements executed by PBE when `enable_global_plancache` is set to `on`.

Example

```
openGauss=# deallocate all;  
DEALLOCATE ALL  
openGauss=# prepare insert_nogpc as insert /*+ no_gpc */ into t1 select c1, c2 from t2 where c1 = $1;  
PREPARE  
openGauss=# execute insert_nogpc(1);  
INSERT 0 1  
openGauss=# select * from db_perf.global_plancache_status where schema_name = 'schema_hint_iud' order by 1,2;  
nodename | query | refcount | valid | databaseid | schema_name | params_num | func_id  
-----+-----+-----+-----+-----+-----+-----+-----  
(0 rows)
```

No result exists in the `db_perf.global_plancache_status` view, that is, no plan is cached globally.

6.9.12 Hint of Parameterized Paths at the Same Level

Function

The `predpush_same_level` hint is used to specify the generation of parameterized paths between tables or MVs at the same level.

Syntax

```
predpush_same_level(src, dest)  
predpush_same_level(src1 src2 ..., dest)
```

NOTE

This parameter takes effect only when the `predpushforce` option in `rewrite_rule` is enabled.

Examples

Prepare parameters, tables, and indexes.

```
openGauss=# set rewrite_rule = 'predpushforce';
SET
openGauss=# create table t1(a int, b int);
CREATE TABLE
openGauss=# create table t2(a int, b int);
CREATE TABLE
openGauss=# create index idx1 on t1(a);
CREATE INDEX
openGauss=# create index idx2 on t2(a);
CREATE INDEX
```

Run the following statement to view the plan:

```
openGauss=# explain select * from t1, t2 where t1.a = t2.a;
QUERY PLAN
-----
Hash Join (cost=27.50..56.25 rows=1000 width=16)
  Hash Cond: (t1.a = t2.a)
    -> Seq Scan on t1 (cost=0.00..15.00 rows=1000 width=8)
    -> Hash (cost=15.00..15.00 rows=1000 width=8)
        -> Seq Scan on t2 (cost=0.00..15.00 rows=1000 width=8)
(5 rows)
```

The filter condition **t1.a = t2.a** is displayed on **Join**. In this case, **predpush_same_level(t1, t2)** can be used to push the condition down to the scan operator of t2.

```
openGauss=# explain select /*+predpush_same_level(t1, t2)*/ * from t1, t2 where t1.a = t2.a;
QUERY PLAN
-----
Nested Loop (cost=0.00..335.00 rows=1000 width=16)
  -> Seq Scan on t1 (cost=0.00..15.00 rows=1000 width=8)
  -> Index Scan using idx2 on t2 (cost=0.00..0.31 rows=1 width=8)
      Index Cond: (a = t1.a)
(4 rows)
```

NOTICE

- **predpush_same_level** can specify multiple **src** parameters in the same condition.
- If the specified **src** and **dest** conditions do not exist or do not meet the parameterized path requirements, this hint does not take effect.

6.9.13 Hint for Materializing a Sub-plan Result

Description

You can materialize a sub-plan result to temporarily store the query record. This hint is used only in the INSERT statement.

When the INSERT INTO ... SELECT statement is used to insert a large amount of data with multiple duplicate rows, the index needs to be compared for multiple times. As a result, the execution takes a long time. This HINT is used to materialize the results of subplans and temporarily store query records to reduce the number of index comparisons and shorten the statement execution time.

Syntax

```
material_subplan
```

Examples

Create a table and insert data into the table.

```
create table test(a int, b int) with(storage_type = ustore);
create index on test(a);
create table test_src(a int, b int);
insert into test_src values(generate_series(1,10), generate_series(1,100000));
```

Normal INSERT INTO...SELECT statement:

```
insert into test select /*+ nestloop(test_src t1)*/ * from test_src where not exists(select 1 from test t1 where
t1.a = test_src.a);
```

Execute plan:

```
QUERY PLAN
-----
Insert on test
-> Nested Loop Anti Join
   -> Seq Scan on test_src
   -> Index Only Scan using test_a_idx on test t1
       Index Cond: (a = test_src.a)
(5 rows)
```

Use the material_subplan hint operator:

```
insert /*+ material_subplan*/ into test select /*+ nestloop(test_src t1)*/ * from test_src where not
exists(select 1 from test t1 where t1.a = test_src.a);
```

The execution plan is as follows:

```
QUERY PLAN
-----
Insert on test
-> Materialize
   -> Nested Loop Anti Join
       -> Seq Scan on test_src
       -> Index Only Scan using test_a_idx on test t1
           Index Cond: (a = test_src.a)
(6 rows)
```

6.10 Tuning with SQL PATCH

SQL PATCH is designed for database administrators (DBAs), O&M personnel, and other roles who need to optimize SQL statements. If performance problems caused by poor plans of service statements are identified through other O&M views or fault locating methods, you can create an SQL patch to optimize service statements based on hints. Currently, the following hints are supported: number of rows, scanning mode, join mode, join sequence, PBE custom/generic plan selection, statement-level parameter setting, and parameterized path. In addition, in case that services are unavailable due to internal system errors that are triggered by specific statements, you can create SQL patches to rectify single-point failures without changing service statements. In this way, errors can be reported in advance to avoid greater loss.

Constraints

1. Patches can be created only by unique SQL ID. If unique SQL IDs conflict, SQL patches that are used for hint-based optimization may affect performance but do not affect semantic correctness.

2. Only hints that do not change SQL semantics can be used as patches. SQL rewriting is not supported.
3. This tool is not applicable to logical backup and restoration.
4. The patch validity cannot be verified during patch creation. If the patch hint has syntax or semantic errors, the query execution is not affected.
5. Only the initial user, O&M administrator, monitoring administrator, and system administrator have the permission to perform this operation.
6. Patches are not shared between databases. When creating SQL patches, you need to connect to the target database.
7. In the centralized deployment scenario where the standby node is readable, you must specify the primary node to run the SQL PATCH command to create, modify, or delete functions and the standby node to report errors.
8. There is a delay in synchronizing an SQL patch to the standby node. The patch takes effect after the standby node replays related logs.
9. This function does not take effect for SQL statements in stored procedures because no unique SQL ID is generated for statements in stored procedures.
10. It is not recommended that the abort patch be used in the database for a long time. It should be used only as a workaround. If the database service is unavailable due to a kernel fault triggered by a specific statement, you must rectify the service fault or upgrade the kernel as soon as possible. After the upgrade, the method of generating unique SQL IDs may change. Therefore, the workaround may become invalid.
11. Currently, except DML statements, unique SQL IDs of SQL statements (such as CREATE TABLE) are generated by hashing the statement text. Therefore, SQL PATCH is sensitive to uppercase and lowercase letters, spaces, and line breaks. That is, even statements of different texts are semantically relative, you still need to create different SQL patches for them. For DML operations, SQL PATCH can take effect for the same statement with different input parameters, regardless of uppercase letters, lowercase letters, and spaces.

Examples

SQL PATCH is implemented based on the unique SQL ID. Therefore, to use SQL PATCH, related O&M parameters must be enabled for the SQL patch to take effect. The unique SQL ID can be obtained from both the WDR and slow SQL view. You must specify the unique SQL ID when creating an SQL patch. The following provides a simple example.

The following provides two simple examples.

Scenario 1: Use SQL PATCH to optimize specific statements based on hints.

```
openGauss=# create table hint_t1(a int);
CREATE TABLE
openGauss=# create index on hint_t1(a);
CREATE INDEX
openGauss=# set track_stmt_stat_level = 'L1,L1'; -- Enable full SQL statistics.
SET
openGauss=# select * from hint_t1 t1 where t1.a = 1; -- Execute the SQL statement.
a | b | c
-----+----
1 | 1 | 1
(1 row)
openGauss=# select unique_query_id, query, query_plan from db_perf.statement_history where query like
```

```
%hint_t1%'; -- Obtain the query plan and unique SQL ID.
-[ RECORD 1 ]-----+-----
unique_query_id | 2578396627
query           | select * from hint_t1 t1 where t1.a = ?;
query_plan      | Datanode Name: sgnode
                | Bitmap Heap Scan on hint_t1 t1 (cost=4.33..15.70 rows=10 p-time=0 p-rows=0 width=12)
                |   Recheck Cond: (a = '****')
                |   -> Bitmap Index Scan on hint_t1_a_idx (cost=0.00..4.33 rows=10 p-time=0 p-rows=0 width=0)
                |       Index Cond: (a = '****')
                |
openGauss=# select * from db_sql_util.create_hint_sql_patch('patch1', 2578396627, 'indexscan(t1)'); --
Specify a hint patch for the specified unique SQL ID.
-[ RECORD 1 ]-----+---
create_hint_sql_patch | t
openGauss=# explain select * from hint_t1 t1 where t1.a = 1; -- Check whether the hint takes effect.
NOTICE: Plan influenced by SQL hint patch
               QUERY PLAN
-----
[Bypass]

query           | select * from hint_t1 t1 where t1.a = ?;
query_plan      | Datanode Name: sgnode
                | Index Scan using hint_t1_a_idx on hint_t1 t1 (cost=0.00..8.27 rows=1 p-time=0 p-rows=0
width=12)
                |   Index Cond: (a = '****')
                |
```

Scenario 2: Run the SQL PATCH command to report an error for a specific statement in advance.

```
openGauss=# select * from db_sql_util.drop_sql_patch('patch1'); -- Delete patch 1.
drop_sql_patch
-----
t
(1 row)
openGauss=# select * from db_sql_util.create_abort_sql_patch('patch2', 2578396627); -- Create an abort
patch for the unique SQL ID of the statement.
create_abort_sql_patch
-----
t
(1 row)

openGauss=# select * from hint_t1 t1 where t1.a = 1; -- An error is reported in advance when the statement
is executed again.
ERROR: Statement 2578396627 canceled by abort patch patch2
```

Helpful Links

The following table lists the system catalogs and interface functions related to SQL PATCH.

Table 6-3 System catalogs and interface functions related to SQL PATCH

Name		Description
System catalog	GS_SQL_PATCH	GS_SQL_PATCH records the status information about all SQL patches.
Interface functions DBE_SQL_UTIL Schema	DBE_SQL_UTIL.create_hint_sql_patch	create_hint_sql_patch is an interface function used to create SQL patches for hints. It returns whether the execution is successful.
	DBE_SQL_UTIL.create_abort_sql_patch	create_abort_sql_patch is an interface function used to create abort SQL patches. It returns whether the execution is successful.
	DBE_SQL_UTIL.drop_sql_patch	drop_sql_patch deletes SQL patches from the connected CN and returns whether the execution is successful.
	DBE_SQL_UTIL.enable_sql_patch	enable_sql_patch enables SQL patches on the connected CN and returns whether the execution is successful.
	DBE_SQL_UTIL.disable_sql_patch	disable_sql_patch disables SQL patches on the connected CN and returns whether the execution is successful.
	DBE_SQL_UTIL.show_sql_patch	show_sql_patch displays the SQL patch corresponding to a specified patch name and returns the running result.

6.11 Optimization Cases

6.11.1 Case: Modifying the GUC Parameter `rewrite_rule`

`rewrite_rule` contains multiple query rewriting rules: **magicset**, **partialpush**, **uniquecheck**, **disablerep**, **intargetlist**, and **predpush**. The following describes the application scenarios of some important rules:

Promoting the Subquery in the Target Column Using `intargetlist`

The query performance can be greatly improved by converting the subquery in the target column to JOIN. The following is an example:

```
openGauss=# set rewrite_rule='none';
SET
```

```
openGauss=# create table t1(c1 int,c2 int);
CREATE TABLE
openGauss=# create table t2(c1 int,c2 int);
CREATE TABLE
openGauss=# explain (verbose on, costs off) select c1,(select avg(c2) from t2 where t2.c2=t1.c2) from t1
where t1.c1<100 order by t1.c2;
QUERY PLAN
-----
Sort
  Output: t1.c1, ((SubPlan 1)), t1.c2
  Sort Key: t1.c2
  -> Seq Scan on public.t1
    Output: t1.c1, (SubPlan 1), t1.c2
    Filter: (t1.c1 < 100)
    SubPlan 1
      -> Aggregate
        Output: avg(t2.c2)
        -> Seq Scan on public.t2
          Output: t2.c1, t2.c2
          Filter: (t2.c2 = t1.c2)
(12 rows)
```

Because the subquery (**select avg(c2) from t2 where t2.c2=t1.c2**) in the target column cannot be pulled up, execution of the subquery is triggered each time a row of data of **t1** is scanned, and the query efficiency is low. If the **intargetlist** parameter is enabled, the subquery is converted to JOIN to improve the query performance.

```
openGauss=# set rewrite_rule='intargetlist';
SET
openGauss=# explain (verbose on, costs off) select c1,(select avg(c2) from t2 where t2.c2=t1.c2) from t1
where t1.c1<100 order by t1.c2;
QUERY PLAN
-----
Sort
  Output: t1.c1, (avg(t2.c2)), t1.c2
  Sort Key: t1.c2
  -> Hash Left Join
    Output: t1.c1, (avg(t2.c2)), t1.c2
    Hash Cond: (t1.c2 = t2.c2)
    -> Seq Scan on public.t1
      Output: t1.c1, t1.c2
      Filter: (t1.c1 < 100)
    -> Hash
      Output: (avg(t2.c2)), t2.c2
      -> HashAggregate
        Output: avg(t2.c2), t2.c2
        Group By Key: t2.c2
        -> Seq Scan on public.t2
          Output: t2.c2
(16 rows)
```

Promoting the Subquery Without Aggregate Using uniquecheck

Ensure that each condition has only one line of output. The subqueries with aggregate functions can be automatically pulled up. For subqueries without aggregate functions, the following is an example:

```
select t1.c1 from t1 where t1.c1 = (select t2.c1 from t2 where t1.c1=t2.c2) ;
```

Rewrite as follows:

```
select t1.c1 from t1 join (select t2.c1 from t2 where t2.c1 is not null group by
t2.c1(unique check)) tt(c1) on tt.c1=t1.c1;
```

To ensure semantic equivalence, the subquery **tt** must ensure that each **group by t2.c1** has only one line of output. Enable the **uniquecheck** query rewriting

parameter to ensure that the query can be pulled up and equivalent. If more than one row of data is output at run time, an error is reported.

```
openGauss=# set rewrite_rule='uniquecheck';
SET
openGauss=# explain verbose select t1.c1 from t1 where t1.c1 = (select t2.c1 from t2 where t1.c1=t2.c1);
QUERY PLAN
-----
Hash Join (cost=43.36..104.40 rows=2149 distinct=[200, 200] width=4)
  Output: t1.c1
  Hash Cond: (t1.c1 = subquery."?column?")
  -> Seq Scan on public.t1 (cost=0.00..31.49 rows=2149 width=4)
    Output: t1.c1, t1.c2
  -> Hash (cost=40.86..40.86 rows=200 width=8)
    Output: subquery."?column?", subquery.c1
    -> Subquery Scan on subquery (cost=36.86..40.86 rows=200 width=8)
      Output: subquery."?column?", subquery.c1
      -> HashAggregate (cost=36.86..38.86 rows=200 width=4)
        Output: t2.c1, t2.c1
        Group By Key: t2.c1
        Filter: (t2.c1 IS NOT NULL)
        Unique Check Required
        -> Seq Scan on public.t2 (cost=0.00..31.49 rows=2149 width=4)
          Output: t2.c1
(16 rows)
```

Note: Because **group by t2.c1 unique check** occurs before the filter condition **t1.c1=t2.c1**, an error may be reported after the query that does not report an error is rewritten. An example is as follows:

There are tables **t1** and **t2**. The data in the tables is as follows:

```
openGauss=# select * from t1 order by c2;
 c1 | c2
----+----
  1 |  1
  2 |  2
  3 |  3
(3 rows)
openGauss=# select * from t2 order by c2;
 c1 | c2
----+----
  1 |  1
  2 |  2
  3 |  3
  4 |  4
  4 |  4
  5 |  5
(6 rows)
```

Disable and enable the **uniquecheck** parameter for comparison. After the parameter is enabled, an error is reported.

```
openGauss=# select t1.c1 from t1 where t1.c1 = (select t2.c1 from t2 where t1.c1=t2.c2) ;
 c1
----
  1
  2
  3
(3 rows)
openGauss=# set rewrite_rule='uniquecheck';
SET
openGauss=# select t1.c1 from t1 where t1.c1 = (select t2.c1 from t2 where t1.c1=t2.c2) ;
ERROR: more than one row returned by a subquery used as an expression
```

6.11.2 Case: Creating an Appropriate Index

Symptom

Query the information about all personnel in the sales department.

```
-- Create a table.
CREATE TABLE staffs (staff_id NUMBER(6) NOT NULL, first_name VARCHAR2(20), last_name
VARCHAR2(25), employment_id VARCHAR2(10), section_id NUMBER(4), state_name VARCHAR2(10), city
VARCHAR2(10));
CREATE TABLE sections(section_id NUMBER(4), place_id NUMBER(4), section_name VARCHAR2(20));
CREATE TABLE states(state_id NUMBER(4));
CREATE TABLE places(place_id NUMBER(4), state_id NUMBER(4));
-- Query before optimization.
EXPLAIN SELECT staff_id,first_name,last_name,employment_id,state_name,city
FROM staffs,sections,states,places
WHERE sections.section_name='Sales'
AND staffs.section_id = sections.section_id
AND sections.place_id = places.place_id
AND places.state_id = states.state_id
ORDER BY staff_id;
-- Create indexes.
CREATE INDEX loc_id_pk ON places(place_id);
CREATE INDEX state_c_id_pk ON states(state_id);
-- Query after optimization.
EXPLAIN SELECT staff_id,first_name,last_name,employment_id,state_name,city
FROM staffs,sections,states,places
WHERE sections.section_name='Sales'
AND staffs.section_id = sections.section_id
AND sections.place_id = places.place_id
AND places.state_id = states.state_id
ORDER BY staff_id;
```

Optimization Analysis

The original execution plan is as follows before creating the **places.place_id** and **states.state_id** indexes:

```
QUERY PLAN
-----
Sort (cost=125.25..126.34 rows=438 width=254)
  Sort Key: staffs.staff_id
  -> Hash Join (cost=64.91..106.03 rows=438 width=254)
    Hash Cond: (states.state_id = places.state_id)
    -> Seq Scan on states (cost=0.00..29.45 rows=1945 width=12)
    -> Hash (cost=64.35..64.35 rows=45 width=266)
      -> Hash Join (cost=33.09..64.35 rows=45 width=266)
        Hash Cond: (places.place_id = sections.place_id)
        -> Seq Scan on places (cost=0.00..25.13 rows=1513 width=24)
        -> Hash (cost=33.02..33.02 rows=6 width=266)
          -> Hash Join (cost=19.16..33.02 rows=6 width=266)
            Hash Cond: (staffs.section_id = sections.section_id)
            -> Seq Scan on staffs (cost=0.00..12.76 rows=276 width=266)
            -> Hash (cost=19.11..19.11 rows=4 width=24)
              -> Seq Scan on sections (cost=0.00..19.11 rows=4 width=24)
              Filter: ((section_name)::text = 'Sales'::text)
  (16 rows)
```

The optimized execution plan is as follows (two indexes have been created on the **places.place_id** and **states.state_id** columns in [Symptom](#)):

```
QUERY PLAN
-----
Sort (cost=107.40..108.49 rows=438 width=254)
  Sort Key: staffs.staff_id
  -> Hash Join (cost=35.37..88.18 rows=438 width=254)
```

```
Hash Cond: (sections.section_id = staffs.section_id)
-> Nested Loop (cost=19.16..66.85 rows=292 width=12)
    -> Hash Join (cost=19.16..50.27 rows=30 width=24)
        Hash Cond: (places.place_id = sections.place_id)
        -> Seq Scan on places (cost=0.00..25.13 rows=1513 width=24)
        -> Hash (cost=19.11..19.11 rows=4 width=24)
            -> Seq Scan on sections (cost=0.00..19.11 rows=4 width=24)
                Filter: ((section_name)::text = 'Sales'::text)
            -> Index Only Scan using state_c_id_pk on states (cost=0.00..0.45 rows=10 width=12)
                Index Cond: (state_id = places.state_id)
        -> Hash (cost=12.76..12.76 rows=276 width=266)
            -> Seq Scan on staffs (cost=0.00..12.76 rows=276 width=266)
(15 rows)
```

6.11.3 Case: Adding NOT NULL for the JOIN Columns

```
SELECT * FROM join_a a JOIN join_b b ON a.b = b.b;
```

The execution plan is as follows:

```
QUERY PLAN
-----
Hash Join (cost=58.35..14677.69 rows=1074607 width=16) (actual time=23.374..23.384 rows=10 loops=1)
  Hash Cond: (a.b = b.b)
    -> Seq Scan on join_a a (cost=0.00..2248.10 rows=100010 width=8) (actual time=0.495..12.551 rows=100010 loops=1)
    -> Hash (cost=31.49..31.49 rows=2149 width=8) (actual time=0.614..0.614 rows=1000 loops=1)
        Buckets: 32768 Batches: 1 Memory Usage: 40kB
        -> Seq Scan on join_b b (cost=0.00..31.49 rows=2149 width=8) (actual time=0.009..0.183 rows=1000 loops=1)
  Total runtime: 23.716 ms
(7 rows)
```

Optimization Analysis

1. According to the execution plan, the sequential scan phase is time consuming.
2. Therefore, you are advised to manually add **NOT NULL** for the **JOIN** column in the statement, as shown below:

```
SELECT
*
SELECT * FROM join_a a JOIN join_b b ON a.b = b.b where a.b IS NOT NULL;
```

The execution plan is as follows:

```
QUERY PLAN
-----
Hash Join (cost=58.22..14560.97 rows=1063762 width=16) (actual time=13.237..13.247 rows=10 loops=1)
  Hash Cond: (a.b = b.b)
    -> Seq Scan on join_a a (cost=0.00..2248.10 rows=99510 width=8) (actual time=12.417..12.422 rows=10 loops=1)
        Filter: (b IS NOT NULL)
        Rows Removed by Filter: 100000
    -> Hash (cost=31.49..31.49 rows=2138 width=8) (actual time=0.566..0.566 rows=1000 loops=1)
        Buckets: 32768 Batches: 1 Memory Usage: 40kB
        -> Seq Scan on join_b b (cost=0.00..31.49 rows=2138 width=8) (actual time=0.011..0.229 rows=1000 loops=1)
            Filter: (b IS NOT NULL)
  Total runtime: 13.556 ms
(10 rows)
```

6.11.4 Case: Modifying a Partitioned Table

Symptom

In the following simple SQL statements, the performance bottlenecks exist in the scan operation on the **normal_date** table.

```
-----
QUERY PLAN
-----
Seq Scan on normal_date (cost=0.00..259.00 rows=30 width=12) (actual time=0.100..3.466 rows=30 loops=1)
  Filter: (("time" >= '2022-09-01 00:00:00'::timestamp without time zone) AND ("time" <= '2022-10-01 00:00:00'::timestamp without time zone))
  Rows Removed by Filter: 9970
  Total runtime: 3.587 ms
(4 rows)
```

Optimization Analysis

Obviously, there are date features in the **time** column of table data in the service layer, and this meet the features of a partitioned table. Replan the table definition of the **normal_date** table. Set the **time** column as a partition key, and month as an interval unit. Define the partitioned table **normal_date_part**. The modified result is as follows, and the performance is improved by nearly 10 times.

```
-----
QUERY PLAN
-----
Partition Iterator (cost=0.00..480.00 rows=30 width=12) (actual time=0.038..0.085 rows=30 loops=1)
  Iterations: 2
  -> Partitioned Seq Scan on normal_date_part (cost=0.00..480.00 rows=30 width=12) (actual time=0.049..0.063 rows=30 loops=2)
    Filter: (("time" >= '2022-09-01 00:00:00'::timestamp without time zone) AND ("time" <= '2022-10-01 00:00:00'::timestamp without time zone))
    Rows Removed by Filter: 31
    Selected Partitions: 3..4
    Total runtime: 0.360 ms
(7 rows)
```

6.11.5 Case: Rewriting SQL Statements to Eliminate Subqueries

Symptom

```
select
  1,
  (select count(*) from normal_date n where n.id = a.id) as GZCS
from normal_date a;
```

This SQL performance is poor. SubPlan exists in the execution plan as follows:

```
-----
QUERY PLAN
-----
Seq Scan on normal_date a (cost=0.00..888118.42 rows=5129 width=4) (actual time=2.394..22194.907 rows=10000 loops=1)
  SubPlan 1
    -> Aggregate (cost=173.12..173.12 rows=1 width=8) (actual time=22179.496..22179.942 rows=10000 loops=10000)
      -> Seq Scan on normal_date n (cost=0.00..173.11 rows=1 width=0) (actual time=11279.349..22159.608 rows=10000 loops=10000)
```

```
Filter: (id = a.id)
Rows Removed by Filter: 99990000
Total runtime: 22196.415 ms
(7 rows)
```

Optimization

The core of this optimization is to eliminate subqueries. Based on the service scenario analysis, *a.id* is not null. In terms of SQL syntax, you can rewrite the SQL statement as follows:

```
select
count(*)
from normal_date n, normal_date a
where n.id = a.id
group by a.id;
```

The plan is as follows:

```
QUERY PLAN
-----
HashAggregate (cost=480.86..532.15 rows=5129 width=12) (actual time=21.539..24.356 rows=10000
loops=1)
  Group By Key: a.id
    -> Hash Join (cost=224.40..455.22 rows=5129 width=4) (actual time=6.402..13.484 rows=10000 loops=1)
        Hash Cond: (n.id = a.id)
        -> Seq Scan on normal_date n (cost=0.00..160.29 rows=5129 width=4) (actual time=0.087..1.459
rows=10000 loops=1)
            -> Hash (cost=160.29..160.29 rows=5129 width=4) (actual time=6.065..6.065 rows=10000 loops=1)
                Buckets: 32768 Batches: 1 Memory Usage: 352kB
            -> Seq Scan on normal_date a (cost=0.00..160.29 rows=5129 width=4) (actual time=0.046..2.738
rows=10000 loops=1)
        Total runtime: 26.844 ms
    (9 rows)
```

NOTE

To ensure that the modified statements have the same functions, **NOT NULL** is added to *normal_date.id*.

6.11.6 Case: Rewriting SQL Statements and Deleting in-clause

Symptom

in-clause/any-clause is a common SQL statement constraint. Sometimes, the clause following **in** or **any** is a constant. For example:

```
select
count(1)
from calc_empfyc_c1_result_tmp_t1
where ls_pid_cusr1 in ('20120405', '20130405');
```

Or

```
select
count(1)
from calc_empfyc_c1_result_tmp_t1
where ls_pid_cusr1 in any('20120405', '20130405');
```

Sometimes, the **in** or **any** clause is used as follows:

```
SELECT
*
FROM test1 t1, test2 t2
WHERE t1.a = any(values(t2.a),(t2.b));
```

a and **b** are two columns in **t2**, and "**t1.a = any(values(t2.ba,(t2.b)))**" is equivalent to "**t1.a = t2.a or t1.a = t2.b**".

Therefore, join-condition is essentially an inequality, and nestloop must be used for this unequal join operation. The corresponding execution plan is as follows:

```
-----
QUERY PLAN
-----
NestLoop (cost=0.00..138614.38 rows=2309100 width=16) (actual time=0.152..19225.483 rows=1000 loops=1)
  Join Filter: (SubPlan 1)
  Rows Removed by Join Filter: 999000
  -> Seq Scan on test1 t1 (cost=0.00..31.49 rows=2149 width=8) (actual time=0.021..3.309 rows=1000 loops=1)
  -> Materialize (cost=0.00..42.23 rows=2149 width=8) (actual time=0.331..1265.810 rows=1000000 loops=1000)
    -> Seq Scan on test2 t2 (cost=0.00..31.49 rows=2149 width=8) (actual time=0.013..0.268 rows=1000 loops=1)
    SubPlan 1
      -> Values Scan on "*VALUES*" (cost=0.00..0.03 rows=2 width=4) (actual time=2890.741..7372.739 rows=1999000 loops=1000000)
  Total runtime: 19227.328 ms
(9 rows)
```

Optimization

The test result shows that both result sets are too large. As a result, nestloop is time-consuming with more than one hour to return results. Therefore, the key to performance optimization is to eliminate nestloop, using more efficient hash join. From the perspective of semantic equivalence, the SQL statements can be written as follows:

```
SELECT
*
FROM (
  SELECT * FROM test1 t1, test2 t2 WHERE t1.a = t2.a
  UNION
  SELECT * FROM test1 t1, test2 t2 WHERE t1.a = t2.b
);
```

The optimized SQL query consists of two equivalent join subqueries, and each subquery can be used for hash join in this scenario. The optimized execution plan is as follows:

```
-----
QUERY PLAN
-----
HashAggregate (cost=1634.99..2096.81 rows=46182 width=16) (actual time=6.369..6.772 rows=1000 loops=1)
  Group By Key: t1.a, t1.b, t2.a, t2.b
  -> Append (cost=58.35..1173.17 rows=46182 width=16) (actual time=0.833..3.414 rows=2000 loops=1)
    -> Hash Join (cost=58.35..355.67 rows=23091 width=16) (actual time=0.832..1.590 rows=1000 loops=1)
      Hash Cond: (t1.a = t2.a)
      -> Seq Scan on test1 t1 (cost=0.00..31.49 rows=2149 width=8) (actual time=0.015..0.156 rows=1000 loops=1)
      -> Hash (cost=31.49..31.49 rows=2149 width=8) (actual time=0.531..0.531 rows=1000 loops=1)
        Buckets: 32768 Batches: 1 Memory Usage: 40kB
        -> Seq Scan on test2 t2 (cost=0.00..31.49 rows=2149 width=8) (actual time=0.010..0.199 rows=1000 loops=1)
    -> Hash Join (cost=58.35..355.67 rows=23091 width=16) (actual time=0.694..1.421 rows=1000 loops=1)
      Hash Cond: (t1.a = t2.b)

7 SQL Reference

7.1 GaussDB SQL

What Is SQL?

SQL is a standard computer language used to control the access to databases and manage data in databases.

SQL provides different statements to enable you to:

- Query data.
- Insert, update, and delete rows.
- Create, replace, modify, and delete objects.
- Control the access to a database and its objects.
- Maintain the consistency and integrity of a database.

SQL consists of commands and functions that are used to manage databases and database objects. SQL can also forcibly implement the rules for data types, expressions, and texts. Therefore, [SQL Reference](#) describes data types, expressions, functions, and operators in addition to SQL syntax.

Development of SQL Standards

The development history of SQL standards is as follows:

- 1986: ANSI X3.135-1986, ISO/IEC 9075:1986, SQL-86
- 1989: ANSI X3.135-1989, ISO/IEC 9075:1989, SQL-89
- 1992: ANSI X3.135-1992, ISO/IEC 9075:1992, SQL-92 (SQL2)
- 1999: ISO/IEC 9075:1999, SQL:1999
- 2003: ISO/IEC 9075:2003, SQL:2003
- 2011: ISO/IEC 9075:2011, SQL:2011
- 2016: ISO/IEC 9075:2016, SQL:2016
- 2019: ISO/IEC 9075:2019, SQL:2019

SQL Standards Supported by GaussDB

By default, GaussDB supports most features of SQL:2016.

7.2 Keywords

SQL statements contain reserved keywords and non-reserved keywords. Standards require that reserved keywords not be used as other identifiers. Non-reserved keywords have special meanings only in a specific environment and can be used as identifiers in other environments.

NOTICE

1. Currently, the non-reserved keywords have the following restrictions when being used as the identifier of a database object:
 1. It cannot be directly used as a column alias. That is, usage similar to `SELECT 1 ABORT` may cause errors.
 2. Keywords `ENTITYESCAPING`, `NOENTITYESCAPING`, and `WELLFORMED` cannot be used as identifiers of table names, column names, table aliases, or column aliases, regardless of whether they are enclosed with double quotation marks. In addition, they cannot be used as function names without double quotation marks.
 3. The `RAW` keyword without double quotation marks cannot be used as the identifier of a table name or function name.
 4. The `SET` keyword without double quotation marks cannot be used as an identifier of a table alias. That is, usage similar to `SELECT * FROM T1 SET` may cause errors.
 5. Keywords such as `BEGIN`, `BY`, `CLOSE`, `CURSOR`, `DECLARE`, `DELETE`, `EXECUTE`, `FUNCTION`, `IF`, `IMMEDIATE`, `INSERT`, `LOOP`, `MOVE`, `OF`, `REF`, `RELEASE`, `RETURN`, `SAVEPOINT`, `STRICT`, `TYPE`, and `UPDATE` without double quotation marks cannot be used as variable names.
 6. When the `SYS_REFCURSOR` keyword is used as the identifier of a database object, if double quotation marks are not attached, a database object named **REFCURSOR** is created. If double quotation marks are attached, a database object named **SYS_REFCURSOR** is created.
 2. Similar to the non-reserved keywords, the non-reserved (cannot be a function or type) keywords cannot be directly used as column aliases, either.
 3. The reserved keyword `CURRENT_TIMESTAMP` with double quotation marks cannot be used as a function name.
-

Identifier Naming Conventions

Identifier naming must comply with the following rules:

- An identifier name can only contain letters, digits, underscores (`_`), and dollar signs (`$`).
- An identifier name must start with a letter or an underscore (`_`).

 NOTE

- The naming rules are recommended but not required.
- In special cases, double quotation marks (") can be used to avoid special character errors.

SQL Keywords

Table 7-1 SQL keywords

Fields listed in the following table cannot be used as column names during table creation.

CTID	XMIN	CMIN	XMAX	CMAX
TABLEOID	XC_NODE_ID	TID	GS_TUPLE_UID	TABLEBUCKETID

7.3 Data Type

Data type is a basic attribute of data that used to distinguish different types of data. Different data types occupy different storage space and support different operations. Data is stored in data tables in the database. Each column of a data

table defines the data type. During storage, data must be stored according to data types.

GaussDB supports implicit conversions between certain data types. For details, see [PG_CAST](#).

7.3.1 Numeric Types

Table 7-2 lists all available types. For digit operators and related built-in functions, see [Mathematical Functions and Operators](#).

Table 7-2 Integer types

Name	Description	Storage Space	Range
TINYINT	Tiny integer, also called INT1	1 byte	0-255
SMALLINT	Small integer, also called INT2	2 bytes	-32,768 to +32,767
INTEGER	Typical choice for integers, also called INT4	4 bytes	-2,147,483,648 to +2,147,483,647
BINARY_INTEGER	INTEGER alias, which is an A-compatible database type	4 bytes	-2,147,483,648 to +2,147,483,647
BIGINT	Big integer, also called INT8	8 bytes	-9,223,372,036,854,775,808 to +9,223,372,036,854,775,807
int16	A 16-byte integer cannot be used to create tables.	16 bytes	-170,141,183,460,469,231,731,687,303,715,884,105,728 to +170,141,183,460,469,231,731,687,303,715,884,105,727

Example:

```
-- Create a table containing TINYINT data.
openGauss=# CREATE TABLE int_type_t1
(
    IT_COL1 TINYINT
);

-- Insert data to the created table.
openGauss=# INSERT INTO int_type_t1 VALUES(10);

-- View data.
openGauss=# SELECT * FROM int_type_t1;
it_col1
-----
10
```

```
(1 row)

-- Delete the table.
openGauss=# DROP TABLE int_type_t1;
-- Create a table containing TINYINT, INTEGER, and BIGINT data.
openGauss=# CREATE TABLE int_type_t2
(
  a TINYINT,
  b TINYINT,
  c INTEGER,
  d BIGINT
);

-- Insert data.
openGauss=# INSERT INTO int_type_t2 VALUES(100, 10, 1000, 10000);

-- View data.
openGauss=# SELECT * FROM int_type_t2;
 a | b | c | d
-----+-----+-----+-----
100 | 10 | 1000 | 10000
(1 row)

-- Delete the table.
openGauss=# DROP TABLE int_type_t2;
```

NOTE

- Only numbers of the TINYINT, SMALLINT, INTEGER, BIGINT, or INT16 type, that is, integers can be stored. Saving a number with a decimal in any of the data types will result in errors.
- The INTEGER type is the common choice, as it offers the best balance between range, storage size, and performance. Generally, use the SMALLINT type only if you are sure that the value range is within the SMALLINT value range. The storage speed of INTEGER is much faster. BIGINT is used only when the range of INTEGER is not large enough.

Table 7-3 Arbitrary precision types

Name	Description	Storage Space	Range
NUMERIC[(p[,s])], DECIMAL[(p[,s])]	The value range of p (precision) is [1,1000], and the value range of s (scale) is [0, <i>p</i>]. NOTE p indicates the total digits, and s indicates the decimal digit.	The precision is specified by users. Every four decimal digits occupy two bytes, and an extra eight-byte overhead is added to the entire data.	Up to 131,072 digits before the decimal point; and up to 16,383 digits after the decimal point when no precision is specified
NUMBER[(p[,s])]	Alias of the NUMERIC type.	The precision is specified by users. Every four decimal digits occupy two bytes, and an extra eight-byte overhead is added to the entire data.	Up to 131,072 digits before the decimal point; and up to 16,383 digits after the decimal point when no precision is specified

Example:

```
-- Create a table.
openGauss=# CREATE TABLE decimal_type_t1
(
    DT_COL1 DECIMAL(10,4)
);

-- Insert data.
openGauss=# INSERT INTO decimal_type_t1 VALUES(123456.122331);

-- Query data in the table.
openGauss=# SELECT * FROM decimal_type_t1;
 dt_col1
-----
123456.1223
(1 row)

-- Delete the table.
openGauss=# DROP TABLE decimal_type_t1;
-- Create a table.
openGauss=# CREATE TABLE numeric_type_t1
(
    NT_COL1 NUMERIC(10,4)
);

-- Insert data.
openGauss=# INSERT INTO numeric_type_t1 VALUES(123456.12354);

-- Query data in the table.
openGauss=# SELECT * FROM numeric_type_t1;
 nt_col1
-----
123456.1235
(1 row)

-- Delete the table.
openGauss=# DROP TABLE numeric_type_t1;
```

** NOTE**

- Compared to the integer types, the arbitrary precision numbers require larger storage space and have lower storage efficiency, operation efficiency, and poorer compression ratio results. The integer type is the common choice when number types are defined. Arbitrary precision numbers are used only when numbers exceed the maximum range indicated by the integers.
- When NUMERIC/DECIMAL is used for defining a column, you are advised to specify the precision (p) and scale (s) for the column.

Table 7-4 Sequence integer

Name	Description	Storage Space	Range
SMALLSERIAL	Two-byte serial integer	2 bytes.	-32,768 to +32,767
SERIAL	Four-byte serial integer	4 bytes.	-2,147,483,648 to +2,147,483,647
BIGSERIAL	Eight-byte serial integer	8 bytes.	-9,223,372,036,854,775,808 to +9,223,372,036,854,775,807

Name	Description	Storage Space	Range
LARGESERIAL	By default, a 16-byte auto-incrementing integer is inserted. The actual value type is the same as that of numeric.	Variable-length type. Every four decimal digits occupy two bytes, and an extra eight-byte overhead is added to the entire data.	There can be a maximum of 131,072 digits before the decimal point and 16,383 digits after the decimal point.

Example:

```
-- Create a table.
openGauss=# CREATE TABLE smallserial_type_tab(a SMALLSERIAL);

-- Insert data.
openGauss=# INSERT INTO smallserial_type_tab VALUES(default);

-- Insert data again.
openGauss=# INSERT INTO smallserial_type_tab VALUES(default);

-- View data.
openGauss=# SELECT * FROM smallserial_type_tab;
a
----
1
2
(2 rows)

-- Create a table.

-- Insert data.
openGauss=# INSERT INTO bigserial_type_tab VALUES(default);

-- Insert data again.
openGauss=# INSERT INTO bigserial_type_tab VALUES(default);

-- View data.
openGauss=# SELECT * FROM bigserial_type_tab;
c
----
1
2
```

```
(2 rows)

-- Create a table.
openGauss=# CREATE TABLE largeserial_type_tab(c LARGESERIAL);

-- Insert data.
openGauss=# INSERT INTO largeserial_type_tab VALUES(default);

-- Insert data.
openGauss=# INSERT INTO largeserial_type_tab VALUES(default);

-- View data.
openGauss=# SELECT * FROM largeserial_type_tab;
 c
---
 1
 2
(2 rows)

-- Delete the table.
openGauss=# DROP TABLE smallserial_type_tab;

openGauss=# DROP TABLE serial_type_tab;

openGauss=# DROP TABLE bigserial_type_tab;
```

 NOTE

SMALLSERIAL, SERIAL, BIGSERIAL, and LARGESERIAL are not real types. They are concepts used for setting a unique identifier for a table. Therefore, an integer column is created and its default value plans to be read from a sequencer. A NOT NULL constraint is used to ensure NULL is not inserted. In most cases you would also want to attach a **UNIQUE** or **PRIMARY KEY** constraint to prevent duplicate values from being inserted unexpectedly, but this is not automatic. Finally, the sequencer belongs to the column. In this case, when the column or the table is deleted, the sequencer is also deleted. Currently, the **SERIAL** column can be specified only when you create a table. You cannot add the **SERIAL** column in an existing table. In addition, **SERIAL** columns cannot be created in temporary tables. Because SERIAL is not a data type, columns cannot be converted to this type.

Table 7-5 Floating point types

Name	Description	Storage Space	Range
REAL, FLOAT4	Single precision floating points, inexact	4 bytes.	-3.402E+38 to +3.402E+38, 6-bit decimal digits.
DOUBLE PRECISION , FLOAT8	Double precision floating points, inexact	8 bytes.	-1.79E+308 to +1.79E+308, 15-bit decimal digits.
FLOAT[(p)]	Floating points, inexact. The value range of p (precision) is [1,53]. NOTE p is the precision, indicating the total number of binary bits.	4 bytes or 8 bytes.	REAL or DOUBLE PRECISION is selected as an internal identifier based on precision (p). If no precision is specified, DOUBLE PRECISION is used as the internal identifier.

Name	Description	Storage Space	Range
BINARY_DOUBLE	Alias of DOUBLE PRECISION.	8 bytes.	-1.79E+308 to +1.79E+308, 15-bit decimal digits.
DEC[(p[,s])]	The value range of p is [1,1000], and the value range of s is [0,<i>p</i>]. If the scenario in the following "NOTE" is met and the precision and scale are not specified, the precision p is 10 and the scale s is 0 by default. This type maps to NUMERIC. For details about the application scenario, see NUMERIC.	The precision is specified by users. Every four decimal digits occupy two bytes, and an extra eight-byte overhead is added to the entire data.	Maximum 131,072 digits before the decimal point and 16,383 digits after the decimal point when the precision and scale are specified to the maximum.
INTEGER[(p[,s])]	The value range of p is [1,1000], and the value range of s is [0,<i>p</i>]. If the precision and scale are not specified, the precision p is 10 and the scale s is 0 by default. If the precision and scale are not specified, this type is mapped to INTEGER. If the precision and scale are specified, this type is mapped to NUMERIC.	The precision is specified by users. Every four decimal digits occupy two bytes, and an extra eight-byte overhead is added to the entire data.	Maximum 131,072 digits before the decimal point and 16,383 digits after the decimal point when the precision and scale are specified to the maximum. If the precision and scale are not specified, the value ranges from -2,147,483,648 to +2,147,483,647.

 NOTE

The binary floating-point data types REAL, FLOAT4, DOUBLE, DOUBLE PRECISION, FLOAT8, FLOAT[(p)], and BINARY_DOUBLE are imprecise numeric types. Their internal storage is approximate, which may result in slight differences during storage and retrieval. When using binary floating-point data types, pay attention to the following points:

- Precise storage and calculation: If precise storage and calculation are required (such as for monetary values), use exact data types (for example, numeric) instead.
- Complex calculation: When you perform complex calculation with imprecise data types to obtain critical data, it is important to carefully evaluate the results.
- Floating-point number comparison: The result of comparing two floating-point numbers for equality may differ from expectations.
- Underflow error: If a floating-point number is too close to zero, it cannot be accurately represented. As a result, an underflow error occurs.

Example:

```
-- Create a table.
openGauss=# CREATE TABLE float_type_t2
(
    FT_COL1 INTEGER,
    FT_COL2 FLOAT4,
    FT_COL3 FLOAT8,
    FT_COL4 FLOAT(3),
    FT_COL5 BINARY_DOUBLE,
    FT_COL6 DECIMAL(10,4),
    FT_COL7 INTEGER(6,3)
);

-- Insert data.
openGauss=# INSERT INTO float_type_t2 VALUES(10,10.365456,123456.1234,10.3214, 321.321, 123.123654,
123.123654);

-- View data.
openGauss=# SELECT * FROM float_type_t2 ;
 ft_col1 | ft_col2 | ft_col3 | ft_col4 | ft_col5 | ft_col6 | ft_col7
-----+-----+-----+-----+-----+-----+-----
      10 | 10.3655 | 123456.1234 | 10.3214 | 321.321 | 123.1237 | 123.124
(1 row)

-- Delete the table.
openGauss=# DROP TABLE float_type_t2;
```

7.3.2 Monetary Types

The money type stores a currency amount with fixed fractional precision.

The range shown in [Table 7-6](#) assumes there are two fractional digits. Input is accepted in a variety of formats, including integer and floating-point literals, as well as typical currency formatting, such as "\$1,000.00". Output is generally in the last format but depends on the locale.

Table 7-6 Monetary type

Name	Description	Storage Space	Range
money	Currency amount	8 bytes	-92233720368547758.08 to +92233720368547758.07

Values of the numeric, int, and bigint data types can be cast to money. Conversion from the real or double precision data type to a money value can be done by casting to numeric type first, for example:

```
openGauss=# SELECT '12.34'::float8::numeric::money;  
money  
-----  
$12.34  
(1 row)
```

However, this is not recommended. Floating point numbers should not be used to handle money due to the potential for rounding errors.

A money value can be cast to numeric without loss of precision. Conversion to other types could potentially lose precision, and must also be done in two stages:

```
openGauss=# SELECT '52093.89'::money::numeric::float8;  
float8  
-----  
52093.89  
(1 row)
```

When a money value is divided by another money value, the result is of the double precision type (that is, a pure number, not money); the currency units cancel each other out in the division.

7.3.3 Boolean Types

Table 7-7 Boolean types

Name	Description	Storage Space	Value
BOOLEAN	Boolean type	1 byte	• true • false • null (unknown)

- Valid literal values for the "true" state include:
TRUE, **'t'**, **'true'**, **'y'**, **'yes'**, **'1'**, **'TRUE'**, **true**, **on**, and all non-zero integers.
- Valid literal values for the "false" state include:
FALSE, **'f'**, **'false'**, **'n'**, **'no'**, **'0'**, **0**, **'FALSE'**, **false**, and **off**.

TRUE and **FALSE** are standard expressions, compatible with SQL statements.

Examples

Boolean values are displayed using the letters t and f.

```
-- Create a table.  
openGauss=# CREATE TABLE bool_type_t1  
(  
    BT_COL1 BOOLEAN,  
    BT_COL2 TEXT  
);  
  
-- Insert data.  
openGauss=# INSERT INTO bool_type_t1 VALUES (TRUE, 'sic est');
```

```
openGauss=# INSERT INTO bool_type_t1 VALUES (FALSE, 'non est');

-- View data.
openGauss=# SELECT * FROM bool_type_t1;
 bt_col1 | bt_col2 
-----+-----
 t      | sic est
 f      | non est
(2 rows)

openGauss=# SELECT * FROM bool_type_t1 WHERE bt_col1 = 't';
 bt_col1 | bt_col2 
-----+-----
 t      | sic est
(1 row)

-- Delete the table.
openGauss=# DROP TABLE bool_type_t1;
```

7.3.4 Character Types

Table 7-8 lists the character data types supported by GaussDB. For string operators and related built-in functions, see [Character Processing Functions and Operators](#).

Table 7-8 Character types

Name	Description	Storage Space
CHAR(n) CHARACTER(n) NCHAR(n)	Fixed-length character string. Empty characters are filled in with blank spaces. n indicates the byte length. If it is not specified, the default precision 1 is used.	The maximum size is 10 MB.
VARCHAR(n) CHARACTER VARYING(n)	Variable-length string. In PG-compatible mode, n indicates the string length. In other compatibility modes, n indicates the byte length.	The maximum size is 10 MB. If n is not contained, the maximum storage length is 1 GB – 85 – Length of the first <i>n</i> columns. For example, the maximum length (of a int, b varchar) is 1 GB – 85 – 4 = 1,073,741,735.
VARCHAR2(n)	Variable-length string. It is the alias of the VARCHAR(n) type. n indicates the byte length.	The maximum size is 10 MB. If n is not contained, the maximum storage length is 1 GB – 85 – Length of the first <i>n</i> columns. For example, the maximum length (of a int, b varchar) is 1 GB – 85 – 4 = 1,073,741,735.

Name	Description	Storage Space
NVARCHAR2(n)	Variable-length string. n indicates the string length.	The maximum size is 10 MB. If n is not contained, the maximum storage length is 1 GB – 85 – Length of the first <i>n</i> columns. For example, the maximum length (of a int, b varchar) is 1 GB – 85 – 4 = 1,073,741,735.
TEXT	Variable-length string.	The maximum size is 1 GB minus 1 byte. However, the size of the column description header and the size of the tuple (less than 1 GB minus 1 byte) where the column is located must also be considered. Therefore, the maximum size of the TEXT type may be less than 1 GB minus 1 byte.
CLOB	Big text object. It is the alias of the TEXT type.	The maximum size is 32 TB minus 1 byte. However, the size of the column description header and the size of the tuple (less than 32 TB minus 1 byte) where the column is located must also be considered. Therefore, the maximum size of the CLOB type may be less than 32 TB minus 1 byte.

 NOTE

1. In addition to the restriction on the size of each column, the total size of each tuple cannot exceed 1 GB minus 1 byte and is affected by the control header information of the column, the control header information of the tuple, and whether null fields exist in the tuple.
2. NCHAR is the alias of the bpchar type, and VARCHAR2(n) is the alias of the VARCHAR(n) type.
3. Only advanced package db_lob supports CLOBs whose size is greater than 1 GB. System functions do not support CLOBs whose size is greater than 1 GB.

In GaussDB, there are two other fixed-length character types, as shown in [Table 7-9](#). The **name** type exists only for the storage of identifiers in the internal system catalogs and is not intended for use by general users. Its length is currently defined as 64 bytes (63 usable characters plus terminator). The char type uses only one byte of storage. It is internally used in the system catalogs as a simplistic enumeration type.

Table 7-9 Special character types

Name	Description	Storage Space
name	Internal type for object names	64 bytes
"char"	Single-byte internal type	1 byte

Examples

```
-- Create a table.
openGauss=# CREATE TABLE char_type_t1
(
    CT_COL1 CHARACTER(4)
);

-- Insert data.
openGauss=# INSERT INTO char_type_t1 VALUES ('ok');

-- Query data in the table.
openGauss=# SELECT ct_col1, char_length(ct_col1) FROM char_type_t1;
 ct_col1 | char_length
-----+-----
    ok   |          4
(1 row)

-- Delete the table.
openGauss=# DROP TABLE char_type_t1;

-- Create a table.
openGauss=# CREATE TABLE char_type_t2
(
    CT_COL1 VARCHAR(5)
);

-- Insert data.
openGauss=# INSERT INTO char_type_t2 VALUES ('ok');

openGauss=# INSERT INTO char_type_t2 VALUES ('good');

-- Specify the type length. An error is reported if an inserted string exceeds this length.
openGauss=# INSERT INTO char_type_t2 VALUES ('too long');
ERROR: value too long for type character varying(5)
CONTEXT: referenced column: ct_col1

-- Specify the type length. A string exceeding this length is truncated.
openGauss=# INSERT INTO char_type_t2 VALUES ('too long'::varchar(5));

-- Query data.
openGauss=# SELECT ct_col1, char_length(ct_col1) FROM char_type_t2;
 ct_col1 | char_length
-----+-----
    ok   |          2
    good |          4
    too l |          5
(3 rows)

-- Delete data.
openGauss=# DROP TABLE char_type_t2;
```

7.3.5 Binary Types

Table 7-10 lists the binary data types supported by GaussDB.

Table 7-10 Binary data types

Name	Description	Storage Space
BLOB	Binary large object (BLOB). Currently, BLOB only supports the following external access APIs: • DBE_LOB.GET_LENGTH • DBE_LOB.READ • DBE_LOB.WRITE • DBE_LOB.WRITE_APPEND • DBE_LOB.COPY • DBE_LOB.ERASE For details about the APIs, see DBE_LOB .	The maximum size is 32 TB (35,184,372,088,832 bytes).
RAW	Variable-length hexadecimal string.	4 bytes plus the actual hexadecimal string. Its maximum length is 1073733621 bytes (1 GB – 8203 bytes).
BYTEA	Variable-length binary string.	4 bytes plus the actual binary string. Its maximum length is 1073733621 bytes (1 GB – 8203 bytes).

 NOTE

In addition to the size limitation on each column, the total size of each tuple cannot exceed 1,073,733,621 bytes (that is, 1 GB minus 8,203 bytes).

Example:

```
-- Create a table.
openGauss=# CREATE TABLE blob_type_t1
(
  BT_COL1 INTEGER,
  BT_COL2 BLOB,
  BT_COL3 RAW,
  BT_COL4 BYTEA
);

-- Insert data.
openGauss=# INSERT INTO blob_type_t1 VALUES(10,empty_blob(),
HEXTORAW('DEADBEEF'),E'\xDEADBEEF');

-- Query data in the table.
openGauss=# SELECT * FROM blob_type_t1;
 bt_col1 | bt_col2 | bt_col3 | bt_col4
-----+-----+-----+-----
    10 |      | DEADBEEF | \xdeadbeef
(1 row)
```

```
-- Delete the table.  
openGauss=# DROP TABLE blob_type_t1;
```

7.3.6 Date/Time Types

Table 7-11 lists the date/time types supported by GaussDB. For the operators and built-in functions of the types, see [Date and Time Processing Functions and Operators](#).

NOTE

If the time format of another database is different from that of GaussDB, modify the value of the **DateStyle** parameter to keep them consistent.

Table 7-11 Date/Time types

Name	Description	Storage Space
DATE	Date. Minimum value: 4713-01-01BC (4713 B.C.). Maximum value: 5874897-12-31AD (5874897 A.C.) NOTE For A compatibility, the database treats empty strings as NULL and replaces DATE with TIMESTAMP(0) WITHOUT TIME ZONE .	4 bytes (8 bytes in A-compatible schema)
TIME [(p)] [WITHOUT TIME ZONE]	Time within one day (without time zone). p indicates the precision after the decimal point. The value ranges from 0 to 6 . Minimum value: 00:00:00 . Maximum value: 24:00:00 .	8 bytes
TIME [(p)] [WITH TIME ZONE]	Time within one day (with time zone). p indicates the precision after the decimal point. The value ranges from 0 to 6 . Minimum value: 00:00:00+1559 . Maximum value: 24:00:00 .	12 bytes
TIMESTAMP[(p)] [WITHOUT TIME ZONE]	Date and time (without a time zone). p indicates the precision after the decimal point. The value ranges from 0 to 6 . Minimum value: 4713-11-24BC 00:00:00.000000 (4713 B.C.). Maximum value: 294277-01-09AD 00:00:00.000000 (294277 A.D.).	8 bytes

Name	Description	Storage Space
TIMESTAMP[(p)] [WITH TIME ZONE]	Date and time (with time zone). TIMESTAMP is also called TIMESTAMPTZ. p indicates the precision after the decimal point. The value ranges from 0 to 6. Minimum value: 4713-11-24BC 00:00:00.000000 (4713 B.C.). Maximum value: 294277-01-09AD 00:00:00.000000 (294277 A.D.). Time zone update: In some countries or regions, the time zone information is frequently updated due to political, economic, and war factors. Therefore, the database system often needs to modify the time zone file accordingly to ensure that the time is correct. Currently, the GaussDB time zone type involves only timestamp with timezone. When a new time zone file takes effect, the existing data is not changed, and the new data is adjusted based on the time zone file information. The capability of the same type of data in the database is different from that in an A-compatible database.	8 bytes
SMALLDATETIME	Date and time (without time zone). The precision level is minute. 31s to 59s are rounded into 1 minute. Minimum value: 4713-11-24BC 00:00:00.000000 (4713 B.C.). Maximum value: 294277-01-09AD 00:00:00.000000 (294277 A.D.).	8 bytes
INTERVAL DAY (l) TO SECOND (p)	Time interval (X days X hours X minutes X seconds). • l: indicates the precision of days. The value ranges from 0 to 6. For compatibility, the precision functions are not supported. • p: indicates the precision of seconds. The value ranges from 0 to 6. The digit 0 at the end of a decimal number is not displayed.	16 bytes

Name	Description	Storage Space
INTERVAL [FIELDS] [(p)]	Time interval. • FIELDS: YEAR, MONTH, DAY, HOUR, MINUTE, SECOND, DAY TO HOUR, DAY TO MINUTE, DAY TO SECOND, HOUR TO MINUTE, HOUR TO SECOND, or MINUTE TO SECOND. • p: indicates the precision of seconds. The value ranges from 0 to 6. p takes effect only when FIELDS is SECOND, DAY TO SECOND, HOUR TO SECOND, or MINUTE TO SECOND. The digit 0 at the end of a decimal number is not displayed.	12 bytes
reltime	Relative time interval. • The format is as follows: X years X mons X days XX:XX:XX. • The Julian calendar is used. It specifies that a year has 365.25 days and a month has 30 days. The relative time interval needs to be calculated based on the input value.	4 bytes
abstime	Date and time. • Format: YYYY-MM-DD hh:mm:ss +timezone. • The value range is from 1901-12-13 20:45:53 GMT to 2038-01-18 23:59:59 GMT. The precision is second.	4 bytes

Example:

```
-- Create a table.
openGauss=# CREATE TABLE date_type_tab(coll date);

-- Insert data.
openGauss=# INSERT INTO date_type_tab VALUES (date '12-10-2010');

-- View data.
openGauss=# SELECT * FROM date_type_tab;
      coll
-----
2010-12-10 00:00:00
(1 row)

-- Delete the table.
openGauss=# DROP TABLE date_type_tab;
```

```
-- Create a table.
openGauss=# CREATE TABLE time_type_tab (da time without time zone ,dai time with time zone,dfgh
timestamp without time zone,dfga timestamp with time zone, vbg smalldatetime);

-- Insert data.
openGauss=# INSERT INTO time_type_tab VALUES ('21:21:21','21:21:21 pst','2010-12-12','2013-12-11
pst','2003-04-12 04:05:06');

-- View data.
openGauss=# SELECT * FROM time_type_tab;
   da   |   dai   |   dfgh   |   dfga   |   vbg
-----+-----+-----+-----+-----
21:21:21 | 21:21:21-08 | 2010-12-12 00:00:00 | 2013-12-11 16:00:00+08 | 2003-04-12 04:05:00
(1 row)

-- Delete the table.
openGauss=# DROP TABLE time_type_tab;

-- Create a table.
openGauss=# CREATE TABLE day_type_tab (a int,b INTERVAL DAY(3) TO SECOND (4));

-- Insert data.
openGauss=# INSERT INTO day_type_tab VALUES (1, INTERVAL '3' DAY);

-- View data.
openGauss=# SELECT * FROM day_type_tab;
 a | b
---+-----
 1 | 3 days
(1 row)

-- Delete the table.
openGauss=# DROP TABLE day_type_tab;

-- Create a table.
openGauss=# CREATE TABLE year_type_tab(a int, b interval year (6));

-- Insert data.
openGauss=# INSERT INTO year_type_tab VALUES(1,interval '2' year);

-- View data.
openGauss=# SELECT * FROM year_type_tab;
 a | b
---+-----
 1 | 2 years
(1 row)

-- Delete the table.
openGauss=# DROP TABLE year_type_tab;
```

Date Inputs

Date and time input is accepted in almost any reasonable formats, including ISO 8601, SQL-compatible, and traditional Postgres. The system allows you to customize the sequence of day, month, and year in the date input. Set the **DateStyle** parameter to **MDY** to select month-day-year interpretation, **DMY** to select day-month-year interpretation, or **YMD** to select year-month-day interpretation.

Remember that any date or time literal input needs to be enclosed with single quotation marks ('), and the syntax is as follows:

```
type [ ( p ) ] 'value'
```

The **p** that can be selected in the precision statement is an integer, indicating the number of fractional digits in the **seconds** column. [Table 7-12](#) shows the input formats of the date type.

Table 7-12 Date input

Example	Description
1999-01-08	ISO 8601 (recommended format). January 8, 1999 in any format.
January 8, 1999	Unambiguous in any datestyle input mode
1/8/1999	January 8 in MDY mode. August 1 in DMY mode
1/18/1999	January 18 in MDY mode, rejected in other modes
01/02/03	- January 2, 2003 in MDY mode - February 1, 2003 in DMY mode - February 3, 2001 in YMD mode
1999-Jan-08	January 8 in any mode
Jan-08-1999	January 8 in any mode
08-Jan-1999	January 8 in any mode
99-Jan-08	January 8 in YMD mode, else error
08-Jan-99	January 8, except error in YMD mode
Jan-08-99	January 8, except error in YMD mode
19990108	ISO 8601: January 8, 1999 in any mode
990108	ISO 8601: January 8, 1999 in any mode
1999.008	Year and day of year
J2451187	Julian date
January 8, 99 BC	Year 99 BC

Example:

```
-- Create a table.
openGauss=# CREATE TABLE date_type_tab(coll date);

-- Insert data.
openGauss=# INSERT INTO date_type_tab VALUES (date '12-10-2010');

-- View data.
openGauss=# SELECT * FROM date_type_tab;
      coll
-----
2010-12-10(1 row)

-- View the date format.
openGauss=# SHOW datestyle;
```

```
DateStyle
-----
ISO, MDY
(1 row)

-- Set the date format.
openGauss=# SET datestyle='YMD';
SET

-- Insert data.
openGauss=# INSERT INTO date_type_tab VALUES(date '2010-12-11');

-- View data.
openGauss=# SELECT * FROM date_type_tab;
      coll
-----
2010-12-10 00:00:00
2010-12-11 00:00:00
(2 rows)

-- Delete the table.
openGauss=# DROP TABLE date_type_tab;
```

Time

The time-of-day types are **TIME [(p)] [WITHOUT TIME ZONE]** and **TIME [(p)] [WITH TIME ZONE]**. **TIME** alone is equivalent to **TIME WITHOUT TIME ZONE**.

If a time zone is specified in the input for **TIME WITHOUT TIME ZONE**, it is silently ignored.

For details about the time input types, see [Table 7-13](#). For details about time zone input types, see [Table 7-14](#).

Table 7-13 Time input

Example	Description
05:06.8	ISO 8601
4:05:06	ISO 8601
4:05	ISO 8601
040506	ISO 8601
4:05 AM	Same as 04:05. Input hours must be less than or equal to 12.
4:05 PM	Same as 16:05. Input hour must be <= 12
04:05:06.789-8	ISO 8601
04:05:06-08:00	ISO 8601
04:05-08:00	ISO 8601
040506-08	ISO 8601
04:05:06 PST	Time zone specified by abbreviation

Example	Description
2003-04-12 04:05:06 America/ New_York	Time zone specified by full name

Table 7-14 Time zone input

Example	Description
PST	Abbreviation (for Pacific Standard Time)
America/New_York	Full time zone name
-8:00	ISO-8601 offset for PST
-800	ISO-8601 offset for PST
-8	ISO-8601 offset for PST

Example:

```
openGauss=# SELECT time '04:05:06';
time
-----
04:05:06
(1 row)

openGauss=# SELECT time '04:05:06 PST';
time
-----
04:05:06
(1 row)

openGauss=# SELECT time with time zone '04:05:06 PST';
timetz
-----
04:05:06-08
(1 row)
```

Special Values

The special values supported by GaussDB are converted to common date/time values when being read. For details, see [Table 7-15](#).

Table 7-15 Special values

Input String	Applicable Type	Description
epoch	date and timestamp	1970-01-01 00:00:00+00 (Unix system time zero)
infinity	timestamp	Infinity, later than any other timestamp
-infinity	timestamp	Infinity, earlier than any other timestamp

Input String	Applicable Type	Description
now	date, time, and timestamp	Start time of the current transaction
today	date and timestamp	Today at midnight
tomorrow	date and timestamp	Tomorrow at midnight
yesterday	date and timestamp	Yesterday at midnight
allballs	time	00:00:00.00 UTC

Example:

```
-- Create a table.

openGauss=# DROP TABLE realtime_type_special;
```

Interval Input

The input of **reltime** can be any valid interval in text format. It can be a number (negative numbers and decimals are also allowed) or a specific time, which must be in SQL standard format, ISO-8601 format, or POSTGRES format. In addition, the text input needs to be enclosed with single quotation marks (").

For details about interval input, see [Table 7-16](#).

Table 7-16 Interval input types

Input	Output	Description
60	2 mons	Numbers are used to indicate intervals. The default unit is day. Decimals and negative numbers are allowed. Particularly, a negative interval syntactically means how long before.
31.25	1 mons 1 days 06:00:00	
-365	-12 mons -5 days	
1 years 1 mons 8 days 12:00:00	1 years 1 mons 8 days 12:00:00	Intervals are in POSTGRES format. They can contain both positive and negative numbers and are case-insensitive. Output is a simplified POSTGRES interval converted from the input.
-13 months -10 hours	-1 years -25 days -04:00:00	
-2 YEARS +5 MONTHS 10 DAYS	-1 years -6 mons -25 days -06:00:00	
P-1.1Y10M	-3 mons -5 days -06:00:00	Intervals are in ISO-8601 format. They can contain both positive and negative numbers and are case-insensitive. Output is a simplified POSTGRES interval converted from the input.
-12H	-12:00:00	

Example:

```
-- Create a table.
openGauss=# CREATE TABLE reltime_type_tab(col1 character(30), col2 reltime);

-- Insert data.
openGauss=# INSERT INTO reltime_type_tab VALUES ('90', '90');
openGauss=# INSERT INTO reltime_type_tab VALUES ('-366', '-366');
openGauss=# INSERT INTO reltime_type_tab VALUES ('1975.25', '1975.25');
openGauss=# INSERT INTO reltime_type_tab VALUES ('-2 YEARS +5 MONTHS 10 DAYS', '-2 YEARS +5 MONTHS 10 DAYS');
openGauss=# INSERT INTO reltime_type_tab VALUES ('30 DAYS 12:00:00', '30 DAYS 12:00:00');
openGauss=# INSERT INTO reltime_type_tab VALUES ('P-1.1Y10M', 'P-1.1Y10M');

-- View data.
openGauss=# SELECT * FROM reltime_type_tab;
      col1      |      col2
-----+-----
90              | 3 mons
-366            | -1 years -18:00:00
1975.25         | 5 years 4 mons 29 days
-2 YEARS +5 MONTHS 10 DAYS | -1 years -6 mons -25 days -06:00:00
30 DAYS 12:00:00 | 1 mon 12:00:00
P-1.1Y10M       | -3 mons -5 days -06:00:00
(6 rows)

-- Delete the table.
openGauss=# DROP TABLE reltime_type_tab;
```

7.3.7 Geometric

Table 7-17 lists the geometric types that can be used in GaussDB. The most fundamental type, the point, forms the basis for all of the other types.

Table 7-17 Geometric types

Name	Storage Space	Description	Representation
point	16 bytes	Point on a plane	(x,y)
lseg	32 bytes	Finite line segment	((x1,y1),(x2,y2))
box	32 bytes	Rectangle	((x1,y1),(x2,y2))
path	16 + 16 x <i>n</i> bytes	Closed path (similar to polygon)	((x1,y1),...)
path	16 + 16 x <i>n</i> bytes	Open path	[(x1,y1),...]
polygon	40 + 16 x <i>n</i> bytes	Polygon (similar to closed path)	((x1,y1),...)
circle	24 bytes	Circle	<(x,y),r> (center point and radius)

A rich set of functions and operators is available in GaussDB to perform various geometric operations, such as scaling, translation, rotation, and determining intersections. For details, see [Geometric Functions and Operators](#).

Points

Points are the fundamental two-dimensional building block for geometric types. Values of the **point** type are specified using either of the following syntax:

```
( x , y )  
x , y
```

x and **y** are the respective coordinates, as floating-point numbers. The value type of the points is float8.

Points are output using the first syntax.

Example:

```
openGauss=# select point(1.1, 2.2);  
point  
-----  
(1.1,2.2)  
(1 row)
```

Line Segments

Line segments (**lseg**) are represented by pairs of points. Values of the **lseg** type are specified using any of the following syntax:

```
[ ( x1 , y1 ) , ( x2 , y2 ) ]  
( ( x1 , y1 ) , ( x2 , y2 ) )  
( x1 , y1 ) , ( x2 , y2 )  
x1 , y1 , x2 , y2
```

(x1,y1) and **(x2,y2)** are the end points of the line segment. The value type of the points is float8.

Line segments are output using the first syntax.

Example:

```
openGauss=# select lseg(point(1.1, 2.2), point(3.3, 4.4));  
lseg  
-----  
[(1.1,2.2),(3.3,4.4)]  
(1 row)
```

Rectangles

Boxes are represented by pairs of points that are opposite corners of the box. Values of the **box** type are specified using any of the following syntax:

```
( ( x1 , y1 ) , ( x2 , y2 ) )  
( x1 , y1 ) , ( x2 , y2 )  
x1 , y1 , x2 , y2
```

(x1,y1) and **(x2,y2)** are any two opposite corners of the rectangle. The value type of the points is float8.

Rectangles are output using the second syntax.

Any two opposite corners can be supplied on input, but in this order, the values will be reordered as needed to store the upper right and lower left corners.

Example:

```
openGauss=# select box(point(1.1, 2.2), point(3.3, 4.4));
      box
-----
(3.3,4.4),(1.1,2.2)
(1 row)
```

Paths

Paths are represented by lists of connected points. Paths can be open, where the first and last points in the list are considered not connected, or closed, where the first and last points are considered connected.

Values of the **path** type are specified using any of the following syntax:

```
[ ( x1 , y1 ) , ... , ( xn , yn ) ]
( ( x1 , y1 ) , ... , ( xn , yn ) )
( x1 , y1 ) , ... , ( xn , yn )
( x1 , y1 , ... , xn , yn )
x1 , y1 , ... , xn , yn
```

The points are the end points of the line segments comprising the path. The value type of the points is float8. Square brackets ([]) indicate an open path, while parentheses (()) indicate a closed path. When the outermost parentheses are omitted, as in the third through fifth syntax, a closed path is assumed.

Paths are output using the first or second syntax.

Example:

```
openGauss=# select path(polygon '((0,0),(1,1),(2,0))');
      path
-----
((0,0),(1,1),(2,0))
(1 row)
```

Polygons

Polygons are represented by lists of points (the vertexes of the polygon). Polygons are very similar to closed paths, but are stored differently and have their own set of support functions.

Values of the **polygon** type are specified using any of the following syntax:

```
(( x1 , y1 ) , ... , ( xn , yn ) )
( x1 , y1 ) , ... , ( xn , yn )
( x1 , y1 , ... , xn , yn )
x1 , y1 , ... , xn , yn
```

A point indicates the vertex of a polygon. The value type of a point is float8.

Polygons are output using the first syntax.

Example:

```
openGauss=# select polygon(box '((0,0),(1,1))');
      polygon
-----
((0,0),(0,1),(1,1),(1,0))
(1 row)
```

Circles

Circles are represented by a center point and radius. Values of the **circle** type are specified using the following syntaxes:

```
< ( x , y ) , r >  
( ( x , y ) , r )  
( x , y ) , r  
x , y , r
```

(x,y) is the center point and **r** is the radius of the circle. The value type of the points is float8.

Circles are output using the first syntax.

Example:

```
openGauss=# select circle(point(0,0),1);  
circle  
-----  
<(0,0),1>  
(1 row)
```

7.3.8 Network Address Types

GaussDB offers data types to store IPv4 and MAC addresses.

It is better to use these types instead of plain-text types to store network addresses, because these types offer input error checking and specialized operators and functions (see [Network Address Functions and Operators](#)).

Table 7-18 Network address types

Name	Storage Space	Description
cidr	7 bytes	IPv4 networks
inet	7 bytes	IPv4 hosts and networks
macaddr	6 bytes	MAC address

cidr

The **cidr** type (Classless Inter-Domain Routing) holds an IPv4 network address. The format for specifying networks is **address/y** where **address** is the network represented as an IPv4 address, and **y** is the number of bits in the netmask. If **y** is omitted, it is calculated using assumptions from the older classful network numbering system, except it will be at least large enough to include all of the octets written in the input.

Table 7-19 cidr type input examples

cidr Input	cidr Output	abbrev(cidr)
192.168.100.128/25	192.168.100.128/25	192.168.100.128/25
192.168/24	192.168.0.0/24	192.168.0/24

cidr Input	cidr Output	abbrev(cidr)
192.168/25	192.168.0.0/25	192.168.0.0/25
192.168.1	192.168.1.0/24	192.168.1/24
192.168	192.168.0.0/24	192.168.0/24
10.1.2	10.1.2.0/24	10.1.2/24
10.1	10.1.0.0/16	10.1/16
10	10.0.0.0/8	10/8
10.1.2.3/32	10.1.2.3/32	10.1.2.3/32

Example:

```
openGauss=# CREATE TABLE cidr_test(id int, c cidr);
CREATE TABLE
openGauss=# INSERT INTO cidr_test VALUES (1, '192.168.100.128/25');
INSERT 0 1
openGauss=# INSERT INTO cidr_test VALUES (2, '192.168/24');
INSERT 0 1
openGauss=# INSERT INTO cidr_test VALUES (3, '192.168/25');
INSERT 0 1
openGauss=# INSERT INTO cidr_test VALUES (4, '192.168.1');
INSERT 0 1
openGauss=# INSERT INTO cidr_test VALUES (5, '192.168');
INSERT 0 1
openGauss=# INSERT INTO cidr_test VALUES (6, '10.1.2');
INSERT 0 1
openGauss=# INSERT INTO cidr_test VALUES (7, '10.1');
INSERT 0 1
openGauss=# INSERT INTO cidr_test VALUES (8, '10');
INSERT 0 1
openGauss=# INSERT INTO cidr_test VALUES (9, '2001:4f8:3:ba::/64');
INSERT 0 1
openGauss=# INSERT INTO cidr_test VALUES (10, '2001:4f8:3:ba:2e0:81ff:fe22:d1f1/128');
INSERT 0 1
openGauss=# INSERT INTO cidr_test VALUES (11, '::ffff:127.0.0.0/120');
INSERT 0 1
openGauss=# INSERT INTO cidr_test VALUES (12, '::ffff:127.0.0.0/128');
INSERT 0 1
openGauss=# SELECT * FROM cidr_test ORDER BY id;
 id |          c          |
-----+-----
  1 | 192.168.100.128/25 |
  2 | 192.168.0.0/24    |
  3 | 192.168.0.0/25    |
  4 | 192.168.1.0/24    |
  5 | 192.168.0.0/24    |
  6 | 10.1.2.0/24       |
  7 | 10.1.0.0/16       |
  8 | 10.0.0.0/8        |
  9 | 2001:4f8:3:ba::/64 |
 10 | 2001:4f8:3:ba:2e0:81ff:fe22:d1f1/128 |
 11 | ::ffff:127.0.0.0/120 |
 12 | ::ffff:127.0.0.0/128 |
(12 rows)

openGauss=# DROP TABLE cidr_test;
DROP TABLE
```

inet

The **inet** type holds an IPv4 host address, and optionally its subnet, all in one field. The subnet is represented by the number of network address bits present in the host address (the "netmask"). If the netmask is 32 and the address is an IPv4 address, then the value does not indicate a subnet, only a single host.

The input format for this type is **address/y** where **address** is an IPv4 address and **y** is the number of bits in the netmask. If **/y** is omitted, the subnet mask is **32** for an IPv4 address, and the value represents just a single host. On display, the **/y** portion is suppressed if the netmask specifies a single host.

The essential difference between the **inet** and **cidr** data types is that **inet** accepts values with nonzero bits to the right of the netmask, whereas **cidr** does not.

Example:

```
openGauss=# CREATE TABLE inet_test(id int, i inet);
CREATE TABLE
openGauss=# INSERT INTO inet_test VALUES (1, '192.168.100.128/25');
INSERT 0 1
openGauss=# INSERT INTO inet_test VALUES (2, '192.168.100.128');
INSERT 0 1
openGauss=# INSERT INTO inet_test VALUES (3, '192.168.1.0/24');
INSERT 0 1
openGauss=# INSERT INTO inet_test VALUES (4, '192.168.1.0/25');
INSERT 0 1
openGauss=# INSERT INTO inet_test VALUES (5, '192.168.1.255/24');
INSERT 0 1
openGauss=# INSERT INTO inet_test VALUES (6, '192.168.1.255/25');
INSERT 0 1
openGauss=# INSERT INTO inet_test VALUES (7, '10.1.2.3/8');
INSERT 0 1
openGauss=# INSERT INTO inet_test VALUES (8, '11.1.2.3/16');
INSERT 0 1
openGauss=# INSERT INTO inet_test VALUES (9, '12.1.2.3/24');
INSERT 0 1
openGauss=# INSERT INTO inet_test VALUES (10, '13.1.2.3/32');
INSERT 0 1
openGauss=# INSERT INTO inet_test VALUES (11, '2001:4f8:3:ba::/64');
INSERT 0 1
openGauss=# INSERT INTO inet_test VALUES (12, '2001:4f8:3:ba:2e0:81ff:fe22:d1f1/128');
INSERT 0 1
openGauss=# INSERT INTO inet_test VALUES (13, '::ffff:127.0.0.0/120');
INSERT 0 1
openGauss=# INSERT INTO inet_test VALUES (14, '::ffff:127.0.0.0/128');
INSERT 0 1
openGauss=# SELECT * FROM inet_test ORDER BY id;
 id |          i
-----+-----
  1 | 192.168.100.128/25
  2 | 192.168.100.128
  3 | 192.168.1.0/24
  4 | 192.168.1.0/25
  5 | 192.168.1.255/24
  6 | 192.168.1.255/25
  7 | 10.1.2.3/8
  8 | 11.1.2.3/16
  9 | 12.1.2.3/24
 10 | 13.1.2.3
 11 | 2001:4f8:3:ba::/64
 12 | 2001:4f8:3:ba:2e0:81ff:fe22:d1f1
 13 | ::ffff:127.0.0.0/120
 14 | ::ffff:127.0.0.0
(14 rows)
```

```
openGauss=# DROP TABLE inet_test;
DROP TABLE
```

macaddr

The **macaddr** type stores MAC addresses, known for example from Ethernet card hardware addresses (although MAC addresses are used for other purposes as well). Input is accepted in the following formats:

```
'08:00:2b:01:02:03'
'08-00-2b-01-02-03'
'08002b:010203'
'08002b-010203'
'0800.2b01.0203'
'08002b010203'
```

These examples would all specify the same address. Upper and lower cases are accepted for the digits a through f. Output is always in the first of the forms shown.

Example:

```
openGauss=# CREATE TABLE macaddr_test(id int, m macaddr);
CREATE TABLE
openGauss=# INSERT INTO macaddr_test VALUES (1, '08:00:2b:01:02:03');
INSERT 0 1
openGauss=# INSERT INTO macaddr_test VALUES (2, '08-00-2b-01-02-03');
INSERT 0 1
openGauss=# INSERT INTO macaddr_test VALUES (3, '08002b:010203');
INSERT 0 1
openGauss=# INSERT INTO macaddr_test VALUES (4, '08002b-010203');
INSERT 0 1
openGauss=# INSERT INTO macaddr_test VALUES (5, '0800.2b01.0203');
INSERT 0 1
openGauss=# INSERT INTO macaddr_test VALUES (6, '08002b010203');
INSERT 0 1
openGauss=# SELECT * FROM macaddr_test ORDER BY id;
 id |      m
-----+-----
  1 | 08:00:2b:01:02:03
  2 | 08:00:2b:01:02:03
  3 | 08:00:2b:01:02:03
  4 | 08:00:2b:01:02:03
  5 | 08:00:2b:01:02:03
  6 | 08:00:2b:01:02:03
(6 rows)

openGauss=# DROP TABLE macaddr_test;
DROP TABLE
```

7.3.9 Bit String Types

Bit strings are strings of 1's and 0's. They can be used to store bit masks.

GaussDB supports two bit string types: **bit(n)** and **bit varying(n)**. Here, *n* is a positive integer. The maximum value of *n* is **83886080**, which is equivalent to 10 MB.

The **bit** type data must match the length *n* exactly. It is an error to attempt to store shorter or longer bit strings. Data of the bit varying type is of variable length up to the maximum length *n*. Longer strings will be rejected. Writing **bit** without a length is equivalent to **bit(1)**, while **bit varying** without a length specification means unlimited length.

 NOTE

- If one explicitly casts a bit-string value to **bit(*n*)**, it will be truncated or zero-padded on the right to be exactly *n* bits, without raising an error.
- Similarly, if one explicitly casts a bit-string value to **bit varying(*n*)**, it will be truncated on the right if it is more than *n* bits.
- When the ADMS platform driver version 8.1.3-200 or earlier is used, use **::bit varying** to convert the bit type. Otherwise, an error may occur.

```
-- Create a table.
openGauss=# CREATE TABLE bit_type_t1
(
    BT_COL1 INTEGER,
    BT_COL2 BIT(3),
    BT_COL3 BIT VARYING(5)
);

-- Insert data.
openGauss=# INSERT INTO bit_type_t1 VALUES(1, B'101', B'00');

-- Specify the type length. An error is reported if an inserted string exceeds this length.
openGauss=# INSERT INTO bit_type_t1 VALUES(2, B'10', B'101');
ERROR: bit string length 2 does not match type bit(3)
CONTEXT: referenced column: bt_col2

-- Specify the type length. Data is converted if it exceeds this length.
openGauss=# INSERT INTO bit_type_t1 VALUES(2, B'10'::bit(3), B'101');

-- View data.
openGauss=# SELECT * FROM bit_type_t1;
 bt_col1 | bt_col2 | bt_col3
-----+-----+-----
      1 | 101    | 00
      2 | 100    | 101
(2 rows)
```

```
-- Delete the table.
openGauss=# DROP TABLE bit_type_t1;
```

7.3.10 UUID

The data type UUID stores universally unique identifiers (UUID) as defined by RFC 4122, ISO/IEF 9834-8:2005, and related standards. This identifier is a 128-bit quantity that is generated by an algorithm chosen to make it very unlikely that the same identifier will be generated by anyone else in the known universe using the same algorithm.

A UUID is written as a sequence of lower-case hexadecimal digits, in several groups separated by hyphens, specifically a group of 8 digits followed by three groups of 4 digits followed by a group of 12 digits, for a total of 32 digits representing the 128 bits. An example of a UUID in this standard form is:

```
a0eebc99-9c0b-4ef8-bb6d-6bb9bd380a11
```

GaussDB also accepts the following alternative forms for input: use of upper-case letters and digits, the standard format surrounded by braces, omitting some or all hyphens, adding a hyphen after any group of four digits. An example is provided as follows:

```
A0EEBC99-9C0B-4EF8-BB6D-6BB9BD380A11
{a0eebc99-9c0b-4ef8-bb6d-6bb9bd380a11}
a0eebc999c0b4ef8bb6d6bb9bd380a11
a0ee-bc99-9c0b-4ef8-bb6d-6bb9-bd38-0a11
```

Output is always in the standard form.

Examples

```
-- Create a table.
openGauss=# CREATE TABLE uuid_test(id int, test uuid);

-- Insert data in the example format.
openGauss=# INSERT INTO uuid_test VALUES(1, 'A0EEBC99-9C0B-4EF8-BB6D-6BB9BD380A11');
openGauss=# INSERT INTO uuid_test VALUES(2, '{a0eebc99-9c0b-4ef8-bb6d-6bb9bd380a11}');
openGauss=# INSERT INTO uuid_test VALUES(3, 'a0eebc999c0b4ef8bb6d6bb9bd380a11');
openGauss=# INSERT INTO uuid_test VALUES(4, 'a0ee-bc99-9c0b-4ef8-bb6d-6bb9-bd38-0a11');

-- View data and output the data in the standard format.
openGauss=# SELECT * FROM uuid_test;
id |          test
----+-----
 1 | a0eebc99-9c0b-4ef8-bb6d-6bb9bd380a11
 2 | a0eebc99-9c0b-4ef8-bb6d-6bb9bd380a11
 3 | a0eebc99-9c0b-4ef8-bb6d-6bb9bd380a11
 4 | a0eebc99-9c0b-4ef8-bb6d-6bb9bd380a11
(4 rows)
```

7.3.11 JSON/JSONB Types

JavaScript Object Notation (JSON) data can be a single scalar, an array, or a key-value pair object. The array and object can be called a container:

- Scalar: a number, Boolean, string, or null
- Array: defined in a pair of square brackets ([]), in which elements can be any type of JSON data, and are not necessarily of the same type.
- Object: defined in a pair of braces ({}), in which objects are stored in the format of key:value. Each key must be a string enclosed by a pair of double quotation marks (""), and its value can be any type of JSON data. In case of duplicate keys, the last key value will be used.

GaussDB offers two types for storing JSON data: JSON and JSONB. The JSON data type stores a complete copy of the input, retaining the entered spaces, duplicate keys, and sequence, while JSONB data is stored in its decomposed binary form, with semantic-irrelevant details and duplicate keys removed and key-values sorted. Therefore, the JSONB data does not need to be parsed.

Basically, both are JSON data types. However, they differ greatly in efficiency. Because JSON data type stores an exact copy of the input text, the data must be parsed on every execution. In contrast, JSONB data is stored in its parsed binary form and can be processed faster, though this makes it slightly slower to input due to the conversion mechanism. In addition, because the JSONB data type is normalized, it supports more operations, for example, comparing sizes according to a specific rule. JSONB also supports indexing, which is a significant advantage.

Input Format

An input must be a JSON-compliant string, which is enclosed in single quotation marks (').

null (null-json): The value can only be **null** in lowercase.

```
openGauss=# SELECT 'null':json; -- suc
json
-----
null
(1 row)
```

```
openGauss=# SELECT 'NULL'::jsonb; -- err
ERROR:  invalid input syntax for type json
```

Number (num-json): The value can be a positive or negative integer, decimal fraction, or 0. The scientific notation is supported.

```
openGauss=# SELECT '1'::json;
json
```

```
-----
1
(1 row)
```

```
openGauss=# SELECT '-1.5'::json;
json
```

```
-----
-1.5
(1 row)
```

```
openGauss=# SELECT '-1.5e-5'::jsonb, '-1.5e+2'::jsonb;
```

```
jsonb | jsonb
-----+-----
-0.000015 | -150
(1 row)
```

```
openGauss=# SELECT '001'::json, '+15'::json, 'NaN'::json; -- Redundant leading zeros, plus signs (+), NaN,
and infinity are not supported.
ERROR:  invalid input syntax for type json
```

Boolean (bool-json): The value can only be **true** or **false** in lowercase.

```
openGauss=# SELECT 'true'::json;
json
```

```
-----
true
(1 row)
```

```
openGauss=# SELECT 'false'::jsonb;
jsonb
```

```
-----
false
(1 row)
```

String (str-json): The value must be a string enclosed in double quotation marks ("").

```
openGauss=# SELECT '"a"'::json;
json
```

```
-----
"a"
(1 row)
```

```
openGauss=# SELECT '"abc"'::jsonb;
jsonb
```

```
-----
"abc"
(1 row)
```

Array (array-json): Arrays are enclosed in square brackets ([]). Elements in the array can be any valid JSON data, and are unnecessarily of the same type.

```
openGauss=# SELECT '[1, 2, "foo", null]'::json;
json
```

```
-----
[1, 2, "foo", null]
(1 row)
```

```
openGauss=# SELECT '[]'::json;
json
```

```
-----
```

```
[]  
(1 row)  
  
openGauss=# SELECT '[1, 2, "foo", null, [], {}]'::jsonb;  
          jsonb  
-----  
[1, 2, "foo", null, [], {}]  
(1 row)
```

Object (object-json): The value is enclosed in braces ({}). The key must be a JSON-compliant string, and the value can be any valid JSON string.

```
openGauss=# SELECT '{}'::json;  
          json  
-----  
{}  
(1 row)  
  
openGauss=# SELECT '{"a": 1, "b": {"a": 2, "b": null}}'::json;  
          json  
-----  
{"a": 1, "b": {"a": 2, "b": null}}  
(1 row)  
  
openGauss=# SELECT '{"foo": [true, "bar"], "tags": {"a": 1, "b": null}}'::jsonb;  
          jsonb  
-----  
{"foo": [true, "bar"], "tags": {"a": 1, "b": null}}  
(1 row)
```

NOTICE

- Note that **'null'::json** and **null::json** are different, which are similar to the strings **str=""** and **str=null**.
- For numbers, when scientific notation is used, JSONB expands them, while JSON stores an exact copy of the input text.

JSONB Advanced Features

- Precautions
 - It cannot be used as a partition key.
 - Foreign tables and MOTs are not supported.

The main difference between JSON and JSONB lies in the storage mode. JSONB stores parsed binary data, which reflects the JSON hierarchy and facilitates direct access. Therefore, JSONB has many advanced features that JSON does not have.

- Format normalization
 - After the input object-json string is parsed into JSONB binary, semantically irrelevant details are naturally discarded, for example, spaces:

```
openGauss=# select ' [1, " a ", {"a" :1  } ] '::jsonb;  
          jsonb  
-----  
[1, " a ", {"a": 1}]  
(1 row)
```
 - For object-json, duplicate key-values are deleted and only the last key-value is retained. For example:

```
openGauss=# select '{"a" : 1, "a" : 2}'::jsonb;  
          jsonb
```

```
-----  
{ "a": 2 }  
(1 row)
```

- For object-jsonb, key-values will be re-sorted. The collation rule is as follows: 1. Longer key-values are sorted last. 2. If the key-values are of the same length, the key-values with a larger ASCII code are sorted after the key-values with a smaller ASCII code:

```
openGauss=# select '{"aa" : 1, "b" : 2, "a" : 3} '::jsonb;  
              jsonb  
-----  
{ "a": 3, "b": 2, "aa": 1 }  
(1 row)
```

- Size comparison

Format normalization ensures that only one form of JSONB data exists in the same semantics. Therefore, sizes may be compared according to a specific rule.

- First, type comparison: **object-jsonb** > **array-jsonb** > **bool-jsonb** > **num-jsonb** > **str-jsonb** > **null-jsonb**
- Content comparison if the data type is the same:
 - str-jsonb: The default text sorting rule of the database is used for comparison. A positive value indicates greater than, a negative value indicates less than, and 0 indicates equal.
 - num-jsonb: numeric comparison
 - bool-jsonb: **true** > **false**
 - array-jsonb: long elements > short elements. If the lengths are the same, compare each element in sequence.
 - object-jsonb: If the length of a key-value pair is longer than that of a short key-value pair, the keys are compared first, and then the values are compared.

NOTICE

For comparison within the object-jsonb type, the final result after format sorting is used for comparison. Therefore, the comparison result may not be intuitive compared with the direct input.

- Creating indexes, primary keys, and foreign keys

- B-tree index

B-tree indexes, primary keys, and foreign keys can be created for the **JSONB** type.

- Inclusion and existence

Querying whether a JSON contains some elements or whether some elements exist in a JSON is an important capability of JSONB.

For details about the operators, see [JSON/JSONB Functions and Operators](#).

- Functions and operators

For details about the functions and operators supported by the JSON/JSONB type, see [JSON/JSONB Functions and Operators](#).

7.3.12 HLL

HyperLoglog (HLL) is an approximation algorithm for efficiently counting the number of distinct values in a dataset. It features faster computing and lower space usage. You only need to store HLL data structures, instead of datasets. When new data is added to a dataset, make hash calculation on the data and insert the result to an HLL. Then, you can obtain the final result based on the HLL.

Table 7-20 compares HLL with other algorithms.

Table 7-20 Comparison between HLL and other algorithms

Item	Sorting Algorithm	Hash Algorithm	HLL
Time complexity	$O(n\log n)$	$O(n)$	$O(n)$
Space complexity	$O(n)$	$O(n)$	$\log(\log n)$
Error rate	0	0	$\approx 0.8\%$
Storage space requirement	Size of original data	Size of original data	The maximum size is 16 KB by default.

HLL has advantages over others in the computing speed and storage space requirement. In terms of time complexity, the sorting algorithm needs $O(n\log n)$ time for sorting, and the hash algorithm and HLL need $O(n)$ time for full table scanning. In terms of storage space requirements, the sorting algorithm and hash algorithm need to store raw data before collecting statistics, whereas the HLL algorithm needs to store only the HLL data structures rather than the raw data, and thereby occupying a fixed space of about 16 KB.

NOTICE

- In the current default specifications, the maximum number of distinct values that can be calculated is about $1.1e + 15$, and the error rate is 0.8%. If the calculation result exceeds the maximum, the error rate of the calculation result will increase, or the calculation will fail and an error will be reported.
- When using this feature for the first time, you need to evaluate the distinct values of the service, properly select configuration parameters, and perform verification to ensure that the accuracy meets requirements.
 - By default, the distinct value is $1.1e + 15$. If the distinct value is NaN, you need to adjust log2m or use another algorithm to calculate the distinct value.
 - The hash algorithm has an extremely low probability of collision. However, you are still advised to select 2 or 3 hash seeds for verification when using the hash algorithm for the first time. If there is only a small difference between the distinct values, you can select any one of the seeds as the hash seed.

Table 7-21 describes main HLL data structures.

Table 7-21 Main HLL data structures

Data Type	Description
hll	The HLL header is a 27-byte field. By default, the data length ranges from 0 KB to 16 KB. The distinct value can be obtained.

When you create an HLL data type, 0 to 4 input parameters are supported. The parameter meanings and specifications are the same as those of the **hll_empty** function. The first parameter is **log2m**, indicating the logarithm of the number of buckets, and its value ranges from 10 to 16. The second parameter is **log2explicit**, indicating the threshold in explicit mode, and its value ranges from 0 to 12. The third parameter is **log2sparse**, indicating the threshold of the Sparse mode, and its value ranges from 0 to 14. The fourth parameter is **duplicatecheck**, indicating whether to enable duplicatecheck, and its value ranges from 0 to 1. When the input parameter is set to **-1**, the default value of the HLL parameter is used. You can run the **\d** or **\d+** command to view the parameters of the HLL type.

NOTE

When the HLL data type is created, the result varies depending on the input parameter behavior:

- When creating an HLL type, do not set the input parameter or set it to **-1**. Use the default value of the corresponding HLL parameter.
- If a valid value is set for the input parameter, the corresponding HLL parameter uses the input value.
- If the input value is invalid, an error is reported when the HLL type is created.

```
-- Create an HLL table without specifying input parameters.
openGauss=# CREATE TABLE t1 (id integer, set hll);
openGauss=# \d t1
      Table "public.t1"
  Column | Type      | Modifiers
-----+-----+-----
 id      | integer   |
 set     | hll       |

-- Create an HLL table, specify the first two input parameters, and use the default values for the last two
input parameters.
openGauss=# CREATE TABLE t2 (id integer, set hll(12,4));
openGauss=# \d t2
      Table "public.t2"
  Column | Type      | Modifiers
-----+-----+-----
 id      | integer   |
 set     | hll(12,4,12,0) |

-- Create an HLL table, specify the third input parameter, and use default values for other parameters.
openGauss=# CREATE TABLE t3(id int, set hll(-1,-1,8,-1));
openGauss=# \d t3
      Table "public.t3"
  Column | Type      | Modifiers
-----+-----+-----
 id      | integer   |
 set     | hll(14,10,8,0) |
```

```
-- When a user creates an HLL table and specifies an invalid input parameter, an error is reported.
openGauss=# CREATE TABLE t4(id int, set hll(5,-1));
ERROR: log2m = 5 is out of range, it should be in range 10 to 16, or set -1 as default

-- Drop the created HLL table.
openGauss=# DROP TABLE t1,t2,t3;
DROP TABLE
```

NOTE

When inserting an HLL object to an HLL table, ensure that the parameters of the HLL type are the same as those of the inserted object. Otherwise, an error is reported.

```
-- Create an HLL table.
openGauss=# CREATE TABLE t1(id integer, set hll(14));

-- Insert an HLL object to a table. The insertion succeeds because parameter types are consistent.
openGauss=# INSERT INTO t1 VALUES (1, hll_empty(14,-1));

-- Insert an HLL object to a table. The insertion fails because parameter types are inconsistent.
openGauss=# INSERT INTO t1(id, set) VALUES (1, hll_empty(14,5));
ERROR: log2explicit does not match: source is 5 and dest is 10

-- Drop the table.
openGauss=# DROP TABLE t1;
```

The following describes HLL application scenarios:

- Scenario 1: "Hello World"

The following example shows how to use the HLL data type:

```
-- Create an HLL table.
openGauss=# CREATE TABLE helloworld (id integer, set hll);

-- Insert an empty HLL to the table.
openGauss=# INSERT INTO helloworld(id, set) VALUES (1, hll_empty());

-- Add a hashed integer to the HLL.
openGauss=# UPDATE helloworld SET set = hll_add(set, hll_hash_integer(12345)) WHERE id = 1;

-- Add a hashed string to the HLL.
openGauss=# UPDATE helloworld SET set = hll_add(set, hll_hash_text('hello world')) WHERE id = 1;

-- Obtain the number of distinct values of the HLL.
openGauss=# SELECT hll_cardinality(set) FROM helloworld WHERE id = 1;
 hll_cardinality
-----
                2
(1 row)

-- Drop the table.
openGauss=# DROP TABLE helloworld;
```

- Scenario 2: Collect statistics about website visitors.

The following example shows how an HLL collects statistics on the number of users visiting a website within a period of time:

```
-- Create a raw data table to show that a user has visited the website at a certain time.
openGauss=# CREATE TABLE facts (
    date        date,
    user_id     integer
);

-- Create a raw data table to show that a user has visited the website at a certain time.
openGauss=# INSERT INTO facts VALUES ('2019-02-20', generate_series(1,100));
openGauss=# INSERT INTO facts VALUES ('2019-02-21', generate_series(1,200));
openGauss=# INSERT INTO facts VALUES ('2019-02-22', generate_series(1,300));
openGauss=# INSERT INTO facts VALUES ('2019-02-23', generate_series(1,400));
openGauss=# INSERT INTO facts VALUES ('2019-02-24', generate_series(1,500));
openGauss=# INSERT INTO facts VALUES ('2019-02-25', generate_series(1,600));
```

```
openGauss=# INSERT INTO facts VALUES ('2019-02-26', generate_series(1,700));
openGauss=# INSERT INTO facts VALUES ('2019-02-27', generate_series(1,800));

-- Create another table and specify an HLL column:
openGauss=# CREATE TABLE daily_uniques (
    date          date UNIQUE,
    users         hll
);

-- Group data by date and insert the data into the HLL.
openGauss=# INSERT INTO daily_uniques(date, users)
    SELECT date, hll_add_agg(hll_hash_integer(user_id))
    FROM facts
    GROUP BY 1;

-- Calculate the numbers of users visiting the website every day.
openGauss=# SELECT date, hll_cardinality(users) FROM daily_uniques ORDER BY date;
    date | hll_cardinality
-----+-----
2019-02-20 |          100
2019-02-21 | 200.217913059312
2019-02-22 | 301.76494508014
2019-02-23 | 400.862858326446
2019-02-24 | 502.626933349694
2019-02-25 | 601.922606454213
2019-02-26 | 696.602316769498
2019-02-27 | 798.111731634412
(8 rows)

-- Calculate the number of users who had visited the website in the week from February 20, 2019 to
February 26, 2019.
openGauss=# SELECT hll_cardinality(hll_union_agg(users)) FROM daily_uniques WHERE date >=
'2019-02-20'::date AND date <= '2019-02-26'::date;
    hll_cardinality
-----
702.941844662509
(1 row)

-- Calculate the number of users who had visited the website yesterday but have not visited the
website today:
openGauss=# SELECT date, (#hll_union_agg(users) OVER two_days) - #users AS lost_uniques FROM
daily_uniques WINDOW two_days AS (ORDER BY date ASC ROWS 1
PRECEDING);
    date | lost_uniques
-----+-----
2019-02-20 |          0
2019-02-21 |          0
2019-02-22 |          0
2019-02-23 |          0
2019-02-24 |          0
2019-02-25 |          0
2019-02-26 |          0
2019-02-27 |          0
(8 rows)

-- Drop the table.
openGauss=# DROP TABLE facts;
openGauss=# DROP TABLE daily_uniques;
```

- Scenario 3: The data to be inserted does not meet the requirements of the HLL data structure.

When inserting data into a column of the HLL type, ensure that the data meets the requirements of the HLL data structure. If the data does not meet the requirements after being parsed, an error will be reported. In the following example, 'E\1234' to be inserted does not meet the requirements of the HLL data structure after being parsed. As a result, an error is reported.

```
openGauss=# CREATE TABLE test(id integer, set hll);
openGauss=# INSERT INTO test VALUES(1, 'E\\1234');
ERROR: not a hll type, size=6 is not enough

openGauss=# DROP TABLE test;
```

7.3.13 Range Types

A range type is a data type that represents the range of a value of an element type (called the subtype of a range). For example, the range of timestamp may be used to express a time range in which a conference room is reserved. In this case, the data type is tsrange (short for timestamp range), and timestamp is the subtype. The subtype must have an overall order so that the element value can be clearly specified within a range, before, or after.

Range types are useful because they can express multiple element values in a single range value and can clearly express concepts such as range overlapping (time and date ranges for time arrangement, price ranges, and instrument ranges).

Built-in Range

The following built-in ranges are available:

- int4range: integer range.
- int8range: bigint range.
- numrange: numeric range.
- tsrange: range of timestamp without the time zone.
- tstzrange: range of timestamp with the time zone
- daterange: date range.

In addition, you can define your own range types. For details, see [CREATE TYPE](#).

Example

```
-- Create a table and insert data into the table.
openGauss=# CREATE TABLE reservation (room int, during tsrange);
openGauss=# INSERT INTO reservation VALUES (1108, '[2010-01-01 14:30, 2010-01-01 15:30)');
-- Inclusion
openGauss=# SELECT int4range(10, 20) @> 3;
?column?
-----
f
(1 row)
-- Overlapping
openGauss=# SELECT numrange(11.1, 22.2) && numrange(20.0, 30.0);
?column?
-----
t
(1 row)
-- Upper bound extraction
openGauss=# SELECT upper(int8range(15, 25));
upper
-----
25
(1 row)
-- Intersection set
openGauss=# SELECT int4range(10, 20) * int4range(15, 25);
?column?
-----
```

```
[15,20)
(1 row)
-- Is the range empty?
openGauss=# SELECT isempty(numrange(1, 5));
isempty
-----
f
(1 row)
-- Drop the table.
openGauss=# DROP TABLE reservation;
```

See the complete list of operators and functions on a range type in [Range Functions and Operators](#).

Including and Excluding Bounds

Each non-empty range has two bounds, a lower bound and an upper bound. All values between the upper and lower bounds are included in the range. An inclusion bound means that the bound value itself is included in the range, while an exclusion bound means that the bound value is not included in the range.

In a textual form of a range, the inclusion lower bound is expressed as "[" and an exclusion lower bound is expressed as "(". Similarly, one containing the upper bound is expressed as "]" and one excluding the upper bound is expressed as ")" (for details, see [Range Input/Output](#)).

The lower_inc and upper_inc functions test the upper and lower bounds of a range value, respectively.

Infinite (Unbounded) Range

When the lower bound of a range is unbounded, it means that all values less than the upper bound are included in the range. Similarly, when the upper bound of a range is unbounded, all values greater than the lower bound are included in the range. When both the upper and lower bounds are unbounded, all values of the element type are considered within the range. The missing bounds are automatically converted to exclusions. You can think of these missing values as positive infinity or negative infinity, but they are special range type values and are considered to be positive and negative infinity values that go beyond any range element type.

Element types with the infinity values can be used as explicit bound values. For example, in the timestamp range, [today, infinity) does not include a special timestamp value infinity.

The lower_inf and upper_inf functions test the infinite upper and lower bounds of a range, respectively.

Range Input/Output

The input of a range value must follow one of the following formats:

```
(lower-bound, upper-bound)
(lower-bound, upper-bound]
[lower-bound, upper-bound)
[lower-bound, upper-bound]
Empty
```

The output of a range value must follow one of the following formats:

[lower-bound, upper-bound)
Empty

Parentheses () or square brackets [] indicate whether the upper and lower bounds are excluded or included. Note that the last format is empty, which represents an empty range (a range that does not contain values).

The value of *lower-bound* can be a valid input character string of the subtype or null, indicating that there is no lower bound. Similarly, *upper-bound* can be a valid input character string of the subtype or null, indicating that there is no upper bound.

Each bound value can be referenced using the quotation marks('') character. This is necessary if the bounds value contains parentheses (), square brackets [], commas (,), quotation marks (''), or backslashes (\). Otherwise, those characters will be considered as the part of the range syntax. To put the quotation mark or backslash in a referenced bound value, put a backslash in front of it (and a pair of double quotation marks in its quoted bound value represents one quotation mark character, which is similar to the single quotation mark rule in SQL character strings). In addition, you can avoid referencing and use backslash escapes to protect all data characters, otherwise they will be used as part of the return syntax. Also, if you want to write a bound value that is an empty string, write '', indicating infinite bounds.

Spaces are allowed before and after a range value, but any space between parentheses() or square brackets[] is used as part of the upper or lower bound value (depending on the element type, the space may or may not represent a value).

Examples:

```
-- 3 is included, 7 is not included, and all values between 3 and 7 are included.
openGauss=# SELECT '[3,7)':int4range;
int4range
-----
[3,7)
(1 row)
-- Neither 3 nor 7 is included, but all values between them are included.
openGauss=# SELECT '(3,7)':int4range;
int4range
-----
[4,7)
(1 row)
-- Only 4 is included.
openGauss=# SELECT '[4,4]':int4range;
int4range
-----
[4,5)
(1 row)
-- Exclude any value (and will be normalized to empty).
openGauss=# SELECT '[4,4)':int4range;
int4range
-----
Empty
(1 row)
```

Constructing Range

Each range type has a constructor function with the same name. Using constructor functions is often more convenient than writing a range literal constant because it avoids extra references to bound values. Constructor functions accept two or three parameters. Two parameters form a range in the standard

form, where the lower bound is included and the upper bound is excluded, and three parameters form a range according to the bound specified by the third parameter. The third parameter must be one of the following character strings: (), (], [), or []. For example:

```
-- The complete format is: lower bound, upper bound, and textual parameters indicating the inclusion/
exclusion of bounds.
openGauss=# SELECT numrange(1.0, 14.0, '()');
numrange
-----
(1.0,14.0]
(1 row)
-- If the third parameter is ignored, it is assumed to be '()'.
openGauss=# SELECT numrange(1.0, 14.0);
numrange
-----
[1.0,14.0)
(1 row)
-- Although '()' is specified here, the value will be converted to the standard format when displayed,
because int8range is a discrete range type (see below).
openGauss=# SELECT int8range(1, 14, '()');
int8range
-----
[2,15)
(1 row)
-- Using NULL for a bound causes the range to be unbounded on that side.
openGauss=# SELECT numrange(NULL, 2.2);
numrange
-----
(,2.2)
(1 row)
```

Discrete Range

A range element type has a well-defined "step" such as integer or date. In these types, if there is no valid value between two elements, they can be said to be adjacent. This is in contrast to a continuous range in which other element values can always be identified between two given values. For example, a range above the numeric type is continuous, and the range of timestamp is also continuous. (Although timestamp has limited precision and can be considered as discrete in theory, it can be considered as continuous because the step is not normally considered.)

Another way to consider discrete range types is to have a clear "next" or "previous" value for each element value. With this idea in mind, you can switch between inclusion and exclusion expressions of a range bound by replacing it with the original given next or previous element value. For example, in an integer range type, [4,8] and (3,9) represent the same set of values, but not for numeric ranges.

A discrete range type should have a *regularization* function that knows the expected step size of the element type. The regularization function can convert the equivalents of the range type to the same expression, in particular consistent with the inclusion or exclusion bounds. If you do not specify a regularization function, ranges with different formats will always be considered as unequal, even if they actually express the same set of values.

The built-in range types int4range, int8range, and daterange use a regularized form that includes the lower bound and excludes the upper bound, that is, []). However, user-defined range types can use other conventions.

Defining New Range

Users can define their own range types. A common reason is to use the range on the subtype that is not provided in the built-in range type. For example, to create the range type subtype float8, run the following command:

```
openGauss=# CREATE TYPE floatrange AS RANGE (
    subtype = float8,
    subtype_diff = float8mi
);
openGauss=# SELECT '[1.234, 5.678]':floatrange;
floatrange
-----
[1.234,5.678]
(1 row)
openGauss=# DROP TYPE floatrange;
```

Because float8 does not have a meaningful "step", the regularization function is not defined in this example.

Defining your own range type also allows you to specify a different subtype B-tree operator class or collection to change the sort order to determine which values fall within the given range.

If the subtype is considered to have a discrete value instead of a continuous value, the **CREATE TYPE** command should specify a canonical function. The regularization function receives an input range value and must return an equivalent range value that may have different bounds and formats. For two ranges, for example, [1, 7] and [1, 8) that represent the same value set, the output must be the same. There is no relationship between choosing which expression to use as the regularization function, as long as two values of equal value in different formats can always be mapped to the same value in the same format. In addition to adjusting the inclusion/exclusion bound format, if the expected compensation is larger than the subtype can store, a regularization function may round the bound value. For example, a range type above a timestamp might be defined as having a one-hour epoch, so the regularization function might need to round off bounds that are not multiples of an hour, or might throw an error directly.

The subtype difference function uses two subtype input values and returns a difference expressed as a float8 value (X minus Y). In the example above, we can use functions under the regular float8 subtraction operator. However, for any other subtype, some type conversion may be required. There may also be a need for innovative ideas on how to express differences as numbers. For maximum extensibility, the subtype_diff function should agree with the sort order of the selected operator class and sort rules. That is, if the first parameter of the sort order is greater than the second parameter, the result should be a positive value.

The following is an example of the subtype_diff function:

```
openGauss=# CREATE FUNCTION time_subtype_diff(x time, y time) RETURNS float8 AS 'SELECT
EXTRACT(EPOCH FROM (x - y))' LANGUAGE sql STRICT IMMUTABLE;
openGauss=# CREATE TYPE timerange AS RANGE (
    subtype = time,
    subtype_diff = time_subtype_diff
);
openGauss=# SELECT '[11:10, 23:00]':timerange;
timerange
-----
[11:10:00,23:00:00]
```

```
(1 row)
openGauss=# DROP TYPE timerange;
openGauss=# DROP FUNCTION time_subtype_diff;
```

For details about how to create a range type, see [CREATE TYPE](#).

Index

B-tree and hash indexes can be created on table columns of the range type. For these index types, basically the only useful range operation is equivalence. Using the corresponding < and > operators, there is a B-tree sort order for range value definitions, but that order is fairly arbitrary and is often less useful in the reality. The B-tree and hash support for range types is primarily designed to allow sorting and hashing within a query, rather than creating an index.

7.3.14 OID Types

OIDs are used internally by GaussDB as primary keys for various system catalogs. OIDs are not added to user-created tables by the system. The OID type represents an object identifier.

The OID type is currently implemented as an unsigned four-byte integer. So, using a user-created table's **OID** column as a primary key is discouraged.

Table 7-22 OID types

Name	Reference	Description	Example
OID	N/A	Numeric object identifier	564182
CID	N/A	Command identifier. This is the data type of the system columns cmin and cmax . Command identifiers are 32-bit quantities.	N/A
XID	N/A	Transaction identifier. This is the data type of the system columns xmin and xmax . Transaction identifiers are also 64-bit quantities.	N/A
TID	N/A	Row identifier. This is the data type of the system column ctid . A row ID is a pair (block number, tuple index within block) that identifies the physical location of the row within its table.	N/A
REGCONFIG	pg_ts_config	Text search configuration	english

Name	Reference	Description	Example
REGDICTIONARY	pg_ts_dict	Text search dictionary	simple
REGOPER	pg_operator	Operator name	N/A
REGOPERATOR	pg_operator	Operator with parameter types	*(integer,integer) or -(NONE,integer)
REGPROC	pg_proc	Function name	sum
REGPROCEDURE	pg_proc	Function with parameter types	sum(int4)
REGCLASS	pg_class	Relation name	pg_type
REGTYPE	pg_type	Data type name	integer

The OID type is used for a column in the database system catalog.

Example:

```
openGauss=# SELECT oid FROM pg_class WHERE relname = 'pg_type';
oid
-----
1247
(1 row)
```

The alias type for **OID** is **REGCLASS** which allows simplified search for **OID** values.

Example:

```
openGauss=# SELECT attrelid,attname,atttypid,attstattarget FROM pg_attribute WHERE attrelid =
'pg_type'::REGCLASS;
attrelid | attname | atttypid | attstattarget
-----+-----+-----+-----
1247 | xc_node_id | 23 | 0
1247 | tableoid | 26 | 0
1247 | cmax | 29 | 0
1247 | xmax | 28 | 0
1247 | cmin | 29 | 0
1247 | xmin | 28 | 0
1247 | oid | 26 | 0
1247 | ctid | 27 | 0
1247 | typname | 19 | -1
1247 | typnamespace | 26 | -1
1247 | typowner | 26 | -1
1247 | typplen | 21 | -1
1247 | typbyval | 16 | -1
1247 | typtype | 18 | -1
1247 | typcategory | 18 | -1
1247 | typispreferred | 16 | -1
1247 | typisdefined | 16 | -1
1247 | typdelim | 18 | -1
1247 | typrelid | 26 | -1
1247 | typelem | 26 | -1
1247 | typarray | 26 | -1
1247 | typinput | 24 | -1
1247 | typoutput | 24 | -1
1247 | typepreceive | 24 | -1
```

1247	typsend		24		-1
1247	typmodin		24		-1
1247	typmodout		24		-1
1247	typanalyze		24		-1

7.3.15 Pseudo-Types

GaussDB type system contains a number of special-purpose entries that are collectively called pseudo-types. A pseudo-type cannot be used as a column data type, but it can be used to declare a function's argument or result type.

Each of the available pseudo-types is useful in situations where a function's behavior does not correspond to simply taking or returning a value of a specific SQL data type. [Table 7-23](#) lists all pseudo-types.

Table 7-23 Pseudo-types

Name	Description
any	Indicates that a function accepts any input data type.
anyelement	Indicates that a function accepts any data type.
anyarray	Indicates that a function accepts any array data type.
anynonarray	Indicates that a function accepts any non-array data type.
anyenum	Indicates that a function accepts any enum data type.
anyrange	Indicates that a function accepts any range data type.
cstring	Indicates that a function accepts or returns a null-terminated C string.
internal	Indicates that a function accepts or returns a server-internal data type.
language_handler	Indicates that a procedural language call handler is declared to return language_handler .
fdw_handler	Indicates that a foreign data wrapper handler is declared to return fdw_handler .
record	Identifies a function returning an unspecified row type.
trigger	Indicates that a trigger function is declared to return trigger .
void	Indicates that a function returns no value.

Name	Description
opaque	Indicates an obsolete type name that formerly served all the above purposes.

Functions coded in C (whether built in or dynamically loaded) can be declared to accept or return any of these pseudo data types. It is up to the function author to ensure that the function will behave safely when a pseudo-type is used as an argument type.

Functions coded in procedural languages can use pseudo-types only as allowed by their implementation languages. At present the procedural languages all forbid use of a pseudo-type as argument type, and allow only **void** and **record** as a result type. Some polymorphic functions support the **anyelement**, **anyarray**, **anynonarray**, **anyenum**, and **anyrange** types.

The internal pseudo-type is used to declare functions that are meant only to be called internally by the database system, and not by direct calling in an SQL query. If a function has at least one internal-type argument, then it cannot be called from SQL. You are advised not to create any function that is declared to return internal unless it has at least one internal argument.

Example:

```
-- Create a table.
openGauss=# create table t1 (a int);

-- Insert two data records.
openGauss=# insert into t1 values(1),(2);

-- Create the showall() function.
openGauss=# CREATE OR REPLACE FUNCTION showall() RETURNS SETOF record
AS $$ SELECT count(*) from t1; $$
LANGUAGE SQL;

-- Call the showall() function.
openGauss=# SELECT showall();
showall
-----
(2)
(1 row)

-- Delete the function.
openGauss=# DROP FUNCTION showall();

-- Drop the table.
openGauss=# drop table t1;
```

7.3.16 ACLItem

The aclitem data type is used to store object permission information. Its internal implementation is of the int type and supports the '*user1* = *privs*/*user2*' format.

The aclitem[] data type is an array consisting of ACLItems. The supported format is {*user1* = *privs1*/*user3*, *user2* = *privs2*/*user3*}.

In the preceding command, *user1*, *user2*, and *user3* indicate the existing users or roles in the database, and *privs* indicates the permissions supported by the database. For details, see [Table 12-34](#).

Example:

```
-- Create users.
openGauss=# CREATE USER user1 WITH PASSWORD 'Aa123456789';
openGauss=# CREATE USER user2 WITH PASSWORD 'Aa123456789';
openGauss=# CREATE USER omm WITH PASSWORD 'Aa123456789';

-- Create a data table table_acl that contains three columns of the int, aclitem, and aclitem[] types.
openGauss=# CREATE TABLE table_acl (id int,priv aclitem,privs aclitem[]);
-- Insert a data record whose content is (1,'user1=arw/omm',{'omm=d/user2,omm=w/omm'}) into the table_acl table.
openGauss=# INSERT INTO table_acl VALUES (1,'user1=arw/omm',{'omm=d/user2,omm=w/omm'});
-- Insert a data record whose content is (2,'user1=aw/omm',{'omm=d/user2'}) into the table_acl table.
openGauss=# INSERT INTO table_acl VALUES (2,'user1=aw/omm',{'omm=d/user2'});
openGauss=# SELECT * FROM table_acl;
id | priv | privs
-----+-----
1 | user1=arw/omm | {omm=d/user2,omm=w/omm}
2 | user1=aw/omm | {omm=d/user2}
(2 rows)

-- Drop the table and users.
openGauss=# DROP USER user1;
openGauss=# DROP USER user2;
openGauss=# DROP USER omm;
openGauss=# DROP TABLE table_acl;
```

7.4 Constant and Macro

Table 7-24 lists the constants and macros that can be used in GaussDB.

Table 7-24 Constant and macro

Parameter	Description	Example
CURRENT_CATALOG	Specifies the current database.	testdb=# SELECT CURRENT_CATALOG; current_database ----- testdb (1 row)
CURRENT_ROLE	Specifies the current user.	openGauss=# SELECT CURRENT_ROLE; current_user ----- omm (1 row)
CURRENT_SCHEMA	Specifies the current database schema.	openGauss=# SELECT CURRENT_SCHEMA; current_schema ----- public (1 row)
CURRENT_USER	Specifies the current user.	openGauss=# SELECT CURRENT_USER; current_user ----- omm (1 row)
LOCALTIMESTAMP	Specifies the current session time (without time zone).	openGauss=# SELECT LOCALTIMESTAMP; timestamp ----- 2015-10-10 15:37:30.968538 (1 row)

Parameter	Description	Example
NULL	This parameter is left blank.	N/A
SESSION_USER	Specifies the current system user.	openGauss=# SELECT SESSION_USER; session_user ----- omm (1 row)
SYSDATE	Specifies the current system date.	openGauss=# SELECT SYSDATE; sysdate ----- 2015-10-10 15:48:53 (1 row)
USER	Specifies the current user, also called CURRENT_USER .	openGauss=# SELECT USER; current_user ----- omm (1 row)

7.5 Functions and Operators

Operators can be used to process one or more operands and can be placed before, after, or between operands. Results are returned after the processing.

Functions encapsulate service logic to implement specific functions. A function may or may not have parameters. After a function is executed, the result is returned.

Users can modify system functions. However, after the modification, the meaning of the functions may change, which results in disorder in system control. Therefore, users are not allowed to manually modify system functions.

7.5.1 Logical Operators

Common logical operators include AND, OR, and NOT. The operation result has three values: **TRUE**, **FALSE**, and **NULL**. NULL indicates unknown. Their priorities are NOT > AND > OR.

Table 7-25 lists the calculation rules, where a and b represent logical expressions.

Table 7-25 Operation rules

a	b	a AND b Result	a OR b Result	NOT a Result
TRUE	TRUE	TRUE	TRUE	FALSE
TRUE	FALSE	FALSE	TRUE	FALSE
TRUE	NULL	NULL	TRUE	FALSE
FALSE	FALSE	FALSE	FALSE	TRUE

a	b	a AND b Result	a OR b Result	NOT a Result
FALSE	NULL	FALSE	NULL	TRUE
NULL	NULL	NULL	NULL	NULL

 NOTE

The operators AND and OR are commutative, that is, you can switch the left and right operand without affecting the result.

7.5.2 Comparison Operators

Comparison operators are available for the most data types and return Boolean values.

All comparison operators are binary operators. Only data types that are the same or can be implicitly converted can be compared using comparison operators.

Table 7-26 describes comparison operators provided by GaussDB.

Table 7-26 Comparison operators

Operator	Description
<	Less than
>	Greater than
<=	Less than or equal to
>=	Greater than or equal to
=	Equal to
<>, !=, or ^=	Not equal to

- Comparison operators are available for all relevant data types. All comparison operators are binary operators that returned values of Boolean type. The calculation priority of the inequality sign is higher than that of the equality sign. If the entered data type is different and cannot be implicitly converted, the comparison fails. For example, an expression such as 1<2<3 is invalid because the less-than sign (<) cannot be used to compare Boolean values and 3.
- Besides, each comparison operator has a corresponding function in the **pg_proc** system catalog. If the value of proleakproof attribute of the corresponding function is **f**, the function is not used to prevent data leakage. If a user only has the permission for a system view, but does not have the permission for the corresponding table, the query plan may not be optimal when the user searches the system view.

7.5.3 Character Processing Functions and Operators

String functions and operators provided by GaussDB are for concatenating strings with each other, concatenating strings with non-strings, and matching the patterns of strings. Note: Except length-related functions, other functions and operators of string processing functions do not support parameters of CLOB whose size is greater than 1 GB.

- `bit_length(string)`

Description: Specifies the number of bits occupied by a string.

Return type: int

Example:

```
openGauss=# SELECT bit_length('world');
 bit_length
-----
         40
(1 row)
```

- `btrim(string text [, characters text])`

Description: Removes the longest string consisting only of characters in **characters** (a space by default) from the start and end of **string**.

Return type: text

Example:

```
openGauss=# SELECT btrim('sring', 'ing');
 btrim
-----
 sr
(1 row)
```

- `char_length(string)` or `character_length(string)`

Description: Specifies the number of characters in a string.

Return type: int

Example:

```
openGauss=# SELECT char_length('hello');
 char_length
-----
          5
(1 row)
```

- `instr(text,text,int,int)`

Description: **instr(string1,string2,int1,int2)** returns the text from **int1** to **int2** in **string1**. The first **int** indicates the start position for matching, and the second **int** indicates the number of matching times.

Return type: int

Example:

```
openGauss=# SELECT instr('abcdabcdabcd', 'bcd', 2, 2);
 instr
-----
      6
(1 row)
```

- `lengthb(text/bpchar)`

Description: Obtains the number of bytes of a specified string.

Return type: int

Example:

```
openGauss=# SELECT lengthb('hello');
lengthb
-----
      5
(1 row)
```

- left(str text, n int)

Description: Returns the first *n* characters in a string. When *n* is negative, all but the last **|n|** characters are returned.

Return type: text

Example:

```
openGauss=# SELECT left('abcde', 2);
left
-----
ab
(1 row)
```

- length(string bytea, encoding name)

Description: Specifies the number of characters in **string** in the given **encoding**. The string must be valid in this encoding.

Return type: int

Example:

```
openGauss=# SELECT length('jose', 'UTF8');
length
-----
      4
(1 row)
```

NOTE

If the length of the bytea type is queried and UTF8 encoding is specified, the maximum length can only be **536870888**.

- lpad(string text, length int [, fill text])

Description: Fills up **string** to **length** by appending the characters **fill** (a space by default). If **string** is already longer than **length**, then it is truncated.

Return type: text

Example:

```
openGauss=# SELECT lpad('hi', 5, 'xyza');
lpad
-----
xyzhi
(1 row)
```

- notlike(x bytea name text, y bytea text)

Description: Compares x and y to check whether they are inconsistent.

Return type: Boolean

Example:

```
openGauss=# SELECT notlike(1,2);
notlike
-----
      t
(1 row)
openGauss=# SELECT notlike(1,1);
notlike
-----
      f
(1 row)
```

- `octet_length(string)`

Description: Specifies the number of bytes in a string.

Return type: int

Example:

```
openGauss=# SELECT octet_length('jose');
octet_length
-----
         4
(1 row)
```

- `overlay(string placing string FROM int [for int])`

Description: Replaces substrings. **FROM int** indicates the start position of the replacement in the first string. **for int** indicates the number of characters replaced in the first string.

Return type: text

Example:

```
openGauss=# SELECT overlay('hello' placing 'world' from 2 for 3 );
overlay
-----
hworldo
(1 row)
```

- `position(substring in string)`

Description: Specifies the position of a substring. Parameters are case-sensitive.

Return type: int. If the character string does not exist, **0** is returned.

Example:

```
openGauss=# SELECT position('ing' in 'string');
position
-----
         4
(1 row)
```

- `pg_client_encoding()`

Description: Specifies the current client-side encoding name.

Return type: name

Example:

```
openGauss=# SELECT pg_client_encoding();
pg_client_encoding
-----
UTF8
(1 row)
```

- `quote_ident(string text)`

Description: Returns the given string suitably quoted to be used as an identifier in an SQL statement string (quotation marks are used as required). Quotation marks are added only if necessary (that is, if the string contains non-identifier characters or would be case-folded). Embedded quotation marks are properly doubled.

Return type: text

Example:

```
openGauss=# SELECT quote_ident('hello world');
quote_ident
-----
"hello world"
(1 row)
```

- `quote_literal(string text)`

Description: Returns the given string suitably quoted to be used as a string literal in an SQL statement string (quotation marks are used as required).

Return type: text

Example:

```
openGauss=# SELECT quote_literal('hello');
quote_literal
-----
'hello'
(1 row)
```

If a command similar to the following exists, the text will be escaped.

```
openGauss=# SELECT quote_literal(E'O\'hello');
quote_literal
-----
'O\'hello'
(1 row)
```

If a command similar to the following exists, the backslash will be properly doubled.

```
openGauss=# SELECT quote_literal('O\'hello');
quote_literal
-----
'E'O\\hello'
(1 row)
```

If the parameter is null, **NULL** is returned. If the parameter may be null, you are advised to use **quote_nullable**.

```
openGauss=# SELECT quote_literal(NULL);
quote_literal
-----
(1 row)
```

- `quote_literal(value anyelement)`

Description: Converts the given value to text and then quotes it as a literal.

Return type: text

Example:

```
openGauss=# SELECT quote_literal(42.5);
quote_literal
-----
'42.5'
(1 row)
```

If a command similar to the following exists, the given value will be escaped.

```
openGauss=# SELECT quote_literal(E'O\'42.5');
quote_literal
-----
'O\'42.5'
(1 row)
```

If a command similar to the following exists, the backslash will be properly doubled.

```
openGauss=# SELECT quote_literal('O\'42.5');
quote_literal
-----
'E'O\\42.5'
(1 row)
```

- `quote_nullable(string text)`

Description: Returns the given string suitably quoted to be used as a string literal in an SQL statement string (quotation marks are used as required).

Return type: text

Example:

```
openGauss=# SELECT quote_nullable('hello');
quote_nullable
-----
'hello'
(1 row)
```

If a command similar to the following exists, the text will be escaped.

```
openGauss=# SELECT quote_nullable(E'O\'hello');
quote_nullable
-----
'O\'hello'
(1 row)
```

If a command similar to the following exists, the backslash will be properly doubled.

```
openGauss=# SELECT quote_nullable('O\'hello');
quote_nullable
-----
E'O\\hello'
(1 row)
```

If the parameter is null, **NULL** is returned.

```
openGauss=# SELECT quote_nullable(NULL);
quote_nullable
-----
NULL
(1 row)
```

- `quote_nullable(value anyelement)`

Description: Converts the given value to text and then quotes it as a literal.

Return type: text

Example:

```
openGauss=# SELECT quote_nullable(42.5);
quote_nullable
-----
'42.5'
(1 row)
```

If a command similar to the following exists, the given value will be escaped.

```
openGauss=# SELECT quote_nullable(E'O\'42.5');
quote_nullable
-----
'O\'42.5'
(1 row)
```

If a command similar to the following exists, the backslash will be properly doubled.

```
openGauss=# SELECT quote_nullable('O\'42.5');
quote_nullable
-----
E'O\\42.5'
(1 row)
```

If the parameter is null, **NULL** is returned.

```
openGauss=# SELECT quote_nullable(NULL);
quote_nullable
-----
NULL
(1 row)
```

- `substring_inner(string [from int] [for int])`

Description: Extracts a substring. **from int** indicates the start position of the truncation. **for int** indicates the number of bytes truncated.

Return type: text

Example:

```
openGauss=# SELECT substring_inner('adcde', 2,3);
substring_inner
-----
dcd
(1 row)
```

- `substring(string [from int] [for int])`

Description: Extracts a substring. **from int** indicates the start position of the truncation. **for int** indicates the number of bytes truncated.

Return type: text

Example:

```
openGauss=# SELECT substring('Thomas' from 2 for 3);
substring
-----
hom
(1 row)
```

- `rawcat(raw,raw)`

Description: Indicates the string concatenation function.

Return type: raw

Example:

```
openGauss=# SELECT rawcat('ab','cd');
rawcat
-----
ABCD
(1 row)
```

- `regexp_count(string text, pattern text [, position int [, flags text]])`

Description: obtains the number of substrings used for matching.

Parameter description:

- **string**: source character string used for matching.
- **pattern**: regular expression pattern string used for matching.
- **position**: sequence number of the character to be matched from the source character string. This parameter is optional. The default value is **1**.
- **flags**: contains zero or multiple single-letter flags that change the matching behavior of the function. This parameter is optional.

Return type: int

Example:

```
openGauss=# SELECT regexp_count('foobarbaz','b(..)', 5) AS RESULT;
result
-----
1
(1 row)
```

- `regexp_instr(string text, pattern text [, position int [, occurrence int [, return_opt int [, flags text]]]])`

Description: obtains the position (starting from 1) of the substring that meets the matching condition. If no substring is matched, **0** is returned.

Parameter description:

- **string**: source character string used for matching.
- **pattern**: regular expression pattern string used for matching.

- **position**: start character of the source string used for matching. This parameter is optional. The default value is **1**.
- **occurrence**: sequence number of the matched substring to be replaced. This parameter is optional. The default value is **1**.
- **return_opt**: specifies whether to return the position of the first or last character of the matched substring. This parameter is optional. If the value is **0**, the position of the first character (starting from 1) of the matched substring is returned. If the value is greater than 0, the position of the next character of the end character of the matched substring is returned. The default value is **0**.
- **flags**: contains zero or multiple single-letter flags that change the matching behavior of the function. This parameter is optional.

Return type: int

Example:

```
openGauss=# SELECT regexp_instr('foobabaz','b(..)', 1, 1, 0) AS RESULT;
result
-----
4
(1 row)

openGauss=# SELECT regexp_instr('foobabaz','b(..)', 1, 2, 0) AS RESULT;
result
-----
7
(1 row)
```

- repeat(string text, number int)

Description: Repeats **string** the specified number of times.

Return type: text

Example:

```
openGauss=# SELECT repeat('Pg', 4);
repeat
-----
PgPgPgPg
(1 row)
```

NOTE

The maximum size of memory allocated at a time cannot exceed 1 GB due to the memory allocation mechanism of the database. Therefore, the maximum value of **number** cannot exceed $(1 \text{ GB} - x) / \text{lengthb}(\text{string}) - 1$. **x** indicates the length of the header information, which is usually greater than 4 bytes. The value varies among different scenarios.

- replace(string text, from text, to text)

Description: Replaces all occurrences in **string** of substring **from** with substring **to**.

Return type: text

Example:

```
openGauss=# SELECT replace('abcdefabcdef', 'cd', 'XXX');
replace
-----
abXXXefabXXXef
(1 row)
```

- replace(string, substring)

Description: Deletes all substrings in a string.

String type: text

Substring type: text

Return type: text

Example:

```
openGauss=# SELECT replace('abcdefabcdef', 'cd');
replace
-----
abefabef
(1 row)
```

- **reverse(str)**

Description: Returns the reversed string.

Return type: text

Example:

```
openGauss=# SELECT reverse('abcde');
reverse
-----
edcba
(1 row)
```

- **right(str text, n int)**

Description: Returns the last *n* characters in a string. When *n* is negative, all but the first **|n|** characters are returned.

Return type: text

Example:

```
openGauss=# SELECT right('abcde', 2);
right
-----
de
(1 row)

openGauss=# SELECT right('abcde', -2);
right
-----
cde
(1 row)
```

- **rpad(string text, length int [, fill text])**

Description: Fills up **string** to **length** by appending the characters **fill** (a space by default). If **string** is already longer than **length**, then it is truncated.

Return type: text

Example:

```
openGauss=# SELECT rpad('hi', 5, 'xy');
rpad
-----
hixyx
(1 row)
```

- **rtrim(string text [, characters text])**

Description: Removes the longest string containing only characters from characters (a space by default) from the end of string.

Return type: text

Example:

```
openGauss=# SELECT rtrim('trimxxxx', 'x');
rtrim
-----
```

```
trim
(1 row)
```

- substrb(text,int,int)

Description: Extracts a substring. The first **int** indicates the start position of the subtraction. The second **int** indicates the number of characters subtracted.

Return type: text

Example:

```
openGauss=# SELECT substrb('string',2,3);
substrb
-----
tri
(1 row)
```

- substrb(text,int)

Description: Extracts a substring. **int** indicates the start position of the extraction.

Return type: text

Example:

```
openGauss=# SELECT substrb('string',2);
substrb
-----
tring
(1 row)
```

- substr(bytea,from,count)

Description: Extracts a substring from **bytea**. **from** specifies the position where the extraction starts. **count** specifies the length of the extracted substring.

Return type: text

Example:

```
openGauss=# SELECT substr('string',2,3);
substr
-----
tri
(1 row)
```

- string || string

Description: Concatenates strings.

Return type: text

Example:

```
openGauss=# SELECT 'MPP' || 'DB' AS RESULT;
result
-----
MPPDB
(1 row)
```

- string || non-string or non-string || string

Description: Concatenates strings and non-strings.

Return type: text

Example:

```
openGauss=# SELECT 'Value: ' || 42 AS RESULT;
result
-----
Value: 42
(1 row)
```

- `split_part(string text, delimiter text, field int)`

Description: Splits **string** on **delimiter** and returns the **fieldth** column (counting from text of the first appeared delimiter).

Return type: text

Example:

```
openGauss=# SELECT split_part('abc~@~def~@~ghi', '~@~', 2);
split_part
-----
def
(1 row)
```

- `strpos(string, substring)`

Description: Specifies the position of a substring. It is the same as **position(substring in string)**. However, the parameter sequences of them are reversed.

Return type: int

Example:

```
openGauss=# SELECT strpos('source', 'rc');
strpos
-----
4
(1 row)
```

- `to_hex(number int or bigint)`

Description: Converts a number to a hexadecimal expression.

Return type: text

Example:

```
openGauss=# SELECT to_hex(2147483647);
to_hex
-----
7fffffff
(1 row)
```

- `translate(string text, from text, to text)`

Description: Any character in **string** that matches a character in **from** is replaced by the corresponding character in **to**. If **from** is longer than **to**, extra characters occurred in **from** are removed.

Return type: text

Example:

```
openGauss=# SELECT translate('12345', '143', 'ax');
translate
-----
a2x5
(1 row)
```

- `length(string)`

Description: Obtains the number of characters in a string.

Return type: integer

Example:

```
openGauss=# SELECT length('abcd');
length
-----
4
(1 row)
```

- `lengthb(string)`

Description: Obtains the number of bytes in a string. The value depends on character sets (GBK and UTF8).

Return type: integer

Example:

```
openGauss=# SELECT lengthb('Chinese');
lengthb
-----
      7
(1 row)
```

- substr(string,from)

Description:

Extracts substrings from a string.

from indicates the start position of the extraction.

- If **from** starts at 0, the value **1** is used.
- If the value of **from** is positive, all characters from **from** to the end are extracted.
- If the value of **from** is negative, the last *n* characters in the string are extracted, and *n* indicates the absolute value of **from**.

Return type: text

Example:

If the value of **from** is positive:

```
openGauss=# SELECT substr('ABCDEF',2);
substr
-----
BCDEF
(1 row)
```

If the value of **from** is negative:

```
openGauss=# SELECT substr('ABCDEF',-2);
substr
-----
EF
(1 row)
```

- substr(string,from,count)

Description:

Extracts substrings from a string.

from indicates the start position of the extraction.

count indicates the length of the extracted substring.

- If **from** starts at 0, the value **1** is used.
- If the value of **from** is positive, extract **count** characters starting from **from**.
- If the value of **from** is negative, extract the last **n count** characters in the string, in which **n** indicates the absolute value of **from**.
- If the value of **count** is smaller than **1**, **null** is returned.

Return type: text

Example:

If the value of **from** is positive:

```
openGauss=# SELECT substr('ABCDEF',2,2);
substr
```

```
-----  
BC  
(1 row)
```

If the value of **from** is negative:

```
openGauss=# SELECT substr('ABCDEF',-3,2);  
substr  
-----  
DE  
(1 row)
```

- **substrb(string,from)**

Description: The functionality of this function is the same as that of SUBSTR(string,from). However, the calculation unit is byte.

Return type: text

Example:

```
openGauss=# SELECT substrb('ABCDEF',-2);  
substrb  
-----  
EF  
(1 row)
```

- **substrb(string,from,count)**

Description: The functionality of this function is the same as that of SUBSTR(string,from,count). However, the calculation unit is byte.

Return type: text

Example:

```
openGauss=# SELECT substrb('ABCDEF',2,2);  
substrb  
-----  
BC  
(1 row)
```

- **trim([leading |trailing |both] [characters] from string)**

Description: Removes the longest string containing only the characters (a space by default) from the start/end/both ends of the string.

Return type: text

Example:

```
openGauss=# SELECT trim(BOTH 'x' FROM 'xTomxx');  
btrim  
-----  
Tom  
(1 row)  
openGauss=# SELECT trim(LEADING 'x' FROM 'xTomxx');  
ltrim  
-----  
Tomxx  
(1 row)  
openGauss=# SELECT trim(TRAILING 'x' FROM 'xTomxx');  
rtrim  
-----  
xTom  
(1 row)
```

- **rtrim(string [, characters])**

Description: Removes the longest string containing only characters from characters (a space by default) from the end of string.

Return type: text

Example:

```
openGauss=# SELECT rtrim('TRIMxxxx','x');
rtrim
-----
TRIM
(1 row)
```

- `ltrim(string [, characters])`

Description: Removes the longest string containing only characters from characters (a space by default) from the start of string.

Return type: text

Example:

```
openGauss=# SELECT ltrim('xxxxTRIM','x');
ltrim
-----
TRIM
(1 row)
```

- `upper(string)`

Description: Converts the string into the uppercase.

Return type: text

Example:

```
openGauss=# SELECT upper('tom');
upper
-----
TOM
(1 row)
```

- `lower(string)`

Description: Converts the string into the lowercase.

Return type: text

Example:

```
openGauss=# SELECT lower('TOM');
lower
-----
tom
(1 row)
```

- `rpadd(string varchar, length int [, fill varchar])`

Description: Fills up **string** to **length** by appending the characters **fill** (a space by default). If **string** is already longer than **length**, then it is truncated.

length in GaussDB indicates the character length. One Chinese character is counted as one character.

Return type: text

Example:

```
openGauss=# SELECT rpadd('hi',5,'xyza');
rpadd
-----
hixyz
(1 row)
openGauss=# SELECT rpadd('hi',5,'abcdefg');
rpadd
-----
hiabc
(1 row)
```

- `instr(string,substring[,position,occurrence])`

Description: Queries and returns the value of the substring position that occurs the **occurrence** (1 by default) times from the **position** (1 by default) in the string.

- If the value of **position** is **0**, **0** is returned.
- If the value of **position** is negative, the search is performed backwards from the last n th character in the string, in which n indicates the absolute value of **position**.

In this function, the calculation unit is character. One Chinese character is one character.

Return type: integer

Example:

```
openGauss=# SELECT instr('corporate floor','or', 3);
instr
-----
      5
(1 row)
openGauss=# SELECT instr('corporate floor','or',-3,2);
instr
-----
      2
(1 row)
```

- **initcap(string)**

Description: Capitalizes the first letter of each word in a string.

Return type: text

Example:

```
openGauss=# SELECT initcap('hi THOMAS');
initcap
-----
Hi Thomas
(1 row)
```

- **ascii(string)**

Description: Indicates the ASCII code of the first character in the string.

Return type: integer

Example:

```
openGauss=# SELECT ascii('xyz');
ascii
-----
    120
(1 row)
```

- **replace(string varchar, search_string varchar, replacement_string varchar)**

Description: Replaces all **search_string** in the string with **replacement_string**.

Return type: text

Example:

```
openGauss=# SELECT replace('jack and jue','j','bl');
replace
-----
black and blue
(1 row)
```

- **lpad(string varchar, length int[, repeat_string varchar])**

Description: Adds a series of **repeat_string** (a space by default) on the left of the string to generate a new string with the total length of n .

If the length of the string is longer than the specified length, the function truncates the string and returns the substrings with the specified length.

Return type: varchar

Example:

```
openGauss=# SELECT lpad('PAGE 1',15,'*');
          lpad
-----
*****PAGE 1
(1 row)
openGauss=# SELECT lpad('hello world',5,'abcd');
          lpad
-----
hello
(1 row)
```

- **concat(str1,str2)**

Description: Concatenates **str1** and **str2** and returns the concatenated string. If **str1** or **str2** is set to **NULL**, **NULL** is returned. Note: **concat** calls the output function of the data type and the return value is uncertain. As a result, the optimizer cannot calculate the result in advance when generating a plan. If there are performance requirements, you are advised to use the operator **||**.

 NOTE

- If **sql_compatibility** is set to 'B' and **str1** or **str2** is set to **NULL**, the returned result is **NULL**.
- The return value of the concat function is of the variable-length type. When the concat function is compared with table data, the character string length is lost in the combination result. As a result, the comparison results are different.

Return type: text

Example:

```
openGauss=# SELECT concat('Hello', ' World!');
          concat
-----
Hello World!
(1 row)
openGauss=# SELECT concat('Hello', NULL);
          concat
-----
Hello
(1 row)
```

- **chr(integer)**

Description: Specifies the character of the ASCII code.

Return type: varchar

Example:

```
openGauss=# SELECT chr(65);
          chr
-----
A
(1 row)
```

- **concat_ws(sep text, str"any" [, str"any" [, ...]])**

Description: Uses the first parameter as the separator, which is associated with all following parameters. The **NULL** parameter is ignored.

NOTICE

- If the first parameter value is **NULL**, the returned result is **NULL**.
- If the first parameter is provided but the parameter value is an empty string ('') and the SQL compatibility mode of the database is set to **A**, the returned result is **NULL**. This is because the A-compatible mode treats the empty string ('') as **NULL**. To resolve this problem, you can change the SQL compatibility mode of the database to **B**, **C**, or **PG**.

Return type: text

Example:

```
openGauss=# SELECT concat_ws(',', 'ABCDE', 2, NULL, 22);
concat_ws
-----
ABCDE,2,22
(1 row)
```

- **nlssort**(string text, sort_method text)

Description: Returns the encoding value of a string in the sorting mode specified by **sort_method**. The encoding value can be used for sorting and determines the sequence of the string in the sorting mode. Currently, **sort_method** can be set to **nls_sort=schinese_pinyin_m** or **nls_sort=generic_m_ci**. **nls_sort=generic_m_ci** supports only the case-insensitive order for English characters.

String type: text

sort_method type: text

Return type: text

Example:

```
openGauss=# CREATE TABLE test(a text);

openGauss=# INSERT into test(a) values ('abC');

openGauss=# insert INTO test(a) VALUES ('abC');

openGauss=# INSERT INTO test(a) VALUES ('abc');

openGauss=# SELECT * FROM test ORDER BY nlssort(a,'nls_sort=schinese_pinyin_m');
a
-----
abc
abC
abC
(3 rows)

openGauss=# SELECT * FROM test ORDER BY nlssort(a, 'nls_sort=generic_m_ci');
a
-----
abC
abc
abC
(3 rows)

openGauss=# DROP TABLE test;
```

- **convert**(string bytea, src_encoding name, dest_encoding name)

Description: Converts the string to **dest_encoding**. **src_encoding** specifies the source code encoding. The string must be valid in this encoding.

Return type: bytea

Example:

```
openGauss=# SELECT convert('text_in_utf8', 'UTF8', 'GBK');
          convert
-----
\x746578745f696e5f75746638
(1 row)
```

 NOTE

If the rule for converting between source to target encoding (for example, GBK and LATIN1) does not exist, the string is returned without conversion. See the `pg_conversion` system catalog for details.

Example:

```
openGauss=# SHOW server_encoding;
 server_encoding
-----
LATIN1
(1 row)

openGauss=# SELECT convert_from('some text', 'GBK');
          convert_from
-----
some text
(1 row)

db_latin1=# SELECT convert_to('some text', 'GBK');
          convert_to
-----
\x736f6d652074657874
(1 row)

db_latin1=# SELECT convert('some text', 'GBK', 'LATIN1');
          convert
-----
\x736f6d652074657874
(1 row)
```

- `convert_from(string bytea, src_encoding name)`

Description: Converts a string using the coding mode of the database.

src_encoding specifies the source code encoding. The string must be valid in this encoding.

Return type: text

Example:

```
openGauss=# SELECT convert_from('text_in_utf8', 'UTF8');
          convert_from
-----
text_in_utf8
(1 row)
```

- `convert_to(string text, dest_encoding name)`

Description: Converts a string to **dest_encoding**.

Return type: bytea

Example:

```
openGauss=# SELECT convert_to('some text', 'UTF8');
          convert_to
-----
encode \x736f6d652074657874
(1 row)
```

- `format(formatstr text [, str"any" [, ...] ])`

Description: Formats a string.

Return type: text

Example:

```
openGauss=# SELECT format('Hello %s, %1$s', 'World');
format
-----
Hello World, World
(1 row)
```

- **md5(string)**

Description: Encrypts a string in MD5 mode and returns a value in hexadecimal form.

 NOTE

The MD5 encryption algorithm is not recommended because it has lower security and poses security risks.

Return type: text

Example:

```
openGauss=# SELECT md5('ABC');
md5
-----
902fbdd2b1df0c4f70b4a5d23525e932
(1 row)
```

- **decode(string text, format text)**

Description: Decodes binary data from textual representation.

Return type: bytea

Example:

```
openGauss=# SELECT decode('MTIzAAE=', 'base64');
decode
-----
\x3132330001
(1 row)
```

- **encode(data bytea, format text)**

Description: Encodes binary data into a textual representation.

Return type: text

Example:

```
openGauss=# SELECT encode(E'123\\000\\001', 'base64');
encode
-----
MTIzAAE=
(1 row)
```

 NOTE

- For a string containing newline characters, for example, a string consisting of a newline character and a space, the values of **length** and **lengthb** in GaussDB are 2.
- In GaussDB, *n* in the CHAR(*n*) type indicates the number of characters. Therefore, for multiple-octet coded character sets, the length returned by the LENGTHB function may be longer than *n*.
- GaussDB supports multiple types of databases, and the value can be **A**, **B**, **C**, or **PG**. If the database type is not specified, **A** is used by default. In this case, the lexical analyzer is different from that of the other three databases, which considers an empty character string as **NULL**. Therefore, when **A** is specified, if an empty string is used as a parameter in the preceding character operation function, no output is displayed. For example:
openGauss=# SELECT translate('12345','123','');
translate

```
-----  
(1 row)
```

This is because the kernel checks whether the input parameter contains **NULL** before calling the corresponding function. If the input parameter contains **NULL**, the kernel does not call the corresponding function. As a result, no output is displayed. In PG-compatible mode, the processing of character strings is the same as that of PG. Therefore, the preceding problem does not occur.

7.5.4 Binary String Functions and Operators

String Operators

SQL defines some string functions that use keywords, rather than commas, to separate arguments.

- **octet_length(string)**

Description: Specifies the number of bytes in a binary string.

Return type: int

Example:

```
openGauss=# SELECT octet_length(E'jo\000se'::bytea) AS RESULT;  
result  
-----  
5  
(1 row)
```

- **overlay(string placing string from int [for int])**

Description: Replaces substrings.

Return type: bytea

Example:

```
openGauss=# SELECT overlay(E'Th\000omas'::bytea placing E'\002\003'::bytea from 2 for 3) AS  
RESULT;  
result  
-----  
\x5402036d6173  
(1 row)
```

- **position(substring in string)**

Description: Specifies the location of a specified substring.

Return type: int

Example:

```
openGauss=# SELECT position(E'\000om'::bytea in E'Th\000omas'::bytea) AS RESULT;  
result
```

```
-----  
3  
(1 row)
```

- `substring(string [from int] [for int])`

Description: Truncates a substring.

Return type: `bytea`

Example:

```
openGauss=# SELECT substring(E'Th\000omas'::bytea from 2 for 3) AS RESULT;  
result  
-----  
\x68006f  
(1 row)
```

- `substr(string, from int [, for int])`

Description: Truncates a substring.

Return type: `bytea`

Example:

```
openGauss=# SELECT substr(E'Th\000omas'::bytea,2, 3) AS RESULT;  
result  
-----  
\x68006f  
(1 row)
```

- `trim([both] bytes from string)`

Description: Removes the longest string containing only bytes from **bytes** from the start and end of **string**.

Return type: `bytea`

Example:

```
openGauss=# SELECT trim(E'\000'::bytea from E'\000Tom\000'::bytea) AS RESULT;  
result  
-----  
\x546f6d  
(1 row)
```

Other Binary String Functions

GaussDB provides common syntax used for calling functions.

- `btrim(string bytea,bytes bytea)`

Description: Removes the longest string containing only bytes from **bytes** from the start and end of **string**.

Return type: `bytea`

Example:

```
openGauss=# SELECT btrim(E'\000trim\000'::bytea, E'\000'::bytea) AS RESULT;  
result  
-----  
\x7472696d  
(1 row)
```

- `get_bit(string, offset)`

Description: Extracts bits from a string.

Return type: `int`

Example:

```
openGauss=# SELECT get_bit(E'Th\000omas'::bytea, 45) AS RESULT;  
result
```

```
-----  
1  
(1 row)
```

- `get_byte(string, offset)`

Description: Extracts bytes from a string.

Return type: int

Example:

```
openGauss=# SELECT get_byte(E'Th\000omas'::bytea, 4) AS RESULT;  
result  
-----  
109  
(1 row)
```

- `rawcmp`

Description: Specifies the raw data type comparison function.

Parameter: raw, raw

Return type: integer

- `raweq`

Description: Specifies the raw data type comparison function.

Parameter: raw, raw

Return type: Boolean

- `rawge`

Description: Specifies the raw data type comparison function.

Parameter: raw, raw

Return type: Boolean

- `rawgt`

Description: Specifies the raw data type comparison function.

Parameter: raw, raw

Return type: Boolean

- `rawin`

Description: Specifies the raw data type parsing function.

Parameter:cstring

Return type: bytea

- `rawle`

Description: Specifies the raw data type parsing function.

Parameter: raw, raw

Return type: Boolean

- `rawlike`

Description: Specifies the raw data type parsing function.

Parameter: raw, raw

Return type: Boolean

- `rawlt`

Description: Specifies the raw data type parsing function.

Parameter: raw, raw

Return type: Boolean

- **rawne**
Description: Compares whether the raw types are the same.
Parameter: raw, raw
Return type: Boolean
- **rawnlike**
Description: Checks whether the raw type matches the mode.
Parameter: raw, raw
Return type: Boolean
- **rawout**
Description: Specifies the RAW output API.
Parameter: bytea
Return type: cstring
- **rawsend**
Description: Converts the bytea type to the binary type.
Parameter: raw
Return type: bytea
- **rawtohex**
Description: Converts the raw format to the hexadecimal format.
Parameter: text
Return type: text
- **set_bit(string,offset, newvalue)**
Description: Sets bits in a string.
Return type: bytea

Example:

```
openGauss=# SELECT set_bit(E'Th\\000omas'::bytea, 45, 0) AS RESULT;  
result  
-----  
\x5468006f6d4173  
(1 row)
```

- **set_byte(string,offset, newvalue)**
Description: Sets bytes in a string.
Return type: bytea

Example:

```
openGauss=# SELECT set_byte(E'Th\\000omas'::bytea, 4, 64) AS RESULT;  
result  
-----  
\x5468006f406173  
(1 row)
```

7.5.5 Bit String Functions and Operators

Bit String Operators

Aside from the usual comparison operators, the following operators can be used. Bit string operands of **&**, **|**, and **#** must be of equal length. In case of bit shifting, the original length of the string is preserved by zero padding (if necessary).

- ||

Description: Connects bit strings.

Example:

```
openGauss=# SELECT B'10001' || B'011' AS RESULT;
result
-----
10001011
(1 row)
```

 NOTE

- It is recommended that a column have no more than 180 consecutive internal joins. A column with over 180 joins will be split into joined consecutive strings.
Example: **str1||str2||str3||str4** is split into **(str1||str2)||(str3||str4)**.
- In A-compatible mode, if bit strings contain a null string, the null string is ignored and other strings are joined. In other compatibility modes, the null string is returned.
Take **str1||NULL||str2** as an example. **str1str2** is returned in A-compatible mode and **NULL** is returned in other compatibility modes.

- &

Description: Specifies the AND operation between bit strings.

Example:

```
openGauss=# SELECT B'10001' & B'01101' AS RESULT;
result
-----
00001
(1 row)
```

- |

Description: Specifies the OR operation between bit strings.

Example:

```
openGauss=# SELECT B'10001' | B'01101' AS RESULT;
result
-----
11101
(1 row)
```

- #

Description: Specifies the OR operation between bit strings if they are inconsistent. If the same positions in the two bit strings are both 1 or 0, the position returns 0.

Example:

```
openGauss=# SELECT B'10001' # B'01101' AS RESULT;
result
-----
11100
(1 row)
```

- ~

Description: Specifies the NOT operation between bit strings.

Example:

```
openGauss=# SELECT ~B'10001' AS RESULT;
result
-----
01110
(1 row)
```

- <<

Description: Shifts left in a bit string.

Example:

```
openGauss=# SELECT B'10001' << 3 AS RESULT;
result
-----
01000
(1 row)
```

- >>

Description: Shifts right in a bit string.

Example:

```
openGauss=# SELECT B'10001' >> 2 AS RESULT;
result
-----
00100
(1 row)
```

The following SQL-standard functions work on bit strings as well as strings: **length**, **bit_length**, **octet_length**, **position**, **substring**, and **overlay**.

The following functions work on bit strings as well as binary strings: **get_bit** and **set_bit**. When working with a bit string, these functions number the first (leftmost) bit of the string as bit 0.

In addition, it is possible to convert between integral values and type **bit**. Example:

```
openGauss=# SELECT 44::bit(10) AS RESULT;
result
-----
0000101100
(1 row)

openGauss=# SELECT 44::bit(3) AS RESULT;
result
-----
100
(1 row)

openGauss=# SELECT cast(-44 as bit(12)) AS RESULT;
result
-----
111111010100
(1 row)

openGauss=# SELECT '1110'::bit(4)::integer AS RESULT;
result
-----
14
(1 row)

openGauss=# select substring('10101111'::bit(8), 2);
substring
-----
0101111
(1 row)
```

NOTE

Casting to just "bit" means casting to bit(1), and so will deliver only the least significant bit of the integer.

7.5.6 Pattern Matching Operators

The database provides three independent methods for implementing pattern matching: SQL LIKE operator, SIMILAR TO operator, and POSIX-style regular expressions. Besides these basic operators, functions can be used to extract or replace matching substrings and to split a string at matching locations.

- LIKE

Description: Specifies whether the string matches the mode string following **LIKE**. The LIKE expression returns true if the string matches the supplied pattern. (As expected, the NOT LIKE expression returns false if LIKE returns true, and vice versa.)

Matching rules:

- This operator can succeed only when its pattern matches the entire string. If you want to match a sequence in any position within the string, the pattern must begin and end with a percent sign.
- The underscore (_) represents (matching) any single character. Percentage (%) indicates the wildcard character of any string.
- To match a literal underscore or percent sign without matching other characters, the respective character in **pattern** must be preceded by the escape character. The default escape character is the backslash but a different one can be selected by using the **ESCAPE** clause.
- To match with escape characters, enter two escape characters. For example, to write a **pattern** constant containing a backslash (\), you need to enter two backslashes in SQL statements.

 NOTE

When **standard_conforming_strings** is set to **off**, any backslashes you write in literal string constants will need to be doubled. So, writing a pattern that matches a single backslash actually involves writing four backslashes in the statement (you can avoid this by selecting a different escape character with **ESCAPE** so that the backslash is no longer a special character of **LIKE**. But the backslash is still the special character of the character text analyzer, so you still need two backslashes.)

In MySQL-compatible schema, it is also possible to select no escape character by writing **ESCAPE ''**. This effectively disables the escape mechanism, which makes it impossible to turn off the special meaning of underscore and percent signs in the schema.

- The keyword **ILIKE** can be used instead of **LIKE** to make the match case-insensitive.
- Operator **~~** is equivalent to **LIKE**, and operator **~~*** corresponds to **ILIKE**.

Example:

```
openGauss=# SELECT 'abc' LIKE 'abc' AS RESULT;
result
-----
t
(1 row)
openGauss=# SELECT 'abc' LIKE 'a%' AS RESULT;
result
-----
t
(1 row)
openGauss=# SELECT 'abc' LIKE '_b_' AS RESULT;
result
```

```
-----  
t  
(1 row)  
openGauss=# SELECT 'abc' LIKE 'c' AS RESULT;  
result  
-----  
f  
(1 row)
```

- **SIMILAR TO**

Description: Returns **true** or **false** depending on whether the pattern matches the given string. It is similar to LIKE, but differs in that it uses the regular expression understanding pattern defined by the SQL standard.

Matching rules:

- Similar to LIKE, this operator succeeds only when its pattern matches the entire string. If you want to match a sequence in any position within the string, the pattern must begin and end with a percent sign.
- The underscore (_) represents (matching) any single character. Percentage (%) indicates the wildcard character of any string.
- SIMILAR TO supports these pattern-matching metacharacters borrowed from POSIX regular expressions:

Metacharacter	Description
	Specifies alternation (either of two alternatives).
*	Specifies repetition of the previous item zero or more times.
+	Specifies repetition of the previous item one or more times.
?	Specifies repetition of the previous item zero or one time.
{m}	Specifies repetition of the previous item exactly <i>m</i> times.
{m,}	Specifies repetition of the previous item <i>m</i> or more times.
{m,n}	Specifies repetition of the previous item at least <i>m</i> times and does not exceed <i>n</i> times.
()	Specifies that parentheses () can be used to group items into a single logical item.
[...]	Specifies a character class, just as in POSIX regular expressions.

- A preamble escape character disables the special meaning of any of these metacharacters. The rules for using escape characters are the same as those for LIKE.

Regular expressions:

The `substring(string from pattern for escape)` function extracts a substring that matches an SQL regular expression pattern.

Example:

```
openGauss=# SELECT 'abc' SIMILAR TO 'abc' AS RESULT;
result
-----
t
(1 row)
openGauss=# SELECT 'abc' SIMILAR TO 'a' AS RESULT;
result
-----
f
(1 row)
openGauss=# SELECT 'abc' SIMILAR TO '%(b|d)%' AS RESULT;
result
-----
t
(1 row)
openGauss=# SELECT 'abc' SIMILAR TO '(b|c)%' AS RESULT;
result
-----
f
(1 row)
```

- POSIX regular expressions

Description: A regular expression is a collation that is an abbreviated definition of a set of strings (a regular set). If a string is a member of a regular set described by a regular expression, the string matches the regular expression. POSIX regular expressions provide a more powerful means for pattern matching than the LIKE and SIMILAR TO operators. [Table 7-27](#) lists all available operators for pattern matching using POSIX regular expressions.

Table 7-27 Regular expression match operators

Operator	Description	Example
~	Matches a regular expression, which is case-sensitive.	'thomas' ~ '.*thomas.*'
~*	Matches a regular expression, which is case-insensitive.	'thomas' ~* '.*Thomas.*'
!~	Does not match a regular expression, which is case-sensitive.	'thomas' !~ '.*Thomas.*'
!~*	Does not match a regular expression, which is case-insensitive.	'thomas' !~* '.*vadim.*'

Matching rules:

- a. Unlike LIKE patterns, a regular expression is allowed to match anywhere within a string, unless the regular expression is explicitly anchored to the beginning or end of the string.
- b. Besides the metacharacters mentioned above, POSIX regular expressions also support the following pattern matching metacharacters:

Metacharacter	Description
^	Specifies the match starting with a string.
\$	Specifies the match at the end of a string.
.	Matches any single character.

Regular expressions:

POSIX-style regular expressions support the following functions:

- The `substring(string from pattern)` function provides a method for extracting a substring that matches the POSIX-style regular expression pattern.
- The `regexp_count(stringtext,patterntext[,positionint[,flagstext]])` function counts the number of substrings that match the POSIX regular expression pattern.
- The `regexp_instr(stringtext,patterntext[,positionint[,occurrenceint[,return_optint[,flagstext]]]])` function obtains the position of a substring that matches the POSIX regular expression pattern.
- The `regexp_substr(string text, pattern text [, position int [, occurrence int [, flags text]])` function provides a method to extract a substring that matches a POSIX-style regular expression pattern.
- The `regexp_replace(string, pattern, replacement [,flags ])` function replaces the substring that matches the POSIX-style regular expression pattern with the new text.
- The `regexp_matches(string text, pattern text [, flags text])` function returns a text array consisting of all captured substrings that match a POSIX-style regular expression pattern.
- The `regexp_split_to_table(string text, pattern text [, flags text])` function splits a string using a POSIX-style regular expression pattern as a delimiter.
- The `regexp_split_to_array(string text, pattern text [, flags text ])` function behaves the same as `regexp_split_to_table`, except that `regexp_split_to_array` returns its result as an array of text.

NOTE

The regular expression split functions ignore zero-length matches, which occur at the beginning or end of a string or after the previous match. This is contrary to the strict definition of regular expression matching. The latter is implemented by `regexp_matches`, but the former is usually the most commonly used behavior in practice.

Example:

```
openGauss=# SELECT 'abc' ~ 'Abc' AS RESULT;
result
-----
f
(1 row)
openGauss=# SELECT 'abc' ~* 'Abc' AS RESULT;
result
-----
t
(1 row)
openGauss=# SELECT 'abc' !~ 'Abc' AS RESULT;
result
-----
t
(1 row)
openGauss=# SELECT 'abc' !~* 'Abc' AS RESULT;
result
-----
f
(1 row)
openGauss=# SELECT 'abc' ~ '^a' AS RESULT;
result
-----
t
(1 row)
openGauss=# SELECT 'abc' ~ '(b|d)' AS RESULT;
result
-----
t
(1 row)
openGauss=# SELECT 'abc' ~ '^ (b|c)' AS RESULT;
result
-----
f
(1 row)
```

Although most regular expression searches can be performed quickly, regular expressions can still be artificially processed to require any length of time and any amount of memory. It is not recommended that you accept the regular expression search pattern from the non-security pattern source. If you must do this, you are advised to add the statement timeout limit. The search with the SIMILAR TO mode has the same security risks as the SIMILAR TO provides many capabilities that are the same as those of the POSIX- style regular expression. The LIKE search is much simpler than the other two options. Therefore, it is more secure to accept the non-secure mode source search.

7.5.7 Mathematical Functions and Operators

Numeric Operators

- +

Description: Addition

Example:

```
openGauss=# SELECT 2+3 AS RESULT;
result
-----
5
(1 row)
```

- -

Description: Subtraction

Example:

```
openGauss=# SELECT 2-3 AS RESULT;
result
-----
-1
(1 row)
```

- *

Description: Multiplication

Example:

```
openGauss=# SELECT 2*3 AS RESULT;
result
-----
6
(1 row)
```

- /

Description: Division (The result is not rounded.)

Example:

```
openGauss=# SELECT 4/2 AS RESULT;
result
-----
2
(1 row)
openGauss=# SELECT 4/3 AS RESULT;
result
-----
1.3333333333333333
(1 row)
```

- +/-

Description: Positive/Negative

Example:

```
openGauss=# SELECT -2 AS RESULT;
result
-----
-2
(1 row)
```

- %

Description: Modulo (to obtain the remainder)

Example:

```
openGauss=# SELECT 5%4 AS RESULT;
result
-----
1
(1 row)
```

- @

Description: Absolute value

Example:

```
openGauss=# SELECT @ -5.0 AS RESULT;
result
-----
5.0
(1 row)
```

- ^

Description: Power (exponent calculation)

Example:

```
openGauss=# SELECT 2.0^3.0 AS RESULT;
      result
-----
8.0000000000000000
(1 row)
```

- $\sqrt{\quad}$

Description: Square root

Example:

```
openGauss=# SELECT  $\sqrt{25.0}$  AS RESULT;
      result
-----
5
(1 row)
```

- $\sqrt[3]{\quad}$

Description: Cubic root

Example:

```
openGauss=# SELECT  $\sqrt[3]{27.0}$  AS RESULT;
      result
-----
3
(1 row)
```

- $!$

Description: Factorial

Example:

```
openGauss=# SELECT 5! AS RESULT;
      result
-----
120
(1 row)
```

- $!!$

Description: Factorial (prefix operator)

Example:

```
openGauss=# SELECT !!5 AS RESULT;
      result
-----
120
(1 row)
```

- $\&$

Description: Binary AND

Example:

```
openGauss=# SELECT 91&15 AS RESULT;
      result
-----
11
(1 row)
```

- $|$

Description: Binary OR

Example:

```
openGauss=# SELECT 32|3 AS RESULT;
      result
-----
35
(1 row)
```

- #

Description: Binary XOR

Example:

```
openGauss=# SELECT 17#5 AS RESULT;
result
-----
      20
(1 row)
```

- ~

Description: Binary NOT

Example:

```
openGauss=# SELECT ~1 AS RESULT;
result
-----
      -2
(1 row)
```

- <<

Description: Binary shift left

Example:

```
openGauss=# SELECT 1<<4 AS RESULT;
result
-----
      16
(1 row)
```

- >>

Description: Binary shift right

Example:

```
openGauss=# SELECT 8>>2 AS RESULT;
result
-----
       2
(1 row)
```

Numeric Operation Functions

- abs(x)

Description: Absolute value

Return type: same as the input

Example:

```
openGauss=# SELECT abs(-17.4);
abs
-----
 17.4
(1 row)
```

- acos(x)

Description: Arc cosine

Return type: double precision

Example:

```
openGauss=# SELECT acos(-1);
acos
-----
3.14159265358979
(1 row)
```

- **asin(x)**
Description: Arc sine
Return type: double precision
Example:

```
openGauss=# SELECT asin(0.5);
      asin
-----
.523598775598299
(1 row)
```
- **atan(x)**
Description: Arc tangent
Return type: double precision
Example:

```
openGauss=# SELECT atan(1);
      atan
-----
.785398163397448
(1 row)
```
- **atan2(y, x)**
Description: Arc tangent of y/x
Return type: double precision
Example:

```
openGauss=# SELECT atan2(2, 1);
      atan2
-----
1.10714871779409
(1 row)
```
- **bitand(integer, integer)**
Description: Performs an AND (&) operation on two integers.
Return type: bigint
Example:

```
openGauss=# SELECT bitand(127, 63);
      bitand
-----
        63
(1 row)
```
- **cbrt(dp)**
Description: Cubic root
Return type: double precision
Example:

```
openGauss=# SELECT cbrt(27.0);
      cbrt
-----
        3
(1 row)
```
- **ceil(x)**
Description: Minimum integer greater than or equal to the parameter
Return type: integer
Example:

```
openGauss=# SELECT ceil(-42.8);
      ceil
-----
```

```
-----  
-42  
(1 row)
```

- **ceiling(dp or numeric)**

Description: Minimum integer (alias of ceil) greater than or equal to the parameter

Return type: dp or numeric. If implicit type conversion is not considered, the return type is the same as the input type.

Example:

```
openGauss=# SELECT ceiling(-95.3);  
ceiling  
-----  
-95  
(1 row)
```

- **cos(x)**

Description: Cosine

Return type: double precision

Example:

```
openGauss=# SELECT cos(-3.1415927);  
cos  
-----  
-.9999999999999999  
(1 row)
```

- **cot(x)**

Description: Cotangent

Return type: double precision

Example:

```
openGauss=# SELECT cot(1);  
cot  
-----  
.642092615934331  
(1 row)
```

- **degrees(dp)**

Description: Converts radians to angles.

Return type: double precision

Example:

```
openGauss=# SELECT degrees(0.5);  
degrees  
-----  
28.6478897565412  
(1 row)
```

- **div(y numeric, x numeric)**

Description: Integer part of y/x

Return type: numeric

Example:

```
openGauss=# SELECT div(9,4);  
div  
-----  
2  
(1 row)
```

- **exp(x)**

Description: Natural exponent

Return type: dp or numeric. If implicit type conversion is not considered, the return type is the same as the input type.

Example:

```
openGauss=# SELECT exp(1.0);
exp
-----
2.7182818284590452
(1 row)
```

- floor(x)

Description: Maximum integer not larger than the parameter

Return type: same as the input

Example:

```
openGauss=# SELECT floor(-42.8);
floor
-----
-43
(1 row)
```

- int1(in)

Description: Converts the input text parameter to a value of the int1 type and returns the value.

Return type: int1

Example:

```
openGauss=# SELECT int1('123');
int1
-----
123
(1 row)
openGauss=# SELECT int1('a');
int1
-----
0
(1 row)
```

- int2(in)

Description: Converts the input parameter to a value of the int2 type and returns the value.

The supported input parameter types include float4, float8, int16, numeric, and text.

Return type: int2

Example:

```
openGauss=# SELECT int2('1234');
int2
-----
1234
(1 row)
openGauss=# SELECT int2(25.3);
int2
-----
25
(1 row)
```

- int4(in)

Description: Converts the input parameter to a value of the int4 type and returns the value.

The supported input parameter types include bit, Boolean, char, double precision, int16, numeric, real, smallint, and text.

Return type: int4

Example:

```
openGauss=# SELECT int4('789');
int4
-----
789
(1 row)

openGauss=# SELECT int4(99.9);
int4
-----
99
(1 row)
```

- float4(in)

Description: Converts the input parameter to a value of the float4 type and returns the value. The supported input parameter types include bigint, double precision, int16, integer, numeric, smallint, and text.

Return type: float4

Example:

```
openGauss=# SELECT float4('789');
float4
-----
789
(1 row)

openGauss=# SELECT float4(99.9);
float4
-----
99.9
(1 row)
```

- float8(in)

Description: Converts the input parameter to a value of the float8 type and returns the value. The supported input parameter types include bigint, int16, integer, numeric, real, smallint, and text.

Return type: float8

Example:

```
openGauss=# SELECT float8('789');
float8
-----
789
(1 row)

openGauss=# SELECT float8(99.9);
float8
-----
99.9
(1 row)
```

- int16(in)

Description: Converts the input parameter to a value of the int16 type and returns the value. The supported input parameter types include bigint, Boolean, double precision, integer, numeric, oid, real, smallint, and tinyint.

Return type: int16

Example:

```
openGauss=# SELECT int16('789');
int16
-----
789
(1 row)
```

```
openGauss=# SELECT int16(99.9);
int16
-----
  99
(1 row)
```

- **numeric(in)**

Description: Converts the input parameter to a value of the numeric type and returns the value. The supported input parameter types include bigint, Boolean, double precision, int16, integer, money, real, and smallint.

Return type: numeric

Example:

```
openGauss=# SELECT "numeric"('789');
numeric
-----
   789
(1 row)
```

```
openGauss=# SELECT "numeric"(99.9);
numeric
-----
   99.9
(1 row)
```

- **oid(in)**

Description: Converts the input parameter to a value of the oid type and returns the value. The supported input parameter types include bigint and int16.

Return type: oid

- **radians(dp)**

Description: Converts angles to radians.

Return type: double precision

Example:

```
openGauss=# SELECT radians(45.0);
radians
-----
.785398163397448
(1 row)
```

- **random()**

Description: Random number between 0.0 and 1.0

Return type: double precision

Example:

```
openGauss=# SELECT random();
random
-----
.824823560658842
(1 row)
```

- **multiply(x double precision or text, y double precision or text)**

Description: Product of x and y.

Return type: double precision

Example:

```
openGauss=# SELECT multiply(9.0, '3.0');
multiply
-----
```

```
      27
(1 row)
openGauss=# SELECT multiply('9.0', 3.0);
      multiply
-----
      27
(1 row)
```

- **ln(x)**

Description: Natural logarithm

Return type: dp or numeric. If implicit type conversion is not considered, the return type is the same as the input type.

Example:

```
openGauss=# SELECT ln(2.0);
      ln
-----
.6931471805599453
(1 row)
```

- **log(x)**

Description: Logarithm with 10 as the base

Return type: same as the input

Example:

```
openGauss=# SELECT log(100.0);
      log
-----
2.0000000000000000
(1 row)
```

- **log(b numeric, x numeric)**

Description: Logarithm with b as the base

Return type: numeric

Example:

```
openGauss=# SELECT log(2.0, 64.0);
      log
-----
6.0000000000000000
(1 row)
```

- **mod(x,y)**

Description: Remainder of x/y (model) If x equals to 0, 0 is returned.

Return type: same as the parameter type

Example:

```
openGauss=# SELECT mod(9,4);
      mod
-----
      1
(1 row)
openGauss=# SELECT mod(9,0);
      mod
-----
      9
(1 row)
```

- **pi()**

Description: π constant value

Return type: double precision

Example:

```
openGauss=# SELECT pi();
      pi
-----
3.14159265358979
(1 row)
```

- **power(a double precision, b double precision)**

Description: b power of a

Return type: double precision

Example:

```
openGauss=# SELECT power(9.0, 3.0);
      power
-----
729.0000000000000000
(1 row)
```

- **round(x)**

Description: Integer closest to the input parameter

Return type: same as the input

Example:

```
openGauss=# SELECT round(42.4);
      round
-----
42
(1 row)

openGauss=# SELECT round(42.6);
      round
-----
43
(1 row)
```

- **round(v numeric, s int)**

Description: s digits are kept after the decimal point.

Return type: numeric

Example:

```
openGauss=# SELECT round(42.4382, 2);
      round
-----
42.44
(1 row)
```

- **setseed(dp)**

Description: Sets seed for the following random() calling (between -1.0 and 1.0, inclusive).

Return type: void

Example:

```
openGauss=# SELECT setseed(0.54823);
      setseed
-----
(1 row)
```

- **sign(x)**

Description: Returns symbols of this parameter.

Return type: -1 indicates minus. 0 indicates 0, and 1 indicates positive numbers.

Example:

```
openGauss=# SELECT sign(-8.4);
sign
-----
-1
(1 row)
```

- **sin(x)**

Description: Sine

Return type: double precision

Example:

```
openGauss=# SELECT sin(1.57079);
sin
-----
.999999999979986
(1 row)
```

- **sqrt(x)**

Description: Square root

Return type: dp or numeric. If implicit type conversion is not considered, the return type is the same as the input type.

Example:

```
openGauss=# SELECT sqrt(2.0);
sqrt
-----
1.414213562373095
(1 row)
```

- **tan(x)**

Description: Tangent

Return type: double precision

Example:

```
openGauss=# SELECT tan(20);
tan
-----
2.23716094422474
(1 row)
```

- **trunc(x)**

Description: Truncates (the integral part).

Return type: same as the input

Example:

```
openGauss=# SELECT trunc(42.8);
trunc
-----
42
(1 row)
```

- **trunc(v numeric, s int)**

Description: Truncates a number with **s** digits after the decimal point.

Return type: numeric

Example:

```
openGauss=# SELECT trunc(42.4382, 2);
trunc
-----
42.43
(1 row)
```

- **smgrne(a smgr, b smgr)**

Description: Compares two integers of the smgr type to check whether they are different.

Return type: Boolean

- smgreq(a smgr, b smgr)

Description: Compares two integers of the smgr type to check whether they are equivalent.

Return type: Boolean

- int1abs

Description: Returns the absolute value of data of the uint8 type.

Parameter: tinyint

Return type: tinyint

- int1and

Description: Returns the bitwise AND result of two data records of the uint8 type.

Parameter: tinyint, tinyint

Return type: tinyint

- int1cmp

Description: Returns the comparison result of two data records of the uint8 type. If the value of the first parameter is greater, **1** is returned. If the value of the second parameter is greater, **-1** is returned. If they are the same, **0** is returned.

Parameter: tinyint, tinyint

Return type: integer

- int1div

Description: Returns the result of dividing two data records of the uint8 type. The result is of the float8 type.

Parameter: tinyint, tinyint

Return type: tinyint

- int1eq

Description: Compares two pieces of data of the uint8 type to check whether they are the same.

Parameter: tinyint, tinyint

Return type: Boolean

- int1ge

Description: Determines whether the value of the first parameter is greater than or equal to the value of the second parameter in two data records of the uint8 type.

Parameter: tinyint, tinyint

Return type: Boolean

- int1gt

Description: Performs a greater-than operation on an unsigned 1-byte integer.

Parameter: tinyint, tinyint

Return type: Boolean

- **int1larger**
Description: Returns the maximum value of an unsigned 1-byte integer.
Parameter: tinyint, tinyint
Return type: tinyint
- **int1le**
Description: Performs a less-than or an equal-to operation on an unsigned 1-byte integer.
Parameter: tinyint, tinyint
Return type: Boolean
- **int1lt**
Description: Performs a less-than operation on an unsigned 1-byte integer.
Parameter: tinyint, tinyint
Return type: Boolean
- **int1smaller**
Description: Calculates the minimum value of an unsigned 1-byte integer.
Parameter: tinyint, tinyint
Return type: tinyint
- **int1inc**
Description: Unsigned 1-byte integer plus 1.
Parameter: tinyint
Return type: tinyint
- **int1mi**
Description: Performs a minus operation on an unsigned 1-byte integer.
Parameter: tinyint, tinyint
Return type: tinyint
- **int1mod**
Description: Performs a MOD operation on unsigned 1-byte integers.
Parameter: tinyint, tinyint
Return type: tinyint
- **int1mul**
Description: Performs a multiplication operation on unsigned 1-byte integer.
Parameter: tinyint, tinyint
Return type: tinyint
- **int1ne**
Description: Performs a not-equal-to operation on an unsigned 1-byte integer.
Parameter: tinyint, tinyint
Return type: Boolean
- **int1pl**
Description: Performs an addition operation on an unsigned 1-byte integer.
Parameter: tinyint, tinyint
Return type: tinyint

- **int1um**
Description: Returns an unsigned 2-byte integer after subtracting the opposite number from the unsigned 1-byte integer.
Parameter: tinyint
Return type: smallint
- **int1xor**
Description: Performs an exclusive OR operation on an unsigned 1-byte integer.
Parameter: tinyint, tinyint
Return type: tinyint
- **cash_div_int1**
Description: Performs a division operation on the money type.
Parameter: money, tinyint
Return type: money
- **cash_mul_int1**
Description: Performs a multiplication operation on the money type.
Parameter: money, tinyint
Return type: money
- **int1not**
Description: Reverts binary bits of an unsigned 1-byte integer.
Parameter: tinyint
Return type: tinyint
- **int1or**
Description: Performs an OR operation on an unsigned 1-byte integer.
Parameter: tinyint, tinyint
Return type: tinyint
- **int1shl**
Description: Shifts an unsigned 1-byte integer leftwards by a specified number of bits.
Parameter: tinyint, integer
Return type: tinyint
- **int1shr**
Description: Shifts an unsigned 1-byte integer rightwards by a specified number of bits.
Parameter: tinyint, integer
Return type: tinyint
- **width_bucket(op numeric, b1 numeric, b2 numeric, count int)**
Description: Returns a bucket to which the operand will be assigned in an equi-depth histogram with **count** buckets, ranging from **b1** to **b2**.
Return type: int
Example:

```
openGauss=# SELECT width_bucket(5.35, 0.024, 10.06, 5);
width_bucket
```

```
-----
      3
(1 row)
```

- width_bucket(op dp, b1 dp, b2 dp, count int)
Description: Returns a bucket to which the operand will be assigned in an equi-depth histogram with **count** buckets, ranging from **b1** to **b2**.
Return type: int
Example:
openGauss=# SELECT width_bucket(5.35, 0.024, 10.06, 5);
width_bucket

7.5.8 Date and Time Processing Functions and Operators

Date and Time Operators

WARNING

When the user uses date/time operators, explicit type prefixes are modified for corresponding operands to ensure that the operands parsed by the database are consistent with what the user expects, and no unexpected results occur.

For example, abnormal mistakes will occur in the following example without an explicit data type.

```
openGauss=# SELECT date '2001-10-01' - '7' AS RESULT;
ERROR:
GAUSS-10416: invalid input syntax for type timestamp: "7"
SQLSTATE: 22007
LINE 1: SELECT date '2001-10-01' - '7' AS RESULT;
           ^
CONTEXT: referenced column: result
```

Table 7-28 Time and date operators

Ope rato r	Example
+	<pre>openGauss=# SELECT date '2001-9-28' + integer '7' AS RESULT; result ----- 2001-10-05 (1 row)</pre>
	<pre>openGauss=# SELECT date '2001-09-28' + interval '1 hour' AS RESULT; result ----- 2001-09-28 01:00:00 (1 row)</pre>
	<pre>openGauss=# SELECT date '2001-09-28' + time '03:00' AS RESULT; result ----- 2001-09-28 03:00:00 (1 row)</pre>

Operator	Example
	<pre>openGauss=# SELECT interval '1 day' + interval '1 hour' AS RESULT; result ----- 1 day 01:00:00 (1 row)</pre>
	<pre>openGauss=# SELECT timestamp '2001-09-28 01:00' + interval '23 hours' AS RESULT; result ----- 2001-09-29 00:00:00 (1 row)</pre>
	<pre>openGauss=# SELECT time '01:00' + interval '3 hours' AS RESULT; result ----- 04:00:00 (1 row)</pre>
-	<pre>openGauss=# SELECT date '2001-10-01' - date '2001-09-28' AS RESULT; result ----- 3days (1 row)</pre>
	<pre>openGauss=# SELECT date '2001-10-01' - integer '7' AS RESULT; result ----- 2001-09-24 00:00:00 (1 row)</pre>
	<pre>openGauss=# SELECT date '2001-09-28' - interval '1 hour' AS RESULT; result ----- 2001-09-27 23:00:00 (1 row)</pre>
	<pre>openGauss=# SELECT time '05:00' - time '03:00' AS RESULT; result ----- 02:00:00 (1 row)</pre>
	<pre>openGauss=# SELECT time '05:00' - interval '2 hours' AS RESULT; result ----- 03:00:00 (1 row)</pre>
	<pre>openGauss=# SELECT timestamp '2001-09-28 23:00' - interval '23 hours' AS RESULT; result ----- 2001-09-28 00:00:00 (1 row)</pre>
	<pre>openGauss=# SELECT interval '1 day' - interval '1 hour' AS RESULT; result ----- 23:00:00 (1 row)</pre>
	<pre>openGauss=# SELECT timestamp '2001-09-29 03:00' - timestamp '2001-09-27 12:00' AS RESULT; result ----- 1 day 15:00:00 (1 row)</pre>

Operator	Example
*	<pre>openGauss=# SELECT 900 * interval '1 second' AS RESULT; result ----- 00:15:00 (1 row)</pre>
	<pre>openGauss=# SELECT 21 * interval '1 day' AS RESULT; result ----- 21 days (1 row)</pre>
	<pre>openGauss=# SELECT double precision '3.5' * interval '1 hour' AS RESULT; result ----- 03:30:00 (1 row)</pre>
/	<pre>openGauss=# SELECT interval '1 hour' / double precision '1.5' AS RESULT; result ----- 00:40:00 (1 row)</pre>

Time/Date Functions

- age(timestamp, timestamp)

Description: Subtracts parameters, producing a result in YYYY-MM-DD format. If the result is negative, the returned result is also negative. The input parameters can contain timezone or not.

Return type: interval

Example:

```
openGauss=# SELECT age(timestamp '2001-04-10', timestamp '1957-06-13');
age
-----
43 years 9 mons 27 days
(1 row)
```

- age(timestamp)

Description: Minuses the current time with the parameter. The input parameter can contain timezone or not.

Return type: interval

Example:

```
openGauss=# SELECT age(timestamp '1957-06-13');
age
-----
60 years 2 mons 18 days
(1 row)
```

- clock_timestamp()

Description: Specifies the current timestamp of the real-time clock.

Return type: timestamp with time zone

Example:

```
openGauss=# SELECT clock_timestamp();
               clock_timestamp
-----
2017-09-01 16:57:36.636205+08
(1 row)
```

- **current_date**

Description: Specifies the current date.

Return type: date

Example:

```
openGauss=# SELECT current_date;
               date
-----
2017-09-01
(1 row)
```

- **current_time**

Description: Specifies the current time.

Return type: time with time zone

Example:

```
openGauss=# SELECT current_time;
               timetz
-----
16:58:07.086215+08
(1 row)
```

- **current_timestamp**

Description: Specifies the current date and time.

Return type: timestamp with time zone

Example:

```
openGauss=# SELECT current_timestamp;
               pg_timestamp
-----
2017-09-01 16:58:19.22173+08
(1 row)
```

- **pg_timestamp()**

Description: Current date and time (start of the current statement).

Return type: timestamp with time zone

Example:

```
openGauss=# SELECT pg_timestamp();
               pg_timestamp
-----
2015-10-14 11:21:28.317367+08
(1 row)
```

- **date_part(text, timestamp)**

Description: Obtains the value of a subdomain in date or time, for example, the year or hour. It is equivalent to **extract(field from timestamp)**.

Timestamp types: abstime, date, interval, reltime, time with time zone, time without time zone, timestamp with time zone, timestamp without time zone

Return type: double precision

Example:

```
openGauss=# SELECT date_part('hour', timestamp '2001-02-16 20:38:40');
               date_part
-----
```

```
20
(1 row)
```

- `timestamp_diff(text, timestamp, timestamp)`

Description: Calculates the difference between two timestamps and truncates the difference to the precision specified by text. In B-compatible database, this function is the same as **`TIMESTAMPDIFF(unit , timestamp_expr1, timestamp_expr2)`**.

Return type: int64

Example:

```
openGauss=# SELECT timestamp_diff('year','2018-01-01','2020-04-01');
timestamp_diff
-----
2
(1 row)
openGauss=# SELECT timestamp_diff('month','2018-01-01','2020-04-01');
timestamp_diff
-----
27
(1 row)
openGauss=# SELECT timestamp_diff('quarter','2018-01-01','2020-04-01');
timestamp_diff
-----
9
(1 row)
openGauss=# SELECT timestamp_diff('week','2018-01-01','2020-04-01');
timestamp_diff
-----
117
(1 row)
openGauss=# SELECT timestamp_diff('day','2018-01-01','2020-04-01');
timestamp_diff
-----
821
(1 row)
openGauss=# SELECT timestamp_diff('hour','2018-01-01 10:10:10','2018-01-01 12:12:12');
timestamp_diff
-----
2
(1 row)
openGauss=# SELECT timestamp_diff('minute','2018-01-01 10:10:10','2018-01-01 12:12:12');
timestamp_diff
-----
122
(1 row)
openGauss=# SELECT timestamp_diff('second','2018-01-01 10:10:10','2018-01-01 10:12:12');
timestamp_diff
-----
122
(1 row)
openGauss=# SELECT timestamp_diff('microsecond','2018-01-01 10:10:10','2018-01-01 10:12:12');
timestamp_diff
-----
122000000
(1 row)
```

- `date_part(text, interval)`

Description: Obtains the subdomain value of the date/time value. When obtaining the month value, if the value is greater than 12, obtain the remainder after it is divided by 12. It is equivalent to **`extract(field from timestamp)`**.

Return type: double precision

Example:

```
openGauss=# SELECT date_part('month', interval '2 years 3 months');
date_part
-----
3
(1 row)
```

- `date_trunc(text, timestamp)`

Description: Truncates to the precision specified by **text**.

Return type: interval, timestamp with time zone, timestamp without time zone

Example:

```
openGauss=# SELECT date_trunc('hour', timestamp '2001-02-16 20:38:40');
date_trunc
-----
2001-02-16 20:00:00
(1 row)
```

- `trunc(timestamp)`

Description: Truncates to day by default.

Example:

```
openGauss=# SELECT trunc(timestamp '2001-02-16
20:38:40');
trunc
-----
2001-02-16 00:00:00
(1 row)
```

- `trunc(arg1, arg2)`

Description: Truncates to the precision specified by **arg2**.

Type of **arg1**: interval, timestamp with time zone, timestamp without time zone

Type of **arg2**: text

Return type: interval, timestamp with time zone, timestamp without time zone

Example:

```
openGauss=# SELECT trunc(timestamp '2001-02-16 20:38:40',
'hour');
trunc
-----
2001-02-16 20:00:00
(1 row)
```

- `daterange(arg1, arg2)`

Description: Obtains time boundary information. The type of **arg1** and **arg2** is **date**.

Return type: daterange

Example:

```
openGauss=# SELECT daterange('2000-05-06','2000-08-08');
daterange
-----
[2000-05-06,2000-08-08)
(1 row)
```

- `daterange(arg1, arg2, text)`

Description: Obtains time boundary information. The type of **arg1** and **arg2** is **date**, and the type of **text** is **text**.

Return type: daterange

Example:

```
openGauss=# SELECT daterange('2000-05-06','2000-08-08','[]');
daterange
-----
[2000-05-06,2000-08-09)
(1 row)
```

- `extract(field from timestamp)`

Description: Obtains the hour.

Return type: double precision

Example:

```
openGauss=# SELECT extract(hour from timestamp '2001-02-16 20:38:40');
date_part
-----
20
(1 row)
```

- `extract(field from interval)`

Description: Obtains the month. If the value is greater than 12, obtain the remainder after it is divided by 12.

Return type: double precision

Example:

```
openGauss=# SELECT extract(month from interval '2 years 3 months');
date_part
-----
3
(1 row)
```

- `isfinite(date)`

Description: Tests for a valid date.

Return type: Boolean

Example:

```
openGauss=# SELECT isfinite(date '2001-02-16');
isfinite
-----
t
(1 row)
```

- `isfinite(timestamp)`

Description: Tests for a valid timestamp.

Return type: Boolean

Example:

```
openGauss=# SELECT isfinite(timestamp '2001-02-16 21:28:30');
isfinite
-----
t
(1 row)
```

- `isfinite(interval)`

Description: Tests for a valid interval.

Return type: Boolean

Example:

```
openGauss=# SELECT isfinite(interval '4 hours');
isfinite
-----
t
(1 row)
```

- **justify_days(interval)**
Description: Adjusts intervals to 30-day time periods, which are represented as months.
Return type: interval
Example:

```
openGauss=# SELECT justify_days(interval '35 days');
justify_days
-----
1 mon 5 days
(1 row)
```
- **justify_hours(interval)**
Description: Sets the time interval in days (24 hours is one day).
Return type: interval
Example:

```
openGauss=# SELECT JUSTIFY_HOURS(INTERVAL '27 HOURS');
justify_hours
-----
1 day 03:00:00
(1 row)
```
- **justify_interval(interval)**
Description: Adjusts **interval** using **justify_days** and **justify_hours**.
Return type: interval
Example:

```
openGauss=# SELECT JUSTIFY_INTERVAL(INTERVAL '1 MON -1 HOUR');
justify_interval
-----
29 days 23:00:00
(1 row)
```
- **localtime**
Description: Specifies the current time.
Return type: time
Example:

```
openGauss=# SELECT localtime AS RESULT;
result
-----
16:05:55.664681
(1 row)
```
- **localtimestamp**
Description: Specifies the current date and time.
Return type: timestamp
Example:

```
openGauss=# SELECT localtimestamp;
timestamp
-----
2017-09-01 17:03:30.781902
(1 row)
```
- **now()**
Description: Specifies the current date and time.
Return type: timestamp with time zone
Example:

```
openGauss=# SELECT now();
          now
-----
2017-09-01 17:03:42.549426+08
(1 row)
```

- `timenow()`

Description: Specifies the current date and time.

Return type: timestamp with time zone

Example:

```
openGauss=# select timenow();
          timenow
-----
2020-06-23 20:36:56+08
(1 row)
```

- `numtodsinterval(num, interval_unit)`

Description: Converts a number to the interval type. **num** is a numeric-typed number. **interval_unit** is a string in the following format: 'DAY' | 'HOUR' | 'MINUTE' | 'SECOND'

You can set the GUC parameter **IntervalStyle** to **a** to be compatible with the interval output format of the function.

Example:

```
openGauss=# SELECT numtodsinterval(100, 'HOUR');
 numtodsinterval
-----
100:00:00
(1 row)

openGauss=# SET intervalstyle = a;
SET
openGauss=# SELECT numtodsinterval(100, 'HOUR');
 numtodsinterval
-----
+0000000004 04:00:00.000000000
(1 row)
```

- `pg_sleep(seconds)`

Description: Specifies the delay time of the server thread in unit of second.

Return type: void

Example:

```
openGauss=# SELECT pg_sleep(10);
 pg_sleep
-----
(1 row)
```

- `statement_timestamp()`

Description: Current date and time (start of the current statement).

Return type: timestamp with time zone

Example:

```
openGauss=# SELECT statement_timestamp();
 statement_timestamp
-----
2017-09-01 17:04:39.119267+08
(1 row)
```

- `sysdate`

Description: Specifies the current date and time.

Return type: timestamp

Example:

```
openGauss=# SELECT sysdate;
           sysdate
-----
2017-09-01 17:04:49
(1 row)
```

- **timeofday()**

Description: Specifies the current date and time (like **clock_timestamp**, but returned as a **text** string)

Return type: text

Example:

```
openGauss=# SELECT timeofday();
           timeofday
-----
Fri Sep 01 17:05:01.167506 2017 CST
(1 row)
```

- **transaction_timestamp()**

Description: Specifies the current date and time (equivalent to **current_timestamp**)

Return type: timestamp with time zone

Example:

```
openGauss=# SELECT transaction_timestamp();
           transaction_timestamp
-----
2017-09-01 17:05:13.534454+08
(1 row)
```

- **add_months(d,n)**

Description: Returns the time point *d* plus *n* months.

d: indicates the value of the timestamp type and the value that can be implicitly converted to the timestamp type.

n: indicates the value of the INTEGER type and the value that can be implicitly converted to the INTEGER type.

Return type: timestamp

Example:

```
openGauss=# SELECT add_months(to_date('2017-5-29', 'yyyy-mm-dd'), 11) FROM sys_dummy;
           add_months
-----
2018-04-29 00:00:00
(1 row)
```

- **last_day(d)**

Description: Returns the date of the last day of the month that contains time point *d*.

Return type: timestamp

Example:

```
openGauss=# SELECT last_day(to_date('2017-01-01', 'YYYY-MM-DD')) AS cal_result;
           cal_result
-----
2017-01-31 00:00:00
(1 row)
```

- **next_day(x,y)**

Description: Calculates the time of the next week y started from x.

Return type: timestamp

Example:

```
openGauss=# SELECT next_day(timestamp '2017-05-25 00:00:00','Sunday')AS cal_result;
cal_result
-----
2017-05-28 00:00:00
(1 row)
```

- **interval(abstime, abstime)**

Description: Creates a time interval with two pieces of absolute time.

Return type: interval

Example:

```
openGauss=# CALL interval(abstime 'May 10, 1947 23:59:12', abstime 'Mon May 1 00:30:30 1995');
interval
-----
["1947-05-10 23:59:12+09" "1995-05-01 00:30:30+08"]
(1 row)
```

- **intervalend(interval)**

Description: Returns the end time of interval.

Return type: abstime

Example:

```
openGauss=# SELECT intervalend(['"Sep 4, 1983 23:59:12" "Oct4, 1983 23:59:12"']);
intervalend
-----
1983-10-04 23:59:12+08
(1 row)
```

- **intervalrel(interval)**

Description: Calculates and returns the relative time of **interval**.

Return type: reltime

Example:

```
openGauss=# SELECT intervalrel(['"Sep 4, 1983 23:59:12" "Oct4, 1983 23:59:12"']);
intervalrel
-----
1 mon
(1 row)
```

- **smalldatetime_ge**

Description: Checks whether the value of the first parameter is greater than or equal to that of the second parameter.

Parameter: smalldatetime, smalldatetime

Return type: Boolean

- **smalldatetime_cmp**

Description: Compares two smalldatetime values to check whether they are the same.

Parameter: smalldatetime, smalldatetime

Return type: integer

- **smalldatetime_eq**

Description: Compares two smalldatetime values to check whether they are the same.

Parameter: smalldatetime, smalldatetime

- Return type: Boolean
- `smalldatetime_gt`
Description: Determines whether the first parameter is greater than the second.
Parameter: `smalldatetime`, `smalldatetime`
Return type: Boolean
 - `smalldatetime_hash`
Description: Calculates the hash value corresponding to a timestamp.
Parameter: `smalldatetime`
Return type: integer
 - `smalldatetime_in`
Description: Inputs a timestamp.
Parameter: `cstring`, `oid`, `integer`
Return type: `smalldatetime`
 - `smalldatetime_larger`
Description: Returns a larger timestamp.
Parameter: `smalldatetime`, `smalldatetime`
Return type: `smalldatetime`
 - `smalldatetime_le`
Description: Checks whether the value of the first parameter is less than or equal to that of the second parameter.
Parameter: `smalldatetime`, `smalldatetime`
Return type: Boolean
 - `smalldatetime_lt`
Description: Determines whether the first parameter is less than the second parameter.
Parameter: `smalldatetime`, `smalldatetime`
Return type: Boolean
 - `smalldatetime_ne`
Description: Compares two timestamps to check whether they are different.
Parameter: `smalldatetime`, `smalldatetime`
Return type: Boolean
 - `smalldatetime_out`
Description: Converts a timestamp into the external form.
Parameter: `smalldatetime`
Return type: `cstring`
 - `smalldatetime_send`
Description: Converts a timestamp to the binary format.
Parameter: `smalldatetime`
Return type: `bytea`

- `smalldatetime_smaller`
Description: Returns a smaller smalldatetime.
Parameter: smalldatetime, smalldatetime
Return type: smalldatetime
- `smalldatetime_to_abstime`
Description: Converts smalldatetime to abstime.
Parameter: smalldatetime
Return type: abstime
- `smalldatetime_to_time`
Description: Converts smalldatetime to time.
Parameter: smalldatetime
Return type: time without time zone
- `smalldatetime_to_timestamp`
Description: Converts smalldatetime to timestamp.
Parameter: smalldatetime
Return type: timestamp without time zone
- `smalldatetime_to_timestamptz`
Description: Converts smalldatetime to timestamptz.
Parameter: smalldatetime
Return type: timestamp with time zone
- `smalldatetime_to_varchar2`
Description: Converts smalldatetime to varchar2.
Parameter: smalldatetime
Return type: character varying

 NOTE

There are multiple methods for obtaining the current time. Select an appropriate API based on the actual service scenario.

1. The following APIs return values based on the start time of the current transaction:

```
CURRENT_DATE  
CURRENT_TIME  
CURRENT_TIME(precision)  
CURRENT_TIMESTAMP(precision)  
LOCALTIME  
LOCALTIMESTAMP  
LOCALTIME(precision)  
LOCALTIMESTAMP(precision)  
transaction_timestamp()  
now()
```

The values transferred by **CURRENT_TIME** and **CURRENT_TIMESTAMP(precision)** contain time zone information. The values transferred by **LOCALTIME** and **LOCALTIMESTAMP** do not contain time zone information. **CURRENT_TIME**, **LOCALTIME**, and **LOCALTIMESTAMP** can specify a precision parameter, which rounds the seconds field of the result to the decimal place. If there is no precision parameter, the result is given the full precision that can be obtained.

Because these functions all return results by the start time of the current transaction, their values do not change throughout the transaction. This can be considered as a feature with the purpose to allow a transaction to have a consistent concept at the "current" time, so that multiple modifications in the same transaction can maintain the same timestamp.

transaction_timestamp() is equivalent to **CURRENT_TIMESTAMP(precision)**, indicating the start time of the transaction where the current statement is located. **now()** is equivalent to **transaction_timestamp()**.

2. The following APIs return the start time of the current statement:
`statement_timestamp()`

`statement_timestamp()` returns the start time of the current statement (more accurately, the time when the last instruction is received from the client). The return values of **statement_timestamp()** and **transaction_timestamp()** are the same during the execution of the first instruction of a transaction, but may be different in subsequent instructions.

3. The following APIs return the actual current time when the function is called:
`clock_timestamp()`
`timeofday()`

clock_timestamp() returns the actual current time, and its value changes even in the same SQL statement. Similar to **clock_timestamp()**, **timeofday()** also returns the actual current time. However, the result of **timeofday()** is a formatted text string instead of a timestamp with time zone information.

Table 7-29 shows the templates for truncating date/time values.

Table 7-29 Truncating date/time values

Item	Format	Description
Microsecond	MICROSECON	Truncates date/time values, accurate to the microsecond (000000–999999).
	US	
	USEC	
	USECOND	

Item	Format	Description
Millisecond	MILLISECON	Truncates date/time values, accurate to the millisecond (000–999).
	MS	
	MSEC	
	MSECOND	
Second	S	Truncates date/time values, accurate to the second (00–59).
	SEC	
	SECOND	
Minute	M	Truncates date/time values, accurate to the minute (00–59).
	MI	
	MIN	
	MINUTE	
Hour	H	Truncates date/time values, accurate to the hour (00–23).
	HH	
	HOUR	
	HR	
Day	D	Truncates date/time values, accurate to the day (01-01 to 12–31)
	DAY	
	DD	
	DDD	
	J	
Week	W	Truncates date/time values, accurate to the week (the first day of the current week).
	WEEK	
Month	MM	Truncates date/time values, accurate to the month (the first day of the current month).
	MON	
	MONTH	
Quarter	Q	Truncates date/time values, accurate to the quarter (the first day of the current quarter).
	QTR	
	QUARTER	
Year	Y	Truncates date/time values, accurate to the year (the first day of the current year).
	YEAR	

Item	Format	Description
	YR	
	YYYY	
Decade	DEC	Truncates date/time values, accurate to the decade (the first day of the current decade).
	DECADE	
Century	C	Truncates date/time values, accurate to the century (the first day of the current century).
	CC	
	CENT	
	CENTURY	
Millennium	MIL	Truncates date/time values, accurate to the millennium (the first day of the current millennium).
	MILLENNIA	
	MILLENNIUM	

TIMESTAMPDIFF

- **TIMESTAMPDIFF**(*unit*, *timestamp_expr1*, *timestamp_expr2*)

The **timestampdiff** function returns the result of **timestamp_expr2** – **timestamp_expr1** in the specified unit. **timestamp_expr1** and **timestamp_expr2** must be value expressions of the timestamp, timestampz, or date type. **unit** specifies the unit of the difference between two dates.

NOTE

This function is valid only when GaussDB is compatible with the MY type (that is, dbcompatibility = 'B'). It is equivalent to **timestamp_diff(text, timestamp, timestamp)**.

- **year**

Year.

```
openGauss=# SELECT TIMESTAMPDIFF(YEAR, '2018-01-01', '2020-01-01');
timestamp_diff
-----
2
(1 row)
```

- **quarter**

Quarter.

```
openGauss=# SELECT TIMESTAMPDIFF(QUARTER, '2018-01-01', '2020-01-01');
timestamp_diff
-----
8
(1 row)
```

- **month**

Month.

```
openGauss=# SELECT TIMESTAMPDIFF(MONTH, '2018-01-01', '2020-01-01');
timestamp_diff
```

- ```

 24
(1 row)
```
- week  
Week.  

```
openGauss=# SELECT TIMESTAMPDIFF(WEEK, '2018-01-01', '2020-01-01');
timestamp_diff

 104
(1 row)
```
- day  
Day.  

```
openGauss=# SELECT TIMESTAMPDIFF(DAY, '2018-01-01', '2020-01-01');
timestamp_diff

 730
(1 row)
```
- hour  
Hour.  

```
openGauss=# SELECT TIMESTAMPDIFF(HOUR, '2020-01-01 10:10:10', '2020-01-01 11:11:11');
timestamp_diff

 1
(1 row)
```
- minute  
Minute.  

```
openGauss=# SELECT TIMESTAMPDIFF(MINUTE, '2020-01-01 10:10:10', '2020-01-01 11:11:11');
timestamp_diff

 61
(1 row)
```
- second  
Second.  

```
openGauss=# SELECT TIMESTAMPDIFF(SECOND, '2020-01-01 10:10:10', '2020-01-01 11:11:11');
timestamp_diff

 3661
(1 row)
```
- microseconds  
The seconds column, including fractional parts, is multiplied by 1,000,000.  

```
openGauss=# SELECT TIMESTAMPDIFF(MICROSECOND, '2020-01-01 10:10:10.000000', '2020-01-01
10:10:10.111111');
timestamp_diff

 111111
(1 row)
```
- timestamp\_expr with the time zone  

```
openGauss=# SELECT TIMESTAMPDIFF(HOUR,'2020-05-01 10:10:10-01','2020-05-01 10:10:10-03');
timestamp_diff

 2
(1 row)
```

## EXTRACT

- **EXTRACT(*field* FROM *source*)**

The **extract** function retrieves subcolumns such as year or hour from date/time values. **source** must be a value expression of type **timestamp**, **time**, or **interval**. (Expressions of type **date** are cast to **timestamp** and can therefore be used as well.) **field** is an identifier or string that selects what column to extract from the source value. The **extract** function returns values of type **double precision**. The following are valid **field** names:

- century

The first century starts at 0001-01-01 00:00:00 AD. This definition applies to all Gregorian calendar countries. There is no century number 0. You go from -1 century to 1 century.

Example:

```
openGauss=# SELECT EXTRACT(CENTURY FROM TIMESTAMP '2000-12-16 12:21:13');
date_part

 20
(1 row)
```

- day

- Specifies the day (1–31) of the month for **timestamp**.

```
openGauss=# SELECT EXTRACT(DAY FROM TIMESTAMP '2001-02-16 20:38:40');
date_part

 16
(1 row)
```

- Specifies the number of days for **interval**.

```
openGauss=# SELECT EXTRACT(DAY FROM INTERVAL '40 days 1 minute');
date_part

 40
(1 row)
```

- decade

Specifies the number of decades.

```
openGauss=# SELECT EXTRACT(DECADE FROM TIMESTAMP '2001-02-16 20:38:40');
date_part

 200
(1 row)
```

- dow

Specifies the day of the week. The value range from 0 (Sunday) to 6 (Saturday).

```
openGauss=# SELECT EXTRACT(DOW FROM TIMESTAMP '2001-02-16 20:38:40');
date_part

 5
(1 row)
```

- doy

Specifies the day of the year (1–365 or 1–366).

```
openGauss=# SELECT EXTRACT(DOY FROM TIMESTAMP '2001-02-16 20:38:40');
date_part

 47
(1 row)
```

- epoch

- Specifies the number of seconds since 1970-01-01 00:00:00-00 UTC (can be negative) for **timestamp with time zone** values.

Specifies the number of seconds since 1970-01-01 00:00:00-00 local time for **date** and **timestamp** values.

Specifies the total number of seconds in the interval for **interval** values.

```
openGauss=# SELECT EXTRACT(EPOCH FROM TIMESTAMP WITH TIME ZONE '2001-02-16
20:38:40.12-08');
date_part

982384720.12
(1 row)
openGauss=# SELECT EXTRACT(EPOCH FROM INTERVAL '5 days 3 hours');
date_part

442800
(1 row)
```

- The following converts an epoch value back to a timestamp.

```
openGauss=# SELECT TIMESTAMP WITH TIME ZONE 'epoch' + 982384720.12 * INTERVAL '1
second' AS RESULT;
result

2001-02-17 12:38:40.12+08
(1 row)
```

- hour

Specifies the hour column (0–23).

```
openGauss=# SELECT EXTRACT(HOUR FROM TIMESTAMP '2001-02-16 20:38:40');
date_part

20
(1 row)
```

- isodow

Specifies the day of the week (1–7).

**1** indicates Monday and **7** indicates Sunday.

#### NOTE

This is identical to **dow** except for Sunday.

```
openGauss=# SELECT EXTRACT(ISODOW FROM TIMESTAMP '2001-02-18 20:38:40');
date_part

7
(1 row)
```

- isoyear

The ISO 8601 year that the date falls in (not applicable to intervals).

Each ISO year begins with the Monday of the week containing January 4, so in early January or late December the ISO year may be different from the Gregorian year. See the **week** column for more information.

```
openGauss=# SELECT EXTRACT(ISOYEAR FROM DATE '2006-01-01');
date_part

2005
(1 row)
openGauss=# SELECT EXTRACT(ISOYEAR FROM DATE '2006-01-02');
date_part

2006
(1 row)
```

- microseconds

The seconds column, including fractional parts, is multiplied by 1,000,000.

```
openGauss=# SELECT EXTRACT(MICROSECONDS FROM TIME '17:12:28.5');
date_part

28500000
(1 row)
```

- millennium

Years in the 1900s are in the second millennium. The third millennium started from 0:00 of January 1, 2001.

```
openGauss=# SELECT EXTRACT(MILLENNIUM FROM TIMESTAMP '2001-02-16 20:38:40');
date_part

3
(1 row)
```

- milliseconds

Seconds column, including fractional parts, is multiplied by 1000. Note that this includes full seconds.

```
openGauss=# SELECT EXTRACT(MILLISECONDS FROM TIME '17:12:28.5');
date_part

28500
(1 row)
```

- minute

Specifies the minute column (0–59).

```
openGauss=# SELECT EXTRACT(MINUTE FROM TIMESTAMP '2001-02-16 20:38:40');
date_part

38
(1 row)
```

- month

Specifies the month column (1–12) for **timestamp** values.

```
openGauss=# SELECT EXTRACT(MONTH FROM TIMESTAMP '2001-02-16 20:38:40');
date_part

2
(1 row)
```

Specifies the number of months after modulo 12 is performed (0–11) for **interval** values.

```
openGauss=# SELECT EXTRACT(MONTH FROM INTERVAL '2 years 13 months');
date_part

1
(1 row)
```

- quarter

Specifies the quarter of the year (1–4) that the date is in.

```
openGauss=# SELECT EXTRACT(QUARTER FROM TIMESTAMP '2001-02-16 20:38:40');
date_part

1
(1 row)
```

- second

Specifies the second column, including fractional parts (0–59).

```
openGauss=# SELECT EXTRACT(SECOND FROM TIME '17:12:28.5');
date_part

28.5
(1 row)
```

- **timezone**  
Time zone offset from UTC, measured in seconds. Positive values correspond to time zones east of UTC, negative values to zones west of UTC.
- **timezone\_hour**  
Hour component of the time zone offset.
- **timezone\_minute**  
Minute component of the time zone offset.
- **week**  
Number of the week of the year that the day is in. By definition (ISO 8601), the first week of a year contains January 4 of that year. (The ISO-8601 week starts on Monday.) In other words, the first Thursday of a year is in week 1 of that year.

Because of this, it is possible for early January dates to be part of the 52nd or 53rd week of the previous year, and late December dates to be part of the 1st week of the next year. For example, **2005-01-01** is part of the 53rd week of year 2004, **2006-01-01** is part of the 52nd week of year 2005, and **2012-12-31** is part of the 1st week of year 2013. You are advised to use the columns **isoyear** and **week** together to ensure consistency.

```
openGauss=# SELECT EXTRACT(WEEK FROM TIMESTAMP '2001-02-16 20:38:40');
date_part

 7
(1 row)
```

- **year**  
Specifies the year column.

```
openGauss=# SELECT EXTRACT(YEAR FROM TIMESTAMP '2001-02-16 20:38:40');
date_part

 2001
(1 row)
```

## date\_part

The **date\_part** function is modeled on the traditional Ingres equivalent to the SQL-standard function **extract**:

- **date\_part('field', source)**

Note that here the **field** parameter needs to be a string value, not a name. The valid field names are the same as those for **extract**. For details, see [EXTRACT](#).

Example:

```
openGauss=# SELECT date_part('day', TIMESTAMP '2001-02-16 20:38:40');
date_part

 16
(1 row)
openGauss=# SELECT date_part('hour', INTERVAL '4 hours 3 minutes');
date_part

 4
(1 row)
```

**Table 7-30** specifies the schema for formatting date and time values.

**Table 7-30** Schema for formatting date and time

| Category              | Format     | Description                                                                                                                                                                                 |
|-----------------------|------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Hour                  | HH         | Number of hours in one day (01–12)                                                                                                                                                          |
|                       | HH12       | Number of hours in one day (01–12)                                                                                                                                                          |
|                       | HH24       | Number of hours in one day (00–23)                                                                                                                                                          |
| Minute                | MI         | Minute (00–59)                                                                                                                                                                              |
| Second                | SS         | Second (00–59)                                                                                                                                                                              |
|                       | FF         | Microsecond (000000–999999)                                                                                                                                                                 |
|                       | FF1        | Microsecond (0–9)                                                                                                                                                                           |
|                       | FF2        | Microsecond (00–99)                                                                                                                                                                         |
|                       | FF3        | Microsecond (000–999)                                                                                                                                                                       |
|                       | FF4        | Microsecond (0000–9999)                                                                                                                                                                     |
|                       | FF5        | Microsecond (00000–99999)                                                                                                                                                                   |
|                       | FF6        | Microsecond (000000–999999)                                                                                                                                                                 |
|                       | SSSSS      | Second after midnight (0–86399)                                                                                                                                                             |
| Morning and afternoon | AM or A.M. | Morning identifier                                                                                                                                                                          |
|                       | PM or P.M. | Afternoon identifier                                                                                                                                                                        |
| Year                  | Y,YYY      | Year with comma (with four digits or more)                                                                                                                                                  |
|                       | SYYYY      | Year with four digits BC                                                                                                                                                                    |
|                       | YYYY       | Year (with four digits or more)                                                                                                                                                             |
|                       | YYY        | Last three digits of a year                                                                                                                                                                 |
|                       | YY         | Last two digits of a year                                                                                                                                                                   |
|                       | Y          | Last one digit of a year                                                                                                                                                                    |
|                       | IYYY       | ISO year (with four digits or more)                                                                                                                                                         |
|                       | IYY        | Last three digits of an ISO year                                                                                                                                                            |
|                       | IY         | Last two digits of an ISO year                                                                                                                                                              |
|                       | I          | Last one digit of an ISO year                                                                                                                                                               |
|                       | RR         | Last two digits of a year (A year of the 20th century can be stored in the 21st century.)                                                                                                   |
|                       | RRRR       | Capable of receiving a year with four digits or two digits. If there are 2 digits, the value is the same as the returned value of RR. If there are 4 digits, the value is the same as YYYY. |

| Category    | Format                                                                            | Description                                                                           |
|-------------|-----------------------------------------------------------------------------------|---------------------------------------------------------------------------------------|
|             | <ul style="list-style-type: none"><li>• BC or B.C.</li><li>• AD or A.D.</li></ul> | Era indicator Before Christ (BC) and After Christ (AD)                                |
| Month       | MONTH                                                                             | Full name of a month in uppercase (9 characters are filled in if the value is empty.) |
|             | MON                                                                               | Month in abbreviated format in uppercase (with three characters)                      |
|             | MM                                                                                | Month (01–12)                                                                         |
|             | RM                                                                                | Month in Roman numerals (I–XII; I=JAN) and uppercase                                  |
| Day         | DAY                                                                               | Full name of a date in uppercase (9 characters are filled in if the value is empty.)  |
|             | DY                                                                                | Day in abbreviated format in uppercase (with three characters)                        |
|             | DDD                                                                               | Day in a year (001–366)                                                               |
|             | DD                                                                                | Day in a month (01–31)                                                                |
|             | D                                                                                 | Day in a week (1–7).                                                                  |
| Week        | W                                                                                 | Week in a month (1–5) (The first week starts from the first day of the month.)        |
|             | WW                                                                                | Week in a year (1–53) (The first week starts from the first day of the year.)         |
|             | IW                                                                                | Week in an ISO year (The first Thursday is in the first week.)                        |
| Century     | CC                                                                                | Century (with two digits) (The 21st century starts from 2001-01-01.)                  |
| Julian date | J                                                                                 | Julian date (starting from January 1 of 4712 BC)                                      |
| Quarter     | Q                                                                                 | Quarter                                                                               |

 **NOTE**

In the table, the rules for RR to calculate years are as follows:

- If the range of the input two-digit year is between 00 and 49:  
If the last two digits of the current year are between 00 and 49, the first two digits of the returned year are the same as the first two digits of the current year.  
If the last two digits of the current year are between 50 and 99, the first two digits of the returned year equal to the first two digits of the current year plus 1.
- If the range of the input two-digit year is between 50 and 99:  
If the last two digits of the current year are between 00 and 49, the first two digits of the returned year equal to the first two digits of the current year minus 1.  
If the last two digits of the current year are between 50 and 99, the first two digits of the returned year are the same as the first two digits of the current year.

## 7.5.9 Type Conversion Functions

### Type Conversion Functions

- `cash_words(money)`

Description: Type conversion function, which converts money into text.

Example:

```
openGauss=# SELECT cash_words('1.23');
 cash_words

One dollar and twenty three cents
(1 row)
```

- `cast(x as y)`

Description: Converts x into the type specified by y.

Example:

```
openGauss=# SELECT cast('22-oct-1997' as timestamp);
 timestamp

1997-10-22 00:00:00
(1 row)
```

- `hextoraw(text)`

Description: Converts a string in hexadecimal format into raw type.

Return type: raw

Example:

```
openGauss=# SELECT hextoraw('7D');
 hextoraw

7D
(1 row)
```

- `numtoday(numeric)`

Description: Converts values of the number type into the timestamp of the specified type.

Return type: timestamp

Example:

```
openGauss=# SELECT numtoday(2);
 numtoday

2 days
(1 row)
```

- `rawtohex(string)`

Description: Converts a string in binary format into hexadecimal format.

The result is the ASCII code of the input characters in hexadecimal format.

Return type: `varchar`

Example:

```
openGauss=# SELECT rawtohex('1234567');
rawtohex

31323334353637
(1 row)
```

- `to_bigint(varchar)`

Description: Converts the character type to the bigint type.

Return type: `bigint`

Example:

```
openGauss=# SELECT to_bigint('123364545554455');
to_bigint

123364545554455
(1 row)
```

- `to_char(datetime/interval [, fmt])`

Description: Converts a DATETIME or INTERVAL value of the DATE/TIMESTAMP/TIMESTAMP WITH TIME ZONE/TIMESTAMP WITH LOCAL TIME ZONE type into the TEXT type according to the format specified by **fmt**.

- The optional parameter **fmt** allows for the following types: date, time, week, quarter, and century. Each type has a unique template. The templates can be combined together. Common templates include HH, MI, SS, YYYY, MM, and DD.
- A template may have a modification word. FM is a common modification word and is used to suppress the preceding zero or the following blank spaces.

Return type: `text`

Example:

```
openGauss=# SELECT to_char(current_timestamp,'HH12:MI:SS');
to_char

10:19:26
(1 row)
openGauss=# SELECT to_char(current_timestamp,'FMHH12:FMMI:FMSS');
to_char

10:19:46
(1 row)
```

- `to_char(double precision/real, text)`

Description: Converts the values of the floating point type into the strings in the specified format.

Return type: `text`

Example:

```
openGauss=# SELECT to_char(125.8::real, '999D99');
to_char

125.80
(1 row)
```

- `to_char(numeric/smallint/integer/bigint/double precision/real[, fmt])`

Descriptions: Converts an integer or a value in floating point format into a string in specified format.

- The optional parameter **fmt** allows for the following types: decimal characters, grouping characters, positive/negative sign and currency sign. Each type has a unique template. The templates can be combined together. Common templates include: 9, 0, millesimal sign (,), and decimal point (.).
- A template can have a modification word, similar to FM. However, FM does not suppress 0 which is output according to the **template0**.
- Use the template X or x to convert an integer value into a string in hexadecimal format.

Return type: text

Example:

```
openGauss=# SELECT to_char(1485,'9,999');
to_char

1,485
(1 row)
openGauss=# SELECT to_char(1148.5,'9,999.999');
to_char

1,148.500
(1 row)
openGauss=# SELECT to_char(148.5,'990999.909');
to_char

0148.500
(1 row)
openGauss=# SELECT to_char(123,'XXX');
to_char

7B
(1 row)
```

- `to_char(interval, text)`

Description: Converts the values of the time interval type into the strings in the specified format.

Return type: text

Example:

```
openGauss=# SELECT to_char(interval '15h 2m 12s', 'HH24:MI:SS');
to_char

15:02:12
(1 row)
```

- `to_char(integer, text)`

Description: Converts the values of the integer type into the strings in the specified format.

Return type: text

Example:

```
openGauss=# SELECT to_char(125, '999');
to_char

125
(1 row)
```

- `to_char(numeric, text)`

Description: Converts the values of the numeric type into the strings in the specified format.

Return type: text

Example:

```
openGauss=# SELECT to_char(-125.8, '999D99S');
to_char

125.80-
(1 row)
```

- `to_char(string)`

Description: Converts the CHAR/VARCHAR/VARCHAR2/CLOB type into the TEXT type.

If this function is used to convert data of the CLOB type, and the value to be converted exceeds the value range of the target type, an error is returned.

Return type: text

Example:

```
openGauss=# SELECT to_char('01110');
to_char

01110
(1 row)
```

- `to_char(timestamp, text)`

Description: Converts the values of the timestamp type into the strings in the specified format.

Return type: text

Example:

```
openGauss=# SELECT to_char(current_timestamp, 'HH12:MI:SS');
to_char

10:55:59
(1 row)
```

#### NOTE

The `to_char` function outputs the incorrect format (**fmt**) without change. For example, if the **fmt** is **FF10**, **FF1** is matched for formatted output, and then **0** is output without change.

- `to_clob(char/nchar/varchar/varchar2/nvarchar/nvarchar2/text/raw)`

Description: Converts the raw type or text character set type CHAR, NCHAR, VARCHAR, VARCHAR2, NVARCHAR, NVARCHAR2, or TEXT to the CLOB type.

Return type: clob

Example:

```
openGauss=# SELECT to_clob('ABCDEF'::RAW(10));
to_clob

ABCDEF
(1 row)
openGauss=# SELECT to_clob('hello111'::CHAR(15));
to_clob

hello111
(1 row)
openGauss=# SELECT to_clob('gauss123'::NCHAR(10));
to_clob

gauss123
(1 row)
```

```

gauss123
(1 row)
openGauss=# SELECT to_clob('gauss234'::VARCHAR(10));
to_clob

gauss234
(1 row)
openGauss=# SELECT to_clob('gauss345'::VARCHAR2(10));
to_clob

gauss345
(1 row)
openGauss=# SELECT to_clob('gauss456'::NVARCHAR2(10));
to_clob

gauss456
(1 row)
openGauss=# SELECT to_clob('World222!'::TEXT);
to_clob

World222!
(1 row)
```

- **to\_date(text)**

Description: Converts values of the text type into the timestamp in the specified format. Currently, only the following two formats are supported:

- Format 1: Date without separators, for example, 20150814. The value must contain the complete year, month, and day.
- Format 2: Date with separators, for example, 2014-08-14. The separator can be any non-digit character.

Return type: timestamp without time zone

Example:

```
openGauss=# SELECT to_date('2015-08-14');
to_date

2015-08-14 00:00:00
(1 row)
```

- **to\_date(text, text)**

Description: Converts the values of the string type into the dates in the specified format.

Return type: timestamp without time zone

Example:

```
openGauss=# SELECT to_date('05 Dec 2000', 'DD Mon YYYY');
to_date

2000-12-05 00:00:00
(1 row)
```

- **to\_number ( expr [, fmt])**

Description: Converts **expr** into a value of the NUMBER type according to the specified format.

For details about the type conversion formats, see [Table 7-31](#).

If a hexadecimal string is converted into a decimal number, the hexadecimal string can include a maximum of 16 bytes if it is to be converted into a sign-free number.

During the conversion from a hexadecimal string to a decimal digit, the format string cannot have a character other than x or X. Otherwise, an error is reported.

Return type: number

Example:

```
openGauss=# SELECT to_number('12,454.8-', '99G999D9S');
to_number

-12454.8
(1 row)
```

- `to_number(text, text)`

Description: Converts the values of the string type into the numbers in the specified format.

Return type: numeric

Example:

```
openGauss=# SELECT to_number('12,454.8-', '99G999D9S');
to_number

-12454.8
(1 row)
```

- `to_timestamp(double precision)`

Description: Converts a Unix century into a timestamp.

Return type: timestamp with time zone

Example:

```
openGauss=# SELECT to_timestamp(1284352323);
to_timestamp

2010-09-13 12:32:03+08
(1 row)
```

- `to_timestamp(string [,fmt])`

Description: Converts a string into a value of the timestamp type according to the format specified by **fmt**. When **fmt** is not specified, perform the conversion according to the format specified by **nls\_timestamp\_format**.

In **to\_timestamp** in GaussDB:

- If the input year *YYYY* is 0, an error will be reported.
- If the input year *YYYY* is less than 0, specify *SYYYYY* in **fmt**. The year with the value of *n* (an absolute value) BC will be output correctly.

Characters in the **fmt** must match the schema for formatting the date and time. Otherwise, an error is reported.

Return type: timestamp without time zone

Example:

```
openGauss=# SHOW nls_timestamp_format;
nls_timestamp_format

DD-Mon-YYYY HH:MI:SS.FF AM
(1 row)

openGauss=# SELECT to_timestamp('12-sep-2014');
to_timestamp

2014-09-12 00:00:00
(1 row)
```

```
openGauss=# SELECT to_timestamp('12-Sep-10 14:10:10.123000','DD-Mon-YY HH24:MI:SS.FF');
to_timestamp

2010-09-12 14:10:10.123
(1 row)
openGauss=# SELECT to_timestamp('-1','YYYYY');
to_timestamp

0001-01-01 00:00:00 BC
(1 row)
openGauss=# SELECT to_timestamp('98','RR');
to_timestamp

1998-01-01 00:00:00
(1 row)
openGauss=# SELECT to_timestamp('01','RR');
to_timestamp

2001-01-01 00:00:00
(1 row)
```

- `to_timestamp(text, text)`

Description: Converts values of the string type into the timestamp of the specified type.

Return type: timestamp

Example:

```
openGauss=# SELECT to_timestamp('05 Dec 2000', 'DD Mon YYYY');
to_timestamp

2000-12-05 00:00:00
(1 row)
```

**Table 7-31** Template patterns for numeric formatting

| Format     | Description                                                           |
|------------|-----------------------------------------------------------------------|
| 9          | Value with specified digits                                           |
| 0          | Values with leading zeros                                             |
| Period (.) | Decimal point                                                         |
| Comma (,)  | Group (thousand) separator                                            |
| PR         | Negative values in angle brackets                                     |
| S          | Signed number (depending on the locale setting)                       |
| L          | Currency symbol (depending on the locale setting)                     |
| D          | Decimal point (depending on the locale setting)                       |
| G          | Group separator (depending on the locale setting)                     |
| MI         | Minus sign in the specified position (if the number is less than 0)   |
| PL         | Plus sign in the specified position (if the number is greater than 0) |
| SG         | Plus or minus sign in the specified position                          |

| Format   | Description                                     |
|----------|-------------------------------------------------|
| RN       | Roman numeral (ranging from 1 to 3999)          |
| TH or th | Ordinal number suffix                           |
| V        | Decimal with specified number of digits shifted |

- `abstime_text`  
Description: Converts abstime to text.  
Parameter: `abstime`  
Return type: `text`
- `abstime_to_smalldatetime`  
Description: Converts abstime to smalldatetime.  
Parameter: `abstime`  
Return type: `smalldatetime`
- `bigint_tid`  
Description: Converts bigint to tid.  
Parameter: `bigint`  
Return type: `tid`
- `bool_int1`  
Description: Converts bool to int1.  
Parameter: `Boolean`  
Return type: `tinyint`
- `bool_int2`  
Description: Converts bool to int2.  
Parameter: `Boolean`  
Return type: `smallint`
- `bool_int8`  
Description: Converts bool to int8.  
Parameter: `Boolean`  
Return type: `bigint`
- `bpchar_date`  
Description: Converts a string to a date.  
Parameter: `character`  
Return type: `date`
- `bpchar_float4`  
Description: Converts a string to float4.  
Parameter: `character`  
Return type: `real`
- `bpchar_float8`

Description: Converts a string to float8.

Parameter: character

Return type: double precision

- `bpchar_int4`

Description: Converts a string to int4.

Parameter: character

Return type: integer

- `bpchar_int8`

Description: Converts a string to int8.

Parameter: character

Return type: bigint

- `bpchar_numeric`

Description: Converts a string to numeric.

Parameter: character

Return type: numeric

- `bpchar_timestamp`

Description: Converts a string to a timestamp.

Parameter: character

Return type: timestamp without time zone

- `bpchar_to_smalldatetime`

Description: Converts a string to smalldatetime.

Parameter: character

Return type: smalldatetime

- `complex_array_in`

Description: Converts the external `complex_array` type to the internal `anyarray` array type.

Parameter: `cstring`, `oid`, `int2vector`

Return type: `anyarray`

- `date_bpchar`

Description: Converts the date type to `bpchar`.

Parameter: `date`

Return type: `character`

- `date_text`

Description: Converts date to text.

Parameter: `date`

Return type: `text`

- `date_varchar`

Description: Converts date to `varchar`.

Parameter: `date`

Return type: `character varying`

- **f4toi1**  
Description: Forcibly converts float4 to uint8.  
Parameter: real  
Return type: tinyint
- **f8toi1**  
Description: Forcibly converts float8 to uint8.  
Parameter: double precision  
Return type: tinyint
- **float4\_bpchar**  
Description: Converts float4 to bpchar.  
Parameter: real  
Return type: character
- **float4\_text**  
Description: Converts float4 to text.  
Parameter: real  
Return type: text
- **float4\_varchar**  
Description: Converts float4 to varchar.  
Parameter: real  
Return type: character varying
- **float8\_bpchar**  
Description: Converts float8 to bpchar.  
Parameter: double precision  
Return type: character
- **float8\_interval**  
Description: Converts float8 to interval.  
Parameter: double precision  
Return type: interval
- **float8\_text**  
Description: Converts float8 to text.  
Parameter: double precision  
Return type: text
- **float8\_varchar**  
Description: Converts float8 to varchar.  
Parameter: double precision  
Return type: character varying
- **i1tof4**  
Description: Converts uint8 to float4.  
Parameter: tinyint  
Return type: real

- **i1tof8**  
Description: Converts uint8 to float8.  
Parameter: tinyint  
Return type: double precision
- **i1toi2**  
Description: Converts uint8 to int16.  
Parameter: tinyint  
Return type: smallint
- **i1toi4**  
Description: Converts uint8 to int32.  
Parameter: tinyint  
Return type: integer
- **i1toi8**  
Description: Converts uint8 to int64.  
Parameter: tinyint  
Return type: bigint
- **i2toi1**  
Description: Converts int16 to uint8.  
Parameter: smallint  
Return type: tinyint
- **i4toi1**  
Description: Converts int32 to uint8.  
Parameter: integer  
Return type: tinyint
- **i8toi1**  
Description: Converts int64 to uint8.  
Parameter: bigint  
Return type: tinyint
- **int1\_avg\_accum**  
Description: Adds the second parameter of the uint8 type to the first parameter. The first parameter is an array of the bigint type.  
Parameter: bigint[], tinyint  
Return type: bigint[]
- **int1\_bool**  
Description: Converts uint8 to bool.  
Parameter: tinyint  
Return type: Boolean
- **int1\_bpchar**  
Description: Converts uint8 to bpchar.  
Parameter: tinyint  
Return type: character

- `int1_mul_cash`  
Description: Returns the product of a parameter of the `int8` type and a parameter of the `cash` type. The return type is `cash`.  
Parameter: `tinyint`, `money`  
Return type: `money`
- `int1_numeric`  
Description: Converts `uint8` to `numeric`.  
Parameter: `tinyint`  
Return type: `numeric`
- `int1_nvarchar2`  
Description: Converts `uint8` to `nvarchar2`.  
Parameter: `tinyint`  
Return type: `nvarchar2`
- `int1_text`  
Description: Converts `uint8` to `text`.  
Parameter: `tinyint`  
Return type: `text`
- `int1_varchar`  
Description: Converts `uint8` to `varchar`.  
Parameter: `tinyint`  
Return type: `character varying`
- `int1in`  
Description: Converts a string into an unsigned 1-byte integer.  
Parameter: `cstring`  
Return type: `tinyint`
- `int1out`  
Description: Converts an unsigned 1-byte integer into a string.  
Parameter: `tinyint`  
Return type: `cstring`
- `int1up`  
Description: Converts an input integer to an unsigned 1-byte integer.  
Parameter: `tinyint`  
Return type: `tinyint`
- `int2_bool`  
Description: Converts a signed two-byte integer to the `bool` type.  
Parameter: `smallint`  
Return type: `Boolean`
- `int2_bpchar`  
Description: Converts a signed two-byte integer to the `bpchar` type.  
Parameter: `smallint`  
Return type: `character`

- `int2_text`  
Description: Converts a signed two-byte integer to the text type.  
Parameter: `smallint`  
Return type: `text`
- `int2_varchar`  
Description: Converts a signed two-byte integer to the varchar type.  
Parameter: `smallint`  
Return type: `character varying`
- `int4_bpchar`  
Description: Converts a signed four-byte integer to `bpchar`.  
Parameter: `integer`  
Return type: `character`
- `int4_text`  
Description: Converts a signed four-byte integer to the text type.  
Parameter: `integer`  
Return type: `text`
- `int4_varchar`  
Description: Converts a signed four-byte integer into `varchar`.  
Parameter: `integer`  
Return type: `character varying`
- `int8_bool`  
Description: Converts an eight-byte signed integer to a Boolean value.  
Parameter: `bigint`  
Return type: `Boolean`
- `int8_bpchar`  
Description: Converts an 8-byte signed integer to `bpchar`.  
Parameter: `bigint`  
Return type: `character`
- `int8_text`  
Description: Converts an eight-byte signed integer to the text type.  
Parameter: `bigint`  
Return type: `text`
- `int8_varchar`  
Description: Converts an eight-byte signed integer to `varchar`.  
Parameter: `bigint`  
Return type: `character varying`
- `intervaltonum`  
Description: Converts the internal `date` type to numeric.  
Parameter: `interval`  
Return type: `numeric`

- `numeric_bpchar`  
Description: Converts numeric to bpchar.  
Parameter: numeric  
Return type: character
- `numeric_int1`  
Description: Converts numeric to a signed one-byte integer.  
Parameter: numeric  
Return type: tinyint
- `numeric_text`  
Description: Converts numeric to text.  
Parameter: numeric  
Return type: text
- `numeric_varchar`  
Description: Converts numeric to varchar.  
Parameter: numeric  
Return type: character varying
- `nvarchar2in`  
Description: Converts c string to varchar.  
Parameter: cstring, oid, integer  
Return type: nvarchar2
- `nvarchar2out`  
Description: Converts text into a c string.  
Parameter: nvarchar2  
Return type: cstring
- `nvarchar2send`  
Description: Converts varchar to binary.  
Parameter: nvarchar2  
Return type: bytea
- `oidvectorin_extend`  
Description: Converts a string to oidvector.  
Parameter: cstring  
Return type: oidvector\_extend
- `oidvectorout_extend`  
Description: Converts oidvector to a string.  
Parameter: oidvector\_extend  
Return type: cstring
- `oidvectorsend_extend`  
Description: Converts oidvector to a string.  
Parameter: oidvector\_extend  
Return type: bytea

- reltime\_text  
Description: Converts reltime to text.  
Parameter: reltime  
Return type: text
- text\_date  
Description: Converts the text type to the date type.  
Parameter: text  
Return type: date
- text\_float4  
Description: Converts text to float4.  
Parameter: text  
Return type: real
- text\_float8  
Description: Converts the text type to float8.  
Parameter: text  
Return type: double precision
- text\_int1  
Description: Converts the text type to int1.  
Parameter: text  
Return type: tinyint
- text\_int2  
Description: Converts the text type to the int2 type.  
Parameter: text  
Return type: smallint
- text\_int4  
Description: Converts the text type to int4.  
Parameter: text  
Return type: integer
- text\_int8  
Description: Converts the text type to the int8 type.  
Parameter: text  
Return type: bigint
- text\_numeric  
Description: Converts the text type to the numeric type.  
Parameter: text  
Return type: numeric
- text\_timestamp  
Description: Converts the text type to the timestamp type.  
Parameter: text  
Return type: timestamp without time zone

- `time_text`  
Description: Converts the time type to the text type.  
Parameter: time without time zone  
Return type: text
- `timestamp_text`  
Description: Converts the timestamp type to the text type.  
Parameter: timestamp without time zone  
Return type: text
- `timestamp_to_smalldatetime`  
Description: Converts the timestamp type to the smalldatetime type.  
Parameter: timestamp without time zone  
Return type: smalldatetime
- `timestamp_varchar`  
Description: Converts the timestamp type to varchar.  
Parameter: timestamp without time zone  
Return type: character varying
- `timestamptz_to_smalldatetime`  
Description: Converts timestamptz to smalldatetime.  
Parameter: timestamp with time zone  
Return type: smalldatetime
- `timestampzone_text`  
Description: Converts the timestampzone type to the text type.  
Parameter: timestamp with time zone  
Return type: text
- `timetz_text`  
Description: Converts the timetz type to the text type.  
Parameter: time with time zone  
Return type: text
- `to_integer`  
Description: Converts data to the integer type.  
Parameter: character varying  
Return type: integer
- `to_interval`  
Description: Converts to the interval type.  
Parameter: character varying  
Return type: interval
- `to_numeric`  
Description: Converts to the numeric type.  
Parameter: character varying  
Return type: numeric

- `to_nvarchar2`  
Description: Converts to the `nvarchar2` type.  
Parameter: numeric  
Return type: `nvarchar2`
- `to_text`  
Description: Converts to the `text` type.  
Parameter: `smallint`  
Return type: `text`
- `to_ts`  
Description: Converts to the `ts` type.  
Parameter: character varying  
Return type: timestamp without time zone
- `to_varchar2`  
Description: Converts to the `varchar2` type.  
Parameter: timestamp without time zone  
Return type: character varying
- `varchar_date`  
Description: Converts `varchar` to `date`.  
Parameter: character varying  
Return type: `date`
- `varchar_float4`  
Description: Converts `varchar` to `float4`.  
Parameter: character varying  
Return type: `real`
- `varchar_float8`  
Description: Converts the `varchar` type to the `float8` type.  
Parameter: character varying  
Return type: double precision
- `varchar_int4`  
Description: Converts the type from `varchar` to `int4`.  
Parameter: character varying  
Return type: integer
- `varchar_int8`  
Description: Converts the `varchar` type to the `int8` type.  
Parameter: character varying  
Return type: `bigint`
- `varchar_numeric`  
Description: Converts `varchar` to `numeric`.  
Parameter: character varying  
Return type: `numeric`

- `varchar_timestamp`  
Description: Converts varchar to timestamp.  
Parameter: character varying  
Return type: timestamp without time zone
- `varchar2_to_smlldatetime`  
Description: Converts varchar2 to smlldatetime.  
Parameter: character varying  
Return type: smalldatetime
- `xidout4`  
Description: The xid output is a four-byte number.  
Parameter: xid32  
Return type: cstring
- `xidsend4`  
Description: Converts xid to the binary format.  
Parameter: xid32  
Return type: bytea

## Encoding Type Conversion

- `convert_to_nocase(text, text)`  
Description: Converts a string into a specified encoding type.  
Return type: bytea  
Example:

```
openGauss=# SELECT convert_to_nocase('12345', 'GBK');
convert_to_nocase

\x3132333435
(1 row)
```

## 7.5.10 Geometric Functions and Operators

### Geometric Operators

- `+`  
Description: Translation  
Example:  

```
openGauss=# SELECT box '((0,0),(1,1))' + point '(2,0,0)' AS RESULT;
result

(3,1),(2,0)
(1 row)
```
- `-`  
Description: Translation  
Example:  

```
openGauss=# SELECT box '((0,0),(1,1))' - point '(2,0,0)' AS RESULT;
result

(-1,1),(-2,0)
(1 row)
```

- **\***  
Description: Scaling out/Rotation  
Example:  

```
openGauss=# SELECT box '((0,0),(1,1))' * point '(2.0,0)' AS RESULT;
result

(2,2),(0,0)
(1 row)
```
- **/**  
Description: Scaling in/Rotation  
Example:  

```
openGauss=# SELECT box '((0,0),(2,2))' / point '(2.0,0)' AS RESULT;
result

(1,1),(0,0)
(1 row)
```
- **#**  
Description: Intersection of two figures  
Example:  

```
openGauss=# SELECT box '((1,-1),(-1,1))' # box '((1,1),(-2,-2))' AS RESULT;
result

(1,1),(-1,-1)
(1 row)
```
- **#**  
Description: Number of paths or polygon vertexes of a figure  
Example:  

```
openGauss=# SELECT # path'((1,0),(0,1),(-1,0))' AS RESULT;
result

3
(1 row)
```
- **@-@**  
Description: Length or circumference of a figure  
Example:  

```
openGauss=# SELECT @-@ path'((0,0),(1,0))' AS RESULT;
result

2
(1 row)
```
- **@@**  
Description: Center of a figure  
Example:  

```
openGauss=# SELECT @@ circle'((0,0),10)' AS RESULT;
result

(0,0)
(1 row)
```
- **<->**  
Description: Distance between two figures  
Example:  

```
openGauss=# SELECT circle'((0,0),1)' <-> circle'((5,0),1)' AS RESULT;
result
```

```

3
(1 row)
```

- **&&**

Description: Overlaps? (One point in common makes this true.)

Example:

```
openGauss=# SELECT box '((0,0),(1,1))' && box '((0,0),(2,2))' AS RESULT;
result

t
(1 row)
```

- **<<**

Description: Is strictly left of (no common horizontal coordinate)?

Example:

```
openGauss=# SELECT circle '((0,0),1)' << circle '((5,0),1)' AS RESULT;
result

t
(1 row)
```

- **>>**

Description: Is strictly right of (no common horizontal coordinate)?

Example:

```
openGauss=# SELECT circle '((5,0),1)' >> circle '((0,0),1)' AS RESULT;
result

t
(1 row)
```

- **&<**

Description: Does not extend to the right of?

Example:

```
openGauss=# SELECT box '((0,0),(1,1))' &< box '((0,0),(2,2))' AS RESULT;
result

t
(1 row)
```

- **&>**

Description: Does not extend to the left of?

Example:

```
openGauss=# SELECT box '((0,0),(3,3))' &> box '((0,0),(2,2))' AS RESULT;
result

t
(1 row)
```

- **<<|**

Description: Is strictly below (no common horizontal coordinate)?

Example:

```
openGauss=# SELECT box '((0,0),(3,3))' <<| box '((3,4),(5,5))' AS RESULT;
result

t
(1 row)
```

- **|>>**

Description: Is strictly above (no common horizontal coordinate)?

Example:

```
openGauss=# SELECT box '((3,4),(5,5))' |>> box '((0,0),(3,3))' AS RESULT;
result

t
(1 row)
```

- &<|

Description: Does not extend above?

Example:

```
openGauss=# SELECT box '((0,0),(1,1))' &<| box '((0,0),(2,2))' AS RESULT;
result

t
(1 row)
```

- |&>

Description: Does not extend below?

Example:

```
openGauss=# SELECT box '((0,0),(3,3))' |&> box '((0,0),(2,2))' AS RESULT;
result

t
(1 row)
```

- <^

Description: Is below (allows touching)?

Example:

```
openGauss=# SELECT box '((0,0),(-3,-3))' <^ box '((0,0),(2,2))' AS RESULT;
result

t
(1 row)
```

- >^

Description: Is above (allows touching)?

Example:

```
openGauss=# SELECT box '((0,0),(2,2))' >^ box '((0,0),(-3,-3))' AS RESULT;
result

t
(1 row)
```

- ?#

Description: Intersect?

Example:

```
openGauss=# SELECT lseg '((-1,0),(1,0))' ?# box '((-2,-2),(2,2))' AS RESULT;
result

t
(1 row)
```

- ?-

Description: Is horizontal?

Example:

```
openGauss=# SELECT ?- lseg '((-1,0),(1,0))' AS RESULT;
result

t
(1 row)
```

- ?-

Description: Are horizontally aligned?

Example:

```
openGauss=# SELECT point '(1,0)' ?- point '(0,0)' AS RESULT;
result

t
(1 row)
```

- ?|

Description: Is vertical?

Example:

```
openGauss=# SELECT ?| lseg '((-1,0),(1,0))' AS RESULT;
result

f
(1 row)
```

- ?|

Description: Are vertically aligned?

Example:

```
openGauss=# SELECT point '(0,1)' ?| point '(0,0)' AS RESULT;
result

t
(1 row)
```

- ?-|

Description: Are perpendicular?

Example:

```
openGauss=# SELECT lseg '((0,0),(0,1))' ?-| lseg '((0,0),(1,0))' AS RESULT;
result

t
(1 row)
```

- ?||

Description: Are parallel?

Example:

```
openGauss=# SELECT lseg '((-1,0),(1,0))' ?|| lseg '((-1,2),(1,2))' AS RESULT;
result

t
(1 row)
```

- @>

Description: Contains?

Example:

```
openGauss=# SELECT circle '((0,0),2)' @> point '(1,1)' AS RESULT;
result

t
(1 row)
```

- <@

Description: Contained in or on?

Example:

```
openGauss=# SELECT point '(1,1)' <@ circle '((0,0),2)' AS RESULT;
result
```

- ```
-----
t
(1 row)
```
- `~=`
Description: Same as?
Example:

```
openGauss=# SELECT polygon '((0,0),(1,1))' ~= polygon '((1,1),(0,0))' AS RESULT;
result
-----
t
(1 row)
```

Geometric Functions

- `area(object)`
Description: Area calculation
Return type: double precision
Example:

```
openGauss=# SELECT area(box '((0,0),(1,1))') AS RESULT;
result
-----
1
(1 row)
```
- `center(object)`
Description: Figure center calculation
Return type: point
Example:

```
openGauss=# SELECT center(box '((0,0),(1,2))') AS RESULT;
result
-----
(0.5,1)
(1 row)
```
- `diameter(circle)`
Description: Circle diameter calculation
Return type: double precision
Example:

```
openGauss=# SELECT diameter(circle '((0,0),2.0)') AS RESULT;
result
-----
4
(1 row)
```
- `height(box)`
Description: Vertical size of box
Return type: double precision
Example:

```
openGauss=# SELECT height(box '((0,0),(1,1))') AS RESULT;
result
-----
1
(1 row)
```
- `isclosed(path)`
Description: A closed path?

Return type: Boolean

Example:

```
openGauss=# SELECTisclosed(path '((0,0),(1,1),(2,0)))' AS RESULT;
result
-----
t
(1 row)
```

- **isopen(path)**

Description: An open path?

Return type: Boolean

Example:

```
openGauss=# SELECT isopen(path '[(0,0),(1,1),(2,0)]') AS RESULT;
result
-----
t
(1 row)
```

- **length(object)**

Description: Length calculation

Return type: double precision

Example:

```
openGauss=# SELECT length(path '((-1,0),(1,0))') AS RESULT;
result
-----
4
(1 row)
```

- **npoints(path)**

Description: Number of points in a path

Return type: int

Example:

```
openGauss=# SELECT npoints(path '[(0,0),(1,1),(2,0)]') AS RESULT;
result
-----
3
(1 row)
```

- **npoints(polygon)**

Description: Number of points in a polygon

Return type: int

Example:

```
openGauss=# SELECT npoints(polygon '((1,1),(0,0))') AS RESULT;
result
-----
2
(1 row)
```

- **pclose(path)**

Description: Converts a path to closed.

Return type: path

Example:

```
openGauss=# SELECT pclose(path '[(0,0),(1,1),(2,0)]') AS RESULT;
result
-----
((0,0),(1,1),(2,0))
(1 row)
```

- **popen(path)**

Description: Converts a path to open.

Return type: path

Example:

```
openGauss=# SELECT popen(path '((0,0),(1,1),(2,0)))' AS RESULT;
result
-----
[(0,0),(1,1),(2,0)]
(1 row)
```

- **radius(circle)**

Description: Circle radius calculation

Return type: double precision

Example:

```
openGauss=# SELECT radius(circle '((0,0),2.0)') AS RESULT;
result
-----
2
(1 row)
```

- **width(box)**

Description: Horizontal size of a box

Return type: double precision

Example:

```
openGauss=# SELECT width(box '((0,0),(1,1))') AS RESULT;
result
-----
1
(1 row)
```

Geometric Type Conversion Functions

- **box(circle)**

Description: Circle to box

Return type: box

Example:

```
openGauss=# SELECT box(circle '((0,0),2.0)') AS RESULT;
result
-----
(1.41421356237309,1.41421356237309),(-1.41421356237309,-1.41421356237309)
(1 row)
```

- **box(point, point)**

Description: Points to box

Return type: box

Example:

```
openGauss=# SELECT box(point '(0,0)', point '(1,1)') AS RESULT;
result
-----
(1,1),(0,0)
(1 row)
```

- **box(polygon)**

Description: Polygon to box

Return type: box

Example:

```
openGauss=# SELECT box(polygon '((0,0),(1,1),(2,0))) AS RESULT;
result
-----
(2,1),(0,0)
(1 row)
```

- circle(box)

Description: Box to circle

Return type: circle

Example:

```
openGauss=# SELECT circle(box '((0,0),(1,1))) AS RESULT;
result
-----
<(0.5,0.5),0.707106781186548>
(1 row)
```

- circle(point, double precision)

Description: Center and radius to circle

Return type: circle

Example:

```
openGauss=# SELECT circle(point '(0,0)', 2.0) AS RESULT;
result
-----
<(0,0),2>
(1 row)
```

- circle(polygon)

Description: Polygon to circle

Return type: circle

Example:

```
openGauss=# SELECT circle(polygon '((0,0),(1,1),(2,0))) AS RESULT;
result
-----
<(1,0.3333333333333333),0.924950591148529>
(1 row)
```

- lseg(box)

Description: Box diagonal to line segment

Return type: lseg

Example:

```
openGauss=# SELECT lseg(box '((-1,0),(1,0))') AS RESULT;
result
-----
[(1,0),(-1,0)]
(1 row)
```

- lseg(point, point)

Description: Points to line segment

Return type: lseg

Example:

```
openGauss=# SELECT lseg(point '(-1,0)', point '(1,0)') AS RESULT;
result
-----
[(-1,0),(1,0)]
(1 row)
```

- **slope(point, point)**
Description: Calculates the slope of a straight line formed by two points.
Return type: double

Example:

```
openGauss=# SELECT slope(point '(1,1)', point '(0,0)') AS RESULT;
result
-----
1
(1 row)
```

- **path(polygon)**
Description: Polygon to path
Return type: path

Example:

```
openGauss=# SELECT path(polygon '((0,0),(1,1),(2,0))') AS RESULT;
result
-----
((0,0),(1,1),(2,0))
(1 row)
```

- **point(double precision, double precision)**
Description: Points
Return type: point

Example:

```
openGauss=# SELECT point(23.4, -44.5) AS RESULT;
result
-----
(23.4,-44.5)
(1 row)
```

- **point(box)**
Description: Center of a box
Return type: point

Example:

```
openGauss=# SELECT point(box '((-1,0),(1,0))') AS RESULT;
result
-----
(0,0)
(1 row)
```

- **point(circle)**
Description: Center of a circle
Return type: point

Example:

```
openGauss=# SELECT point(circle '((0,0),2.0)') AS RESULT;
result
-----
(0,0)
(1 row)
```

- **point(lseg)**
Description: Center of a line segment
Return type: point

Example:

```
openGauss=# SELECT point(lseg '((-1,0),(1,0))') AS RESULT;
result
```

```
-----  
(0,0)  
(1 row)
```

- point(polygon)

Description: Center of a polygon

Return type: point

Example:

```
openGauss=# SELECT point(polygon '((0,0),(1,1),(2,0))') AS RESULT;  
result  
-----  
(1,0.3333333333333333)  
(1 row)
```

- polygon(box)

Description: Box to 4-point polygon

Return type: polygon

Example:

```
openGauss=# SELECT polygon(box '((0,0),(1,1))') AS RESULT;  
result  
-----  
((0,0),(0,1),(1,1),(1,0))  
(1 row)
```

- polygon(circle)

Description: Circle to 12-point polygon

Return type: polygon

Example:

```
openGauss=# SELECT polygon(circle '((0,0),2.0)') AS RESULT;  
result  
-----  
-----  
((-2,0),(-1.73205080756888,1),(-1,1.73205080756888),(-1.22464679914735e-16,2),  
(1,1.73205080756888),(1.73205080756888,1),(2,2.44929359829471e-16),  
(1.73205080756888,-0.9999999999999999),(1,-1.73205080756888),(3.67394039744206e-16,-2),  
(-0.9999999999999999,-1.73205080756888),(-1.73205080756888,-1))  
(1 row)
```

- polygon(npts, circle)

Description: Circle to **npts**-point polygon

Return type: polygon

Example:

```
openGauss=# SELECT polygon(12, circle '((0,0),2.0)') AS RESULT;  
result  
-----  
-----  
((-2,0),(-1.73205080756888,1),(-1,1.73205080756888),(-1.22464679914735e-16,2),  
(1,1.73205080756888),(1.73205080756888,1),(2,2.44929359829471e-16),  
(1.73205080756888,-0.9999999999999999),(1,-1.73205080756888),(3.67394039744206e-16,-2),  
(-0.9999999999999999,-1.73205080756888),(-1.73205080756888,-1))  
(1 row)
```

- polygon(path)

Description: Path to polygon

Return type: polygon

Example:

```
openGauss=# SELECT polygon(path '((0,0),(1,1),(2,0)))' AS RESULT;  
result  
-----  
((0,0),(1,1),(2,0))  
(1 row)
```

7.5.11 Network Address Functions and Operators

cidr and inet Operators

The operators <<, <=, >>, and >= test for subnet inclusion. They consider only the network parts of the two addresses (ignoring any host part) and determine whether one network is identical to or a subnet of the other.

- <

Description: Is less than

Example:

```
openGauss=# SELECT inet '192.168.1.5' < inet '192.168.1.6' AS RESULT;  
result  
-----  
t  
(1 row)
```

- <=

Description: Is less than or equals

Example:

```
openGauss=# SELECT inet '192.168.1.5' <= inet '192.168.1.5' AS RESULT;  
result  
-----  
t  
(1 row)
```

- =

Description: Equals

Example:

```
openGauss=# SELECT inet '192.168.1.5' = inet '192.168.1.5' AS RESULT;  
result  
-----  
t  
(1 row)
```

- >=

Description: Is greater than or equals

Example:

```
openGauss=# SELECT inet '192.168.1.5' >= inet '192.168.1.5' AS RESULT;  
result  
-----  
t  
(1 row)
```

- >

Description: Is greater than

Example:

```
openGauss=# SELECT inet '192.168.1.5' > inet '192.168.1.4' AS RESULT;  
result
```

- ```

t
(1 row)
```
- <>

Description: Does not equal to

Example:

```
openGauss=# SELECT inet '192.168.1.5' <> inet '192.168.1.4' AS RESULT;
result

t
(1 row)
```
- <<

Description: Is contained in

Example:

```
openGauss=# SELECT inet '192.168.1.5' << inet '192.168.1/24' AS RESULT;
result

t
(1 row)
```
- <<=

Description: Is contained in or equals

Example:

```
openGauss=# SELECT inet '192.168.1/24' <<= inet '192.168.1/24' AS RESULT;
result

t
(1 row)
```
- >>

Description: Contains

Example:

```
openGauss=# SELECT inet '192.168.1/24' >> inet '192.168.1.5' AS RESULT;
result

t
(1 row)
```
- >>=

Description: Contains or equals

Example:

```
openGauss=# SELECT inet '192.168.1/24' >>= inet '192.168.1/24' AS RESULT;
result

t
(1 row)
```
- ~

Description: Bitwise NOT

Example:

```
openGauss=# SELECT ~ inet '192.168.1.6' AS RESULT;
result

63.87.254.249
(1 row)
```
- &

Description: Performs an AND operation on each bit of the two network addresses.

Example:

```
openGauss=# SELECT inet '192.168.1.6' & inet '10.0.0.0' AS RESULT;
result

0.0.0.0
(1 row)
```

- |

Description: Performs an OR operation on each bit of the two network addresses.

Example:

```
openGauss=# SELECT inet '192.168.1.6' | inet '10.0.0.0' AS RESULT;
result

202.168.1.6
(1 row)
```

- +

Description: Addition

Example:

```
openGauss=# SELECT inet '192.168.1.6' + 25 AS RESULT;
result

192.168.1.31
(1 row)
```

- -

Description: Subtraction

Example:

```
openGauss=# SELECT inet '192.168.1.43' - 36 AS RESULT;
result

192.168.1.7
(1 row)
```

- -

Description: Subtraction

Example:

```
openGauss=# SELECT inet '192.168.1.43' - inet '192.168.1.19' AS RESULT;
result

24
(1 row)
```

## cidr and inet Functions

The **abbrev**, **host**, and **text** functions are primarily intended to offer alternative display formats.

- abbrev(inet)

Description: Abbreviated display format as text

Return type: text

Example:

```
openGauss=# SELECT abbrev(inet '10.1.0.0/16') AS RESULT;
result
```

- ```
-----
10.1.0.0/16
(1 row)
```
- **abbrev(cidr)**
Description: Abbreviated display format as text
Return type: text
Example:

```
openGauss=# SELECT abbrev(cidr '10.1.0.0/16') AS RESULT;
result
-----
10.1/16
(1 row)
```
 - **broadcast(inet)**
Description: Broadcast address for networks
Return type: inet
Example:

```
openGauss=# SELECT broadcast('192.168.1.5/24') AS RESULT;
result
-----
192.168.1.255/24
(1 row)
```
 - **family(inet)**
Description: Extracts family of addresses, **4** for IPv4.
Return type: int
Example:

```
openGauss=# SELECT family('127.0.0.1') AS RESULT;
result
-----
4
(1 row)
```
 - **host(inet)**
Description: Extracts IP addresses as text.
Return type: text
Example:

```
openGauss=# SELECT host('192.168.1.5/24') AS RESULT;
result
-----
192.168.1.5
(1 row)
```
 - **hostmask(inet)**
Description: Constructs the host mask for a network.
Return type: inet
Example:

```
openGauss=# SELECT hostmask('192.168.23.20/30') AS RESULT;
result
-----
0.0.0.3
(1 row)
```
 - **masklen(inet)**
Description: Extracts subnet mask length.
Return type: int

Example:

```
openGauss=# SELECT masklen('192.168.1.5/24') AS RESULT;
result
-----
      24
(1 row)
```

- **netmask(inet)**

Description: Constructs the subnet mask for a network.

Return type: inet

Example:

```
openGauss=# SELECT netmask('192.168.1.5/24') AS RESULT;
result
-----
255.255.255.0
(1 row)
```

- **network(inet)**

Description: Extracts the network part of an address.

Return type: cidr

Example:

```
openGauss=# SELECT network('192.168.1.5/24') AS RESULT;
result
-----
192.168.1.0/24
(1 row)
```

- **set_masklen(inet, int)**

Description: Sets subnet mask length for the **inet** value.

Return type: inet

Example:

```
openGauss=# SELECT set_masklen('192.168.1.5/24', 16) AS RESULT;
result
-----
192.168.1.5/16
(1 row)
```

- **set_masklen(cidr, int)**

Description: Sets subnet mask length for the **cidr** value.

Return type: cidr

Example:

```
openGauss=# SELECT set_masklen('192.168.1.0/24::cidr, 16) AS RESULT;
result
-----
192.168.0.0/16
(1 row)
```

- **text(inet)**

Description: Extracts IP addresses and subnet mask length as text.

Return type: text

Example:

```
openGauss=# SELECT text(inet '192.168.1.5') AS RESULT;
result
-----
192.168.1.5/32
(1 row)
```

Any **cidr** value can be cast to **inet** implicitly or explicitly; therefore, the functions shown above as operating on **inet** also work on **cidr** values. An **inet** value can be cast to **cidr**. After the conversion, any bits to the right of the subnet mask are silently zeroed to create a valid **cidr** value. In addition, you can cast a text string to **inet** or **cidr** using normal casting syntax. For example, **inet(expression)** or **colname::cidr**.

macaddr Functions

The function **trunc(macaddr)** returns a MAC address with the last 3 bytes set to zero.

- trunc(macaddr)**
Description: Sets last 3 bytes to zero.
Return type: macaddr
Example:

```
openGauss=# SELECT trunc(macaddr '12:34:56:78:90:ab') AS RESULT;
          result
-----
12:34:56:00:00:00
(1 row)
```

The **macaddr** type also supports the standard relational operators (such as > and <=) for lexicographical ordering, and the bitwise arithmetic operators (~, & and |) for NOT, AND and OR.

7.5.12 JSON/JSONB Functions and Operators

For details about the JSON/JSONB data type, see [JSON/JSONB Types](#).

Table 7-32 JSON/JSONB common operators

Operator	Left Operand Type	Right Operand Type	Return Type	Description	Example
->	Array - json(b)	int	json(b)	Obtains the array-json element. If the index does not exist, NULL is returned.	<pre>SELECT '["a":"foo"],["b":"bar"], {"c":"baz"}'::json->2; ?column? ----- {"c":"baz"} (1 row)</pre>
->	object-json(b)	text	json(b)	Obtains the value by a key. If no record is found, NULL is returned.	<pre>SELECT '{"a": {"b":"foo"}}'::json->'a'; ?column? ----- {"b":"foo"} (1 row)</pre>

O p e r a t o r	Left Oper and Type	Rig ht Ope rand Type	Re tu rn Ty pe	Description	Example
- > >	Array - json(b)	int	te xt	Obtains the JSON array element. If the index does not exist, NULL is returned.	<pre>SELECT '[1,2,3]::json->>2; ?column? ----- 3 (1 row)</pre>
- > >	objec t- json(b)	text	te xt	Obtains the value by a key. If no record is found, NULL is returned.	<pre>SELECT '{"a":1,"b":2}::json->>'b'; ?column? ----- 2 (1 row)</pre>
# >	conta iner- json (b)	tex t[]	jso n(b)	Obtains the JSON object in the specified path. If the path does not exist, NULL is returned.	<pre>SELECT '{"a": {"b":{"c": "foo"}}}::json #>'a,b'; ?column? ----- {"c": "foo"} (1 row)</pre>
# > >	conta iner- json (b)	tex t[]	te xt	Obtains the JSON object in the specified path. If the path does not exist, NULL is returned.	<pre>SELECT '{"a":[1,2,3],"b":[4,5,6]}::json #>>'a,2'; ?column? ----- 3 (1 row)</pre>

 CAUTION

For the #> and #>> operators, if no data can be found in the specified path, no error is reported and a **NULL** value is returned.

Table 7-33 Additional JSONB support for operators

Operator	Right Operand Type	Description	Example
@>	jsonb	Specifies whether the top layer of the JSON on the left contains all items of the top layer of the JSON on the right.	'{"a":1, "b":2}':::jsonb @> '{"b":2}':::jsonb
<@	jsonb	Specifies whether all items in the JSON file on the left exist at the top layer of the JSON file on the right.	'{"b":2}':::jsonb <@ '{"a":1, "b":2}':::jsonb
?	text	Specifies whether the string of the key or element exists at the top layer of the JSON value.	'{"a":1, "b":2}':::jsonb ? 'b'
?	text[]	Specifies whether any of these array strings exists as top-layer keys.	'{"a":1, "b":2, "c":3}':::jsonb ? array['b', 'c']
?&	text[]	Specifies whether all these array strings exist as top-layer keys.	'["a", "b"]':::jsonb ? & array['a', 'b']
=	jsonb	Determines the size between two JSONB files, which is the same as the jsonb_eq function.	/
<>	jsonb	Determines the size between two JSONB files, which is the same as the jsonb_ne function.	/

Operator	Right Operand Type	Description	Example
<	jsonb	Determines the size between two JSONB files, which is the same as the jsonb_lt function.	/
>	jsonb	Determines the size between two JSONB files, which is the same as the jsonb_gt function.	/
<=	jsonb	Determines the size between two JSONB files, which is the same as the jsonb_le function.	/
>=	jsonb	Determines the size between two JSONB files, which is the same as the jsonb_ge function.	/

Functions Supported by JSON/JSONB

- array_to_json(anyarray [, pretty_bool])

Description: Returns an array as JSON. It combines a multi-dimensional array into a JSON array. Line feeds will be added between one-dimensional elements if **pretty_bool** is **true**.

Return type: json

For example:

```
openGauss=# SELECT array_to_json('{{1,5},{99,100}}':int[]);
 array_to_json
-----
 [[1,5],[99,100]]
 (1 row)
```

- row_to_json(record [, pretty_bool])

Description: Returns a row as JSON. Line feeds will be added between level-1 elements if **pretty_bool** is **true**.

Return type: json

For example:

```
openGauss=# SELECT row_to_json(row(1,'foo'));
 row_to_json
-----
 [{"1":"foo"}]
```

```
-----  
{ "f1":1,"f2":"foo"} (1 row)
```

- `json_array_element(array-json, integer)`, `jsonb_array_element(array-jsonb, integer)`

Description: Same as the operator ``->``, which returns the element with the specified index in the array.

Return type: json, jsonb

For example:

```
openGauss=# SELECT json_array_element('[1,true,[1,[2,3  
]],null]',2);  
json_array_element  
-----  
[1,[2,3]]  
(1 row)
```

- `json_array_element_text(array-json, integer)`, `jsonb_array_element_text(array-jsonb, integer)`

Description: Same as the operator ``->>``, which returns the element with the specified index in the array.

Return type: text, text

For example:

```
openGauss=# SELECT json_array_element_text('[1,true,[1,[2,3]],null]',2);  
json_array_element_text  
-----  
[1,[2,3]]  
(1 row)
```

- `json_object_field(object-json, text)`, `jsonb_object_field(object-jsonb, text)`

Description: Same as the operator ``->``, which returns the value of a specified key in an object.

Return type: json, json

For example:

```
openGauss=# SELECT json_object_field('{ "a": { "b": "foo" } }', 'a');  
json_object_field  
-----  
{ "b": "foo" }  
(1 row)
```

- `json_object_field_text(object-json, text)`, `jsonb_object_field_text(object-jsonb, text)`

Description: Same as the operator ``->``, which returns the value of a specified key in an object.

Return type: text, text

For example:

```
openGauss=# SELECT json_object_field_text('{ "a": { "b": "foo" } }', 'a');  
json_object_field_text  
-----  
{ "b": "foo" }  
(1 row)
```

- `json_extract_path(json, VARIADIC text[])`, `jsonb_extract_path((jsonb, VARIADIC text[])`

Description: Equivalent to the operator ``#>`` searches for JSON based on the path specified by `$2` and returns the result.

Return type: json, jsonb

For example:

```
openGauss=# SELECT json_extract_path('{\"f2\":{\"f3\":1},\"f4\":{\"f5\":99,\"f6\":\"stringy\"}}', 'f4','f6');
json_extract_path
-----
"stringy"
(1 row)
```

- `json_extract_path_op(json, text[]), jsonb_extract_path_op(jsonb, text[])`

Description: It is equivalent to the operator ``#>``, searches for JSON based on the path specified by `$2`, and returns the result.

Return type: json, jsonb

For example:

```
openGauss=# SELECT json_extract_path_op('{\"f2\":{\"f3\":1},\"f4\":{\"f5\":99,\"f6\":\"stringy\"}}',
ARRAY['f4','f6']);
json_extract_path_op
-----
"stringy"
(1 row)
```

- `json_extract_path_text(json, VARIADIC text[]), jsonb_extract_path_text(jsonb, VARIADIC text[])`

Description: It is equivalent to the operator ``#>>``, searches for JSON based on the path specified by `$2`, and returns the result.

Return type: text, text

For example:

```
openGauss=# SELECT json_extract_path_text('{\"f2\":{\"f3\":1},\"f4\":{\"f5\":99,\"f6\":\"stringy\"}}', 'f4','f6');
json_extract_path_text
-----
stringy
(1 row)
```

- `json_extract_path_text_op(json, text[]), jsonb_extract_path_text_op(jsonb, text[])`

Description: It is equivalent to the operator ``#>>>``, searches for JSON based on the path specified by `$2`, and returns the result.

Return type: text, text

For example:

```
openGauss=# SELECT json_extract_path_text_op('{\"f2\":{\"f3\":1},\"f4\":{\"f5\":99,\"f6\":\"stringy\"}}',
ARRAY['f4','f6']);
json_extract_path_text_op
-----
stringy
(1 row)
```

- `Json_array_elements(array-json), jsonb_array_elements(array-jsonb)`

Description: Splits an array. Each element returns a row.

Return type: json, jsonb

For example:

```
openGauss=# SELECT json_array_elements('[1,true,[1,2,3],null]');
json_array_elements
-----
1
true
[1,[2,3]]
null
(4 rows)
```

- `Json_array_elements_text(array-json), jsonb_array_elements_text(array-jsonb)`

Description: Splits an array. Each element returns a row.

Return type: text, text

For example:

```
openGauss=# SELECT * FROM json_array_elements_text('[1,true,[1,[2,3]],null]');
 value
-----
 1
 true
[1,[2,3]]
(4 rows)
```

- `json_array_length(array-json), jsonb_array_length(array-jsonb)`

Description: Returns the array length.

Return type: integer

For example:

```
openGauss=# SELECT json_array_length('[1,2,3,{"f1":1,"f2":[5,6]},4,null]');
 json_array_length
-----
                6
(1 row)
```

- `json_each(object-json), jsonb_each(object-jsonb)`

Description: Splits each key-value pair of an object into one row and two columns.

Return type: `setof(key text, value json), setof(key text, value jsonb)`

For example:

```
openGauss=# SELECT * FROM json_each('{\"f1\":[1,2,3],\"f2\":{\"f3\":1},\"f4\":null}');
 key | value
-----+-----
 f1  | [1,2,3]
 f2  | {\"f3\":1}
 f4  | null
(3 rows)
```

- `json_each_text(object-json), jsonb_each_text(object-jsonb)`

Description: Splits each key-value pair of an object into one row and two columns.

Return type: `setof(key text, value text), setof(key text, value text)`

For example:

```
openGauss=# SELECT * FROM json_each_text('{\"f1\":[1,2,3],\"f2\":{\"f3\":1},\"f4\":null}');
 key | value
-----+-----
 f1  | [1,2,3]
 f2  | {\"f3\":1}
 f4  | 
(3 rows)
```

- `json_object_keys(object-json), jsonb_object_keys(object-jsonb)`

Description: Returns all keys at the top layer of the object.

Return type: SETOF text

For example:

```
openGauss=# SELECT json_object_keys('{\"f1\":\"abc\", \"f2\":{\"f3\":\"a\", \"f4\":\"b\"}, \"f1\":\"abcd\"}');
 json_object_keys
-----
 f1
 f2
 f1
(3 rows)
```

- JSONB deduplication operations:

```
openGauss=# SELECT jsonb_object_keys('{\"f1\":\"abc\", \"f2\":{\"f3\":\"a\", \"f4\":\"b\"}, \"f1\":\"abcd\"}');
 jsonb_object_keys
-----
```

```
f1  
f2  
(2 rows)
```

- `json_populate_record(anyelement, object-json [, bool])`,
`jsonb_populate_record(anyelement, object-jsonb [, bool])`

Description: *\$1* must be a compound parameter. Each key-value in the **object-json** file is split. The key is used as the column name to match the column name in *\$1* and fill in the *\$1* format.

Return type: anyelement, anyelement

For example:

```
openGauss=# CREATE TYPE jpop as (a text, b int, c bool);  
CREATE TYPE  
openGauss=# SELECT * FROM json_populate_record(null::jpop, '{"a":"blurfl","x":43.2}');  
  a  | b | c  
-----+-----  
blurfl |  |  
(1 row)
```

```
openGauss=# SELECT * FROM json_populate_record((1,1,null)::jpop, '{"a":"blurfl","x":43.2}');  
  a  | b | c  
-----+-----  
blurfl | 1 |  
(1 row)
```

- `json_populate_record_set(anyelement, array-json [, bool])`,
`jsonb_populate_record_set(anyelement, array-jsonb [, bool])`

Description: Performs the preceding operations on each element in the *\$2* array by referring to the **json_populate_record** and **jsonb_populate_record** functions. Therefore, each element in the *\$2* array must be of the **object-json** type.

Return type: setof anyelement, setof anyelement

For example:

```
openGauss=# CREATE TYPE jpop as (a text, b int, c bool);  
CREATE TYPE  
openGauss=# SELECT * FROM json_populate_recordset(null::jpop, '{"a":1,"b":2},{a":3,"b":4}');  
  a  | b | c  
----+----  
  1  | 2 |  
  3  | 4 |  
(2 rows)
```

- `json_typeof(json)`, `jsonb_typeof(jsonb)`

Description: Checks the JSON type.

Return type: text, text

For example:

```
openGauss=# SELECT value, json_typeof(value) FROM (values (json '123.4'), (json '"foo"'), (json  
'true'), (json 'null'), (json '[1, 2, 3]'), (json '{"x":"foo", "y":123}'), (NULL::json)) AS data(value);  
  value  | json_typeof  
-----+-----  
  123.4  | number  
  "foo"   | string  
  true    | boolean  
  null    | null  
  [1, 2, 3] | array  
  {"x":"foo", "y":123} | object  
  |  
(7 rows)
```

- `json_build_array( [VARIADIC "any"] )`

Description: Constructs a JSON array from a variable parameter list.

Return type: array-json

For example:

```
openGauss=# SELECT json_build_array('a',1,'b',1.2,'c',true,'d',null,'e',json '{"x": 3, "y": [1,2,3]}','');
               json_build_array
-----
["a", 1, "b", 1.2, "c", true, "d", null, "e", {"x": 3, "y": [1,2,3]}, ""]
(1 row)
```

- `json_build_object( [VARIADIC "any"] )`

Description: Constructs a JSON object from a variable parameter list. The number of input parameters must be an even number. Every two input parameters form a key-value pair. Note that the value of a key cannot be null.

Return type: object-json

For example:

```
openGauss=# SELECT json_build_object(1,2);
               json_build_object
-----
{"1" : 2}
(1 row)
```

- `json_to_record(object-json, bool)`

Description: Like all functions that return **record**, the caller must explicitly define the structure of the record with an AS clause. The key-value pair of **object-json** is split and reassembled. The key is used as a column name to match and fill in the structure of the specified record.

Return type: record

For example:

```
openGauss=# SELECT * FROM json_to_record('{"a":1,"b":"foo","c":"bar"}',true) AS x(a int, b text, d text);
 a | b | d
---+---+---
 1 | foo | 
(1 row)
```

- `json_to_recordset(array-json, bool)`

Description: Executes the preceding function on each element in the array by referring to the `json_to_record` function. Therefore, each element in the array must be object-json.

Return type: SETOF record

For example:

```
openGauss=# SELECT * FROM json_to_recordset(
  openGauss( # '{"a":1,"b":"foo","d":false},{a":2,"b":"bar","c":true}]' ,
  openGauss( # false
  openGauss( # ) as x(a int, b text, c boolean);
 a | b | c
---+---+---
 1 | foo | 
 2 | bar | t
(2 rows)
```

- `json_object(text[]), json_object(text[], text[])`

Description: Constructs an **object-json** from a text array. This is an overloaded function. When the input parameter is a text array, the array length must be an even number, and members are considered as alternate key-value pairs. When two text arrays are used, the first array is considered as a key, and the second array a value. The lengths of the two arrays must be the same. Note that the value of a key cannot be null.

Return type: object-json

For example:

```
openGauss=# SELECT json_object('{a,1,b,2,3,NULL,"d e f","a b c"}');
               json_object
-----
{"a": "1", "b": "2", "3": null, "d e f": "a b c"}
(1 row)
openGauss=# SELECT json_object('{a,b,"a b c"}', '{a,1,1}');
               json_object
-----
{"a": "a", "b": "1", "a b c": "1"}
(1 row)
```

- **json_agg(any)**

Description: Aggregates values into a JSON array.

Return type: array-json

For example:

```
openGauss=# SELECT * FROM classes;
 name | score
-----+-----
 A    |    2
 A    |    3
 D    |    5
 D    |
(4 rows)
openGauss=# SELECT name, json_agg(score) score FROM classes GROUP BY name ORDER BY name;
 name |      score
-----+-----
 A    | [2, 3]
 D    | [5, null]
      | [null]
(3 rows)
```

- **json_object_agg(any, any)**

Description: Aggregates values into a JSON object.

Return type: object-json

For example:

```
openGauss=# SELECT * FROM classes;
 name | score
-----+-----
 A    |    2
 A    |    3
 D    |    5
 D    |
(4 rows)

openGauss=# SELECT json_object_agg(name, score) FROM classes GROUP BY name ORDER BY
name;
               json_object_agg
-----
{"A": 2, "A": 3 }
{"D": 5, "D": null }
(2 rows)
```

- **jsonb_contained(jsonb, jsonb)**

Description: Same as the operator `<@`, determines whether all elements in \$1 exist at the top layer of \$2.

Return type: Boolean

For example:

```
openGauss=# SELECT jsonb_contained('[1,2,3]', '[1,2,3,4]');
 jsonb_contained
-----
t
(1 row)
```

- **jsonb_contains(jsonb, jsonb)**

Description: Same as the operator `@>`, checks whether all top-layer elements in \$1 are contained in \$2.

Return type: Boolean

For example:

```
openGauss=# SELECT jsonb_contains('[1,2,3,4]', '[1,2,3]');
 jsonb_contains
-----
t
(1 row)
```

- `jsonb_exists(jsonb, text)`

Description: Same as the operator `?`, determines whether all elements in the string array \$2 exist at the top layer of \$1 in the form of **key\elem\scalar**.

Return type: Boolean

For example:

```
openGauss=# SELECT jsonb_exists('["1",2,3]', '1');
 jsonb_exists
-----
t
(1 row)
```

- `jsonb_exists_all(jsonb, text[])`

Description: Same as the operator `?&`, checks whether all elements in the string array \$2 exist at the top layer of \$1 in the form of **key\elem\scalar**.

Return type: Boolean

For example:

```
openGauss=# SELECT jsonb_exists_all('["1","2",3]', '{1, 2}');
 jsonb_exists_all
-----
t
(1 row)
```

- `jsonb_exists_any(jsonb, text[])`

Description: Same as the operator `?|`, checks whether all elements in the string array \$2 exist at the top layer of \$1 in the form of **key\elem\scalar**.

Return type: Boolean

For example:

```
openGauss=# SELECT jsonb_exists_any('["1","2",3]', '{1, 2, 4}');
 jsonb_exists_any
-----
t
(1 row)
```

- `jsonb_cmp(jsonb, jsonb)`

Description: Compares values. A positive value indicates greater than, a negative value indicates less than, and 0 indicates equal.

Return type: integer

For example:

```
openGauss=# SELECT jsonb_cmp('["a", "b"]', '{"a":1, "b":2}');
 jsonb_cmp
-----
-1
(1 row)
```

- `jsonb_eq(jsonb, jsonb)`

Description: Same as the operator `=`, compares two values.

Return type: Boolean

For example:

```
openGauss=# SELECT jsonb_eq('["a", "b"]', '{"a":1, "b":2}');
 jsonb_eq
-----
f
(1 row)
```

- `jsonb_ne(jsonb, jsonb)`

Description: Same as the operator ``<>``, compares two values.

Return type: Boolean

For example:

```
openGauss=# SELECT jsonb_ne('["a", "b"]', '{"a":1, "b":2}');
 jsonb_ne
-----
t
(1 row)
```

- `jsonb_gt(jsonb, jsonb)`

Description: Same as the operator ``>``, compares two values.

Return type: Boolean

For example:

```
openGauss=# SELECT jsonb_gt('["a", "b"]', '{"a":1, "b":2}');
 jsonb_gt
-----
f
(1 row)
```

- `jsonb_ge(jsonb, jsonb)`

Description: Same as the operator ``>=``, compares two values.

Return type: Boolean

For example:

```
openGauss=# SELECT jsonb_ge('["a", "b"]', '{"a":1, "b":2}');
 jsonb_ge
-----
f
(1 row)
```

- `jsonb_lt(jsonb, jsonb)`

Description: Same as the operator ``<``, compares two values.

Return type: Boolean

For example:

```
openGauss=# SELECT jsonb_lt('["a", "b"]', '{"a":1, "b":2}');
 jsonb_lt
-----
t
(1 row)
```

- `jsonb_le(jsonb, jsonb)`

Description: Same as the operator ``<=``, compares two values.

Return type: Boolean

For example:

```
openGauss=# SELECT jsonb_le('["a", "b"]', '{"a":1, "b":2}');
 jsonb_le
-----
t
(1 row)
```

- `to_json(anyelement)`

Description: Converts parameters to ``json``.

Return type: json

For example:

```
openGauss=# SELECT to_json('{1,5}::text[]);
to_json
-----
["1","5"]
(1 row)
```

- jsonb_hash(jsonb)

Description: Performs the hash operation on JSONB.

Return type: integer

For example:

```
openGauss=# SELECT jsonb_hash('[1,2,3]');
jsonb_hash
-----
-559968547
(1 row)
```

- Other functions

Description: Internal functions used by JSON and JSONB aggregate functions.

```
json_agg_transfn
json_agg_finalfn
json_object_agg_transfn
json_object_agg_finalfn
```

7.5.13 HLL Functions and Operators

Hash Functions

- hll_hash_boolean(bool)

Description: Hashes data of the Boolean type.

Return type: hll_hashval

Example:

```
openGauss=# SELECT hll_hash_boolean(FALSE);
hll_hash_boolean
-----
-5451962507482445012
(1 row)
```

- hll_hash_boolean(bool, int32)

Description: Configures a hash seed (that is, change the hash policy) and hashes data of the bool type.

Return type: hll_hashval

Example:

```
openGauss=# SELECT hll_hash_boolean(FALSE, 10);
hll_hash_boolean
-----
-1169037589280886076
(1 row)
```

- hll_hash_smallint(smallint)

Description: Hashes data of the smallint type.

Return type: hll_hashval

Example:

```
openGauss=# SELECT hll_hash_smallint(100::smallint);
hll_hash_smallint
-----
```

```
962727970174027904
(1 row)
```

NOTE

If parameters with the same numeric value are hashed using different data types, the data will differ, because hash functions select different calculation policies for each type.

- `hll_hash_smallint(smallint, int32)`

Description: Configures a hash seed (that is, change the hash policy) and hashes data of the smallint type.

Return type: `hll_hashval`

Example:

```
openGauss=# SELECT hll_hash_smallint(100::smallint, 10);
hll_hash_smallint
-----
-9056177146160443041
(1 row)
```

- `hll_hash_integer(integer)`

Description: Hashes data of the integer type.

Return type: `hll_hashval`

Example:

```
openGauss=# SELECT hll_hash_integer(0);
hll_hash_integer
-----
5156626420896634997
(1 row)
```

- `hll_hash_integer(integer, int32)`

Description: Hashes data of the integer type and configures a hash seed (that is, change the hash policy).

Return type: `hll_hashval`

Example:

```
openGauss=# SELECT hll_hash_integer(0, 10);
hll_hash_integer
-----
-5035020264353794276
(1 row)
```

- `hll_hash_bigint(bigint)`

Description: Hashes data of the bigint type.

Return type: `hll_hashval`

Example:

```
openGauss=# SELECT hll_hash_bigint(100::bigint);
hll_hash_bigint
-----
-2401963681423227794
(1 row)
```

- `hll_hash_bigint(bigint, int32)`

Description: Hashes data of the bigint type and configures a hash seed (that is, change the hash policy).

Return type: `hll_hashval`

Example:

```
openGauss=# SELECT hll_hash_bigint(100::bigint, 10);
hll_hash_bigint
```

```
-----  
-2305749404374433531  
(1 row)
```

- **hll_hash_bytea(bytea)**

Description: Hashes data of the bytea type.

Return type: hll_hashval

Example:

```
openGauss=# SELECT hll_hash_bytea(E'\x');  
hll_hash_bytea  
-----  
0  
(1 row)
```

- **hll_hash_bytea(bytea, int32)**

Description: Hashes data of the bytea type and configures a hash seed (that is, change the hash policy).

Return type: hll_hashval

Example:

```
openGauss=# SELECT hll_hash_bytea(E'\x', 10);  
hll_hash_bytea  
-----  
7233188113542599437  
(1 row)
```

- **hll_hash_text(text)**

Description: Hashes data of the text type.

Return type: hll_hashval

Example:

```
openGauss=# SELECT hll_hash_text('AB');  
hll_hash_text  
-----  
-5666002586880275174  
(1 row)
```

- **hll_hash_text(text, int32)**

Description: Hashes data of the text type and configures a hash seed (that is, change the hash policy).

Return type: hll_hashval

Example:

```
openGauss=# SELECT hll_hash_text('AB', 10);  
hll_hash_text  
-----  
-2215507121143724132  
(1 row)
```

- **hll_hash_any(anytype)**

Description: Hashes data of any type.

Return type: hll_hashval

Example:

```
openGauss=# SELECT hll_hash_any(1);  
hll_hash_any  
-----  
-1316670585935156930  
(1 row)  
  
openGauss=# SELECT hll_hash_any('08:00:2b:01:02:03':macaddr);  
hll_hash_any
```

```
-----  
-3719950434455589360  
(1 row)
```

- `hll_hash_any(anytype, int32)`

Description: Hashes data of any type and configures a hash seed (that is, change the hash policy).

Return type: `hll_hashval`

Example:

```
openGauss=# SELECT hll_hash_any(1, 10);  
hll_hash_any  
-----  
7048553517657992351  
(1 row)
```

- `hll_hashval_eq(hll_hashval, hll_hashval)`

Description: Compares two pieces of data of the **`hll_hashval`** type to check whether they are the same.

Return type: Boolean

Example:

```
openGauss=# SELECT hll_hashval_eq(hll_hash_integer(1), hll_hash_integer(1));  
hll_hashval_eq  
-----  
t  
(1 row)
```

- `hll_hashval_ne(hll_hashval, hll_hashval)`

Description: Compares two pieces of data of the **`hll_hashval`** type to check whether they are different.

Return type: Boolean

Example:

```
openGauss=# SELECT hll_hashval_ne(hll_hash_integer(1), hll_hash_integer(1));  
hll_hashval_ne  
-----  
f  
(1 row)
```

Log Functions

There are three HLL modes: explicit, sparse, and full. When the data size is small, the explicit mode is used. In this mode, distinct values are calculated without errors. As the number of distinct values increases, the HLL mode is switched to the sparse and full modes in sequence. The two modes have no difference in the calculation result, but vary in the calculation efficiency of HLL functions and the storage space of HLL objects. The following functions can be used to view some HLL parameters:

- `hll_print(hll)`

Description: Prints some debugging parameters of an HLL.

Example:

```
openGauss=# SELECT hll_print(hll_empty());  
hll_print  
-----  
type=1(HLL_EMPTY), log2m=14, log2explicit=10, log2sparse=12, duplicatecheck=0  
(1 row)
```

- `hll_type(hll)`

Description: Checks the type of the current HLL. The return values are described as follows: **0** indicates **HLL_UNINIT**, an HLL object that is not initialized. **1** indicates **HLL_EMPTY**, an empty HLL object. **2** indicates **HLL_EXPLICIT**, an HLL object in explicit mode. **3** indicates **HLL_SPARSE**, an HLL object in sparse mode. **4** indicates **HLL_FULL**, an HLL object in full mode. **5** indicates **HLL_UNDEFINED**, an invalid HLL object.

Example:

```
openGauss=# SELECT hll_type(hll_empty());
 hll_type
-----
      1
(1 row)
```

- **hll_log2m(hll)**

Description: Checks the value of **log2m** in the current HLL data structure. **log2m** is the logarithm of the number of buckets. This value affects the error rate of calculating distinct values by HLL. The error rate = $\pm 1.04/\sqrt{2^{\log 2m}}$. If the value of **log2m** ranges from 10 to 16, HLL sets the number of buckets to $2^{\log 2m}$. When the value of **log2explicit** is explicitly set to **-1**, the built-in default value is used.

Example:

```
openGauss=# SELECT hll_log2m(hll_empty());
 hll_log2m
-----
      14
(1 row)

openGauss=# SELECT hll_log2m(hll_empty(10));
 hll_log2m
-----
      10
(1 row)

openGauss=# SELECT hll_log2m(hll_empty(-1));
 hll_log2m
-----
      14
(1 row)
```

- **hll_log2explicit(hll)**

Description: Queries the **log2explicit** value in the current HLL data structure. Generally, the HLL changes from the explicit mode to the sparse mode and then to the full mode. This process is called the promotion hierarchy policy. You can change the value of **log2explicit** to change the policy. For example, if the value of **log2explicit** is **0**, the explicit mode will be skipped and the sparse mode is directly entered. When the value of **log2explicit** is explicitly set to a value ranging from 1 to 12, HLL will switch to the sparse mode when the length of the data segment exceeds $2^{\log 2explicit}$. When the value of **log2explicit** is explicitly set to **-1**, the built-in default value is used.

Example:

```
openGauss=# SELECT hll_log2explicit(hll_empty());
 hll_log2explicit
-----
      10
(1 row)

openGauss=# SELECT hll_log2explicit(hll_empty(12, 8));
 hll_log2explicit
-----
```

```
      8
(1 row)

openGauss=# SELECT hll_log2explicit(hll_empty(12, -1));
 hll_log2explicit 
-----
      10
(1 row)
```

- **hll_log2sparse(hll)**

Description: Queries the value of **log2sparse** in the current HLL data structure. Generally, the HLL changes from the explicit mode to the sparse mode and then to the full mode. This process is called the promotion hierarchy policy. You can adjust the value of **log2sparse** to change the policy. For example, if the value of **log2sparse** is **0**, the system skips the sparse mode and directly enters the full mode. If the value of **log2sparse** is explicitly set to a value ranging from 1 to 14, HLL will switch to the full mode when the length of the data segment exceeds $2^{\text{log2sparse}}$. When the value of **log2sparse** is explicitly set to **-1**, the built-in default value is used.

Example:

```
openGauss=# SELECT hll_log2sparse(hll_empty());
 hll_log2sparse 
-----
      12
(1 row)

openGauss=# SELECT hll_log2sparse(hll_empty(12, 8, 10));
 hll_log2sparse 
-----
      10
(1 row)

openGauss=# SELECT hll_log2sparse(hll_empty(12, 8, -1));
 hll_log2sparse 
-----
      12
(1 row)
```

- **hll_duplicatecheck(hll)**

Description: Specifies whether duplicate check is enabled. The value **0** indicates that it is disabled and the value **1** indicates that it is enabled. This function is disabled by default. If there are many duplicate values, you can enable this function to improve efficiency. When the value of **duplicatecheck** is explicitly set to **-1**, the built-in default value is used.

Example:

```
openGauss=# SELECT hll_duplicatecheck(hll_empty());
 hll_duplicatecheck 
-----
      0
(1 row)

openGauss=# SELECT hll_duplicatecheck(hll_empty(12, 8, 10, 1));
 hll_duplicatecheck 
-----
      1
(1 row)

openGauss=# SELECT hll_duplicatecheck(hll_empty(12, 8, 10, -1));
 hll_duplicatecheck 
-----
      0
(1 row)
```

Functional Functions

- `hll_empty()`

Description: Creates an empty HLL.

Return type: hll

Example:

```
openGauss=# SELECT hll_empty();
          hll_empty
-----
\x484c4c0000000002b0500000000000000000000000000000000000000000000000
(1 row)
```

- `hll_empty(int32 log2m)`

Description: Creates an empty HLL and sets the **log2m** parameter. The parameter value ranges from 10 to 16. If the input is **-1**, the built-in default value is used.

Return type: HLL

Example:

[illegible]

- `hll_empty(int32 log2m, int32 log2explicit)`

Description: Creates an empty HLL and sets the **log2m** and **log2explicit** parameters in sequence. The value of **log2explicit** ranges from 0 to 12. The value **0** indicates that the explicit mode is skipped. This parameter is used to set the threshold of the explicit mode. When the length of the data segment reaches $2^{\text{log2explicit}}$, the mode is switched to the sparse or full mode. If the input is **-1**, the built-in default value of **log2explicit** is used.

Return type: HLL

Example:

```
openGauss=# SELECT hll_empty(10, 4);  
                hll_empty  
-----  
\x484c4c00000000000130400000000000000000000000000000  
(1 row)  
  
openGauss=# SELECT hll_empty(10, -1);  
                hll_empty  
-----  
\x484c4c00000000002b040000000000000000000000000000  
(1 row)
```

- `hll_empty(int32 log2m, int32 log2explicit, int64 log2sparse)`

Description: Creates an empty HLL and sets the **log2m**, **log2explicit** and **log2sparse** parameters in sequence. The value of **log2sparse** ranges from 0 to 14. The value **0** indicates that the sparse mode is skipped. This parameter is used to set the threshold of the sparse mode. When the length of the data segment reaches $2^{\text{log2sparse}}$, the mode is switched to the full mode. If the input is **-1**, the built-in default value of **log2sparse** is used.

Return type: HLL

Example:

```
openGauss=# SELECT hll_empty(10, 4, 8);
```

```
\x484c4c000000000012040000000000000000000000000000000000000000000000  
(1 row)
```

```
openGauss=# SELECT hll_empty(10, 4, -1);
          hll_empty
-----
\x484c4c000000000013040000000000000000000000000000000000000000000000
(1 row)
```

- `hll_empty(int32 log2m, int32 log2explicit, int64 log2sparse, int32 duplicatecheck)`

Description: Creates an empty HLL and sets the **log2m**, **log2explicit**, **log2sparse**, and **duplicatecheck** parameters in sequence. The value of **duplicatecheck** is **0** or **1**, indicating whether the duplicate check mode is enabled. By default, this mode is disabled. If the input is **-1**, the built-in default value of **duplicatecheck** is used.

Return type: HLL

Example:

[illegible]

```
openGauss=# SELECT hll_empty(10, 4, 8, -1);
           hll_empty
-----
\x484c4c0000000000120400000000000000000000000000000000000000
(1 row)
```

- `hll add(hll, hll hashval)`

Description: Adds **hll_hashval** to an HLL.

Return type: HLL

Example:

```
openGauss=# SELECT hll_add(hll_empty(), hll_hash_integer(1));
          hll_add
-----
\x484c4c08000002002b09000000000000f03f3e2921ff133fbaed3e2921ff133fbaed00
(1 row)
```

- `hll add rev(hll hashval, hll)`

Description: Adds **hll_hashval** to an HLL. This function works the same as **hll_add**, except that the positions of parameters are switched.

Return type: HLL

Example:

```
openGauss=# SELECT hll_add_rev(hll_hash_integer(1), hll_empty());
               hll_add_rev
-----
\x484c4c08000002002b09000000000000f03f3e2921ff133fbaed3e2921ff133fbaed00
(1 row)
```

- $\text{hll} \text{ eq}(\text{hll}, \text{hll})$

Description: Compares two HLLs to check whether they are the same.

Return type: Boolean

Example:

```
openGauss=# SELECT hll_eq(hll_add(hll_empty(), hll_hash_integer(1)), hll_add(hll_empty(),
hll_hash_integer(2)));
 hll_eq
-----
f
(1 row)
```

- **hll_ne(hll, hll)**

Description: Compares two HLLs to check whether they are different.

Return type: Boolean

Example:

```
openGauss=# SELECT hll_ne(hll_add(hll_empty(), hll_hash_integer(1)), hll_add(hll_empty(),
hll_hash_integer(2)));
 hll_ne
-----
t
(1 row)
```

- **hll_cardinality(hll)**

Description: Calculates the number of distinct values of an HLL.

Return type: int

Example:

```
openGauss=# SELECT hll_cardinality(hll_empty() || hll_hash_integer(1));
 hll_cardinality
-----
1
(1 row)
```

- **hll_union(hll, hll)**

Description: Performs an UNION operation on two HLL data structures to obtain one HLL.

Return type: HLL

Example:

```
openGauss=# SELECT hll_union(hll_add(hll_empty(), hll_hash_integer(1)), hll_add(hll_empty(),
hll_hash_integer(2)));
               hll_union
-----
\x484c4c10002000002b090000000000000004000000000000000b3ccc49320cca1ae3e2921ff133fba
ed00
(1 row)
```

Aggregate Functions

- **hll_add_agg(hll_hashval)**

Description: Groups hashed data into HLL

Return type: HLL

Example:

```
-- Prepare data.
openGauss=# CREATE TABLE t_id(id int);
openGauss=# INSERT INTO t_id VALUES(generate_series(1,500));
openGauss=# CREATE TABLE t_data(a int, c text);
openGauss=# INSERT INTO t_data SELECT mod(id,2), id FROM t_id;

-- Create a table and specify an HLL column.
openGauss=# CREATE TABLE t_a_c_hll(a int, c hll);
```

```
-- Use GROUP BY on column a to group data, and insert the data to the HLL.
openGauss=# INSERT INTO t_a_c_hll SELECT a, hll_add_agg(hll_hash_text(c)) FROM t_data GROUP
BY a;

-- Calculate the number of distinct values for each group in the HLL.
openGauss=# SELECT a, #c as cardinality FROM t_a_c_hll ORDER BY a;
 a | cardinality
---+-----
 0 | 247.862354346299
 1 | 250.908710610377
(2 rows)
```

- **hll_add_agg(hll_hashval, int32 log2m)**

Description: Groups hashed data into HLL and specifies the **log2m** parameter. The value ranges from 10 to 16. If the input is **-1** or **NULL**, the built-in default value is used.

Return type: HLL

Example:

```
openGauss=# SELECT hll_cardinality(hll_add_agg(hll_hash_text(c), 12)) FROM t_data;
 hll_cardinality
-----
497.965240179228
(1 row)
```

- **hll_add_agg(hll_hashval, int32 log2m, int32 log2explicit)**

Description: Groups hashed data into HLL and specifies the **log2m** and **log2explicit** parameters in sequence. The value of **log2explicit** ranges from 0 to 12. The value **0** indicates that the explicit mode is skipped. This parameter is used to set the threshold of the explicit mode. When the length of the data segment reaches $2^{\text{log2explicit}}$, the mode is switched to the sparse or full mode. If the input is **-1** or **NULL**, the built-in default value of **log2explicit** is used.

Return type: HLL

Example:

```
openGauss=# SELECT hll_cardinality(hll_add_agg(hll_hash_text(c), NULL, 1)) FROM t_data;
 hll_cardinality
-----
498.496062953313
(1 row)
```

- **hll_add_agg(hll_hashval, int32 log2m, int32 log2explicit, int64 log2sparse)**

Description: Groups hashed data into HLL and sets the parameters **log2m**, **log2explicit**, and **log2sparse** in sequence. The value of **log2sparse** ranges from 0 to 14. The value **0** indicates that the sparse mode is skipped. This parameter is used to set the threshold of the sparse mode. When the length of the data segment reaches $2^{\text{log2sparse}}$, the mode is switched to the full mode. If the input is **-1** or **NULL**, the built-in default value of **log2sparse** is used.

Return type: HLL

Example:

```
openGauss=# SELECT hll_cardinality(hll_add_agg(hll_hash_text(c), NULL, 6, 10)) FROM t_data;
 hll_cardinality
-----
498.496062953313
(1 row)
```

- **hll_add_agg(hll_hashval, int32 log2m, int32 log2explicit, int64 log2sparse, int32 duplicatecheck)**

Description: Groups hashed data into HLL and specifies the **log2m**, **log2explicit**, **log2sparse**, and **duplicatecheck** parameters. The value of

duplicatecheck can be **0** or **1**, indicating whether to enable this mode. By default, this mode is disabled. If the input is **-1** or **NULL**, the built-in default value of **duplicatecheck** is used.

Return type: HLL

Example:

```
openGauss=# SELECT hll_cardinality(hll_add_agg(hll_hash_text(c), NULL, 6, 10, -1)) FROM t_data;
hll_cardinality
-----
498.496062953313
(1 row)
```

- **hll_union_agg(hll)**

Description: Performs an UNION operation on multiple pieces of data of the HLL type to obtain one HLL.

Return type: HLL

Example:

```
-- Perform the UNION operation on data of the HLL type in each group to obtain one HLL, and
-- calculate the number of distinct values:
openGauss=# SELECT #hll_union_agg(c) as cardinality FROM t_a_c_hll;
cardinality
-----
498.496062953313
(1 row)

-- Drop tables.
openGauss=# DROP TABLE t_id;
openGauss=# DROP TABLE t_data;
openGauss=# DROP TABLE t_a_c_hll;
```

NOTE

To perform the UNION operation on data in multiple HLLs, ensure that the HLLs have the same precision. Otherwise, **UNION** cannot be performed. This constraint also applies to the **hll_union(hll, hll)** function.

Obsolete Functions

Some old HLL functions are deprecated due to version upgrade. You can replace them with similar functions.

- **hll_schema_version(hll)**

Description: Checks the schema version in the current HLL. In earlier versions, the schema version is fixed at **1**, which is used to verify the header of the HLL field. After refactoring, the HLL field is added to the header for verification. The schema version is no longer used.

- **hll_regwidth(hll)**

Description: Queries the bucket size in the HLL data structure. In earlier versions, the value of **regwidth** ranges from 1 to 5, which has a large error and limits the upper limit of the cardinality estimation. After refactoring, the value of **regwidth** is fixed at **6** and the **regwidth** variable is not used.

- **hll_expthresh(hll)**

Description: Obtains the **expthresh** value in the current HLL. The **hll_log2explicit(hll)** function is used to replace similar functions.

- **hll_sparseon(hll)**

Description: Specifies whether to enable the sparse mode. Use **hll_log2sparse(hll)** to replace similar functions. The value **0** indicates that the sparse mode is disabled.

Built-in Functions

HyperLogLog (HLL) has a series of built-in functions for internal data processing. Generally, users do not need to know how to use these functions. For details, see [Table 7-34](#).

Table 7-34 Built-in Functions

Function	Description
hll_in	Receives hll data in string format.
hll_out	Sends hll data in string format.
hll_recv	Receives hll data in bytea format.
hll_send	Sends hll data in bytea format.
hll_trans_in	Receives hll_trans_type data in string format.
hll_trans_out	Sends hll_trans_type data in string format.
hll_trans_recv	Receives hll_trans_type data in bytea format.
hll_trans_send	Sends hll_trans_type data in bytea format.
hll_tpmmod_in	Receives tpmmod data.
hll_tpmmod_out	Sends tpmmod data.
hll_hashval_in	Receives hll_hashval data.
hll_hashval_out	Sends hll_hashval data.
hll_add_trans0	It is similar to hll_add . No input parameter is specified during initialization. It is usually used in the first phase of DNs in aggregation operations.
hll_add_trans1	It is similar to hll_add . An input parameter is specified during initialization. It is usually used in the first phase of DNs in aggregation operations.
hll_add_trans2	It is similar to hll_add . Two input parameters are specified during initialization. It is usually used in the first phase of DNs in aggregation operations.
hll_add_trans3	It is similar to hll_add . Three input parameters are specified during initialization. It is usually used in the first phase of DNs in aggregation operations.
hll_add_trans4	It is similar to hll_add . Four input parameters are specified during initialization. It is usually used in the first phase of DNs in aggregation operations.

Function	Description
hll_union_trans	It is similar to hll_union and is used in the first phase of DNs in aggregation operations.
hll_union_collect	It is similar to hll_union and is used in the second phase of DNs in aggregation operations to summarize the results of each DN.
hll_pack	It is used in the third phase of DNs in aggregation operations to convert a user-defined type hll_trans_type to the hll type.
hll	Converts an HLL type to another HLL type. Input parameters can be specified.
hll_hashval	Converts the bigint type to the hll_hashval type.
hll_hashval_int4	Converts the int4 type to the hll_hashval type.

Operators

- **=**
Description: Compares the values of HLL and **hll_hashval** types to check whether they are the same.

Return type: Boolean

Example:

```
--hll
openGauss=# SELECT (hll_empty() || hll_hash_integer(1)) = (hll_empty() || hll_hash_integer(1));
column
-----
t
(1 row)

--hll_hashval
openGauss=# SELECT hll_hash_integer(1) = hll_hash_integer(1);
?column?
-----
t
(1 row)
```

- **<> or !=**
Description: Compares the values of HLL and **hll_hashval** types to check whether they are different.

Return type: Boolean

Example:

```
--hll
openGauss=# SELECT (hll_empty() || hll_hash_integer(1)) <> (hll_empty() || hll_hash_integer(2));
?column?
-----
t
(1 row)

--hll_hashval
openGauss=# SELECT hll_hash_integer(1) <> hll_hash_integer(2);
?column?
-----
```

- ```
t
(1 row)
```

• `||`

Description: Represents the functions of **hll\_add**, **hll\_union**, and **hll\_add\_rev**.  
Return type: HLL  
Example:

```
--hll_add
openGauss=# SELECT hll_empty() || hll_hash_integer(1);
 ?column?

\x484c4c08000002002b090000000000000f03f3e2921ff133fbaed3e2921ff133fbaed00
(1 row)

--hll_add_rev
openGauss=# SELECT hll_hash_integer(1) || hll_empty();
 ?column?

\x484c4c08000002002b090000000000000f03f3e2921ff133fbaed3e2921ff133fbaed00
(1 row)

--hll_union
openGauss=# SELECT (hll_empty() || hll_hash_integer(1)) || (hll_empty() || hll_hash_integer(2));
 ?column?

\x484c4c10002000002b090000000000000004000000000000000b3ccc49320cca1ae3e2921ff133fbaed00
(1 row)
```

• `#`

Description: Calculates the number of distinct values of an HLL. It works the same as the **hll\_cardinality** function.  
Return type: int  
Example:

```
openGauss=# SELECT #(hll_empty() || hll_hash_integer(1));
 ?column?

 1
(1 row)
```

## 7.5.14 SEQUENCE Functions

The sequence functions provide a simple method to ensure security of multiple users for users to obtain sequence values from sequence objects.

- `nextval(regclass)`

Description: Specifies an increasing sequence and returns a new value.

### NOTE

To avoid blocking of concurrent transactions that obtain numbers from the same sequence, a `nextval` operation is never rolled back; that is, once a value has been fetched it is considered used, even if the transaction that did the `nextval` later aborts. This means that aborted transactions may leave unused "holes" in the sequence of assigned values. Therefore, GaussDB sequences cannot be used to obtain sequence without gaps.

**NOTICE**

The nextval function can be executed only on the primary node. It is not supported on standby nodes.

Return type: numeric

The nextval function can be called in either of the following ways: (In example 2, the sequence name cannot contain a dot.)

```
openGauss=# CREATE SEQUENCE seqDemo;
-- Example 1:
openGauss=# SELECT nextval('seqDemo');
nextval

1
(1 row)
-- Example 2:
openGauss=# SELECT seqDemo.nextval;
nextval

2
(1 row)
openGauss=# DROP SEQUENCE seqDemo;
```

- **currval(regclass)**

Description: Returns the last value returned by nextval in the current session. If nextval has not been called for the specified sequence in the current session, an error is reported when currval is called.

Return type: numeric

The currval function can be called in either of the following ways: (In example 2, the sequence name cannot contain a dot.)

```
openGauss=# CREATE SEQUENCE seq1;
openGauss=# SELECT nextval('seq1');
-- Example 1:
openGauss=# SELECT currval('seq1');
currval

1
(1 row)
-- Example 2:
openGauss=# SELECT seq1.currval;
currval

1
(1 row)
openGauss=# DROP SEQUENCE seq1;
```

- **lastval()**

Description: Returns the last value returned by nextval in the current session. This function is equivalent to currval, except that it does not use sequence names as parameters. It fetches the sequence used by nextval last time in the current session. If nextval has not been called in the current session, an error is reported when lastval is called.

Return type: numeric

Example:

```
openGauss=# CREATE SEQUENCE seq1;
openGauss=# SELECT nextval('seq1');
openGauss=# SELECT lastval();
lastval

```

```
1
(1 row)
openGauss=# DROP SEQUENCE seq1;
```

- **setval(regclass, numeric)**

Description: Sets the current value of a sequence.

Return type: numeric

Example:

```
openGauss=# CREATE SEQUENCE seqDemo;
openGauss=# SELECT nextval('seqDemo');
openGauss=# SELECT setval('seqDemo',5);
setval
```

```
5
(1 row)
openGauss=# DROP SEQUENCE seqDemo;
```

- **setval(regclass, numeric, Boolean)**

Description: Sets the current value of a sequence and the is\_called sign.

Return type: numeric

Example:

```
openGauss=# CREATE SEQUENCE seqDemo;
openGauss=# SELECT nextval('seqDemo');
openGauss=# SELECT setval('seqDemo',5,true);
setval
```

```
5
(1 row)
openGauss=# DROP SEQUENCE seqDemo;
```

#### NOTE

The current session will take effect immediately after **setval** is performed. If other sessions have buffered sequence values, **setval** will take effect only after the values are used up. Therefore, to prevent sequence value conflicts, you are advised to use **setval** with caution.

Because the sequence is non-transactional, the change caused by **setval** will not be undone by transaction rollback.

#### NOTICE

The **nextval** function can be executed only on the primary node. It is not supported on standby nodes.

- **pg\_sequence\_last\_value(sequence\_oid oid, OUT cache\_value int16, OUT last\_value int16)**

Description: Obtains the parameters of a specified sequence, including the cache value and current value.

Return type: int16, int16

## 7.5.15 Array Functions and Operators

### Array Operators

- **=**

Description: Specifies whether two arrays are equal.

Example:

```
openGauss=# SELECT ARRAY[1.1,2.1,3.1]::int[] = ARRAY[1,2,3] AS RESULT ;
result

t
(1 row)
```

- <>

Description: Specifies whether two arrays are not equal.

Example:

```
openGauss=# SELECT ARRAY[1,2,3] <> ARRAY[1,2,4] AS RESULT;
result

t
(1 row)
```

- <

Description: Specifies whether an array is less than another.

Example:

```
openGauss=# SELECT ARRAY[1,2,3] < ARRAY[1,2,4] AS RESULT;
result

t
(1 row)
```

- >

Description: Specifies whether an array is greater than another.

Example:

```
openGauss=# SELECT ARRAY[1,4,3] > ARRAY[1,2,4] AS RESULT;
result

t
(1 row)
```

- <=

Description: Specifies whether an array is less than another.

Example:

```
openGauss=# SELECT ARRAY[1,2,3] <= ARRAY[1,2,3] AS RESULT;
result

t
(1 row)
```

- >=

Description: Specifies whether an array is greater than or equal to another.

Example:

```
openGauss=# SELECT ARRAY[1,4,3] >= ARRAY[1,4,3] AS RESULT;
result

t
(1 row)
```

- @>

Description: Specifies whether an array contains another.

Example:

```
openGauss=# SELECT ARRAY[1,4,3] @> ARRAY[3,1] AS RESULT;
result

t
(1 row)
```

- <@

Description: Specifies whether an array is contained in another.

Example:

```
openGauss=# SELECT ARRAY[2,7] <@ ARRAY[1,7,4,2,6] AS RESULT;
result

t
(1 row)
```

- &&

Description: Specifies whether an array overlaps another (have common elements).

Example:

```
openGauss=# SELECT ARRAY[1,4,3] && ARRAY[2,1] AS RESULT;
result

t
(1 row)
```

- ||

Description: Array-to-array concatenation

Example:

```
openGauss=# SELECT ARRAY[1,2,3] || ARRAY[4,5,6] AS RESULT;
result

{1,2,3,4,5,6}
(1 row)
openGauss=# SELECT ARRAY[1,2,3] || ARRAY[[4,5,6],[7,8,9]] AS RESULT;
result

{{1,2,3},{4,5,6},{7,8,9}}
(1 row)
```

- ||

Description: Element-to-array concatenation

Example:

```
openGauss=# SELECT 3 || ARRAY[4,5,6] AS RESULT;
result

{3,4,5,6}
(1 row)
```

- ||

Description: Array-to-element concatenation

Example:

```
openGauss=# SELECT ARRAY[4,5,6] || 7 AS RESULT;
result

{4,5,6,7}
(1 row)
```

Array comparisons compare the array contents element-by-element, using the default B-tree comparison function for the element data type. In multidimensional arrays, the elements are accessed in row-major order. If the contents of two arrays are equal but the dimensionality is different, the first difference in the dimensionality information determines the sort order.

## Array Functions

- `array_append(anyarray, anyelement)`

Description: Appends an element to the end of an array, and only supports one-dimensional arrays.

Return type: `anyarray`

Example:

```
openGauss=# SELECT array_append(ARRAY[1,2], 3) AS RESULT;
result

{1,2,3}
(1 row)
```

- `array_prepend(anyelement, anyarray)`

Description: Appends an element to the beginning of an array, and only supports one-dimensional arrays.

Return type: `anyarray`

Example:

```
openGauss=# SELECT array_prepend(1, ARRAY[2,3]) AS RESULT;
result

{1,2,3}
(1 row)
```

- `array_cat(anyarray, anyarray)`

Description: Concatenates two arrays, and supports multi-dimensional arrays.

Return type: `anyarray`

Example:

```
openGauss=# SELECT array_cat(ARRAY[1,2,3], ARRAY[4,5]) AS RESULT;
result

{1,2,3,4,5}
(1 row)

openGauss=# SELECT array_cat(ARRAY[[1,2],[4,5]], ARRAY[6,7]) AS RESULT;
result

{{1,2},{4,5},{6,7}}
(1 row)
```

- `array_union(anyarray, anyarray)`

Description: Concatenates two arrays, and supports only one-dimensional arrays.

Return type: `anyarray`

Example:

```
openGauss=# SELECT array_union(ARRAY[1,2,3], ARRAY[3,4,5]) AS RESULT;
result

{1,2,3,3,4,5}
(1 row)
```

- `array_union_distinct(anyarray, anyarray)`

Description: Concatenates two arrays and deduplicates them. Only one-dimensional arrays are supported.

Return type: `anyarray`

Example:

```
openGauss=# SELECT array_union_distinct(ARRAY[1,2,3], ARRAY[3,4,5]) AS RESULT;
result

{1,2,3,4,5}
(1 row)
```

- `array_intersect(anyarray, anyarray)`

Description: Intersects two arrays. Only one-dimensional arrays are supported.

Return type: anyarray

Example:

```
openGauss=# SELECT array_intersect(ARRAY[1,2,3], ARRAY[3,4,5]) AS RESULT;
result

{3}
(1 row)
```

- `array_intersect_distinct(anyarray, anyarray)`

Description: Intersects two arrays and deduplicates them. Only one-dimensional arrays are supported.

Return type: anyarray

Example:

```
openGauss=# SELECT array_intersect_distinct(ARRAY[1,2,2], ARRAY[2,2,4,5]) AS RESULT;
result

{2}
(1 row)
```

- `array_except(anyarray, anyarray)`

Description: Calculates the difference between two arrays. Only one-dimensional arrays are supported.

Return type: anyarray

Example:

```
openGauss=# SELECT array_except(ARRAY[1,2,3], ARRAY[3,4,5]) AS RESULT;
result

{1,2}
(1 row)
```

- `array_except_distinct(anyarray, anyarray)`

Description: Calculates the difference between two arrays and deduplicates them. Only one-dimensional arrays are supported.

Return type: anyarray

Example:

```
openGauss=# SELECT array_except_distinct(ARRAY[1,2,2,3], ARRAY[3,4,5]) AS RESULT;
result

{1,2}
(1 row)
```

- `array_ndims(anyarray)`

Description: Returns the number of dimensions of an array.

Return type: int

Example:

```
openGauss=# SELECT array_ndims(ARRAY[[1,2,3], [4,5,6]]) AS RESULT;
result

2
(1 row)
```

- `array_dims(anyarray)`

Description: Returns the low-order flag bits and high-order flag bits of each dimension in an array.

Return type: text

Example:

```
openGauss=# SELECT array_dims(ARRAY[[1,2,3], [4,5,6]]) AS RESULT;
result

[1:2][1:3]
(1 row)
```

- `array_length(anyarray, int)`

Description: Returns the length of the requested array dimension. **int** is the requested array dimension.

Return type: int

Example:

```
openGauss=# SELECT array_length(array[1,2,3], 1) AS RESULT;
result

3
(1 row)

openGauss=# SELECT array_length(array[[1,2,3],[4,5,6]], 2) AS RESULT;
result

3
(1 row)
```

- `array_lower(anyarray, int)`

Description: Returns lower bound of the requested array dimension. **int** is the requested array dimension.

Return type: int

Example:

```
openGauss=# SELECT array_lower('[0:2]={1,2,3}::int[]', 1) AS RESULT;
result

0
(1 row)
```

- `array_upper(anyarray, int)`

Description: Returns upper bound of the requested array dimension. **int** is the requested array dimension.

Return type: int

Example:

```
openGauss=# SELECT array_upper(ARRAY[1,8,3,7], 1) AS RESULT;
result

4
(1 row)
```

- `array_upper(anyarray, int)`

Description: Returns upper bound of the requested array dimension. **int** is the requested array dimension.

Return type: int

Example:

```
openGauss=# SELECT array_upper(ARRAY[1,8,3,7], 1) AS RESULT;
result
```

```

4
(1 row)
```

- `array_remove(anyarray, anyelement)`

Description: Removes all specified elements from an array. Only one-dimensional arrays are supported.

Return type: anyarray

Example:

```
openGauss=# SELECT array_remove(ARRAY[1,8,8,7], 8) AS RESULT;
result

{1,7}
(1 row)
```

- `array_to_string(anyarray, text [, text])`

Description: Uses the first **text** as the new delimiter and the second **text** to replace **NULL** values.

Return type: text

Example:

```
openGauss=# SELECT array_to_string(ARRAY[1, 2, 3, NULL, 5], ',', '**') AS RESULT;
result

1,2,3,*,5
(1 row)
```

- `array_delete(anyarray)`

Description: Clears elements in an array and returns an empty array of the same type.

Return type: anyarray

Example:

```
openGauss=# SELECT array_delete(ARRAY[1,8,3,7]) AS RESULT;
result

{}
(1 row)
```

- `array_deleteidx(anyarray, int)`

Description: Deletes specified index elements from an array and returns an array consisting of the remaining elements.

Return type: anyarray

Example:

```
openGauss=# SELECT array_deleteidx(ARRAY[1,2,3,4,5], 1) AS RESULT;
result

{2,3,4,5}
(1 row)
```

- `array_extendnull(anyarray, int)`

Description: Adds a specified number of null elements to the end of an array.

Return type: anyarray

Example:

```
openGauss=# SELECT array_extendnull(ARRAY[1,8,3,7],1) AS RESULT;
result

{1,8,3,7,null}
(1 row)
```

- `array_trim(anyarray, int)`

Description: Deletes a specified number of elements from the end of an array.

Return type: `anyarray`

Example:

```
openGauss=# SELECT array_trim(ARRAY[1,8,3,7],1) AS RESULT;
result

{1,8,3}
(1 row)
```

- `array_exists(anyarray, int)`

Description: Checks whether the second parameter is a valid index of an array.

Return type: `Boolean`

Example:

```
openGauss=# SELECT array_exists(ARRAY[1,8,3,7],1) AS RESULT;
result

t
(1 row)
```

- `array_next(anyarray, int)`

Description: Returns the index of the element following a specified index in an array based on the second input parameter.

Return type: `int`

Example:

```
openGauss=# SELECT array_next(ARRAY[1,8,3,7],1) AS RESULT;
result

2
(1 row)
```

- `array_prior(anyarray, int)`

Description: Returns the index of the element followed by a specified index in an array based on the second input parameter.

Return type: `int`

Example:

```
openGauss=# SELECT array_prior(ARRAY[1,8,3,7],2) AS RESULT;
result

1
(1 row)
```

- `string_to_array(text, text [, text])`

Description: Uses the second **text** as the new delimiter and the third **text** as the substring to be replaced by **NULL** values. A substring can be replaced by **NULL** values only when it is the same as the third **text**.

Return type: `text[]`

Example:

```
openGauss=# SELECT string_to_array('xx~^~yy~^~zz', '~^~', 'yy') AS RESULT;
result

{xx,NULL,zz}
(1 row)
openGauss=# SELECT string_to_array('xx~^~yy~^~zz', '~^~', 'y') AS RESULT;
result

```

```
{xx,yy,zz}
(1 row)
```

- **unnest(anyarray)**

Description: Expands an array to a set of rows.

Return type: setof anyelement

Example:

```
openGauss=# SELECT unnest(ARRAY[1,2]) AS RESULT;
result

1
2
(2 rows)
```

In **string\_to\_array**, if the delimiter parameter is NULL, each character in the input string will become a separate element in the resulting array. If the delimiter is an empty string, then the entire input string is returned as a one-element array. Otherwise the input string is split at each occurrence of the delimiter string.

In **string\_to\_array**, if the null-string parameter is omitted or NULL, none of the substrings of the input will be replaced by NULL.

In **array\_to\_string**, if the null-string parameter is omitted or NULL, any null elements in the array are simply skipped and not represented in the output string.

- **\_pg\_keysequal**

Description: Checks whether two smallint arrays are the same.

Parameter: smallint[], smallint[]

Return type: Boolean

#### NOTE

This function exists in the information\_schema namespace.

## 7.5.16 Range Functions and Operators

### Range Operators

- **=**

Description: Equals

Example:

```
openGauss=# SELECT int4range(1,5) = '[1,4]::int4range AS RESULT;
result

t
(1 row)
```

- **<>**

Description: Does not equal to

Example:

```
openGauss=# SELECT numrange(1.1,2.2) <> numrange(1.1,2.3) AS RESULT;
result

t
(1 row)
```

- **<**

Description: Is less than

Example:

```
openGauss=# SELECT int4range(1,10) < int4range(2,3) AS RESULT;
result

t
(1 row)
```

- >

Description: Is greater than

Example:

```
openGauss=# SELECT int4range(1,10) > int4range(1,5) AS RESULT;
result

t
(1 row)
```

- <=

Description: Is less than or equals

Example:

```
openGauss=# SELECT numrange(1.1,2.2) <= numrange(1.1,2.2) AS RESULT;
result

t
(1 row)
```

- >=

Description: Is greater than or equals

Example:

```
openGauss=# SELECT numrange(1.1,2.2) >= numrange(1.1,2.0) AS RESULT;
result

t
(1 row)
```

- @>

Description: Contains ranges

Example:

```
openGauss=# SELECT int4range(2,4) @> int4range(2,3) AS RESULT;
result

t
(1 row)
```

- @>

Description: Contains elements

Example:

```
openGauss=# SELECT '[2011-01-01,2011-03-01]::tsrange @> '2011-01-10'::timestamp AS RESULT;
result

t
(1 row)
```

- <@

Description: Range is contained by

Example:

```
openGauss=# SELECT int4range(2,4) <@ int4range(1,7) AS RESULT;
result

t
(1 row)
```

- <@

Description: Element is contained by

Example:

```
openGauss=# SELECT 42 <@ int4range(1,7) AS RESULT;
result

f
(1 row)
```
- &&

Description: Overlap (have points in common)

Example:

```
openGauss=# SELECT int8range(3,7) && int8range(4,12) AS RESULT;
result

t
(1 row)
```
- <<

Description: Strictly left of

Example:

```
openGauss=# SELECT int8range(1,10) << int8range(100,110) AS RESULT;
result

t
(1 row)
```
- >>

Description: Strictly right of

Example:

```
openGauss=# SELECT int8range(50,60) >> int8range(20,30) AS RESULT;
result

t
(1 row)
```
- &<

Description: Does not extend to the right of

Example:

```
openGauss=# SELECT int8range(1,20) &< int8range(18,20) AS RESULT;
result

t
(1 row)
```
- &>

Description: Does not extend to the left of

Example:

```
openGauss=# SELECT int8range(7,20) &> int8range(5,10) AS RESULT;
result

t
(1 row)
```
- -|-

Description: Is adjacent to

Example:

```
openGauss=# SELECT numrange(1.1,2.2) -|- numrange(2.2,3.3) AS RESULT;
result
```

- t  
(1 row)
- +  
Description: Union  
Example:  
openGauss=# SELECT numrange(5,15) + numrange(10,20) AS RESULT;  
result  
-----  
[5,20)  
(1 row)
- \*  
Description: Intersection  
Example:  
openGauss=# SELECT int8range(5,15) \* int8range(10,20) AS RESULT;  
result  
-----  
[10,15)  
(1 row)
- -  
Description: Difference  
Example:  
openGauss=# SELECT int8range(5,15) - int8range(10,20) AS RESULT;  
result  
-----  
[5,10)  
(1 row)

The simple comparison operators `<`, `>`, `<=`, and `>=` compare the lower bounds first, and only if those are equal, compare the upper bounds.

The `<<`, `>>`, and `-|-` operators always return false when an empty range is involved; that is, an empty range is not considered to be either before or after any other range.

The union and difference operators will fail if the resulting range would need to contain two disjoint sub-ranges.

## Range Functions

The lower and upper functions return null if the range is empty or the requested bound is infinite. The `lower_inc`, `upper_inc`, `lower_inf`, and `upper_inf` functions all return false for an empty range.

- `numrange(numeric, numeric, [text])`  
Description: Specifies a range.  
Return type: Range's element type  
Example:  
openGauss=# SELECT numrange(1.1,2.2) AS RESULT;  
result  
-----  
[1.1,2.2)  
(1 row)  
openGauss=# SELECT numrange(1.1,2.2, '()') AS RESULT;  
result  
-----

(1.1,2.2)  
(1 row)

- **lower(anyrange)**

Description: Lower bound of a range

Return type: Range's element type

Example:

```
openGauss=# SELECT lower(numrange(1.1,2.2)) AS RESULT;
result

1.1
(1 row)
```

- **upper(anyrange)**

Description: Upper bound of a range

Return type: Range's element type

Example:

```
openGauss=# SELECT upper(numrange(1.1,2.2)) AS RESULT;
result

2.2
(1 row)
```

- **isempty(anyrange)**

Description: Is the range empty?

Return type: Boolean

Example:

```
openGauss=# SELECT isempty(numrange(1.1,2.2)) AS RESULT;
result

f
(1 row)
```

- **lower\_inc(anyrange)**

Description: Is the lower bound inclusive?

Return type: Boolean

Example:

```
openGauss=# SELECT lower_inc(numrange(1.1,2.2)) AS RESULT;
result

t
(1 row)
```

- **upper\_inc(anyrange)**

Description: Is the upper bound inclusive?

Return type: Boolean

Example:

```
openGauss=# SELECT upper_inc(numrange(1.1,2.2)) AS RESULT;
result

f
(1 row)
```

- **lower\_inf(anyrange)**

Description: Is the lower bound infinite?

Return type: Boolean

Example:

```
openGauss=# SELECT lower_inf('(',')::daterange) AS RESULT;
result

t
(1 row)
```

- `upper_inf(anyrange)`

Description: Is the upper bound infinite?

Return type: Boolean

Example:

```
openGauss=# SELECT upper_inf('(',')::daterange) AS RESULT;
result

t
(1 row)
```

- `elem_contained_by_range(anyelement, anyrange)`

Description: Determines whether an element is within the range.

Return type: Boolean

Example:

```
openGauss=# SELECT elem_contained_by_range('2', numrange(1.1,2.2));
elem_contained_by_range

t
(1 row)
```

## 7.5.17 Aggregate Functions

### Aggregate Functions

- `sum(expression)`

Description: Specifies the sum of expressions across all input values.

Return type:

Generally, same as the argument data type. In the following cases, type conversion occurs:

- **BIGINT** for **SMALLINT** or **INT** arguments
- **NUMBER** for **BIGINT** arguments
- **DOUBLE PRECISION** for floating-point arguments

Example:

```
openGauss=# CREATE TABLE tab(a int);
CREATE TABLE
openGauss=# INSERT INTO tab values(1);
INSERT 0 1
openGauss=# INSERT INTO tab values(2);
INSERT 0 1
openGauss=# SELECT sum(a) FROM tab;
sum

3
(1 row)
```

- `max(expression)`

Description: Specifies the maximum value of expression across all input values.

Parameter type: any array, numeric, string, or date/time type

Return type: same as the argument type

Example:

```
openGauss=# CREATE TABLE max_t1(a int, b int);

openGauss=# INSERT INTO max_t1 VALUES(1,2),(2,3),(3,4),(4,5);

openGauss=# SELECT MAX(a) FROM max_t1;
max

4
(1 row)

openGauss=# DROP TABLE max_t1;
```

- **min(expression)**

Description: Specifies the minimum value of expression across all input values.

Parameter type: any array, numeric, string, or date/time type

Return type: same as the argument type

Example:

```
openGauss=# CREATE TABLE min_t1(a int, b int);

openGauss=# INSERT INTO min_t1 VALUES(1,2),(2,3),(3,4),(4,5);

openGauss=# SELECT MIN(a) FROM min_t1;
min

1
(1 row)

openGauss=# DROP TABLE min_t1;
```

- **avg(expression)**

Description: Specifies the average (arithmetic mean) of all input values.

Return type:

**NUMBER** for any integer-type argument.

**DOUBLE PRECISION** for floating-point arguments.

Otherwise, it is the same as the input data type.

Example:

```
openGauss=# CREATE TABLE avg_t1(a int, b int);

openGauss=# INSERT INTO avg_t1 VALUES(1,2),(2,3),(3,4),(4,5);

openGauss=# SELECT AVG(a) FROM avg_t1;
avg

2.5000000000000000
(1 row)

openGauss=# DROP TABLE avg_t1;
```

- **count(expression)**

Description: Specifies the number of input rows for which the value of the expression is not null.

Return type: bigint

Example:

```
openGauss=# CREATE TABLE count_t1(a int, b int);

openGauss=# INSERT INTO count_t1 VALUES (NULL,1),(1,2),(2,3),(3,4),(4,5);
```

```
openGauss=# SELECT COUNT(a) FROM count_t1;
count

 4
(1 row)

openGauss=# DROP TABLE count_t1;
```

- **count(\*)**

Description: Returns the number of input rows.

Return type: bigint

Example:

```
openGauss=# CREATE TABLE count_t1(a int, b int);

openGauss=# INSERT INTO count_t1 VALUES (NULL,1),(1,2),(2,3),(3,4),(4,5);

openGauss=# SELECT COUNT(*) FROM count_t1;
count

 5
(1 row)

openGauss=# DROP TABLE count_t1;
```

- **median(expression) [over (query partition clause)]**

Description: Returns the median of an expression. **NULL** will be ignored by the median function during calculation. The **DISTINCT** keyword can be used to exclude duplicate records in an expression. The data type of the input expression can be numeric (including integer, double, and bigint) or interval. For other data types, the median cannot be calculated.

Return type: double or interval

Example:

```
SELECT median(id) FROM (values(1), (2), (3), (4), (null)) test(id);
median

 2.5
(1 row)
```

- **array\_agg(expression)**

Description: Concatenates input values, including nulls, into an array.

Return type: array of the argument type

Example:

```
openGauss=# CREATE TABLE array_agg_t1(a int, b int);

openGauss=# INSERT INTO array_agg_t1 VALUES (NULL,1),(1,2),(2,3),(3,4),(4,5);

openGauss=# SELECT ARRAY_AGG(a) FROM array_agg_t1;
array_agg

{NULL,1,2,3,4}
(1 row)

openGauss=# DROP TABLE array_agg_t1;
```

- **string\_agg(expression, delimiter)**

Description: Concatenates input values into a string, separated by delimiter.

Return type: same as the argument type

Example:

```
openGauss=# CREATE TABLE string_agg_t1(a int, b int);

openGauss=# INSERT INTO string_agg_t1 VALUES (NULL,1),(1,2),(2,3),(3,4),(4,5);

openGauss=# SELECT STRING_AGG(a,',') FROM string_agg_t1;
 string_agg

1;2;3;4
(1 row)

openGauss=# DROP TABLE string_agg_t1;
```

- **listagg(expression [, delimiter]) WITHIN GROUP(ORDER BY order-list)**

Description: Sorts aggregation column data according to the mode specified by **WITHIN GROUP** and concatenates the data to a string using the specified delimiter.

- **expression**: Required. It specifies an aggregation column name or a column-based valid expression. It does not support the **DISTINCT** keyword and the **VARIADIC** parameter.
- **delimiter**: Optional. It specifies a delimiter, which can be a string constant or a deterministic expression based on a group of columns. The default value is empty.
- **order-list**: Required. It specifies the sorting mode in a group.

Return type: text

Example:

The aggregation column is of the text character set type.

```
openGauss=# CREATE TABLE listagg_t1(a int, b text);

openGauss=# INSERT INTO listagg_t1 VALUES (NULL,'a1'),(1,'b2'),(1,'c3'),(2,'d4'),(2,'e5'),(3,'f6');

openGauss=# SELECT a,LISTAGG(b,',') WITHIN GROUP(ORDER BY b) FROM listagg_t1 group by a;
 a | listagg
---+-----
 1 | b2;c3
 2 | d4;e5
 3 | f6
 | a1
(4 rows)

openGauss=# DROP TABLE listagg_t1;
```

The aggregation column is of the integer type.

```
openGauss=# CREATE TABLE listagg_t1(a int, b int);

openGauss=# INSERT INTO listagg_t1 VALUES (NULL,1),(1,2),(1,3),(2,4),(2,5),(3,6);

openGauss=# SELECT a,LISTAGG(b,',') WITHIN GROUP(ORDER BY b) FROM listagg_t1 group by a;
 a | listagg
---+-----
 1 | 2;3
 2 | 4;5
 3 | 6
 | 1
(4 rows)

openGauss=# DROP TABLE listagg_t1;
```

The aggregation column is of the floating point type.

```
openGauss=# CREATE TABLE listagg_t1(a int, b float);

openGauss=# INSERT INTO listagg_t1 VALUES (NULL,1.111),(1,2.222),(1,3.333),(2,4.444),(2,5.555),
(3,6.666);
```

```
openGauss=# SELECT a,LISTAGG(b,',') WITHIN GROUP(ORDER BY b) FROM listagg_t1 group by a;
a | listagg
-----+-----
1 | 2.222000;3.333000
2 | 4.444000;5.555000
3 | 6.666000
 | 1.111000
(4 rows)
```

```
openGauss=# DROP TABLE listagg_t1;
```

The aggregation column is of the time type.

```
openGauss=# CREATE TABLE listagg_t1(a int, b timestamp);
```

```
openGauss=# INSERT INTO listagg_t1 VALUES (NULL,'2000-01-01'),(1,'2000-02-02'),(1,'2000-03-03'),
(2,'2000-04-04'),(2,'2000-05-05'),(3,'2000-06-06');
```

```
openGauss=# SELECT a,LISTAGG(b,',') WITHIN GROUP(ORDER BY b) FROM listagg_t1 group by a;
a | listagg
-----+-----
1 | 2000-02-02 00:00:00;2000-03-03 00:00:00
2 | 2000-04-04 00:00:00;2000-05-05 00:00:00
3 | 2000-06-06 00:00:00
 | 2000-01-01 00:00:00
(4 rows)
```

```
openGauss=# DROP TABLE listagg_t1;
```

The aggregation column is of the time interval type.

```
openGauss=# CREATE TABLE listagg_t1(a int, b interval);
```

```
openGauss=# INSERT INTO listagg_t1 VALUES (NULL,'1 days'),(1,'2 days'),(1,'3 days'),(2,'4 days'),(2,'5
days'),(3,'6 days');
```

```
openGauss=# SELECT a,LISTAGG(b,',') WITHIN GROUP(ORDER BY b) FROM listagg_t1 group by a;
a | listagg
-----+-----
1 | 2 days;3 days
2 | 4 days;5 days
3 | 6 days
 | 1 day
(4 rows)
```

```
openGauss=# DROP TABLE listagg_t1;
```

By default, the delimiter is empty.

```
openGauss=# CREATE TABLE listagg_t1(a int, b interval);
```

```
openGauss=# INSERT INTO listagg_t1 VALUES (NULL,'1 days'),(1,'2 days'),(1,'3 days'),(2,'4 days'),(2,'5
days'),(3,'6 days');
```

```
openGauss=# SELECT a,LISTAGG(b) WITHIN GROUP(ORDER BY b) FROM listagg_t1 group by a;
a | listagg
-----+-----
1 | 2 days3 days
2 | 4 days5 days
3 | 6 days
 | 1 day
(4 rows)
```

```
openGauss=# DROP TABLE listagg_t1;
```

When **listagg** is used as a window function, the **OVER** clause does not support the window sorting of **ORDER BY**, and the **listagg** column is an ordered aggregation of the corresponding groups.

```
openGauss=# CREATE TABLE listagg_t1(a int, b interval);
```

```
openGauss=# INSERT INTO listagg_t1 VALUES (NULL,'1 days'),(1,'2 days'),(1,'3 days'),(2,'4 days'),(2,'5
days'),(3,'6 days');
```

```
openGauss=# SELECT a,LISTAGG(b) WITHIN GROUP(ORDER BY b) OVER(PARTITION BY a) FROM
listagg_t1;
a | listagg
-----+-----
1 | 2 days3 days
1 | 2 days3 days
2 | 4 days5 days
2 | 4 days5 days
3 | 6 days
 | 1 day
(6 rows)

openGauss=# DROP TABLE listagg_t1;
```

- covar\_pop(Y, X)

Description: Specifies the overall covariance.

Return type: double precision

Example:

```
openGauss=# CREATE TABLE covar_pop_t1(a int, b int);

openGauss=# INSERT INTO covar_pop_t1 VALUES (NULL,11),(11,21),(11,31),(21,41),(21,51),(31,61);

openGauss=# SELECT COVAR_POP(a,b) FROM covar_pop_t1;
covar_pop

 100
(1 row)

openGauss=# DROP TABLE covar_pop_t1;
```

- covar\_samp(Y, X)

Description: Specifies the sample covariance.

Return type: double precision

Example:

```
openGauss=# CREATE TABLE covar_samp_t1(a int, b int);

openGauss=# INSERT INTO covar_samp_t1 VALUES (NULL,11),(11,21),(11,31),(21,41),(21,51),(31,61);

openGauss=# SELECT COVAR_SAMP(a,b) FROM covar_samp_t1;
covar_samp

 125
(1 row)

openGauss=# DROP TABLE covar_samp_t1;
```

- stddev\_pop(expression)

Description: Specifies the overall standard deviation.

Return type: **double precision** for floating-point arguments, otherwise **numeric**

Example:

```
openGauss=# CREATE TABLE stddev_pop_t1(a int, b int);

openGauss=# INSERT INTO stddev_pop_t1 VALUES (NULL,11),(11,21),(11,31),(21,41),(21,51),(31,61);

openGauss=# SELECT STDDEV_POP(a) FROM stddev_pop_t1;
stddev_pop

7.4833147735478828
(1 row)

openGauss=# DROP TABLE stddev_pop_t1;
```

- **stddev\_samp(expression)**

Description: Specifies the sample standard deviation of the input values.

Return type: **double precision** for floating-point arguments, otherwise **numeric**

Example:

```
openGauss=# CREATE TABLE stddev_samp_t1(a int, b int);

openGauss=# INSERT INTO stddev_samp_t1 VALUES (NULL,11),(11,21),(11,31),(21,41),(21,51),(31,61);

openGauss=# SELECT STDDEV_SAMP(a) FROM stddev_samp_t1;
 stddev_samp

8.3666002653407555
(1 row)

openGauss=# DROP TABLE stddev_samp_t1;
```

- **var\_pop(expression)**

Description: Specifies the population variance of the input values (square of the population standard deviation).

Return type: **double precision** for floating-point arguments, otherwise **numeric**

Example:

```
openGauss=# CREATE TABLE var_pop_t1(a int, b int);

openGauss=# INSERT INTO var_pop_t1 VALUES (NULL,11),(11,21),(11,31),(21,41),(21,51),(31,61);

openGauss=# SELECT VAR_POP(a) FROM var_pop_t1;
 var_pop

56.0000000000000000
(1 row)

openGauss=# DROP TABLE var_pop_t1;
```

- **var\_samp(expression)**

Description: Specifies the sample variance of the input values (square of the sample standard deviation).

Return type: **double precision** for floating-point arguments, otherwise **numeric**

Example:

```
openGauss=# CREATE TABLE var_samp_t1(a int, b int);

openGauss=# INSERT INTO var_samp_t1 VALUES (NULL,11),(11,21),(11,31),(21,41),(21,51),(31,61);

openGauss=# SELECT VAR_SAMP(a) FROM var_samp_t1;
 var_samp

70.0000000000000000
(1 row)

openGauss=# DROP TABLE var_samp_t1;
```

- **bit\_and(expression)**

Description: bitwise AND of all non-null input values, or null if none

Return type: same as the argument type

Example:

```
openGauss=# CREATE TABLE bit_and_t1(a int, b int);
```

```
openGauss=# INSERT INTO bit_and_t1 VALUES (NULL,11),(1,2),(1,3),(2,4),(2,5),(3,6);

openGauss=# SELECT BIT_AND(a) FROM bit_and_t1;
 bit_and

 0
(1 row)

openGauss=# DROP TABLE bit_and_t1;
```

- **bit\_or(expression)**

Description: bitwise OR of all non-null input values, or null if none

Return type: same as the argument type

Example:

```
openGauss=# CREATE TABLE bit_or_t1(a int, b int);

openGauss=# INSERT INTO bit_or_t1 VALUES (NULL,11),(1,2),(1,3),(2,4),(2,5),(3,6);

openGauss=# SELECT BIT_OR(a) FROM bit_or_t1;
 bit_or

 3
(1 row)

openGauss=# DROP TABLE bit_or_t1;
```

- **bool\_and(expression)**

Description: Its value is **true** if all input values are **true**, otherwise **false**.

Return type: Boolean

Example:

```
openGauss=# SELECT bool_and(100 < 2500);
 bool_and

 t
(1 row)
```

- **bool\_or(expression)**

Description: Its value is **true** if at least one input value is **true**, otherwise **false**.

Return type: Boolean

Example:

```
openGauss=# SELECT bool_or(100 < 2500);
 bool_or

 t
(1 row)
```

- **corr(Y, X)**

Description: Specifies the correlation coefficient.

Return type: double precision

Example:

```
openGauss=# CREATE TABLE corr_t1(a int, b int);

openGauss=# INSERT INTO corr_t1 VALUES (NULL,11),(1,2),(1,3),(2,4),(2,5),(3,6);

openGauss=# SELECT CORR(a,b) FROM corr_t1;
 corr

.944911182523068
(1 row)
```

```
openGauss=# DROP TABLE corr_t1;
```

- **every(expression)**

Description: Equivalent to **bool\_and**

Return type: Boolean

Example:

```
openGauss=# SELECT every(100 <2500);
every

t
(1 row)
```

- **regr\_avgx(Y, X)**

Description: Specifies the average of the independent variable (**sum(X)/Y**).

Return type: double precision

Example:

```
openGauss=# CREATE TABLE regr_t1(a int, b int);

openGauss=# INSERT INTO regr_t1 VALUES (NULL,11),(1,2),(1,3),(2,4),(2,5),(3,6);

openGauss=# SELECT REGR_AVGX(a,b) FROM regr_t1;
regr_avgx

4
(1 row)

openGauss=# DROP TABLE regr_t1;
```

- **regr\_avgy(Y, X)**

Description: Specifies the average of the dependent variable (**sum(Y)/X**).

Return type: double precision

Example:

```
openGauss=# CREATE TABLE regr_avgy_t1(a int, b int);

openGauss=# INSERT INTO regr_avgy_t1 VALUES (NULL,11),(1,2),(1,3),(2,4),(2,5),(3,6);

openGauss=# SELECT REGR_AVGY(a,b) FROM regr_avgy_t1;
regr_avgy

1.8
(1 row)

openGauss=# DROP TABLE regr_avgy_t1;
```

- **regr\_count(Y, X)**

Description: Specifies the number of input rows in which both expressions are non-null.

Return type: bigint

Example:

```
openGauss=# CREATE TABLE regr_count_t1(a int, b int);

openGauss=# INSERT INTO regr_count_t1 VALUES (NULL,11),(1,2),(1,3),(2,4),(2,5),(3,6);

openGauss=# SELECT REGR_COUNT(a,b) FROM regr_count_t1;
regr_count

5
(1 row)

openGauss=# DROP TABLE regr_count_t1;
```

- **regr\_intercept(Y, X)**

Description: Specifies the y-intercept of the least-squares-fit linear equation determined by the (X, Y) pairs.

Return type: double precision

Example:

```
openGauss=# CREATE TABLE regr_intercept_t1(a int, b int);

openGauss=# INSERT INTO regr_intercept_t1 VALUES (NULL,11),(1,2),(1,3),(2,4),(2,5),(3,6);

openGauss=# SELECT REGR_INTERCEPT(b,a) FROM regr_intercept_t1;
regr_intercept

.785714285714286
(1 row)

openGauss=# DROP TABLE regr_intercept_t1;
```

- **regr\_r2(Y, X)**

Description: Specifies the square of the correlation coefficient.

Return type: double precision

Example:

```
openGauss=# CREATE TABLE regr_r2_t1(a int, b int);

openGauss=# INSERT INTO regr_r2_t1 VALUES (NULL,11),(1,2),(1,3),(2,4),(2,5),(3,6);

openGauss=# SELECT REGR_R2(b,a) FROM regr_r2_t1;
regr_r2

.892857142857143
(1 row)

openGauss=# DROP TABLE regr_r2_t1;
```

- **regr\_slope(Y, X)**

Description: Specifies the slope of the least-squares-fit linear equation determined by the (X, Y) pairs.

Return type: double precision

Example:

```
openGauss=# CREATE TABLE regr_slope_t1(a int, b int);

openGauss=# INSERT INTO regr_slope_t1 VALUES (NULL,11),(1,2),(1,3),(2,4),(2,5),(3,6);

openGauss=# SELECT REGR_SLOPE(b,a) FROM regr_slope_t1;
regr_slope

1.78571428571429
(1 row)

openGauss=# DROP TABLE regr_slope_t1;
```

- **regr\_sxx(Y, X)**

Description:  $\text{sum}(Y^2) - \text{sum}(X)^2/N$  (sum of squares of the independent variables)

Return type: double precision

Example:

```
openGauss=# CREATE TABLE regr_sxx_t1(a int, b int);

openGauss=# INSERT INTO regr_sxx_t1 VALUES (NULL,11),(1,2),(1,3),(2,4),(2,5),(3,6);
```

```
openGauss=# SELECT REGR_SXX(b,a) FROM regr_sxx_t1;
regr_sxx

 2.8
(1 row)
```

```
openGauss=# DROP TABLE regr_sxx_t1;
```

- **regr\_sxy(Y, X)**

Description:  **$\text{sum}(X*Y) - \text{sum}(X) * \text{sum}(Y)/N$**  ("sum of products" of independent times dependent variable)

Return type: double precision

Example:

```
openGauss=# CREATE TABLE regr_sxy_t1(a int, b int);

openGauss=# INSERT INTO regr_sxy_t1 VALUES (NULL,11),(1,2),(1,3),(2,4),(2,5),(3,6);

openGauss=# SELECT REGR_SXY(b,a) FROM regr_sxy_t1;
regr_sxy

 5
(1 row)

openGauss=# DROP TABLE regr_sxy_t1;
```

- **regr\_syy(Y, X)**

Description:  **$\text{sum}(Y^2) - \text{sum}(X)^2/N$**  ("sum of squares" of the dependent variable)

Return type: double precision

Example:

```
openGauss=# CREATE TABLE regr_syy_t1(a int, b int);

openGauss=# INSERT INTO regr_syy_t1 VALUES (NULL,11),(1,2),(1,3),(2,4),(2,5),(3,6);

openGauss=# SELECT REGR_SYY(b,a) FROM regr_syy_t1;
regr_syy

 10
(1 row)

openGauss=# DROP TABLE regr_syy_t1;
```

- **stddev(expression)**

Description: Specifies the alias of **stddev\_samp**.

Return type: **double precision** for floating-point arguments, otherwise **numeric**

Example:

```
openGauss=# CREATE TABLE stddev_t1(a int, b int);

openGauss=# INSERT INTO stddev_t1 VALUES (NULL,11),(1,2),(1,3),(2,4),(2,5),(3,6);

openGauss=# SELECT STDDEV(a) FROM stddev_t1;
stddev

.83666002653407554798
(1 row)

openGauss=# DROP TABLE stddev_t1;
```

- **variance(expexpression,ression)**

Description: Specifies the alias of **var\_samp**.

Return type: **double precision** for floating-point arguments, otherwise **numeric**

Example:

```
openGauss=# CREATE TABLE variance_t1(a int, b int);

openGauss=# INSERT INTO variance_t1 VALUES (NULL,11),(1,2),(1,3),(2,4),(2,5),(3,6);

openGauss=# SELECT VARIANCE(a) FROM variance_t1;
 variance

.700000000000000000000000
(1 row)

openGauss=# DROP TABLE variance_t1;
```

- **delta**

Description: Returns the difference between the current row and the previous row.

Parameter: numeric

Return type: numeric

- **checksum(expression)**

Description: Returns the **CHECKSUM** value of all input values. This function can be used to check whether the data in the tables is the same before and after the backup, restoration, or migration of the GaussDB database (databases other than GaussDB are not supported). Before and after database backup, database restoration, or data migration, you need to manually run SQL commands to obtain the execution results. Compare the obtained execution results to check whether the data in the tables before and after the backup or migration is the same.

 **NOTE**

- For large tables, the execution of the **CHECKSUM** function may take a long time.
- If the **CHECKSUM** values of two tables are different, it indicates that the contents of the two tables are different. Using the hash function in the **CHECKSUM** function may incur conflicts. There is low possibility that two tables with different contents may have the same **CHECKSUM** value. The same problem may occur when **CHECKSUM** is used for columns.
- If the time type is timestamp, timestamptz, or smalldatetime, ensure that the time zone settings are the same when calculating the **CHECKSUM** value.
- If the **CHECKSUM** value of a column is calculated and the column type can be changed to TEXT by default, set *expression* to the column name.
- If the **CHECKSUM** value of a column is calculated and the column type cannot be converted to TEXT by default, set *expression* to *Column name::TEXT*.
- If the **CHECKSUM** value of all columns is calculated, set *expression* to *Table name::TEXT*.

The following types of data can be converted into TEXT types by default: char, name, int8, int2, int1, int4, raw, pg\_node\_tree, float4, float8, bpchar, varchar, nvarchar, nvarchar2, date, timestamp, timestamptz, numeric, and smalldatetime. Other types need to be forcibly converted to TEXT.

Return type: numeric

Example:

The following shows the **CHECKSUM** value of a column that can be converted to the TEXT type by default:

```
openGauss=# CREATE TABLE checksum_t1(a int, b int);

openGauss=# INSERT INTO checksum_t1 VALUES (NULL,11),(1,2),(1,3),(2,4),(2,5),(3,6);

openGauss=# SELECT CHECKSUM(a) FROM checksum_t1;
checksum

18126842830
(1 row)

openGauss=# DROP TABLE checksum_t1;
```

The following shows the **CHECKSUM** value of a column that cannot be converted to the TEXT type by default. Note that the **CHECKSUM** parameter is set to *Column name::TEXT*.

```
openGauss=# CREATE TABLE checksum_t1(a int, b int);

openGauss=# INSERT INTO checksum_t1 VALUES (NULL,11),(1,2),(1,3),(2,4),(2,5),(3,6);

openGauss=# SELECT CHECKSUM(a::TEXT) FROM checksum_t1;
checksum

18126842830
(1 row)

openGauss=# DROP TABLE checksum_t1;
```

The following shows the **CHECKSUM** value of all columns in a table. Note that the **CHECKSUM** parameter is set to *Table name::TEXT*. The table name is not modified by its schema.

```
openGauss=# CREATE TABLE checksum_t1(a int, b int);

openGauss=# INSERT INTO checksum_t1 VALUES (NULL,11),(1,2),(1,3),(2,4),(2,5),(3,6);

openGauss=# SELECT CHECKSUM(checksum_t1::TEXT) FROM checksum_t1;
checksum

11160522226
(1 row)

openGauss=# DROP TABLE checksum_t1;
```

- **mode()** WITHIN GROUP (ORDER BY value anyelement)

Description: Returns the value with the highest occurrence frequency in a column. If multiple values have the same frequency, the smallest value is returned. The sorting mode is the same as the default sorting mode of the column type. **value** is an input parameter and can be of any type.

Return type: same as the input parameter type

Example:

```
openGauss=# SELECT mode() WITHIN GROUP (ORDER BY value) FROM (values(1, 'a'), (2, 'b'), (2, 'c')) v(value, tag);
mode

2
(1 row)
openGauss=# SELECT mode() WITHIN GROUP (ORDER BY tag) FROM (values(1, 'a'), (2, 'b'), (2, 'c')) v(value, tag);
mode

a
(1 row)
```

## 7.5.18 Window Functions

### Window Functions

Window functions and the **OVER** clause are used together. The **OVER** clause is used for grouping data and sorting the elements in a group. Window functions are used for generating sequence numbers for the values in the group.

#### NOTE

**order by** in a window function must be followed by a column name. If it is followed by a number, the number is processed as a constant value and the target column is not ranked.

- **RANK()**

Description: Generates non-consecutive sequence numbers for the values in each group. The same values have the same sequence number.

Return type: bigint

Example:

```
openGauss=# CREATE TABLE rank_t1(a int, b int);

openGauss=# INSERT INTO rank_t1 VALUES(1,1),(1,1),(1, 2),(1, 3),(2, 4),(2, 5),(3,6);

openGauss=# SELECT a,b,RANK() OVER(PARTITION BY a ORDER BY b) FROM rank_t1;
a | b | rank
---+---+-----
1 | 1 | 1
1 | 1 | 1
1 | 2 | 3
1 | 3 | 4
2 | 4 | 1
2 | 5 | 2
3 | 6 | 1
(7 rows)

openGauss=# DROP TABLE rank_t1;
```

- **ROW\_NUMBER()**

Description: Generates consecutive sequence numbers for the values in each group. The same values have different sequence numbers.

Return type: bigint

Example:

```
openGauss=# CREATE TABLE row_number_t1(a int, b int);

openGauss=# INSERT INTO row_number_t1 VALUES(1,1),(1,1),(1, 2),(1, 3),(2, 4),(2, 5),(3,6);

openGauss=# SELECT a,b,ROW_NUMBER() OVER(PARTITION BY a ORDER BY b) FROM
row_number_t1;
a | b | row_number
---+---+-----
1 | 1 | 1
1 | 1 | 2
1 | 2 | 3
1 | 3 | 4
2 | 4 | 1
2 | 5 | 2
3 | 6 | 1
(7 rows)

openGauss=# DROP TABLE row_number_t1;
```

- **DENSE\_RANK()**

Description: Generates consecutive sequence numbers for the values in each group. The same values have the same sequence number.

Return type: bigint

Example:

```
openGauss=# CREATE TABLE dense_rank_t1(a int, b int);

openGauss=# INSERT INTO dense_rank_t1 VALUES(1,1),(1,1),(1, 2),(1, 3),(2, 4),(2, 5),(3,6);

openGauss=# SELECT a,b,DENSE_RANK() OVER(PARTITION BY a ORDER BY b) FROM dense_rank_t1;
 a | b | dense_rank
---+---+-----
 1 | 1 | 1
 1 | 1 | 1
 1 | 2 | 2
 1 | 3 | 3
 2 | 4 | 1
 2 | 5 | 2
 3 | 6 | 1
(7 rows)

openGauss=# DROP TABLE dense_rank_t1;
```

- **PERCENT\_RANK()**

Description: The PERCENT\_RANK function is used for generating corresponding sequence numbers for the values in each group. That is, the function calculates the value according to the formula: Sequence number =  $(\text{rank} - 1) / (\text{totalrows} - 1)$ . **rank** is the corresponding sequence number generated based on the **RANK** function for the value and **totalrows** is the total number of elements in a group.

Return type: double precision

Example:

```
openGauss=# CREATE TABLE percent_rank_t1(a int, b int);

openGauss=# INSERT INTO percent_rank_t1 VALUES(1,1),(1,1),(1, 2),(1, 3),(2, 4),(2, 5),(3,6);

openGauss=# SELECT a,b,PERCENT_RANK() OVER(PARTITION BY a ORDER BY b) FROM
percent_rank_t1;
 a | b | percent_rank
---+---+-----
 1 | 1 | 0
 1 | 1 | 0
 1 | 2 | .6666666666666667
 1 | 3 | 1
 2 | 4 | 0
 2 | 5 | 1
 3 | 6 | 0
(7 rows)

openGauss=# DROP TABLE percent_rank_t1;
```

- **CUME\_DIST()**

Description: Generates accumulative distribution sequence numbers for the values in each group. That is, the function calculates the value according to the following formula: Sequence number = Number of rows preceding or peer with current row/Total rows.

Return type: double precision

Example:

```
openGauss=# CREATE TABLE cume_dist_t1(a int, b int);

openGauss=# INSERT INTO cume_dist_t1 VALUES(1,1),(1,1),(1, 2),(1, 3),(2, 4),(2, 5),(3,6);
```

```
openGauss=# SELECT a,b,CUME_DIST() OVER(PARTITION BY a ORDER BY b) FROM cume_dist_t1;
a | b | cume_dist
---+---+-----
1 | 1 | .5
1 | 1 | .5
1 | 2 | .75
1 | 3 | 1
2 | 4 | .5
2 | 5 | 1
3 | 6 | 1
(7 rows)

openGauss=# DROP TABLE cume_dist_t1;
```

- NTILE(num\_buckets integer)

Description: Equally allocates sequential data sets to the buckets whose quantity is specified by **num\_buckets** according to **num\_buckets integer** and allocates the bucket number to each row. Divide the partition as evenly as possible.

Return type: integer

Example:

```
openGauss=# CREATE TABLE ntile_t1(a int, b int);

openGauss=# INSERT INTO ntile_t1 VALUES(1,1),(1,1),(1, 2),(1, 3),(2, 4),(2, 5),(3,6);

openGauss=# SELECT a,b,NTILE(2) OVER(PARTITION BY a ORDER BY b) FROM ntile_t1;
a | b | ntile
---+---+-----
1 | 1 | 1
1 | 1 | 1
1 | 2 | 2
1 | 3 | 2
2 | 4 | 1
2 | 5 | 2
3 | 6 | 1
(7 rows)

openGauss=# DROP TABLE ntile_t1;
```

- LAG(value any [, offset integer [, default any ]])

Description: Generates lag values for the corresponding values in each group. That is, the value of the row obtained by moving forward the row corresponding to the current value by **offset** (integer) is the sequence number. If the row does not exist after the moving, the result value is the default value. If omitted, **offset** defaults to **1** and **default** to **NULL**. The type of the **default** value must be the same as that of the **value** value.

Return type: same as the parameter type

Example:

```
-- Create a table and insert data into the table.
openGauss=# CREATE TABLE ta1 (hire_date date, last_name varchar(20), department_id int);
CREATE TABLE
openGauss=# INSERT INTO ta1 values('07-DEC-02', 'Raphaely', 30);
INSERT 0 1
openGauss=# INSERT INTO ta1 values('24-JUL-05', 'Tobias', 30);
INSERT 0 1
openGauss=# INSERT INTO ta1 values('24-DEC-05', 'Baida', 30);
INSERT 0 1
openGauss=# INSERT INTO ta1 values('18-MAY-03', 'Khoo', 30);
INSERT 0 1
openGauss=# INSERT INTO ta1 values('15-NOV-06', 'Himuro', 30);
INSERT 0 1
openGauss=# INSERT INTO ta1 values('10-AUG-07', 'Colmenares', 30);
```

```
INSERT 0 1
openGauss=# INSERT INTO ta1 values('10-MAY-07', 'yq', 11);
INSERT 0 1
openGauss=# INSERT INTO ta1 values('10-MAY-08', 'zi', 11);
INSERT 0 1
openGauss=# INSERT INTO ta1 values('', 'yq1', 30);
INSERT 0 1
openGauss=# INSERT INTO ta1 values(null, 'yq2', 30);
INSERT 0 1
openGauss=# INSERT INTO ta1 values('10-DEC-07', 'yq3', 30);
INSERT 0 1
openGauss=# INSERT INTO ta1 values(null, null, 11);
INSERT 0 1
openGauss=# INSERT INTO ta1 values(null, null, 11);
INSERT 0 1

-- Call LAG and set offset to 3 and default to null.
openGauss=# SELECT hire_date, last_name, department_id, lag(hire_date, 3, null) OVER (PARTITION
BY department_id ORDER BY last_name) AS "NextHired" FROM ta1 ORDER BY department_id;
 hire_date | last_name | department_id | NextHired
-----+-----+-----+-----
2007-05-10 00:00:00 | yq | 11 |
2008-05-10 00:00:00 | zi | 11 |
 | | 11 |
 | | 11 | 2007-05-10 00:00:00
2005-12-24 00:00:00 | Baida | 30 |
2007-08-10 00:00:00 | Colmenares | 30 |
2006-11-15 00:00:00 | Himuro | 30 |
2003-05-18 00:00:00 | Khoo | 30 | 2005-12-24 00:00:00
2002-12-07 00:00:00 | Raphaely | 30 | 2007-08-10 00:00:00
2005-07-24 00:00:00 | Tobias | 30 | 2006-11-15 00:00:00
 | yq1 | 30 | 2003-05-18 00:00:00
 | yq2 | 30 | 2002-12-07 00:00:00
2007-12-10 00:00:00 | yq3 | 30 | 2005-07-24 00:00:00
(13 rows)

openGauss=# DROP TABLE ta1;
```

- LEAD(value any [, offset integer [, default any ]])

Description: Generates leading values for the corresponding values in each group. That is, the value of the row obtained by moving backward the row corresponding to the current value by **offset** (integer) is the sequence number. If the row after the moving exceeds the total number of rows for the current group, the result value is the default value. If omitted, **offset** defaults to **1** and **default** to **NULL**. The type of the **default** value must be the same as that of the **value** value.

Return type: same as the parameter type

Example:

```
openGauss=# CREATE TABLE ta1 (hire_date date, last_name varchar(20), department_id int);
CREATE TABLE
openGauss=# INSERT INTO ta1 values('07-DEC-02', 'Raphaely', 30);
INSERT 0 1
openGauss=# INSERT INTO ta1 values('24-JUL-05', 'Tobias', 30);
INSERT 0 1
openGauss=# INSERT INTO ta1 values('24-DEC-05', 'Baida', 30);
INSERT 0 1
openGauss=# INSERT INTO ta1 values('18-MAY-03', 'Khoo', 30);
INSERT 0 1
openGauss=# INSERT INTO ta1 values('15-NOV-06', 'Himuro', 30);
INSERT 0 1
openGauss=# INSERT INTO ta1 values('10-AUG-07', 'Colmenares', 30);
INSERT 0 1
openGauss=# INSERT INTO ta1 values('10-MAY-07', 'yq', 11);
INSERT 0 1
openGauss=# INSERT INTO ta1 values('10-MAY-08', 'zi', 11);
INSERT 0 1

(13 rows)

openGauss=# DROP TABLE ta1;
```

- **FIRST\_VALUE(value any)**

Description: Returns the first value of each group.

Return type: same as the parameter type

Example:

```
openGauss=# CREATE TABLE first_value_t1(a int, b int);

openGauss=# INSERT INTO first_value_t1 VALUES(1,1),(1,1),(1, 2),(1, 3),(2, 4),(2, 5),(3,6);

openGauss=# SELECT a,b,FIRST_VALUE(b) OVER(PARTITION BY a ORDER BY b) FROM first_value_t1;
 a | b | first_value
---+---+-----
 1 | 1 | 1
 1 | 1 | 1
 1 | 2 | 1
 1 | 3 | 1
 2 | 4 | 4
 2 | 5 | 4
 3 | 6 | 6
(7 rows)

openGauss=# DROP TABLE first_value_t1;
```

- **LAST\_VALUE(value any)**

Description: Returns the last value of each group.

Return type: same as the parameter type

Example:

```
openGauss=# CREATE TABLE last_value_t1(a int, b int);

openGauss=# INSERT INTO last_value_t1 VALUES(1,1),(1,1),(1, 2),(1, 3),(2, 4),(2, 5),(3,6);

openGauss=# SELECT a,b,LAST_VALUE(b) OVER(PARTITION BY a ORDER BY b) FROM last_value_t1;
 a | b | last_value
---+---+-----
 1 | 1 | 6
 1 | 1 | 6
 1 | 2 | 6
 1 | 3 | 6
 2 | 4 | 6
 2 | 5 | 6
 3 | 6 | 6
```

```
-----+-----
1 | 1 | 1
1 | 1 | 1
1 | 2 | 2
1 | 3 | 3
2 | 4 | 4
2 | 5 | 5
3 | 6 | 6
(7 rows)
```

```
openGauss=# DROP TABLE last_value_t1;
```

- **DELTA**

Description: Returns the difference between the current row and the previous row.

Parameter: numeric

Return type: numeric

- **NTH\_VALUE(value any, nth integer)**

Description: Returns the *n*th row for a group. If the row does not exist, **NULL** is returned by default.

Return type: same as the parameter type

Example:

```
openGauss=# CREATE TABLE nth_value_t1(a int, b int);
```

```
openGauss=# INSERT INTO nth_value_t1 VALUES(1,1),(1,1),(1, 2),(1, 3),(2, 4),(2, 5),(3,6);
```

```
openGauss=# SELECT a,b,NTH_VALUE(b, 2) OVER(PARTITION BY a order by b) FROM nth_value_t1;
a | b | nth_value
```

```
-----+-----
1 | 1 | 1
1 | 1 | 1
1 | 2 | 1
1 | 3 | 1
2 | 4 | 5
2 | 5 | 5
3 | 6 |
(7 rows)
```

```
openGauss=# DROP TABLE nth_value_t1;
```

## 7.5.19 Security Functions

### Security Functions

- **gs\_encrypt\_aes128(encryptstr,keyststr)**

Description: Encrypts **encryptstr** strings using **keyststr** as the encryption password and returns encrypted strings. The value of **keyststr** ranges from 8 to 16 bytes and contains at least three types of the following characters: uppercase letters, lowercase letters, digits, and special characters.

Return type: text

Length of the return value: At least 92 bytes and no more than  $(4 * [Len / 3] + 68)$  bytes, where *Len* indicates the length of the data before encryption (unit: byte).

Example:

```
openGauss=# SELECT gs_encrypt_aes128('MPPDB','Asdf1234');
```

```
gs_encrypt_aes128
```

```

gwditQLQG8NhFw4OuoKhhQJoXojhFLYkjeG0aYdSctLCnIUgkNwvYI04KbuhmcGZp8jWizBdR1vU9Cspjuzl
0lbz12A=
(1 row)
```

**NOTE**

An encryption password is required during the execution of this function. For security purposes, the gsql tool does not record the SQL statements containing the function name in the execution history. That is, the execution history of this function cannot be found in gsql by paging up and down.

- **gs\_encrypt(encryptstr,keyst, encrypttype)**

Description: Encrypts **encryptstr** strings using **keyst** as the encryption password and returns encrypted strings based on **encrypttype**. The value of **keyst** contains 8 to 16 bytes and at least three types of the following characters: uppercase letters, lowercase letters, digits, and special characters. The value of **encrypttype** can be **aes128** or **sm4**.

Return type: text

Example:

```
openGauss=# SELECT gs_encrypt('MPPDB','Asdf1234','sm4');
gs_encrypt

ZBzOmaGA4Bb+coyucJ0B8AkIShqc
(1 row)
```

**NOTE**

An encryption password is required during the execution of this function. For security purposes, the gsql tool does not record the SQL statements containing the function name in the execution history. That is, the execution history of this function cannot be found in gsql by paging up and down.

- **gs\_decrypt\_aes128(decryptstr,keyst)**

Description: Decrypts **decrypt** strings using **keyst** as the decryption password and returns decrypted strings. The **keyst** used for decryption must be consistent with that used for encryption. **keyst** cannot be empty.

**NOTE**

This parameter needs to be used with the **gs\_encrypt\_aes128** encryption function.

Return type: text

Example:

```
openGauss=# SELECT
gs_decrypt_aes128('gwditQLQG8NhFw4OuoKhhQJoXojhFLYkjeG0aYdSctLCnIUgkNwvYI04KbuhmcGZp8j
WizBdR1vU9Cspjuzl0lbz12A=','1234');
gs_decrypt_aes128

MPPDB
(1 row)
```

**NOTE**

A decryption password is required during the execution of this function. For security purposes, the gsql tool does not record the SQL statements containing the function name in the execution history. That is, the execution history of this function cannot be found in gsql by paging up and down.

- **gs\_decrypt(decryptstr,keyst,decrypttype)**

Description: Decrypts **decrypt** strings using **keyst** as the decryption password and returns decrypted strings based on **decrypttype**. The **decrypttype** and

**keystr** used for decryption must be consistent with **encrypttype** and **keystr** used for encryption. The value of **keystr** cannot be empty. The value of **decrypttype** can be **aes128** or **sm4**.

This function needs to be used with the **gs\_encrypt** encryption function.

Return type: text

Example:

```
openGauss=# SELECT gs_decrypt('ZBzOmaGA4Bb+coyucJ0B8AkIShq', 'Asdf1234', 'sm4');
gs_decrypt

MPPDB
(1 row)
```

#### NOTE

A decryption password is required during the execution of this function. For security purposes, the gsqr tool does not record the SQL statements containing the function name in the execution history. That is, the execution history of this function cannot be found in gsqr by paging up and down.

- **gs\_password\_deadline()**

Description: Indicates the number of remaining days before the password of the current user expires.

Return type: interval

Example:

```
openGauss=# SELECT gs_password_deadline();
gs_password_deadline

83 days 17:44:32.196094
(1 row)
```

- **gs\_password\_notifytime()**

Description: Specifies the number of days prior to password expiration that a user will receive a reminder.

Return type: int32

- **login\_audit\_messages(BOOLEAN)**

Description: Queries login information about a login user.

Return type: tuple

Example:

- Check the date, time, and IP address of the last successful login.

```
openGauss=> SELECT * FROM login_audit_messages(true);
username | database | logintime | mytype | result | client_conninfo
-----+-----+-----+-----+-----+-----
omm | openGauss | 2020-06-29 21:56:40+08 | login_success | ok | gsqr@[local]
(1 row)
```

- Check the number, date, and time of failed attempts since the previous successful login.

```
openGauss=> SELECT * FROM login_audit_messages(false);
username | database | logintime | mytype | result | client_conninfo
-----+-----+-----+-----+-----+-----
omm | openGauss | 2020-06-29 21:57:55+08 | login_failed | failed | [unknown]@[local]
omm | openGauss | 2020-06-29 21:57:53+08 | login_failed | failed | [unknown]@[local]
(2 rows)
```

- **login\_audit\_messages\_pid**

Description: Queries login information about a login user. Different from **login\_audit\_messages**, this function queries login information based on

**backendid**. Information about subsequent logins of the same user does not alter the query result of previous logins and cannot be found using this function.

Return type: tuple

 **NOTE**

When the thread pool is enabled, **backendid** obtained in the same session may change due to thread switchover. As a result, the return values are different when the function is called for multiple times. You are advised not to call this function when the thread pool is enabled.

Example:

- Check the date, time, and IP address of the last successful login.

```
openGauss=> SELECT * FROM login_audit_messages_pid(true);
username | database | logintime | mytype | result | client_conninfo | backendid
-----+-----+-----+-----+-----+-----+-----
omm | openGauss | 2020-06-29 21:56:40+08 | login_success | ok | gsqr@[local] |
139823109633792
(1 row)
```

- Check the number, date, and time of failed attempts since the previous successful login.

```
openGauss=> SELECT * FROM login_audit_messages_pid(false);
username | database | logintime | mytype | result | client_conninfo | backendid
-----+-----+-----+-----+-----+-----+-----
omm | openGauss | 2020-06-29 21:57:55+08 | login_failed | failed | [unknown]@[local] |
139823109633792
omm | openGauss | 2020-06-29 21:57:53+08 | login_failed | failed | [unknown]@[local] |
139823109633792
(2 rows)
```

- **inet\_server\_addr**

Description: Displays the server IP address.

Return type: inet

Example:

```
openGauss=# SELECT inet_server_addr();
inet_server_addr

10.10.0.13
(1 row)
```

 **NOTE**

- The client IP address 10.10.0.50 and server IP address 10.10.0.13 are used as an example.
- If the database is connected to the local PC, the value is empty.
- **inet\_client\_addr**

Description: Displays the client IP address.

Return type: inet

Example:

```
openGauss=# SELECT inet_client_addr();
inet_client_addr

10.10.0.50
(1 row)
```

 **NOTE**

- The client IP address 10.10.0.50 and server IP address 10.10.0.13 are used as an example.
- If the database is connected to the local PC, the value is empty.

- **pg\_query\_audit**

Description: Views audit logs of the primary database node.

Return type: record

The following table describes return fields.

| Name            | Type                     | Description                                 |
|-----------------|--------------------------|---------------------------------------------|
| time            | timestamp with time zone | Operation time                              |
| type            | text                     | Operation                                   |
| result          | text                     | Operation result                            |
| userid          | oid                      | User ID                                     |
| username        | text                     | Name of the user who performs the operation |
| database        | text                     | Database name                               |
| client_conninfo | text                     | Client connection information               |
| object_name     | text                     | Object name                                 |
| detail_info     | text                     | Operation details                           |
| node_name       | text                     | Node name                                   |
| thread_id       | text                     | Thread ID                                   |
| local_port      | text                     | Local port                                  |
| remote_port     | text                     | Remote port                                 |

- **pg\_delete\_audit**

Description: Deletes audit logs in a specified period.

Return type: void

- **alldigitsmasking**

Description: Specifies the internal function of the masking policy, which is used to anonymize all characters.

Parameter: col text, letter character default '0'

Return type: text

- **creditcardmasking**

Description: Specifies the internal function of the masking policy, which is used to anonymize all credit card information.

Parameter: col text, letter character default 'x'

Return type: text

- randommasking

Description: Specifies the internal function of the masking policy. The random policy is used.

Parameter: col text

Return type: text

- fullemailmasking

Description: Specifies the internal function of the masking policy, which is used to anonymize the text before the last period (.) except the at sign (@).

Parameter: col text, letter character default 'x'

Return type: text

- basicemailmasking

Description: Specifies the internal function of the masking policy, which is used to anonymize the text before the first at sign (@).

Parameter: col text, letter character default 'x'

Return type: text

- shufflemasking

Description: Specifies the internal function of the masking policy, which is used to sort characters out of order.

Parameter: col text

Return type: text

## 7.5.20 Set Returning Functions

### Series Generating Functions

- generate\_series(start, stop)

Description: Generates a series of values, from **start** to **stop** with a step size of one.

Parameter type: int, bigint, numeric

Return type: setof int, setof bigint, setof numeric (same as the parameter type)

- generate\_series(start, stop, step)

Description: Generates a series of values, from **start** to **stop** with a step size of **step**.

Parameter type: int, bigint, numeric

Return type: setof int, setof bigint, setof numeric (same as the parameter type)

- generate\_series(start, stop, step interval)

Description: Generates a series of values, from **start** to **stop** with a step size of **step**.

Parameter type: timestamp or timestamp with time zone

Return type: setof timestamp or setof timestamp with time zone (same as parameter type)

When **step** is positive, zero rows are returned if **start** is greater than **stop**. Conversely, when **step** is negative, zero rows are returned if **start** is less than **stop**. Zero rows are also returned for **NULL** inputs. It is an error for **step** to be zero.

Example:

```
openGauss=# SELECT * FROM generate_series(2,4);
generate_series

 2
 3
 4
(3 rows)

openGauss=# SELECT * FROM generate_series(5,1,-2);
generate_series

 5
 3
 1
(3 rows)

openGauss=# SELECT * FROM generate_series(4,3);
generate_series

(0 rows)

-- This example applies to the date-plus-integer operator.
openGauss=# SELECT current_date + s.a AS dates FROM generate_series(0,14,7) AS s(a);
dates

2017-06-02
2017-06-09
2017-06-16
(3 rows)

openGauss=# SELECT * FROM generate_series('2008-03-01 00:00'::timestamp, '2008-03-04 12:00', '10
hours');
generate_series

2008-03-01 00:00:00
2008-03-01 10:00:00
2008-03-01 20:00:00
2008-03-02 06:00:00
2008-03-02 16:00:00
2008-03-03 02:00:00
2008-03-03 12:00:00
2008-03-03 22:00:00
2008-03-04 08:00:00
(9 rows)
```

## Subscript Generating Functions

- `generate_subscripts(array anyarray, dim int)`  
Description: Generates a series comprising the given array's subscripts.  
Return type: setof int
- `generate_subscripts(array anyarray, dim int, reverse boolean)`  
Description: Generates a series comprising the given array's subscripts. When **reverse** is true, the series is returned in reverse order.  
Return type: setof int

**generate\_subscripts** is a function that generates the set of valid subscripts for the specified dimension of the given array. Zero rows are returned for arrays that do

not have the requested dimension, or for NULL arrays (but valid subscripts are returned for NULL array elements). Example:

```
-- Basic usage
openGauss=# SELECT generate_subscripts('{NULL,1,NULL,2}'::int[], 1) AS s;
s

1
2
3
4
(4 rows)
-- Unnest a 2D array:
openGauss=# CREATE OR REPLACE FUNCTION unnest2(anyarray)
RETURNS SETOF anyelement AS $$
SELECT $1[i][j]
 FROM generate_subscripts($1,1) g1(i),
 generate_subscripts($1,2) g2(j);
$$ LANGUAGE sql IMMUTABLE;

openGauss=# SELECT * FROM unnest2(ARRAY[[1,2],[3,4]]);
unnest2

1
2
3
4
(4 rows)

-- Delete the function.
openGauss=# DROP FUNCTION unnest2;
```

## 7.5.21 Conditional Expression Functions

### Conditional Expression Functions

- `coalesce(expr1, expr2, ..., exprn)`

Description:

Returns the first of its parameters that are not null.

**COALESCE(expr1, expr2)** is equivalent to **CASE WHEN expr1 IS NOT NULL THEN expr1 ELSE expr2 END**.

Example:

```
openGauss=# SELECT coalesce(NULL,'hello');
coalesce

hello
(1 row)
```

Note:

- If all the expressions are equivalent to NULL in the expression list, this function returns **NULL**.
- This value is replaced by the default value when data is displayed.
- Like a **CASE** expression, **COALESCE** only evaluates the parameters that are needed to determine the result. That is, parameters to the right of the first not-**NULL** parameter are not evaluated.

- `decode(base_expr, compare1, value1, Compare2,value2, ... default)`

Description: Compares **base\_expr** with each **compare(n)** and **returns value(n)** if they are matched. If no match occurs, **default** is returned.

Example:

```
openGauss=# SELECT decode('A','A',1,'B',2,0);
case

1
(1 row)
```

- **nullif(expr1, expr2)**

Description: Returns **NULL** only when **expr1** is equal to **expr2**. Otherwise, **expr1** is returned.

**nullif(expr1, expr2)** is equivalent to **CASE WHEN expr1 = expr2 THEN NULL ELSE expr1 END**.

Example:

```
openGauss=# SELECT nullif('hello','world');
nullif

hello
(1 row)
```

Note:

Assume the two parameter data types are different:

- If implicit conversion exists between the two data types, implicitly convert the parameter of lower priority to this data type using the data type of higher priority. If the conversion succeeds, computation is performed.

Otherwise, an error is returned. Example:

```
openGauss=# SELECT nullif('1234'::VARCHAR,123::INT4);
nullif

1234
(1 row)
```

```
openGauss=# SELECT nullif('1234'::VARCHAR,'2012-12-24'::DATE);
ERROR: invalid input syntax for type timestamp: "1234"
```

- If implicit conversion is not applied between two data types, an error is returned. Example:

```
openGauss=# SELECT nullif(TRUE::BOOLEAN,'2012-12-24'::DATE);
ERROR: operator does not exist: boolean = timestamp without time zone
LINE 1: SELECT nullif(TRUE::BOOLEAN,'2012-12-24'::DATE) FROM sys_dummy;
 ^
HINT: No operator matches the given name and argument type(s). You might need to add explicit type casts.
```

- **nvl( expr1 , expr2 )**

Description:

- If **expr1** is **NULL**, **expr2** is returned.
- If **expr1** is not **NULL**, **expr1** is returned.

Example:

```
openGauss=# SELECT nvl('hello','world');
nvl

hello
(1 row)
```

Note: Parameters **expr1** and **expr2** can be of any data type. If **expr1** and **expr2** are of different data types, NVL checks whether **expr2** can be implicitly converted to **expr1**. If it can, the data type of **expr1** is returned. Otherwise, an error is returned.

- **greatest(expr1 [, ...])**

Description: Selects the largest value from a list of any number of expressions.

Return type:

Example:

```
openGauss=# SELECT greatest(1*2,2-3,4-1);
greatest

 3
(1 row)
openGauss=# SELECT greatest('HARRY', 'HARRIOT', 'HAROLD');
greatest

HARRY
(1 row)
```

- `least(expr1 [, ...])`

Description: Selects the smallest value from a list of any number of expressions.

Example:

```
openGauss=# SELECT least(1*2,2-3,4-1);
least

 -1
(1 row)
openGauss=# SELECT least('HARRY','HARRIOT','HAROLD');
least

HAROLD
(1 row)
```

- `EMPTY_BLOB()`

Description: Initiates a BLOB variable in an **INSERT** or an **UPDATE** statement to a **NULL** value.

Return type: BLOB

Example:

```
-- Create a table.
openGauss=# CREATE TABLE blob_tb(b blob,id int);
-- Insert data.
openGauss=# INSERT INTO blob_tb VALUES (empty_blob(),1);
-- Drop the table.
openGauss=# DROP TABLE blob_tb;
```

Note: The length is 0 obtained using **DBE\_LOB.GET\_LENGTH**.

## 7.5.22 System Information Functions

### Session Information Functions

- `current_catalog`  
Description: Name of the current database (called "catalog" in the SQL standard)

Return type: name

Example:

```
testdb=# SELECT current_catalog;
current_database

testdb
(1 row)
```

- `current_database()`  
Description: Name of the current database  
Return type: name

Example:

```
testdb=# SELECT current_database();
current_database

testdb
(1 row)
```

- `current_query()`

Description: Text of the currently executing query, as committed by the client (might contain more than one statement)

Return type: text

Example:

```
openGauss=# SELECT current_query();
current_query

SELECT current_query();
(1 row)
```

- `current_schema()`

Description: Name of current schema

Return type: name

Example:

```
openGauss=# SELECT current_schema();
current_schema

public
(1 row)
```

Remarks: **current\_schema** returns the first valid schema name in the search path. (If the search path is empty or contains no valid schema name, **NULL** is returned.) This is the schema that will be used for any tables or other named objects that are created without specifying a target schema.

- `current_schemas(Boolean)`

Description: Names of schemas in search path

Return type: name[]

Example:

```
openGauss=# SELECT current_schemas(true);
current_schemas

{pg_catalog,public}
(1 row)
```

Note:

**current\_schemas(Boolean)** returns an array of the names of all schemas presently in the search path. The Boolean option determines whether implicitly included system schemas such as **pg\_catalog** are included in the returned search path.

#### NOTE

The search path can be altered at run time by running the following command:

```
SET search_path TO schema [, schema, ...]
```

- `current_user`

Description: Username in the current execution environment

Return type: name

Example:

```
openGauss=# SELECT current_user;
current_user

omm
(1 row)
```

Note: **current\_user** is the user identifier that is applicable for permission checking. Normally it is equal to the session user, but it can be changed with **SET ROLE**. It also changes during the execution of functions with the attribute **SECURITY DEFINER**.

- **definer\_current\_user**

Description: Username in the current execution environment

Return type: name

Example:

```
openGauss=# SELECT definer_current_user();
definer_current_user

omm
(1 row)
```

- **pg\_current\_sessionid()**

Description: Session ID of the current execution context

Return type: text

Example:

```
openGauss=# SELECT pg_current_sessionid();
pg_current_sessionid

1579228402.140190434944768
(1 row)
```

Note: **pg\_current\_sessionid()** is used to obtain the session ID in the current execution context. The structure of the value is *Timestamp. Session ID*. When **enable\_thread\_pool** is set to **off**, the actual session ID is the thread ID.

- **pg\_current\_sessid**

Description: Session ID of the current execution context

Return type: text

Example:

```
openGauss=# select pg_current_sessid();
pg_current_sessid

140308875015936
(1 row)
```

Note: In thread pool mode, the ID of the current session is obtained. In non-thread pool mode, the backend thread ID of the current session is obtained.

- **pg\_current\_userid**

Description: Current user ID.

Return type: text

```
openGauss=# SELECT pg_current_userid();
pg_current_userid

10
(1 row)
```

- **working\_version\_num()**

Description: Returns a version number regarding system compatibility.

Return type: int

Example:

```
openGauss=# SELECT working_version_num();
working_version_num

 92231
(1 row)
```

- **tablespace\_oid\_name(oid)**

Description: Queries the tablespace name based on the tablespace OID.

Return type: text

Example:

```
openGauss=# select tablespace_oid_name(1663);
tablespace_oid_name

pg_default
(1 row)
```

- **inet\_client\_addr()**

Description: Remote connection address. **inet\_client\_addr** returns the IP address of the current client.

 **NOTE**

It is available only in remote connection mode.

Return type: inet

Example:

```
openGauss=# SELECT inet_client_addr();
inet_client_addr

10.10.0.50
(1 row)
```

- **inet\_client\_port()**

Description: Remote connection port. And **inet\_client\_port** returns the port number of the current client.

 **NOTE**

It is available only in remote connection mode.

Return type: int

Example:

```
openGauss=# SELECT inet_client_port();
inet_client_port

 33143
(1 row)
```

- **inet\_server\_addr()**

Description: Local connection address. **inet\_server\_addr** returns the IP address on which the server accepted the current connection.

 **NOTE**

It is available only in remote connection mode.

Return type: inet

Example:

```
openGauss=# SELECT inet_server_addr();
inet_server_addr
```

```

10.10.0.13
(1 row)
```

- `inet_server_port()`

Description: Local connection port. **inet\_server\_port** returns the port number. All these functions return **NULL** if the current connection is via a UDS.

 **NOTE**

It is available only in remote connection mode.

Return type: int

Example:

```
openGauss=# SELECT inet_server_port();
inet_server_port

8000
(1 row)
```

- `pg_backend_pid()`

Description: Process ID of the server process attached to the current session

Return type: int

Example:

```
openGauss=# SELECT pg_backend_pid();
pg_backend_pid

140229352617744
(1 row)
```

- `pg_conf_load_time()`

Description: Configures load time. **pg\_conf\_load\_time** returns the timestamp with time zone when the server configuration files were last loaded.

Return type: timestamp with time zone

Example:

```
openGauss=# SELECT pg_conf_load_time();
pg_conf_load_time

2017-09-01 16:05:23.89868+08
(1 row)
```

- `pg_my_temp_schema()`

Description: OID of the temporary schema of a session. The value is **0** if the OID does not exist.

Return type: oid

Example:

```
openGauss=# SELECT pg_my_temp_schema();
pg_my_temp_schema

0
(1 row)
```

Note: **pg\_my\_temp\_schema** returns the OID of the current session's temporary schema, or zero if it has none (because it has not created any temporary tables). **pg\_is\_other\_temp\_schema** returns true if the given OID is the OID of another session's temporary schema.

- `pg_is_other_temp_schema(oid)`

Description: Specifies whether the schema is the temporary schema of another session.

Return type: Boolean

Example:

```
openGauss=# SELECT pg_is_other_temp_schema(25356);
pg_is_other_temp_schema

f
(1 row)
```

- `pg_listening_channels()`

Description: Channel names that the session is currently listening on

Return type: SETOF text

Example:

```
openGauss=# SELECT pg_listening_channels();
pg_listening_channels

(0 rows)
```

Note: **pg\_listening\_channels** returns a set of names of channels that the current session is listening to.

- `pg_postmaster_start_time()`

Description: Server start time **pg\_postmaster\_start\_time** returns the **timestamp with time zone** when the server started.

Return type: timestamp with time zone

Example:

```
openGauss=# SELECT pg_postmaster_start_time();
pg_postmaster_start_time

2017-08-30 16:02:54.99854+08
(1 row)
```

- `pg_get_ruledef(rule_oid)`

Description: Obtains the **CREATE RULE** command for a rule.

Return type: text

Example:

```
openGauss=# select * from pg_get_ruledef(24828);
pg_get_ruledef

CREATE RULE t1_ins AS ON INSERT TO t1 DO INSTEAD INSERT INTO t2 (id) VALUES (new.id);
(1 row)
```

- `sessionid2pid()`

Description: Obtains PID information from a session ID (for example, the **sessid** column in **gs\_session\_stat**).

Return type: int8

Example:

```
openGauss=# select sessionid2pid(sessid::cstring) from gs_session_stat limit 2;
sessionid2pid

139973107902208
139973107902208
(2 rows)
```

- `session_context( 'namespace' , 'parameter')`

Description: Obtains and returns the parameter values of a specified namespace.

Return type: VARCHAR

Example:

```
openGauss=# SELECT session_context('USERENV', 'CURRENT_SCHEMA');
session_context

public
(1 row)
```

Note: Currently, the **current\_user**, **current\_schema**, **client\_info**, **ip\_address**, **sessionid**, and **sid** parameters are supported.

- **pg\_trigger\_depth()**

Description: Current nesting level of triggers

Return type: int

Example:

```
openGauss=# SELECT pg_trigger_depth();
pg_trigger_depth

0
(1 row)
```

- **session\_user**

Description: Session username.

Return type: name

Example:

```
openGauss=# SELECT session_user;
session_user

omm
(1 row)
```

Note: **session\_user** is usually the user who initiated the current database connection, but administrators can change this setting with **SET SESSION AUTHORIZATION**.

- **user**

Description: Equivalent to **current\_user**.

Return type: name

Example:

```
openGauss=# SELECT user;
current_user

omm
(1 row)
```

- **getpgusername()**

Description: Obtains the database username.

Return type: name

Example:

```
openGauss=# select getpgusername();
getpgusername

GaussDB_userna
(1 row)
```

- **getdatabaseencoding()**

Description: Obtains the database encoding mode.

Return type: name

Example:

```
openGauss=# select getdatabaseencoding();
getdatabaseencoding

SQL_ASCII
(1 row)
```

- `version()`

Description: Version information. **version** returns a string describing a server's version.

Return type: text

Example:

```
openGauss=# select version();
version

(GaussDB Kernel VxxxRxxxCxx build fab4f5ea) compiled at 2021-10-24 11:58:22 commit 3086 last mr
6592 release
(1 row)
```

- `opengauss_version()`

Description: openGauss version information

Return type: text

The following is an example. Replace *x.x.x* in the query result with the actual value.

```
openGauss=# select opengauss_version();
opengauss_version

x.x.x
(1 row)
```

- `gs_deployment()`

Description: Information about the deployment mode of the current system

Return type: text

Example:

```
openGauss=# select gs_deployment();
gs_deployment

BusinessCentralized
(1 row)
```

- `get_hostname()`

Description: Returns the host name of the current node.

Return type: text

Example:

```
openGauss=# SELECT get_hostname();
get_hostname

linux-user
(1 row)
```

- `get_nodename()`

Description: Returns the name of the current node.

Return type: text

Example:

```
openGauss=# SELECT get_nodename();
get_nodename

```

```
datanode1
(1 row)
```

- `get_schema_oid(cstring)`

Description: Returns the OID of the queried schema.

Return type: oid

Example:

```
openGauss=# SELECT get_schema_oid('public');
get_schema_oid

2200
(1 row)
```

- `get_client_info()`

Description: Returns client information.

Return type: record

## Access privilege inquiry function

The DDL permissions, including ALTER, DROP, COMMENT, INDEX and VACUUM, are inherent permissions implicitly owned by the owner.

The following access permission query function only specifies whether a user has a certain permission on an object. That is, the permission on the object recorded in the **acl** column of the system catalog is returned.

- `has_any_column_privilege(user, table, privilege)`

Description: Queries whether a specified user has permission for any column of table.

**Table 7-35** Parameter type description

| Parameter | Valid Input Parameter Type |
|-----------|----------------------------|
| user      | name, oid                  |
| table     | text, oid                  |
| privilege | text                       |

Return type: Boolean

- `has_any_column_privilege(table, privilege)`

Description: Queries whether the current user has permission to access any column of table. For details about the valid parameter types, see [Table 7-35](#).

Return type: Boolean

**has\_any\_column\_privilege** checks whether a user can access any column of a table in a particular way. Its parameter possibilities are analogous to **has\_table\_privilege**, except that the desired access permission must be some combination of SELECT, INSERT, UPDATE, COMMENT or REFERENCES.

 NOTE

Note that having any of these permissions at the table level implicitly grants it for each column of the table, so **has\_any\_column\_privilege** will always return **true** if **has\_table\_privilege** does for the same parameters. A success message is also returned if a column-level permission is granted for at least one column.

- **has\_column\_privilege**(user, table, column, privilege)

Description: Specifies whether a specified user has permission for columns.

**Table 7-36** Parameter type description

| Parameter | Valid Input Parameter Type |
|-----------|----------------------------|
| user      | name, oid                  |
| table     | text, oid                  |
| column    | text, smallint             |
| privilege | text                       |

Return type: Boolean

- **has\_column\_privilege**(table, column, privilege)

Description: Specifies whether the current user has permission to access columns. For details about the valid parameter types, see [Table 7-36](#).

Return type: Boolean

**has\_column\_privilege** checks whether a user can access a column in a particular way. Its argument possibilities are analogous to **has\_table\_privilege**, with the addition that the column can be specified either by name or attribute number. The desired access permission must be some combination of SELECT, INSERT, UPDATE, COMMENT or REFERENCES.

 NOTE

Note that having any of these permissions at the table level indicates that the permission is implicitly granted for each column of the table.

- **has\_database\_privilege**(user, database, privilege)

Description: Specifies whether a specified user has permission for accessing databases. The parameters are described as follows:

**Table 7-37** Parameter type description

| Parameter | Valid Input Parameter Type |
|-----------|----------------------------|
| user      | name, oid                  |
| database  | text, oid                  |
| privilege | text                       |

Return type: Boolean

- `has_database_privilege(database, privilege)`

Description: Specifies whether the current user has permission to access a database. For details about the valid parameter types, see [Table 7-37](#).

Return type: Boolean

Note: **has\_database\_privilege** checks whether a user can access a database in a particular way. Its argument possibilities are analogous to **has\_table\_privilege**. The desired access permission must be some combination of CREATE, CONNECT, TEMPORARY, ALTER, DROP, COMMENT or TEMP (which is equivalent to TEMPORARY).

- `has_directory_privilege(user, directory, privilege)`

Description: Specifies whether a specified user has permission for accessing directories.

**Table 7-38** Parameter type description

| Parameter | Valid Input Parameter Type |
|-----------|----------------------------|
| user      | name, oid                  |
| directory | text, oid                  |
| privilege | text                       |

Return type: Boolean

- `has_directory_privilege(directory, privilege)`

Description: Specifies whether the current user has permission to access a directory. For details about the valid parameter types, see [Table 7-38](#).

Return type: Boolean

- `has_foreign_data_wrapper_privilege(user, fdw, privilege)`

Description: Specifies whether a specified user has permission for accessing foreign data wrappers.

**Table 7-39** Parameter type description

| Parameter | Valid Input Parameter Type |
|-----------|----------------------------|
| user      | name, oid                  |
| fdw       | text, oid                  |
| privilege | text                       |

Return type: Boolean

- `has_foreign_data_wrapper_privilege(fdw, privilege)`

Description: Specifies whether the current user has permission for accessing foreign data wrappers. For details about the valid parameter types, see [Table 7-39](#).

Return type: Boolean

Note: **has\_foreign\_data\_wrapper\_privilege** checks whether a user can access a foreign data wrapper in a particular way. Its argument possibilities are analogous to **has\_table\_privilege**. The desired access permission must be USAGE.

- **has\_function\_privilege**(user, function, privilege)

Description: Specifies whether a specified user has permission for accessing functions.

**Table 7-40** Parameter type description

| Parameter | Valid Input Parameter Type |
|-----------|----------------------------|
| user      | name, oid                  |
| function  | text, oid                  |
| privilege | text                       |

Return type: Boolean

- **has\_function\_privilege**(function, privilege)

Description: Specifies whether the current user has permission for accessing functions. For details about the valid parameter types, see [Table 7-40](#).

Return type: Boolean

Note: **has\_function\_privilege** checks whether a user can access a function in a particular way. Its argument possibilities are analogous to **has\_table\_privilege**. When a function is specified by a text string rather than by OID, the allowed input is the same as that for the **regprocedure** data type (see [OID Types](#)). The access permission must be EXECUTE, ALTER, DROP, or COMMENT.

- **has\_language\_privilege**(user, language, privilege)

Description: Specifies whether a specified user has permission for accessing languages.

**Table 7-41** Parameter type description

| Parameter | Valid Input Parameter Type |
|-----------|----------------------------|
| user      | name, oid                  |
| language  | text, oid                  |
| privilege | text                       |

Return type: Boolean

- `has_language_privilege(language, privilege)`  
Description: Specifies whether the current user has permission for accessing languages. For details about the valid parameter types, see [Table 7-41](#).  
Return type: Boolean  
Note: **has\_language\_privilege** checks whether a user can access a procedural language in a particular way. Its argument possibilities are analogous to **has\_table\_privilege**. The desired access permission must be USAGE.
- `has_nodegroup_privilege(user, nodegroup, privilege)`  
Description: Checks whether a user has permission to access a database node.  
Return type: Boolean

**Table 7-42** Parameter type description

| Parameter | Valid Input Parameter Type |
|-----------|----------------------------|
| user      | name, oid                  |
| nodegroup | text, oid                  |
| privilege | text                       |

- `has_nodegroup_privilege(nodegroup, privilege)`  
Description: Checks whether a user has permission to access a database node. The parameter is similar to **has\_table\_privilege**. The access permission must be USAGE, CREATE, COMPUTE, ALTER, or DROP.  
Return type: Boolean
- `has_schema_privilege(user, schema, privilege)`  
Description: Specifies whether a specified user has permission for accessing schemas.  
Return type: Boolean
- `has_schema_privilege(schema, privilege)`  
Description: Specifies whether the current user has permission for accessing schemas.  
Return type: Boolean  
Note: **has\_schema\_privilege** checks whether a user can access a schema in a particular way. Its argument possibilities are analogous to **has\_table\_privilege**. The desired access permission must be some combination of CREATE, USAGE, ALTER, DROP or COMMENT.
- `has_server_privilege(user, server, privilege)`  
Description: Specifies whether a specified user has permission for accessing foreign servers.  
Return type: Boolean
- `has_server_privilege(server, privilege)`  
Description: Specifies whether the current user has permission for accessing foreign servers.  
Return type: Boolean

Note: **has\_server\_privilege** checks whether a user can access a foreign server in a particular way. Its argument possibilities are analogous to **has\_table\_privilege**. The access permission must be USAGE, ALTER, DROP, or COMMENT.

- **has\_table\_privilege(user, table, privilege)**

Description: Specifies whether a specified user has permission for accessing tables.

Return type: Boolean

- **has\_table\_privilege(table, privilege)**

Description: Specifies whether the current user has permission for accessing tables.

Return type: Boolean

Note: **has\_table\_privilege** checks whether a user can access a table in a particular way. The user can be specified by name or by OID (**pg\_authid.oid**), or be set to **public** which indicates the PUBLIC role. If this parameter is omitted, **current\_user** is used. The table can be specified by name or by OID. When it is specified by name, the name can be schema-qualified if necessary. The desired access permission is specified by a text string, which must be SELECT, INSERT, UPDATE, DELETE, TRUNCATE, REFERENCES, TRIGGER, ALTER, DROP, COMMENT, INDEX or VACUUM. Optionally, **WITH GRANT OPTION** can be added to a permission type to test whether the permission is held with grant option. Also, multiple permission types can be listed separated by commas, in which case the result will be **true** if any of the listed permissions is held.

Example:

```
openGauss=# SELECT has_table_privilege('tpcds.web_site', 'select');
has_table_privilege

t
(1 row)

openGauss=# SELECT has_table_privilege('omm', 'tpcds.web_site', 'select,INSERT WITH GRANT
OPTION ');
has_table_privilege

t
(1 row)
```

- **has\_tablespace\_privilege(user, tablespace, privilege)**

Description: Specifies whether a specified user has permission for tablespaces.

Return type: Boolean

- **has\_tablespace\_privilege(tablespace, privilege)**

Description: Specifies whether the current user has permission for tablespaces.

Return type: Boolean

Note: **has\_tablespace\_privilege** checks whether a user can access a tablespace in a particular way. Its argument possibilities are analogous to **has\_table\_privilege**. The access permission must be CREATE, ALTER, DROP, or COMMENT.

- **pg\_has\_role(user, role, privilege)**

Description: Specifies whether a specified user has permission for accessing roles.

Return type: Boolean

- `pg_has_role(role, privilege)`

Description: Specifies whether the current user has permission for accessing roles.

Return type: Boolean

Note: **pg\_has\_role** checks whether a user can access a role in a particular way. Its parameter possibilities are analogous to those of **has\_table\_privilege**, except that **public** cannot be used as a username. The desired access permission must be some combination of MEMBER and USAGE. MEMBER denotes direct or indirect membership in the role (that is, the SET ROLE permission), while USAGE denotes the permissions of the role are available without SET ROLE.

- `has_any_privilege(user, privilege)`

Description: Queries whether a specified user has certain ANY permission. If multiple permissions are queried at the same time, **true** is returned as long as one permission is obtained.

Return type: Boolean

**Table 7-43** Parameter type description

| Parameter | Valid Input Parameter Type | Description | Range             |
|-----------|----------------------------|-------------|-------------------|
| user      | name                       | User        | Existing username |

| Parameter | Valid Input Parameter Type | Description    | Range                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-----------|----------------------------|----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| privilege | text                       | ANY permission | Available values:<br>CREATE ANY TABLE [WITH ADMIN OPTION]<br>ALTER ANY TABLE [WITH ADMIN OPTION]<br>DROP ANY TABLE [WITH ADMIN OPTION]<br>SELECT ANY TABLE [WITH ADMIN OPTION]<br>INSERT ANY TABLE [WITH ADMIN OPTION]<br>UPDATE ANY TABLE [WITH ADMIN OPTION]<br>DELETE ANY TABLE [WITH ADMIN OPTION]<br>CREATE ANY SEQUENCE [WITH ADMIN OPTION]<br>CREATE ANY INDEX [WITH ADMIN OPTION]<br>CREATE ANY FUNCTION [WITH ADMIN OPTION]<br>EXECUTE ANY FUNCTION [WITH ADMIN OPTION]<br>CREATE ANY PACKAGE [WITH ADMIN OPTION]<br>EXECUTE ANY PACKAGE [WITH ADMIN OPTION]<br>CREATE ANY TYPE [WITH ADMIN OPTION] |

## Schema Visibility Inquiry Functions

Each function performs the visibility check for one type of database object. For functions and operators, an object in the search path is visible if there is no object of the same name and parameter data type earlier in the path. For operator classes, both name and associated index access methods are considered.

All these functions require OIDs to identify the objects to be checked. If you want to test an object by name, it is convenient to use the OID alias type (**regclass**, **regtype**, **regprocedure**, **regoperator**, **regconfig**, or **regdictionary**).

For example, a table is said to be visible if its containing schema is in the search path and no table of the same name appears earlier in the search path. This is

equivalent to the statement that the table can be referenced by name without explicit schema qualification. For example, to list the names of all visible tables:

```
openGauss=# SELECT relname FROM pg_class WHERE pg_table_is_visible(oid);
```

- `pg_collation_is_visible(collation_oid)`  
Description: Specifies whether the collation is visible in search path.  
Return type: Boolean
- `pg_conversion_is_visible(conversion_oid)`  
Description: Specifies whether the conversion is visible in search path.  
Return type: Boolean
- `pg_function_is_visible(function_oid)`  
Description: Specifies whether the function is visible in search path.  
Return type: Boolean
- `pg_opclass_is_visible(opclass_oid)`  
Description: Specifies whether the operator class is visible in search path.  
Return type: Boolean
- `pg_operator_is_visible(operator_oid)`  
Description: Specifies whether the operator is visible in search path.  
Return type: Boolean
- `pg_opfamily_is_visible(opclass_oid)`  
Description: Specifies whether the operator family is visible in search path.  
Return type: Boolean
- `pg_table_is_visible(table_oid)`  
Description: Specifies whether the table is visible in search path.  
Return type: Boolean
- `pg_ts_config_is_visible(config_oid)`  
Description: Specifies whether the text search configuration is visible in search path.  
Return type: Boolean
- `pg_ts_dict_is_visible(dict_oid)`  
Description: Specifies whether the text search dictionary is visible in search path.  
Return type: Boolean
- `pg_ts_parser_is_visible(parser_oid)`  
Description: Specifies whether the text search parser is visible in search path.  
Return type: Boolean
- `pg_ts_template_is_visible(template_oid)`  
Description: Specifies whether the text search template is visible in search path.  
Return type: Boolean
- `pg_type_is_visible(type_oid)`  
Description: Specifies whether the type (or domain) is visible in search path.  
Return type: Boolean

## System Catalog Information Functions

- `format_type(type_oid, typemod)`

Description: Obtains the SQL name of a data type.

Return type: text

Note: **format\_type** returns the SQL name of a data type based on the OID of the data type and possible modifiers. If the specific modifier is unknown, pass **NULL** at the position of the modifier. Modifiers are generally meaningful only for data types with length restrictions. The SQL name returned by **format\_type** contains the length of the data type, which can be calculated by taking `sizeof(int32)` from actual storage length [actual storage len - `sizeof(int32)`] in the unit of bytes. 32-bit space is required to store the customized length set by users. So the actual storage length contains 4 bytes more than the customized length. In the following example, the SQL name returned from **format\_type** is `character varying(6)`, indicating the length of `varchar` type is 6 bytes. So the actual storage length of `varchar` type is 10 bytes.

```
openGauss=# SELECT format_type((SELECT oid FROM pg_type WHERE typname='varchar'), 10);
format_type

character varying(6)
(1 row)
```

- `getdistributekey(table_name)`

Description: Obtains a distribution key for a hash table. Distribution is not supported in a standalone system and the return value of this function is empty.

- `pg_check_authid(role_oid)`

Description: Checks whether a role name with a given OID exists.

Return type: Boolean

Example:

```
openGauss=# select pg_check_authid(1);
pg_check_authid

f
(1 row)
```

- `pg_describe_object(catalog_id, object_id, object_sub_id)`

Description: Obtains the description of a database object.

Return type: text

Note: **pg\_describe\_object** returns a description of a database object specified by catalog OID, object OID and a (possibly zero) sub-object ID. This is useful to determine the identity of an object as stored in the **pg\_depend** catalog.

- `pg_get_constraintdef(constraint_oid)`

Description: Obtains the definition of a constraint.

Return type: text

- `pg_get_constraintdef(constraint_oid, pretty_bool)`

Description: Obtains the definition of a constraint.

Return type: text

Note: **pg\_get\_constraintdef** and **pg\_get\_indexdef** respectively reconstruct the creating command for a constraint and an index.

- `pg_get_expr(pg_node_tree, relation_oid)`  
Description: Decompiles internal form of an expression, assuming that any Vars in it refer to the relationship indicated by the second parameter.  
Return type: text
- `pg_get_expr(pg_node_tree, relation_oid, pretty_bool)`  
Description: Decompiles internal form of an expression, assuming that any Vars in it refer to the relationship indicated by the second parameter.  
Return type: text  
Note: **pg\_get\_expr** decompiles the internal form of an individual expression, such as the default value for a column. It can be useful when examining the contents of system catalogs. If the expression might contain Vars, specify the OID of the relationship they refer to as the second parameter; if no Vars are expected, zero is sufficient.
- `pg_get_functiondef(func_oid)`  
Description: Obtains the definition of a function.  
Return type: text  
Example:  

```
openGauss=# select * from pg_get_functiondef(598);
headerlines | definition
-----+-----
4 | CREATE OR REPLACE FUNCTION pg_catalog.abbrev(inet)+
 | RETURNS text +
 | LANGUAGE internal +
 | IMMUTABLE STRICT NOT FENCED NOT SHIPPABLE +
 | AS $function$inet_abbrev$function$ +
 |
(1 row)
```
- `pg_get_function_arguments(func_oid)`  
Description: Obtains the parameter list of the function's definition (with default values).  
Return type: text  
Note: **pg\_get\_function\_arguments** returns the parameter list of a function, in the form it would need to appear in within **CREATE FUNCTION**.
- `pg_get_function_identity_arguments(func_oid)`  
Description: Obtains the parameter list to identify a function (without default values).  
Return type: text  
Note: **pg\_get\_function\_identity\_arguments** returns the parameter list necessary to identify a function, in the form it would need to appear in within **ALTER FUNCTION**. This form omits default values.
- `pg_get_function_result(func_oid)`  
Description: Obtains the **RETURNS** clause for a function.  
Return type: text  
Note: **pg\_get\_function\_result** returns the appropriate **RETURNS** clause for the function.
- `pg_get_indexdef(index_oid)`  
Description: Obtains the **CREATE INDEX** command for an index.  
Return type: text

## Example:

```
openGauss=# select * from pg_get_indexdef(16416);
 pg_get_indexdef

CREATE INDEX test3_b_idx ON test3 USING btree (b) TABLESPACE pg_default
(1 row)
```

- `pg_get_indexdef(index_oid, dump_schema_only)`

Description: Obtains the **CREATE INDEX** command for indexes in dump scenarios. For an interval partitioned table that contains a local index, if **dump\_schema\_only** is set to **true**, the returned index creation statement does not contain the local index information of the automatically created partition. If **dump\_schema\_only** is set to **false**, the returned index creation statement contains the local index information of the automatically created partition. For a non-interval partitioned table or an interval partitioned table that does not contain a local index, the value of **dump\_schema\_only** does not affect the returned result of the function.

Return type: text

## Example:

```
openGauss=# CREATE TABLE sales
openGauss=# (prod_id NUMBER(6),
openGauss=# cust_id NUMBER,
openGauss=# time_id DATE,
openGauss=# channel_id CHAR(1),
openGauss=# promo_id NUMBER(6),
openGauss=# quantity_sold NUMBER(3),
openGauss=# amount_sold NUMBER(10,2)
openGauss=#)
PARTITION BY RANGE(time_id) INTERVAL('1 day')
openGauss=# (
openGauss=# partition p1 VALUES LESS THAN ('2019-02-01 00:00:00'),
openGauss=# partition p2 VALUES LESS THAN ('2019-02-02 00:00:00')
openGauss=#);
CREATE TABLE
openGauss=# create index index_sales on sales(prod_id) local (PARTITION idx_p1 ,PARTITION idx_p2);
CREATE INDEX
openGauss=#-- If the data to be inserted does not match any partition, create a partition and insert
the data into the new partition.
openGauss=# INSERT INTO sales VALUES(1, 12, '2019-02-05 00:00:00', 'a', 1, 1, 1);
INSERT 0 1
openGauss=# select oid from pg_class where relname = 'index_sales';
 oid

24632
(1 row)
openGauss=# select * from pg_get_indexdef(24632, true);
 pg_get_indexdef

CREATE INDEX index_sales ON sales USING btree (prod_id) LOCAL(PARTITION idx_p1, PARTITION
idx_p2) TABLESPACE pg_default
(1 row)
openGauss=# select * from pg_get_indexdef(24632, false);
 pg_get_indexdef

CREATE INDEX index_sales ON sales USING btree (prod_id) LOCAL(PARTITION idx_p1, PARTITION
idx_p2, PARTITION sys_p1_prod_id_idx) TA
BLESPEACE pg_default
(1 row)
```

- `pg_get_indexdef(index_oid, column_no, pretty_bool)`

Description: Obtains the **CREATE INDEX** command for an index, or definition of just one index column when **column\_no** is not zero.

Example:

```
openGauss=# select * from pg_get_indexdef(16416, 0, false);
 pg_get_indexdef

CREATE INDEX test3_b_idx ON test3 USING btree (b) TABLESPACE pg_default
(1 row)
openGauss=# select * from pg_get_indexdef(16416, 1, false);
 pg_get_indexdef

b
(1 row)
```

Return type: text

Note: **pg\_get\_functiondef** returns a complete **CREATE OR REPLACE FUNCTION** statement for a function.

- **pg\_get\_keywords()**

Description: Obtains the list of SQL keywords and their categories.

Return type: SETOF record

Note: **pg\_get\_keywords** returns a set of records describing the SQL keywords recognized by the server. The **word** column contains the keyword. The **catcode** column contains a category code: **U** for unreserved, **C** for column name, **T** for type or function name, or **R** for reserved. The **catdesc** column contains a possibly-localized string describing the category.

- **pg\_get\_userbyid(role\_oid)**

Description: Obtains the role name with a given OID.

Return type: name

Note: **pg\_get\_userbyid** extracts a role's name given its OID.

- **pg\_check\_authid(role\_id)**

Description: Checks whether a user exists based on **role\_id**.

Return type: text

Example:

```
openGauss=# select pg_check_authid(20);
 pg_check_authid

f
(1 row)
```

- **pg\_get\_viewdef(view\_name)**

Description: Obtains the underlying **SELECT** command for a view.

Return type: text

- **pg\_get\_viewdef(view\_name, pretty\_bool)**

Description: Obtains the underlying **SELECT** command for a view, lines with columns are wrapped to 80 columns if **pretty\_bool** is set to **true**.

Return type: text

Note: **pg\_get\_viewdef** reconstructs the **SELECT** query that defines a view. Most of these functions come in two variants. When the function has the parameter **pretty\_bool** and the value is true, it can optionally "pretty-print" the result. The pretty-printed format is more readable. The other one is the default format which is more likely to be interpreted in the same way by future versions. Avoid using pretty-printed output for dump purposes. Passing

**false** to the pretty-print parameter generates the same result as a variant without this parameter.

- `pg_get_viewdef(view_oid)`

Description: Obtains the underlying **SELECT** command for a view.

Return type: text

- `pg_get_viewdef(view_oid, pretty_bool)`

Description: Obtains the underlying **SELECT** command for a view, lines with columns are wrapped to 80 columns if **pretty\_bool** is set to **true**.

Return type: text

- `pg_get_viewdef(view_oid, wrap_column_int)`

Description: Obtains the underlying **SELECT** command for a view, wrapping lines with columns as specified, printing is implied.

Return type: text

- `pg_get_tabledef(table_oid)`

Description: Obtains a table definition based on **table\_oid**.

Example:

```
openGauss=# select * from pg_get_tabledef(16384);
 pg_get_tabledef

SET search_path = public;
CREATE TABLE t1 (
 c1 bigint DEFAULT nextval('serial'::regclass)+
)
WITH (orientation=row)
TO GROUP group1;
(1 row)
```

Return type: text

- `pg_get_tabledef(table_name)`

Description: Obtains a table definition based on **table\_name**.

Example:

```
openGauss=# select * from pg_get_tabledef('t1');
 pg_get_tabledef

SET search_path = public;
CREATE TABLE t1 (
 c1 bigint DEFAULT nextval('serial'::regclass)+
)
WITH (orientation=row)
TO GROUP group1;
(1 row)
```

Return type: text

Remarks: **pg\_get\_tabledef** reconstructs the **CREATE** statement of the table definition, including the table definition, index information, and comments. Users need to create the dependent objects of the table, such as groups, schemas, tablespaces, and servers. The table definition does not include the statements for creating these dependent objects.

- `pg_options_to_table(reloptions)`

Description: Obtains the set of storage option name/value pairs.

Return type: SETOF record

Note: **pg\_options\_to\_table** returns the set of storage option name/value pairs (**option\_name/option\_value**) when passed **pg\_class.reloptions** or **pg\_attribute.attoptions**.

- pg\_tablespace\_databases(tablespace\_oid)**

Description: Obtains the set of database OIDs that have objects in the specified tablespace.

Return type: SETOF oid

Note: **pg\_tablespace\_databases** allows a tablespace to be examined. It returns the set of OIDs of databases that have objects stored in the tablespace. If this function returns any rows, the tablespace is not empty and cannot be dropped. To display the specific objects populating the tablespace, you will need to connect to the databases identified by **pg\_tablespace\_databases** and query their **pg\_class** catalogs.
- pg\_tablespace\_location(tablespace\_oid)**

Description: Obtains the path in the file system that this tablespace is located in.

Return type: text
- pg\_typeof(any)**

Description: Obtains the data type of any value.

Return type: regtype

Note: **pg\_typeof** returns the OID of the data type of the value that is passed to it. This can be helpful for troubleshooting or dynamically constructing SQL queries. The function is declared as returning **regtype**, which is an OID alias type (see [OID Types](#)). This means that it is the same as an OID for comparison purposes but displays as a type name.

Example:

```
openGauss=# SELECT pg_typeof(33);
pg_typeof

integer
(1 row)

openGauss=# SELECT typen FROM pg_type WHERE oid = pg_typeof(33);
typen

4
(1 row)
```
- collation for (any)**

Description: Obtains the collation of the parameter.

Return type: text

Note: The expression **collation for** returns the collation of the value that is passed to it.

Example:

```
openGauss=# SELECT collation for (description) FROM pg_description LIMIT 1;
pg_collation_for

"default"
(1 row)
```

The value might be quoted and schema-qualified. If no collation is derived for the argument expression, then a null value is returned. If the parameter is not of a collectable data type, then an error is thrown.
- pg\_get\_serial\_sequence(tablename, colname)**

Description: Obtains the sequence of the corresponding table name and column name.

Return type: text

Example:

```
openGauss=# select * from pg_get_serial_sequence('t1', 'c1');
pg_get_serial_sequence

public.serial
(1 row)
```

- `pg_sequence_parameters(sequence_oid)`

Description: Obtains the parameters of a specified sequence, including the start value, minimum value, maximum value, and incremental value.

Return type: int16, int16, int16, int16, Boolean

Example:

```
openGauss=# select * from pg_sequence_parameters(16420);
start_value | minimum_value | maximum_value | increment | cycle_option
-----+-----+-----+-----+-----
101 | 1 | 9223372036854775807 | 1 | f
(1 row)
```

## Comment Information Functions

- `col_description(table_oid, column_number)`

Description: Obtains the comment for a table column.

Return type: text

Note: **col\_description** returns the comment for a table column, which is specified by the OID of its table and its column number.

- `obj_description(object_oid, catalog_name)`

Description: Obtains the comment for a database object.

Return type: text

Note: The two-parameter form of **obj\_description** returns the comment for a database object specified by its OID and the name of the containing system catalog. For example, **obj\_description(123456,'pg\_class')** would retrieve the comment for the table with OID 123456. The one-parameter form of **obj\_description** requires only the object OID.

**obj\_description** cannot be used for table columns since columns do not have OIDs of their own.

- `obj_description(object_oid)`

Description: Obtains the comment for a database object.

Return type: text

- `shobj_description(object_oid, catalog_name)`

Description: Obtains the comment for a shared database object.

Return type: text

Note: **shobj\_description** is used just like **obj\_description** except the former is used for retrieving comments on shared objects. Some system catalogs are global to all databases in GaussDB, and the comments for objects in them are stored globally as well.

## Transaction IDs and Snapshots

Internal transaction IDs (XIDs) are 64 bits. **txid\_snapshot**, the data type used by these functions, stores information about transaction ID visibility at a particular moment. [Table 7-44](#) describes its components.

**Table 7-44** Snapshot components

| Name     | Description                                                                                                                                                                                                                                                                                                                                                                                                                      |
|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| xmin     | Earliest transaction ID (txid) that is still active. All earlier transactions will either be committed and visible, or rolled back.                                                                                                                                                                                                                                                                                              |
| xmax     | First as-yet-unassigned txid. All txids greater than or equal to this are not yet started as of the time of the snapshot, so they are invisible.                                                                                                                                                                                                                                                                                 |
| xip_list | Active txids at the time of the snapshot. The list includes only those active txids between <b>xmin</b> and <b>xmax</b> ; there might be active txids higher than <b>xmax</b> . A txid that is <b>xmin</b> ≤ <b>txid</b> < <b>xmax</b> and not in this list was already completed at the time of the snapshot, and is either visible or dead according to its commit status. The list does not include txids of subtransactions. |

**txid\_snapshot**'s textual representation is **xmin:xmax:xip\_list**.

For example, **10:20:10,14,15** means **xmin=10**, **xmax=20**, **xip\_list=10, 14, 15**.

The following functions provide server transaction information in an exportable form. The main use of these functions is to determine which transactions were committed between two snapshots.

- **txid\_current()**  
Description: Obtains the current transaction ID.  
Return type: bigint
- **gs\_txid\_oldestxmin()**  
Description: Obtains the minimum transaction ID (specified by **oldesxmin**).  
Return type: bigint
- **txid\_current\_snapshot()**  
Description: Obtains the current snapshot.  
Return type: txid\_snapshot
- **txid\_snapshot\_xip(txid\_snapshot)**  
Description: Obtains in-progress transaction IDs in a snapshot.  
Return type: SETOF bigint
- **txid\_snapshot\_xmax(txid\_snapshot)**  
Description: Obtains **xmax** of snapshots.  
Return type: bigint
- **txid\_snapshot\_xmin(txid\_snapshot)**  
Description: Obtains **xmin** of snapshots.

- Return type: bigint
- `txid_visible_in_snapshot(bigint, txid_snapshot)`  
Description: Specifies whether the transaction ID is visible in a snapshot (do not use subtransaction IDs).  
Return type: Boolean
  - `get_local_prepared_xact()`  
Description: Obtains the two-phase residual transaction information of the current node, including the transaction ID, GID of the two-phase transaction, prepared time, owner OID, database OID, and node name of the current node.  
Return type: xid, text, timestamptz, oid, oid, text
  - `get_remote_prepared_xacts()`  
Description: Obtains the two-phase residual transaction information of all remote nodes, including the transaction ID, GID of the two-phase transaction, prepared time, owner name, database name, and node name.  
Return type: xid, text, timestamptz, name, name, text
  - `global_clean_prepared_xacts(text, text)`  
Description: Concurrently cleans two-phase residual transactions. Only the **gs\_clean** tool can call this function for the cleaning. In other situations, **false** is returned. This function is not supported in the centralized mode.  
Return type: Boolean
  - `gs_get_next_xid_csn()`  
Description: Returns the values of **next\_xid** and **next\_csn** on all nodes globally.  
The return values are as follows:

**Table 7-45** `gs_get_next_xid_csn` parameters

| Column   | Description                              |
|----------|------------------------------------------|
| nodename | Node name.                               |
| next_xid | Next transaction ID of the current node. |
| next_csn | Next CSN of the current node.            |

- `pg_control_system()`  
Description: Returns the status of the system control file.  
Return type: SETOF record
- `pg_control_checkpoint()`  
Description: Returns the system checkpoint status.  
Return type: SETOF record
- `pv_built_in_functions`  
Description: Displays information about all built-in system functions.  
Parameter: nan  
Return type: pronom name, pronomspace oid, proowner oid, proleng oid, procost real, prorows real, provariadic oid, protransform regproc, proisagg

Boolean, proiswindow Boolean, prosecdef Boolean, proleakproof Boolean, proisstrict Boolean, prorerset Boolean, provolatile "char", pronargs smallint, pronargdefaults smallint, prorettytype oid, proargtypes oidvector, proallargtypes integer[], proargmodes "char"[], proargnames text[], proargdefaults pg\_node\_tree, prosrc text, probin text, proconfig text[], proacl aclitem[], prodefaultargpos int2vector, fencedmode Boolean, proshippable Boolean, propackage Boolean, oid oid

- `pv_thread_memory_detail`

Description: Returns the memory information of each thread.

Parameter: nan

Return type: threadid text, tid bigint, thrdtype text, contextname text, level smallint, parent text, totalsize bigint, freesize bigint, usedsize bigint

- `pg_stat_file_recursive`

Description: Lists all files in a path.

Parameter: location text

- `pg_shared_memory_detail`

Description: Returns usage information about all generated shared memory contexts. For details about each column, see [GS\\_SHARED\\_MEMORY\\_DETAIL](#).

Parameter: nan

Return type: contextname text, level smallint, parent text, totalsize bigint, freesize bigint, usedsize bigint

- `get_gtm_lite_status`

**Description:** Returns the backup XID and CSN on the GTM for fault locating. This system function is not supported in GTM-FREE mode or centralized deployment.

- `gs_stat_get_wlm_plan_operator_info`

Description: Obtains operator plan information from the internal hash table.

Parameter: oid

Return type: datname text, queryid int8, plan\_node\_id int4, startup\_time int8, total\_time int8, actual\_rows int8, max\_peak\_memory int4, query\_dop int4, parent\_node\_id int4, left\_child\_id int4, right\_child\_id int4, operation text, orientation text, strategy text, options text, condition text, projection text

- `pg_stat_get_partition_tuples_hot_updated(oid)`

Description: Returns statistics on the number of hot-updated tuples in a partition with a specified partition ID.

Parameter: oid

Return type: bigint

- `gs_session_memory_detail_tp`

Description: Returns the memory usage of the session. For details, see [gs\\_session\\_memory\\_detail](#).

Parameter: nan

Return type: sessid text, sesstype text, contextname text, level smallint, parent text, totalsize bigint, freesize bigint, usedsize bigint

- `gs_thread_memory_detail`

Description: Returns the memory information of each thread.

Parameter: nan

Return type: threadid text, tid bigint, thrdtype text, contextname text, level smallint, parent text, totalsize bigint, freesize bigint, usedsize bigint

- pg\_stat\_get\_wlm\_realtime\_operator\_info

Description: Obtains the operator information of the real-time execution plan from the internal hash table.

Parameter: nan

Return type: queryid bigint, pid bigint, plan\_node\_id integer, plan\_node\_name text, start\_time timestamp with time zone, duration bigint, status text, query\_dop integer, estimated\_rows bigint, tuple\_processed bigint, min\_peak\_memory integer, max\_peak\_memory integer, average\_peak\_memory integer, memory\_skew\_percent integer, min\_spill\_size integer, max\_spill\_size integer, average\_spill\_size integer, spill\_skew\_percent integer, min\_cpu\_time bigint, max\_cpu\_time bigint, total\_cpu\_time bigint, cpu\_skew\_percent integer, warning text

- pg\_stat\_get\_wlm\_operator\_info

Description: Obtains the operator information of the execution plan from the internal hash table.

Parameter: nan

Return type: queryid bigint, pid bigint, plan\_node\_id integer, plan\_node\_name text, start\_time timestamp with time zone, duration bigint, query\_dop integer, estimated\_rows bigint, tuple\_processed bigint, min\_peak\_memory integer, max\_peak\_memory integer, average\_peak\_memory integer, memory\_skew\_percent integer, min\_spill\_size integer, max\_spill\_size integer, average\_spill\_size integer, spill\_skew\_percent integer, min\_cpu\_time bigint, max\_cpu\_time bigint, total\_cpu\_time bigint, cpu\_skew\_percent integer, warning text

- pg\_stat\_get\_wlm\_node\_resource\_info

Description: Obtains the resource information of the current node.

Parameter: nan

Return type: min\_mem\_util integer, max\_mem\_util integer, min\_cpu\_util integer, max\_cpu\_util integer, min\_io\_util integer, max\_io\_util integer, used\_mem\_rate integer

- pg\_stat\_get\_session\_wlmstat

Description: Returns the load information of the current session.

Parameter: pid integer

Return type: datid oid, threadid bigint, sessionid bigint, threadpid integer, usesysid oid, appname text, query text, priority bigint, block\_time bigint, elapsed\_time bigint, total\_cpu\_time bigint, skew\_percent integer, statement\_mem integer, active\_points integer, dop\_value integer, current\_cgroup text, current\_status text, enqueue\_state text, attribute text, is\_plana Boolean, node\_group text, srespool name

- pg\_stat\_get\_wlm\_instance\_info

Description: Returns the load information of the current instance.

Parameter: nan

Return type: instancename text, timestamp, timestamp with time zone, used\_cpu integer, free\_memory integer, used\_memory integer, io\_await double

precision, io\_util double precision, disk\_read double precision, disk\_write double precision, process\_read bigint, process\_write bigint, logical\_read bigint, logical\_write bigint, read\_counts bigint, write\_counts bigint

- `pg_stat_get_wlm_instance_info_with_cleanup`

Description: Returns the load information of the current instance and saves the information to the system catalog.

Parameter: nan

Return type: instancename text, timestamp, timestamp with time zone, used\_cpu integer, free\_memory integer, used\_memory integer, io\_await double precision, io\_util double precision, disk\_read double precision, disk\_write double precision, process\_read bigint, process\_write bigint, logical\_read bigint, logical\_write bigint, read\_counts bigint, write\_counts bigint

- `pg_stat_get_wlm_realtime_session_info`

Description: Returns the load information of the real-time session.

Parameter: nan

Return type: nodename text, threadid bigint, block\_time bigint, duration bigint, estimate\_total\_time bigint, estimate\_left\_time bigint, schemaname text, query\_band text, spill\_info text, control\_group text, estimate\_memory integer, min\_peak\_memory integer, max\_peak\_memory integer, average\_peak\_memory integer, memory\_skew\_percent integer, min\_spill\_size integer, max\_spill\_size integer, average\_spill\_size integer, spill\_skew\_percent integer, min\_dn\_time bigint, max\_dn\_time bigint, average\_dn\_time bigint, dntime\_skew\_percent integer, min\_cpu\_time bigint, max\_cpu\_time bigint, total\_cpu\_time bigint, cpu\_skew\_percent integer, min\_peak\_iops integer, max\_peak\_iops integer, average\_peak\_iops integer, iops\_skew\_percent integer, warning text, query text, query\_plan text, cpu\_top1\_node\_name text, cpu\_top2\_node\_name text, cpu\_top3\_node\_name text, cpu\_top4\_node\_name text, cpu\_top5\_node\_name text, mem\_top1\_node\_name text, mem\_top2\_node\_name text, mem\_top3\_node\_name text, mem\_top4\_node\_name text, mem\_top5\_node\_name text, cpu\_top1\_value bigint, cpu\_top2\_value bigint, cpu\_top3\_value bigint, cpu\_top4\_value bigint, cpu\_top5\_value bigint, mem\_top1\_value bigint, mem\_top2\_value bigint, mem\_top3\_value bigint, mem\_top4\_value bigint, mem\_top5\_value bigint, top\_mem\_dn text, top\_cpu\_dn text

- `pg_stat_get_wlm_session_iostat_info`

Description: Returns the session load I/O information.

Parameter: nan

Return type: threadid bigint, maxcurr\_iops integer, mincurr\_iops integer, maxpeak\_iops integer, minpeak\_iops integer, iops\_limits integer, io\_priority integer, curr\_io\_limits integer

- `pg_stat_get_wlm_statistics`

Description: Returns session load statistics.

Parameter: nan

Return type: statement text, block\_time bigint, elapsed\_time bigint, total\_cpu\_time bigint, qualification\_time bigint, skew\_percent integer, control\_group text, status text, action text

## 7.5.23 System Administration Functions

### 7.5.23.1 Configuration Settings Functions

Configuration setting functions are used for querying and modifying configuration parameters during running.

- `current_setting(setting_name)`

Description: Specifies the current setting.

Return type: text

Note: **current\_setting** obtains the current setting of **setting\_name** by query. It is equivalent to the **SHOW** statement.

Example:

```
openGauss=# SELECT current_setting('datestyle');
```

```
current_setting

ISO, MDY
(1 row)
```

- `set_working_grand_version_num_manually(tmp_version)`

Description: Upgrades new features of the database by switching the authorization version.

Return type: void

- `shell_in(type)`

Description: Inputs a route for the shell type that has not yet been filled.

Return type: void

- `shell_out(type)`

Description: Outputs a route for the shell type that has not yet been filled.

Return type: void

- `set_config(setting_name, new_value, is_local)`

Description: Sets the parameter and returns a new value.

Return type: text

Note: **set\_config** sets **setting\_name** to **new\_value**. If **is\_local** is set to **true**, **new\_value** applies only to the current transaction. If you want **new\_value** to apply for the current session, set the value to **false** instead. The function corresponds to the **SET** statement.

Example:

```
openGauss=# SELECT set_config('log_statement_stats', 'off', false);
```

```
set_config

off
(1 row)
```

### 7.5.23.2 Universal File Access Functions

Universal file access functions provide local access APIs for files on a database server. Only files in the database directory and the **log\_directory** directory can be accessed. Use a relative path for files in the database directory, and a path

matching the **log\_directory** configuration setting for log files. Only the database initial user can use these functions.

- **pg\_ls\_dir**(dirname text)

Description: Lists files in a directory.

Return type: setof text

Note: **pg\_ls\_dir** returns all the names in the specified directory, except the special entries "." and "..".

Example:

```
openGauss=# SELECT pg_ls_dir('./');
 pg_ls_dir

.postgresql.conf.swp
postgresql.conf
pg_tblspc
PG_VERSION
pg_ident.conf
core
server.crt
pg_serial
pg_twophase
postgresql.conf.lock
pg_stat_tmp
pg_notify
pg_subtrans
pg_ctl.lock
pg_xlog
pg_clog
base
pg_snapshots
postmaster.opts
postmaster.pid
server.key.rand
server.key.cipher
pg_multixact
pg_errorinfo
server.key
pg_hba.conf
pg_replslot
.pg_hba.conf.swp
cacert.pem
pg_hba.conf.lock
global
gaussdb.state
(32 rows)
```

- **pg\_read\_file**(filename text, offset bigint, length bigint)

Description: Returns the content of a text file.

Return type: text

Note: **pg\_read\_file** returns part of a text file. It can return a maximum of *length* bytes from *offset*. The actual size of fetched data is less than *length* if the end of the file is reached first. If *offset* is negative, it is the length rolled back from the file end. If *offset* and *length* are omitted, the entire file is returned.

Example:

```
openGauss=# SELECT pg_read_file('postmaster.pid',0,100);
 pg_read_file

53078 +
/srv/BigData/hadoop/data1/dbnode+
1500022474 +
```

```
8000 +
/var/run/FusionInsight +
localhost +
2
(1 row)
```

- `pg_read_binary_file(filename text [, offset bigint, length bigint,missing_ok boolean])`

Description: Returns the content of a binary file.

Return type: bytea

Note: **pg\_read\_binary\_file** is similar to **pg\_read\_file**, except that the result is a **bytea** value; accordingly, no encoding checks are performed. In combination with the **convert\_from** function, this function can be used to read a file in a specified encoding.

```
openGauss=# SELECT convert_from(pg_read_binary_file('filename'), 'UTF8');
```

- `pg_stat_file(filename text)`

Description: Returns status information about a file.

Return type: record

Note: **pg\_stat\_file** returns a record containing the file size, last access timestamp, last modification timestamp, last file status change timestamp, and a Boolean value indicating if it is a directory. Typical use cases are as follows:

```
openGauss=# SELECT * FROM pg_stat_file('filename');
openGauss=# SELECT (pg_stat_file('filename')).modification;
```

Example:

```
openGauss=# SELECT convert_from(pg_read_binary_file('postmaster.pid'), 'UTF8');
convert_from
```

```

4881 +
/srv/BigData/gaussdb/data1/dbnode+
1496308688 +
25108 +
/opt/user/Bigdata/gaussdb/gaussdb_tmp +
* +
25108001 43352069 +
(1 row)
```

```
openGauss=# SELECT * FROM pg_stat_file('postmaster.pid');
```

```
size | access | modification | change
| creation | isdir
-----+-----
117 | 2017-06-05 11:06:34+08 | 2017-06-01 17:18:08+08 | 2017-06-01 17:18:08+08
| f
(1 row)
openGauss=# SELECT (pg_stat_file('postmaster.pid')).modification;
modification

2017-06-01 17:18:08+08
(1 row)
```

### 7.5.23.3 Server Signal Functions

Server signal functions send control signals to other server processes. Only a system administrator has the permission to execute the following functions:

- `pg_cancel_backend(pid int)`

Description: Cancels a statement that is being executed by a backend thread.

Return type: Boolean

Note: **pg\_cancel\_backend** sends a query cancellation (SIGINT) signal to the backend process identified by **pid**. The PID of an active backend process can be found in the **pid** column of the **pg\_stat\_activity** view, or can be found by listing the database process using **ps** on the server. A user with the SYSADMIN permission, the owner of the database connected to the backend process, the owner of the backend process, or a user who inherits permissions of the built-in role **gs\_role\_signal\_backend** has the permission to use this function.

- **pg\_cancel\_session**(pid bigint, sessionid bigint)

Description: Cancels the statement that is being executed by an active session in thread pool mode. When the input parameters **pid** and **sessionid** are the same and both are thread IDs, the function of **pg\_cancel\_backend** is the same as that of **pg\_cancel\_backend**.

Return type: Boolean

#### NOTE

The input parameters of **pg\_cancel\_session** can be queried using the **pid** and **sessionid** columns in **pg\_stat\_activity**. The input parameters can be used to clear the statements that are being executed by active sessions in thread pool mode.

- **pg\_reload\_conf**()

Description: Causes all server processes to reload their configuration files.

Return type: Boolean

Note: **pg\_reload\_conf** sends a SIGHUP signal to the server. As a result, all server processes reload their configuration files.

- **pg\_rotate\_logfile**()

Description: Rotates the log files of the server.

Return type: Boolean

Note: **pg\_rotate\_logfile** sends a signal to the log file manager, instructing the manager to immediately switch to a new output file. This function works only when **redirect\_stderr** is used for log output. Otherwise, no log file manager subprocess exists.

- **pg\_terminate\_backend**(pid int)

Description: Terminates a backend thread.

Return type: Boolean

Note: Each of these functions returns **true** if they are successful and **false** otherwise. A user with the SYSADMIN permission, the owner of the database connected to the backend thread, the owner of the backend thread, or a user who inherits permissions of the built-in role **gs\_role\_signal\_backend** can use this function.

---

#### NOTICE

This function can terminate non-thread pool threads and active thread pool threads, but cannot terminate inactive thread pool threads.

---

Example:

```
openGauss=# SELECT pid from pg_stat_activity;
 pid

140657876268816
(1 rows)

openGauss=# SELECT pg_terminate_backend(140657876268816);
pg_terminate_backend

t
(1 row)
```

- `pg_terminate_session(pid int64, sessionid int64)`

Description: Terminates a backend session in thread pool mode.

Return type: Boolean

Note: Each of these functions returns **true** if they are successful and **false** otherwise. A user with the SYSADMIN permission, the owner of the database connected to the session, the owner of the session, or a user who inherits permissions of the built-in role `gs_role_signal_backend` has the permission to use this function.

---

#### NOTICE

When the input parameters **pid** and **sessionid** are the same and both are thread IDs, this function can terminate non-thread pool threads and active thread pool threads.

When the input parameters **pid** and **sessionid** are different, this function can terminate active sessions or close inactive sessions and the socket connection of the client.

- 
- `pg_terminate_active_session_socket(pid int64, sessionid int64)`

Description: Closes the socket connection between an active session and the client.

Return type: Boolean

Note: Each of these functions returns **true** if they are successful and **false** otherwise. This function can be used only by the initial user.

## 7.5.23.4 Backup and Restoration Control Functions

### Backup Control Functions

Backup control functions help with online backup.

- `pg_create_restore_point(name text)`

Description: Creates a named point for performing a restore (requires an administrator role).

Return type: text

Note: **pg\_create\_restore\_point** creates a named transaction log record that can be used as a restoration target, and returns the corresponding transaction log location. The given name can then be used with **recovery\_target\_name** to specify the point up to which restoration will proceed. Avoid creating multiple restoration points with the same name, since restoration will stop at the first one whose name matches the restoration target.

- **pg\_current\_xlog\_location()**  
Description: Obtains the write position of the current transaction log.  
Return type: text  
Note: **pg\_current\_xlog\_location** displays the write position of the current transaction log in the same format as those of the previous functions. Read-only operations do not require SYSADMIN permissions.
- **pg\_current\_xlog\_insert\_location()**  
Description: Obtains the insert position of the current transaction log.  
Return type: text  
Note: **pg\_current\_xlog\_insert\_location** displays the insert position of the current transaction log. The insertion point is the logical end of the transaction log at any instant, while the write location is the end of what has been written out from the server's internal buffers. The write position is the end that can be detected externally from the server. This operation can be performed to archive only some of completed transaction log files. The insert position is mainly used for commissioning the server. Read-only operations do not require SYSADMIN permissions.
- **gs\_current\_xlog\_insert\_end\_location()**  
Description: Obtains the insert position of the current transaction log.  
Return type: text  
Note: **gs\_current\_xlog\_insert\_end\_location** displays the insert position of the current transaction log.
- **pg\_start\_backup(label text [, fast boolean ])**  
Description: Starts to perform online backup. **operation\_mode** can be enabled only by SYSADMIN, replication role, or OPRADMIN.  
Return type: text  
Note: **pg\_start\_backup** receives a user-defined backup label (usually the name of the position where the backup dump file is stored). This function writes a backup label file to the data directory of the database and then returns the start position of backed up transaction logs in text mode.  

```
openGauss=# SELECT pg_start_backup('label_goes_here');
pg_start_backup

0/30000020
(1 row)
```
- **pg\_stop\_backup()**  
Description: Completes online backup. **operation\_mode** can be enabled only by SYSADMIN, replication role, or OPRADMIN.  
Return type: text  
Note: **pg\_stop\_backup** deletes the label file created by **pg\_start\_backup** and creates a backup history file in the transaction log archive area. The history file includes the label given to **pg\_start\_backup**, the start and end transaction log locations for the backup, and the start and end time of the backup. The return value is the backup's ending transaction log location. After the end position is calculated, the insert position of the current transaction log automatically goes ahead to the next transaction log file. In this way, the ended transaction log file can be immediately archived so that backup is complete.

- **pg\_switch\_xlog()**  
Description: Switches to a new transaction log file. **operation\_mode** can be enabled only by SYSADMIN or OPRADMIN.  
Return type: text  
Note: **pg\_switch\_xlog** moves to the next transaction log file so that the current log file can be archived (if continuous archive is used). The return value is the ending transaction log location + 1 within the just-completed transaction log file. If there has been no transaction log activity since the last transaction log switchover, pg\_switch\_xlog does not move but returns the start location of the transaction log file currently in use.
- **pg\_xlogfile\_name(location text)**  
Description: Converts the position string in a transaction log to a file name.  
Return type: text  
Note: **pg\_xlogfile\_name** extracts only the transaction log file name. If the given transaction log position is the transaction log file border, a transaction log file name will be returned for both the two functions. This is usually the desired behavior for managing transaction log archiving, since the preceding file is the last one that currently needs to be archived.
- **pg\_xlogfile\_name\_offset(location text)**  
Description: Converts the position string in a transaction log to a file name and returns the byte offset in the file.  
Return type: text, integer  
Note: **pg\_xlogfile\_name\_offset** can extract transaction log file names and byte offsets from the returned results of the preceding functions. Example:  

```
openGauss=# SELECT * FROM pg_xlogfile_name_offset(pg_stop_backup());
NOTICE: pg_stop_backup cleanup done, waiting for required WAL segments to be archived
NOTICE: pg_stop_backup complete, all required WAL segments have been archived
 file_name | file_offset
-----+-----
000000010000000000000003 | 272
(1 row)
```
- **pg\_xlog\_location\_diff(location text, location text)**  
Description: Calculates the difference in bytes between two transaction log locations.  
Return type: numeric
- **pg\_cbm\_tracked\_location()**  
Description: Queries the LSN location parsed by CBM.  
Return type: text
- **pg\_cbm\_get\_merged\_file(startLSNArg text, endLSNArg text)**  
Description: Combines CBM files within the specified LSN range into one and returns the name of the combined file.  
Return type: text  
Note: Only SYSADMIN or OPRADMIN can obtain the CBM combination file.
- **pg\_cbm\_get\_changed\_block(startLSNArg text, endLSNArg text)**  
Description: Combines CBM files within the specified LSN range into a table and return records of this table.  
Return type: records

Note: The table records returned by **pg\_cbm\_get\_changed\_block** include the start LSN, end LSN, tablespace OID, database OID, table relfilenode, table fork number, whether the table is deleted, whether the table is created, whether the table is truncated, number of pages in the truncated table, number of modified pages, and list of modified page numbers.

- **pg\_cbm\_recycle\_file**(targetLSNArg text)  
Description: Deletes the CBM files that are no longer used and returns the first LSN after the deletion.  
Return type: text
- **pg\_cbm\_force\_track**(targetLSNArg text,timeOut int)  
Description: Forcibly executes the CBM trace to the specified Xlog position and returns the Xlog position of the actual trace end point.  
Return type: text
- **pg\_enable\_delay\_ddl\_recycle**()  
Description: Enables DDL delay and returns the Xlog position of the enabling point. You need to enable **operation\_mode** as an administrator or O&M administrator.  
Return type: text
- **pg\_disable\_delay\_ddl\_recycle**(barrierLSNArg text, isForce bool)  
Description: Disables DDL delay and returns the Xlog range where DDL delay takes effect. You need to enable **operation\_mode** as an administrator or O&M administrator.  
Return type: records
- **pg\_enable\_delay\_xlog\_recycle**()  
Description: Enables Xlog recycle delay. This function is used in primary database node restoration. **operation\_mode** can be enabled only by an administrator or OPRADMIN.  
Return type: void
- **pg\_disable\_delay\_xlog\_recycle**()  
Description: Disables Xlog recycle delay. This function is used in primary database node restoration. **operation\_mode** can be enabled only by an administrator or OPRADMIN.  
Return type: void
- **pg\_cbm\_rotate\_file**(rotate\_lsn text)  
Description: Forcibly switches the file after the CBM parses **rotate\_lsn**. This function is called during the build process.  
Return type: void
- **gs\_roach\_stop\_backup**(backupid text)  
Description: Stops a backup started by the internal backup tool GaussRoach. It is similar to the **pg\_stop\_backup system** function but is more lightweight.  
Return type: text. The content is the insertion position of the current log.
- **gs\_roach\_enable\_delay\_ddl\_recycle**(backupid name)  
Description: Enables DDL delay and returns the log location of the enabling point. It is similar to the **pg\_enable\_delay\_ddl\_recycle** system function but is more lightweight. In addition, different **backupid** values can be used to concurrently enable DDL statements with delay.

Return type: text. The content is the log location of the start point.

- `gs_roach_disable_delay_ddl_recycle(backupid text)`

Description: Disables DDL delay and returns the log range where DDL delay takes effect. It is similar to the **pg\_enable\_delay\_ddl\_recycle** system function but is more lightweight. In addition, different **backupid** values can be used to concurrently disable DDL statements with delay.

Return type: records. The content is the range of logs for which DDL is delayed to take effect.

- `gs_roach_switch_xlog(request_ckpt bool)`

Description: Switches the currently used log segment file and triggers a full checkpoint if **request\_ckpt** is set to **true**.

Return type: text. The content is the location of the segment log.

- `gs_block_dw_io(timeout int, identifier text)`

Description: Blocks dual-write page flushing.

Parameter description:

- `timeout`

Block duration.

Value range: [0,3600] (s). The value **0** indicates that the block duration is 0s.

- `identifier`

ID of the operation.

Value range: a string, supporting only uppercase letters, lowercase letters, digits, and underscores (\_).

Return type: Boolean

Note: To call this function, the user must have the SYSADMIN or OPRADMIN permission. An O&M administrator must enable **operation\_mode**.

- `gs_is_dw_io_blocked()`

Description: Checks whether disk flushing on the current dual-write page is blocked. If disk flushing is blocked, **true** is returned.

Return type: Boolean

Note: To call this function, the user must have the SYSADMIN or OPRADMIN permission. An O&M administrator must enable **operation\_mode**.

## Restoration Control Functions

Restoration control functions provide information about the status of standby nodes. These functions may be executed both during restoration and in normal running.

- `pg_is_in_recovery()`

Description: Returns **true** if restoration is still in progress.

Return type: Boolean

- `pg_last_xlog_receive_location()`

Description: Obtains the last transaction log location received and synchronized to disk by streaming replication. While streaming replication is in progress, this will increase monotonically. If restoration has been

completed, then this value will remain static at the value of the last WAL record received and synchronized to disk during restoration. If streaming replication is disabled or if it has not yet started, the function returns a null value.

Return type: text

- `pg_last_xlog_replay_location()`

Description: Obtains last transaction log location replayed during restoration. If restoration is still in progress, this will increase monotonically. If restoration has been completed, then this value will remain static at the value of the last WAL record received during that restoration. When the server has been started normally without restoration, the function returns a null value.

Return type: text

- `pg_last_xact_replay_timestamp()`

Description: Obtains the timestamp of last transaction replayed during restoration. This is the time to commit a transaction or abort a WAL record on the primary node. If no transactions have been replayed during restoration, this function will return a null value. If restoration is still in progress, this will increase monotonically. If restoration has been completed, then this value will remain static at the value of the last WAL record received during that restoration. If the server normally starts without manual intervention, this function will return a null value.

Return type: timestamp with time zone

Restoration control functions control restoration processes. These functions may be executed only during restoration.

- `pg_is_xlog_replay_paused()`

Description: Returns **true** if restoration is paused.

Return type: Boolean

- `pg_xlog_replay_pause()`

Description: Pauses restoration immediately.

Return type: void

- `pg_xlog_replay_resume()`

Description: Restarts restoration if it was paused.

Return type: void

- `gs_get_active_archiving_standby()`

Description: Queries information about archive standby nodes in the same shard. The standby node name, archive location, and number of archived logs are returned.

Return type: text, text, int

- `gs_pitr_get_warning_for_xlog_force_recycle()`

Description: Checks whether logs are recycled because a large number of logs are stacked in the archive slot after archiving is enabled.

Return type: Boolean

- `gs_pitr_clean_history_global_barriers(stop_barrier_timestamp cstring)`

Description: Clears all barrier records generated before the specified time. The earliest barrier record is returned. The input parameter is of the cstring type

and is a Linux timestamp. You need to perform this operation as an administrator or O&M administrator.

Return type: text

- `gs_pitr_archive_slot_force_advance(stop_barrier_timestamp cstring)`  
Description: Forcibly updates the archive slot and clears unnecessary barrier records. The new archive slot location is returned. The input parameter is of the `cstring` type and is a Linux timestamp. You need to perform this operation as an administrator or O&M administrator.

Return type: text

While restoration is paused, no further database changes are applied. In hot standby mode, all new queries will see the same consistent snapshot of the database, and no further query conflicts will be generated until restoration is resumed.

If streaming replication is disabled, the paused state may continue indefinitely without problem. While streaming replication is in progress, WAL records will continue to be received, which will eventually fill available disk space. This progress depends on the duration of the pause, the rate of WAL generation, and available disk space.

### 7.5.23.5 DR Control Functions for Dual Database Instances

DR control functions for dual-database instances can be used to create an archive slot. The archive slot specifies the OBS information for storing physical logs.

- `pg_create_physical_replication_slot_extern(slotname text, dummy_standby bool, extra_content text, need_recycle_xlog bool)`  
Description: Creates an OBS or a NAS archive slot. **slotname** indicates the slot name of the DR standby node. The primary and standby nodes must use the same slot name. **dummy\_standby** specifies whether one primary and multiple standby nodes are deployed. The value **false** indicates one primary and multiple standby nodes, and the value **true** indicates not. **extra\_content** contains some information about the archive slot. For an OBS archive slot, the format is **OBS;obs\_server\_ip;obs\_bucket\_name;obs\_ak;obs\_sk;archive\_path;is\_recovery;is\_vote\_replicate**, where **OBS** indicates the archive media of the archive slot, **obs\_server\_ip** indicates the IP address of OBS, **obs\_bucket\_name** indicates the bucket name, **obs\_ak** indicates the AK of OBS, **obs\_sk** indicates the SK of OBS, **archive\_path** indicates the archive path **i**, and **is\_recovery** indicates whether the slot is an archive slot or a recovery slot. The value **0** indicates that the slot is an archive slot and is used by the primary database instance. The value **1** indicates that the slot is a recovery slot and is used by the DR database instance. **is\_vote\_replicate** specifies whether the voting copy is archived first. The value **0** indicates that the synchronous standby node is archived first, and the value **1** indicates that the voting copy is archived first. This column is reserved in the current version and is not adapted yet. For a NAS archive slot, the format is **NAS;archive\_path;is\_recovery;is\_vote\_replicate**. Compared with the OBS archive slot, the NAS archive slot does not have the OBS configuration information, while the meanings of other fields are the same.  
If the media is not specified, the OBS archive slot is used by default. The **extra\_content** format is

**obs\_server\_ip;obs\_bucket\_name;obs\_ak;obs\_sk;archive\_path;is\_recovery;is\_vote\_replicate. need\_recycle\_xlog** specifies whether to recycle old archived logs when creating an archive slot. The value **true** indicates that old archived logs are recycled, and the value **false** indicates that old archived logs are not recycled.

Return type: records, including **slotname** and **xlog\_position** of the current standby for DR.

Note: Users who call this function must have the SYSADMIN permission or the REPLICATION permission, or inherit permissions of the built-in role **gs\_role\_replication**. Currently, multiple archive slots cannot be created.

Example:

Create an OBS archive slot.

```
openGauss=# select * from pg_create_physical_replication_slot_exten('uuid', false, 'OBS;obs.cn-north-7.ulanhqab.huawei.com;dyk;19D772JBCACXX3KWS51D;*****;openGauss_uuid/dn1;0;0', false);
 slotname | xlog_position
-----+-----
 uuid |
(1 row)
```

Create a NAS archive slot.

```
openGauss=# select * from pg_create_physical_replication_slot_exten('uuid', false, 'NAS;/data/nas/media/openGauss_uuid/dn1;0;0', false);
 slotname | xlog_position
-----+-----
 uuid |
```

- **gs\_set\_obs\_delete\_location(delete\_location text)**

Description: Sets the location where OBS archived logs can be deleted. The value of **delete\_location** is an LSN. The logs before this location have been replayed and flushed to disks in the DR database instance and can be deleted on OBS.

Return type: **xlog\_file\_name** text, indicating the name of the log file that can be deleted. The value of this parameter is returned regardless of whether OBS is deleted successfully.

```
openGauss=# select gs_set_obs_delete_location('0/54000000');
 gs_set_obs_delete_location

 00000001000000000000000054_00
(1 row)
```

- **gs\_set\_obs\_delete\_location\_with\_slotname(cstring, cstring )**

Description: Sets the location where OBS archived logs can be deleted in a DR relationship. The first parameter indicates the LSN. The logs before this location have been replayed and flushed to disks in the DR database instance and can be deleted on OBS. The second parameter indicates the name of the archive slot.

Return type: **xlog\_file\_name** text, indicating the name of the log file that can be deleted. The value of this parameter is returned regardless of whether OBS is deleted successfully.

- **gs\_hadr\_do\_switchover()**

Description: Truncates services during a planned switchover in the primary database instance in OBS-based remote DR solutions.

Return type: Boolean, indicating whether the service truncation is successful and whether the switchover process can be performed normally.

- **gs\_streaming\_dr\_in\_switchover()**  
Description: Truncates services during a planned switchover in the primary database instance in streaming replication-based remote DR solutions.  
Return type: Boolean, indicating whether the service truncation is successful and whether the switchover process can be performed normally.

### 7.5.23.6 DR Query Functions for Dual-Database Instances

- **gs\_get\_global\_barrier\_status()**  
Description: If two-city 3DC DR is enabled, logs of the primary database instance and standby database instance for DR are synchronized through OBS. The barrier log is flushed to the disk of the primary database instance. The progress of archiving logs of the primary database instance and the progress of replaying logs of the standby database instance for DR are determined by replaying the standby database instance for DR.  
**gs\_get\_global\_barrier\_status** is used to query the latest global barrier that has been archived in OBS for the primary database instance.  
Return type: text  
**global\_barrier\_id**: globally latest barrier ID.  
**global\_achive\_barrier\_id**: globally latest archived barrier ID.
- **gs\_get\_global\_barriers\_status()**  
Description: If two-city 3DC DR solutions based on OBS are enabled, logs of the primary database instance and multiple standby database instances for DR are synchronized through OBS. The barrier log is flushed to the disk of the primary database instance. The progress of archiving logs of the primary database instance and the progress of replaying logs of the standby database instances for DR are determined by replaying the standby database instances for DR. **gs\_get\_global\_barriers\_status** is used to query the latest global barrier that has been archived in OBS for the primary database instance.  
Return type: text  
**slot\_name**: name of the slot used for DR.  
**global\_barrier\_id**: globally latest barrier ID.  
**global\_achive\_barrier\_id**: globally latest archived barrier ID.
- **gs\_get\_local\_barrier\_status()**  
Description: If two-city 3DC DR is enabled, logs of the primary database instance and standby database instance for DR are synchronized through OBS. The barrier log is flushed to the disk of the primary database instance. The progress of archiving logs of the primary database instance and the progress of replaying logs of the standby database instance for DR are determined by replaying the standby database instance for DR. **gs\_get\_local\_barrier\_status** is used to query the current log replay status of each node of the standby database instance for DR.  
Return type: text  
**barrier\_id**: latest barrier ID of a node of the standby database instance for DR.  
**barrier\_lsn**: LSN of the latest barrier ID returned by a node in the standby database instance for DR.

**archive\_lsn:** location of archived logs obtained by a node in the standby database instance for DR. This parameter does not take effect currently.

**flush\_lsn:** location of logs that have been flushed to disks on a node in the standby database instance for DR.

- `gs_upload_obs_file('slot_name', 'src_file', 'dest_file')`

Description: Function used by the primary database instance to upload data to OBS if two-city 3DC DR is enabled.

Return type: void

**slot\_name:** name of the replication slot created for the primary database instance.

**src\_file:** location of the file to be uploaded in the data directory of the primary database instance.

**dest\_file:** location of the file to be uploaded to OBS.

- `gs_download_obs_file('slot_name', 'src_file', 'dest_file')`

Description: Function used by the standby database instance for DR to download data from OBS to the localhost if two-city 3DC DR is enabled.

Return type: void

**slot\_name:** name of the replication slot created for the database instance for DR.

**src\_file:** location of files to be downloaded from OBS.

**dest\_file:** location of the downloaded file in the data directory of the standby database instance for DR.

- `gs_get_obs_file_context('file_name', 'slot_name')`

Description: Queries file content on OBS if two-city 3DC DR is enabled.

Return type: text

**file\_name:** name of the file on OBS.

**slot\_name:** name of the replication slot created for the primary database instance or database instance for DR.

- `gs_set_obs_file_context('file_name', 'file_context', 'slot_name')`

Description: Creates a file on OBS and writes content into the file if two-city 3DC DR is enabled.

Return type: text

**file\_name:** name of the file on OBS.

**file\_context:** content to be written into the file.

**slot\_name:** name of the replication slot created for the primary database instance or database instance for DR.

- `gs_get_hadr_key_cn()`

Description: Creates a file on OBS and writes content into the file if two-city 3DC DR is enabled.

Return type: text

**file\_name:** name of the file on OBS.

**file\_context:** content to be written into the file.

**slot\_name:** name of the replication slot created for the primary database instance or database instance for DR.

- **gs\_hadr\_has\_barrier\_creator()**

Description: Checks whether the **barrier\_creator** thread exists on the current node if two-city 3DC DR is enabled. If the thread exists, **true** is returned (the SYSADMIN permission is required).

Return type: Boolean

Note: This function is used only when a planned switchover is performed on the standby database instance for DR.
- **gs\_hadr\_in\_recovery()**

Description: Checks whether the current node is in barrier-based log restoration if two-city 3DC DR is enabled. If the current node is in barrier-based log restoration, **true** is returned. The standby database instance for DR can be promoted to the production database instance through the switchover process only after the log restoration is complete (the SYSADMIN permission is required).

Return type: Boolean

Note: This function is used only when a planned switchover is performed on the standby database instance for DR.
- **gs\_streaming\_dr\_get\_switchover\_barrier()**

Description: Checks whether the DN instance of the standby database instance for DR has received the switchover barrier logs and replayed the logs in two-city 3DC DR solutions based on streaming replication. If it has, **true** is returned. In the standby database instance for DR, the procedure for promoting the standby database instance for DR to the production database instance in the switchover process can be started only after the switchover barrier logs of all DN instances are replayed (restricted to system administrators).

Return type: Boolean

Note: This function is used only when a planned switchover is performed on the standby database instance for DR in streaming DR solutions.
- **gs\_streaming\_dr\_service\_truncation\_check()**

Description: Checks whether the DN instance of the primary database instance has sent the switchover barrier logs in two-city 3DC DR solutions based on streaming replication. If it has, **true** is returned. The procedure for demoting the production database instance to the standby database instance for DR in the switchover process can be started only after the logs are sent (the SYSADMIN permission is required).

Return type: Boolean

Note: This function is used only when a planned switchover is performed on the standby database instance for DR.
- **gs\_hadr\_local\_rto\_and\_rpo\_stat()**

Description: Displays the log flow control information about the primary and standby database instances in the streaming DR scenario. (This view can be used only on the primary DN of the primary database instance. Statistics cannot be obtained from the standby DN or the standby database instance.)

Return type: record. The types and meanings of the fields are as follows:

| Parameter               | Type | Description                                                                                                                                         |
|-------------------------|------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| hadr_sender_node_name   | text | Node name, including the primary database instance and the main standby node of the standby database instance.                                      |
| hadr_receiver_node_name | text | Name of the main standby node of the standby database instance.                                                                                     |
| source_ip               | text | IP address of the primary DN of the primary database instance.                                                                                      |
| source_port             | int  | Communication port of the primary DN of the primary database instance.                                                                              |
| dest_ip                 | text | IP address of the main standby DN of the standby database instance.                                                                                 |
| dest_port               | int  | Communication port of the main standby DN of the standby database instance.                                                                         |
| current_rto             | int  | Flow control information, that is, log RTO time of the current primary and standby database instances (unit: second).                               |
| target_rto              | int  | Flow control information, that is, the RTO time between the target primary and standby database instances (unit: second).                           |
| current_rpo             | int  | Flow control information, that is, log RPO time of the current primary and standby database instances (unit: second).                               |
| target_rpo              | int  | Flow control information, that is, the RPO time between the target primary and standby database instances (unit: second).                           |
| rto_sleep_time          | int  | RTO flow control information, that is, the expected sleep time (unit: $\mu$ s) required by walsender on the host to reach the specified RTO.        |
| rpo_sleep_time          | int  | RPO flow control information, that is, the expected sleep time (unit: $\mu$ s) required for inserting Xlogs on the host to reach the specified RPO. |

- gs\_hadr\_remote\_rto\_and\_rpo\_stat()

Description: Displays the log flow control information of the primary and standby database instances of other non-local data shards in streaming DR mode. This function is not supported in centralized deployment scenarios.

### 7.5.23.7 Snapshot Synchronization Functions

Snapshot synchronization functions save the current snapshot and return its identifier.

- `pg_export_snapshot()`

Description: Saves the current snapshot and returns its identifier.

Return type: text

Note: **pg\_export\_snapshot** saves the current snapshot and returns a text string identifying the snapshot. This string must be passed to clients that want to import the snapshot. A snapshot can be imported when the **set transaction snapshot snapshot\_id;** command is executed. Doing so is possible only when the transaction is set to the **SERIALIZABLE** or **REPEATABLE READ** isolation level. GaussDB does not support these two isolation levels currently. The output of the function cannot be used as the input of **set transaction snapshot**.

- `pg_export_snapshot_and_csn()`

Description: Saves the current snapshot and returns its identifier. Compared with **pg\_export\_snapshot()**, **pg\_export\_snapshot()** returns a CSN, indicating the CSN of the current snapshot.

Return type: text

### 7.5.23.8 Database Object Functions

#### Database Object Size Functions

Database object size functions calculate the actual disk space used by database objects.

- `pg_column_size(any)`

Description: Specifies the number of bytes used to store a particular value (possibly compressed)

Return type: int

Note: **pg\_column\_size** displays the space for storing an independent data value.

```
openGauss=# SELECT pg_column_size(1);
 pg_column_size

 4
(1 row)
```

- `pg_database_size(oid)`

Description: Specifies the disk space used by the database with the specified OID.

Return type: bigint

- `pg_database_size(name)`

Description: Specifies the disk space used by the database with the specified name.

Return type: bigint

Note: **pg\_database\_size** receives the OID or name of a database and returns the disk space used by the corresponding object.

Example:

```
openGauss=# SELECT pg_database_size('testdb');
pg_database_size

51590112
(1 row)
```

- **pg\_relation\_size(oid)**  
Description: Abbreviation of **pg\_relation\_size** (... , 'main'), specifying the disk space used by the table with a specified OID or index.  
Return type: bigint
- **pg\_relation\_size(relation regclass, fork text)**  
Description: Specifies the disk space used by the specified bifurcating tree ('main', 'fsm', or 'vm') of a certain table or index.  
Return type: bigint
- **pg\_relation\_size(relation regclass)**  
Description: Is an abbreviation of **pg\_relation\_size**(..., 'main').  
Return type: bigint  
Note: **pg\_relation\_size** receives the OID or name of a table or an index, and returns the size.
- **pg\_partition\_size(oid,oid)**  
Description: Specifies the disk space used by the partition with a specified OID. The first **oid** is the OID of the table and the second **oid** is the OID of the partition.  
Return type: bigint
- **pg\_partition\_size(text, text)**  
Description: Specifies the disk space used by the partition with a specified name. The first **text** is the table name and the second **text** is the partition name.  
Return type: bigint
- **pg\_partition\_indexes\_size(oid,oid)**  
Description: Specifies the disk space used by the index of the partition with a specified OID. The first **oid** is the OID of the table and the second **oid** is the OID of the partition.  
Return type: bigint
- **pg\_partition\_indexes\_size(text,text)**  
Description: Specifies the disk space used by the index of the partition with a specified name. The first **text** is the table name and the second **text** is the partition name.  
Return type: bigint
- **pg\_indexes\_size(regclass)**  
Description: Specifies the total disk space used by the index appended to the specified table.  
Return type: bigint
- **pg\_size\_pretty(bigint)**  
Description: Converts a size in bytes expressed as a 64-bit integer into a human-readable format with size units.

Return type: text

- `pg_size_pretty(numeric)`

Description: Converts a size in bytes expressed as a numeric value into a human-readable format with size units.

Return type: text

Note: **pg\_size\_pretty** formats the results of other functions into a human-readable format. KB/MB/GB/TB can be used.

- `pg_table_size(regclass)`

Description: Specifies the disk space used by the specified table, excluding indexes (but including TOAST, free space mapping, and visibility mapping).

Return type: bigint

- `pg_tablespace_size(oid)`

Description: Specifies the disk space used by the tablespace with a specified OID.

Return type: bigint

- `pg_tablespace_size(name)`

Description: Specifies the disk space used by the tablespace with a specified name.

Return type: bigint

Note: `pg_tablespace_size` receives the OID or name of a database and returns the disk space used by the corresponding object.

- `pg_total_relation_size(oid)`

Description: Specifies the disk space used by the table with a specified OID, including the index data.

Return type: bigint

- `pg_total_relation_size(regclass)`

Description: Specifies the total disk space used by the specified table, including all indexes and TOAST data.

Return type: bigint

- `pg_total_relation_size(text)`

Description: Specifies the disk space used by the table with a specified name, including the index data. The table name can be schema-qualified.

Return type: bigint

Note: `pg_total_relation_size` receives the OID or name of a table, and returns the sizes of the data and related indexes in bytes.

- `datalength(any)`

Description: Specifies the number of bytes used by an expression of a specified data type (data management space, data compression, or data type conversion is not considered).

Return type: int

Note: **datalength** is used to calculate the space of an independent data value.

Example:

```
openGauss=# SELECT datalength(1);
datalength
```

-----

4

(1 row)

The following table lists the supported data types and calculation methods.

| Data Type                 |                                         |                  | Storage Space                                                                                                        |
|---------------------------|-----------------------------------------|------------------|----------------------------------------------------------------------------------------------------------------------|
| Numeri<br>c data<br>types | Integ<br>er<br>types                    | TINYINT          | 1                                                                                                                    |
|                           |                                         | SMALLINT         | 2                                                                                                                    |
|                           |                                         | INTEGER          | 4                                                                                                                    |
|                           |                                         | BINARY_INTEGER   | 4                                                                                                                    |
|                           |                                         | BIGINT           | 8                                                                                                                    |
|                           | Arbitr<br>ary<br>precis<br>ion<br>types | DECIMAL          | Every four decimal digits occupy two bytes. The digits before and after the decimal point are calculated separately. |
|                           |                                         | NUMERIC          | Every four decimal digits occupy two bytes. The digits before and after the decimal point are calculated separately. |
|                           |                                         | NUMBER           | Every four decimal digits occupy two bytes. The digits before and after the decimal point are calculated separately. |
|                           | Sequ<br>ence<br>integ<br>er             | SMALLSERIAL      | 2                                                                                                                    |
|                           |                                         | SERIAL           | 4                                                                                                                    |
|                           |                                         | BIGSERIAL        | 8                                                                                                                    |
|                           |                                         | LARGESERIAL      | Every four decimal digits occupy two bytes. The digits before and after the decimal point are calculated separately. |
|                           | Floati<br>ng<br>point<br>types          | FLOAT4           | 4                                                                                                                    |
|                           |                                         | DOUBLE PRECISION | 8                                                                                                                    |
|                           |                                         | FLOAT8           | 8                                                                                                                    |
|                           |                                         | BINARY_DOUBLE    | 8                                                                                                                    |

|                      |                 |                |                                                                                                                      |
|----------------------|-----------------|----------------|----------------------------------------------------------------------------------------------------------------------|
|                      |                 | FLOAT[(p)]     | Every four decimal digits occupy two bytes. The digits before and after the decimal point are calculated separately. |
|                      |                 | DEC[(p,s)]     | Every four decimal digits occupy two bytes. The digits before and after the decimal point are calculated separately. |
|                      |                 | INTEGER[(p,s)] | Every four decimal digits occupy two bytes. The digits before and after the decimal point are calculated separately. |
| Boolean data types   | Boolean type    | BOOLEAN        | 1                                                                                                                    |
| Character data types | Character types | CHAR           | n                                                                                                                    |
|                      |                 | CHAR(n)        | n                                                                                                                    |
|                      |                 | CHARACTER(n)   | n                                                                                                                    |
|                      |                 | NCHAR(n)       | n                                                                                                                    |
|                      |                 | VARCHAR(n)     | n                                                                                                                    |
|                      |                 | CHARACTER      | Actual number of bytes of a character                                                                                |
|                      |                 | VARYING(n)     | Actual number of bytes of a character                                                                                |
|                      |                 | VARCHAR2(n)    | Actual number of bytes of a character                                                                                |
|                      |                 | NVARCHAR(n)    | Actual number of bytes of a character                                                                                |
|                      |                 | NVARCHAR2(n)   | Actual number of bytes of a character                                                                                |
|                      |                 | TEXT           | Actual number of bytes of a character                                                                                |
|                      |                 | CLOB           | Actual number of bytes of a character                                                                                |

## Database Object Position Functions

- `pg_relation_filenode(relation regclass)`  
Description: Specifies the ID of a filenode with the specified relationship.  
Return type: oid  
Description: `pg_relation_filenode` receives the OID or name of a table, index, or sequence, and returns the **filenode** number allocated to it. **filenode** is the basic component of the file name used by the relationship. For most tables, the result is the same as that of **pg\_class.relfilenode**. For a specified system directory, **relfilenode** is set to **0** and this function must be used to obtain the correct value. If a relationship that is not stored is transmitted, such as a view, this function returns **NULL**.
- `pg_relation_filepath(relation regclass)`  
Description: Specifies the name of a file path with the specified relationship.  
Return type: text  
Description: **pg\_relation\_filepath** is similar to **pg\_relation\_filenode**, except that **pg\_relation\_filepath** returns the whole file path name for the relationship (relative to the data directory **PGDATA** of the database).
- `pg_filenode_relation(tablespace oid, filenode oid)`  
Description: Obtains the table names corresponding to the tablespace and relfilenode.  
Return type: regclass
- `pg_partition_filenode(partition_oid)`  
Description: Obtains **filenode** corresponding to the OID lock of a specified partitioned table.  
Return type: oid
- `pg_partition_filepath(partition_oid)`  
Description: Specifies the file path name of a partition.  
Return type: text

## Recycle Bin Object Functions

- `gs_is_recycle_object(classid, objid, objname)`  
Description: Determines whether an object is in the recycle bin.  
Return type: Boolean

### 7.5.23.9 Advisory Lock Functions

Advisory lock functions manage advisory locks.

- `pg_advisory_lock(key bigint)`  
Description: Obtains an exclusive session-level advisory lock.  
Return type: void  
Note: **pg\_advisory\_lock** locks resources defined by an application. The resources can be identified using a 64-bit or two nonoverlapped 32-bit key values. If another session locks the resources, the function blocks the resources until they can be used. The lock is exclusive. Multiple locking requests are pushed into the stack. Therefore, if the same resource is locked three times, it must be unlocked three times so that it is released to another session.
- `pg_advisory_lock(key1 int, key2 int)`  
Description: Obtains an exclusive session-level advisory lock.  
Return type: void  
Note: Only users with the SYSADMIN permission can add session-level exclusive advisory locks to the key-value pair (65535, 65535).
- `pg_advisory_lock(lock_id int4, lock_id int4, database_name Name)`  
Description: Obtains the exclusive advisory lock of a specified database by inputting the lock ID and database name.  
Return type: void
- `pg_advisory_lock_shared(key bigint)`  
Description: Obtains a shared session-level advisory lock.  
Return type: void
- `pg_advisory_lock_shared(key1 int, key2 int)`  
Description: Obtains a shared session-level advisory lock.  
Return type: void  
Note: **pg\_advisory\_lock\_shared** works in the same way as **pg\_advisory\_lock**, except that **pg\_advisory\_lock\_shared** obtains an advisory lock shared with other sessions requesting the lock, while **pg\_advisory\_lock** obtains an exclusive advisory lock.
- `pg_advisory_unlock(key bigint)`  
Description: Releases an exclusive session-level advisory lock.  
Return type: Boolean
- `pg_advisory_unlock(key1 int, key2 int)`  
Description: Releases an exclusive session-level advisory lock.  
Return type: Boolean

Note: **pg\_advisory\_unlock** releases the obtained exclusive advisory lock. If the release is successful, the function returns **true**. If the lock was not held, it will return **false**. In addition, an SQL warning will be reported by the server.

- **pg\_advisory\_unlock(lock\_id int4, lock\_id int4, database\_name Name)**

Description: Releases an exclusive advisory lock of a specified database by inputting the lock ID and database name.

Return type: Boolean

Note: If the release is successful, **true** is returned. If no lock is held, **false** is returned.

- **pg\_advisory\_unlock\_shared(key bigint)**

Description: Releases a shared session-level advisory lock.

Return type: Boolean

- **pg\_advisory\_unlock\_shared(key1 int, key2 int)**

Description: Releases a shared session-level advisory lock.

Return type: Boolean

Note: **pg\_advisory\_unlock\_shared** works in the same way as **pg\_advisory\_unlock**, except it releases a shared session-level advisory lock.

- **pg\_advisory\_unlock\_all()**

Description: Releases all advisory locks owned by the current session.

Return type: void

Note: **pg\_advisory\_unlock\_all** releases all advisory locks owned by the current session. The function is implicitly called when the session ends even if the client is abnormally disconnected.

- **pg\_advisory\_xact\_lock(key bigint)**

Description: Obtains an exclusive transaction-level advisory lock.

Return type: void

- **pg\_advisory\_xact\_lock(key1 int, key2 int)**

Description: Obtains an exclusive transaction-level advisory lock.

Return type: void

Note: **pg\_advisory\_xact\_lock** works in the same way as **pg\_advisory\_lock**, except the lock is automatically released at the end of the current transaction and cannot be released explicitly. Only users with the SYSADMIN permission can add transaction-level exclusive advisory locks to the key-value pair (65535, 65535).

- **pg\_advisory\_xact\_lock\_shared(key bigint)**

Description: Obtains a shared transaction-level advisory lock.

Return type: void

- **pg\_advisory\_xact\_lock\_shared(key1 int, key2 int)**

Description: Obtains a shared transaction-level advisory lock.

Return type: void

Note: **pg\_advisory\_xact\_lock\_shared** works in the same way as **pg\_advisory\_lock\_shared**, except the lock is automatically released at the end of the current transaction and cannot be released explicitly.

- `pg_try_advisory_lock(key bigint)`  
Description: Obtains an exclusive session-level advisory lock if available.  
Return type: Boolean  
Note: **pg\_try\_advisory\_lock** is similar to **pg\_advisory\_lock**, except **pg\_try\_advisory\_lock** does not block the resource until the resource is released. It either immediately obtains the lock and returns **true** or returns **false**, which indicates the lock cannot be performed currently.
- `pg_try_advisory_lock(key1 int, key2 int)`  
Description: Obtains an exclusive session-level advisory lock if available.  
Return type: Boolean  
Note: Only users with the SYSADMIN permission can add session-level exclusive advisory locks to the key-value pair (65535, 65535).
- `pg_try_advisory_lock_shared(key bigint)`  
Description: Obtains a shared session-level advisory lock if available.  
Return type: Boolean
- `pg_try_advisory_lock_shared(key1 int, key2 int)`  
Description: Obtains a shared session-level advisory lock if available.  
Return type: Boolean  
Note: **pg\_try\_advisory\_lock\_shared** works in the same way as **pg\_try\_advisory\_lock**, except that **pg\_try\_advisory\_lock\_shared** attempts to obtain a shared lock instead of an exclusive lock.
- `pg_try_advisory_xact_lock(key bigint)`  
Description: Obtains an exclusive transaction-level advisory lock if available.  
Return type: Boolean
- `pg_try_advisory_xact_lock(key1 int, key2 int)`  
Description: Obtains an exclusive transaction-level advisory lock if available.  
Return type: Boolean  
Note: **pg\_try\_advisory\_xact\_lock** works in the same way as **pg\_try\_advisory\_lock**, except the lock, if acquired, is automatically released at the end of the current transaction and cannot be released explicitly. Only users with the SYSADMIN permission can add transaction-level exclusive advisory locks to the key-value pair (65535, 65535).
- `pg_try_advisory_xact_lock_shared(key bigint)`  
Description: Obtains a shared transaction-level advisory lock if available.  
Return type: Boolean
- `pg_try_advisory_xact_lock_shared(key1 int, key2 int)`  
Description: Obtains a shared transaction-level advisory lock if available.  
Return type: Boolean  
Note: **pg\_try\_advisory\_xact\_lock\_shared** works in the same way as **pg\_try\_advisory\_lock\_shared**, except the lock, if acquired, is automatically released at the end of the current transaction and cannot be released explicitly.
- `lock_cluster_ddl()`

Description: Attempts to obtain a session-level exclusive advisory lock for all active primary database nodes in the database.

Return type: Boolean

Note: Only users with the SYSADMIN permission can call this function.

- `unlock_cluster_ddl()`

Description: Attempts to add a session-level exclusive advisory lock on the primary database node.

Return type: Boolean

### 7.5.23.10 Logical Replication Functions

- `pg_create_logical_replication_slot('slot_name', 'plugin_name')`

Description: Creates a logical replication slot.

Parameter description:

- `slot_name`

Indicates the name of the streaming replication slot.

Value range: a string, supporting only lowercase letters, digits, underscores (`_`), question marks (`?`), hyphens (`-`), and periods (`.`). One or two periods cannot be used alone as the replication slot name.

- `plugin_name`

Indicates the name of the plug-in.

Value range: a string, supporting "**mppdb\_decoding**".

Return type: name, text

Note: The first return value is the slot name, and the second one is the start LSN for decoding in the logical replication slot. Users who call this function must have the SYSADMIN permission or the REPLICATION permission, or inherit the permissions of the built-in role `gs_role_replication`. Currently, this function can be called only on the primary node.

- `pg_create_physical_replication_slot('slot_name', 'isDummyStandby')`

Description: Creates a physical replication slot.

Parameter description:

- `slot_name`

Indicates the name of the streaming replication slot.

Value range: a string, supporting only lowercase letters, digits, underscores (`_`), question marks (`?`), hyphens (`-`), and periods (`.`). One or two periods cannot be used alone as the replication slot name.

- `isDummyStandby`

Not supported in the current version.

Return type: name, text

Note: Users who call this function must have the SYSADMIN permission or the REPLICATION permission, or inherit permissions of the built-in role `gs_role_replication`.

- `pg_drop_replication_slot('slot_name')`

Description: Deletes a streaming replication slot.

Parameter description:

- slot\_name

Indicates the name of the streaming replication slot.

Value range: a string, supporting only lowercase letters, digits, underscores (\_), question marks (?), hyphens (-), and periods (.). One or two periods cannot be used alone as the replication slot name.

Return type: void

Note: Users who call this function must have the SYSADMIN permission or the REPLICATION permission, or inherit permissions of the built-in role `gs_role_replication`. Currently, this function can be called only on the primary node.

- `pg_logical_slot_peek_changes('slot_name', 'LSN', upto_nchanges, 'options_name', 'options_value')`

Description: Performs decoding but does not go to the next streaming replication slot. (The decoded result will be returned again during the next decoding.)

Parameter description:

- slot\_name

Indicates the name of the streaming replication slot.

Value range: a string, supporting only lowercase letters, digits, underscores (\_), question marks (?), hyphens (-), and periods (.). One or two periods cannot be used alone as the replication slot name.

- LSN

Indicates a target LSN. Decoding is performed only when an LSN is less than or equal to this value.

Value range: a string, in the format of *xlogid/xrecoff*, for example, **'1/2AAFC60'**. (If this parameter is set to **NULL**, the target LSN indicating the end position of decoding is not specified.)

- upto\_nchanges

Indicates the number of decoded records (including the **begin** and **commit** timestamps). Assume that there are three transactions, which involve 3, 5, and 7 records, respectively. If **upto\_nchanges** is set to **4**, 8 records of the first two transactions will be decoded. Specifically, decoding is stopped when the number of decoded records exceeds the value of **upto\_nchanges** after decoding in the first two transactions is finished.

Value range: a non-negative integer

 **NOTE**

If any of the **LSN** and **upto\_nchanges** values are reached, decoding ends.

- **options**: Specifies optional parameters, consisting of **options\_name** and **options\_value**.

- include-xids

Specifies whether the decoded **data** column contains XID information.

Valid value: **0** and **1**. The default value is **1**.

- **0**: The decoded **data** column does not contain XID information.

- **1**: The decoded **data** column contains XID information.
- **skip-empty-xacts**  
Specifies whether to ignore empty transaction information during decoding.  
Valid value: **0** and **1**. The default value is **0**.
  - **0**: The empty transaction information is not ignored during decoding.
  - **1**: The empty transaction information is ignored during decoding.
- **include-timestamp**  
Specifies whether decoded information contains the **commit** timestamp.  
Valid value: **0** and **1**. The default value is **0**.
  - **0**: The decoded information does not contain the **commit** timestamp.
  - **1**: The decoded information contains the **commit** timestamp.
- **only-local**  
Specifies whether to decode only local logs.  
Value range: **0** and **1**. The default value is **1**.
  - **0**: Non-local logs and local logs are decoded.
  - **1**: Only local logs are decoded.
- **force-binary**  
Specifies whether to output the decoding result in binary format.  
Value range: **0** and **1**. The default value is **0**.
  - **0**: The decoding result is output in binary format.
- **white-table-list**  
Whitelist parameter, including the schema and table name to be decoded.  
Value range: a string that contains table names in the whitelist. Different tables are separated by commas (,). An asterisk (\*) is used to fuzzily match all tables. Schema names and table names are separated by periods (.). No space character is allowed. The following is an example:

```
select * from pg_logical_slot_peek_changes('slot1', NULL, 4096, 'white-table-list', 'public.t1,public.t2');
```
- **max-txn-in-memory**  
Memory control parameter. The unit is MB. If the memory occupied by a single transaction is greater than the value of this parameter, data is flushed to disks.  
Value range: an integer ranging from 0 to 100. The default value is **0**, indicating that memory control is disabled.

- **max-reorderbuffer-in-memory**

Memory control parameter. The unit is GB. If the total memory (including the cache) of transactions being concatenated in the sender thread is greater than the value of this parameter, the current decoding transaction is flushed to disks.

Value range: an integer ranging from 0 to 100. The default value is **0**, indicating that memory control is disabled.

Return type: text, xid, text

Note: The function returns the decoding result. Each decoding result contains three columns, corresponding to the above return types and indicating the LSN position, XID, and decoded content, respectively.

Users who call this function must have the SYSADMIN permission or the REPLICATION permission, or inherit the permissions of the built-in role `gs_role_replication`.

- **pg\_logical\_slot\_get\_changes**('slot\_name', 'LSN', upto\_nchanges, 'options\_name', 'options\_value')

Description: Performs decoding and goes to the next streaming replication slot.

Parameter: This function has the same parameters as **pg\_logical\_slot\_peek\_changes**. For details, see [pg\\_logical\\_slot\\_peek\\_ch...](#)

Note: Users who call this function must have the SYSADMIN permission or the REPLICATION permission, or inherit permissions of the built-in role `gs_role_replication`. Currently, this function can be called only on the primary node.

- **pg\_logical\_slot\_peek\_binary\_changes**('slot\_name', 'LSN', upto\_nchanges, 'options\_name', 'options\_value')

Description: Performs decoding in binary format and does not go to the next streaming replication slot. (The decoded data can be obtained again during the next decoding.)

Parameter description:

- **slot\_name**

Indicates the name of the streaming replication slot.

Value range: a string, supporting only lowercase letters, digits, underscores (`_`), question marks (`?`), hyphens (`-`), and periods (`.`). One or two periods cannot be used alone as the replication slot name.

- **LSN**

Indicates a target LSN. Decoding is performed only when an LSN is less than or equal to this value.

Value range: a string, in the format of *xlogid/xrecoff*, for example, **'1/2AAFC60'**. (If this parameter is set to **NULL**, the target LSN indicating the end position of decoding is not specified.)

- **upto\_nchanges**

Indicates the number of decoded records (including the **begin** and **commit** timestamps). Assume that there are three transactions, which involve 3, 5, and 7 records, respectively. If **upto\_nchanges** is set to **4**, 8 records of the first two transactions will be decoded. Specifically, decoding is stopped when the number of decoded records exceeds the

value of **upto\_nchanges** after decoding in the first two transactions is finished.

Value range: a non-negative integer

 **NOTE**

If any of the **LSN** and **upto\_nchanges** values are reached, decoding ends.

- **options**: Specifies optional parameters, consisting of **options\_name** and **options\_value**.

- **include-xids**

Specifies whether the decoded **data** column contains XID information.

Valid value: **0** and **1**. The default value is **1**.

- **0**: The decoded **data** column does not contain XID information.
- **1**: The decoded **data** column contains XID information.

- **skip-empty-xacts**

Specifies whether to ignore empty transaction information during decoding.

Valid value: **0** and **1**. The default value is **0**.

- **0**: The empty transaction information is not ignored during decoding.
- **1**: The empty transaction information is ignored during decoding.

- **include-timestamp**

Specifies whether decoded information contains the **commit** timestamp.

Valid value: **0** and **1**. The default value is **0**.

- **0**: The decoded information does not contain the **commit** timestamp.
- **1**: The decoded information contains the **commit** timestamp.

- **only-local**

Specifies whether to decode only local logs.

Value range: **0** and **1**. The default value is **1**.

- **0**: Non-local logs and local logs are decoded.
- **1**: Only local logs are decoded.

- **force-binary**

Specifies whether to output the decoding result in binary format.

Value range: **0** or **1**. The default value is **0**. The result is output in binary format.

- **white-table-list**

Whitelist parameter, including the schema and table name to be decoded.

Value range: a string that contains table names in the whitelist. Different tables are separated by commas (,). An asterisk (\*) is used to fuzzily match all tables. Schema names and table names are separated by periods (.). No space character is allowed. The following is an example:

```
select * from pg_logical_slot_peek_binary_changes('slot1', NULL, 4096, 'white-table-list', 'public.t1,public.t2');
```

Return type: text, xid, bytea

Note: The function returns the decoding result. Each decoding result contains three columns, corresponding to the above return types and indicating the LSN position, XID, and decoded content in binary format, respectively. Users who call this function must have the SYSADMIN permission or the REPLICATION permission, or inherit the permissions of the built-in role `gs_role_replication`.

- `pg_logical_slot_get_binary_changes('slot_name', 'LSN', upto_nchanges, 'options_name', 'options_value')`

Description: Performs decoding in binary format and does not go to the next streaming replication slot.

Parameter: This function has the same parameters as **`pg_logical_slot_peek_binary_changes`**. For details, see [•pg\\_logical\\_slot\\_peek\\_bi...](#)

Note: Users who call this function must have the SYSADMIN permission or the REPLICATION permission, or inherit permissions of the built-in role `gs_role_replication`.

- `pg_replication_slot_advance ('slot_name', 'LSN')`

Description: Directly goes to the streaming replication slot for a specified LSN, without outputting any decoded result.

Parameter description:

- `slot_name`

Indicates the name of the streaming replication slot.

Value range: a string, supporting only lowercase letters, digits, underscores (\_), question marks (?), hyphens (-), and periods (.). One or two periods cannot be used alone as the replication slot name.

- `LSN`

Indicates a target LSN. Next decoding will be performed only in transactions whose commit position is greater than this value. If an input LSN is smaller than the position recorded in the current streaming replication slot, an error is reported. If the input LSN is greater than the LSN of the current physical log, the latter LSN will be directly used for decoding.

Value range: a string, in the format of *xlogid/xrecoff*

Return type: name, text

Note: A return result contains the slot name and LSN that is actually used for decoding. Users who call this function must have the SYSADMIN permission or the REPLICATION permission, or inherit the permissions of the built-in role `gs_role_replication`. Currently, this function can be called only on the primary node.

- `pg_logical_get_area_changes('LSN_start', 'LSN_end', upto_nchanges, 'decoding_plugin', 'xlog_path', 'options_name', 'options_value')`

Description: Specifies an LSN range or an Xlog file for decoding when no DDL operation is performed.

The constraints are as follows:

- When the API is called, only when **wal\_level** is set to **logical**, the generated log files can be parsed. If the used Xlog file is not of the logical level, the decoded content does not have the corresponding value and type, and there is no other impact.
- The Xlog file can be parsed only by a copy of a fully homogeneous DN to ensure that the metadata corresponding to the data can be found and no DDL or VACUUM FULL operation is performed.
- You can find the Xlog to be parsed.
- Do not read too many Xlog files at a time. You are advised to read one Xlog file at a time. It is estimated that the memory occupied by one Xlog file is two to three times the size of the Xlog file.
- The Xlog file before scale-out cannot be decoded.

Parameter description:

- **LSN\_start**

Specifies the LSN at the start of decoding.

Value range: a string, in the format of *xlogid/xrecoff*, for example, **'1/2AAFC60'**. If this parameter is set to NULL, the start position of decoding logs is not limited.

- **LSN\_end**

Specifies the LSN at the end of decoding.

Value range: a string, in the format of *xlogid/xrecoff*, for example, **'1/2AAFC60'**. (If this parameter is set to **NULL**, the target LSN indicating the end position of decoding is not specified.)

- **upto\_nchanges**

Indicates the number of decoded records (including the **begin** and **commit** timestamps). Assume that there are three transactions, which involve 3, 5, and 7 records, respectively. If **upto\_nchanges** is set to **4**, 8 records of the first two transactions will be decoded. Specifically, decoding is stopped when the number of decoded records exceeds the value of **upto\_nchanges** after decoding in the first two transactions is finished.

Value range: a non-negative integer

#### NOTE

If any of the **LSN** and **upto\_nchanges** values are reached, decoding ends.

- **decoding\_plugin**

Decoding plug-in, which is a .so plug-in that specifies the output format of the decoded content.

Value range: **mppdb\_decoding** and **sql\_decoding**.

- **xlog\_path**

Decoding plug-in, which specifies the Xlog absolute path and file level of the decoding file.

Value range: **NULL** or a character string of the absolute path of the Xlog file.

- **options**: This parameter is optional and consists of multiple pairs of **options\_name** and **options\_value**. You can retain the default values. For details, see [pg\\_logical\\_slot\\_peek\\_changes](#).

Example:

```
openGauss=# SELECT pg_current_xlog_location();
pg_current_xlog_location

0/E62E238
(1 row)

openGauss=# create table t1 (a int primary key,b int,c int);
NOTICE: CREATE TABLE / PRIMARY KEY will create implicit index "t1_pkey" for table "t1"
CREATE TABLE
openGauss=# insert into t1 values(1,1,1);
INSERT 0 1
openGauss=# insert into t1 values(2,2,2);
INSERT 0 1

openGauss=# select data from pg_logical_get_area_changes('0/
E62E238',NULL,NULL,'sql_decoding',NULL);
 location | xid | data
-----+-----+-----
0/E62E8D0 | 27213 | COMMIT (at 2022-01-26 15:08:03.349057+08) 3020226
0/E6325F0 | 27214 | COMMIT (at 2022-01-26 15:08:07.309869+08) 3020234
.....
```

- **pg\_get\_replication\_slots()**

Description: Obtains the replication slot list.

Return type: text, text, text, oid, Boolean, xid, xid, text, Boolean, text

Example:

```
openGauss=# select * from pg_get_replication_slots();
 slot_name | plugin | slot_type | datoid | active | xmin | catalog_xmin | restart_lsn |
 dummy_standby | confirmed_flush
-----+-----+-----+-----+-----+-----+-----+-----+-----
dn_s1 | | physical | 0 | t | | | 0/23DB14E0 | f |
slot1 | mppdb_decoding | logical | 16304 | f | | | 60966 | 0/1AFA1BB0 | f |
0/23DA5700
(2 rows)
```

- **gs\_get\_parallel\_decode\_status()**

Description: Monitors the length of the read log queue and decoding result queue of each decoder thread to locate the concurrent decoding performance bottleneck.

Return type: text, int, text, text, text, int64, int64

Example:

```
openGauss=# select * from gs_get_parallel_decode_status();
 slot_name | parallel_decode_num | read_change_queue_length | decode_change_queue_length |
 reader_lsn | working_txn_cnt | working_txn_memory
-----+-----+-----+-----+-----+-----+-----
slot1 | 2 | queue0: 1005, queue1: 320 | queue0: 63, queue1: 748 | 0/1DCE2578
| 42 | 192927504
(1 row)
```

Note: In the return values, **slot\_name** indicates the replication slot name, **parallel\_decode\_num** indicates the number of parallel decoder threads in the replication slot, **read\_change\_queue\_length** indicates the current length of

the log queue read by each decoder thread, **decode\_change\_queue\_length** indicates the current length of the decoding result queue of each decoder thread, **reader\_lsn** indicates the log location read by the reader thread, **working\_txn\_cnt** indicates the number of transactions being concatenated in the current sender thread, and **working\_txn\_memory** indicates the total memory (in bytes) occupied by the concatenation transactions in the sender thread.

- **pg\_replication\_origin\_create** (node\_name)

Description: Creates a replication source with a given external name and returns the internal ID assigned to it.

Note: The user who calls this function must have the SYSADMIN permission.

Parameter description:

- node\_name  
Specifies the name of the replication source to be created.  
Value range: a string, supporting only letters, digits, underscores (\_), question marks (?), hyphens (-), and periods (.).

Return type: oid

- **pg\_replication\_origin\_drop** (node\_name)

Description: Deletes a previously created replication source, including any associated replay progress.

Note: The user who calls this function must have the SYSADMIN permission.

Parameter description:

- node\_name  
Specifies the name of the replication source to be deleted.  
Value range: a string, supporting only letters, digits, underscores (\_), question marks (?), hyphens (-), and periods (.).

- **pg\_replication\_origin\_oid** (node\_name)

Description: Searches for a replication source by name and returns the internal ID. If no such replication source is found, an error is thrown.

Note: The user who calls this function must have the SYSADMIN permission.

Parameter description:

- node\_name  
Specifies the name of the replication source to be queried.  
Value range: a string, supporting only letters, digits, underscores (\_), question marks (?), hyphens (-), and periods (.).

Return type: oid

- **pg\_replication\_origin\_session\_setup** (node\_name)

Description: Marks the current session for replaying from a given origin, allowing you to track replay progress. This parameter can be used only when no origin is selected. Run the **pg\_replication\_origin\_session\_reset** command to cancel the configuration.

Note: The user who calls this function must have the SYSADMIN permission.

Parameter description:

- node\_name

Specifies the name of the replication source.

Value range: a string, supporting only letters, digits, underscores (\_), question marks (?), hyphens (-), and periods (.).

- `pg_replication_origin_session_reset ()`  
Description: Cancels the **pg\_replication\_origin\_session\_setup()** effect.  
Note: The user who calls this function must have the SYSADMIN permission.
- `pg_replication_origin_session_is_setup ()`  
Description: Returns a true value if a replication source is selected in the current session.  
Note: The user who calls this function must have the SYSADMIN permission.  
Return type: Boolean
- `pg_replication_origin_session_progress (flush)`  
Description: Returns the replay position of the replication source selected in the current session.  
Note: The user who calls this function must have the SYSADMIN permission.  
Parameter description:
  - `flush`  
Determines whether the corresponding local transaction has been flushed to disk.  
Value range: BooleanReturn type: LSN
- `pg_replication_origin_xact_setup (origin_lsn, origin_timestamp)`  
Description: Marks the current transaction as recommitted at a given LSN and timestamp. This function can be called only when **pg\_replication\_origin\_session\_setup** is used to select a replication source.  
Note: The user who calls this function must have the SYSADMIN permission.  
Parameter description:
  - `origin_lsn`  
Position for replaying the replication source.  
Value range: LSN
  - `origin_timestamp`  
Time point when a transaction is committed  
Value range: timestamp with time zone
- `pg_replication_origin_xact_reset ()`  
Description: Cancels the **pg\_replication\_origin\_xact\_setup()** effect.  
Note: The user who calls this function must have the SYSADMIN permission.
- `pg_replication_origin_advance (node_name, lsn)`  
Description:  
Sets the replication progress of a given node to a given position. This is primarily used to set the initial position, or to set a new position after a configuration change or similar change.  
Note: Improper use of this function may cause inconsistent replication data.  
Note: The user who calls this function must have the SYSADMIN permission.

Parameter description:

- node\_name

Specifies the name of an existing replication source.

Value range: a string, supporting only letters, digits, underscores (\_), question marks (?), hyphens (-), and periods (.).

- lsn

Position for replaying the replication source.

Value range: LSN

- pg\_replication\_origin\_progress (node\_name, flush)

Description: Returns the position for replaying the given replication source.

Note: The user who calls this function must have the SYSADMIN permission.

Parameter description:

- node\_name

Specifies the name of the replication source.

Value range: a string, supporting only letters, digits, underscores (\_), question marks (?), hyphens (-), and periods (.).

- flush

Determines whether the corresponding local transaction has been flushed to disk.

Value range: Boolean

- pg\_show\_replication\_origin\_status()

Description: Displays the replication status of the replication source.

Note: The user who calls this function must have the SYSADMIN permission.

Return type:

- **local\_id**: OID, which specifies the ID of the replication source.
- **external\_id**: text, which specifies the name of the replication source.
- **remote\_lsn**: LSN of the replication source.
- **local\_lsn**: local LSN.

### 7.5.23.11 Segment-Page Storage Functions

- local\_segment\_space\_info(tablespace\_name TEXT, database\_name TEXT)

Description: Generates usage information about all extent groups in the tablespace.

Return type:

|              |                                                                             |
|--------------|-----------------------------------------------------------------------------|
| node_name    | Node name                                                                   |
| extent_size  | Extent specifications of an extent group. The unit is the number of blocks. |
| forknum      | Fork number                                                                 |
| total_blocks | Total number of extents in a physical file                                  |

|                  |                                                                                                                                                                                                |
|------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| meta_data_blocks | Number of blocks occupied by the metadata managed in a tablespace, including the space header and map page but excluding the segment head                                                      |
| used_data_blocks | Number of extents used for storing data, including the segment head                                                                                                                            |
| utilization      | Percentage of the number of used blocks to the total number of blocks, that is, (the value of <b>used_data_blocks</b> + the value of <b>meta_data_block</b> )/the value of <b>total_blocks</b> |
| high_water_mark  | High-water mark, indicating the number of allocated extents and maximum physical page number. Blocks that exceed the high-water mark are not used and can be directly recycled.                |

Example:

```
select * from local_segment_space_info('pg_default', 'testdb');
 node_name | extent_size | forknum | total_blocks | meta_data_blocks | used_data_blocks |
utilization | high_water_mark
-----+-----+-----+-----+-----+-----+-----
dn_6001_6002_6003 | 1 | 0 | 16384 | 4157 | 1 | .253784 |
4158
dn_6001_6002_6003 | 8 | 0 | 16384 | 4157 | 8 | .254211 |
4165
(2 rows)
```

- pg\_stat\_segment\_extent\_usage(int4 tablespace oid, int4 database oid, int4 extent\_type, int4 forknum)

Description: Specifies the usage information of each allocated extent in an extent group returned each time. **extent\_type** indicates the type of the extent group. The value is an integer ranging from 1 to 5. If the value is not within the range, an error is reported. **forknum** indicates the fork number. The value is an integer ranging from 0 to 4. Currently, only the following values are valid: **0** for data files, **1** for FSM files, and **2** for visibility map files.

Return type:

| Name           | Description                                                                                                                                                  |
|----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| start_block    | Start physical page number of an extent                                                                                                                      |
| extent_size    | Size of an extent                                                                                                                                            |
| usage_type     | Usage type of an extent, for example, <b>segment head</b> and <b>data extent</b>                                                                             |
| owner_location | Object location of an extent to which a pointer points. For example, the owner of a data extent is the head of the segment to which the data extent belongs. |

| Name         | Description                                                                                                                                                                                            |
|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| special_data | Position of an extent in its owner. The value of this field is related to the usage type. For example, special data of a data extent is the extent ID in the segment to which the data extent belongs. |

The value of **usage\_type** is enumerated. The meaning of each value is as follows:

- **Non-bucket table segment head**: data segment head of a non-hash bucket table
- **Non-bucket table fork head**: fork segment header of a non-segment-page table
- **Data extent**: data block

Example:

```
select * from pg_stat_segment_extent_usage((select oid::int4 from pg_tablespace where
spcname='pg_default'), (select oid::int4 from pg_database where datname='testdb'), 1, 0);
```

| start_block | extent_size | usage_type  | owner_location | special_data |
|-------------|-------------|-------------|----------------|--------------|
| 4157        | 1           | Data extent | 4294967295     | 0            |
| 4158        | 1           | Data extent | 4157           | 0            |

- **local\_space\_shrink**(tablespacename TEXT, databasename TEXT)

Description: Shrinks specified physical segment-page space on the current node. Only the currently connected database can be shrunk.

Return value: empty

- **gs\_space\_shrink**(int4 tablespace, int4 database, int4 extent\_type, int4 forknum)

Description: Works similar to **local\_space\_shrink**, that is, shrinks specified physical segment-page space. However, the parameters are different. The input parameters are the OIDs of the tablespace and database, and the value of **extent\_type** is an integer ranging from 2 to 5. Note: The value 1 of **extent\_type** indicates segment-page metadata. Currently, the physical file that contains the metadata cannot be shrunk. This function is used only by tools. You are advised not to use it directly.

Return value: empty

- **pg\_stat\_remain\_segment\_info**()

Description: Displays residual extents on the current node due to faults. Residual extents are classified into two types: segments that are allocated but not used and extents that are allocated but not used. The main difference is that a segment contains multiple extents. During reclamation, all extents in the segment need to be recycled.

Return type:

| Name     | Description   |
|----------|---------------|
| space_id | Tablespace ID |

|          |                                                                                                                     |
|----------|---------------------------------------------------------------------------------------------------------------------|
| db_id    | Database ID                                                                                                         |
| block_id | Extent ID                                                                                                           |
| type     | Extent type. The options are as follows:<br><b>ALLOC_SEGMENT</b> , <b>DROP_SEGMENT</b> , and <b>SHRINK_EXTENT</b> . |

The values of **type** are described as follows:

- **ALLOC\_SEGMENT**: When a user creates a segment-page table and the segment is just allocated but the transaction of creating a table is not committed, the node is faulty. As a result, the segment is not used after being allocated.
- **DROP\_SEGMENT**: When a user deletes a segment-page table and the transaction is successfully committed, the bit corresponding to the segment page of the table is not reset and a fault, such as power failure, occurs. As a result, the segment is not used or released.
- **SHRINK\_EXTENT**: When a user shrinks a segment-page table and does not release the idle extent, a fault, such as power failure, occurs. As a result, the extent remains and cannot be reused.

Example:

```
select * from pg_stat_remain_segment_info();
space_id | db_id | block_id | type
-----+-----+-----+-----
1663 | 16385 | 4156 | ALLOC_SEGMENT
```

- `pg_free_remain_segment(int4 spaceId, int4 dbId, int4 segmentId)`

Description: Releases a specified residual extent. The value must be obtained from the **pg\_stat\_remain\_segment\_info** function. The function verifies input values. If the specified extent is not among the recorded residual extents, an error message is returned. If the specified extent is a single extent, the extent is released independently. If it is a segment, the segment and all extents in the segment are released.

Return value: empty

### 7.5.23.12 Other Functions

- `plan_seed()`

Description: Obtains the seed value of the previous query statement (internal use).

Return type: int

- `pg_stat_get_env()`

Description: Obtains the environment variable information of the current node. Only users with the SYSADMIN or MONADMIN permission can access the environment variable information.

Return type: record

Example:

```
openGauss=# select pg_stat_get_env();
pg_stat_get_env
```

```

(sgnode,"localhost,XXX.XXX.XXX.XXX",28589,26000,/home/omm,/home/omm/data/
single_node,pg_log)
(1 row)
```

- `pg_catalog.plancache_clean()`  
Description: Clears the global plan cache that is not used on nodes.  
Return type: Boolean
- `pg_catalog.plancache_status()`  
Description: Displays information about the global plan cache on nodes. The information returned by the function is the same as that in [GLOBAL\\_PLANCACHE\\_STATUS](#).  
Return type: record
- `textlen(text)`  
Description: Provides the method of querying the logical length of text.  
Return type: int
- `threadpool_status()`  
Description: Displays the status of worker threads and sessions in the thread pool.  
Return type: record
- `get_local_active_session()`  
Description: Provides sampling records of the historical active sessions stored in the memory of the current node.  
Return type: record
- `pg_stat_get_thread()`  
Description: Provides status information about all threads on the current node. Users with the SYSADMIN or MONADMIN permission can view information about all threads, and common users can view only their own thread information.  
Return type: record
- `pg_stat_get_sql_count()`  
Description: Provides the counts of the SELECT, UPDATE, INSERT, DELETE, and MERGE INTO statements executed on the current node. Users with the SYSADMIN or MONADMIN permission can view information about all users, and common users can view only their own statistics.  
Return type: record
- `pg_stat_get_data_senders()`  
Description: Provides detailed information about the data-copy sender thread active at the moment.  
Return type: record
- `get_wait_event_info()`  
Description: Provides detailed information about the wait event.  
Return type: record
- `generate_wdr_report(begin_snap_id bigint, end_snap_id bigint, report_type cstring, report_scope cstring, node_name cstring)`

Description: Generates system diagnosis reports based on two snapshots. You need to run the command in the system database. By default, the initial user or users with the MONADMIN permission can access the database. The result can be queried only in the system database but cannot be queried in the user database.

Return type: record

**Table 7-46** generate\_wdr\_report parameter description

| Parameter     | Description                                                                                                                                                                                                                                                                                                                | Range                                                                                                                                                                    |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| begin_snap_id | Snapshot ID that starts the diagnosis report period.                                                                                                                                                                                                                                                                       | N/A                                                                                                                                                                      |
| end_snap_id   | Snapshot ID that ends the diagnosis report period. By default, the value of <b>end_snap_id</b> is greater than that of <b>begin_snap_id</b> .                                                                                                                                                                              | N/A                                                                                                                                                                      |
| report_type   | Specifies the type of the generated report.                                                                                                                                                                                                                                                                                | <ul style="list-style-type: none"><li>• <b>summary</b></li><li>• <b>detail</b></li><li>• <b>all</b>: Both <b>summary</b> and <b>detail</b> are included.</li></ul>       |
| report_scope  | Specifies the scope for a report to be generated.                                                                                                                                                                                                                                                                          | <ul style="list-style-type: none"><li>• <b>cluster</b>: database-level information</li><li>• <b>node</b>: node-level information</li></ul>                               |
| node_name     | When <b>report_scope</b> is set to <b>node</b> , set this parameter to the name of the corresponding node. (You can run the <b>select * from pg_node_env;</b> command to query the node name.)<br><br>If <b>report_scope</b> is set to <b>cluster</b> , this parameter can be omitted, left blank, or set to <b>NULL</b> . | <ul style="list-style-type: none"><li>• <b>cluster</b>: This value is omitted, left blank or set to <b>NULL</b>.</li><li>• <b>node</b>: a node name in GaussDB</li></ul> |

- create\_wdr\_snapshot()

Description: Manually generates system diagnosis snapshots. This function requires the SYSADMIN permission.

Return type: text

- kill\_snapshot()

Description: Kills the WDR snapshot backend thread. Users who call this function must have the SYSADMIN permission, the REPLICATION permission, or inherit permissions of the built-in role gs\_role\_replication.

Return type: void

- `capture_view_to_json(text,integer)`

Description: Saves the view result to the directory specified by GUC: **perf\_directory**. If **is\_crossdb** is set to **1**, the view is accessed once for all databases. If the value of **is\_crossdb** is **0**, the current database is accessed only once. Only users with the SYSADMIN or MONADMIN permission can execute this function.

Return type: int

- `reset_unique_sql`

Description: Clears the unique SQL statements in the memory of the database node. (The SYSADMIN permission is required.)

Return type: Boolean

**Table 7-47** reset\_unique\_sql parameter description

| Parameter   | Type | Description                                                                                                                                                                                                                                                                  |
|-------------|------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| scope       | text | Clearance scope type. The options are as follows: <ul style="list-style-type: none"><li>• <b>GLOBAL</b>: Clears all nodes. If the value is <b>GLOBAL</b>, this function can be executed only on the primary node.</li><li>• <b>LOCAL</b>: Clears the current node.</li></ul> |
| clean_type  | text | <ul style="list-style-type: none"><li>• <b>BY_USERID</b>: Unique SQL statements are cleared based on user IDs.</li><li>• <b>BY_CNID</b>: Unique SQL statements are cleared based on primary node IDs.</li><li>• <b>ALL</b>: All data is cleared.</li></ul>                   |
| clean_value | int8 | Clearance value corresponding to the clearance type. If the second parameter is set to <b>ALL</b> , the third parameter does not take effect and can be set to any value.                                                                                                    |

- `wdr_xdb_query(db_name_str text, query text)`

Description: Provides the capability of executing local cross-database queries. For example, when connecting to the **testdb** database, access tables in the **test** database.

```
select col1 from wdr_xdb_query('dbname=test','select col1 from t1') as dd(col1 int);
```

Return type: record

- **pg\_wlm\_jump\_queue(pid int)**

Description: Moves a task to the top of the queue of the primary node of the database.

Return type: Boolean

- **true**: success
- **false**: failure

- **gs\_wlm\_switch\_cgroup(pid int, cgroup text)**

Description: Moves a job to another Cgroup to change the job priority.

Return type: Boolean

- **true**: success
- **false**: failure

- **pv\_session\_memctx\_detail(threadid tid, MemoryContextName text)**

Description: Records information about the memory context

**MemoryContextName** of the thread **tid** into the *threadid\_timestamp.log* file in the *\$GAUSSLOG/pg\_log/\${node\_name}/dumpmem* directory. *threadid* can be obtained from *sessid* in the **GS\_SESSION\_MEMORY\_DETAIL** view. In the officially released version, only the **MemoryContextName** that is an empty string (two single quotation marks indicate that the input is an empty string) is accepted. In this case, all memory context information is recorded. Otherwise, no operation is performed. For the DEBUG version for internal development and test personnel to debug, you can specify the **MemoryContextName** to be counted. In this case, all the memory usage of the context is recorded in the specified file. Only the administrator can execute this function.

Return type: Boolean

- **true**: success
- **false**: failure

- **pg\_shared\_memctx\_detail(MemoryContextName text)**

Description: Records information about the memory context

**MemoryContextName** into the *threadid\_timestamp.log* file in the *\$GAUSSLOG/pg\_log/\${node\_name}/dumpmem* directory. This function is provided only for internal development and test personnel to debug in the DEBUG version. Calling this function in the officially released version does not involve any operation. Only the administrator can execute this function.

Return type: Boolean

- **true**: success
- **false**: failure

- **local\_bgwriter\_stat()**

Description: Displays the information about pages flushed by the bgwriter thread of this instance, number of pages in the candidate buffer chain, and buffer elimination information.

Return type: record

- `local_candidate_stat()`

Description: Displays the number of pages in the candidate buffer chain of this instance and buffer elimination information, including the normal buffer pool and segment buffer pool.

Return type: record

- `local_ckpt_stat()`

Description: Displays the information about checkpoints and flushing pages of the current instance.

Return type: record

- `local_double_write_stat()`

Description: Displays the doublewrite file status of the current instance.

Return type: record

**Table 7-48** `local_double_write_stat` parameters

| Parameter                          | Type | Description                                                                                                                     |
|------------------------------------|------|---------------------------------------------------------------------------------------------------------------------------------|
| <code>node_name</code>             | text | Instance name                                                                                                                   |
| <code>curr_dwn</code>              | int8 | Sequence number of the doublewrite file                                                                                         |
| <code>curr_start_page</code>       | int8 | Start page for restoring the doublewrite file                                                                                   |
| <code>file_trunc_num</code>        | int8 | Number of times that the doublewrite file is reused                                                                             |
| <code>file_reset_num</code>        | int8 | Number of reset times after the doublewrite file is full                                                                        |
| <code>total_writes</code>          | int8 | Total number of I/Os of the doublewrite file                                                                                    |
| <code>low_threshold_writes</code>  | int8 | Number of I/Os for writing doublewrite files with low efficiency (the number of I/O flushing pages at a time is less than 16)   |
| <code>high_threshold_writes</code> | int8 | Number of I/Os for writing doublewrite files with high efficiency (the number of I/O flushing pages at a time is more than 421) |
| <code>total_pages</code>           | int8 | Total number of pages that are flushed to the doublewrite file area                                                             |
| <code>low_threshold_pages</code>   | int8 | Number of pages that are flushed with low efficiency                                                                            |
| <code>high_threshold_pages</code>  | int8 | Number of pages that are flushed with high efficiency                                                                           |
| <code>file_id</code>               | int8 | ID of the current doublewrite file                                                                                              |

- `local_single_flush_dw_stat()`

Description: Displays the elimination of doublewrite files on a single page in the instance.

Return type: record

- `local_pagewriter_stat()`

Description: Displays the page flushing information and checkpoint information of the current instance.

Return type: record

- `local_redo_stat()`

Description: Displays the replay status of the current standby instance.

Return type: record

Note: The returned replay status includes the current replay position and the replay position of the minimum restoration point.

- `local_recovery_status()`

Description: Displays log flow control information about the primary and standby nodes.

Return type: record

- `gs_wlm_node_recover(boolean isForce)`

Description: Obtains top SQL query statement-level statistics recorded in the current memory. If the input parameter is not **0**, the information is cleared from the memory.

Return type: record

- `gs_cgroup_map_ng_conf(group name)`

Description: Reads the Cgroup configuration file of a specified logical database.

Return type: record

- `gs_wlm_switch_cgroup(sess_id int8, cgroup name)`

Description: Switches the Cgroup of a specified session.

Return type: record

- `comm_client_info()`

Description: Queries information about active client connections of a single node.

Return type: SETOF record

- `pg_get_flush_lsn()`

Description: Returns the location of the Xlog flushed from the current node.

Return type: text

- `pg_get_sync_flush_lsn()`

Description: Returns the location of the Xlog flushed by the majority on the current node.

Return type: text

- `dbe_perf.get_global_full_sql_by_timestamp(start_timestamp timestamp with time zone, end_timestamp timestamp with time zone)`

Description: Obtains full SQL information at the database level. The result can be queried only in the system database but cannot be queried in the user database.

Return type: record

**Table 7-49** db\_perf.get\_global\_full\_sql\_by\_timestamp parameter description

| Parameter       | Type                     | Description                              |
|-----------------|--------------------------|------------------------------------------|
| start_timestamp | timestamp with time zone | Start point of the SQL start time range. |
| end_timestamp   | timestamp with time zone | End point of the SQL start time range.   |

- db\_perf.get\_global\_slow\_sql\_by\_timestamp(start\_timestamp timestamp with time zone, end\_timestamp timestamp with time zone)

Description: Obtains slow SQL information at the database level. The result can be queried only in the system database but cannot be queried in the user database.

Return type: record

**Table 7-50** db\_perf.get\_global\_slow\_sql\_by\_timestamp parameter description

| Parameter       | Type                     | Description                              |
|-----------------|--------------------------|------------------------------------------|
| start_timestamp | timestamp with time zone | Start point of the SQL start time range. |
| end_timestamp   | timestamp with time zone | End point of the SQL start time range.   |

- statement\_detail\_decode(detail text, format text, pretty boolean)

Description: Parses the **details** column in a full or slow SQL statement. The result can be queried only in the system database but cannot be queried in the user database.

Return type: text

**Table 7-51** statement\_detail\_decode parameter description

| Parameter     | Type | Description                                                |
|---------------|------|------------------------------------------------------------|
| <b>detail</b> | text | Set of events generated by the SQL statement (unreadable). |
| format        | text | Parsing output format. The value is <b>plaintext</b> .     |

| Parameter | Type    | Description                                                                                                                                                                                                                                                                                                                                     |
|-----------|---------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| pretty    | boolean | Specifies whether to display the text in pretty format when <b>format</b> is set to <b>plaintext</b> . The options are as follows: <ul style="list-style-type: none"> <li>The value <b>true</b> indicates that events are separated by <b>\n</b>.</li> <li>The value <b>false</b> indicates that events are separated by commas (,).</li> </ul> |

- `pg_control_system()`  
Description: Returns the status of the system control file.  
Return type: SETOF record
- `pg_control_checkpoint()`  
Description: Returns the system checkpoint status.  
Return type: SETOF record
- `get_prepared_pending_xid`  
Description: Returns nextxid when restoration is complete.  
Parameter: nan  
Return type: text
- `pg_clean_region_info`  
Description: Clears the region map.  
Parameter: nan  
Return type: character varying
- `pg_get_delta_info`  
Description: Obtains delta information from a single DN.  
Parameter: rel text, schema\_name text  
Return type: part\_name text, live\_tuple bigint, data\_size bigint, and blocknum bigint
- `pg_get_replication_slot_name`  
Description: Obtains the slot name.  
Parameter: nan  
Return type: text
- `pg_get_running_xacts`  
Description: Obtains running xact.  
Parameter: **nan**  
Return type: handle integer, gxid xid, state tinyint, node text, xmin xid, vacuum Boolean, timeline bigint, prepare\_xid xid, pid bigint, and next\_xid xid
- `pg_get_variable_info`  
Description: Obtains the shared memory variable *cache*.  
Parameter: nan  
Return type: node\_name text, nextOid oid, nextXid xid, oldestXid xid, xidVacLimit xid, oldestXidDB oid, lastExtendCSNLogpage xid,

- startExtendCSNLogpage xid, nextCommitSeqNo xid, latestCompletedXid xid, and startupMaxXid xid
- **pg\_get\_xidlimit**  
Description: Obtains transaction ID information from the shared memory.  
Parameter: nan  
Return type: nextXid xid, oldestXid xid, xidVacLimit xid, xidWarnLimit xid, xidStopLimit xid, xidWrapLimit xid, and oldestXidDB oid
- **pg\_stat\_file\_recursive**  
Description: Lists all files in the path.  
Parameter: location text  
Return type: path text, filename text, size bigint, and isdir Boolean
- **pg\_stat\_get\_activity\_for temptable**  
Description: Returns records of backend processes related to the temporary table.  
Parameter: nan  
Return type: datid oid, timelineid integer, tempid integer, and sessionid bigint
- **pg\_stat\_get\_activity\_ng**  
Description: Returns records of backend processes related to nodegroup.  
Parameter: pid bigint  
Return type: datid oid, pid bigint, sessionid bigint, and node\_group text
- **pg\_stat\_get\_cgroup\_info**  
Description: Returns Cgroup information.  
Parameter: **nan**  
Return type: cgroup\_name text, percent integer, usage\_percent integer, shares bigint, usage bigint, cpuset text, relpath text, valid text, and node\_group text
- **pg\_stat\_get\_realtime\_info\_internal**  
Description: Returns real-time information. Currently, this API is unavailable. **FailedToGetSessionInfo** is returned.  
Parameter: oid, oid, bigint, cstring, oid  
Return type: text
- **pg\_test\_err\_contain\_err**  
Description: Tests the error type and return information.  
Parameter: integer  
Return type: void
- **get\_global\_user\_transaction()**  
Description: Returns transaction information about each user on all nodes.  
Return type: node\_name name, username name, commit\_counter bigint, rollback\_counter bigint, resp\_min bigint, resp\_max bigint, resp\_avg bigint, resp\_total bigint, bg\_commit\_counter bigint, bg\_rollback\_counter bigint, bg\_resp\_min bigint, bg\_resp\_max bigint, bg\_resp\_avg bigint, and bg\_resp\_total bigint
- **pg\_collation\_for**

Description: Returns the collation rule corresponding to the input parameter string.

Parameter: any (Explicit type conversion is required for constants.)

Return type: text

- `pgxc_unlock_for_sp_database(name Name)`

Description: Releases a specified database lock.

Parameter: database name

Return type: Boolean

- `pgxc_lock_for_sp_database(name Name)`

Description: Locks a specified database.

Parameter: database name

Return type: Boolean

- `copy_error_log_create()`

Description: Creates the error table (**public.pgxc\_copy\_error\_log**) required for creating the **COPY FROM** error tolerance mechanism.

Return type: Boolean

#### NOTE

- This function attempts to create the **public.pgxc\_copy\_error\_log** table. For details about the table, see [Table 7-52](#).
- In addition, it creates a B-tree index on the **relname** column and executes **REVOKE ALL on public.pgxc\_copy\_error\_log FROM public** to manage permissions on the error table (the permissions are the same as those of the **COPY** statement).
- **public.pgxc\_copy\_error\_log** is a row-store table. Therefore, this function can be executed and **COPY** error tolerance is available only when row-store tables can be created in the database instance. Note that after the GUC parameter **enable\_hadoop\_env** is enabled, row-store tables cannot be created in the database instance (the default value is **off** for GaussDB).
- Same as the error table and the **COPY** statement, the function requires **SYSADMIN** or higher permissions.
- If the **public.pgxc\_copy\_error\_log** table or the **copy\_error\_log\_relname\_idx** index exists before the function creates it, the function will report an error and roll back.

**Table 7-52** Error table `public.pgxc_copy_error_log`

| Column    | Type                     | Description                                                              |
|-----------|--------------------------|--------------------------------------------------------------------------|
| relname   | character varying        | Table name, in the form of <i>Schema name.Table name</i> .               |
| begintime | timestamp with time zone | Time when a data format error was reported                               |
| filename  | character varying        | Name of the source data file where a data format error occurs            |
| lineno    | bigint                   | Number of the row where a data format error occurs in a source data file |

| Column    | Type | Description                                               |
|-----------|------|-----------------------------------------------------------|
| rawrecord | text | Raw record of a data format error in the source data file |
| detail    | text | Error details                                             |

- dynamic\_func\_control(scope text, function\_name text, action text, "{params}" text[])

Description: Dynamically enables built-in functions. Currently, only full SQL statements can be dynamically enabled.

Return type: record

**Table 7-53** Parameter description of dynamic\_func\_control

| Parameter     | Type   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

- gs\_xlogdump\_lsn(start\_lsn text, end\_lsn text)**  
Description: Parses Xlogs within the specified LSN range and returns the path for storing the parsed content. You can use **pg\_current\_xlog\_location()** to obtain the current Xlog location.  
Return type: text  
Parameters: LSN start position and LSN end position

Note: Only SYSADMIN or OPRADMIN can execute this function.

- `gs_xlogdump_xid(c_xid xid)`

Description: Parses Xlogs of a specified XID and returns the path for storing the parsed content. You can use `txid_current()` to obtain the current XID.

Parameter: XID

Return type: text

Note: Only SYSADMIN or OPRADMIN can execute this function.

- `gs_xlogdump_tablepath(path text, blocknum bigint, relation_type text)`

Description: Parses logs corresponding to a specified table page and returns the path for storing the parsed content.

Return type: text

Note: Only SYSADMIN or OPRADMIN can execute this function.

**Table 7-55** `gs_xlogdump_tablepath` parameters

| Parameter     | Type   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

- `gs_xlogdump_parsepage_tablepath(path text, blocknum bigint, relation_type text, read_memory boolean)`

Description: Parses the specified table page and logs corresponding to the table page and returns the path for storing the parsed content. It can be regarded as one execution of **gs\_parse\_page\_bypath** and **gs\_xlogdump\_tablepath**. The prerequisite for executing this function is that the table file exists. To view logs of deleted tables, call **gs\_xlogdump\_tablepath**.

Return type: text

Note: Only SYSADMIN or OPRADMIN can execute this function.

**Table 7-56** `gs_xlogdump_parsepage_tablepath` parameters

| Parameter     | Type   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|---------------|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| path          | text   | <ul style="list-style-type: none"><li>• For an ordinary table or segment-page table, the relative path is <i>Tablespace name/ Database OID/ Relfilenode of the table (physical file name)</i>. For example, <b>base/16603/16394</b>.</li><li>• You can run the <b>pg_relation_filepath(table_name text)</b> command to query the relative path of the table file. To obtain the path of the partitioned table, view the <b>pg_partition</b> system catalog and call <b>pg_partition_filepath(partition_oid)</b>.</li><li>• Valid path formats are as follows:<ul style="list-style-type: none"><li>– global/relNode</li><li>– base/dbNode/relNode</li><li>– pg_tblspc/spcNode/version_dir/dbNode/relNode</li></ul></li></ul> |

| Parameter   | Type    | Description                                                                                                                                                                                                                                                                                         |
|-------------|---------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| read_memory | boolean | <ul style="list-style-type: none"><li>• <b>false</b>: The system parses the page from the disk file.</li><li>• <b>true</b>: The system attempts to parse the page from the shared buffer. If the page does not exist in the shared buffer, the system parses the page from the disk file.</li></ul> |

- `gs_index_verify(Oid oid, uint32 blkno)`

Description: Checks whether the sequence of keys on the UB-tree index page or index tree is correct.

Return type: record

**Table 7-57** `gs_index_verify` parameters

| Parameter | Type   | Description                                                                                                                                                                                                                                    |
|-----------|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| oid       | Oid    | <ul style="list-style-type: none"><li>• Index file relfilenode, which can be queried using <b><code>select relfilenode from pg_class where relname='Index file name'</code></b>.</li></ul>                                                     |
| blkno     | uint32 | <ul style="list-style-type: none"><li>• <b>0</b>: indicates that all pages in the index tree are checked.</li><li>• If the value is greater than 0, the index page whose page code is equal to the value of <b>blkno</b> is checked.</li></ul> |

- `gs_index_recycle_queue(Oid oid, int type, uint32 blkno)`

Description: Parses the UB-tree index recycling queue information.

Return type: record

**Table 7-58** `gs_index_recycle_queue` parameters

| Parameter | Type   | Description                                                                                                                                                                                                                                                 |
|-----------|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| oid       | Oid    | <ul style="list-style-type: none"><li>• Index file relfilenode, which can be queried using <b><code>select relfilenode from pg_class where relname='Index file name'</code></b>.</li></ul>                                                                  |
| type      | int    | <ul style="list-style-type: none"><li>• <b>0</b>: indicates that the entire queue to be recycled is parsed.</li><li>• <b>1</b>: indicates that the entire empty page queue is parsed.</li><li>• <b>2</b>: indicates that a single page is parsed.</li></ul> |
| blkno     | uint32 | <ul style="list-style-type: none"><li>• ID of the recycling queue page. This parameter is valid only when <b>type</b> is set to <b>2</b>. The value of <b>blkno</b> ranges from 1 to 4294967294.</li></ul>                                                  |

- `gs_stat_wal_entrytable(int64 idx)`  
Description: Exports the content of the WAL insertion status table in the Xlog.  
Return type: record

**Table 7-59** `gs_stat_wal_entrytable` parameters

| Category         | Parameter | Type   | Description                                                                                                                                                                                                    |
|------------------|-----------|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Input parameter  | idx       | int64  | <ul style="list-style-type: none"><li>• <b>-1</b>: queries all elements in an array.</li><li>• <b>0–Maximum value</b>: content of a specific array element.</li></ul>                                          |
| Output parameter | idx       | uint64 | Records the indexes in the corresponding array.                                                                                                                                                                |
| Output parameter | endsln    | uint64 | Records the LSN label.                                                                                                                                                                                         |
| Output parameter | lrc       | int32  | Records the corresponding LRC.                                                                                                                                                                                 |
| Output parameter | status    | uint32 | Specifies whether the Xlog corresponding to the current entry has been completely copied to the WAL buffer. <ul style="list-style-type: none"><li>• <b>0</b>: Not copied.</li><li>• <b>1</b>: Copied</li></ul> |

- `gs_walwriter_flush_position()`  
Description: Outputs the refresh position of write-ahead logs.  
Return type: record

**Table 7-60** gs\_walwriter\_flush\_position parameters

| Category         | Parameter               | Type   | Description                                                                                                                                                                |
|------------------|-------------------------|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Output parameter | last_flush_status_entry | int32  | Index obtained after the Xlog flushes the tblEntry of the last flushed disk.                                                                                               |
| Output parameter | last_scanned_lrc        | int32  | LRC obtained after the Xlog flushes the last tblEntry scanned last time.                                                                                                   |
| Output parameter | curr_lrc                | int32  | Latest LRC usage in the WALInsertStatusEntry status table. The LRC indicates the LRC value corresponding to the WALInsertStatusEntry when the next Xlog record is written. |
| Output parameter | curr_byte_pos           | uint64 | The latest Xlog location after the Xlog is written to the WAL file, which is also the next Xlog insertion point.                                                           |
| Output parameter | prev_byte_size          | uint32 | Length of the previous Xlog record.                                                                                                                                        |
| Output parameter | flush_result            | uint64 | Location of the current global Xlog flush.                                                                                                                                 |
| Output parameter | send_result             | uint64 | Xlog sending location on the current host.                                                                                                                                 |
| Output parameter | shm_rqst_write_pos      | uint64 | The write position of the LogwrtRqst request in the XLogCtl recorded in the shared memory.                                                                                 |
| Output parameter | shm_rqst_flush_pos      | uint64 | The flush position of the LogwrtRqst request in the XLogCtl recorded in the shared memory.                                                                                 |
| Output parameter | shm_result_write_pos    | uint64 | The write position of the LogwrtResult request in the XLogCtl recorded in the shared memory.                                                                               |

| Category         | Parameter            | Type   | Description                                                                                  |
|------------------|----------------------|--------|----------------------------------------------------------------------------------------------|
| Output parameter | shm_result_flush_pos | uint64 | The flush position of the LogwrtResult request in the XLogCtl recorded in the shared memory. |
| Output parameter | curr_time            | text   | Current time.                                                                                |

- gs\_walwriter\_flush\_stat(int operation)

Description: Collects statistics on the frequency of writing and synchronizing WALs, data volume, and Xlog file information.

Return type: record

**Table 7-61** gs\_walwriter\_flush\_stat parameters

| Category         | Parameter                    | Type   | Description                                                                                                                                                                                                                                    |
|------------------|------------------------------|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Input parameter  | operation                    | int    | <ul style="list-style-type: none"><li>• <b>-1</b>: Disables the statistics function. (Default value)</li><li>• <b>0</b>: Enable the statistics function.</li><li>• <b>1</b>: Query statistics.</li><li>• <b>2</b>: Reset statistics.</li></ul> |
| Output parameter | write_times                  | uint64 | Number of times that the Xlog calls the <b>write</b> API.                                                                                                                                                                                      |
| Output parameter | sync_times                   | uint64 | Number of times that the Xlog calls the <b>sync</b> API.                                                                                                                                                                                       |
| Output parameter | total_xlog_sync_bytes        | uint64 | Total number of backend thread requests for writing data to Xlogs.                                                                                                                                                                             |
| Output parameter | total_actual_xlog_sync_bytes | uint64 | Total number of Xlogs that call the <b>sync</b> API for disk flushing.                                                                                                                                                                         |

| Category         | Parameter              | Type   | Description                                                                        |
|------------------|------------------------|--------|------------------------------------------------------------------------------------|
| Output parameter | avg_write_bytes        | uint32 | Number of Xlogs written each time the <b>XLogWrite</b> API is called.              |
| Output parameter | avg_actual_write_bytes | uint32 | Number of Xlogs written each time the <b>write</b> API is called.                  |
| Output parameter | avg_sync_bytes         | uint32 | Average number of Xlogs for requesting the <b>sync</b> API each time.              |
| Output parameter | avg_actual_sync_bytes  | uint32 | Actual number of Xlogs for disk flushing by calling the <b>sync</b> API each time. |
| Output parameter | total_write_time       | uint64 | Total time of calling the write operation (unit: $\mu$ s).                         |
| Output parameter | total_sync_time        | uint64 | Total time for calling the <b>sync</b> API (unit: $\mu$ s).                        |
| Output parameter | avg_write_time         | uint32 | Average time for calling the <b>write</b> API each time (unit: $\mu$ s).           |
| Output parameter | avg_sync_time          | uint32 | Average time for calling the <b>sync</b> API each time (unit: $\mu$ s).            |
| Output parameter | curr_init_xlog_segno   | uint64 | ID of the latest Xlog segment file.                                                |
| Output parameter | curr_open_xlog_segno   | uint64 | ID of the Xlog segment file that is being written.                                 |

| Category         | Parameter       | Type | Description                               |
|------------------|-----------------|------|-------------------------------------------|
| Output parameter | last_reset_time | text | Time when statistics were last collected. |
| Output parameter | curr_time       | text | Current time.                             |

- gs\_catalog\_attribute\_records()

Description: Returns the definition of each column in a system catalog specified by OID. Only common system catalogs whose OIDs are less than 10000 are supported. Indexes and TOAST tables are not supported.

Parameter: OID of the system catalog

Return type: record

- gs\_comm\_proxy\_thread\_status()

Description: Collects statistics on data packets sent and received by the proxy communications library **comm\_proxy** when a user-mode network is configured for the database instance.

Parameter: nan

Return type: record

#### NOTE

The query result of this function is displayed only when the user-mode network is deployed in a centralized environment and **enable\_dfx in comm\_proxy\_attr** is set to **true**. In other scenarios, an error message is displayed, indicating that queries are not supported.

- pg\_ls\_tmpdir()

Description: Returns the name, size, and last modification time of each file in the temporary directory (**pgsql\_tmp**) of the default tablespace.

Parameter: nan

Return type: record

Note: Only SYSADMIN or MONADMIN can execute this function.

| Category         | Parameter    | Type       | Description                 |
|------------------|--------------|------------|-----------------------------|
| Output parameter | name         | text       | File name                   |
| Output parameter | size         | int8       | File size (unit: byte)      |
| Output parameter | modification | timestampz | Last file modification time |

- pg\_ls\_tmpdir(oid)

Description: Returns the name, size, and last modification time of each file in the temporary directory (**pgsql\_tmp**) of the specified tablespace.

Parameter: oid

Return type: record

Note: Only SYSADMIN or MONADMIN can execute this function.

| Category         | Parameter    | Type       | Description                 |
|------------------|--------------|------------|-----------------------------|
| Input parameter  | oid          | oid        | Tablespace ID               |
| Output parameter | name         | text       | File name                   |
| Output parameter | size         | int8       | File size (unit: byte)      |
| Output parameter | modification | timestampz | Last file modification time |

- pg\_ls\_waldir()

Description: Returns the name, size, and last modification time of each file in the WAL directory.

Parameter: nan

Return type: record

Note: Only SYSADMIN or MONADMIN can execute this function.

| Category         | Parameter    | Type       | Description                 |
|------------------|--------------|------------|-----------------------------|
| Output parameter | name         | text       | File name                   |
| Output parameter | size         | int8       | File size (unit: byte)      |
| Output parameter | modification | timestampz | Last file modification time |

- gs\_write\_term\_log(void)

Description: Writes a log to record the current **term** value of a DN. The standby DN returns **false**. After the data is successfully written to the primary DN, **true** is returned.

Return type: Boolean

### 7.5.23.13 Undo System Functions

- gs\_undo\_meta(type, zoneld, location)

Description: Specifies metadata of each module in the undo system.

Parameter description:

- **type** (metadata type)  
The value **0** indicates the metadata corresponding to **Undo Zone(Record)**.  
The value **1** indicates the metadata corresponding to **Undo Zone(Transaction Slot)**.  
The value **2** indicates the metadata corresponding to **Undo Space(Record)**.  
The value **3** indicates the metadata corresponding to **Undo Space(Transaction Slot)**.
- **zoneId** (undo zone ID)  
The value **-1** indicates the metadata of all undo zones.  
The value range 0–1024 x 1024 indicates the metadata of the corresponding zone ID.
- **location** (read location)  
The value **0** indicates that data is read from the current memory.  
The value **1** indicates that data is read from a physical file.

Return type: record

**Table 7-62** Output example of `gs_undo_meta(0,-1,0)`

| Category         | Parameter   | Type | Description                                                                                                                                        |
|------------------|-------------|------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| Output parameter | zoneId      | oid  | ID of the undo zone                                                                                                                                |
| Output parameter | persistType | oid  | Persistence level                                                                                                                                  |
| Output parameter | insert      | text | Position of the next undo record to be inserted                                                                                                    |
| Output parameter | discard     | text | Position of the undo record that is recycled in common mode                                                                                        |
| Output parameter | end         | text | Position of the undo record that is forcibly recycled. Values smaller than the value of this parameter indicate that the record has been recycled. |
| Output parameter | used        | text | Used undo space                                                                                                                                    |
| Output parameter | lsn         | text | LSN to modify the zone                                                                                                                             |

| Category         | Parameter | Type | Description                         |
|------------------|-----------|------|-------------------------------------|
| Output parameter | pid       | oid  | ID of the process bound to the zone |

- `gs_undo_translot(location, zoneld)`

Description: Specifies transaction slot information of the undo system.

Parameter description:

- **location** (read location)  
The value **0** indicates that data is read from the current memory.  
The value **1** indicates that data is read from a physical file.
- **zoneld** (undo zone ID)  
The value **-1** indicates the metadata of all undo zones.  
The value range **0–1024 x 1024** indicates the metadata of the corresponding zone ID.

Return type: record

**Table 7-63** Output example of `gs_undo_translot(0,-1)`

| Category         | Parameter    | Type | Description                                                                                                                                          |
|------------------|--------------|------|------------------------------------------------------------------------------------------------------------------------------------------------------|
| Output parameter | groupid      | oid  | ID of the used undo zone                                                                                                                             |
| Output parameter | xactId       | text | Transaction ID                                                                                                                                       |
| Output parameter | startUndoPtr | text | Position where the undo record is inserted at the start of the transaction corresponding to a slot                                                   |
| Output parameter | endUndoPtr   | text | Position where the undo record is inserted at the end of the transaction corresponding to a slot                                                     |
| Output parameter | lsn          | text | Pointer to the corresponding slot                                                                                                                    |
| Output parameter | slot_states  | oid  | Transaction state. The options are as follows: <b>0</b> : committed; <b>1</b> : being executed; <b>2</b> : being rolled back; <b>3</b> : rolled back |

- `gs_stat_undo()`

Description: Undo statistics.

Return type: record

**Table 7-64** gs\_stat\_undo parameters

| Category         | Parameter              | Type   | Description                                                                                                                                                                                                                                                                                |
|------------------|------------------------|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Output parameter | curr_used_zone_count   | uint32 | Number of used undo zones.                                                                                                                                                                                                                                                                 |
| Output parameter | top_used_zones         | text   | Information about the first three undo zones with the maximum usage. The output format is as follows: <ul style="list-style-type: none"><li>● <b>zoneld1</b>: used size of zone 1.</li><li>● <b>zoneld2</b>: used size of zone 2.</li><li>● <b>zoneld3</b>: used size of zone 3.</li></ul> |
| Output parameter | curr_used_undo_size    | uint32 | Total size of the undo tablespace that is being used. The unit is MB.                                                                                                                                                                                                                      |
| Output parameter | undo_threshold         | uint32 | Calculation result of the value of the GUC parameter <b>undo_space_limit_size</b> x 80%. The unit is MB.                                                                                                                                                                                   |
| Output parameter | oldest_xid_in_undo     | uint64 | XID of the transaction recycled to the undo space. The undo records generated by the transaction whose XID is smaller than the value of XID are recycled.                                                                                                                                  |
| Output parameter | oldest_xmin            | uint64 | Oldest active transaction.                                                                                                                                                                                                                                                                 |
| Output parameter | total_undo_chain_len   | int64  | Total length of all accessed undo chains.                                                                                                                                                                                                                                                  |
| Output parameter | max_undo_chain_len     | int64  | Maximum length of the accessed undo chain.                                                                                                                                                                                                                                                 |
| Output parameter | create_undo_file_count | uint32 | Number of created undo files.                                                                                                                                                                                                                                                              |

| Category         | Parameter               | Type   | Description                   |
|------------------|-------------------------|--------|-------------------------------|
| Output parameter | discard_undo_file_count | uint32 | Number of deleted undo files. |

- `gs_undo_record(undoptr)`  
Description: Undo record resolution.  
Parameter description:
  - **undoptr** (undo record pointer)Return type: record
- `gs_undo_dump_parsepage_mv(relpath text, blkno bigint, reltype text, rmem boolean)`  
Description: Parses the page header information of the disk page in the Ustore table, header information of each tuple, flag bit information, and all historical undo version information that can be queried.  
Return type: text  
Note: Only SYSADMIN or OPRADMIN can execute this function.

**NOTE**

Currently, this API supports only Ustore tables.

**Table 7-65** `gs_undo_dump_parsepage_mv` parameters

| Category        | Parameter | Type   | Description                                                                                                                                                                                                                                         |
|-----------------|-----------|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Input parameter | relpath   | text   | Relative path of the Ustore table data file, in the format of <i>Tablespace name/Database OID/relfilenode</i> . For example, <b>base/16603/16384</b> . You can run the <b>pg_relation_filepath('tablename')</b> command to query the relative path. |
| Input parameter | blkno     | bigint | <ul style="list-style-type: none"><li>• <b>-1</b>: All block pages are parsed.</li><li>• <b>0–MaxBlocNumber</b>: A specified block page is parsed.</li></ul>                                                                                        |
| Input parameter | reltype   | text   | Table type. Currently, only the Ustore table is supported. The value is <b>uheap</b> .                                                                                                                                                              |

| Category         | Parameter | Type    | Description                                                                                                                                                                             |
|------------------|-----------|---------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Input parameter  | rmem      | boolean | <ul style="list-style-type: none"><li>false</li><li>true</li></ul> Currently, the value can only be <b>false</b> , indicating that the corresponding page is parsed from the disk file. |
| Output parameter | output    | text    | Absolute path of the parsing result file.                                                                                                                                               |

- `gs_undo_meta_dump_zone(zone_id int, read_memory boolean)`  
Description: Parses zone metadata in the undo module.  
Return type: record

**Table 7-66** gs\_undo\_meta\_dump\_zone parameters

| Category         | Parameter    | Type    | Description                                                                                                                                                                    |
|------------------|--------------|---------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Input parameter  | zone_id      | int     | Undo zone ID <ul style="list-style-type: none"><li>-1: All undo zones are queried.</li><li><b>0-1048575</b>: The undo zone metadata is queried based on the zone ID.</li></ul> |
| Input parameter  | read_memory  | boolean | <ul style="list-style-type: none"><li><b>true</b>: Data is read from the current memory.</li><li><b>false</b>: Data is read from the physical file.</li></ul>                  |
| Output parameter | zone_id      | int     | Undo zone ID                                                                                                                                                                   |
| Output parameter | persist_type | int     | Persistence level <ul style="list-style-type: none"><li><b>0</b>: ordinary table</li><li><b>1</b>: unlogged table</li><li><b>2</b>: temporary table</li></ul>                  |
| Output parameter | insert       | text    | Position of the next undo record to be inserted                                                                                                                                |

| Category         | Parameter    | Type | Description                                                                                                                                        |
|------------------|--------------|------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| Output parameter | discard      | text | Position of the undo record that is recycled in common mode                                                                                        |
| Output parameter | forcediscard | text | Position of the undo record that is forcibly recycled. Values smaller than the value of this parameter indicate that the record has been recycled. |
| Output parameter | lsn          | text | LSN to modify the zone                                                                                                                             |

- `gs_undo_meta_dump_spaces(zone_id int, read_memory boolean)`  
Description: Parses the metadata of the undo record space and undo slot space in the undo module.  
Return type: record

**Table 7-67** `gs_undo_meta_dump_spaces` parameters

| Category         | Parameter             | Type    | Description                                                                                                                                                                               |
|------------------|-----------------------|---------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Input parameter  | zone_id               | int     | Undo zone ID <ul style="list-style-type: none"><li>• <b>-1</b>: All undo zones are queried.</li><li>• <b>0-1048575</b>: The undo zone metadata is queried based on the zone ID.</li></ul> |
| Input parameter  | read_memory           | boolean | <ul style="list-style-type: none"><li>• <b>true</b>: Data is read from the current memory.</li><li>• <b>false</b>: Data is read from the physical file.</li></ul>                         |
| Output parameter | zone_id               | int     | Undo zone ID                                                                                                                                                                              |
| Output parameter | undorecord_space_tail | text    | End position of the undo record space                                                                                                                                                     |

| Category         | Parameter             | Type | Description                             |
|------------------|-----------------------|------|-----------------------------------------|
| Output parameter | undorecord_space_head | text | Start position of the undo record space |
| Output parameter | undorecord_space_lsn  | text | LSN of the modified undo record space   |
| Output parameter | undoslot_space_tail   | text | End position of the undo slot space     |
| Output parameter | undoslot_space_head   | text | Start position of the undo slot space   |
| Output parameter | undo_slot_space_lsn   | text | LSN of the modified undo slot space     |

- `gs_undo_meta_dump_slot(zone_id int, read_memory boolean)`  
Description: Parses slot metadata in the undo module.  
Return type: record

**Table 7-68** `gs_undo_meta_dump_slot` parameters

| Category         | Parameter   | Type    | Description                                                                                                                                                                               |
|------------------|-------------|---------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Input parameter  | zone_id     | int     | Undo zone ID <ul style="list-style-type: none"><li>• <b>-1</b>: All undo zones are queried.</li><li>• <b>0-1048575</b>: The undo zone metadata is queried based on the zone ID.</li></ul> |
| Input parameter  | read_memory | boolean | <ul style="list-style-type: none"><li>• <b>true</b>: Data is read from the current memory.</li><li>• <b>false</b>: Data is read from the physical file.</li></ul>                         |
| Output parameter | zone_id     | int     | Undo zone ID                                                                                                                                                                              |

| Category         | Parameter          | Type | Description                                                                                                          |
|------------------|--------------------|------|----------------------------------------------------------------------------------------------------------------------|
| Output parameter | allocate           | text | Allocation position of the undo transaction slot                                                                     |
| Output parameter | recycle            | text | Recycling position of the undo transaction slot                                                                      |
| Output parameter | frozen_xid         | text | Frozen XID, which is used to determine the visibility                                                                |
| Output parameter | global_frozen_xid  | text | Minimum frozen XID in the system. Transactions whose XID is smaller than the value of this parameter are visible.    |
| Output parameter | recycle_xid        | text | Recycled XID. Transactions whose XID is smaller than the value of this parameter are recycled.                       |
| Output parameter | global_recycle_xid | text | Minimum recycled XID in the system. Transactions whose XID is smaller than the value of this parameter are recycled. |

- gs\_undo\_translot\_dump\_slot(zone\_id int, read\_memory boolean)  
Description: Parses slots in a zone.  
Return type: record

**Table 7-69** gs\_undo\_translot\_dump\_slot parameters

| Category        | Parameter | Type | Description                                                                                                                                                             |
|-----------------|-----------|------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Input parameter | zone_id   | oid  | Undo zone ID <ul style="list-style-type: none"><li>-1: All undo zones are queried.</li><li>0-1048575: The undo zone metadata is queried based on the zone ID.</li></ul> |

| Category         | Parameter      | Type    | Description                                                                                                                                                                                      |
|------------------|----------------|---------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Input parameter  | read_memory    | boolean | <ul style="list-style-type: none"><li>• <b>true</b>: Data is read from the current memory.</li><li>• <b>false</b>: Data is read from the physical file.</li></ul>                                |
| Output parameter | zone_id        | text    | Undo zone ID                                                                                                                                                                                     |
| Output parameter | slot_xid       | text    | Transaction ID                                                                                                                                                                                   |
| Output parameter | start_undo_ptr | text    | Position where the undo record is inserted at the start of the transaction corresponding to a slot                                                                                               |
| Output parameter | end_undo_ptr   | text    | Position where the undo record is inserted at the end of the transaction corresponding to a slot                                                                                                 |
| Output parameter | slot_ptr       | text    | Position of a transaction slot.                                                                                                                                                                  |
| Output parameter | slot_states    | oid     | Transaction state <ul style="list-style-type: none"><li>• <b>0</b>: committed</li><li>• <b>1</b>: being executed</li><li>• <b>2</b>: being rolled back</li><li>• <b>3</b>: rolled back</li></ul> |

- `gs_undo_translot_dump_xid(slot_xid xid, read_memory boolean)`  
Description: Parses the slot in a zone based on the XID.  
Return type: record

**Table 7-70** `gs_undo_translot_dump_xid` parameters

| Category        | Parameter | Type | Description       |
|-----------------|-----------|------|-------------------|
| Input parameter | slot_xid  | xid  | XID to be queried |

| Category         | Parameter      | Type    | Description                                                                                                                                                                                      |
|------------------|----------------|---------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Input parameter  | read_memory    | boolean | <ul style="list-style-type: none"><li>• <b>true</b>: Data is read from the current memory.</li><li>• <b>false</b>: Data is read from the physical file.</li></ul>                                |
| Output parameter | zone_id        | text    | Undo zone ID                                                                                                                                                                                     |
| Output parameter | slot_xid       | text    | Transaction ID                                                                                                                                                                                   |
| Output parameter | start_undo_ptr | text    | Position where the undo record is inserted at the start of the transaction corresponding to a slot                                                                                               |
| Output parameter | end_undo_ptr   | text    | Position where the undo record is inserted at the end of the transaction corresponding to a slot                                                                                                 |
| Output parameter | lsn            | text    | LSN of the modified slot                                                                                                                                                                         |
| Output parameter | slot_states    | oid     | Transaction state <ul style="list-style-type: none"><li>• <b>0</b>: committed</li><li>• <b>1</b>: being executed</li><li>• <b>2</b>: being rolled back</li><li>• <b>3</b>: rolled back</li></ul> |

- **gs\_undo\_dump\_record(undoptr bigint)**  
Description: Parses undo records.  
Return type: record

**Table 7-71** gs\_undo\_dump\_record parameters

| Category         | Parameter | Type   | Description                                     |
|------------------|-----------|--------|-------------------------------------------------|
| Input parameter  | undoptr   | bigint | Start position of the undo record to be parsed. |
| Output parameter | undoptr   | bigint | Start position of the undo record to be parsed. |

| Category         | Parameter    | Type | Description                                             |
|------------------|--------------|------|---------------------------------------------------------|
| Output parameter | xactid       | text | Transaction ID.                                         |
| Output parameter | cid          | text | Command ID.                                             |
| Output parameter | relid        | text | Relation OID.                                           |
| Output parameter | relfilenode  | text | Relfinode of the file.                                  |
| Output parameter | utype        | text | Undo record type                                        |
| Output parameter | blkprev      | text | Position of the previous undo record in the same block. |
| Output parameter | blockno      | text | Block number.                                           |
| Output parameter | uoffset      | text | Undo record offset.                                     |
| Output parameter | prevurp      | text | Position of the previous undo record.                   |
| Output parameter | payloadlen   | text | Length of the undo record data.                         |
| Output parameter | oldxactid    | text | Previous XID.                                           |
| Output parameter | partitionoid | text | Partition OID.                                          |
| Output parameter | tablespace   | text | Tablespace.                                             |

| Category         | Parameter         | Type | Description                              |
|------------------|-------------------|------|------------------------------------------|
| Output parameter | alreadyread_bytes | text | Length of the read undo record.          |
| Output parameter | prev_undorec_len  | text | Length of the previous undo record.      |
| Output parameter | td_id             | text | ID of the transaction directory.         |
| Output parameter | reserved          | text | Specifies whether to reserve the record. |
| Output parameter | flag              | text | Flag 1.                                  |
| Output parameter | flag2             | text | Flag 2.                                  |
| Output parameter | t_hoff            | text | Length of the undo record data header.   |

- gs\_undo\_dump\_xid(undo\_xid xid)  
Description: Parses undo records based on the XID.  
Return type: record

**Table 7-72** gs\_undo\_dump\_xid parameters

| Category         | Parameter | Type | Description                                    |
|------------------|-----------|------|------------------------------------------------|
| Input parameter  | undo_xid  | xid  | XID                                            |
| Output parameter | undoptr   | xid  | Start position of the undo record to be parsed |
| Output parameter | xactid    | text | XID                                            |

| Category         | Parameter         | Type | Description                                            |
|------------------|-------------------|------|--------------------------------------------------------|
| Output parameter | cid               | text | command id                                             |
| Output parameter | reloid            | text | relation oid                                           |
| Output parameter | relfilenode       | text | Relfinode of the file                                  |
| Output parameter | utype             | text | Undo record type                                       |
| Output parameter | blkprev           | text | Position of the previous undo record in the same block |
| Output parameter | blockno           | text | Block number                                           |
| Output parameter | uoffset           | text | Undo record offset                                     |
| Output parameter | prevurp           | text | Position of the previous undo record                   |
| Output parameter | payloadlen        | text | Length of the undo record data                         |
| Output parameter | oldxactid         | text | Previous XID                                           |
| Output parameter | partitionoid      | text | Partition OID                                          |
| Output parameter | tablespace        | text | Tablespace                                             |
| Output parameter | alreadyread_bytes | text | Length of the read undo record                         |

| Category         | Parameter         | Type | Description                              |
|------------------|-------------------|------|------------------------------------------|
| Output parameter | prev_undo_rec_len | text | Length of the previous undo record       |
| Output parameter | td_id             | text | ID of the transaction directory          |
| Output parameter | reserved          | text | Specifies whether to reserve the record. |
| Output parameter | flag              | text | Flag 1                                   |
| Output parameter | flag2             | text | Flag 2                                   |
| Output parameter | t_hoff            | text | Length of the undo record data header    |

- `gs_verify_undo_record(type, startIdx, endIdx, location)`

Description: Verifies the Undo record.

Return type: record

 **NOTE**

This API is reserved for extension and cannot be used.

- `gs_verify_undo_translot(type, startIdx, endIdx, location)`

Description: Verifies the Undo transaction slot.

Return type: record

 **NOTE**

This API is reserved for extension and cannot be used.

- `gs_verify_undo_meta(type, startIdx, endIdx, location)`

Description: Verifies the Undo meta information.

Return type: record

 **NOTE**

This API is reserved for extension and cannot be used.

## 7.5.24 Statistics Information Functions

Statistics information functions are divided into the following two categories: functions that access databases, using the OID of each table or index in a database to mark the database for which statistics are generated; functions that

access servers, identified by the server process ID, whose value ranges from 1 to the number of currently active servers.

- `pg_stat_get_db_conflict_tablespace(oid)`  
Description: Specifies the number of queries canceled due to a conflict between the restored tablespace and the deleted tablespace in the database.  
Return type: bigint
- `pg_control_group_config()`  
Description: Prints Cgroup configurations on the current node. Only users with the SYSADMIN permission can execute this function.  
Return type: record
- `pg_stat_get_db_stat_reset_time(oid)`  
Description: Specifies the most recent time when database statistics were reset. It is initialized to the system time during the first connection to each database. The reset time is updated when you call **pg\_stat\_reset** on the database and execute **pg\_stat\_reset\_single\_table\_counters** against any table or index in it.  
Return type: timestampz
- `pg_stat_get_function_total_time(oid)`  
Description: Specifies the total wall clock time spent in the function, in microseconds. The time spent on this function calling other functions is included.  
Return type: bigint
- `pg_stat_get_xact_tuples_returned(oid)`  
Description: Specifies the number of rows read through sequential scans when the parameter is a table in the current transaction or the number of index entries returned when the parameter is an index.  
Return type: bigint
- `pg_lock_status()`  
Description: Queries information about locks held by open transactions. All users can execute this function.  
Return type: For details, see the return result of **PG\_LOCKS**, which is obtained by querying this function.
- `pg_stat_get_xact_numscans(oid)`  
Description: Specifies the number of sequential scans performed when the parameter is a table in the current transaction or the number of index scans performed when the parameter is an index.  
Return type: bigint
- `pg_stat_get_xact_blocks_fetched(oid)`  
Description: Specifies the number of disk block fetch requests for a table or an index in the current transaction.  
Return type: bigint
- `pg_stat_get_xact_blocks_hit(oid)`  
Description: Specifies the number of disk block fetch requests for tables or indexes found in cache in the current transaction.  
Return type: bigint

- `pg_stat_get_xact_function_calls(oid)`  
Description: Specifies the number of times the function is called in the current transaction.  
Return type: `bigint`
- `pg_stat_get_xact_function_self_time(oid)`  
Description: Specifies the time spent on this function in the current transaction, excluding the time spent on this function internally calling other functions.  
Return type: `bigint`
- `pg_stat_get_xact_function_total_time(oid)`  
Description: Specifies the total wall clock time (in microseconds) spent on the function in the current transaction, including the time spent on this function internally calling other functions.  
Return type: `bigint`
- `pg_stat_get_wal_senders()`  
Description: Queries walsender information on the primary node.  
Return type: `setofrecord`  
The following table describes return columns.

**Table 7-73** Return column description

| Column                             | Type                     | Description                             |
|------------------------------------|--------------------------|-----------------------------------------|
| <code>pid</code>                   | <code>bigint</code>      | Thread ID of the WAL sender             |
| <code>sender_pid</code>            | <code>integer</code>     | Lightweight thread ID of the WAL sender |
| <code>local_role</code>            | <code>text</code>        | Type of the primary node                |
| <code>peer_role</code>             | <code>text</code>        | Type of the standby node                |
| <code>peer_state</code>            | <code>text</code>        | Status of the standby node              |
| <code>state</code>                 | <code>text</code>        | Status of the WAL sender                |
| <code>catchup_start</code>         | timestamp with time zone | Startup time of a catchup task          |
| <code>catchup_end</code>           | timestamp with time zone | End time of a catchup task              |
| <code>sender_sent_location</code>  | <code>text</code>        | Sending position of the primary node    |
| <code>sender_write_location</code> | <code>text</code>        | Writing position of the primary node    |

| Column                     | Type | Description                                        |
|----------------------------|------|----------------------------------------------------|
| sender_flush_location      | text | Flushing position of the primary node              |
| sender_replay_location     | text | Redo position of the primary node                  |
| receiver_received_location | text | Receiving position of the standby node             |
| receiver_write_location    | text | Writing position of the standby node               |
| receiver_flush_location    | text | Flushing position of the standby node              |
| receiver_replay_location   | text | Redo position of the standby node                  |
| sync_percent               | text | Synchronization percentage                         |
| sync_state                 | text | Synchronization status                             |
| sync_group                 | text | Group to which the synchronous replication belongs |
| sync_priority              | text | Priority of synchronous replication                |
| sync_most_available        | text | Maximum availability mode                          |
| channel                    | text | Channel information of the WAL sender              |

- `get_paxos_replication_info()`  
Description: Queries the primary/standby replication status in Paxos mode.  
Return type: setofrecord  
The following table describes return columns.

**Table 7-74** Return column description

| Column                | Type | Description                                                                            |
|-----------------------|------|----------------------------------------------------------------------------------------|
| paxos_write_location  | text | Position of the Xlog that has been written to the Distribute Consensus Framework (DCF) |
| paxos_commit_location | text | Position of the Xlog agreed in the DCF                                                 |

| Column                | Type | Description                      |
|-----------------------|------|----------------------------------|
| local_write_location  | text | Writing position of a node       |
| local_flush_location  | text | Flushing position of a node      |
| local_replay_location | text | Redo position of a node          |
| dcf_replication_info  | text | DCF module information of a node |

- `pg_stat_get_stream_replications()`  
Description: Queries the primary/standby replication status.  
Return type: setofrecord  
The following table describes return values.

**Table 7-75** Return values

| Return Parameter   | Type    | Description           |
|--------------------|---------|-----------------------|
| local_role         | text    | Local role            |
| static_connections | integer | Connection statistics |
| db_state           | text    | Database status       |
| detail_information | text    | Detailed information  |

- `pg_stat_get_db_numbackends(oid)`  
Description: Specifies the number of active server processes for a database.  
Return type: integer
- `pg_stat_get_db_xact_commit(oid)`  
Description: Specifies the number of transactions committed in a database.  
Return type: bigint
- `pg_stat_get_db_xact_rollback(oid)`  
Description: Specifies the number of transactions rolled back in a database.  
Return type: bigint
- `pg_stat_get_db_blocks_fetched(oid)`  
Description: Specifies the number of disk blocks fetch requests for a database.  
Return type: bigint
- `pg_stat_get_db_blocks_hit(oid)`  
Description: Specifies the number of disk block fetch requests found in cache for a database.  
Return type: bigint

- `pg_stat_get_db_tuples_returned(oid)`  
Description: Specifies the number of tuples returned for a database.  
Return type: bigint
- `pg_stat_get_db_tuples_fetched(oid)`  
Description: Specifies the number of tuples fetched for a database.  
Return type: bigint
- `pg_stat_get_db_tuples_inserted(oid)`  
Description: Specifies the number of tuples inserted in a database.  
Return type: bigint
- `pg_stat_get_db_tuples_updated(oid)`  
Description: Specifies the number of tuples updated in a database.  
Return type: bigint
- `pg_stat_get_db_tuples_deleted(oid)`  
Description: Specifies the number of tuples deleted in a database.  
Return type: bigint
- `pg_stat_get_db_conflict_lock(oid)`  
Description: Specifies the number of lock conflicts in a database.  
Return type: bigint
- `pg_stat_get_db_deadlocks(oid)`  
Description: Specifies the number of deadlocks in a database.  
Return type: bigint
- `pg_stat_get_numscans(oid)`  
Description: Specifies the number of sequential row scans done if parameters are in a table or the number of index scans done if parameters are in an index.  
Return type: bigint
- `pg_stat_get_role_name(oid)`  
Description: Obtains the username based on the user OID. Only users with the SYSADMIN or MONADMIN permission can access the information.  
Return type: text  
Example:

```
openGauss=# select pg_stat_get_role_name(10);
 pg_stat_get_role_name

 aabbcc
(1 row)
```
- `pg_stat_get_tuples_returned(oid)`  
Description: Specifies the number of sequential row scans done if parameters are in a table or the number of index scans done if parameters are in an index.  
Return type: bigint
- `pg_stat_get_tuples_fetched(oid)`  
Description: Specifies the number of table rows fetched by bitmap scans if parameters are in a table or the number of table rows fetched by simple index scans using the index if parameters are in an index.

- Return type: bigint
- `pg_stat_get_tuples_inserted(oid)`  
Description: Specifies the number of rows inserted into a table.  
Return type: bigint
  - `pg_stat_get_tuples_updated(oid)`  
Description: Specifies the number of rows updated in a table.  
Return type: bigint
  - `pg_stat_get_tuples_deleted(oid)`  
Description: Specifies the number of rows deleted from a table.  
Return type: bigint
  - `pg_stat_get_tuples_changed(oid)`  
Description: Specifies the total number of inserted, updated, and deleted rows after a table was last analyzed or autoanalyzed.  
Return type: bigint
  - `pg_stat_get_tuples_hot_updated(oid)`  
Description: Specifies the number of rows hot updated in a table.  
Return type: bigint
  - `pg_stat_get_live_tuples(oid)`  
Description: Specifies the number of live rows in a table.  
Return type: bigint
  - `pg_stat_get_dead_tuples(oid)`  
Description: Specifies the number of dead rows in a table.  
Return type: bigint
  - `pg_stat_get_blocks_fetched(oid)`  
Description: Specifies the number of disk block fetch requests for a table or an index.  
Return type: bigint
  - `pg_stat_get_blocks_hit(oid)`  
Description: Specifies the number of disk block requests found in cache for a table or an index.  
Return type: bigint
  - `pg_stat_get_partition_tuples_inserted(oid)`  
Description: Specifies the number of rows in the corresponding table partition.  
Return type: bigint
  - `pg_stat_get_partition_tuples_updated(oid)`  
Description: Specifies the number of rows that have been updated in the corresponding table partition.  
Return type: bigint
  - `pg_stat_get_partition_tuples_deleted(oid)`  
Description: Specifies the number of rows deleted from the corresponding table partition.  
Return type: bigint

- `pg_stat_get_partition_tuples_changed(oid)`  
Description: Specifies the total number of inserted, updated, and deleted rows after a table partition was last analyzed or autoanalyzed.  
Return type: `bigint`
- `pg_stat_get_partition_live_tuples(oid)`  
Description: Specifies the number of live rows in a partitioned table.  
Return type: `bigint`
- `pg_stat_get_partition_dead_tuples(oid)`  
Description: Specifies the number of dead rows in a partitioned table.  
Return type: `bigint`
- `pg_stat_get_xact_tuples_fetched(oid)`  
Description: Specifies the number of tuple rows scanned in a transaction.  
Return type: `bigint`
- `pg_stat_get_xact_tuples_inserted(oid)`  
Description: Specifies the number of tuple inserted into the active subtransactions related to a table.  
Return type: `bigint`
- `pg_stat_get_xact_tuples_deleted(oid)`  
Description: Specifies the number of deleted tuples in the active subtransactions related to a table.  
Return type: `bigint`
- `pg_stat_get_xact_tuples_hot_updated(oid)`  
Description: Specifies the number of hot updated tuples in the active subtransactions related to a table.  
Return type: `bigint`
- `pg_stat_get_xact_tuples_updated(oid)`  
Description: Specifies the number of updated tuples in the active subtransactions related to a table.  
Return type: `bigint`
- `pg_stat_get_xact_partition_tuples_inserted(oid)`  
Description: Specifies the number of inserted tuples in the active subtransactions related to a table partition.  
Return type: `bigint`
- `pg_stat_get_xact_partition_tuples_deleted(oid)`  
Description: Specifies the number of deleted tuples in the active subtransactions related to a table partition.  
Return type: `bigint`
- `pg_stat_get_xact_partition_tuples_hot_updated(oid)`  
Description: Specifies the number of hot updated tuples in the active subtransactions related to a table partition.  
Return type: `bigint`
- `pg_stat_get_xact_partition_tuples_updated(oid)`

Description: Specifies the number of updated tuples in the active subtransactions related to a table partition.

Return type: bigint

- `pg_stat_get_last_vacuum_time(oid)`

Description: Specifies the most recent time when the autovacuum thread is manually started to clear a table.

Return type: timestampz

- `pg_stat_get_last_autovacuum_time(oid)`

Description: Specifies the time of the last vacuum initiated by the autovacuum daemon on a table.

Return type: timestampz

- `pg_stat_get_vacuum_count(oid)`

Description: Specifies the number of times a table is manually cleared.

Return type: bigint

- `pg_stat_get_autovacuum_count(oid)`

Description: Specifies the number of times the autovacuum daemon is started to clear a table.

Return type: bigint

- `pg_stat_get_last_analyze_time(oid)`

Description: Specifies the last time when a table starts to be analyzed manually or by the autovacuum thread.

Return type: timestampz

- `pg_stat_get_last_autoanalyze_time(oid)`

Description: Specifies the time when the last analysis initiated by the autovacuum daemon on a table.

Return type: timestampz

- `pg_stat_get_analyze_count(oid)`

Description: Specifies the number of times a table is manually analyzed.

Return type: bigint

- `pg_stat_get_autoanalyze_count(oid)`

Description: Specifies the number of times the autovacuum daemon analyzes a table.

Return type: bigint

- `pg_total_autovac_tuples(bool)`

Description: Returns tuple records related to the total autovac, such as **nodename**, **nspname**, **relname**, and tuple IUDs. The input parameter specifies whether to query the **relation** information.

Return type: setofrecord

The following table describes return parameters.

**Table 7-76** Description

| Return Parameter      | Type   | Description                                             |
|-----------------------|--------|---------------------------------------------------------|
| nodename              | name   | Node name                                               |
| nspname               | name   | Name of a namespace                                     |
| relname               | name   | Name of an object, such as a table, an index, or a view |
| partname              | name   | Partition name                                          |
| n_dead_tuples         | bigint | Number of dead rows in a table partition                |
| n_live_tuples         | bigint | Number of live rows in a table partition                |
| changes_since_analyze | bigint | Number of changes generated by ANALYZE                  |

- pg\_autovac\_status(oid)

Description: Returns autovac information, such as **nodename**, **nspname**, **relname**, **analyze**, **vacuum**, thresholds of **analyze** and **vacuum**, and the number of analyzed or vacuumed tuples. Only users with the SYSADMIN permission can use this function.

Return type: setofrecord

The following table describes return parameters.

**Table 7-77** Return parameter description

| Return Parameter | Type    | Description                                             |
|------------------|---------|---------------------------------------------------------|
| nspname          | text    | Name of a namespace                                     |
| relname          | text    | Name of an object, such as a table, an index, or a view |
| nodename         | text    | Node name                                               |
| doanalyze        | Boolean | Specifies whether to execute ANALYZE.                   |
| anltuples        | bigint  | Number of ANALYZE tuples                                |
| anlthresh        | bigint  | ANALYZE threshold                                       |
| dovacuum         | Boolean | Specifies whether to execute VACUUM.                    |
| vactuples        | bigint  | Number of VACUUM tuples                                 |

| Return Parameter | Type   | Description      |
|------------------|--------|------------------|
| vacthresh        | bigint | VACUUM threshold |

- pg\_autovac\_timeout(oid)

Description: Returns the number of consecutive timeouts during the autovac operation on a table. If the table information is invalid or the node information is abnormal, **NULL** will be returned.

Return type: bigint

- pg\_stat\_get\_last\_data\_changed\_time(oid)

Description: Returns the time when **INSERT**, **UPDATE**, **DELETE**, or **EXCHANGE/TRUNCATE/DROP PARTITION** was last performed on a table. The data in the **last\_data\_changed** column of the [PG\\_STAT\\_ALL\\_TABLES](#) view is calculated by using this function. The performance of obtaining the last modification time by using the view is poor when the table has a large amount of data. In this case, you are advised to use the function.

Return type: timestamptz

- pg\_stat\_set\_last\_data\_changed\_time(oid)

Description: Manually changes the time when **INSERT**, **UPDATE**, **DELETE**, or **EXCHANGE/TRUNCATE/DROP PARTITION** was last performed.

Return type: void

- pg\_backend\_pid()

Description: Specifies the thread ID of the server thread attached to the current session.

Return type: integer

- pg\_stat\_get\_activity(integer)

Description: Returns a record about the backend with the specified PID. A record for each active backend in the system is returned if **NULL** is specified. The returned result does not contain the **connection\_info** column. The initial user, system administrators and users with the MONADMIN permission can view all data. Common users can only query their own results.

Example:

```
openGauss=# select * from pg_stat_get_activity(139881386280704);
 datid | pid | sessionid | usesysid | application_name | state |
 query | waiting | xact_start | | query_start |
 backend_start | state_change | client_addr | client_hostname | client_port | enqueue
 | query_id | srespool | global_sessionid | unique_sql_id | trace_id

```

Return type: setofrecord

The following table describes return parameters.

**Table 7-78** Description

| Return Parameter | Type                     | Description                                                                                                                                                                                                               |
|------------------|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| datid            | oid                      | OID of the database that the user session connects to in the backend                                                                                                                                                      |
| pid              | bigint                   | Backend thread ID                                                                                                                                                                                                         |
| sessionid        | bigint                   | Session ID                                                                                                                                                                                                                |
| usesysid         | oid                      | OID of the user logged in to the backend                                                                                                                                                                                  |
| application_name | text                     | Name of the application connected to the backend                                                                                                                                                                          |
| state            | text                     | Overall status of the backend                                                                                                                                                                                             |
| query            | text                     | Latest query at the backend. If <b>state</b> is <b>active</b> , this column shows the ongoing query. In all other states, it shows the last query that was executed.                                                      |
| waiting          | Boolean                  | Specifies whether the backend is currently waiting for a lock. If the backend is currently waiting for a lock, the value is <b>true</b> .                                                                                 |
| xact_start       | timestamp with time zone | Time when current transaction was started (null if no transaction is active).<br><br>If the current query is the first of its transaction, the value of this column is the same as that of the <b>query_start</b> column. |
| query_start      | timestamp with time zone | Time when the currently active query was started, or time when the last query was started if <b>state</b> is not <b>active</b>                                                                                            |

| Return Parameter | Type                     | Description                                                                                                                                                                                                                |
|------------------|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| backend_start    | timestamp with time zone | Time when this process was started, that is, when the client connected to the server                                                                                                                                       |
| state_change     | timestamp with time zone | Time when <b>state</b> was last modified                                                                                                                                                                                   |
| client_addr      | inet                     | IP address of the client connected to the backend. If this column is <b>NULL</b> , it indicates either the client is connected via a Unix socket on the server or this is an internal process, such as <b>AUTOVACUUM</b> . |
| client_hostname  | text                     | Host name of the connected client, as reported by a reverse DNS lookup of <b>client_addr</b> . This column will be non-null only for IP connections and only when <b>log_hostname</b> is enabled.                          |
| client_port      | integer                  | TCP port number that the client uses for communication with the backend ( <b>-1</b> if a Unix socket is used)                                                                                                              |
| enqueue          | text                     | Unsupported currently                                                                                                                                                                                                      |
| query_id         | bigint                   | ID of a query                                                                                                                                                                                                              |
| srespool         | name                     | Name of the resource pool                                                                                                                                                                                                  |
| global_sessionid | text                     | Global session ID                                                                                                                                                                                                          |
| unique_sql_id    | bigint                   | Unique SQL statement ID                                                                                                                                                                                                    |
| trace_id         | text                     | Driver-specific trace ID, which is associated with an application request                                                                                                                                                  |

- pg\_stat\_get\_activity\_with\_conninfo(integer)

Description: Returns a record about the background process with the specified PID. A record for each active background process in the system is returned if **NULL** is specified. The initial user, system administrators and users with the MONADMIN permission can view all data. Common users can only query their own results.

Return type: setofrecord

The following table describes return values.

**Table 7-79** Return values

| Return Value     | Return Type | Description                                                                                                                                                          |
|------------------|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| datid            | oid         | OID of the database that the user session connects to in the backend                                                                                                 |
| pid              | bigint      | Backend thread ID                                                                                                                                                    |
| sessionid        | bigint      | Session ID                                                                                                                                                           |
| usesysid         | oid         | OID of the user logged in to the backend                                                                                                                             |
| application_name | text        | Name of the application connected to the backend                                                                                                                     |
| state            | text        | Overall status of the backend.                                                                                                                                       |
| query            | text        | Latest query at the backend. If <b>state</b> is <b>active</b> , this column shows the ongoing query. In all other states, it shows the last query that was executed. |
| waiting          | Boolean     | Specifies whether the backend is currently waiting for a lock. If the backend is currently waiting for a lock, the value is <b>true</b> .                            |

| Return Value    | Return Type              | Description                                                                                                                                                                                                        |
|-----------------|--------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| xact_start      | timestamp with time zone | Time when current transaction was started (null if no transaction is active). If the current query is the first of its transaction, the value of this column is the same as that of the <b>query_start</b> column. |
| query_start     | timestamp with time zone | Time when the currently active query was started, or time when the last query was started if <b>state</b> is not <b>active</b>                                                                                     |
| backend_start   | timestamp with time zone | Time when this process was started, that is, when the client connected to the server                                                                                                                               |
| state_change    | timestamp with time zone | Time when <b>state</b> was last modified                                                                                                                                                                           |
| client_addr     | inet                     | IP address of the client connected to the backend. If this column is <b>null</b> , it indicates either the client is connected via a UDS on the server or this is an internal process, such as autovacuum.         |
| client_hostname | text                     | Host name of the connected client, as reported by a reverse DNS lookup of <b>client_addr</b> . This column will be non-null only for IP connections and only when <b>log_hostname</b> is enabled.                  |
| client_port     | integer                  | TCP port number that the client uses for communication with the backend (–1 if a Unix socket is used)                                                                                                              |
| enqueue         | text                     | Unsupported currently                                                                                                                                                                                              |

| Return Value     | Return Type | Description                                                                                                                            |
|------------------|-------------|----------------------------------------------------------------------------------------------------------------------------------------|
| query_id         | bigint      | ID of a query                                                                                                                          |
| connection_info  | text        | A string in JSON format recording the driver type, driver version, driver deployment path, and process owner of the connected database |
| srespool         | name        | Name of the resource pool                                                                                                              |
| global_sessionid | text        | Global session ID                                                                                                                      |
| unique_sql_id    | bigint      | Unique SQL statement ID                                                                                                                |
| trace_id         | text        | Driver-specific trace ID, which is associated with an application request.                                                             |

- `pg_stat_get_function_calls(oid)`  
Description: Specifies the number of times the function has been called.  
Return type: `bigint`
- `pg_stat_get_function_self_time(oid)`  
Description: Specifies the time spent in only this function. The time spent on this function calling other functions is excluded.  
Return type: `bigint`
- `pg_stat_get_backend_idset()`  
Description: Sets the number of currently active server processes (from 1 to the number of active server processes).  
Return type: `setofinteger`
- `pg_stat_get_backend_pid(integer)`  
Description: Specifies the ID of a specified server thread.  
Return type: `bigint`
- `pg_stat_get_backend_dbid(integer)`  
Description: Specifies the ID of a database connected to a specified server process.  
Return type: `oid`
- `pg_stat_get_backend_userid(integer)`  
Description: Specifies the user ID of a specified server process. This function can be called only by system administrators.  
Return type: `oid`
- `pg_stat_get_backend_activity(integer)`

Description: Queries the current activity of a specified server process. The query result can be obtained only when the user who calls this function is a system administrator or the same user as that of the session being queried and **track\_activities** is enabled.

Return type: text

- `pg_stat_get_backend_waiting(integer)`

Description: Returns a true value if a specified server process is waiting for a lock, but only when the user who calls this function is a system administrator or the same user as that of the session being queried and **track\_activities** is enabled.

Return type: Boolean

- `pg_stat_get_backend_activity_start(integer)`

Description: Specifies the time when a specified server process's currently executing query is started only when the user who calls this function is a system administrator or the same user as that of the session being queried and **track\_activities** is enabled.

Return type: timestamp with time zone

- `pg_stat_get_backend_xact_start(integer)`

Description: Specifies the time when a specified server process's currently executing transaction is started only when the user who calls this function is a system administrator or the same user as that of the session being queried and **track\_activities** is enabled.

Return type: timestamp with time zone

- `pg_stat_get_backend_start(integer)`

Description: Specifies the time when a specified server process is started. If the current user is neither a system administrator nor the same user as that of the session being queried, **NULL** is returned.

Return type: timestamp with time zone

- `pg_stat_get_backend_client_addr(integer)`

Description: Specifies the IP address of a backend connected to a specified client. If the connection is over a UDS, or if the current user is neither a system administrator nor the same user as that of the session being queried, **NULL** will be returned.

Return type: inet

- `pg_stat_get_backend_client_port(integer)`

Description: Specifies the TCP port of a backend connected to a specified client. If the connection is over a UDS, **-1** will be returned. If the current user is neither a system administrator nor the same user as that of the session being queried, **NULL** will be returned.

Return type: integer

- `pg_stat_get_bgwriter_timed_checkpoints()`

Description: Specifies the time when the background writer starts scheduled checkpoints (because the **checkpoint\_timeout** time has expired).

Return type: bigint

- `pg_stat_get_bgwriter_requested_checkpoints()`

Description: Specifies the time when the background writer starts checkpoints based on requests from the backend because **checkpoint\_segments** has been exceeded or the **CHECKPOINT** command has been executed.

Return type: bigint

- `pg_stat_get_bgwriter_buf_written_checkpoints()`

Description: Specifies the number of buffers written by the background writer during checkpoints.

Return type: bigint

- `pg_stat_get_bgwriter_buf_written_clean()`

Description: Specifies the number of buffers written by the background writer for routine cleaning of dirty pages.

Return type: bigint

- `pg_stat_get_bgwriter_maxwritten_clean()`

Description: Specifies the time when the background writer stops its cleaning scan because it has written more buffers than specified in the **bgwriter\_lru\_maxpages** parameter.

Return type: bigint

- `pg_stat_get_buf_written_backend()`

Description: Specifies the number of buffers written by the backend because they need to allocate a new buffer.

Return type: bigint

- `pg_stat_get_buf_alloc()`

Description: Specifies the total number of the allocated buffers.

Return type: bigint

- `pg_stat_clear_snapshot()`

Description: Clears the current statistics snapshot. This function can be executed only by SYSADMIN and MONADMIN.

Return type: void

- `pg_stat_reset()`

Description: Resets all statistics counters for the current database to zero (the SYSADMIN permission is required).

Return type: void

- `pg_stat_reset_shared(text)`

Description: Resets all statistics counters for the current database in each node in a shared cluster to zero (the SYSADMIN permission is required).

Return type: void

- `pg_stat_reset_single_table_counters(oid)`

Description: Resets statistics for a single table or index in the current database to zero (the SYSADMIN permission is required).

Return type: void

- `pg_stat_reset_single_function_counters(oid)`

Description: Resets statistics for a single function in the current database to zero (the SYSADMIN permission is required).

Return type: void

- **fenced\_udf\_process(integer)**  
Description: Shows the number of local UDF Master and Work processes. If the input parameter is set to **1**, the number of master processes is queried. If the input parameter is set to **2**, the number of worker processes is queried. If the input parameter is set to **3**, all worker processes are terminated.  
Return type: text
- **total\_cpu()**  
Description: Obtains the CPU time used by the current node, in jiffies.  
Return type: bigint
- **total\_memory()**  
Description: Obtains the size of the virtual memory used by the current node, in KB.  
Return type: bigint
- **pg\_stat\_get\_db\_cu\_hdd\_asyn(oid)**  
Description: Obtains the times CU is asynchronously read from a disk by a database of the current node.  
Return type: bigint
- **pg\_stat\_bad\_block(text, int, int, int, int, int, timestamp with time zone, timestamp with time zone)**  
Description: Obtains damage information about pages or CUs after the current node is started.  
Example:  

```
select * from pg_stat_bad_block();
```

  
Return type: record
- **pg\_stat\_bad\_block\_clear()**  
Description: Deletes the page and CU damage information that is read and recorded on the node (the SYSADMIN permission is required).  
Return type: void
- **gs\_respool\_exception\_info(pool text)**  
Description: Queries the query rule of a specified resource pool.  
Return type: record
- **gs\_control\_group\_info(pool text)**  
Description: Queries information about Cgroups associated with a resource pool.  
Return type: record

The command output is as follows:

| Attribute | Value               | Description                   |
|-----------|---------------------|-------------------------------|
| name      | class_a:workload_a1 | Class name and workload name. |
| class     | class_a             | Class Cgroup name.            |
| workload  | workload_a1         | Workload Cgroup name.         |

| Attribute | Value | Description                                                                               |
|-----------|-------|-------------------------------------------------------------------------------------------|
| type      | DEFWD | Cgroup type ( <b>Top</b> , <b>CLASS</b> , <b>BAKWD</b> , <b>DEFWD</b> , or <b>TSWD</b> ). |
| gid       | 87    | Cgroup ID.                                                                                |
| shares    | 30    | Percentage of CPU resources to those on the parent node.                                  |
| limits    | 0     | Percentage of CPU cores to those on the parent node.                                      |
| rate      | 0     | Allocation ratio in Timeshare.                                                            |
| cpucores  | 0-3   | Number of CPU cores.                                                                      |

- `gs_all_control_group_info()`  
Description: Collects information about all Cgroups in the database.  
Return type: record
- `gs_get_control_group_info()`  
Description: Collects information about all Cgroups.  
Return type: record
- `get_instr_workload_info(integer)`  
Description: Obtains the transaction volume and time information on the primary database node.  
Return type: record

| Attribute         | Value  | Description                                                     |
|-------------------|--------|-----------------------------------------------------------------|
| resourcepool_oid  | 10     | OID of the resource pool (the logic is equivalent to the load). |
| commit_counter    | 4      | Number of frontend transactions that were committed.            |
| rollback_counter  | 1      | Number of frontend transactions that were rolled back.          |
| resp_min          | 949    | Minimum response time of frontend transactions (unit: $\mu$ s). |
| resp_max          | 201891 | Maximum response time of frontend transactions (unit: $\mu$ s). |
| resp_avg          | 43564  | Average response time of frontend transactions (unit: $\mu$ s). |
| resp_total        | 217822 | Total response time of frontend transactions (unit: $\mu$ s).   |
| bg_commit_counter | 910    | Number of backend transactions that were committed.             |

| Attribute               | Value        | Description                                                    |
|-------------------------|--------------|----------------------------------------------------------------|
| bg_rollback_count<br>er | 0            | Number of backend transactions that were rolled back.          |
| bg_resp_min             | 97           | Minimum response time of backend transactions (unit: $\mu$ s). |
| bg_resp_max             | 678080687    | Maximum response time of backend transactions (unit: $\mu$ s). |
| bg_resp_avg             | 327847884    | Average response time of backend transactions (unit: $\mu$ s). |
| bg_resp_total           | 298341575300 | Total response time of backend transactions (unit: $\mu$ s).   |

- `pv_instance_time()`

Description: Obtains the time consumed in each execution phase on the current node.

Return type: record

| Stat_name<br>Attribute  | Value   | Description                                                                |
|-------------------------|---------|----------------------------------------------------------------------------|
| DB_TIME                 | 1062385 | Total end-to-end wall time consumed by all threads (unit: $\mu$ s).        |
| CPU_TIME                | 311777  | Total CPU time consumed by all threads (unit: $\mu$ s).                    |
| EXECUTION_TIME          | 380037  | Total time consumed on the executor (unit: $\mu$ s).                       |
| PARSE_TIME              | 6033    | Total time consumed for parsing SQL statements (unit: $\mu$ s).            |
| PLAN_TIME               | 173356  | Total time consumed for generating an execution plan (unit: $\mu$ s).      |
| REWRITE_TIME            | 2274    | Total time consumed on query rewriting (unit: $\mu$ s).                    |
| PL_EXECUTION_TI<br>ME   | 0       | Total time consumed for executing PL/<br>pgSQL statements (unit: $\mu$ s). |
| PL_COMPILATION<br>_TIME | 557     | Total time consumed for compiling SQL<br>statements (unit: $\mu$ s).       |
| NET_SEND_TIME           | 1673    | Total time consumed for sending data<br>over network (unit: $\mu$ s).      |
| DATA_IO_TIME            | 426622  | Total time consumed for data read and<br>write (unit: $\mu$ s).            |

- **DBE\_PERF.get\_global\_instance\_time()**  
Description: Provides the time consumed in each key phase in the entire database. To query this function, you must have the MONADMIN permission.  
Return type: record
- **get\_instr\_unique\_sql()**  
Description: Obtains information about execution statements (normalized SQL statements) on the current node as a user with the SYSADMIN permission.  
Return type: record
- **reset\_unique\_sql(text, text, bigint)**  
Description: Resets information about system execution statements (normalized SQL statements) information as a user with the SYSADMIN permission. The value of the first parameter can be **global** or **local**. **global** indicates that information on all nodes is cleared, and **local** indicates that only information on the current node is cleared. The value of the second parameter can be **ALL**, **BY\_USERID**, or **BY\_CNID**. **ALL** indicates that all information is cleared. **BY\_USERID** indicates that the SQL information of the user specified by **USERID** is cleared. **BY\_CNID** indicates that the SQL information related to the primary node of the database in the system is cleared. The third parameter indicates **CNID** and **USERID**. If the second parameter is set to **ALL**, the third parameter does not take effect and can be set to any value.  
Return type: Boolean

 **NOTE**

In the standalone system, the function of the value **global** is the same as that of the value **local** and the second parameter cannot set to be **BY\_CNID**.

- **get\_instr\_wait\_event(NULL)**  
Description: Obtains the statistics on wait events of the current node.  
Return type: record
- **get\_instr\_user\_login()**  
Description: Obtains the number of user login and logout times on the current node. Only users with the SYSADMIN or MONADMIN permission can execute this function.  
Return type: record
- **get\_instr\_rt\_percentile(integer)**  
Description: Obtains the distribution information about the response time of 80% and 95% SQL statements of the database.  
Return type: record
- **get\_node\_stat\_reset\_time()**  
Description: Obtains statistics about reset (restart, primary/standby switchover, and database deletion) time of the current node.  
Return type: record
- **DBE\_PERF.get\_global\_os\_runtime()**  
Description: Displays the running status of the current OS. To query this function, you must have the MONADMIN permission.

Return type: record

- DBE\_PERF.get\_global\_os\_threads()

Description: Provides information about the threads under all normal nodes of the entire database. To query this function, you must have the MONADMIN permission.

Return type: record

- DBE\_PERF.get\_summary\_workload\_sql\_count()

Description: Provides statistics about the number of SELECT, UPDATE, INSERT, DELETE, DDL, DML, and DCL statements of different service loads in the entire database. To query this function, you must have the MONADMIN permission.

Return type: record

- DBE\_PERF.get\_summary\_workload\_sql\_elapse\_time()

Description: Provides statistics about the number of SELECT, UPDATE, INSERT, and DELETE statements and response time information (TOTAL, AVG, MIN, and MAX) for different loads in the entire database. To query this function, you must have the MONADMIN permission.

Return type: record

- DBE\_PERF.get\_global\_workload\_transaction()

Description: Obtains the transaction volume and time information on all nodes of the database. To query this function, you must have the MONADMIN permission.

Return type: record

- DBE\_PERF.get\_global\_session\_stat()

Description: Obtains the session status information on all nodes of the database. To query this function, you must have the MONADMIN permission.

Return type: record

#### NOTE

There are 17 status information items: **commit**, **rollback**, **sql**, **table\_scan**, **blocks\_fetched**, **physical\_read\_operation**, **shared\_blocks\_dirtied**, **local\_blocks\_dirtied**, **shared\_blocks\_read**, **local\_blocks\_read**, **blocks\_read\_time**, **blocks\_write\_time**, **sort\_imemory**, **sort\_idisk**, **cu\_mem\_hit**, **cu\_hdd\_sync\_read**, and **cu\_hdd\_asyread**.

- DBE\_PERF.get\_global\_session\_time()

Description: Provides the time consumed in each key phase of each node in the entire database. To query this function, you must have the MONADMIN permission.

Return type: record

- DBE\_PERF.get\_global\_session\_memory()

Description: Displays statistics about memory usage at the session level on each node in the unit of MB, including all the memory allocated to GaussDB and stream threads on DN for jobs currently executed by users. To query this function, you must have the MONADMIN permission.

Return type: record

- DBE\_PERF.get\_global\_session\_memory\_detail()

Description: Displays statistics about thread memory usage on each node by MemoryContext node. To query this function, you must have the MONADMIN permission.

Return type: record

- `create_wlm_session_info(int flag)`

Description: Clears top SQL query statement-level statistics recorded in the current memory. Only the administrator can execute this function.

Return type: int

- `pg_stat_get_wlm_session_info(int flag)`

Description: Obtains top SQL query statement-level statistics recorded in the current memory. If the input parameter is not 0, the information is cleared from the memory. Only users with the SYSADMIN or MONADMIN permission can execute this function.

Return type: record

- `gs_paxos_stat_replication()`

Description: Queries the standby node information on the primary node. Currently, only the centralized DCF mode is supported.

Return type: setofrecord

The following table describes return columns.

| Column                                | Type | Description                                                               |
|---------------------------------------|------|---------------------------------------------------------------------------|
| <code>local_role</code>               | text | Role of the node that sends logs                                          |
| <code>peer_role</code>                | text | Role of the node that receives logs                                       |
| <code>local_dcf_role</code>           | text | DCF role of the node that sends logs                                      |
| <code>peer_dcf_role</code>            | text | DCF role of the node that receives logs                                   |
| <code>peer_state</code>               | text | Status of the node that receives logs                                     |
| <code>sender_write_location</code>    | text | Location in the Xlog buffer where the node that sends logs is written     |
| <code>sender_commit_location</code>   | text | Consistency point reached for the DCF logs of the node that sends logs    |
| <code>sender_flush_location</code>    | text | Location in the Xlog disk where the node that sends logs is written       |
| <code>sender_replay_location</code>   | text | Location where the node that sends logs replays logs                      |
| <code>receiver_write_location</code>  | text | Location in the Xlog buffer where the node that receives logs is written  |
| <code>receiver_commit_location</code> | text | Consistency point reached for the DCF logs of the node that receives logs |
| <code>receiver_flush_location</code>  | text | Location in the Xlog disk where the node that receives logs is written    |

|                          |      |                                                          |
|--------------------------|------|----------------------------------------------------------|
| receiver_replay_location | text | Location where the node that receives logs replays Xlogs |

- `gs_wlm_get_resource_pool_info(int)`  
Description: Obtains resource usage statistics of all users. The input parameter can be any value of the INT type or be **NULL**.  
Return type: record
- `gs_wlm_get_all_user_resource_info()`  
Description: Obtains resource usage statistics of all users.  
Return type: record
- `gs_wlm_get_user_info(int)`  
Description: Obtains information about all users. The input parameter is of the int type and can be any int value or **NULL**. Only users with the SYSADMIN permission can execute this function.  
Return type: record
- `gs_wlm_readjust_user_space()`  
Description: Corrects the storage space usage of all users. Only the administrator can execute this function.  
Return type: record
- `gs_wlm_readjust_user_space_through_username(text name)`  
Description: Corrects the storage space usage of a specified user. Common users can use this function to modify only their own usage. Only the administrator can modify the usage of all users. If the value of **name** is **0000**, the usage of all users needs to be modified.  
Return type: record
- `gs_wlm_readjust_user_space_with_reset_flag(text name, boolean isfirst)`  
Description: Corrects the storage space usage of a specified user. If the input parameter **isfirst** is set to **true**, statistics are collected from 0. Otherwise, statistics are collected from the previous result. Common users can use this function to modify only their own usage. Only the administrator can modify the usage of all users. If the value of **name** is **0000**, the usage of all users needs to be modified.  
Return type: record
- `gs_wlm_session_respool(bigint)`  
Description: Obtains the session resource pool information about all backend threads. The input parameter can be any value of the bigint type or can be null.  
Return type: record
- `gs_io_wait_status()`

Description: This API does not support single-node systems or centralized systems and is unavailable currently.

- `global_stat_get_hotkeys_info()`

Description: Obtains the statistics on hot keys in the entire database instance. This API does not support single-node systems or centralized systems and is unavailable currently.

- `global_stat_clean_hotkeys()`

Description: Clears statistics on hot keys in the entire database instance. This API does not support single-node systems or centralized systems and is unavailable currently.

- `DBE_PERF.get_global_session_stat_activity()`

Description: Displays information about threads that are running on each node in the database. To query this function, you must have the MONADMIN permission.

Return type: record

- `DBE_PERF.get_global_thread_wait_status()`

Description: Displays the blocking status of backend threads and auxiliary threads on all nodes. To query this function, you must have the SYSADMIN or MONADMIN permission.

Return type: record

- `DBE_PERF.get_global_operator_history_table()`

Description: Displays the operator-related records (persistent) generated after jobs are executed on the primary database node of the current user. To query this function, you must have the MONADMIN permission.

Return type: record

- `DBE_PERF.get_global_operator_history()`

Description: Displays the operator-related records generated after jobs are executed on the primary database node of the current user. To query this function, you must have the SYSADMIN or MONADMIN permission.

Return type: record

- `DBE_PERF.get_global_operator_runtime()`

Description: Displays real-time operator-related records of jobs executed on the primary database node of the current user. To query this function, you must have the SYSADMIN or MONADMIN permission.

Return type: record

- `DBE_PERF.get_global_statement_complex_history()`

Description: Displays the historical records of complex queries on the primary database node of the current user. To query this function, you must have the MONADMIN permission.

Return type: record

- `DBE_PERF.get_global_statement_complex_history_table()`

Description: Displays the historical records (persistent) of complex queries on the primary database node of the current user. To query this function, you must have the MONADMIN permission.

Return type: record

- `DBE_PERF.get_global_statement_complex_runtime()`  
Description: Displays the real-time information of complex queries on the primary database node of the current user. To query this function, you must have the SYSADMIN or MONADMIN permission.  
Return type: record
- `DBE_PERF.get_global_memory_node_detail()`  
Description: Displays the memory usage of a certain database on all nodes. To query this function, you must have the MONADMIN permission.  
Return type: record
- `DBE_PERF.get_global_shared_memory_detail()`  
Description: Displays the usage information about all the shared memory contexts of all nodes. To query this function, you must have the MONADMIN permission.  
Return type: record
- `DBE_PERF.get_global_statio_all_indexes()`  
Description: Displays statistics about each index displayed in a row in the current database, showing I/O statistics about accesses to that specific index. To query this function, you must have the MONADMIN permission.  
Return type: record
- `DBE_PERF.get_summary_stat_all_tables()`  
Description: Displays statistics about a row in each table (including the TOAST table) in the aggregated data of each node. To query this function, you must have the MONADMIN permission.  
Return type: record
- `DBE_PERF.get_global_stat_all_tables()`  
Description: Displays statistics about a row in each table (including the TOAST table) of data on each node. To query this function, you must have the MONADMIN permission.  
Return type: record
- `DBE_PERF.get_local_toastname_and_toastindexname()`  
Description: Provides the mapping between the name and index of the local TOAST table and its associated table. To query this function, you must have the MONADMIN permission.  
Return type: record
- `DBE_PERF.get_summary_statio_all_indexes()`  
Description: Collects statistics about each index displayed in a row in the current databases of all nodes and displays the I/O statistics of a specific index. To query this function, you must have the MONADMIN permission.  
Return type: record
- `DBE_PERF.get_global_statio_all_sequences()`  
Description: Provides I/O status information about all sequences in the namespace. To query this function, you must have the MONADMIN permission.  
Return type: record

- DBE\_PERF.get\_global\_statio\_all\_tables()  
Description: Displays the I/O statistics about each table in databases on each node. To query this function, you must have the MONADMIN permission.  
Return type: record
- DBE\_PERF.get\_summary\_statio\_all\_tables()  
Description: Collects I/O statistics about each table in databases in the database. To query this function, you must have the MONADMIN permission.  
Return type: record
- DBE\_PERF.get\_local\_toast\_relation()  
Description: Provides the mapping between the name of the local TOAST table and its associated table. To query this function, you must have the MONADMIN permission.  
Return type: record
- DBE\_PERF.get\_global\_statio\_sys\_indexes()  
Description: Displays the I/O status information about all system catalog indexes in namespaces on each node. To query this function, you must have the MONADMIN permission.  
Return type: record
- DBE\_PERF.get\_summary\_statio\_sys\_indexes()  
Description: Collects the I/O status information about all system catalog indexes in namespaces on each node. To query this function, you must have the MONADMIN permission.  
Return type: record
- DBE\_PERF.get\_global\_statio\_sys\_sequences()  
Description: Provides the I/O status information about all the system sequences in the namespace. To query this function, you must have the MONADMIN permission.  
Return type: record
- DBE\_PERF.get\_global\_statio\_sys\_tables()  
Description: Provides I/O status information about all system catalogs in namespaces on each node. To query this function, you must have the MONADMIN permission.  
Return type: record
- DBE\_PERF.get\_summary\_statio\_sys\_tables()  
Description: Displays the I/O status information of all system catalogs in the namespace in the database. To query this function, you must have the MONADMIN permission.  
Return type: record
- DBE\_PERF.get\_global\_statio\_user\_indexes()  
Description: Displays the I/O status information about all user relationship table indexes in namespaces on each node. To query this function, you must have the MONADMIN permission.  
Return type: record
- DBE\_PERF.get\_summary\_statio\_user\_indexes()

Description: Displays the I/O status information about all user relationship table indexes in namespaces in the database. To query this function, you must have the MONADMIN permission.

Return type: record

- DBE\_PERF.get\_global\_statio\_user\_sequences()

Description: Displays the I/O status information about all user sequences in the namespace of each node. To query this function, you must have the MONADMIN permission.

Return type: record

- DBE\_PERF.get\_global\_statio\_user\_tables()

Description: Displays the I/O status information about all user relationship tables in namespaces on each node. To query this function, you must have the MONADMIN permission.

Return type: record

- DBE\_PERF.get\_summary\_statio\_user\_tables()

Description: Displays the I/O status information about all user relationship tables in namespaces in the database. To query this function, you must have the MONADMIN permission.

Return type: record

- DBE\_PERF.get\_stat\_db\_cu()

Description: Queries CU hits in a database and in each node in the database. To query this function, you must have the MONADMIN permission.

Return type: record

- DBE\_PERF.get\_global\_stat\_all\_indexes()

Description: Displays statistics of each index in databases on all nodes. To query this function, you must have the MONADMIN permission.

Return type: record

- DBE\_PERF.get\_summary\_stat\_all\_indexes()

Description: Collects statistics of each index in all databases on all nodes. To query this function, you must have the MONADMIN permission.

Return type: record

- DBE\_PERF.get\_global\_stat\_sys\_tables()

Description: Displays statistics about the system catalogs of all the namespaces in **pg\_catalog** and **information\_schema** schemas on each node. To query this function, you must have the MONADMIN permission.

Return type: record

- DBE\_PERF.get\_summary\_stat\_sys\_tables()

Description: Collects statistics about the system catalogs of all the namespaces in **pg\_catalog** and **information\_schema** schemas on each node. To query this function, you must have the MONADMIN permission.

Return type: record

- DBE\_PERF.get\_global\_stat\_sys\_indexes()

Description: Displays index status information about all the system catalogs in the **pg\_catalog** and **information\_schema** schemas on each node. To query this function, you must have the MONADMIN permission.

Return type: record

- DBE\_PERF.get\_summary\_stat\_sys\_indexes()

Description: Collects statistics about index status information about all the system catalogs in the pg\_catalog and information\_schema schemas on each node. To query this function, you must have the MONADMIN permission.

Return type: record

- DBE\_PERF.get\_global\_stat\_user\_tables()

Description: Displays the status information about customized ordinary tables in all namespaces. To query this function, you must have the MONADMIN permission.

Return type: record

- DBE\_PERF.get\_summary\_stat\_user\_tables()

Description: Collects statistics about the status information about customized ordinary tables in all namespaces. To query this function, you must have the MONADMIN permission.

Return type: record

- DBE\_PERF.get\_global\_stat\_user\_indexes()

Description: Displays the status information about the index of customized ordinary tables in all databases. To query this function, you must have the MONADMIN permission.

Return type: record

- DBE\_PERF.get\_summary\_stat\_user\_indexes()

Description: Collects statistics about the status information about the index of customized ordinary tables in all databases. To query this function, you must have the MONADMIN permission.

Return type: record

- DBE\_PERF.get\_global\_stat\_database()

Description: Displays database statistics of all nodes. To query this function, you must have the MONADMIN permission.

Return type: record

- DBE\_PERF.get\_global\_stat\_database\_conflicts()

Description: Collects statistics on the database of all nodes. To query this function, you must have the MONADMIN permission.

Return type: record

- DBE\_PERF.get\_global\_stat\_xact\_all\_tables()

Description: Displays transaction status information about all ordinary tables and TOAST tables in all namespaces. To query this function, you must have the MONADMIN permission.

Return type: record

- DBE\_PERF.get\_summary\_stat\_xact\_all\_tables()

Description: Collects statistics about transaction status information about all ordinary tables and TOAST tables in all namespaces. To query this function, you must have the MONADMIN permission.

Return type: record

- DBE\_PERF.get\_global\_stat\_xact\_sys\_tables()  
Description: Displays transaction status information about all system catalogs in namespaces on all nodes. To query this function, you must have the MONADMIN permission.  
Return type: record
- DBE\_PERF.get\_summary\_stat\_xact\_sys\_tables()  
Description: Collects statistics about transaction status information about all system catalogs in namespaces on all nodes. To query this function, you must have the MONADMIN permission.  
Return type: record
- DBE\_PERF.get\_global\_stat\_xact\_user\_tables()  
Description: Displays the transaction status information of the user tables in the namespaces on all nodes. To query this function, you must have the MONADMIN permission.  
Return type: record
- DBE\_PERF.get\_summary\_stat\_xact\_user\_tables()  
Description: Collects statistics about the transaction status information of the user tables in the namespaces on all nodes. To query this function, you must have the MONADMIN permission.  
Return type: record
- DBE\_PERF.get\_global\_stat\_user\_functions()  
Description: Displays the transaction status information of user-defined functions in the namespaces on all nodes. To query this function, you must have the MONADMIN permission.  
Return type: record
- DBE\_PERF.get\_global\_stat\_xact\_user\_functions()  
Description: Collects statistics about the transaction status information of user-defined functions in the namespaces on all nodes. To query this function, you must have the MONADMIN permission.  
Return type: record
- DBE\_PERF.get\_global\_stat\_bad\_block()  
Description: Displays information about table and index read failures on all nodes. To query this function, you must have the MONADMIN permission.  
Return type: record
- DBE\_PERF.get\_global\_file\_redo\_iostat()  
Description: Collects statistics on information about table and index read failures on all nodes. To query this function, you must have the MONADMIN permission.  
Return type: record
- DBE\_PERF.get\_global\_file\_iostat()  
Description: Displays statistics about data file I/Os on all nodes. To query this function, you must have the MONADMIN permission.  
Return type: record
- DBE\_PERF.get\_global\_locks()

Description: Displays lock information of all nodes. To query this function, you must have the SYSADMIN or MONADMIN permission.

Return type: record

- DBE\_PERF.get\_global\_replication\_slots()

Description: Displays logical replication information on all nodes. To query this function, you must have the SYSADMIN or MONADMIN permission.

Return type: record

- DBE\_PERF.get\_global\_bgwriter\_stat()

Description: Displays statistics about the background writer process's activities on all nodes. To query this function, you must have the MONADMIN permission.

Return type: record

- DBE\_PERF.get\_global\_replication\_stat()

Description: Displays information about log synchronization status on each node, such as the locations where the sender sends logs and where the receiver receives logs. To query this function, you must have the MONADMIN permission.

Return type: record

- DBE\_PERF.get\_global\_transactions\_running\_xacts()

Description: Displays information about running transactions on each node. To query this function, you must have the MONADMIN permission.

Return type: record

- DBE\_PERF.get\_summary\_transactions\_running\_xacts()

Description: Collects statistics of information about running transactions on each node. To query this function, you must have the MONADMIN permission.

Return type: record

- DBE\_PERF.get\_global\_transactions\_prepared\_xacts()

Description: Displays information about transactions that are currently prepared for two-phase commit on each node. To query this function, you must have the MONADMIN permission.

Return type: record

- DBE\_PERF.get\_summary\_transactions\_prepared\_xacts()

Description: Collects statistics information about transactions that are currently prepared for two-phase commit on each node. To query this function, you must have the MONADMIN permission.

Return type: record

- DBE\_PERF.get\_summary\_statement()

Description: Displays the status information of the historically-executed statements on each node. To query this function, you must have the SYSADMIN or MONADMIN permission.

Return type: record

- DBE\_PERF.get\_global\_statement\_count()

Description: Displays the number of SELECT, UPDATE, INSERT, and DELETE statements and response time information (TOTAL, AVG, MIN, and MAX) on

each node. To query this function, you must have the MONADMIN permission.

Return type: record

- DBE\_PERF.get\_global\_config\_settings()

Description: Displays GUC parameter configuration information on each node. To query this function, you must have the MONADMIN permission.

Return type: record

- DBE\_PERF.get\_global\_wait\_events()

Description: Displays the wait event status information on each node. To query this function, you must have the MONADMIN permission.

Return type: record

- DBE\_PERF.get\_statement\_responsetime\_percentile()

Description: Obtains the response time distribution for 80% and 95% SQL statements of the database. To query this function, you must have the MONADMIN permission.

Return type: record

- DBE\_PERF.get\_summary\_user\_login()

Description: Collects statistics about number of user login and logout times on each node in the database. To query this function, you must have the MONADMIN permission.

Return type: record

- DBE\_PERF.get\_global\_record\_reset\_time()

Description: Displays the statistics about reset (restart, primary/standby switchover, and database deletion) time of the database. To query this function, you must have the MONADMIN permission.

Return type: record

- DBE\_PERF.track\_memory\_context(context\_list text)

Description: Sets the memory context whose memory allocation details need to be collected. The input parameter is the memory context names, which are separated by commas (,), for example, **ThreadTopMemoryContext**, **SessionCacheMemoryContext**. Note that the memory context names are context-sensitive. In addition, the length of a single memory context is 63, and the excess part is truncated. The maximum number of memory contexts that can be collected at a time is 16. If the number of memory contexts exceeds 16, the setting fails. Each time this function is called, the previous collection result is cleared. When the input parameter is set to "", the collection function is disabled. Only the initial user or a user with the MONADMIN permission can execute this function.

Return type: Boolean

- DBE\_PERF.track\_memory\_context\_detail()

Description: Obtains the memory allocation details of the memory context specified by the **DBE\_PERF.track\_memory\_context** function. For details, see the **DBE\_PERF.track\_memory\_context\_detail** view. Only the initial user or a user with the MONADMIN permission can execute this function.

Return type: record

- pg\_stat\_get\_mem\_mbytes\_reserved(tid)

Description: Collects statistics on variables related to resource management, which is used only for fault locating.

Parameter: thread ID

Return type: text

- `gs_wlm_user_resource_info(name text)`

Description: Queries a user's resource quota and resource usage.

Return type: record

- `pg_stat_get_file_stat()`

Description: Collects statistics on data file I/Os to indicate I/O performance and detect performance problems such as abnormal I/O operations.

Return type: record

- `pg_stat_get_redo_stat()`

Description: Displays statistics on the replay of session thread logs.

Return type: record

- `pg_stat_get_status(int8)`

Description: Tests the blocking status about the backend thread and auxiliary thread of the current instance.

Return type: record

- `get_local_rel_iostat()`

Description: Queries the accumulated I/O status of data files on the current node.

Return type: record

- `DBE_PERF.get_global_rel_iostat()`

Description: Displays statistics about data file I/Os on all nodes. To query this function, you must have the MONADMIN permission.

Return type: record

- `DBE_PERF.global_threadpool_status()`

Description: Displays the status of worker threads and sessions in thread pools on all nodes. For details about the columns returned by the function, see [GLOBAL\\_THREADPOOL\\_STATUS](#).

Return type: record

- `remote_bgwriter_stat()`

Description: Displays the information about pages flushed by the bgwriter threads of all instances in the database, number of pages in the candidate buffer chain, and buffer elimination information. (The query result does not contain the information about the current node and cannot be used on DNs.) This is not supported in centralized mode.

Return type: record

- `pv_os_run_info()`

Description: Displays the running status of the current OS. For details about the columns, see [GS\\_OS\\_RUN\\_INFO](#).

Parameter: nan

Return type: SETOF record

- `pv_session_stat()`  
Description: Collects session status information by session thread or autovacuum thread. For details about the columns, see [GS\\_SESSION\\_STAT](#).  
Parameter: **nan**  
Return type: SETOF record
- `pv_session_time()`  
Description: Collects statistics on the running time of session threads and the time consumed in each execution phase. For details about the columns, see [GS\\_SESSION\\_TIME](#).  
Parameter: **nan**  
Return type: SETOF record
- `pg_stat_get_db_temp_bytes()`  
Description: Collects statistics on the total amount of data written to temporary files through database query. All temporary files are counted, regardless of why the temporary file was created, and regardless of the **log\_temp\_files** setting.  
Parameter: **oid**  
Return type: bigint
- `pg_stat_get_db_temp_files()`  
Description: Queries the number of temporary files created in the database. All temporary files are counted, regardless of why the temporary file was created (for example, sorting or hashing), and regardless of the **log\_temp\_files** setting.  
Parameter: **oid**  
Return type: bigint
- `create_wlm_instance_statistics_info`  
Description: Saves the historical monitoring data of the current instance persistently.  
Parameter: **nan**  
Return type: integer
- `remote_candidate_stat()`  
Description: Displays the checkpoint information and log flushing information about all instances in the database (except the current node). Centralized systems are not supported.  
Return type: record
- `remote_ckpt_stat()`  
Description: Displays the checkpoint information and log flushing information about all instances in the database (except the current node). Centralized systems are not supported.  
Return type: record
- `remote_single_flush_dw_stat()`  
Description: Displays the single-page doublewrite file status of all instances in the database (except the current node). Centralized systems are not supported.  
Return type: record

- `remote_double_write_stat()`  
Description: Displays doublewrite file status of all instances in the database (except the current node). Centralized systems are not supported.  
Return type: record
- `remote_pagewriter_stat()`  
Description: Displays the page flushing information and checkpoint information about all instances in the database (except the current node). Centralized systems are not supported.  
Return type: record
- `remote_recovery_status()`  
Description: Displays log flow control information about the primary and standby nodes (except the current node). Centralized systems are not supported.  
Return type: record
- `remote_redo_stat()`  
Description: Displays the log replay status of all instances in the database (except the current node). Centralized systems are not supported.  
Return type: record
- `dbe_perf.gs_stat_activity_timeout(int)`  
Description: Obtains information about query jobs whose execution time exceeds the timeout threshold on the current node. The correct result can be returned only when the GUC parameter **track\_activities** is set to **on**. The timeout threshold ranges from 0 to 2147483.  
Return type: SETOF record

| Name             | Type        | Description                                                                                                                                                                                  |

| application_name | text        | Name of the application connected to the backend                                                                                                                                             |
| query            | text        | Query that is being executed on the backend                                                                                                                                                  |
| xact_start       | timestamptz | Time when the current transaction is started                                                                                                                                                 |
| query_start      | timestamptz | Time when the current query starts For a stored procedure, function, or package, the first query time is queried and does not change with the running of statements in the stored procedure. |
| query_id         | bigint      | Query statement ID                                                                                                                                                                           |

- **gs\_wlm\_user\_resource\_info(name text)**  
Description: Queries a user's resource quota and resource usage. Common users can query only their own information. Administrators can query information about all users.  
Return type: record
- **create\_wlm\_instance\_statistics\_info**  
Description: Saves the historical monitoring data of the current instance persistently.  
Parameter: **nan**  
Return type: integer
- **gs\_wlm\_persistent\_user\_resource\_info()**  
Description: Archives all user resource usage statistics to the `gs_wlm_user_resource_history` system catalog. To query this function, you must have the SYSADMIN permission.  
Return type: record
- **create\_wlm\_operator\_info(int flag)**  
Description: Clears top SQL operator-level statistics recorded in the current memory. If the input parameter is greater than 0, the information is archived to `gs_wlm_operator_info`. Otherwise, the information is not archived. Only users with the SYSADMIN permission can execute this function.  
Return type: int
- **GS\_ALL\_NODEGROUP\_CONTROL\_GROUP\_INFO(text)**  
Description: Provides Cgroup information for all logical database instances. Before calling this function, you need to specify the name of the logical database instance to be queried.  
For example, to query the Cgroup information for the '**installation**' logical database instance, run the following command:  

```
SELECT * FROM GS_ALL_NODEGROUP_CONTROL_GROUP_INFO('installation')
```

  
Return type: record

The following table describes return columns.

| Name     | Type   | Description                                             |
|----------|--------|---------------------------------------------------------|
| name     | text   | Cgroup name.                                            |
| type     | text   | Cgroup type.                                            |
| gid      | bigint | Cgroup ID.                                              |
| classgid | bigint | ID of the class Cgroup where a workload Cgroup belongs. |
| class    | text   | Class Cgroup.                                           |
| workload | text   | Workload Cgroup.                                        |
| shares   | bigint | CPU quota allocated to the Cgroup.                      |
| limits   | bigint | Limit of CPU resources allocated to a Cgroup.           |

| Name     | Type   | Description                                       |
|----------|--------|---------------------------------------------------|
| wdlevel  | bigint | Workload Cgroup level.                            |
| cpucores | text   | Information about the CPU cores used by a Cgroup. |

- `gs_total_nodegroup_memory_detail`  
Description: Returns information about the memory used by the current logical database, in MB.  
Return type: SETOF record
- `local_redo_time_count()`  
Description: Returns the time consumption statistics on each process of each replayer thread on the current node (valid data exists only on the standby node).

The return values are as follows:

`local_redo_time_count` parameters

| Column                   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>thread_name</code> | Thread name.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>step1_total</code> | Total duration of step 1. The process of each thread is as follows: <ul style="list-style-type: none"><li>• Ultimate RTO:<ul style="list-style-type: none"><li><b>batch redo</b>: obtains a log from a queue.</li><li><b>redo manager</b>: obtains a log from a queue.</li><li><b>redo worker</b>: obtains a log from a queue.</li><li><b>txn manager</b>: reads a log from a queue.</li><li><b>txn worker</b>: reads a log from a queue.</li><li><b>read worker</b>: reads an Xlog page (overall) from a file.</li><li><b>read page worker</b>: obtains a log from a queue.</li><li><b>startup</b>: obtains a log from a queue.</li></ul></li><li>• Parallel replay:<ul style="list-style-type: none"><li><b>page redo</b>: obtains a log from a queue.</li><li><b>startup</b>: reads a log.</li></ul></li></ul> |

- local\_xlog\_redo\_statics()

Description: Returns the statistics on each type of logs that have been replayed on the current node (valid data exists only on the standby node).

The return values are as follows:

**Table 7-80** local\_xlog\_redo\_stats parameters

| Column    | Description                                                                                                                                                                                                                                          |
|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| xlog_type | Log types.                                                                                                                                                                                                                                           |
| rmid      | Resource manager ID.                                                                                                                                                                                                                                 |
| info      | Xlog operation.                                                                                                                                                                                                                                      |
| num       | Number of logs.                                                                                                                                                                                                                                      |
| extra     | Valid values are available for page replay logs and xact logs. <ul style="list-style-type: none"><li>• The page replay logs indicate the number of pages read from the disk.</li><li>• The xact logs indicate the number of deleted files.</li></ul> |

- `gs_get_shared_memctx_detail(text)`

Description: Returns the memory allocation details of the specified memory context, including the file, line number, and size of each memory allocation (the size of the same line in the same file is accumulated). Only the memory context queried through the **pg\_shared\_memory\_detail** view can be queried. The input parameter is the memory context name (that is, the **contextname** column in the result returned by the **pg\_shared\_memory\_detail** view). To query this function, you must have the SYSADMIN or MONADMIN permission.

Return type: SETOF record

| Name | Type | Description                                                                                                                             |
|------|------|-----------------------------------------------------------------------------------------------------------------------------------------|
| file | text | Name of the file where the memory is applied for.                                                                                       |
| line | int8 | Line number of the code in the file where the requested memory is located.                                                              |
| size | int8 | Size of the allocated memory. The value is accumulated if the memory is allocated for multiple times to the same line of the same file. |

- `gs_get_session_memctx_detail(text)`

Description: Returns the memory allocation details of the specified memory context, including the file, line number, and size of each memory allocation (the size of the same line in the same file is accumulated). This parameter is valid only in thread pool mode. Only the memory context queried through the **gs\_session\_memory\_context** view can be queried. The input parameter is the memory context name (that is, the **contextname** column in the result

returned by the **gs\_session\_memory\_context** view). To query this function, you must have the SYSADMIN or MONADMIN permission.

Return type: SETOF record

| Name | Type | Description                                                                                                                                       |
|------|------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| file | text | Name of the file where the memory is applied for.                                                                                                 |
| line | int8 | Line number of the code in the file where the requested memory is located.                                                                        |
| size | int8 | Size of the allocated memory, in bytes. The value is accumulated if the memory is allocated for multiple times to the same line of the same file. |

#### NOTE

This view takes effect only in thread pool mode.

- **gs\_get\_history\_memory\_detail(cstring)**  
Description: Queries historical memory snapshot information. The input parameter type is cstring. The value can be **NULL** or the name of the memory snapshot log file.
  - If the value of the input parameter is **NULL**, the list of all memory snapshot log files on the current node is displayed.
  - If the value of the input parameter is the name of the memory snapshot log file in the list queried in [a](#), the detailed information about the memory snapshot recorded in the log file is displayed.
  - If you enter any other input parameter, the system displays a message indicating that the input parameter is incorrect or the file fails to be opened.

To query this function, you must have the SYSADMIN or MONADMIN permission.

Return type: text

| Name        | Type | Description                                                                                                                                                                                                                                 |
|-------------|------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| memory_info | text | Memory information. If the input parameter of the function is set to <b>NULL</b> , the memory snapshot file list is displayed. If the input parameter is set to the name of the memory snapshot file, the content of the file is displayed. |

- **gs\_stack()**  
Description: Displays the call stack of a thread. To query this function, you must have the SYSADMIN or MONADMIN permission.  
Parameter: tid, which indicates the thread ID. **tid** is an optional parameter. If it is specified, the function returns the call stack of the thread corresponding to **tid**. If it is not specified, the function returns the call stacks of all threads.

Return value: If **tid** is specified, the return value is of the TEXT type. If **tid** is not specified, the return value is a SETOF record.

Example:

Run **select \* from gs\_stack(tid)** to obtain the call stack of a specified thread.

```
openGauss=# select * from gs_stack(139663481165568);
gs_stack
```

```

__poll + 0x2d
WaitLatchOrSocket(Latch volatile*, int, int, long) + 0x29f
WaitLatch(Latch volatile*, int, long) + 0x2e
JobScheduleMain() + 0x90f
int GaussDbThreadMain<(knl_thread_role)9>(knl_thread_arg*) + 0x456+
InternalThreadFunc(void*) + 0x2d
ThreadStarterFunc(void*) + 0xa4
start_thread + 0xc5
clone + 0x6d
(1 row)
```

Run **select \* from gs\_stack()** to obtain the call stacks of all threads.

```
openGauss=# select * from gs_stack();
```

```
-[RECORD
```

```

 | ThreadStarterFunc(void*) + 0xa4
 | start_thread + 0xc5
 | clone + 0x6d
```

- **gs\_get\_thread\_memctx\_detail(tid,text)**

Description: Returns the memory allocation details of the specified memory context, including the file, line number, and size of each memory allocation (the size of the same line in the same file is accumulated). Only the memory context queried through the **gs\_thread\_memory\_context** view is supported. The first input parameter is the thread ID (the **tid** column of the data returned by the **gs\_thread\_memory\_context**), and the second parameter is the memory context name (the **contextname** column of the data returned by **gs\_thread\_memory\_context**). To query this function, you must have the SYSADMIN or MONADMIN permission.

Return type: SETOF record

| Name | Type | Description                                       |
|------|------|---------------------------------------------------|
| file | text | Name of the file where the memory is applied for. |

| Name | Type | Description                                                                                                                                       |
|------|------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| line | int8 | Line number of the code in the file where the requested memory is located.                                                                        |
| size | int8 | Size of the allocated memory, in bytes. The value is accumulated if the memory is allocated for multiple times to the same line of the same file. |

## 7.5.25 Trigger Functions

- pg\_get\_triggerdef(oid)

Description: Obtains the definition information of a trigger.

Parameter: OID of the trigger to be queried

Return type: text

Example:

```
openGauss=# select pg_get_triggerdef(oid) from pg_trigger;
 pg_get_triggerdef

CREATE TRIGGER tg1 BEFORE INSERT ON gtest26 FOR EACH STATEMENT EXECUTE PROCEDURE
gtest_trigger_func()
CREATE TRIGGER tg03 AFTER INSERT ON gtest26 FOR EACH ROW WHEN ((new.a IS NOT NULL))
EXECUTE PROCEDURE gtest_trigger_func()
(2 rows)
```

- pg\_get\_triggerdef(oid, boolean)

Description: Obtains the definition information of a trigger.

Parameter: OID of the trigger to be queried and whether it is displayed in pretty mode

### NOTE

Boolean parameters take effect only when the WHEN condition is specified during trigger creation.

Return type: text

Example:

```
openGauss=# select pg_get_triggerdef(oid,true) from pg_trigger;
 pg_get_triggerdef

CREATE TRIGGER tg1 BEFORE INSERT ON gtest26 FOR EACH STATEMENT EXECUTE PROCEDURE
gtest_trigger_func()
CREATE TRIGGER tg03 AFTER INSERT ON gtest26 FOR EACH ROW WHEN (new.a IS NOT NULL)
EXECUTE PROCEDURE gtest_trigger_func()
(2 rows)

openGauss=# select pg_get_triggerdef(oid,false) from pg_trigger;
 pg_get_triggerdef

CREATE TRIGGER tg1 BEFORE INSERT ON gtest26 FOR EACH STATEMENT EXECUTE PROCEDURE
gtest_trigger_func()
CREATE TRIGGER tg03 AFTER INSERT ON gtest26 FOR EACH ROW WHEN ((new.a IS NOT NULL))
EXECUTE PROCEDURE gtest_trigger_func()
(2 rows)
```

## 7.5.26 Hash Function

- `hash_array(anyarray)`

Description: Hashes an array, obtains the result of an array element using the hash function, and returns the combination result.

Parameter: data of the anyarray type

Return type: integer

Example:

```
openGauss=# SELECT hash_array(ARRAY[[1,2,3],[1,2,3]]);
 hash_array

-382888479
(1 row)
```

- `hash_group(key)`

Description: Calculates the hash value of each column in the Group Clause in the streaming engine. (Due to specification changes, the current version no longer supports this feature. Do not use it.)

Parameter: **key** indicates the value of each column in the Group Clause.

Return type: 32-bit hash value

Example:

```
Perform the following steps in sequence.
openGauss=# CREATE TABLE tt(a int, b int,c int,d int);
NOTICE: The 'DISTRIBUTE BY' clause is not specified. Using 'a' as the distribution column by default.
HINT: Please use 'DISTRIBUTE BY' clause to specify suitable data distribution column.
CREATE TABLE
openGauss=# SELECT * FROM tt;
 a | b | c | d
---+---+---+---
(0 rows)

openGauss=# INSERT INTO tt VALUES(1,2,3,4);
INSERT 0 1
openGauss=# SELECT * FROM tt;
 a | b | c | d
---+---+---+---
 1 | 2 | 3 | 4
(1 row)

openGauss=# INSERT INTO tt VALUES(5,6,7,8);
INSERT 0 1
openGauss=# SELECT * FROM tt;
 a | b | c | d
---+---+---+---
 1 | 2 | 3 | 4
 5 | 6 | 7 | 8
(2 rows)

openGauss=# SELECT hash_group(a,b) FROM tt WHERE a=1 and b=2;
 hash_group

 990882385
(1 row)

openGauss=# DROP TABLE tt;
DROP TABLE
```

- `hash_numeric(numeric)`

Description: Calculates the hash value of numeric data.

Parameter: data of the numeric type.

Return type: integer

Example:

```
openGauss=# SELECT hash_numeric(30);
 hash_numeric

-282860963
(1 row)
```

- **hash\_range(anyrange)**

Description: Calculates the hash value of a range.

Parameter: data of the anyrange type

Return type: integer

Example:

```
openGauss=# SELECT hash_range(numrange(1.1,2.2));
 hash_range

683508754
(1 row)
```

- **hashbpchar(character)**

Description: Calculates the hash value of bpchar.

Parameter: data of the character type

Return type: integer

Example:

```
openGauss=# SELECT hashbpchar('hello');
 hashbpchar

-1870292951
(1 row)
```

- **hashchar(char)**

Description: Converts char and Boolean data into hash values.

Parameter: data of the char or bool type

Return type: integer

Example:

```
openGauss=# SELECT hashbpchar('hello');
 hashbpchar

-1870292951
(1 row)
```

```
openGauss=# SELECT hashchar('true');
 hashchar

1686226652
(1 row)
```

- **hashenum(anyenum)**

Description: Converts enumerated values to hash values.

Parameter: data of the anyenum type

Return type: integer

Example:

```
openGauss=# CREATE TYPE b1 AS ENUM('good', 'bad', 'ugly');
CREATE TYPE
openGauss=# CALL hashenum('good'::b1);
 hashenum
```

```

1821213359
(1 row)
openGauss=# DROP TYPE b1;
DROP TYPE
```

- **hashfloat4(real)**

Description: Converts float4 values to hash values.

Parameter: data of the real type

Return type: integer

Example:

```
openGauss=# SELECT hashfloat4(12.1234);
hashfloat4

1398514061
(1 row)
```

- **hashfloat8(double precision)**

Description: Converts float8 values to hash values.

Parameter: data of the double precision type

Return type: integer

Example:

```
openGauss=# SELECT hashfloat8(123456.1234);
hashfloat8

1673665593
(1 row)
```

- **hashinet(inet)**

Description: Supports hashing indexes on inet or cidr. Returns the hash value of inet.

Parameter: data of the inet type

Return type: integer

Example:

```
openGauss=# SELECT hashinet('127.0.0.1 '::inet);
hashinet

-1435793109
(1 row)
```

- **hashint1(tinyint)**

Description: Converts INT1 values to hash values.

Parameter: data of the tinyint type

Return type: uint32

Example:

```
openGauss=# SELECT hashint1(20);
hashint1

-2014641093
(1 row)
```

- **hashint2(smallint)**

Description: Converts INT2 values to hash values.

Parameter: data of the smallint type

Return type: uint32

Example:

```
openGauss=# SELECT hashint2(20000);
 hashint2

-863179081
(1 row)
```

## 7.5.27 Prompt Message Function

- report\_application\_error

Description: This function can be used to throw errors during PL execution.

Return type: void

**Table 7-81** report\_application\_error parameter description

| Parameter | Type | Description                                                                           | Required (Yes/No) |
|-----------|------|---------------------------------------------------------------------------------------|-------------------|
| log       | text | Content of an error message.                                                          | Yes               |
| code      | int4 | Error code corresponding to an error message. The value ranges from -20999 to -20000. | No                |

Example:

```
openGauss=# CREATE OR REPLACE FUNCTION GET_RESULT_UNKNOWNN(
openGauss(# IN context_id int, /*context_id*/
openGauss(# IN col_type text /*col_type*/
openGauss(#)RETURNS INTEGER
openGauss-# AS $$
openGauss$$ BEGIN
openGauss$$ if col_type is NULL then
openGauss$$ PG_CATALOG.REPORT_APPLICATION_ERROR('invalid input for the third parameter
col_type should not be null');
openGauss$$ end if;
openGauss$$ PG_CATALOG.REPORT_APPLICATION_ERROR('UnSupport data type for
column_value(context: '||context_id||', '||PG_CATALOG.QUOTE_LITERAL(col_type)||')');
openGauss$$ return -1;
openGauss$$ END;
openGauss$$ $$ LANGUAGE plpgsql;
CREATE FUNCTION
openGauss=# CALL GET_RESULT_UNKNOWNN(NULL, NULL);
ERROR: invalid input for the third parameter col_type should not be null
CONTEXT: SQL statement "CALL pg_catalog.report_application_error('invalid input for the third
parameter col_type should not be null')
PL/pgSQL function get_result_unknown(integer,text) line 4 at PERFORM
```

## 7.5.28 Global Temporary Table Functions

- pg\_get\_gtt\_relstats(relOid)

Description: Displays basic information about a global temporary table specified by the current session.

Parameter: OID of the global temporary table

Return type: record

Example:

```
openGauss=# select * from pg_get_gtt_relstats(74069);
 relfilenode | relpages | reltuples | relallvisible | relfrozensxid | relminmxid
-----+-----+-----+-----+-----+-----
 74069 | 58 | 13000 | 0 | 11151 | 0
(1 row)
```

- pg\_get\_gtt\_statistics(relOid, attnum, "::text)

Description: Displays statistics about a single column in a global temporary table specified by the current session.

Parameter: `OID` and the **attnum** attribute of the global temporary table

Return type: record

Example:

[illegible]

- `pg_gtt_attached_pid(relOid)`

Description: Displays PIDs and session IDs of all threads that are using the specified global temporary table. If the thread pool is enabled and the session that is using the global temporary table is in the detach state, then the PID is **0** and **sessionid** indicates the session ID.

Parameter: OID of the global temporary table

Return type: record

Example:

```
openGauss=# select * from pg_gtt_attached_pid(74069);
relid | pid | sessionid
-----+-----+-----
74069 | 139648170456832 | 139648170456832
74069 | 139648123270912 | 139648123270912
(2 rows)
```

- `dbperf.get_global_full_sql_by_timestamp(start_timestamp timestamp, end_timestamp timestamp)`

Description: Obtains full SQL information at the instance level.

Return type: record

**Table 7-82** `dbperf.get_global_full_sql_by_timestamp` parameter description

| Parameter                    | Type      | Description                              |
|------------------------------|-----------|------------------------------------------|
| <code>start_timestamp</code> | timestamp | Start point of the SQL start time range. |
| <code>end_timestamp</code>   | timestamp | End point of the SQL start time range.   |

- `dbperf.get_global_slow_sql_by_timestamp(start_timestamp timestamp, end_timestamp timestamp)`

Description: Obtains slow SQL information at the instance level.

Return type: record

**Table 7-83** `dbperf.get_global_slow_sql_by_timestamp` parameter description

| Parameter                    | Type      | Description                              |
|------------------------------|-----------|------------------------------------------|
| <code>start_timestamp</code> | timestamp | Start point of the SQL start time range. |
| <code>end_timestamp</code>   | timestamp | End point of the SQL start time range.   |

- `statement_detail_decode(detail text, format text, pretty bool)`

Parses the details column in a full or slow SQL statement.

**Table 7-84** `statement_detail_decode` parameter description

| Parameter           | Type | Description                                                                                                                                                                                                                                                                                                                                            |
|---------------------|------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>detail</code> | text | Set of events generated by the SQL statement (unreadable).                                                                                                                                                                                                                                                                                             |
| <code>format</code> | text | Parsing output format. The value is <b>plaintext</b> or <b>json</b> .                                                                                                                                                                                                                                                                                  |
| <code>pretty</code> | bool | Specifies whether to display the text in pretty format when <b>format</b> is set to <b>plaintext</b> . The options are as follows: <ul style="list-style-type: none"><li>• The value <b>true</b> indicates that events are separated by <code>\n</code>.</li><li>• The value <b>false</b> indicates that events are separated by commas (,).</li></ul> |

- `pg_list_gtt_relfrozenxids()`  
Description: Displays the frozen XID of each session.  
If the value of **pid** is **0**, the earliest frozen XID of all sessions is displayed.  
Parameter: none  
Return type: record  
Example:

```
openGauss=# select * from pg_list_gtt_relfrozenxids();
 pid | relfrozenxid
-----+-----
139648123270912 | 11151
139648170456832 | 11155
 0 | 11151
(3 rows)
```

## 7.5.29 Fault Injection System Function

- `gs_fault_inject(int64, text, text, text, text, text)`  
Description: This function cannot be called. WARNING information "unsupported fault injection" is reported when this function is called, which does not affect or change the database.  
Parameter: fault injection of the int64 type (**0**: CLOG extended page; **1**: CLOG page reading; **2**: forcible deadlock)
  - If the first input parameter of text is set to **2** and the second input parameter of text is set to **1**, the second input parameter deadlock occurs. Other input parameters are not deadlocked. When the first input parameter is **0** or **1**, the second input parameter indicates the number of the start page from which the CLOG starts to be extended or read.
  - The third input parameter of text indicates the number of extended or read pages when the first input parameter is **0** or **1**.
  - The fourth to sixth input parameters of text are reserved.Return type: int64

## 7.5.30 AI Feature Functions

- `gs_index_advise(text)`  
Description: Recommends an index for a single query statement.  
Parameter: SQL statement string  
Return type: record
- `hypopg_create_index(text)`  
Description: Creates a virtual index.  
Parameter: character string of the statement for creating an index  
Return type: record
- `hypopg_display_index()`  
Description: Displays information about all created virtual indexes.  
Parameter: none  
Return type: record
- `hypopg_drop_index(oid)`

Description: Deletes a specified virtual index.

Parameter: OID of the index

Return type: Boolean

- `hypopg_reset_index()`

Description: Clears all virtual indexes.

Parameter: none

Return type: none

- `hypopg_estimate_size(oid)`

Description: Estimates the space required for creating a specified index.

Parameter: OID of the index

Return type: int8

- `check_engine_status(ip text, port text)`

Description: Tests whether a predictor engine provides services on a specified IP address and port.

Parameter: IP address and port number of the predictor engine.

Return type: text

#### NOTE

This function is unavailable in the current version.

- `encode_plan_node(optname text, orientation text, strategy text, options text, dop int8, quals text, projection text)`

Description: Encodes the plan operator information in the input parameters.

Parameter: plan operator information

Return type: text

#### NOTE

This function is an internal function. You are advised not to use it directly.

- `model_train_opt(template text, model text)`

Description: Trains a given query performance prediction model.

Parameters: template name and model name of the performance prediction model

Return type: startup\_time\_accuracy FLOAT8, total\_time\_accuracy FLOAT8, rows\_accuracy FLOAT8, peak\_memory\_accuracy FLOAT8

#### NOTE

This function is unavailable in the current version.

- `track_model_train_opt(ip text, port text)`

Description: Returns the training log address of the specified IP address and port predictor engine.

Parameter: IP address and port number of the predictor engine

Return type: text

#### NOTE

This function is unavailable in the current version.

- `encode_feature_perf_hist(datname text)`  
Description: Encodes historical plan operators collected in the target database.  
Parameter: database name  
Return type: queryid bigint, plan\_node\_id int, parent\_node\_id int, left\_child\_id int, right\_child\_id int, encode text, startup\_time bigint, total\_time bigint, rows bigint, and peak\_memory int
- `gather_encoding_info(datname text)`  
Description: Calls `encode_feature_perf_hist` to save the encoded data persistently.  
Parameter: database name  
Return type: int

## 7.5.31 Dynamic Data Masking Functions

### NOTE

This function is an internal function.

- `creditcardmasking(col text, letter char default 'x')`  
Description: Replaces the digits before the last four bits following the col string with letters.  
Parameter: Character string to be replaced or character string used for replacement  
Return type: text
- `basicmailmasking(col text, letter char default 'x')`  
Description: Replaces the characters before the first at sign (@) in the col string with letters.  
Parameter: Character string to be replaced or character string used for replacement  
Return type: text
- `fullmailmasking(col text, letter char default 'x')`  
Description: Replaces the characters (except @) before the last period (.) in the col string with letters.  
Parameter: Character string to be replaced or character string used for replacement  
Return type: text
- `alldigitsmasking(col text, letter char default '0')`  
Description: Replaces the digits in the col string with letters.  
Parameter: Character string to be replaced or character string used for replacement  
Return type: text
- `shufflemasking(col text)`  
Description: Sorts the characters in the col string out of order.  
Parameter: Character string to be replaced or character string used for replacement  
Return type: text

- **randommasking(col text)**  
Description: Randomizes the characters in the col string.  
Parameter: Character string to be replaced or character string used for replacement  
Return type: text
- **regexpmasking**  
Description: Specifies the internal function of the masking policy, which is used to replace characters using a regular expression.  
Parameter: col text, reg text, replace\_text text, pos INTEGER default 0, reg\_len INTEGER default -1  
Return type: text

## 7.5.32 Hierarchical Recursion Query Functions

The following functions can be used in a hierarchical recursion query statement to return information about the connection path.

- **sys\_connect\_by\_path(col, separator)**  
Description: Returns the connection path from the root node to the current row. This function applies only to hierarchical recursion queries.  
The **col** parameter indicates the name of the column displayed in the path. Only columns of the CHAR, VARCHAR, NVARCHAR2, and TEXT types are supported. The **separator** parameter indicates the separator between path nodes.  
Return type: text

Example:

```
openGauss=# select *, sys_connect_by_path(name, '-') from connect_table start with id = 1 connect by
prior id = pid;
 id | pid | name | sys_connect_by_path
-----+-----+-----+-----
 1 | 0 | a | -a
 2 | 1 | b | -a-b
 4 | 1 | d | -a-d
 3 | 2 | c | -a-b-c
(4 rows)
```

- **connect\_by\_root(col)**  
Description: Returns the value of a column in the top-most parent row of the current row. This function applies only to hierarchical recursion queries.  
The **col** parameter indicates the name of an output column.  
Return type: data type of the specified column **col**.

Example:

```
openGauss=# select *, connect_by_root(name) from connect_table start with id = 1 connect by prior
id = pid;
 id | pid | name | connect_by_root
-----+-----+-----+-----
 1 | 0 | a | a
 2 | 1 | b | a
 4 | 1 | d | a
 3 | 2 | c | a
(4 rows)
```

## 7.5.33 Internal Functions

The following functions of GaussDB use internal data types, which cannot be directly called by users.

- Selectivity calculation functions

|                          |                         |                          |                        |                       |                          |                  |
|--------------------------|-------------------------|--------------------------|------------------------|-----------------------|--------------------------|------------------|
| areajoin<br>el           | areasel                 | arraycon<br>tjoin<br>sel | arraycon<br>tsel       | contjoin<br>el        | contsel                  | eqjoin<br>sel    |

- Auxiliary function for the primary DN to remotely read the data page from the standby DN.

**gs\_read\_block\_from\_remote** is used to read the pages of a non-segment-page table file. By default, only the initial user can view the data. Other users can use the data only after being granted with permissions.

**gs\_read\_segment\_block\_from\_remote** is used to read the pages of a segment-page table file. By default, only the initial user can view the data. Other users can use the data only after being granted with permissions.

- Auxiliary function for the primary DN to remotely read the data file from the standby DN.

The **gs\_read\_file\_from\_remote** command is used to read a specified file. After obtaining the file size using the **gs\_read\_file\_size\_from\_remote** function, **gs\_repair\_file** reads the remote file segment by segment using this function. By default, only the initial user can view the data. Other users can use the data only after being granted with permissions.

The **gs\_read\_file\_size\_from\_remote** command is used to read the size of a specified file. This command is used to read the size of a specified file. Before using the **gs\_repair\_file** function to repair a file, you need to obtain the size of the file from the remote end to verify the missing file information and repair the missing files one by one. By default, only the initial user can view the data. Other users can use the data only after being granted with permissions.

## 7.5.34 Global SysCache Feature Functions

- gs\_gsc\_table\_detail(database\_id default NULL, rel\_id default NULL)

Description: Queries global system cache table metadata in a database. The user who calls this function must have the SYSADMIN permission.

Parameter: Specifies the database and table whose global system cache is to be queried. The default value of **database\_id** is **NULL** or **-1**, indicating all databases. The value **0** indicates a shared table. Other values indicate the specified database and shared table. **rel\_id** indicates the OID of the specified table. The default value **NULL** or **-1** indicates all tables. Other values indicate the specified table. If the table does not exist, an error is reported. If the OID does not exist, a null result is returned.

Return type: Tuple

Example:

```
select * from gs_gsc_table_detail(-1) limit 1;
```

| database_oid | database_name | reloid | relname                 | relnamespace | reltype | reloftype | relowner | relam | relfilenode | reltablespace | relhasindex | relisshared | relkind | relnatts | relhasoids | relhaspkey | parttype | tdhasuids | attnames | extinfo |

|              | 1664          | f      | t                       | i            | 1       | f         | f        | n     | f           | 'rolname'     |             |             |         |          |            |            |          |           |          |         |

(1 row)

- gs\_gsc\_catalog\_detail(database\_id default NULL, rel\_id default NULL)

Description: Queries the system table row information cached in the global system in a database. The user who calls this function must have the SYSADMIN permission.

Parameter: Specifies the database and table whose global system cache is to be queried. The default value of **database\_id** is **NULL** or **-1**, indicating all databases. The value **0** indicates a shared table. Other values indicate the specified database and shared table. **rel\_id** indicates the ID of the specified table, including all system catalogs that have system caches. The default value **NULL** or **-1** indicates all tables. Other values indicate the specified table. If the database does not exist, an error is reported. If the table does not exist, a null result is returned.

Return type: Tuple

Example:

```
openGauss=#
select * from gs_gsc_catalog_detail(16574, 1260);
```

- gs\_gsc\_clean(database\_id default NULL)

Description: Clears the global syscache cache. Note that data in use will not be cleared. The user who calls this function must have the SYSADMIN permission.

Parameter: Specifies the database whose global system cache needs to be cleared. The default value **NULL** or **-1** indicates that the global system cache of all databases is cleared. The value **0** indicates that the global system cache of only the shared table is cleared. Other values indicate that the global system cache of the specified database and shared table is cleared. If **database\_id** does not exist, an error is reported.

Return type: Boolean

Example:

```
openGauss=# select * from gs_gsc_clean();
gs_gsc_clean

t
(1 row)
```

- gs\_gsc\_dbstat\_info(database\_id default NULL)

Description: Obtains GSC memory statistics on the local node, including cache query, hit, loading, expiration, and occupied space information of tuples, relationships, and partitions, database-level elimination information, thread reference information, and memory usage information. This parameter can be used to locate performance problems. For example, if the value of the hits/searches array is far less than 1, the value of **global\_syscache\_threshold** may be too small. As a result, the query hit ratio decreases. The user who calls this function must have the SYSADMIN permission.

Parameter: Specifies the global system cache statistics of the database to be queried. **NULL** or **-1** indicates that all databases are queried. **0** indicates that only the information about the shared table is queried. Other values indicate that the information about the specified database and shared table is queried. If an invalid value is entered, an error is reported, indicating that **database\_id** does not exist.

Return type: Tuple

Example:

```
openGauss=# select * from gs_gsc_dbstat_info();
database_id | database_name | tup_searches | tup_hits | tup_miss | tup_count | tup_dead | tup_memory |
rel_searches | rel_hits | rel_miss | rel_count | rel_dead | rel_memory | part_searches | part_hits | part_miss | part_count | part_dead |
part_memory | total_memory | swa_pout_count | refcount
-----+-----+-----+-----+-----+-----+-----+-----+
| 0 | 300 | 235 | 31 | 22 | 2 | 9752 | 598 | 108 |
| 1 | 18 | 0 | 77720 | 0 | 0 | 0 | 0 | 0 | 0 | 752912 |
```

```
 0 | 0
 16574 | testdb | 3368 | 2289 | 329 | 273 | 0 | 92593 | 1113 |
524 | 4

 0 | 10
(2 rows)
```

## 7.5.35 Data Damage Detection and Repair Functions

- `gs_verify_data_file(verify_segment bool)`

Description: Checks whether files in the current database of the current instance are lost. The verification only checks whether intermediate segments are lost in the main file of the data table. The default value is **false**, indicating that the segment-page table data file is not verified. If this parameter is set to **true**, only segment-page table files are checked. By default, only the initial user, users with the SYSADMIN permission, and users with the OPRADMIN permission in the O&M mode can view the information. Other users can view the information only after being granted permissions.

The returned result is as follows:

- Non-segment-page table: **rel\_oid** and **rel\_name** indicate the table OID and table name of the corresponding file, and **miss\_file\_path** indicates the relative path of the lost file.
- Segment-page table: All tables are stored in the same file. Therefore, **rel\_oid** and **rel\_name** cannot display information about a specific table. For a segment-page table, if the first file is damaged, the subsequent files such as .1 and .2 are not checked. For example, if 3, 3.1, and 3.2 are damaged, only 3 damage can be detected. When the number of segment-page files is less than 5, the files that are not generated are also detected during function detection. For example, if there are only files 1 and 2, files 3, 4, and 5 are detected during segment-page file detection. In the following examples, the first is an example of checking a non-segment-page table, and the second is an example of checking a segment-page table.

Parameter description:

- `verify_segment`

Specifies the range of files to be checked. **false** indicates that non-segment-page tables are verified. **true** indicates that segment-page tables are verified.

The value can be **true** or **false** (default value).

Return type: record.

Example (The abnormal line is displayed only when an exception is detected. Otherwise, no line is displayed.):

Check a non-segment-page table.

```
openGauss=# select * from gs_verify_data_file();
node_name | rel_oid | rel_name | miss_file_path
-----+-----+-----+-----
dn_6001_6002_6003 | 16554 | test | base/16552/24745
```

Verify a segment-page table.

```
openGauss=# select * from gs_verify_data_file(true);
node_name | rel_oid | rel_name | miss_file_path
-----+-----+-----+-----
dn_6001_6002_6003 | 0 | none | base/16573/2
```

- **gs\_repair\_file**(tableoid Oid, path text, timeout int)  
Description: Repairs the file based on the input parameters. Only the primary DN with normal primary/standby connection is supported. The parameter is set based on the OID and path returned by the **gs\_verify\_data\_file** function. The value of table OID for a segment-page table ranges from 0 to 4294967295. (The internal verification determines whether a file is a segment-page table file based on the file path. The table OID is not used for a segment-page table file.) If the repair is successful, **true** is returned. If the repair fails, the failure cause is displayed. By default, only the initial user, users with the SYSADMIN permission, and users with the OPRADMIN permission in the O&M mode on the primary DN can view the information. Other users can view the information only after being granted permissions.

---

**⚠ CAUTION**

1. If a file on a DN is damaged, a verification error at the PANIC level is reported when the DN is promoted to primary. The DN cannot be promoted to primary, which is normal.
2. If a file exists but its size is 0, the file will not be repaired. To repair the file, you need to delete the file whose size is 0 and then repair it.
3. You can delete a file only after the file descriptor is automatically closed. You can manually restart the process or perform a primary/standby switchover.

---

Parameter description:

- **tableoid**  
OID of the table corresponding to the file to be repaired. Set this parameter based on the **rel\_oid** column in the list returned by the **gs\_verify\_data\_file** function.  
Value range: OID ranging from 0 to 4294967295. Note: A negative value will be forcibly converted to a non-negative integer.
- **path**  
Path of the file to be repaired. Set this parameter based on the **miss\_file\_path** column in the list returned by the **gs\_verify\_data\_file** function.  
Value range: a string
- **timeout**  
Specifies the duration for waiting for the standby DN to replay. The repair file needs to wait for the standby DN to be put back to the corresponding location on the current primary DN. Set this parameter based on the replay duration of the standby DN.  
Value range: 60s to 3600s.

Return type: Boolean.

Example (Set **tableoid** and **path** based on the output of **gs\_verify\_data\_file**):

```
openGauss=# select * from gs_repair_file(16554,'base/16552/24745',360);
gs_repair_file

t
```

- `local_bad_block_info()`

Description: Displays the page damage of the instance. You can read the page from the disk and record the page CRC failure. By default, only the initial user, users with the SYSADMIN attribute, users with the MONADMIN attribute, users with the OPRADMIN attribute in the O&M mode, and monitoring users can view the information. Other users can view the information only after being granted permissions.

In the displayed information, **file\_path** indicates the relative path of the damaged file. If the table is a segment-page table, the logical information instead of the actual physical file information is displayed. **block\_num** indicates the number of the page where the file is damaged. The page number starts from 0. **check\_time** indicates the time when the page damage is detected. **repair\_time** indicates the time when the page is repaired.

Return type: record.

Example (Related entries are displayed only when there are damaged records. Otherwise, no log is displayed.):

```
openGauss=# select * from local_bad_block_info();
node_name | spc_node | db_node | rel_node | bucket_node | fork_num | block_num | file_path |
check_time | repair_time
-----+-----+-----+-----+-----+-----+-----+-----+
dn_6001_6002_6003 | 1663 | 16552 | 24745 | -1 | 0 | 0 | base/16552/24745 |
2022-01-13 20:19:08.385004+08 | 2022-01-13 20:19:08.407314+08
```

- `local_clear_bad_block_info()`

Description: Deletes data of repaired pages from **local\_bad\_block\_info**, that is, information whose **repair\_time** is not empty. By default, only the initial user, users with the SYSADMIN attribute, users with the OPRADMIN attribute in the O&M mode, and monitoring users can view the information. Other users can view the information only after being granted permissions.

Return type: Boolean.

Example:

```
openGauss=# select * from local_clear_bad_block_info();
result

t
```

- `gs_verify_and_tryrepair_page` (path text, blocknum oid, verify\_mem bool, is\_segment bool)

Description: Verifies the page specified by the instance. By default, only the initial user, users with the SYSADMIN attribute, and users with the OPRADMIN attribute in O&M mode on the primary DN can view the table. Other users can view the table only after being granted permissions.

In the command output, **disk\_page\_res** indicates the verification result of the page on the disk, **mem\_page\_res** indicates the verification result of the page in the memory, and **is\_repair** indicates whether the repair function is triggered during the verification. **t** indicates that the page is repaired, and **f** indicates that the page is not repaired.

Note:

1. If a page on a DN is damaged, a verification error at the PANIC level is reported when the DN is promoted to primary. The DN cannot be promoted to primary, which is normal. Damaged pages of hash bucket tables cannot be repaired.

2. The repair triggered by this function can only repair pages in the memory. The repair takes effect only after the memory pages are flushed to disks.

Parameters:

- path  
Path of the damaged file. Set this parameter based on the **file\_path** column in the **local\_bad\_block\_info** file. To verify the undo pages of the Ustore table, enter the path of the undo pages to be verified.  
Value range: a string
- blocknum  
Page number of the damaged file. Set this parameter based on the **block\_num** column in the **local\_bad\_block\_info** file. If you want to verify the undo pages of the Ustore table, enter the block number of the undo pages to be verified.  
Value range: OID ranging from 0 to 4294967295. Note: A negative value will be forcibly converted to a non-negative integer.
- verify\_mem  
Specifies whether to verify a specified page in the memory. If this parameter is set to **false**, only pages on the disk are verified. If this parameter is set to **true**, pages in the memory and on the disk are verified. If a page on the disk is damaged, the system verifies the basic information of the page in the memory and flushes the page to the disk to restore the page. If a page is not found in the memory during memory page verification, the page on the disk is read through the memory API. During this process, if the disk page is faulty, the remote read automatic repair function is triggered.  
Value range: The value is of a Boolean type and can be **true** or **false**.
- is\_segment  
Determines whether the table is a segment-page table. Set this parameter based on the value of **bucket\_node** in the **local\_bad\_block\_info** file. If the value of **bucket\_node** is **-1**, the table is not a segment-page table. In this case, set **is\_segment** to **false**. If the value of **bucket\_node** is not **-1**, set **is\_segment** to **true**.  
Value range: The value is of a Boolean type and can be **true** or **false**.

Return type: record.

Examples (Set parameters based on the output of **local\_bad\_block\_info**. Otherwise, an error is reported.):

```
openGauss=# select * from gs_verify_and_tryrepair_page('base/16552/24745',0,false,false);
node_name | path | blocknum | disk_page_res | mem_page_res | is_repair
-----+-----+-----+-----+-----+-----
dn_6001_6002_6003 | base/16552/24745 | 0 | page verification succeeded. | | f
```

- **gs\_repair\_page**(path text, blocknum oid, is\_segment bool, timeout int)  
Description: Restores the specified page of the instance. This function can be used only by the primary DN that is properly connected to the primary and standby DNs. If the page is successfully restored, **true** is returned. If an error occurs during the restoration, an error message is displayed. By default, only the initial user, users with the SYSADMIN attribute, and users with the OPRADMIN attribute in O&M mode on the primary DN can view the table. Other users can view the table only after being granted permissions.

Note: If a page on a DN is damaged, a verification error at the PANIC level is reported when the DN is promoted to primary. The DN cannot be promoted to primary, which is normal. Damaged pages of hash bucket tables cannot be repaired.

Parameter description:

- path  
Path of the damaged page. Set this parameter based on the **file\_path** column in **local\_bad\_block\_info** or the **path** column in the **gs\_verify\_and\_tryrepair\_page** function.  
Value range: a string
- blocknum  
Number of the damaged page. Set this parameter based on the **block\_num** column in **local\_bad\_block\_info** or the **blocknum** column in the **gs\_verify\_and\_tryrepair\_page** function.  
Value range: OID ranging from 0 to 4294967295. Note: A negative value will be forcibly converted to a non-negative integer.
- is\_segment  
Determines whether the table is a segment-page table. The value of this parameter is determined by the value of **bucket\_node** in **local\_bad\_block\_info**. If the value of **bucket\_node** is **-1**, the table is not a segment-page table and **is\_segment** is set to **false**. If the value of **bucket\_node** is not **-1**, **is\_segment** is set to **true**.  
Value range: The value is of a Boolean type and can be **true** or **false**.
- timeout  
Duration of waiting for standby DN replay. The page to be repaired needs to wait for the standby DN to be replayed to the location of the current primary DN. Set this parameter based on the replay duration of the standby DN.  
Value range: 60s to 3600s.

Return type: Boolean.

Examples (Set parameters based on the output of **local\_bad\_block\_info**. Otherwise, an error is reported.):

```
openGauss=# select * from gs_repair_page('base/16552/24745',0,false,60);
result

t
```

- **gs\_verify\_urq**(index\_oid oid, queue\_type text, blocknum bigint, verify\_type text)

Description: Verifies the correctness of the index recycling queue or the performance of obtaining index pages from the recycling queue.

Parameter description: See [Table 7-85](#).

Return type: record.

**Table 7-85** gs\_verify\_urq parameters

| Category         | Parameter   | Type   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|------------------|-------------|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Input parameter  | index_oid   | oid    | UB-tree index OID.                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Input parameter  | queue_type  | text   | Specifies the queue type: <ul style="list-style-type: none"><li>• <b>empty queue</b>: potential queue</li><li>• <b>free queue</b>: available queue</li><li>• <b>single page</b>: single page of the queue</li></ul>                                                                                                                                                                                                                                    |
| Input parameter  | blocknum    | bigint | Specifies the page number: <ul style="list-style-type: none"><li>• If the queue type is single page, all tuples of <b>blocknum</b> on a single page are verified. The value range is [0,Queue file size/8192).</li><li>• If the queue type is empty queue or free queue and <b>blocknum</b> is not set to <b>0</b>, all tuples on all pages of this queue are verified. If <b>blocknum</b> is set to <b>0</b>, page tuples are not verified.</li></ul> |
| Input parameter  | verify_type | text   | Specifies the verification type: <ul style="list-style-type: none"><li>• <b>physics</b>: verifies the physical structure of a queue.</li><li>• <b>performance</b>: verifies the performance of obtaining pages from the recycling queue.</li></ul>                                                                                                                                                                                                     |
| Output parameter | verify_code | text   | Error code                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Output parameter | detail      | text   | Error description                                                                                                                                                                                                                                                                                                                                                                                                                                      |

**Example:**

```
openGauss=# select * from gs_verify_urq(16387,'free queue',1,'physics');
verify_code | detail
-----+-----
```

 **NOTE**

Currently, this API only supports Ustore index tables and does not support partition local indexes.

- gs\_repair\_urq(index\_oid oid)

Description: Rebuilds an index to recycle queues (potential and available queues). If the rebuild is successful, **reinitial the recycle queue of index relation successfully** is displayed.

Parameter description: index\_oid (UB-tree index OID)

Return type: text

Note: The current function can be called only on the primary node.

Example:

```
openGauss=# select * from gs_repair_urq(16387);
 result

reinitial the recycle queue of index relation successfully.
```

#### NOTE

Currently, this API only supports Ustore index tables and does not support partition local indexes.

## 7.5.36 Other System Functions

Other system functions are classified into PG-compatible functions and internal functions. These functions are not recommended. If you need to use them, contact Huawei technical support.

### PG-compatible Functions and Operators

The following table lists the built-in functions and operators of GaussDB that are compatible with PG.

|                             |                       |                        |                 |                    |                   |                       |
|-----------------------------|-----------------------|------------------------|-----------------|--------------------|-------------------|-----------------------|
| _pg_char_max_length         | _pg_char_octet_length | _pg_datetime_precision | _pg_expandarray | _pg_index_position | _pg_interval_type | _pg_numeric_precision |
| _pg_numeric_precision_radix | _pg_numeric_scale     | _pg_truetypid          | _pg_truetypmod  | abbrev             | abs               | abstime               |

## Internal Functions

The following lists the functions used by GaussDB to implement internal system functions. You are advised not to use these functions. If you need to use them, contact Huawei technical support.

- locktag\_decode(locktag text)  
Description: Parses lock details from **locktag**.  
Return type: text
- smgreq(a smgr, b smgr)  
Description: Compares two smgrs to check whether they are the same.  
Parameter: smgr, smgr  
Return type: Boolean
- smgrne(a smgr, b smgr)  
Description: Checks whether the two smgrs are different.  
Parameter: smgr, smgr  
Return type: Boolean

- `xidin4`  
Description: Inputs a 4-byte xid.  
Parameter: `cstring`  
Return type: `xid32`
- `set_hashbucket_info`  
Description: Sets hash bucket information.  
Parameter: `text`  
Return type: `Boolean`
- `int1send`  
Description: Packs unsigned 1-byte integers into the internal data buffer stream.  
Parameter: `tinyint`  
Return type: `bytea`
- `listagg`  
Description: Specifies aggregate functions of the list type.  
Parameter: `smallint`, `text`  
Return type: `text`
- `log_fdw_validator`  
Description: Specifies validation functions.  
Parameter: `text[]`, `oid`  
Return type: `void`
- `nvarchar2typmodin`  
Description: Obtains the typmod information of the varchar type.  
Parameter: `cstring[]`  
Return type: `integer`
- `nvarchar2typmodout`  
Description: Obtains the typmod information of the varchar type, constructs a character string, and returns the character string.  
Parameter: `integer`  
Return type: `cstring`
- `read_disable_conn_file`  
Description: Reads forbidden connection files.  
Parameter: `nan`  
Return type: `disconn_mode text`, `disconn_host text`, `disconn_port text`, `local_host text`, `local_port text`, `redo_finished text`
- `update_pgjob`  
Description: Updates a job.  
Parameter: `bigint`, `"char"`, `bigint`, `timestamp without time zone`, `timestamp without time zone`, `timestamp without time zone`, `timestamp without time zone`, `timestamp without time zone`, `smallint`, `text`

Return type: void

- `enum_cmp`

Description: Specifies the enumeration comparison function, which is used to determine whether two enumeration classes are equal and determine their relative sizes.

Parameter: anyenum, anyenum

Return type: integer

- `enum_eq`

Description: Specifies the enumeration comparison function, which is used to implement the equal sign (=).

Parameter: anyenum, anyenum

Return type: Boolean

- `enum_first`

Description: Returns the first element in the enumeration class.

Parameter: anyenum

Return type: anyenum

- `enum_ge`

Description: Specifies the enumeration comparison function, which is used to implement the greater-than sign (>) and equal sign (=).

Parameter: anyenum, anyenum

Return type: Boolean

- `enum_gt`

Description: Specifies the enumeration comparison function, which is used to implement the greater-than sign (>).

Parameter: anyenum, anyenum

Return type: Boolean

- `enum_in`

Description: Specifies the enumeration comparison function, which is used to determine whether an element is in an enumeration class.

Parameter:cstring, oid

Return type: anyenum

- `enum_larger`

Description: Specifies the enumeration comparison function, which is used to implement the greater-than sign (>).

Parameter: anyenum, anyenum

Return type: anyenum

- `enum_last`

Description: Returns the last element in the enumeration class.

Parameter: anyenum

Return type: anyenum

- `enum_le`  
Description: Specifies the enumeration comparison function, which is used to implement the less-than sign (<) and equal sign (=).  
Parameter: anyenum, anyenum  
Return type: Boolean
- `enum_lt`  
Description: Specifies the enumeration comparison function, which is used to implement the less-than sign (<).  
Parameter: anyenum, anyenum  
Return type: Boolean
- `enum_smaller`  
Description: Specifies the enumeration comparison function, which is used to implement the less-than sign (<).  
Parameter: anyenum, anyenum  
Return type: Boolean
- `node_oid_name`  
Description: Not supported.  
Parameter: oid  
Return type: cstring
- `pg_buffercache_pages`  
Description: Reads data from the shared buffer.  
Parameter: nan  
Return type: bufferid integer, relfilenode oid, bucketid smallint, reltablespace oid, reldatabase oid, relforknumber smallint, relblocknumber bigint, isdirty Boolean, usage\_count smallint
- `pg_check_xidlimit`  
Description: Checks whether nextxid is greater than or equal to xidwarnlimit.  
Parameter: nan  
Return type: Boolean
- `pg_comm_delay`  
Description: Displays the delay status of the communications library of a single DN.  
Parameter: nan  
Return type: text, text, integer, integer, integer, integer
- `pg_comm_rcv_stream`  
Description: Displays the receiving stream status of all communication libraries on a single DN.  
Parameter: nan  
Return type: text, bigint, text, bigint, integer, integer, integer, text, bigint, integer, integer, integer, bigint, bigint, bigint, bigint, bigint

- `pg_comm_send_stream`  
Description: Displays the sending stream status of all communication libraries on a single DN.  
Parameter: nan  
Return type: text, bigint, text, bigint, integer, integer, integer, text, bigint, integer, integer, integer, bigint, bigint, bigint, bigint
- `pg_comm_status`  
Description: Displays the communication status of a single DN.  
Parameter: nan  
Return type: text, integer, integer, bigint, bigint, bigint, bigint, bigint, integer, integer, integer, integer
- `pg_log_comm_status`  
Description: Prints some logs on the DN.  
Parameter: nan  
Return type: Boolean
- `pg_parse_clog`  
Description: Parses clog to obtain the status of xid.  
Parameter: nan  
Return type: xid xid, status text
- `pg_pool_ping`  
Description: Sets PoolerPing.  
Parameter: Boolean  
Return type: SETOF Boolean
- `pg_resume_bkp_flag`  
Description: Obtains the delay Xlog flag for backup and restoration.  
Parameter: slot\_name name  
Return type: start\_backup\_flag Boolean, to\_delay Boolean, ddl\_delay\_recycle\_ptr text, rewind\_time text
- `psortoptions`  
Description: Returns the psort attribute.  
Parameter: text[], Boolean  
Return type: bytea
- `xideq4`  
Description: Compares two values of the xid type to check whether they are the same.  
Parameter: xid32, xid32  
Return type: Boolean
- `xideqint8`  
Description: Compares values of the xid type and int8 type to check whether they are the same.  
Parameter: xid, bigint

- Return type: Boolean
- xidlt**  
 Description: Returns whether xid1 < xid2 is true.  
 Parameter: xid, xid  
 Return type: Boolean
  - xidlt4**  
 Description: Returns whether xid1 < xid2 is true.  
 Parameter: xid32, xid32  
 Return type: Boolean

## 7.5.37 Obsolete Functions

The following functions in GaussDB have been deprecated in the latest version:

|                               |                                    |                                       |                                        |                                          |                                         |                                    |

## 7.6 Expressions

### 7.6.1 Simple Expressions

#### Logical Expressions

[Logical Operators](#) lists the operators and calculation rules of logical expressions.

#### Comparative Expressions

[Comparison Operators](#) lists the common comparative operators.

In addition to comparative operators, you can also use the following sentence structure:

- BETWEEN operator  
**a BETWEEN x AND y** is equivalent to **a >= x AND a <= y**.  
**a NOT BETWEEN x AND y** is equivalent to **a < x OR a > y**.
- To check whether a value is null, use:  
expression IS NULL  
expression IS NOT NULL  
or an equivalent (non-standard) sentence structure:  
expression ISNULL  
expression NOTNULL

---

#### NOTICE

Do not write **expression=NULL** or **expression<>(!=)NULL**, because **NULL** represents an unknown value, and these expressions cannot determine whether two unknown values are equal.

---

- is distinct from/is not distinct from
  - is distinct from  
If the data types and values of A and B are different, the value is **true**.  
If the data types and values of A and B are the same, the value is **false**.  
Empty values are considered the same.
  - is not distinct from

If the data types and values of A and B are different, the value is **false**.  
If the data types and values of A and B are the same, the value is **true**.  
Empty values are considered the same.

## Pseudocolumn

### ROWNUM

**ROWNUM** is a pseudocolumn that returns a number indicating the row number of the result obtained from the query. The value of **ROWNUM** in the first row is **1**, the value of **ROWNUM** in the second row is **2**, and so on. The return type of **ROWNUM** is BIGINT. **ROWNUM** can be used to limit the total number of rows returned by a query. For example, the following statement limits the maximum number of records returned from the table **Students** to 10.

```
openGauss=# CREATE TABLE Students (name varchar(20), id int) with (STORAGE_TYPE = USTORE);
openGauss=# INSERT INTO Students VALUES ('Jack', 35);
openGauss=# INSERT INTO Students VALUES ('Leon', 15);
openGauss=# INSERT INTO Students VALUES ('James', 24);
openGauss=# INSERT INTO Students VALUES ('Taker', 81);
openGauss=# INSERT INTO Students VALUES ('Mary', 25);
openGauss=# INSERT INTO Students VALUES ('Rose', 64);
openGauss=# INSERT INTO Students VALUES ('Perl', 18);
openGauss=# INSERT INTO Students VALUES ('Under', 57);
openGauss=# INSERT INTO Students VALUES ('Angel', 101);
openGauss=# INSERT INTO Students VALUES ('Frank', 20);
openGauss=# INSERT INTO Students VALUES ('Charlie', 40);

-- Output the first 10 rows of data records in the Students table.
openGauss=# SELECT * FROM Students WHERE rownum <= 10;
 name | id
-----+-----
 Jack | 35
 Leon | 15
 James | 24
 Taker | 81
 Mary | 25
 Rose | 64
 Perl | 18
 Under | 57
 Angel | 101
 Frank | 20
(10 rows)

openGauss=# DROP TABLE Students;
DROP TABLE
```

## Examples

```
openGauss=# SELECT 2 BETWEEN 1 AND 3 AS RESULT;
 result

 t
(1 row)

openGauss=# SELECT 2 >= 1 AND 2 <= 3 AS RESULT;
 result

 t
(1 row)

openGauss=# SELECT 2 NOT BETWEEN 1 AND 3 AS RESULT;
 result

 f
```

```
(1 row)

openGauss=# SELECT 2 < 1 OR 2 > 3 AS RESULT;
result

f
(1 row)

openGauss=# SELECT 2+2 IS NULL AS RESULT;
result

f
(1 row)

openGauss=# SELECT 2+2 IS NOT NULL AS RESULT;
result

t
(1 row)

openGauss=# SELECT 2+2 ISNULL AS RESULT;
result

f
(1 row)

openGauss=# SELECT 2+2 NOTNULL AS RESULT;
result

t
(1 row)

openGauss=# SELECT 2+2 IS DISTINCT FROM NULL AS RESULT;
result

t
(1 row)

openGauss=# SELECT 2+2 IS NOT DISTINCT FROM NULL AS RESULT;
result

f
(1 row)
```

## 7.6.2 Condition Expressions

Data that meets the requirements specified by conditional expressions are filtered during SQL statement execution.

Conditional expressions include the following types:

- CASE

**CASE** expressions are similar to the **CASE** statements in other coding languages.

**Figure 7-1** shows the syntax of a **CASE** expression.

**Figure 7-1** case::=

A **CASE** clause can be used in a valid expression. **condition** is an expression that returns a value of Boolean type.

- If the result is true, the result of the **CASE** expression is the required result.
- If the result is false, the following **WHEN** or **ELSE** clauses are processed in the same way.
- If every **WHEN condition** is false, the result of the expression is the result of the **ELSE** clause. If the **ELSE** clause is omitted and has no match condition, the result is NULL.

Example:

```
openGauss=# CREATE TABLE case_when_t1(CW_COL1 INT);

openGauss=# INSERT INTO case_when_t1 VALUES (1), (2), (3);

openGauss=# SELECT * FROM case_when_t1;
cw_col1

1
2
3
(3 rows)

openGauss=# SELECT CW_COL1, CASE WHEN CW_COL1=1 THEN 'one' WHEN CW_COL1=2 THEN
'two' ELSE 'other' END FROM case_when_t1 ORDER BY 1;
cw_col1 | case
-----+-----
1 | one
2 | two
3 | other
(3 rows)

openGauss=# DROP TABLE case_when_t1;
```

- **DECODE**

**Figure 7-2** shows the syntax of a **DECODE** expression.

**Figure 7-2** decode::=

Compare each following **compare(n)** with **base\_expr**. **value(n)** is returned if a **compare(n)** matches the **base\_expr** expression. If no match occurs, default is returned.

**Conditional Expression Functions** describes the examples.

```
openGauss=# SELECT DECODE('A','A',1,'B',2,0);
case

1
(1 row)
```

- **COALESCE**

**Figure 7-3** shows the syntax of a **COALESCE** expression.

**Figure 7-3** coalesce::=

**COALESCE** returns its first not-**NULL** value. If all the parameters are **NULL**, **NULL** is returned. This value is replaced by the default value when data is displayed. Like a **CASE** expression, **COALESCE** only evaluates the parameters that are needed to determine the result. That is, parameters to the right of the first non-null parameter are not evaluated.

Example:

```
openGauss=# CREATE TABLE c_tabl(description varchar(10), short_description varchar(10), last_value
varchar(10)) ;
```

```
openGauss=# INSERT INTO c_tabl VALUES('abc', 'efg', '123');
openGauss=# INSERT INTO c_tabl VALUES(NULL, 'efg', '123');
```

```
openGauss=# INSERT INTO c_tabl VALUES(NULL, NULL, '123');
```

```
openGauss=# SELECT description, short_description, last_value, COALESCE(description,
short_description, last_value) FROM c_tabl ORDER BY 1, 2, 3, 4;
```

| description | short_description | last_value | coalesce |
|-------------|-------------------|------------|----------|
| abc         | efg               | 123        | abc      |
|             | efg               | 123        | efg      |
|             |                   | 123        | 123      |

(3 rows)

```
openGauss=# DROP TABLE c_tabl;
```

If **description** is not **NULL**, the value of **description** is returned. Otherwise, parameter **short\_description** is calculated. If **short\_description** is not **NULL**, the value of **short\_description** is returned. Otherwise, parameter **last\_value** is calculated. If **last\_value** is not **NULL**, the value of **last\_value** is returned. Otherwise, **none** is returned.

```
openGauss=# SELECT COALESCE(NULL,'Hello World');
coalesce

Hello World
(1 row)
```

- **NULLIF**

**Figure 7-4** shows the syntax of a **NULLIF** expression.

**Figure 7-4** nullif::=

Only if **value1** is equal to **value2** can **NULLIF** return the **NULL** value. Otherwise, **value1** is returned.

Example:

```
openGauss=# CREATE TABLE null_if_t1 (
NI_VALUE1 VARCHAR(10),
NI_VALUE2 VARCHAR(10))
```

```
);

openGauss=# INSERT INTO null_if_t1 VALUES('abc', 'abc');
openGauss=# INSERT INTO null_if_t1 VALUES('abc', 'efg');

openGauss=# SELECT NI_VALUE1, NI_VALUE2, NULLIF(NI_VALUE1, NI_VALUE2) FROM null_if_t1
ORDER BY 1, 2, 3;

ni_value1 | ni_value2 | nullif
-----+-----+-----
abc | abc |
abc | efg | abc
(2 rows)
openGauss=# DROP TABLE null_if_t1;
```

If the value of **value1** is equal to that of **value2**, **NULL** is returned. Otherwise, the value of **value1** is returned.

```
openGauss=# SELECT NULLIF('Hello','Hello World');
nullif

Hello
(1 row)
```

- GREATEST (maximum value) and LEAST (minimum value)

**Figure 7-5** shows the syntax of a **GREATEST** expression.

**Figure 7-5** greatest::=

You can select the maximum value from any numerical expression list.

```
openGauss=# SELECT greatest(9000,15555,2.01);
greatest

15555
(1 row)
```

**Figure 7-6** shows the syntax of a **LEAST** expression.

**Figure 7-6** least::=

You can select the minimum value from any numerical expression list.

Each of the preceding numeric expressions can be converted into a common data type, which will be the data type of the result.

The NULL values in the list will be ignored. The result is **NULL** only if the results of all expressions are **NULL**.

```
openGauss=# SELECT least(9000,2);
least

2
(1 row)
```

**Conditional Expression Functions** describes the examples.

- NVL

**Figure 7-7** shows the syntax of an **NVL** expression.

**Figure 7-7** nvl::=

If the value of **value1** is **NULL**, the value of **value2** is returned. Otherwise, the value of **value1** is returned.

Example:

```
openGauss=# SELECT nvl(null,1);
nvl

1
(1 row)

openGauss=# SELECT nvl ('Hello World',1);
nvl

Hello World
(1 row)
```

## 7.6.3 Subquery Expressions

Subquery expressions include the following types:

- EXISTS/NOT EXISTS

**Figure 7-8** shows the syntax of an **EXISTS/NOT EXISTS** expression.

**Figure 7-8** EXISTS/NOT EXISTS::=

The parameter of an **EXISTS** expression is an arbitrary **SELECT** statement, or subquery. The subquery is evaluated to determine whether it returns any rows. If it returns at least one row, the result of **EXISTS** is true. If the subquery returns no rows, the result of **EXISTS** is false.

The subquery will generally only be executed long enough to determine whether at least one row is returned, not all the way to completion.

Example:

```
openGauss=# CREATE TABLE exists_t1(a int, b int);
openGauss=# INSERT INTO exists_t1 VALUES(1, 2),(2, 3),(3, 4),(4, 5);

openGauss=# CREATE TABLE exists_t2(a int, c int);
openGauss=# INSERT INTO exists_t2 VALUES(3, 4),(4, 5),(5, 6),(6, 7);

openGauss=# SELECT * FROM exists_t1 t1 WHERE EXISTS (SELECT * FROM exists_t2 t2 WHERE t2.a =
t1.a);
```

```
a | b
---+---
3 | 4
4 | 5
(2 rows)

openGauss=# DROP TABLE exists_t1, exists_t2;
```

- IN/NOT IN

**Figure 7-9** shows the syntax of an **IN/NOT IN** expression.

**Figure 7-9** IN/NOT IN::=

The right-hand side is a parenthesized subquery, which must return exactly one column. The left-hand expression is evaluated and compared to each row of the subquery result. The result of **IN** is true if any equal subquery row is found. The result is false if no equal row is found (including the case where the subquery returns no rows).

This is in accordance with SQL normal rules for Boolean combinations of null values. If the columns corresponding to two rows equal and are not empty, the two rows are equal to each other. If any columns corresponding to the two rows do not equal and are not empty, the two rows are not equal to each other. Otherwise, the result is **NULL**. If there are no equal right-hand values and at least one right-hand row yields null, the result of **IN** will be null, not false.

Example:

```
openGauss=# CREATE TABLE in_t1(a int, b int);
openGauss=# INSERT INTO in_t1 VALUES(1, 2),(2, 3),(3, 4),(4, 5);

openGauss=# CREATE TABLE in_t2(a int, c int);
openGauss=# INSERT INTO in_t2 VALUES(3, 4),(4, 5),(5, 6),(6, 7);

openGauss=# SELECT * FROM in_t1 t1 WHERE t1.a IN (SELECT t2.a FROM in_t2 t2);
a | b
---+---
3 | 4
4 | 5
(2 rows)

openGauss=# DROP TABLE in_t1, in_t2;
```

- ANY/SOME

**Figure 7-10** shows the syntax of an **ANY/SOME** expression.

**Figure 7-10** any/some::=

The right-hand side is a parenthesized subquery, which must return exactly one column. The left-hand expression is evaluated and compared to each row of the subquery result using the given operator, which must yield a Boolean result. The result of **ANY** is "true" if any true result is obtained. The result is "false" if no true result is found (including the case where the subquery returns no rows). **SOME** is a synonym of **ANY**. **IN** can be equivalently replaced with **ANY**.

Example:

```
openGauss=# CREATE TABLE any_t1(a int, b int);
openGauss=# INSERT INTO any_t1 VALUES(1, 2),(2, 3),(3, 4),(4, 5);

openGauss=# CREATE TABLE any_t2(a int, c int);
openGauss=# INSERT INTO any_t2 VALUES(3, 4),(4, 5),(5, 6),(6, 7);

openGauss=# SELECT * FROM any_t1 t1 WHERE t1.a < ANY(SELECT t2.a FROM any_t2 t2 where t2.a =
3 or t2.a = 4);
 a | b
----+----
 1 | 2
 2 | 3
 3 | 4
(3 rows)

openGauss=# DROP TABLE any_t1, any_t2;
```

- **ALL**

**Figure 7-11** shows the syntax of an **ALL** expression.

**Figure 7-11** all::=

The right-hand side is a parenthesized subquery, which must return exactly one column. The left-hand expression is evaluated and compared to each row of the subquery result using the given operator, which must yield a Boolean result. The result of **ALL** is true if all values are true (including the case where the subquery returns no rows). The result is false if any false result is found.

Example:

```
openGauss=# CREATE TABLE all_t1(a int, b int);
openGauss=# INSERT INTO all_t1 VALUES(1, 2),(2, 3),(3, 4),(4, 5);

openGauss=# CREATE TABLE all_t2(a int, c int);
openGauss=# INSERT INTO all_t2 VALUES(3, 4),(4, 5),(5, 6),(6, 7);

openGauss=# SELECT * FROM all_t1 t1 WHERE t1.a < ALL(SELECT t2.a FROM all_t2 t2 where t2.a = 3
or t2.a = 4);
 a | b
----+----
 1 | 2
 2 | 3
(2 rows)

openGauss=# DROP TABLE all_t1, all_t2;
```

## 7.6.4 Array Expressions

### IN

*expression* **IN** (*value* [, ...])

The parentheses on the right contain an expression list. The expression result on the left is compared with the content in the expression list. If the content in the list meets the expression result on the left, the result of **IN** is **true**. If no result meets the requirements, the result of **IN** is **false**.

Example:

```
openGauss=# SELECT 8000+500 IN (10000, 9000) AS RESULT;
result

f
(1 row)
```

#### NOTE

If the expression result is null or the expression list does not meet the expression conditions and at least one empty value is returned for the expression list on the right, the result of **IN** is **null** rather than **false**. This method is consistent with the Boolean rules used when SQL statements return empty values.

### NOT IN

*expression* **NOT IN** (*value* [, ...])

The parentheses on the right contain an expression list. The expression result on the left is compared with the content in the expression list. If the content in the list does not meet the expression result on the left, the result of **NOT IN** is **true**. If any content meets the expression result, the result of **NOT IN** is **false**.

Example:

```
openGauss=# SELECT 8000+500 NOT IN (10000, 9000) AS RESULT;
result

t
(1 row)
```

#### NOTE

- If the query statement result is null or the expression list does not meet the expression conditions and at least one empty value is returned for the expression list on the right, the result of **NOT IN** is null rather than false. This method is consistent with the Boolean rules used when SQL statements return empty values.
- In all situations, X **NOT IN** Y equals to **NOT**(X **IN** Y).

### ANY/SOME (array)

*expression operator* **ANY** (*array expression*)

*expression operator* **SOME** (*array expression*)

The right side is a parenthesized expression, which must yield an array value. The result of the expression on the left uses operators to compute and compare the results in each row of the array expression. The comparison result must be a Boolean value.

```
openGauss=# SELECT 8000+500 < SOME (array[10000,9000]) AS RESULT;
result

t
(1 row)

openGauss=# SELECT 8000+500 < ANY (array[10000,9000]) AS RESULT;
result

t
(1 row)
```

#### NOTE

- If at least one comparison result is true, the result of ANY is true.
- If no comparison result is true, the result of ANY is false.
- If no comparison result is true and the array expression generates at least one null value, the value of **ANY** is **NULL** rather than **false**. This method is consistent with the Boolean rules used when SQL statements return empty values.
- SOME is a synonym of ANY.

## ALL (array)

*expression operator ALL (array expression)*

The right side is a parenthesized expression, which must yield an array value. The result of the expression on the left uses operators to compute and compare the results in each row of the array expression. The comparison result must be a Boolean value.

- The result of **ALL** is **true** if all comparisons yield **true** (including the case where the array has zero elements).
- The result of **ALL** is **false** if one or multiple comparisons yield **false**.
- If the array expression yields a null array, the result of **ALL** will be null. If the left-hand expression yields null, the result of **ALL** is ordinarily null (though a non-strict comparison operator could possibly yield a different result). Also, if the array on the right contains any null elements and no false comparison result is found, the result of **ALL** is **NULL**, not true (again, assuming a strict comparison operator). This method is consistent with the Boolean rules used when SQL statements return empty values.

```
openGauss=# SELECT 8000+500 < ALL (array[10000,9000]) AS RESULT;
result

t
(1 row)
```

## 7.6.5 Row Expressions

The syntax is as follows:

*row\_constructor operator row\_constructor*

Both sides of the row expression are row constructors. The values of both rows must have the same number of fields and they are compared with each other. The row comparison allows operators including =, <>, <, <=, and >= or a similar operator.

For operators <, <=, >, and >=, the columns in rows are compared from left to right until a pair of columns that are not equal or are empty are detected. If the pair of columns contains at least one null value, the comparison result is null. Otherwise, the comparison result of this pair of columns is the final result. If no unequal or empty column is found, the values in the two rows are equal. The final result is determined based on the operator meaning.

Operations on XML data are not supported.

Example:

```
openGauss=# SELECT ROW(1,2,NULL) < ROW(1,3,0) AS RESULT;
result

t
(1 row)

openGauss=# select (4,5,6) > (3,2,1) as result;
result

t
(1 row)

openGauss=# select (4,1,1) > (3,2,1) as result;
result

t
(1 row)

openGauss=# select ('test','data') > ('data','data') as result;
result

t
(1 row)

openGauss=# select (4,1,1) > (3,2,null) as result;
result

t
(1 row)

openGauss=# select (null,1,1) > (3,2,1) as result;
result

(1 row)

openGauss=# select (null,5,6) > (null,5,6) as result;
result

(1 row)

openGauss=# select (4,5,6) > (4,5,6) as result;
result

f
(1 row)

openGauss=# select (2,2,5) >= (2,2,3) as result;
result

t
(1 row)

openGauss=# select (2,2,1) <= (2,2,3) as result;
result

```

```
t
(1 row)
```

The use of operators = and <> is slightly different from other operators. If all columns in the two rows are not empty and meet the operator condition, the two rows meet the operator condition. If any column in the two rows is not empty and does not meet the operator condition, the two rows do not meet the operator condition. If any column in the two rows is empty, the comparison result is null.

Example:

```
openGauss=# select (1,2,3) = (1,2,3) as result;
result

t
(1 row)

openGauss=# select (1,2,3) <> (2,2,3) as result;
result

t
(1 row)

openGauss=# select (2,2,3) <> (2,2,null) as result;
result

(1 row)

openGauss=# select (null,5,6) <> (null,5,6) as result;
result

(1 row)
```

## 7.7 Type Conversion

### 7.7.1 Overview

#### Context

SQL is a typed language. That is, every data item has an associated data type which determines its behavior and allowed usage. GaussDB has an extensible type system that is more general and flexible than other SQL implementations. Hence, most type conversion behaviors in GaussDB are governed by general rules. This allows the use of mixed-type expressions.

The GaussDB scanner/parser divides lexical elements into five fundamental categories: integers, floating-point numbers, strings, identifiers, and keywords. Constants of most non-numeric types are first classified as strings. The SQL language definition allows specifying type names with constant strings. For example, the query:

```
openGauss=# SELECT text 'Origin' AS "label", point '(0,0)' AS "value";
label | value
-----+-----
Origin | (0,0)
(1 row)
```

has two literal constants, of type **text** and **point**. If a type is not specified for a string literal, then the placeholder type **unknown** is assigned initially.

There are four fundamental SQL constructs requiring distinct type conversion rules in GaussDB parser:

- **Function calls**  
Much of the SQL type system is built around a rich set of functions. Functions can have one or more arguments. Since SQL permits function overloading, the function name alone does not uniquely identify the function to be called. The parser must select the right function based on the data types of the supplied arguments.
- **Operators**  
SQL allows expressions with prefix and postfix unary (one-argument) operators, as well as binary (two-argument) operators. Like functions, operators can be overloaded, so the same problem of selecting the right operator exists.
- **Value storage**  
The INSERT and UPDATE statements place the results of expressions into a table. The expressions in the statement must be matched up with, and perhaps converted to, the types of the target columns.
- **UNION, CASE, and Related Constructs**  
Since all query results from a unionized **SELECT** statement must appear in a single set of columns, the types of the results of each **SELECT** clause must be matched up and converted to a uniform set. Similarly, the result expressions of a **CASE** construct must be converted to a common type so that the **CASE** expression as a whole has a known output type. The same holds for **ARRAY** constructs, and for the **GREATEST** and **LEAST** functions.

The system catalog `pg_cast` stores information about which conversions, or casts, exist between which data types, and how to perform those conversions. For details, see [PG\\_CAST](#).

The return type and conversion behavior of an expression are determined during semantic analysis. Data types are divided into several basic type categories, including Boolean, **numeric**, **string**, **bitstring**, **datetime**, **timespan**, **geometric**, and **network**. Within each category there can be one or more preferred types, which are preferred when there is a choice of possible types. With careful selection of preferred types and available implicit casts, it is possible to ensure that ambiguous expressions (those with multiple candidate parsing solutions) can be resolved in a useful way.

All type conversion rules are designed based on the following principles:

- Implicit conversions should never have surprising or unpredictable outcomes.
- There should be no extra overhead in the parser or executor if a query does not need implicit type conversion. That is, if a query is well-formed and the types already match, then the query should execute without spending extra time in the parser and without introducing unnecessary implicit conversion calls in the query.
- Additionally, if a query usually requires an implicit conversion for a function, and if then the user defines a new function with the correct argument types, the parser should use this new function.

## 7.7.2 Operators

### Operator Type Resolution

1. Select the operators to be considered from the **pg\_operator** system catalog. Considered operators are those with the matching name and argument count. If the search path finds multiple available operators, only the most suitable one is considered.
2. Look for the best match.
  - a. Discard candidate operators for which the input types do not match and cannot be converted (using an implicit conversion) to match. **unknown** literals are assumed to be convertible to anything for this purpose. If only one candidate remains, use it; else continue to the next step.
  - b. Run through all candidates and keep those with the most exact matches on input types. In this case, the domain types are considered the same as their basic types. Keep all candidates if none survives these tests. If only one candidate remains, use it; else continue to the next step.
  - c. Run through all candidates and keep those that accept preferred types (of the input data type's type category) at the most positions where type conversion will be required. Keep all candidates if none accepts preferred types. If only one candidate remains, use it; else continue to the next step.
  - d. If any input arguments are **unknown**, check the type categories accepted at those argument positions by the remaining candidates. At each position, select the string category if any candidate accepts that category. (This bias towards string is appropriate since an unknown-type literal looks like a string.) Otherwise, if all the remaining candidates accept the same type category, select that category; otherwise fail because the correct choice cannot be deduced without more clues. Now discard candidates that do not accept the selected type category. Furthermore, if any candidate accepts a preferred type in that category, discard candidates that accept non-preferred types for that argument. Keep all candidates if none survives these tests. If only one candidate remains, use it; else continue to the next step.
  - e. If there are both **unknown** and known-type arguments, and all the known-type arguments have the same type, assume that the **unknown** arguments are also of that type, and check which candidates can accept that type at the unknown-argument positions. If exactly one candidate passes this test, use it. Otherwise, an error occurs.

---

#### CAUTION

After an operator is found, if the type of the input parameter is different from that of the operator, implicit type conversion may occur. After the conversion, unpredictable behavior may occur. If the behavior is incorrect after implicit conversion, you can use explicit type conversion to avoid this problem. For example, after the fixed-length `bpchar` type is converted to the variable-length text type, spaces at the end of the character string are deleted. If the character string is compared with other character strings, errors may occur.

---

## Examples

Example 1: Use factorial operator type resolution. There is only one factorial operator (postfix !) defined in the system catalog, and it takes an argument of type **bigint**. The scanner assigns an initial type of **bigint** to the argument in this query expression:

```
openGauss=# SELECT 40 ! AS "40 factorial";
 40 factorial

8159152832478977343456112695961158942720000000000
(1 row)
```

So the parser does a type conversion on the operand and the query is equivalent to:

```
openGauss=# SELECT CAST(40 AS bigint) ! AS "40 factorial";
```

Example 2: String concatenation operator type resolution. A string-like syntax is used for working with string types and for working with complex extension types. Strings with unspecified type are matched with likely operator candidates. An example with one unspecified argument:

```
openGauss=# SELECT text 'abc' || 'def' AS "text and unknown";
text and unknown

abcdef
(1 row)
```

In this example, the parser looks for an operator whose parameters are of the text type. Such an operator is found.

Here is a concatenation of two values of unspecified types:

```
openGauss=# SELECT 'abc' || 'def' AS "unspecified";
unspecified

abcdef
(1 row)
```

### NOTE

In this case there is no initial hint for which type to use, since no types are specified in the query. So, the parser looks for all candidate operators and finds that there are candidates accepting both string-category and bit-string-category inputs. Since string category is preferred when available, that category is selected, and then the preferred type for strings, **text**, is used as the specific type to resolve the unknown-type literals as.

Example 3: Absolute-value and negation operator type resolution. The GaussDB operator catalog has several entries for the prefix operator @. All the entries implement absolute-value operations for various numeric data types. One of these entries is for type **float8**, which is the preferred type in the numeric category. Therefore, GaussDB will use that entry when faced with an unknown input:

```
openGauss=# SELECT @ '-4.5' AS "abs";
abs

4.5
(1 row)
```

Here the system has implicitly resolved the unknown-type literal as type **float8** before applying the chosen operator.

Example 4: Use the array inclusion operator type resolution as an example. Here is another example of resolving an operator with one known and one unknown input:

```
openGauss=# SELECT array[1,2] <@ '{1,2,3}' as "is subset";
is subset

t
(1 row)
```

#### NOTE

The GaussDB operator catalog has several entries for the infix operator <@, but the only two that could possibly accept an integer array on the left side are array inclusion (anyarray <@ anyarray) and range inclusion (anyelement <@ anyrange). Since none of these polymorphic pseudo-types (see [Pseudo-Types](#)) is considered preferred, the parser cannot resolve the ambiguity on that basis. However, the last resolution rule tells it to assume that the unknown-type literal is of the same type as the other input, that is, integer array. Now only one of the two operators can match, so array inclusion is selected. (Had range inclusion been selected, we would have gotten an error, because the string does not have the right format to be a range literal.)

## 7.7.3 Functions

### Function Type Resolution

1. Select the functions to be considered from the **pg\_proc** system catalog. If a non-schema-qualified function name was used, the functions in the current search path are considered. If a qualified function name was given, only functions in the specified schema are considered.  
If the search path finds multiple functions of different argument types, a proper function in the path is considered.
2. Check for a function accepting exactly the input argument types. If the function exists, use it. Cases involving **unknown** will never find a match at this step.
3. If no exact match is found, see if the function call appears to be a special type conversion request.
4. Look for the best match.
  - a. Discard candidate functions for which the input types do not match and cannot be converted (using an implicit conversion) to match. **unknown** literals are assumed to be convertible to anything for this purpose. If only one candidate remains, use it; else continue to the next step.
  - b. Run through all candidates and keep those with the most exact matches on input types. Domains are considered the same as their base type for this purpose. Keep all candidates if none has exact matches. If only one candidate remains, use it; else continue to the next step.
  - c. Run through all candidates and keep those that accept preferred types at the most positions where type conversion will be required. Keep all candidates if none accepts preferred types. If only one candidate remains, use it; else continue to the next step.
  - d. If any input arguments are **unknown**, check the type categories accepted at those argument positions by the remaining candidates. At each position, select the string category if any candidate accepts that category. (This bias towards string is appropriate since an unknown-type literal

looks like a string.) Otherwise, if all the remaining candidates accept the same type category, select that category; otherwise fail because the correct choice cannot be deduced without more clues. Now discard candidates that do not accept the selected type category. Furthermore, if any candidate accepts a preferred type in that category, discard candidates that accept non-preferred types for that argument. Keep all candidates if none survives these tests. If only one candidate remains, use it; else continue to the next step.

- e. If there are both **unknown** and known-type arguments, and all the known-type arguments have the same type, assume that the **unknown** arguments are also of that type, and check which candidates can accept that type at the **unknown**-argument positions. If exactly one candidate passes this test, use it. Otherwise, an error occurs.

## Examples

Example 1: Use the rounding function argument type resolution as the first example. There is only one **round** function that takes two arguments; it takes a first argument of type **numeric** and a second argument of type **integer**. So the following query automatically converts the first argument of type **integer** to **numeric**:

```
openGauss=# SELECT round(4, 4);
round

4.0000
(1 row)
```

That query is actually transformed by the parser to:

```
openGauss=# SELECT round(CAST (4 AS numeric), 4);
```

Since numeric constants with decimal points are initially assigned the type **numeric**, the following query will require no type conversion and therefore might be slightly more efficient:

```
openGauss=# SELECT round(4.0, 4);
```

Example 2: Use the substring function type resolution as the second example. There are several **substr** functions, one of which takes types **text** and **integer**. If called with a string constant of unspecified type, the system chooses the candidate function that accepts an argument of the preferred category **string** (namely of type **text**).

```
openGauss=# SELECT substr('1234', 3);
substr

34
(1 row)
```

If the string is declared to be of type **varchar**, as might be the case if it comes from a table, then the parser will try to convert it to become **text**:

```
openGauss=# SELECT substr(varchar '1234', 3);
substr

34
(1 row)
```

This is transformed by the parser to effectively become:

```
openGauss=# SELECT substr(CAST (varchar '1234' AS text), 3);
```

#### NOTE

The parser learns from the **pg\_cast** catalog that **text** and **varchar** are binary-compatible, meaning that one can be passed to a function that accepts the other without doing any physical conversion. Therefore, no type conversion is really inserted in this case.

And, if the function is called with an argument of type **integer**, the parser will try to convert that to **text**:

```
openGauss=# SELECT substr(1234, 3);
substr

34
(1 row)
```

This is transformed by the parser to effectively become:

```
openGauss=# SELECT substr(CAST (1234 AS text), 3);
substr

34
(1 row)
```

## 7.7.4 Value Storage

### Value Storage Type Resolution

1. Search for an exact match with the target column.
2. Try to convert the expression to the target type. This will succeed if there is a registered cast between the two types. If the expression is an unknown-type literal, the content of the literal string will be fed to the input conversion routine for the target type.
3. Check to see if there is a sizing cast for the target type. A sizing cast is a cast from that type to itself. If one is found in the **pg\_cast** catalog, apply it to the expression before storing into the destination column. The implementation function for such a cast always takes an extra parameter of type **integer**. The parameter receives the destination column's **atttypmod** value (typically its declared length, although the interpretation of **atttypmod** varies for different data types), and may take a third Boolean parameter that says whether the cast is explicit or implicit. The cast function is responsible for applying any length-dependent semantics such as size checking or truncation.

### Examples

Use the **character** storage type conversion as an example. For a target column declared as **character(20)** the following statement shows that the stored value is sized correctly:

```
openGauss=# CREATE SCHEMA tpcds;
openGauss=# CREATE TABLE tpcds.value_storage_t1 (
VS_COL1 CHARACTER(20)
);
openGauss=# INSERT INTO tpcds.value_storage_t1 VALUES('abcdef');
openGauss=# SELECT VS_COL1, octet_length(VS_COL1) FROM tpcds.value_storage_t1;
vs_col1 | octet_length
-----+-----
abcdef | 20
(1 row)
```

```
)
openGauss=# DROP TABLE tpceds.value_storage_t1;
openGauss=# DROP SCHEMA tpceds;
```

#### NOTE

What has happened here is that the two unknown literals are resolved to **text** by default, allowing the || operator to be resolved as **text** concatenation. Then the **text** result of the operator is converted to **bpchar** ("blank-padded char", the internal name of the **character** data type) to match the target column type. Since the conversion from **text** to **bpchar** is binary-coercible, this conversion does not insert any real function call. Finally, the sizing function **bpchar(bpchar, integer, Boolean)** is found in the system catalog and used for the operator's result and the stored column length. This type-specific function performs the required length check and addition of padding spaces.

## 7.7.5 UNION, CASE, and Related Constructs

SQL **UNION** constructs must match up possibly dissimilar types to become a single result set. The resolution algorithm is applied separately to each output column of a union query. The **INTERSECT** and **EXCEPT** construct resolve dissimilar types in the same way as **UNION**. The **CASE**, **ARRAY**, **VALUES**, **GREATEST** and **LEAST** constructs use the identical algorithm to match up their component expressions and select a result data type.

### Type Resolution for UNION, CASE, and Related Constructs

- If all inputs are of the same type, and it is not **unknown**, resolve as that type.
- If all inputs are of type **unknown**, resolve as type **text** (the preferred type of the string category). Otherwise, **unknown** inputs are ignored.
- If the inputs are not all of the same type category, a failure will be resulted. (Type **unknown** is not included in this case.)
- If the inputs are all of the same type category, choose the top preferred type in that category. (Exception: The **UNION** operation regards the type of the first branch as the selected type.)

#### NOTE

**typcategory** in the **pg\_type** system catalog indicates the data type category.  
**typispreferred** indicates whether a type is preferred in **typcategory**.

- Convert all inputs to the selected type. (Retain the original lengths of strings). Fail if there is not an implicit conversion from a given input to the selected type.
- If the input contains the json, txid\_snapshot, sys\_refcursor, or geometry type, **UNION** cannot be performed.

### Type Resolution for CASE and COALESCE in TD Compatibility Type

- If all inputs are of the same type, and it is not **unknown**, resolve as that type.
- If all inputs are of type **unknown**, resolve as type **text**.
- If inputs are of the string type (including **unknown** which is resolved as type **text**) and digit type, resolve as the string type. If the inputs are not of the two types, an error will be reported.
- If the inputs are all of the same type category, choose the top preferred type in that category.

- Convert all inputs to the selected type. Fail if there is not an implicit conversion from a given input to the selected type.

## Type Resolution for CASE in ORA Compatibility Type

**decode(expr, search1, result1, search2, result2, ..., defresult):** When the **sql\_beta\_feature** is set to **a\_style\_coerce**, the final return value type of the expression is set to the data type of result1 or a higher-precision data type in the same type as result1, as that in ORA-compatible mode. (For example, numeric and int are both numeric data types, but numeric has higher precision and priority than int.) For CASE WHEN, the behavior is the same as the default behavior in ORA-compatible mode.

- If all inputs are of the same type, and it is not **unknown**, resolve as that type. Otherwise, proceed to the next step.
- Set the data type of result1 to the final return value type preferType, which belongs to preferCategory.
- Consider the data types of result2, result3, and defresult in sequence. If the type category is also preferCategory, which is the same as that of result1, check whether the precision (priority) is higher than that of preferType. If it is, update preferType to a data type with a higher precision. If the type category is not preferCategory, check whether the category can be implicitly converted to preferType. If it cannot, an error is reported.
- Uses the data type recorded by preferType as the return value type of the expression. The expression result is implicitly converted to this data type.

Note:

There is a special case where the character type of a super-large number is converted to the numeric type, for example, **select decode(1, 2, 2, '53465465676465454657567678676')**, in which the large number exceeds the range of the bigint and double types. If result1 is of the numeric type and does not meet the condition that all inputs are of the same type, the type of the return value is set to numeric to be compatible with this special case.

Note 2:

Priority of the numeric types: numeric > float8 > float4 > int8 > int4 > int2 > int1

Priority of the character types: text > varchar = nvarchar2 > bpchar > char

Priority of date types: timestamptz > timestamp > smalldatetime > date > abstime > timetz > time

Priority of date span types: interval > tinterval > reltime.

Note 3:

The following figure shows the supported implicit type conversion when **set sql\_beta\_feature** is set to '**a\_style\_coerce**' in ORA-compatible mode. \ indicates that conversion is not required, **yes** indicates that conversion is supported, and the blank value indicates that conversion is not supported.

|               | bool | int1 | int2 | int4 | int8 | float4 | float8 | numeric | money | char | bpchar | varchar2 | nvarchar2 | text/clob | raw | blob | date | time | timetz | timestamp | timestampz | smalldatetime | interval | retime | abstime |
|---------------|------|------|------|------|------|--------|--------|---------|-------|------|--------|----------|-----------|-----------|-----|------|------|------|--------|-----------|------------|---------------|----------|--------|---------|
| bool          | \    |      |      |      |      |        |        |         |       |      |        |          |           |           |     |      |      |      |        |           |            |               |          |        |         |
| int1          |      | \    | yes  | yes  | yes  | yes    | yes    | yes     |       | yes  | yes    | yes      | yes       | yes       |     |      |      |      |        |           |            |               |          |        |         |
| int2          |      | yes  | \    | yes  | yes  | yes    | yes    | yes     |       | yes  | yes    | yes      | yes       | yes       |     |      |      |      |        |           |            |               |          |        |         |
| int4          |      |      | yes  | yes  | \    | yes    | yes    | yes     |       | yes  | yes    | yes      | yes       | yes       |     |      |      |      |        |           |            |               |          |        |         |
| int8          |      |      | yes  | yes  | yes  | \      | yes    | yes     |       | yes  | yes    | yes      | yes       | yes       |     |      |      |      |        |           |            |               |          |        |         |
| float4        |      |      | yes  | yes  | yes  | yes    | \      | yes     |       | yes  | yes    | yes      | yes       | yes       |     |      |      |      |        |           |            |               |          |        |         |
| float8        |      |      | yes  | yes  | yes  | yes    | yes    | \       | yes   |      | yes    | yes      | yes       | yes       |     |      |      |      |        |           |            |               |          |        |         |
| numeric       |      |      | yes  | yes  | yes  | yes    | yes    | \       |       | yes  | yes    | yes      | yes       | yes       |     |      |      |      |        |           |            |               |          |        |         |
| money         |      |      |      |      |      |        |        |         | \     |      |        |          |           |           |     |      |      |      |        |           |            |               |          |        |         |
| char          |      | yes  | yes  | yes  | yes  | yes    | yes    | yes     |       | \    | yes    | yes      | yes       | yes       |     |      |      |      |        |           |            |               |          |        |         |
| bpchar        |      | yes  | yes  | yes  | yes  | yes    | yes    | yes     |       | yes  | \      | yes      | yes       | yes       |     |      |      |      |        |           |            |               |          |        |         |
| varchar2      |      | yes  | yes  | yes  | yes  | yes    | yes    | yes     |       | yes  | yes    | \        | yes       | yes       | yes |      |      |      |        |           |            |               |          |        |         |
| nvarchar2     |      | yes  | yes  | yes  | yes  | yes    | yes    | yes     |       | yes  | yes    | yes      | \         | yes       |     |      |      |      |        |           |            |               |          |        |         |
| text/clob     |      | yes  | yes  | yes  | yes  | yes    | yes    | yes     |       | yes  | yes    | yes      | yes       | \         |     |      |      |      |        |           |            |               |          |        |         |
| raw           |      |      |      |      |      |        |        |         |       |      |        | yes      |           | yes       | \   | yes  |      |      |        |           |            |               |          |        |         |
| blob          |      |      |      |      |      |        |        |         |       |      |        |          |           | yes       | \   |      |      |      |        |           |            |               |          |        |         |
| date          |      |      |      |      |      |        |        |         |       |      | yes    | yes      | yes       | yes       |     |      | \    |      | yes    | yes       | yes        | yes           |          |        | yes     |
| time          |      |      |      |      |      |        |        |         |       |      |        |          |           | yes       |     |      |      | \    | yes    |           |            |               |          |        |         |
| timetz        |      |      |      |      |      |        |        |         |       |      |        |          |           | yes       |     |      |      | yes  | \      |           |            |               |          |        |         |
| timestamp     |      |      |      |      |      |        |        |         |       |      | yes    | yes      | yes       | yes       |     | yes  |      |      | \      |           | yes        | yes           |          |        | yes     |
| timestampz    |      |      |      |      |      |        |        |         |       |      |        |          | yes       | yes       |     | yes  |      |      | yes    | \         | yes        |               |          |        | yes     |
| smalldatetime |      |      |      |      |      |        |        |         |       |      |        | yes      |           | yes       |     | yes  |      |      | yes    | yes       | \          |               |          |        | yes     |
| interval      |      |      |      |      |      |        |        |         |       |      |        | yes      | yes       | yes       |     |      |      |      |        |           |            | \             | yes      |        |         |
| retime        |      |      |      |      |      |        |        |         |       |      |        |          |           | yes       |     |      |      |      |        |           |            | yes           | \        |        |         |
| abstime       |      |      |      |      |      |        |        |         |       |      |        |          |           | yes       |     | yes  |      |      |        | yes       | yes        | yes           |          |        | \       |

## Examples

Example 1: Use type resolution with underspecified types in a union as the first example. Here, the unknown-type literal **'b'** will be resolved to type **text**.

```
openGauss=# SELECT text 'a' AS "text" UNION SELECT 'b';
text

a
b
(2 rows)
```

Example 2: Use type resolution in a simple union as the second example. The literal **1.2** is of type **numeric**, and the **integer** value **1** can be cast implicitly to **numeric**, so that type is used.

```
openGauss=# SELECT 1.2 AS "numeric" UNION SELECT 1;
numeric

1
1.2
(2 rows)
```

Example 3: Use type resolution in a transposed union as the third example. Since type **real** cannot be implicitly cast to **integer**, but **integer** can be implicitly cast to **real**, the union result type is resolved as **real**.

```
openGauss=# SELECT 1 AS "real" UNION SELECT CAST('2.2' AS REAL);
real

1
2.2
(2 rows)
```

Example 4: In the **TD** type, if input parameters for **COALESCE** are of **int** and **varchar** types, resolve as type **varchar**. In the **A** type, an error is reported.

```
-- In the A type, create the a_1 database compatible with A.
openGauss=# CREATE DATABASE a_1 dbcompatibility = 'A';
```

```
-- Switch to the a_1 database.
openGauss=# \c a_1

-- Create the t1 table.
a_1=# CREATE TABLE t1(a int, b varchar(10));

-- Show the execution plan of a statement for querying the types int and varchar of input parameters for COALESCE.
a_1=# EXPLAIN SELECT coalesce(a, b) FROM t1;
ERROR: COALESCE types integer and character varying cannot be matched
LINE 1: EXPLAIN SELECT coalesce(a, b) FROM t1;
 ^
CONTEXT: referenced column: coalesce

-- Delete the table.
a_1=# DROP TABLE t1;

-- Switch to the testdb database.
a_1=# \c testdb

-- In the TD type, create the td_1 database compatible with Teradata.
openGauss=# CREATE DATABASE td_1 dbcompatibility = 'C';

-- Switch to the td_1 database.
openGauss=# \c td_1

-- Create the t2 table.
td_1=# CREATE TABLE t2(a int, b varchar(10));

-- Show the execution plan of a statement for querying the types int and varchar of input parameters for COALESCE.
td_1=# EXPLAIN VERBOSE select coalesce(a, b) from t2;
 QUERY PLAN

Data Node Scan (cost=0.00..0.00 rows=0 width=0)
 Output: (COALESCE((t2.a)::character varying, t2.b))
 Node/s: All dbnodes
 Remote query: SELECT COALESCE(a::character varying, b) AS "coalesce" FROM public.t2
(4 rows)

-- Delete the table.
td_1=# DROP TABLE t2;

-- Switch to the testdb database.
td_1=# \c testdb

-- Delete databases in A and TD types.
openGauss=# DROP DATABASE a_1;
openGauss=# DROP DATABASE td_1;
```

Example 5: In ORA-compatible mode, set the final return value type of the expression to the data type of result1 or a higher-precision data type whose category is the same as that of the data type of result1.

```
-- In the ORA type, create the ora_1 database compatible with ORA.
openGauss=# CREATE DATABASE ora_1 dbcompatibility = 'A';

-- Switch to the ora_1 database.
openGauss=# \c ora_1

-- Enable the decode compatibility parameters.
set sql_beta_feature='a_style_coerce';

-- Create the t1 table.
ora_1=# CREATE TABLE t1(c_int int, c_float8 float8, c_char char(10), c_text text, c_date date);

-- Insert data.
ora_1=# INSERT INTO t1 VALUES(1, 2, '3', '4', date '12-10-2010');
```

```
-- The data type of result1 is char and that of defresult is text. The precision of text is higher, and the type
of the return value is changed to text from char.
ora_1=# SELECT decode(1, 2, c_char, c_text) AS result, pg_typeof(result) FROM t1;
result | pg_typeof
-----+-----
4 | text
(1 row)

-- The data type of result1 is int, which is a numeric type. The type of the return value is set to numeric.
ora_1=# SELECT decode(1, 2, c_int, c_float8) AS result, pg_typeof(result) FROM t1;
result | pg_typeof
-----+-----
2 | numeric
(1 row)

-- The implicit conversion from the data type of defresult to that of result1 does not exist. An error is
reported.
ora_1=# SELECT decode(1, 2, c_int, c_date) FROM t1;
ERROR: CASE types integer and timestamp without time zone cannot be matched
LINE 1: SELECT decode(1, 2, c_int, c_date) FROM t1;
 ^
CONTEXT: referenced column: c_date

-- Disable the decode compatibility parameters.
set sql_beta_feature='none';

-- Delete the table.
ora_1=# DROP TABLE t1;
DROP TABLE

-- Switch to the testdb database.
ora_1=# \c testdb

-- Delete the ORA-compatible database.
openGauss=# DROP DATABASE ora_1;
DROP DATABASE
```

## 7.8 System Operation

GaussDB runs SQL statements to perform different system operations, such as setting variables, displaying the execution plan, and collecting garbage data.

### Setting Variables

For details about how to set various parameters for a session or transaction, see [SET](#).

### Displaying the Execution Plan

For details about how to display the execution plan that GaussDB makes for SQL statements, see [EXPLAIN](#).

### Specifying a Checkpoint in Transaction Logs

By default, WALs periodically specify checkpoints in a transaction log. **CHECKPOINT** forces an immediate checkpoint when the related command is issued, without waiting for a regular checkpoint scheduled by the system. For details, see [CHECKPOINT](#).

## Collecting Unnecessary Data

For details about how to collect garbage data and analyze a database as required, see [VACUUM](#).

## Collecting Statistics

For details about how to collect statistics on tables in databases, see [ANALYZE | ANALYZE](#).

## Setting the Constraint Check Mode for the Current Transaction

For details about how to set the constraint check mode for the current transaction, see [SET CONSTRAINTS](#).

## Shutting Down The Current Database Node

For details about shutting down the current database node, see [SHUTDOWN](#).

# 7.9 Controlling Transactions

A transaction is a user-defined sequence of database operations, which form an integral unit of work.

## Starting a Transaction

GaussDB starts a transaction using **START TRANSACTION** and **BEGIN**. For details, see [START TRANSACTION](#) and [BEGIN](#).

## Setting a Transaction

GaussDB sets a transaction using **SET TRANSACTION** or **SET LOCAL TRANSACTION**. For details, see [SET TRANSACTION](#).

## Committing a Transaction

GaussDB commits all operations of a transaction using **COMMIT** or **END**. For details, see [COMMIT | END](#).

## Rolling Back a Transaction

If a fault occurs during a transaction and the transaction cannot proceed, the system performs rollback to cancel all the completed database operations related to the transaction. See [ROLLBACK](#).

### NOTE

If an execution request (not in a transaction block) received in the database contains multiple statements, the request is packed into a transaction. If one of the statements fails, the entire request will be rolled back.

## 7.10 DDL Syntax Overview

Data definition language (DDL) is used to define or modify an object in a database, such as a table, an index, or a view.

### NOTE

GaussDB does not support DDL when the primary node of the database is incomplete. For example, if the primary node of the database in the database is faulty, creating a database or a table will fail.

### Defining a Database

A database is the warehouse for organizing, storing, and managing data. Defining a database includes creating a database, altering the database attributes, and deleting the database. For details about related SQL statements, see [Table 7-86](#).

**Table 7-86** SQL statements for defining a database

| Function                      | SQL Statement                   |
|-------------------------------|---------------------------------|
| Creating a database           | <a href="#">CREATE DATABASE</a> |
| Altering a database attribute | <a href="#">ALTER DATABASE</a>  |
| Deleting a database           | <a href="#">DROP DATABASE</a>   |

### Defining a schema

A schema is the set of a group of database objects and is used to control the access to the database objects. For details about related SQL statements, see [Table 7-87](#).

**Table 7-87** SQL statements for defining a schema

| Function                    | SQL Statement                 |
|-----------------------------|-------------------------------|
| Creating a schema           | <a href="#">CREATE SCHEMA</a> |
| Altering a schema attribute | <a href="#">ALTER SCHEMA</a>  |
| Deleting a schema           | <a href="#">DROP SCHEMA</a>   |

### Defining a Tablespace

A tablespace is used to manage data objects and corresponds to a catalog on a disk. For details about related SQL statements, see [Table 7-88](#).

**Table 7-88** SQL statements for defining a tablespace

| Function                        | SQL Statement                     |
|---------------------------------|-----------------------------------|
| Creating a tablespace           | <a href="#">CREATE TABLESPACE</a> |
| Altering a tablespace attribute | <a href="#">ALTER TABLESPACE</a>  |
| Deleting a tablespace           | <a href="#">DROP TABLESPACE</a>   |

## Defining a Table

A table is a special data structure in a database and is used to store data objects and relationship between data objects. For details about related SQL statements, see [Table 7-89](#).

**Table 7-89** SQL statements for defining a table

| Function                   | SQL Statement                |
|----------------------------|------------------------------|
| Creating a table           | <a href="#">CREATE TABLE</a> |
| Altering a table attribute | <a href="#">ALTER TABLE</a>  |
| Deleting a table           | <a href="#">DROP TABLE</a>   |

## Defining a Partitioned Table

A partitioned table is a logical table used to improve query performance and does not store data (data is stored in ordinary tables). For details about related SQL statements, see [Table 7-90](#).

**Table 7-90** SQL statements for defining a partitioned table

| Function                               | SQL Statement                          |
|----------------------------------------|----------------------------------------|
| Creating a partitioned table           | <a href="#">CREATE TABLE PARTITION</a> |
| Creating a partition                   | <a href="#">ALTER TABLE PARTITION</a>  |
| Altering a partitioned table attribute | <a href="#">ALTER TABLE PARTITION</a>  |
| Deleting a partition                   | <a href="#">ALTER TABLE PARTITION</a>  |
| Deleting a partitioned table           | <a href="#">DROP TABLE</a>             |

## Defining an Index

An index indicates the sequence of values in one or more columns in a database table. It is a data structure that improves the speed of data access to specific

information in a database table. For details about related SQL statements, see [Table 7-91](#).

**Table 7-91** SQL statements for defining an index

| Function                    | SQL Statement                |
|-----------------------------|------------------------------|
| Creating an index           | <a href="#">CREATE INDEX</a> |
| Altering an index attribute | <a href="#">ALTER INDEX</a>  |
| Deleting an index           | <a href="#">DROP INDEX</a>   |
| Rebuilding an index         | <a href="#">REINDEX</a>      |

## Defining a Stored Procedure

A stored procedure is a set of SQL statements for achieving specific functions and is stored in the database after compiling. Users can specify a name and provide parameters (if necessary) to execute the stored procedure. For details about related SQL statements, see [Table 7-92](#).

**Table 7-92** SQL statements for defining a stored procedure

| Function                    | SQL Statement                    |
|-----------------------------|----------------------------------|
| Creating a stored procedure | <a href="#">CREATE PROCEDURE</a> |
| Deleting a stored procedure | <a href="#">DROP PROCEDURE</a>   |

## Defining a Function

In GaussDB, a function is similar to a stored procedure, which is a set of SQL statements. The function and stored procedure are used the same. For details about related SQL statements, see [Table 7-93](#).

**Table 7-93** SQL statements for defining a function

| Function                      | SQL Statement                   |
|-------------------------------|---------------------------------|
| Creating a function           | <a href="#">CREATE FUNCTION</a> |
| Altering a function attribute | <a href="#">ALTER FUNCTION</a>  |
| Deleting a function           | <a href="#">DROP FUNCTION</a>   |

## Defining a Package

A package consists of the package specification and package body. It is used to manage stored procedures and functions by class, which is similar to classes in languages such as Java and C++.

**Table 7-94** SQL statements for defining a package

| Function                     | SQL Statement         |
|------------------------------|-----------------------|
| Creating a package           | <b>CREATE PACKAGE</b> |
| Deleting a package           | <b>DROP PACKAGE</b>   |
| Altering a package attribute | <b>ALTER PACKAGE</b>  |

## Defining a View

A view is a virtual table exported from one or more basic tables. It is used to control data accesses of users. [Table 7-95](#) lists the related SQL statements.

**Table 7-95** SQL statements for defining a view

| Function        | SQL Statement      |
|-----------------|--------------------|
| Creating a view | <b>CREATE VIEW</b> |
| Deleting a view | <b>DROP VIEW</b>   |

## Defining a Cursor

To process SQL statements, the stored procedure process allocates a memory fragment to store the context. Cursors are handles or pointers to context regions. With a cursor, the stored procedure can control alterations in context areas. For details, see [Table 7-96](#).

**Table 7-96** SQL statements for defining a cursor

| Function                    | SQL Statement |
|-----------------------------|---------------|
| Creating a cursor           | <b>CURSOR</b> |
| Moving a cursor             | <b>MOVE</b>   |
| Fetching data from a cursor | <b>FETCH</b>  |
| Closing a cursor            | <b>CLOSE</b>  |

## Defining an Aggregate Function

**Table 7-97** SQL statements for defining an aggregate function

| Function                        | SQL Statement                    |
|---------------------------------|----------------------------------|
| Creating an aggregate function  | <a href="#">CREATE AGGREGATE</a> |
| Modifying an aggregate function | <a href="#">ALTER AGGREGATE</a>  |
| Deleting an aggregate function  | <a href="#">DROP AGGREGATE</a>   |

## Defining Data Type Conversion

**Table 7-98** SQL statements for defining a data type

| Function                                   | SQL Statement               |
|--------------------------------------------|-----------------------------|
| Creating user-defined data type conversion | <a href="#">CREATE CAST</a> |
| Deleting user-defined data type conversion | <a href="#">DROP CAST</a>   |

## Defining an Operator

**Table 7-99** SQL statements for defining an operator

| Function              | SQL Statement                   |
|-----------------------|---------------------------------|
| Creating an operator  | <a href="#">CREATE OPERATOR</a> |
| Modifying an operator | <a href="#">ALTER OPERATOR</a>  |
| Deleting an operator  | <a href="#">DROP OPERATOR</a>   |

## Defining a Data Type

**Table 7-100** SQL statements for defining a data type

| Function              | SQL Statement               |
|-----------------------|-----------------------------|
| Creating a data type  | <a href="#">CREATE TYPE</a> |
| Modifying a data type | <a href="#">ALTER TYPE</a>  |
| Deleting a data type  | <a href="#">DROP TYPE</a>   |

## 7.11 DML Syntax Overview

Data manipulation language (DML) is used to perform operations on data in database tables, such as inserting, updating, querying, or deleting data.

### Inserting Data

Inserting data refers to adding one or multiple records to a database table. For details, see [INSERT](#).

### Updating Data

Updating data refers to modifying one or multiple records in a database table. For details, see [UPDATE](#).

### Querying Data

The database query statement **SELECT** is used to search required information in a database. For details, see [SELECT](#).

### Deleting Data

GaussDB provides two statements for deleting data from database tables. To delete data meeting specified conditions from a database table, see [DELETE](#). To delete all data from a database table, see [TRUNCATE](#).

**TRUNCATE** can quickly delete all data from a database table, which achieves the effect same as that running **DELETE** to delete data without specifying conditions from each table. Deletion efficiency using **TRUNCATE** is faster because **TRUNCATE** does not scan tables. Therefore, **TRUNCATE** is useful in large tables.

### Copying Data

GaussDB provides a statement for copying data between tables and files. For details, see [COPY](#).

### Locking a Table

GaussDB provides multiple lock modes to control concurrent accesses to table data. For details, see [LOCK](#).

### Calling a Function

GaussDB provides three statements for calling functions. These statements are the same in the syntax structure. For details, see [CALL](#).

### Session Management

A session is a connection established between the user and the database. [Table 7-101](#) lists the related SQL statements.

**Table 7-101** SQL statements related to sessions

| Function           | SQL Statement                             |
|--------------------|-------------------------------------------|
| Altering a session | <a href="#">ALTER SESSION</a>             |
| Killing a session  | <a href="#">ALTER SYSTEM KILL SESSION</a> |

## 7.12 DCL Syntax Overview

Data control language (DCL) is used to create users and roles and set or modify database users or role rights.

### Defining a Role

A role is used to manage permissions. For database security, management and operation permissions can be granted to different roles. For details about related SQL statements, see [Table 7-102](#).

**Table 7-102** SQL statements for defining a role

| Description              | SQL Statement               |
|--------------------------|-----------------------------|
| Creating a role          | <a href="#">CREATE ROLE</a> |
| Altering role attributes | <a href="#">ALTER ROLE</a>  |
| Dropping a role          | <a href="#">DROP ROLE</a>   |

### Defining a User

A user is used to log in to a database. Different permissions can be granted to users for managing data accesses and operations of the users. For details about related SQL statements, see [Table 7-103](#).

**Table 7-103** SQL statements for defining a user

| Description              | SQL Statement               |
|--------------------------|-----------------------------|
| Creating a User          | <a href="#">CREATE USER</a> |
| Altering user attributes | <a href="#">ALTER USER</a>  |
| Dropping a user          | <a href="#">DROP USER</a>   |

### Granting Rights

GaussDB provides a statement for granting rights to data objects and roles. For details, see [GRANT](#).

## Revoking Rights

GaussDB provides a statement for revoking rights. For details, see [REVOKE](#).

## Setting Default Rights

GaussDB allows users to set rights for objects that will be created. For details, see [ALTER DEFAULT PRIVILEGES](#)

## Shutting Down The Current Node

GaussDB allows users to run the **shutdown** command to shut down the current database node. For details, see [SHUTDOWN](#).

# 7.13 SQL Syntax

## 7.13.1 ABORT

### Description

Rolls back the current transaction and cancels the changes in the transaction.

This command is equivalent to [ROLLBACK](#), and is present only for historical reasons. Now ROLLBACK is recommended.

### Precautions

ABORT has no impact outside a transaction, but will throw a NOTICE message.

### Syntax

```
ABORT [WORK | TRANSACTION] ;
```

### Parameters

- **WORK | TRANSACTION**  
Specifies an optional keyword, which has no effect except increasing readability.

### Examples

```
-- Create the customer_demographics_t1 table.
openGauss=# CREATE TABLE customer_demographics_t1
(
 CD_DEMO_SK INTEGER NOT NULL,
 CD_GENDER CHAR(1) ,
 CD_MARITAL_STATUS CHAR(1) ,
 CD_EDUCATION_STATUS CHAR(20) ,
 CD_PURCHASE_ESTIMATE INTEGER ,
 CD_CREDIT_RATING CHAR(10) ,
 CD_DEP_COUNT INTEGER ,
 CD_DEP_EMPLOYED_COUNT INTEGER ,
 CD_DEP_COLLEGE_COUNT INTEGER ,
)
;
```

```
-- Insert data.
openGauss=# INSERT INTO customer_demographics_t1 VALUES(1920801,'M', 'U', 'DOCTOR DEGREE', 200,
'GOOD', 1, 0,0);

-- Start a transaction.
openGauss=# START TRANSACTION;

-- Update the column.
openGauss=# UPDATE customer_demographics_t1 SET cd_education_status= 'Unknown';

-- Abort the transaction. All updates are rolled back.
openGauss=# ABORT;

-- Query data.
openGauss=# SELECT * FROM customer_demographics_t1 WHERE cd_demo_sk = 1920801;
cd_demo_sk | cd_gender | cd_marital_status | cd_education_status | cd_purchase_estimate | cd_credit_rating
| cd_dep_count | cd_dep_employed_count | cd_dep_college_count

[SET TRANSACTION](#), [COMMIT | END](#), and [ROLLBACK](#)

## 7.13.2 ALTER AGGREGATE

### Description

Alters the definition of an aggregate function, including the name, owner, and schema.

### Precautions

To use ALTER AGGREGATE, you must be the owner of the aggregate function. To change the schema of an aggregate function, you must have the CREATE permission on the new schema. To change the owner, you must be a direct or indirect member of the new role, and the role must have the CREATE permission on the aggregate function's schema. (This restricts the owner from doing anything except for deleting and rebuilding aggregate functions. However, a user with the SYSADMIN permission can change the ownership of an aggregate function in any way.)

### Syntax

```
ALTER AGGREGATE name (argtype [, ...]) RENAME TO new_name
ALTER AGGREGATE name (argtype [, ...]) OWNER TO new_owner
ALTER AGGREGATE name (argtype [, ...]) SET SCHEMA new_schema
```

### Parameters

- **name**  
Name (optionally schema-qualified) of an existing aggregate function.

- **argtype**  
Input data type of the aggregate function. To reference a zero-parameter aggregate function, you can write an asterisk (\*) instead of a list of input data types.
- **new\_name**  
New name of the aggregate function.
- **new\_owner**  
New owner of the aggregate function.
- **new\_schema**  
New schema of the aggregate function.

## Examples

Rename the aggregate function myavg that accepts integer-type parameters to **my\_average**.

```
ALTER AGGREGATE myavg(integer) RENAME TO my_average;
```

Change the owner of the aggregate function myavg that accepts integer-type parameters to **joe**.

```
ALTER AGGREGATE myavg(integer) OWNER TO joe;
```

Move the aggregate function myavg that accepts integer-type parameters to **myschema**.

```
ALTER AGGREGATE myavg(integer) SET SCHEMA myschema;
```

## Compatibility

The SQL standard does not contain the ALTER AGGREGATE statement.

## Helpful Links

[CREATE AGGREGATE](#) and [DROP AGGREGATE](#)

## 7.13.3 ALTER AUDIT POLICY

### Description

Alters the unified audit policy.

### Precautions

- Only users with the POLADMIN or SYSADMIN permission, or the initial user can perform this operation.
- The unified audit policy takes effect only after **enable\_security\_policy** is enabled.

### Syntax

```
ALTER AUDIT POLICY [IF EXISTS] policy_name { ADD | REMOVE } { [privilege_audit_clause]
[access_audit_clause] };
ALTER AUDIT POLICY [IF EXISTS] policy_name MODIFY (filter_group_clause);
```

```
ALTER AUDIT POLICY [IF EXISTS] policy_name DROP FILTER;
ALTER AUDIT POLICY [IF EXISTS] policy_name COMMENTS policy_comments;
ALTER AUDIT POLICY [IF EXISTS] policy_name { ENABLE | DISABLE };
```

- **privilege\_audit\_clause**  
PRIVILEGES ({ DDL | ALL } [ ON LABEL ( resource\_label\_name [, ... ] ) ] )
- **access\_audit\_clause**  
ACCESS ({ DML | ALL } [ ON LABEL ( resource\_label\_name [, ... ] ) ] )
- **filter\_group\_clause**  
FILTER ON { filter\_type ( filter\_value [, ... ] ) } [, ... ]

## Parameters

- **policy\_name**  
Specifies the audit policy name, which must be unique.  
Value range: a string that complies with the [Identifier Naming Conventions](#).
- **DDL**  
Specifies the operations that are audited in the database: **CREATE**, **ALTER**, **DROP**, **ANALYZE**, **COMMENT**, **GRANT**, **REVOKE**, **SET**, **SHOW**, **LOGIN\_ANY**, **LOGIN\_FAILURE**, **LOGIN\_SUCCESS**, and **LOGOUT**.
- **DML**  
Specifies the operations that are audited in the database: **SELECT**, **COPY**, **DEALLOCATE**, **DELETE**, **EXECUTE**, **INSERT**, **PREPARE**, **REINDEX**, **TRUNCATE**, and **UPDATE**.
- **ALL**  
Specifies all operations supported by the specified DDL or DML statements in the database. When the form is { DDL | ALL }, **ALL** indicates all DDL operations. When the form is { DML | ALL }, **ALL** indicates all DML operations.
- **filter\_type**  
Specifies the types of information to be filtered by the policy: **IP**, **ROLES**, and **APP**.
- **filter\_value**  
Specifies the detailed information to be filtered.
- **policy\_comments**  
Records description information of the audit policy.
- **ENABLE|DISABLE**  
Enables or disables the unified audit policy. If **ENABLE|DISABLE** is not specified, **ENABLE** is used by default.

## Examples

See [Examples](#) in "CREATE AUDIT POLICY."

## Helpful Links

[CREATE AUDIT POLICY](#) and [DROP AUDIT POLICY](#)

## 7.13.4 ALTER DATABASE

### Description

Alters a database, including its name, owner, object isolation, and connection limitation.

### Precautions

- Only the database owner or a user granted with the ALTER permission can run the **ALTER DATABASE** command. System administrators have this permission by default. The following are permission restrictions depending on attributes to be modified:
  - To change the database name, you must have the CREATEDB permission.
  - To change a database owner, you must be a database owner or system administrator and a member of the new owner role, with the CREATEDB permission.
  - To change the default tablespace of the database, the user must have the CREATE permission for creating tablespaces. This statement physically migrates tables and indexes in a default tablespace to a new tablespace. Note that tables and indexes outside the default tablespace are not affected.
- You are not allowed to rename a database in use. To rename it, connect to another database.

### Syntax

- Modify the maximum number of connections to the database.

```
ALTER DATABASE database_name
[WITH] CONNECTION LIMIT connlimit;
```

- Rename the database.

```
ALTER DATABASE database_name
RENAME TO new_name;
```

- Change the database owner.

```
ALTER DATABASE database_name
OWNER TO new_owner;
```

- Change the default tablespace of the database.

```
ALTER DATABASE database_name
SET TABLESPACE new_tablespace;
```

#### NOTE

If some tables or objects in the database have been created in **new\_tablespace**, the default tablespace of the database cannot be changed to **new\_tablespace**. An error will be reported during the execution.

- Modify the session parameter value of the database.

```
ALTER DATABASE database_name
SET configuration_parameter { { TO | = } { value | DEFAULT } | FROM CURRENT };
```

- Reset the database configuration parameter.

```
ALTER DATABASE database_name RESET
{ configuration_parameter | ALL };
```

- Modify the object isolation attribute of the database.

```
ALTER DATABASE database_name [WITH] { ENABLE | DISABLE } PRIVATE OBJECT;
```

 **NOTE**

- To modify the object isolation attribute of a database, the database must be connected. Otherwise, the modification will fail.
- For a new database, the object isolation attribute is disabled by default. After this attribute is enabled, common users can view only the objects (such as tables, functions, views, and columns) that they have the permission to access. This attribute does not take effect for administrators. After this attribute is enabled, administrators can still view all database objects.

## Parameters

- **database\_name**  
Specifies the name of the database whose attributes are to be modified.  
Value range: a string that complies with the [Identifier Naming Conventions](#).
- **connlimit**  
Specifies the maximum number of concurrent connections that can be made to this database (excluding administrators' connections).  
Value range: an integer ranging from  $-1$  to  $2^{31} - 1$ . You are advised to set this parameter to an integer ranging from 1 to 50. The default value  $-1$  indicates that there is no restriction on the number of concurrent connections.
- **new\_name**  
Specifies the new name of a database.  
Value range: a string that complies with the [Identifier Naming Conventions](#).
- **new\_owner**  
Specifies the new owner of a database.  
Value range: a string. It must be a valid username.
- **new\_tablespace**  
Specifies the new default tablespace of a database. The tablespace exists in the database. The default tablespace is pg\_default.  
Value range: a string. It must be a valid tablespace name.
- **configuration\_parameter**
  - **value**  
Sets a specified database session parameter to a specified value. If the value is **DEFAULT** or **RESET**, the default setting is used in the new session. **OFF** disables the setting.  
Value range: a string.
    - **DEFAULT**
    - **OFF**
    - **RESET**
  - **FROM CURRENT**  
Uses the value of **configuration\_parameter** of the current session.
- **FROM CURRENT**  
Sets the value of the database based on the current connected session.

- **RESET configuration\_parameter**  
Resets the specified database session parameter.
- **RESET ALL**  
Resets all database session parameters.

 **NOTE**

- Modify the default tablespace of a database by moving the table or index in the old tablespace into the new tablespace. This operation does not affect the tables or indexes in other non-default tablespaces.
- The modified database session parameter values will take effect in the next session.

## Examples

See [Examples](#) in "CREATE DATABASE."

## Helpful Links

[CREATE DATABASE](#) and [DROP DATABASE](#)

## 7.13.5 ALTER DEFAULT PRIVILEGES

### Description

Allows you to set the permissions that will be applied to objects created in the future. (It does not affect permissions granted to existing objects.)

### Precautions

Only the permissions for tables (including views), sequences, functions, and types can be changed.

### Syntax

```
ALTER DEFAULT PRIVILEGES
[FOR { ROLE | USER } target_role [, ...]]
[IN SCHEMA schema_name [, ...]]
abbreviated_grant_or_revoke;
```

- The abbreviated\_grant\_or\_revoke clause grants or revokes permissions on some objects.

```
grant_on_tables_clause
| grant_on_sequences_clause
| grant_on_functions_clause
| grant_on_types_clause
| revoke_on_tables_clause
| revoke_on_sequences_clause
| revoke_on_functions_clause
| revoke_on_types_clause
```

- grant\_on\_tables\_clause grants permissions on tables.  
GRANT { { SELECT | INSERT | UPDATE | DELETE | TRUNCATE | REFERENCES | ALTER | DROP |  
COMMENT | INDEX | VACUUM }  
[, ...] | ALL [ PRIVILEGES ] }  
ON TABLES  
TO { [ GROUP ] role\_name | PUBLIC } [, ...]  
[ WITH GRANT OPTION ]
- grant\_on\_sequences\_clause grants permissions on sequences.

```
GRANT { { SELECT | UPDATE | USAGE | ALTER | DROP | COMMENT }
[, ...] | ALL [PRIVILEGES] }
ON SEQUENCES
TO { [GROUP] role_name | PUBLIC } [, ...]
[WITH GRANT OPTION]
```

- **grant\_on\_functions\_clause** grants permissions on functions.

```
GRANT { { EXECUTE | ALTER | DROP | COMMENT } [, ...] | ALL [PRIVILEGES] }
ON FUNCTIONS
TO { [GROUP] role_name | PUBLIC } [, ...]
[WITH GRANT OPTION]
```

- **grant\_on\_types\_clause** grants permissions on types.

```
GRANT { { USAGE | ALTER | DROP | COMMENT } [, ...] | ALL [PRIVILEGES] }
ON TYPES
TO { [GROUP] role_name | PUBLIC } [, ...]
[WITH GRANT OPTION]
```

- **revoke\_on\_tables\_clause** revokes permissions on tables.

```
REVOKE [GRANT OPTION FOR]
{ { SELECT | INSERT | UPDATE | DELETE | TRUNCATE | REFERENCES | ALTER | DROP | COMMENT |
INDEX | VACUUM }
[, ...] | ALL [PRIVILEGES] }
ON TABLES
FROM { [GROUP] role_name | PUBLIC } [, ...]
[CASCADE | RESTRICT | CASCADE CONSTRAINTS]
```

- **revoke\_on\_sequences\_clause** revokes permissions on sequences.

```
REVOKE [GRANT OPTION FOR]
{ { SELECT | UPDATE | USAGE | ALTER | DROP | COMMENT }
[, ...] | ALL [PRIVILEGES] }
ON SEQUENCES
FROM { [GROUP] role_name | PUBLIC } [, ...]
[CASCADE | RESTRICT | CASCADE CONSTRAINTS]
```

- **revoke\_on\_functions\_clause** revokes permissions on functions.

```
REVOKE [GRANT OPTION FOR]
{ { EXECUTE | ALTER | DROP | COMMENT } [, ...] | ALL [PRIVILEGES] }
ON FUNCTIONS
FROM { [GROUP] role_name | PUBLIC } [, ...]
[CASCADE | RESTRICT | CASCADE CONSTRAINTS]
```

- **revoke\_on\_types\_clause** revokes permissions on types.

```
REVOKE [GRANT OPTION FOR]
{ { USAGE | ALTER | DROP | COMMENT } [, ...] | ALL [PRIVILEGES] }
ON TYPES
FROM { [GROUP] role_name | PUBLIC } [, ...]
[CASCADE | RESTRICT | CASCADE CONSTRAINTS]
```

## Parameters

- **target\_role**

Specifies the name of an existing role. If **FOR ROLE/USER** is omitted, the current role is assumed.

Value range: an existing role name.

- **schema\_name**

Specifies the name of an existing schema.

**target\_role** must have the CREATE permission for **schema\_name**.

Value range: an existing schema name.

- **role\_name**

Specifies the name of an existing role to grant or revoke permissions for.

Value range: an existing role name.

**NOTICE**

To drop a role for which the default permissions have been granted, reverse the changes in its default permissions or use DROP OWNED BY to get rid of the default permission entry for the role.

## Examples

```
-- Grant the SELECT permission on all the tables (and views) in tpcds to every user.
openGauss=# ALTER DEFAULT PRIVILEGES IN SCHEMA tpcds GRANT SELECT ON TABLES TO PUBLIC;

-- Create a common user jack.
openGauss=# CREATE USER jack PASSWORD '*****';

-- Grant the INSERT permission on all the tables in tpcds to the user jack.
openGauss=# ALTER DEFAULT PRIVILEGES IN SCHEMA tpcds GRANT INSERT ON TABLES TO jack;

-- Revoke the preceding permissions.
openGauss=# ALTER DEFAULT PRIVILEGES IN SCHEMA tpcds REVOKE SELECT ON TABLES FROM PUBLIC;
openGauss=# ALTER DEFAULT PRIVILEGES IN SCHEMA tpcds REVOKE INSERT ON TABLES FROM jack;

-- Drop user jack.
openGauss=# DROP USER jack CASCADE;

-- Drop the schema.
openGauss=# DROP SCHEMA tpcds;
```

## Helpful Links

[GRANT](#) and [REVOKE](#)

## 7.13.6 ALTER DIRECTORY

### Description

Alters directory attributes.

### Precautions

- Currently, only the directory owner can be changed.
- When **enable\_access\_server\_directory** is set to **off**, only the initial user is allowed to change the directory owner. When **enable\_access\_server\_directory** is set to **on**, users with the SYSADMIN permission and the directory object owner can change the directory object owner, and the user who changes the owner is required to be a member of the new owner.

### Syntax

```
ALTER DIRECTORY directory_name
 OWNER TO new_owner;
```

### Parameters

- directory\_name**  
Specifies the name of a directory to be modified. The value must be an existing directory name.

- **new\_owner**  
Specifies the new owner of the directory.

## Examples

```
-- Create a directory.
openGauss=# CREATE OR REPLACE DIRECTORY dir as '/tmp/';

-- Create a user.
openGauss=# CREATE USER system PASSWORD '*****!';

-- Change the owner of the directory.
openGauss=# ALTER DIRECTORY dir OWNER TO system;

-- Drop a directory.
openGauss=# DROP DIRECTORY dir;
```

## Helpful Links

[CREATE DIRECTORY](#) and [DROP DIRECTORY](#)

## 7.13.7 ALTER FUNCTION

### Description

Alters the attributes of a custom function.

### Precautions

Only the function owner or a user granted the ALTER permission can run the **ALTER FUNCTION** command. System administrators have this permission by default. The following are permission restrictions depending on attributes to be modified:

- If a function involves operations on temporary tables, ALTER FUNCTION cannot be used.
- To modify the owner or schema of a function, you must be a function owner or system administrator and a member of the new owner role.
- Only system administrators and the initial user can change the schema of a function to public.

### Syntax

- Modify the additional parameters of the user-defined function.  
**ALTER FUNCTION** function\_name ( [ { [ argname ] [ argmode ] argtype } [, ...] ] )  
action [ ... ] [ RESTRICT ];

The syntax of the ACTION clause is as follows:

```
{CALLED ON NULL INPUT | RETURNS NULL ON NULL INPUT | STRICT}
| {IMMUTABLE | STABLE | VOLATILE}
| {SHIPPABLE | NOT SHIPPABLE}
| {NOT FENCED | FENCED}
| [NOT] LEAKPROOF
| { [EXTERNAL] SECURITY INVOKER | [EXTERNAL] SECURITY DEFINER }
| AUTHID { DEFINER | CURRENT_USER }
| COST execution_cost
| ROWS result_rows
| SET configuration_parameter { { TO | = } { value | DEFAULT } } FROM CURRENT}
| RESET {configuration_parameter | ALL}
```

- Rename the user-defined function.  

```
ALTER FUNCTION function_name ([{ [argname] [argmode] argtype} [, ...]])
 RENAME TO new_name;
```
- Change the owner of the user-defined function.  

```
ALTER FUNCTION function_name ([{ [argname] [argmode] argtype} [, ...]])
 OWNER TO new_owner;
```
- Modify the schema of the user-defined function.  

```
ALTER FUNCTION function_name ([{ [argname] [argmode] argtype} [, ...]])
 SET SCHEMA new_schema;
```

## Parameters

- **function\_name**  
Specifies the name of the function to be modified.  
Value range: an existing function name.
- **argmode**  
Specifies whether a parameter is an input or output parameter.  
Value range:
  - **IN**: declares input parameters.
  - **OUT**: declares output parameters.
  - **INOUT**: declares input and output parameters.
  - **VARIADIC**: declares parameters of the array type.
- **argname**  
Specifies the parameter name.  
Value range: a string that complies with the [Identifier Naming Conventions](#).
- **argtype**  
Specifies the parameter type of the function.
- **CALLED ON NULL INPUT**  
Declares that some parameters of the function can be called in normal mode if the parameter values are **NULL**. Omitting this parameter is the same as specifying it.
- **RETURNS NULL ON NULL INPUT**  
**STRICT**  
Specifies that a function always returns **NULL** when the value of any of its parameters is **NULL**. If this parameter is specified, the function is not executed when there is **NULL** parameter; instead a NULL result is assumed automatically.  
**RETURNS NULL ON NULL INPUT** and **STRICT** have the same functions.
- **IMMUTABLE**  
Specifies that the function always returns the same result if the parameter values are the same.
- **STABLE**  
Specifies that the function cannot modify the database, and that within a single table scan it will consistently return the same result for the same parameter value, but its result varies by SQL statements.
- **VOLATILE**

Specifies that the function value can change in a single table scan and no optimization is performed.

- **LEAKPROOF**

Specifies that the function has no side effect and the parameter contains only the return value. **LEAKPROOF** can be set only by system administrators.

- **EXTERNAL**

(Optional) The purpose is to be compatible with SQL. This feature applies to all functions, not only external functions.

- **SECURITY INVOKER**

**AUTHID CURRENT\_USER**

Specifies that the function will be executed with the permissions of the user who calls it. Omitting this parameter is the same as specifying it.

**SECURITY INVOKER** and **AUTHID CURRENT\_USER** have the same functions.

- **SECURITY DEFINER**

**AUTHID DEFINER**

Specifies that the function will be executed with the permissions of the user who created it.

**AUTHID DEFINER** and **SECURITY DEFINER** have the same functions.

- **COST execution\_cost**

Estimates the execution cost of a function.

The unit of **execution\_cost** is **cpu\_operator\_cost**.

Value range: a positive integer.

- **ROWS result\_rows**

Estimates the number of rows returned by the function. This is only allowed when the function is declared to return a set.

Value range: a positive number. The default value is **1000**.

- **configuration\_parameter**

- **value**

Sets a specified database session parameter to a specified value. If the value is **DEFAULT** or **RESET**, the default setting is used in the new session. **OFF** disables the setting.

Value range: a string.

- **DEFAULT**

- **OFF**

- **RESET**

- Specified default value

- **FROM CURRENT**

Uses the value of **configuration\_parameter** of the current session.

- **new\_name**

Specifies the new name of a function. To change the schema of a function, you must have the CREATE permission on the new schema.

Value range: a string that complies with the [Identifier Naming Conventions](#).

- **new\_owner**

Specifies the new owner of a function. To change the owner of a function, the new owner must have the CREATE permission on the schema to which the function belongs.

Value range: an existing user role.

- **new\_schema**

Specifies the new schema of a function.

Value range: an existing schema.

## Examples

See [Examples](#) in "CREATE FUNCTION."

## Helpful Links

[CREATE FUNCTION](#) and [DROP FUNCTION](#)

## 7.13.8 ALTER GLOBAL CONFIGURATION

### Description

Adds or changes the **key-value** of the gs\_global\_config system catalog. You can modify an existing parameter or add a new one.

### Precautions

- Only the initial database user can run this command.
- The parameter name cannot be **weak\_password** or **undostoragetype**.

### Syntax

```
ALTER GLOBAL CONFIGURATION with(name=value, name=value...);
```

### Parameters

- **name**  
Parameter name, which is of the text type. The value cannot be **weak\_password** or **undostoragetype**.
- **value**  
Parameter value, which is of the text type.

## Examples

```
-- Insert.
openGauss=# ALTER GLOBAL CONFIGURATION with(redis_is_ok = true);

-- Query.
openGauss=# SELECT * FROM gs_global_config;
 name | value
-----+-----
 buckets_len | 16384
undostoragetype | page
```

```
redis_is_ok | true
(3 rows)

-- Alter.
openGauss=# ALTER GLOBAL CONFIGURATION with(redis_is_ok = false);

-- Query.
openGauss=# SELECT * FROM gs_global_config;
 name | value
-----+-----
 buckets_len | 16384
 undostoragetype | page
 redis_is_ok | false
(3 rows)

-- Drop.
openGauss=# DROP GLOBAL CONFIGURATION redis_is_ok;

-- Query.
openGauss=# SELECT * FROM gs_global_config;
 name | value
-----+-----
 buckets_len | 16384
 undostoragetype | page
(2 rows)
```

## Helpful Links

### [DROP GLOBAL CONFIGURATION](#)

## 7.13.9 ALTER GROUP

### Description

Alters the attributes of a user group.

### Precautions

ALTER GROUP is an alias for ALTER ROLE, and it is not a standard SQL command and not recommended. Users can use ALTER ROLE directly.

### Syntax

- Add users to a group.  

```
ALTER GROUP group_name
 ADD USER user_name [, ...];
```
- Remove users from a group.  

```
ALTER GROUP group_name
 DROP USER user_name [, ...];
```
- Change the name of the group.  

```
ALTER GROUP group_name
 RENAME TO new_name;
```

### Parameters

See [Parameters](#) in "ALTER ROLE."

### Examples

```
-- Create a user group.
openGauss=# CREATE GROUP super_users WITH PASSWORD '*****';
```

```
-- Create a user.
openGauss=# CREATE ROLE lche WITH PASSWORD '*****';

-- Create a user.
openGauss=# CREATE ROLE jim WITH PASSWORD '*****';

-- Add users to a group.
openGauss=# ALTER GROUP super_users ADD USER lche, jim;

-- Remove users from a group.
openGauss=# ALTER GROUP super_users DROP USER jim;

-- Change the name of the group.
openGauss=# ALTER GROUP super_users RENAME TO normal_users;

-- Drop users.
openGauss=# DROP ROLE lche, jim;

-- Drop the user group.
openGauss=# DROP GROUP normal_users;
```

## Helpful Links

[CREATE GROUP](#), [DROP GROUP](#), and [ALTER ROLE](#)

## 7.13.10 ALTER INDEX

### Description

ALTER INDEX modifies the definition of an existing index.

It has the following forms:

- IF EXISTS  
Sends a notice instead of an error if the specified index does not exist.
- RENAME TO  
Changes only the name of the index. The stored data is not affected.
- SET TABLESPACE  
This option changes the index tablespace to the specified tablespace and moves index-related data files to the new tablespace.
- SET ( { STORAGE\_PARAMETER = value } [, ...] )  
Changes one or more index-method-specific storage parameters of an index. Note that the index content will not be modified immediately by this statement. You may need to use REINDEX to rebuild the index based on different parameters to achieve the expected effect.
- RESET ( { storage\_parameter } [, ...] )  
Resets one or more index-method-specific storage parameters of an index to the default value. Similar to the SET statement, REINDEX may be used to completely update the index.
- [ MODIFY PARTITION index\_partition\_name ] UNUSABLE  
Sets the indexes on a table or index partition to be unavailable.
- REBUILD [ PARTITION index\_partition\_name ]  
Rebuilds indexes on a table or an index partition.

- **RENAME PARTITION**  
Renames an index partition.
- **MOVE PARTITION**  
Modifies the tablespace to which an index partition belongs.

## Precautions

Only the index owner or a user who has the INDEX permission on the table where the index resides can run the **ALTER INDEX** command. System administrators have this permission by default.

## Syntax

- Rename a table index.  

```
ALTER INDEX [IF EXISTS] index_name
 RENAME TO new_name;
```
- Alter the tablespace to which a table index belongs.  

```
ALTER INDEX [IF EXISTS] index_name
 SET TABLESPACE tablespace_name;
```
- Modify the storage parameter of a table index.  

```
ALTER INDEX [IF EXISTS] index_name
 SET ({storage_parameter = value} [, ...]);
```
- Reset the storage parameter of a table index.  

```
ALTER INDEX [IF EXISTS] index_name
 RESET (storage_parameter [, ...]);
```
- Set a table index or an index partition to be unavailable.  

```
ALTER INDEX [IF EXISTS] index_name
 [MODIFY PARTITION index_partition_name] UNUSABLE;
```
- Rebuild a table index or index partition.  

```
ALTER INDEX index_name
 REBUILD [PARTITION index_partition_name];
```
- Rename an index partition.  

```
ALTER INDEX [IF EXISTS] index_name
 RENAME PARTITION index_partition_name TO new_index_partition_name;
```
- Modify the tablespace to which an index partition belongs.  

```
ALTER INDEX [IF EXISTS] index_name
 MOVE PARTITION index_partition_name TABLESPACE new_tablespace;
```

## Parameters

- **index\_name**  
Specifies the index name to be modified.
- **new\_name**  
Specifies the new name of the index.  
Value range: a string that complies with the [Identifier Naming Conventions](#).
- **tablespace\_name**  
Specifies the tablespace name.  
Value range: an existing tablespace name.
- **storage\_parameter**  
Specifies the name of an index-method-specific parameter.
- **value**

Specifies the new value for an index-method-specific storage parameter. This might be a number or a word depending on the parameter.

- **new\_index\_partition\_name**  
Specifies the new name of an index partition.
- **index\_partition\_name**  
Specifies the name of an index partition.
- **new\_tablespace**  
Specifies a new tablespace.

## Examples

See [Examples](#) in "CREATE INDEX."

## Helpful Links

[CREATE INDEX](#), [DROP INDEX](#), and [REINDEX](#)

## 7.13.11 ALTER LANGUAGE

This version does not support this syntax.

## 7.13.12 ALTER MASKING POLICY

### Description

Alters a masking policy.

### Precautions

- Only users with the POLADMIN or SYSADMIN permission, or the initial user can perform this operation.
- The masking policy takes effect only after **enable\_security\_policy** is enabled.

### Syntax

- Modify the policy description.  
`ALTER MASKING POLICY policy_name COMMENTS policy_comments;`
- Modify the masking method.  
`ALTER MASKING POLICY policy_name [ADD | REMOVE | MODIFY] masking_actions[, ...]*;`  
The syntax of **masking\_action**:  
`masking_function ON LABEL(label_name[, ...]*)`
- Modify the scenarios where the masking policy takes effect.  
`ALTER MASKING POLICY policy_name MODIFY(FILTER ON FILTER_TYPE(filter_value[, ...]*)[, ...]*);`
- Remove the filters of the masking policy.  
`ALTER MASKING POLICY policy_name DROP FILTER;`
- Enable or disable the masking policy.  
`ALTER MASKING POLICY policy_name [ENABLE | DISABLE];`

### Parameters

- **policy\_name**  
Specifies the name of a masking policy, which must be unique.

Value range: a string that complies with the [Identifier Naming Conventions](#).

- **policy\_comments**

Adds or modifies description of the masking policy.

- **masking\_function**

Specifies eight preset masking methods or user-defined functions. Schemas are supported.

The maskall function is not preset. It is hard-coded and cannot be displayed by running `\df`.

The masking methods during presetting are as follows:

```
maskall | randommasking | creditcardmasking | basicemailmasking | fullemailmasking |
shufflemasking | alldigitsmasking | regexprmasking
```

- **label\_name**

Specifies the resource label name.

- **FILTER\_TYPE**

Specifies the types of information to be filtered by the masking policy, including **IP**, **ROLES**, and **APP**.

- **filter\_value**

Specifies the detailed information to be filtered, such as the IP address, app name, and username.

- **ENABLE|DISABLE**

Enables or disables the masking policy. If **ENABLE|DISABLE** is not specified, **ENABLE** is used by default.

## Examples

```
-- Create users dev_mask and bob_mask.
openGauss=# CREATE USER dev_mask PASSWORD '*****';
openGauss=# CREATE USER bob_mask PASSWORD '*****';

-- Create table tb_for_masking.
openGauss=# CREATE TABLE tb_for_masking(col1 text, col2 text, col3 text);

-- Create a resource label for sensitive column col1.
openGauss=# CREATE RESOURCE LABEL mask_lb1 ADD COLUMN(tb_for_masking.col1);

-- Create a resource label for sensitive column col2.
openGauss=# CREATE RESOURCE LABEL mask_lb2 ADD COLUMN(tb_for_masking.col2);

-- Create a masking policy for the operation of accessing sensitive column col1.
openGauss=# CREATE MASKING POLICY maskpol1 maskall ON LABEL(mask_lb1);

-- Add description for masking policy maskpol1.
openGauss=# ALTER MASKING POLICY maskpol1 COMMENTS 'masking policy for tb_for_masking.col1';

-- Modify masking policy maskpol1 to add a masking method.
openGauss=# ALTER MASKING POLICY maskpol1 ADD randommasking ON LABEL(mask_lb2);

-- Modify masking policy maskpol1 to remove a masking method.
openGauss=# ALTER MASKING POLICY maskpol1 REMOVE randommasking ON LABEL(mask_lb2);

-- Modify masking policy maskpol1 to modify a masking method.
openGauss=# ALTER MASKING POLICY maskpol1 MODIFY randommasking ON LABEL(mask_lb1);

-- Modify masking policy maskpol1 so that it takes effect only for scenarios where users are dev_mask and bob_mask, the client tool is gsql, and the IP addresses are 10.20.30.40 and 127.0.0.0/24.
openGauss=# ALTER MASKING POLICY maskpol1 MODIFY (FILTER ON ROLES(dev_mask, bob_mask),
APP(gsql), IP('10.20.30.40', '127.0.0.0/24'));
```

```
-- Modify masking policy maskpol1 so that it takes effect for all user scenarios.
openGauss=# ALTER MASKING POLICY maskpol1 DROP FILTER;

-- Disable masking policy maskpol1.
openGauss=# ALTER MASKING POLICY maskpol1 DISABLE;

-- Drop a masking policy.
openGauss=# DROP MASKING POLICY maskpol1;

-- Drop resource labels.
openGauss=# DROP RESOURCE LABEL mask_lb1, mask_lb2;

-- Drop the tb_for_masking table.
openGauss=# DROP TABLE tb_for_masking;

-- Drop the dev_mask and bob_mask users.
openGauss=# DROP USER dev_mask, bob_mask;
```

## 7.13.13 ALTER MATERIALIZED VIEW

### Description

Alters multiple auxiliary attributes of an existing materialized view.

Statements and actions that can be used for ALTER MATERIALIZED VIEW are a subset of ALTER TABLE and have the same meaning when used for materialized views. For details, see [ALTER TABLE](#).

### Precautions

- Only the owner of a materialized view or a system administrator has the ALTER MATERIALIZED VIEW permission.
- The materialized view structure cannot be modified.

### Syntax

- Alter the owner of the materialized view.  

```
ALTER MATERIALIZED VIEW [IF EXISTS] mv_name
OWNER TO new_owner;
```
- Modify the column of a materialized view.  

```
ALTER MATERIALIZED VIEW [IF EXISTS] mv_name
RENAME [COLUMN] column_name TO new_column_name;
```
- Rename a materialized view.  

```
ALTER MATERIALIZED VIEW [IF EXISTS] mv_name
RENAME TO new_name;
```

### Parameters

- **mv\_name**  
Specifies the name of an existing materialized view, which can be schema-qualified.  
Value range: a string that complies with the [Identifier Naming Conventions](#).

- **column\_name**  
Specifies the name of a new or existing column.  
Value range: a string that complies with the [Identifier Naming Conventions](#).
- **new\_column\_name**  
Specifies the new name of an existing column.
- **new\_owner**  
Specifies the username of the new owner of a materialized view.
- **new\_name**  
Specifies the new name of a materialized view.

## Examples

```
-- Create a table.
openGauss=# CREATE TABLE my_table (c1 int, c2 int) WITH(STORAGE_TYPE=ASTORE);

-- Create a complete-refresh materialized view.
openGauss=# CREATE MATERIALIZED VIEW foo AS SELECT * FROM my_table;

-- Rename the materialized view foo to bar.
openGauss=# ALTER MATERIALIZED VIEW foo RENAME TO bar;

-- Drop a complete-refresh materialized view.
openGauss=# DROP MATERIALIZED VIEW bar;

-- Drop the my_table table.
openGauss=# DROP TABLE my_table;
```

[DROP MATERIALIZED VIEW](#), [REFRESH INCREMENTAL MATERIALIZED VIEW](#),  
and [REFRESH MATERIALIZED VIEW](#)

## 7.13.14 ALTER OPERATOR

### Description

Alters the definition of an operator.

### Precautions

ALTER OPERATOR changes the definition of an operator. Currently, the only function available is to change the owner of the operator.

To use ALTER OPERATOR, you must be the owner of the operator. To modify the owner, you must also be a direct or indirect member of the new owning role, and that member must have CREATE permission on the operator's schema. (These restrict that the owner cannot be changed by doing anything other than deleting or rebuilding the operator. However, a user with the SYSADMIN permission can change the ownership of any operator in any way.)

### Syntax

```
ALTER OPERATOR name ({ left_type | NONE } , { right_type | NONE }) OWNER TO new_owner
ALTER OPERATOR name ({ left_type | NONE } , { right_type | NONE }) SET SCHEMA new_schema
```

## Parameters

- **name**  
Name of an existing operator.
- **left\_type**  
Data type of the left operand for the operator; if there is no left operand, write **NONE**.
- **right\_type**  
Data type of the right operand for the operator; if there is no right operand, write **NONE**.
- **new\_owner**  
New owner of the operator.
- **new\_schema**  
New schema name of the operator.

## Examples

Alter a user-defined operator for text a @@ b:

```
ALTER OPERATOR @@ (text, text) OWNER TO joe;
```

## Compatibility

The SQL standard does not contain the ALTER OPERATOR statement.

## Helpful Links

[CREATE OPERATOR](#), [CREATE OPERATOR CLASS](#), and [DROP OPERATOR](#)

## 7.13.15 ALTER PACKAGE

### Description

Alters the attributes of a package.

### Precautions

Currently, only users with the ALTER PACKAGE OWNER permission can run this command. By default, system administrators have the permission. The restrictions are as follows:

- The current user must be the owner of the package or a system administrator and a member of the new owner role.

### Syntax

- Alter the owner of a package.  

```
ALTER PACKAGE package_name OWNER TO new_owner;
```

### Parameters

- **package\_name**

Specifies the name of the package to be modified.

Value range: an existing package name. Only one package can be modified at a time.

- **new\_owner**

Specifies the new owner of a package. To change the owner of a package, the new owner must have the CREATE permission on the schema to which the package belongs.

Value range: an existing user role.

## Examples

For details, see [CREATE PACKAGE](#).

## Helpful Links

[CREATE PACKAGE](#) and [DROP PACKAGE](#)

## 7.13.16 ALTER PROCEDURE

### Description

Modify the owner of a user-defined stored procedure.

### Precautions

Only the owner of a stored procedure or a user granted with the ALTER permission can run the **ALTER PROCEDURE** command. System administrators have this permission by default. The following are permission restrictions depending on attributes to be modified:

- If a stored procedure involves operations on temporary tables, ALTER PROCEDURE cannot be used.
- To modify the owner or schema of a stored procedure, you must be the owner of the stored procedure or system administrator and a member of the new owner role.
- Only system administrators and the initial user can change the schema of a stored procedure to a public schema.

### Syntax

- Modify the additional parameters of a user-defined stored procedure.

```
ALTER PROCEDURE procedure_name ([{ [argname] [argmode] argtype } [, ...]])
action [...] [RESTRICT];
```

The syntax of the ACTION clause is as follows:

```
{ CALLED ON NULL INPUT | STRICT }
| { IMMUTABLE | STABLE | VOLATILE }
| { SHIPPABLE | NOT SHIPPABLE }
| { NOT FENCED | FENCED }
| [NOT] LEAKPROOF
| { [EXTERNAL] SECURITY INVOKER | [EXTERNAL] SECURITY DEFINER }
| AUTHID { DEFINER | CURRENT_USER }
| COST execution_cost
| ROWS result_rows
| SET configuration_parameter { { TO | = } { value | DEFAULT } } FROM CURRENT}
| RESET { configuration_parameter | ALL }
```

- Modify the name of a user-defined stored procedure.  

```
ALTER PROCEDURE proname ([{ [argname] [argmode] argtype} [, ...]])
 RENAME TO new_name;
```
- Modify the owner of a user-defined stored procedure.  

```
ALTER PROCEDURE proname ([{ [argname] [argmode] argtype} [, ...]])
 OWNER TO new_owner;
```
- Modify the schema of a user-defined stored procedure.  

```
ALTER PROCEDURE proname ([{ [argname] [argmode] argtype} [, ...]])
 SET SCHEMA new_schema;
```

## Parameters

- **procedure\_name**  
Specifies the name of the stored procedure to be modified.  
Value range: an existing stored procedure name.
- **argmode**  
Specifies whether a parameter is an input or output parameter.  
Value range: **IN**, **OUT**, **INOUT**, and **VARIADIC**.
- **argname**  
Specifies the parameter name.  
Value range: a string that complies with the [Identifier Naming Conventions](#).
- **argtype**  
Specifies the type of the stored procedure parameter.
- **CALLED ON NULL INPUT**  
Declares that some parameters of the stored procedure can be called in normal mode if the parameter values are **NULL**. Omitting this parameter is the same as specifying it.
- **IMMUTABLE**  
Specifies that the stored procedure always returns the same result if the parameter values are the same.
- **STABLE**  
Specifies that the stored procedure cannot modify the database, and that within a single table scan it will consistently return the same result for the same parameter value, but its result varies by SQL statements.
- **VOLATILE**  
Specifies that the stored procedure value can change in a single table scan and no optimization is performed.
- **LEAKPROOF**  
Specifies that the stored procedure has no side effect and the parameter contains only the return value. **LEAKPROOF** can be set only by system administrators.
- **EXTERNAL**  
(Optional) The purpose is to be compatible with SQL. This feature applies to all functions, not only external functions.
- **SECURITY INVOKER**  
**AUTHID CURRENT\_USER**

Specifies that the stored procedure will be executed with the permissions of the user who calls it. Omitting this parameter is the same as specifying it.

**SECURITY INVOKER** and **AUTHID CURRENT\_USER** have the same functions.

- **SECURITY DEFINER**

**AUTHID DEFINER**

Specifies that the stored procedure will be executed with the permissions of the user who created it.

**AUTHID DEFINER** and **SECURITY DEFINER** have the same functions.

- **COST execution\_cost**

Estimates the execution cost of the stored procedure.

The unit of **execution\_cost** is **cpu\_operator\_cost**.

Value range: a positive integer.

- **ROWS result\_rows**

Estimates the number of rows returned by the stored procedure. This is only allowed when the stored procedure is declared to return a set.

Value range: a positive number. The default value is **1000**.

- **configuration\_parameter**

- **value**

Sets a specified database session parameter to a specified value. If the value is **DEFAULT** or **RESET**, the default setting is used in the new session. **OFF** disables the setting.

Value range: a string.

- **DEFAULT**
    - **OFF**
    - **RESET**
    - Specified default value

- **FROM CURRENT**

Uses the value of **configuration\_parameter** of the current session.

- **new\_name**

Specifies the new name of the stored procedure. To change the schema of a stored procedure, you must have the CREATE permission on the new schema.

Value range: a string that complies with the [Identifier Naming Conventions](#).

- **new\_owner**

Specifies the new owner of the stored procedure. To change the owner of a stored procedure, the new owner must have the CREATE permission on the schema to which the stored procedure belongs.

Value range: an existing user role.

- **new\_schema**

Specifies the new schema of the stored procedure.

Value range: an existing schema.

## Examples

See [Examples](#) in "CREATE FUNCTION."

## Helpful Links

[CREATE PROCEDURE](#) and [DROP PROCEDURE](#)

## 7.13.17 ALTER RESOURCE LABEL

### Description

Alters resource labels.

### Precautions

Only users with the POLADMIN or SYSADMIN permission, or the initial user can perform this operation.

### Syntax

```
ALTER RESOURCE LABEL label_name (ADD|REMOVE)
label_item_list[, ...]*;
```

- **label\_item\_list**  
resource\_type(resource\_path[, ...]\*)
- **resource\_type**  
TABLE | COLUMN | SCHEMA | VIEW | FUNCTION

### Parameters

- **label\_name**  
Specifies the resource label name.  
Value range: a string that complies with the [Identifier Naming Conventions](#).
- **resource\_type**  
Specifies the type of database resources to be labeled.
- **resource\_path**  
Specifies the path of database resources.

## Examples

```
-- Create basic table table_for_label.
openGauss=# CREATE TABLE table_for_label(col1 int, col2 text);

-- Create resource label table_label.
openGauss=# CREATE RESOURCE LABEL table_label ADD COLUMN(table_for_label.col1);

-- Attach resource label table_label to col2.
openGauss=# ALTER RESOURCE LABEL table_label ADD COLUMN(table_for_label.col2)

-- Remove table_label from an item.
openGauss=# ALTER RESOURCE LABEL table_label REMOVE COLUMN(table_for_label.col1);

-- Drop the resource label table_label.
openGauss=# DROP RESOURCE LABEL table_label;
```

```
-- Drop the base table table_for_label.
openGauss=# DROP TABLE table_for_label;
```

## Helpful Links

[CREATE RESOURCE LABEL](#) and [DROP RESOURCE LABEL](#)

## 7.13.18 ALTER ROLE

### Description

Alters role attributes.

### Precautions

None

### Syntax

- Modify the permissions of a role.

```
ALTER ROLE role_name [[WITH] option [...]];
```

The option clause for granting permissions is as follows:

```
{CREATEDB | NOCREATEDB}
| {CREATEROLE | NOCREATEROLE}
| {INHERIT | NOINHERIT}
| {AUDITADMIN | NOAUDITADMIN}
| {SYSADMIN | NOSYSADMIN}
| {MONADMIN | NOMONADMIN}
| {OPRADMIN | NOOPRADMIN}
| {POLADMIN | NOPOLADMIN}
| {USEFT | NOUSEFT}
| {LOGIN | NOLOGIN}
| {REPLICATION | NOREPLICATION}
| {VCADMIN | NOVCADMIN}
| {PERSISTENCE | NOPERSISTENCE}
| CONNECTION LIMIT connlimit
| [ENCRYPTED | UNENCRYPTED] PASSWORD 'password' [EXPIRED]
| [ENCRYPTED | UNENCRYPTED] IDENTIFIED BY 'password' [REPLACE 'old_password' | EXPIRED]
| [ENCRYPTED | UNENCRYPTED] PASSWORD { 'password' | DISABLE | EXPIRED }
| [ENCRYPTED | UNENCRYPTED] IDENTIFIED BY { 'password' [REPLACE 'old_password'] |
DISABLE }
| VALID BEGIN 'timestamp'
| VALID UNTIL 'timestamp'
| PERM SPACE 'spacelimit'
| PGUSER
```

- Rename a role.

```
ALTER ROLE role_name
RENAME TO new_name;
```

- Lock or unlock.

```
ALTER ROLE role_name
ACCOUNT { LOCK | UNLOCK };
```

- Set parameters for a role.

```
ALTER ROLE role_name [IN DATABASE database_name]
SET configuration_parameter {{ TO | = } { value | DEFAULT } | FROM CURRENT};
```

- Reset parameters for a role.

```
ALTER ROLE role_name
[IN DATABASE database_name] RESET {configuration_parameter|ALL};
```

## Parameters

- **role\_name**  
Specifies a role name.  
Value range: an existing role name. If a role name contains uppercase letters, enclose the name with double quotation marks ("").
- **IN DATABASE database\_name**  
Modifies the parameters of a role in a specified database.
- **SET configuration\_parameter {{ TO | = } { value | DEFAULT } | FROM CURRENT}**  
Sets parameters for a role. Session parameters modified by **ALTER ROLE** apply to a specified role and take effect in the next session triggered by the role.  
Value range:  
For details about the values of **configuration\_parameter** and **value**, see [SET](#).  
**DEFAULT**: clears the value of **configuration\_parameter**.  
**configuration\_parameter** will inherit the default value of the new session generated for the role.  
**FROM CURRENT**: uses the value of **configuration\_parameter** of the current session.
- **RESET {configuration\_parameter|ALL}**  
Clears the value of **configuration\_parameter**. The statement has the same effect as that of **SET configuration\_parameter TO DEFAULT**.  
Value range: **ALL** indicates that the values of all parameters are cleared.
- **ACCOUNT LOCK | ACCOUNT UNLOCK**
  - **ACCOUNT LOCK**: locks an account to forbid login to databases.
  - **ACCOUNT UNLOCK**: unlocks an account to allow login to databases.
- **PGUSER**  
In the current version, the PGUSER permission of a role cannot be modified.
- **PASSWORD/IDENTIFIED BY 'password'**  
Resets or changes the user password. Except the initial user, other administrators and common users need to enter the correct old password when changing their own passwords. Only the initial user or users with the SYSADMIN or CREATEROLE permission can reset the password of a common user without entering the old password. The initial user can reset passwords of system administrators. A system administrator cannot reset passwords of other system administrators. The user password should be enclosed in single quotation marks ('').
- **EXPIRED**  
Invalidates the password. Only the initial user or users with the SYSADMIN or CREATEROLE permission can invalidate user passwords. A system administrator can invalidate their own passwords or the passwords of other system administrators. The password of the initial user cannot be invalidated.  
The user whose password is invalid can log in to the database but cannot perform the query operation. The query operation can be performed only after the password is changed or an administrator resets the password.

For details about other parameters, see [Parameters](#) in "CREATE ROLE."

## Examples

See [Examples](#) in "CREATE ROLE."

## Helpful Links

# 7.13.19 ALTER ROW LEVEL SECURITY POLICY

## Description

Alters an existing row-level security policy, including the policy name and the users and expressions affected by the policy.

## Precautions

Only the table owner or a system administrator can perform this operation.

## Syntax

```
ALTER [ROW LEVEL SECURITY] POLICY [IF EXISTS] policy_name ON table_name RENAME TO
new_policy_name;
```

```
ALTER [ROW LEVEL SECURITY] POLICY policy_name ON table_name
[TO { role_name | PUBLIC } [, ...]]
[USING (using_expression)];
```

## Parameters

- **policy\_name**  
Specifies the name of a row-level security policy.
- **table\_name**  
Specifies the name of a table to which a row-level security policy is applied.
- **new\_policy\_name**  
Specifies the new name of a row-level security policy.
- **role\_name**  
Specifies names of users affected by a row-level security policy. PUBLIC indicates that the row-level security policy will affect all users.
- **using\_expression**  
Specifies an expression defined for a row-level security policy. The return value is of the Boolean type.

## Examples

```
-- Create data table all_data.
openGauss=# CREATE TABLE all_data(id int, role varchar(100), data varchar(100));

-- Create a row-level security policy to specify that the current user can view only their own data.
openGauss=# CREATE ROW LEVEL SECURITY POLICY all_data_rls ON all_data USING(role =
CURRENT_USER);
openGauss=# \d+ all_data
 Table "public.all_data"
Column | Type | Modifiers | Storage | Stats target | Description
-----+-----+-----+-----+-----+-----
```

```
id | integer | | plain | |
role | character varying(100) | | extended | |
data | character varying(100) | | extended | |
Row Level Security Policies:
 POLICY "all_data_rls"
 USING (((role)::name = "current_user"()))
Has OIDs: no
Location Nodes: ALL DATANODES
Options: orientation=row

-- Create users alice and bob.
openGauss=# CREATE ROLE alice WITH PASSWORD '*****';
openGauss=# CREATE ROLE bob WITH PASSWORD '*****';

-- Change the name of the all_data_rls policy.
openGauss=# ALTER ROW LEVEL SECURITY POLICY all_data_rls ON all_data RENAME TO all_data_new_rls;

-- Change the users affected by the row-level security policy.
openGauss=# ALTER ROW LEVEL SECURITY POLICY all_data_new_rls ON all_data TO alice, bob;
openGauss=# \d+ all_data
 Table "public.all_data"
 Column | Type | Modifiers | Storage | Stats target | Description
-----+-----+-----+-----+-----+-----
id | integer | | plain | |
role | character varying(100) | | extended | |
data | character varying(100) | | extended | |
Row Level Security Policies:
 POLICY "all_data_new_rls"
 TO alice,bob
 USING (((role)::name = "current_user"()))
Has OIDs: no
Location Nodes: ALL DATANODES
Options: orientation=row, enable_rowsecurity=true

-- Modify the expression defined for the row-level security policy.
openGauss=# ALTER ROW LEVEL SECURITY POLICY all_data_new_rls ON all_data USING (id > 100 AND role
= current_user);
openGauss=# \d+ all_data
 Table "public.all_data"
 Column | Type | Modifiers | Storage | Stats target | Description
-----+-----+-----+-----+-----+-----
id | integer | | plain | |
role | character varying(100) | | extended | |
data | character varying(100) | | extended | |
Row Level Security Policies:
 POLICY "all_data_new_rls"
 TO alice,bob
 USING (((id > 100) AND ((role)::name = "current_user"())))
Has OIDs: no
Location Nodes: ALL DATANODES
Options: orientation=row, enable_rowsecurity=true

-- Drop users alice and bob.
openGauss=# DROP ROLE alice, bob;

-- Drop the policy.
openGauss=# DROP ROW LEVEL SECURITY POLICY all_data_new_rls ON all_data;

-- Drop the all_data table.
openGauss=# DROP TABLE all_data;
```

## Helpful Links

[CREATE ROW LEVEL SECURITY POLICY](#) and [DROP ROW LEVEL SECURITY POLICY](#)

## 7.13.20 ALTER SCHEMA

### Description

Alters schema attributes.

### Precautions

- Only the owner of a schema or users granted the ALTER permission on the schema can run the **ALTER SCHEMA** command. System administrators have this permission by default. To change the owner of a schema, you must be the owner of the schema or a system administrator and a member of the new owner role.
- Only the initial user is allowed to change the owner of the pg\_catalog system schema. Changing the names of the built-in system schemas may make some functions unavailable or even affect the normal running of the database. By default, the names of the built-in system schemas cannot be changed. To ensure forward compatibility, you can change the names of the built-in system schemas only when the system is being started or upgraded or when **allow\_system\_table\_mods** is set to **on**.

### Syntax

- Rename a schema.  

```
ALTER SCHEMA schema_name
 RENAME TO new_name;
```
- Change the owner of a schema.  

```
ALTER SCHEMA schema_name
 OWNER TO new_owner;
```

### Parameters

- **schema\_name**  
Specifies the name of an existing schema.  
Value range: an existing schema name.
- **RENAME TO new\_name**  
Renames a schema. If a non-SYSADMIN user wants to change the schema name, the user must have the CREATE permission on the database.  
**new\_name**: new name of the schema.  
Value range: a string that complies with the [Identifier Naming Conventions](#).
- **OWNER TO new\_owner**  
Changes the owner of a schema. To do this as a non-system administrator, you must be a direct or indirect member of the new owner role, and that role must have the CREATE permission on the database.  
**new\_owner**: new owner of the schema.  
Value range: an existing username or role name.

### Examples

```
-- Create the ds schema.
openGauss=# CREATE SCHEMA ds;
```

```
-- Rename the current schema ds to ds_new.
openGauss=# ALTER SCHEMA ds RENAME TO ds_new;

-- Create user jack.
openGauss=# CREATE USER jack PASSWORD '*****';

-- Change the owner of ds_new to jack.
openGauss=# ALTER SCHEMA ds_new OWNER TO jack;

-- Drop user jack and schema ds_new.
openGauss=# DROP SCHEMA ds_new;
openGauss=# DROP USER jack;
```

## Helpful Links

[CREATE SCHEMA](#) and [DROP SCHEMA](#)

### 7.13.21 ALTER SEQUENCE

#### Description

Alters the parameters of an existing sequence.

#### Precautions

- Only the sequence owner or a user granted with the ALTER permission can run the **ALTER SEQUENCE** command. System administrators have this permission by default. To modify a sequence owner, you must be the sequence owner or a system administrator and a member of the new owner role.
- In the current version, you can modify only the owner, owning column, and maximum value. To change other parameters, drop the sequence and create it again. Then, use the Setval function to restore parameter values.
- ALTER SEQUENCE MAXVALUE cannot be used in transactions, functions, or stored procedures.
- After the maximum value of a sequence is changed, the cache of the sequence in all sessions is cleared.
- If the LARGE identifier is used when a sequence is created, the LARGE identifier must be used when the sequence is altered.
- The ALTER SEQUENCE statement blocks the calling of nextval, setval, curval, and lastval.

#### Syntax

- Change the owning column of a sequence.  

```
ALTER [LARGE] SEQUENCE [IF EXISTS] name
 [MAXVALUE maxvalue | NO MAXVALUE | NOMAXVALUE | CACHE cache]
 [OWNED BY { table_name.column_name | NONE }] ;
```
- Change the owner of a sequence.  

```
ALTER [LARGE] SEQUENCE [IF EXISTS] name OWNER TO new_owner;
```

#### Parameters

- **name**  
Specifies the name of the sequence to be modified.

- **IF EXISTS**  
Sends a notice instead of an error when you are modifying a nonexistent sequence.
- **CACHE**  
Specifies the number of sequences stored in the memory for quick access purposes. If this parameter is not specified, the old cache value is retained.
- **OWNED BY**  
Joins a sequence with a specified column included in a table. In this way, the sequence will be dropped when you drop its joined column or the table where the column belongs to.  
  
If the sequence has been joined with another table before you use this option, the new join will overwrite the old one.  
  
The joined table and sequence must be owned by the same user and in the same schema.  
  
If **OWNED BY NONE** is used, all existing joins will be dropped.
- **new\_owner**  
Specifies the username of the new owner of the sequence. To change the owner, you must also be a direct or indirect member of the new role, and this role must have the CREATE permission on the sequence's schema.

## Examples

```
-- Create an ascending sequence named serial, starting from 101.
openGauss=# CREATE SEQUENCE serial START 101;

-- Create a table and specify default values for the sequence.
openGauss=# CREATE TABLE T1(C1 bigint default nextval('serial'));

-- Change the owning column of serial to T1.C1.
openGauss=# ALTER SEQUENCE serial OWNED BY T1.C1;

-- Drop a sequence and a table.
openGauss=# DROP SEQUENCE serial cascade;
openGauss=# DROP TABLE T1;
```

## Helpful Links

[CREATE SEQUENCE](#) and [DROP SEQUENCE](#)

## 7.13.22 ALTER SERVER

### Description

Adds, alters, or deletes the parameters of an existing server. You can query existing servers from the pg\_foreign\_server system catalog.

### Precautions

Only the server owner or a user granted the ALTER permission can run the **ALTER SERVER** command. By default, system administrators have the permission. To modify a server owner, you must be the server owner or system administrator and a member of the new owner role.

When multi-layer quotation marks are used for sensitive columns (such as **password** and **secret\_access\_key**) in **OPTIONS**, the semantics is different from that in the scenario where quotation marks are not used. Therefore, sensitive columns are not identified for anonymization.

## Syntax

- Change the parameters for a foreign server.

```
ALTER SERVER server_name [VERSION 'new_version']
[OPTIONS ({[ADD | SET | DROP] option ['value']} [, ...])];
```

In **OPTIONS**, **ADD**, **SET**, and **DROP** are operations to be performed. If these operations are not specified, ADD operations will be performed by default. **option** and **value** are the parameters of the corresponding operation.

- Change the name of a foreign server.

```
ALTER SERVER server_name
RENAME TO new_name;
```

## Parameters

- server\_name**

Specifies the name of the server to be modified.

- new\_version**

Specifies the latest version of the server.

- OPTIONS**

Changes options of the server. **ADD**, **SET**, and **DROP** are operations to be performed. If the operation is not specified explicitly, ADD operations will be performed. The option name must be unique, and the name and value are also validated with the foreign data wrapper library of the server.

In addition to the connection parameters supported by libpq, the following parameters are provided:

- **fdw\_startup\_cost**

Estimates the startup time required for a foreign table scan, including the time to establish a connection, analyze the request at the remote server, and generate a plan. The default value is **100**.

- **fdw\_tuple\_cost**

Specifies the additional consumption when each tuple is scanned on a remote server. The value specifies the extra consumption of data transmission between servers. The default value is **0.01**.

- new\_name**

Specifies the new name of the server.

## Examples

```
-- Create my_server.
openGauss=# CREATE SERVER my_server FOREIGN DATA WRAPPER log_fdw;

-- Change the name of a foreign server.
openGauss=# ALTER SERVER my_server
RENAME TO my_server_1;

-- Drop my_server_1.
openGauss=# DROP SERVER my_server_1;
```

### 7.13.23 ALTER SESSION

#### Description

ALTER SESSION defines or modifies the conditions or parameters that affect the current session. Modified session parameters are kept until the current session is disconnected.

#### Precautions

- If the **START TRANSACTION** statement is not executed before the **SET TRANSACTION** statement, the transaction is ended instantly and the statement does not take effect.
- You can use the **transaction\_mode(s)** method declared in the **START TRANSACTION** statement to avoid using the **SET TRANSACTION** statement.

#### Syntax

- Set transaction parameters of a session.  

```
ALTER SESSION SET [SESSION CHARACTERISTICS AS] TRANSACTION
 { ISOLATION LEVEL { READ COMMITTED } | { READ ONLY | READ WRITE } } [, ...] ;
```
- Set other GUC parameters of a session.  

```
ALTER SESSION SET
 {{config_parameter { { TO | = } { value | DEFAULT }
 | FROM CURRENT }}
 | TIME ZONE time_zone

 | SCHEMA 'schema'
 | NAMES encoding_name
 | ROLE role_name PASSWORD 'password'
 | SESSION AUTHORIZATION { role_name PASSWORD 'password' | DEFAULT }
 | XML OPTION { DOCUMENT | CONTENT }
 } ;
```

#### Parameters

- **SESSION**  
Specifies that the specified parameters take effect for the current session. If neither **SESSION** nor **LOCAL** appears, **SESSION** is the default value.  
If this command is executed in a transaction, the effect of the command disappears after the transaction is rolled back. Once the surrounding transaction is committed, the effect will persist until the end of the session, unless the parameters are reset by another SET statement.
- **TIME ZONE time\_zone**  
Specifies the local time zone for the current session.  
Value range: a valid local time zone. The corresponding GUC parameter is **TimeZone**. The default value is **PRC**.
- **CURRENT\_SCHEMA schema**  
Specifies the current schema.

Value range: an existing schema name. If the schema name does not exist, the value of **CURRENT\_SCHEMA** will be empty.

- **SCHEMA schema**

Specifies the current schema. Here the schema is a string.

Example: set schema 'public';

- **NAMES encoding\_name**

Specifies the client character encoding. This statement is equivalent to **set client\_encoding to encoding\_name**.

Value range: a valid character encoding name. The GUC parameter corresponding to this option is **client\_encoding**. The default encoding is **UTF8**.

- **XML OPTION option**

Specifies the XML parsing mode.

Value range: **CONTENT** (default) and **DOCUMENT**.

- **config\_parameter**

Specifies the name of a configurable GUC parameter. You can use **SHOW ALL** to view the available GUC parameters.

## Examples

```
-- Create the ds schema.
openGauss=# CREATE SCHEMA ds;

-- Set the search path of the schema.
openGauss=# SET SEARCH_PATH TO ds, public;

-- Set the time/date type to the traditional Postgres format (date before month).
openGauss=# SET DATESTYLE TO postgres, dmy;

-- Set the character code of the current session to UTF8.
openGauss=# ALTER SESSION SET NAMES 'UTF8';

-- Set the time zone to Berkeley of California.
openGauss=# SET TIME ZONE 'PST8PDT';

-- Set the time zone to Italy.
openGauss=# SET TIME ZONE 'Europe/Rome';

-- Set the current schema.
openGauss=# ALTER SESSION SET CURRENT_SCHEMA TO tpcds;

-- Set XML OPTION to DOCUMENT.
openGauss=# ALTER SESSION SET XML OPTION DOCUMENT;

-- Create the role joe, and set the session role to joe.
openGauss=# CREATE ROLE joe WITH PASSWORD '*****!';
openGauss=# ALTER SESSION SET SESSION AUTHORIZATION joe PASSWORD '*****!';

-- Switch to the default user.
openGauss=> ALTER SESSION SET SESSION AUTHORIZATION default;

-- Drop the ds schema.
openGauss=# DROP SCHEMA ds;

-- Drop the role joe.
openGauss=# DROP ROLE joe;

-- Start a transaction and set the transaction level.
openGauss=# START TRANSACTION;
```

```
openGauss=# ALTER SESSION SET TRANSACTION READ ONLY;
openGauss=# END;
```

## 7.13.24 ALTER SYNONYM

### Description

Alters the attributes of the SYNONYM object.

### Precautions

- Currently, only the owner of the SYNONYM object can be changed.
- Only system administrators have the permission to modify the owner of the SYNONYM object.
- The new owner must have the CREATE permission on the schema where the SYNONYM object resides.

### Syntax

```
ALTER SYNONYM synonym_name
OWNER TO new_owner;
```

### Parameters

- **synonym\_name**  
Specifies the name of the synonym to be modified, which can contain the schema name.  
Value range: a string that complies with the [Identifier Naming Conventions](#).
- **new\_owner**  
Specifies the new owner of the SYNONYM object.  
Value range: a string. It must be a valid username.

### Examples

```
-- Create synonym t1.
openGauss=# CREATE OR REPLACE SYNONYM t1 FOR ot.t1;

-- Create user u1.
openGauss=# CREATE USER u1 PASSWORD '*****';

-- Change the owner of synonym t1 to u1.
openGauss=# ALTER SYNONYM t1 OWNER TO u1;

-- Drop synonym t1.
openGauss=# DROP SYNONYM t1;

-- Drop user u1.
openGauss=# DROP USER u1;
```

## 7.13.25 ALTER SYSTEM KILL SESSION

### Description

**ALTER SYSTEM KILL SESSION** ends a session.

### Precautions

None

### Syntax

```
ALTER SYSTEM KILL SESSION 'session_sid, serial' [IMMEDIATE];
```

### Parameters

- **session\_sid, serial**  
Specifies the SID and SERIAL of a session (To obtain the values, see the example.)  
Value range: SIDs and SERIALs of all sessions that can be queried from the system catalog dv\_sessions.
- **IMMEDIATE**  
Specifies that a session will be ended instantly after the statement is executed.

### Examples

```
-- Query session information.
openGauss=# SELECT sa.sessionid AS sid,0::integer AS serial#,ad.rolname AS username FROM
pg_stat_get_activity(NULL) AS sa LEFT JOIN pg_authid ad ON(sa.usesysid = ad.oid)WHERE
sa.application_name <> 'JobScheduler';
 sid | serial# | username
-----+-----+-----
140131075880720 | 0 | omm
140131025549072 | 0 | omm
140131073779472 | 0 | omm
140131071678224 | 0 | omm
140131125774096 | 0 |
140131127875344 | 0 |
140131113629456 | 0 |
140131094742800 | 0 |
(8 rows)

-- End the session whose SID is 140131075880720.
openGauss=# ALTER SYSTEM KILL SESSION '140131075880720,0' IMMEDIATE;
```

## 7.13.26 ALTER TABLE

### Description

Alters tables, including modifying table definitions, renaming tables, renaming specified columns in tables, renaming table constraints, setting table schemas, enabling or disabling row-level security policies, and adding or updating multiple columns.

## Precautions

- The owner of a table, users granted with the ALTER permission on the table, or users granted with the ALTER ANY TABLE permission can run the **ALTER TABLE** command. System administrators have the permission to run the command by default. To modify the owner or schema of a table, you must be the table owner or a system administrator and a member of the new owner role.
- The tablespace of a partitioned table cannot be modified, but the tablespace of a partition can be modified.
- The storage parameter **ORIENTATION** cannot be modified.
- Currently, **SET SCHEMA** can only set schemas to user schemas. It cannot set a schema to a system internal schema.
- Auto-increment columns cannot be added, or a column whose **DEFAULT** value contains the nextval() expression cannot be added.
- Row-level security cannot be enabled for foreign tables and temporary tables.
- When you delete a PRIMARY KEY constraint by constraint name, the NOT NULL constraint is not deleted. If necessary, manually delete the NOT NULL constraint.
- When JDBC is used, the **DEFAULT** value can be set through **PreparedStatement**.
- If you add a column using ADD COLUMN, all existing rows in the table are initialized to the column's default value (**NULL** if no **DEFAULT** value is specified).

If no **DEFAULT** value is specified for the new column, **NULL** is used, and no full table update is triggered.

If the new column has a **DEFAULT** value, the column must meet all the following requirements. Otherwise, the entire table is updated, leading to additional overheads and affecting online services.

1. The data type is BOOL, BYTEA, SMALLINT, BIGINT, SMALLINT, INTEGER, NUMERIC, FLOAT, DOUBLE PRECISION, CHAR, VARCHAR, TEXT, TIMESTAMPTZ, TIMESTAMP, DATE, TIME, TIMETZ, or INTERVAL.

2. The length of the **DEFAULT** value of the added column cannot exceed 128 bytes.

3. The **DEFAULT** value of the added column does not contain the volatile function.

4. The **DEFAULT** value is required and cannot be **NULL**.

If you are not sure whether condition 3 is met, check whether the **provolatile** attribute of the function in the PG\_RPOC system catalog is 'v'.

## Syntax

- Modify the definition of a table.  

```
ALTER TABLE [IF EXISTS] { table_name [*] | ONLY table_name | ONLY (table_name) }
action [, ...];
```

  - There are several clauses of **column\_clause**:  

```
ADD [COLUMN] column_name data_type [COLLATE collation] [column_constraint [...]]
| MODIFY column_name data_type
| MODIFY column_name [CONSTRAINT constraint_name] NOT NULL [ENABLE]
| MODIFY column_name [CONSTRAINT constraint_name] NULL
```

```
| DROP [COLUMN] [IF EXISTS] column_name [RESTRICT | CASCADE]
| ALTER [COLUMN] column_name [SET DATA] TYPE data_type [COLLATE collation] [USING
expression]
| ALTER [COLUMN] column_name { SET DEFAULT expression | DROP DEFAULT }
| ALTER [COLUMN] column_name { SET | DROP } NOT NULL
| ALTER [COLUMN] column_name SET STATISTICS [PERCENT] integer
| ADD STATISTICS ((column_1_name, column_2_name [, ...]))
| DELETE STATISTICS ((column_1_name, column_2_name [, ...]))
| ALTER [COLUMN] column_name SET ({attribute_option = value} [, ...])
| ALTER [COLUMN] column_name RESET (attribute_option [, ...])
| ALTER [COLUMN] column_name SET STORAGE { PLAIN | EXTERNAL | EXTENDED | MAIN }
```

 NOTE

- **ADD [ COLUMN ] column\_name data\_type [ COLLATE collation ] [ column\_constraint [ ... ] ]**

Adds a column to a table. If you add a column using ADD COLUMN, all existing rows in the table are initialized to the column's default value (**NULL** if no **DEFAULT** value is specified).

- **ADD ( { column\_name data\_type } [, ...] )**

Adds columns in the table.

- **MODIFY ( { column\_name data\_type | column\_name [ CONSTRAINT constraint\_name ] NOT NULL [ ENABLE ] | column\_name [ CONSTRAINT constraint\_name ] NULL } [, ...] )**

Modifies the data type of an existing column in the table. Running this command will clear the statistics of this column. You are advised to collect the statistics of this column again after the modification.

- **DROP [ COLUMN ] [ IF EXISTS ] column\_name [ RESTRICT | CASCADE ]**

Drops a column from a table. Indexes and constraints related to the column are automatically dropped. If an object not belonging to the table depends on the column, **CASCADE** must be specified, such as a view.

The DROP COLUMN statement does not physically remove the column, but simply makes it invisible to SQL operations. Subsequent INSERT and UPDATE operations on the table will store a **NULL** value for the column. Therefore, dropping a column takes a short period of time but does not immediately release the tablespace on the disks, because the space occupied by the dropped column is not recycled. The space will be recycled when **VACUUM** is executed.

- **ALTER [ COLUMN ] column\_name [ SET DATA ] TYPE data\_type [ COLLATE collation ] [ USING expression ]**

Alters the type of a column in a table. Indexes and simple table constraints on the column will automatically use the new data type by reparsing the originally supplied expression.

If the original data type of a column and the modified data type are binary compatible, you do not need to rewrite the entire table when running this statement. In other scenarios, the entire table is rewritten. You can check whether the original type and target type are binary compatible in the PG\_CAST system catalog. If **castmethod** is 'b', they are binary compatible. For example, if the data type of the source table is text and is converted to int, table rewriting is triggered. If it is converted to clob, table rewriting is not triggered. If table rewriting is triggered, the deleted space on the table is recycled immediately.

Running this command will clear the statistics of this column. You are advised to collect the statistics of this column again after the modification.

- **ALTER [ COLUMN ] column\_name { SET DEFAULT expression | DROP DEFAULT }**

Sets or drops the default value for a column. The default values only apply to subsequent INSERT operations; they do not cause rows already in the table to change. Defaults can also be created for views, in which case they are inserted into INSERT statements on the view before the view's ON INSERT rule is applied.

- **ALTER [ COLUMN ] column\_name { SET | DROP } NOT NULL**

Alters whether a column is marked to allow **NULL** values or to reject **NULL** values. You can only use SET NOT NULL when the column contains non-**NULL** values.

- **ALTER [ COLUMN ] column\_name SET STATISTICS [PERCENT] integer**

Specifies the per-column statistics-collection target for subsequent ANALYZE operations. The target can be set in the range from 0 to 10000. Set it to -1 to revert to using the default system statistics target.

- **ALTER [ COLUMN ] column\_name SET ( {attribute\_option = value} [, ... ] )**  
**ALTER [ COLUMN ] column\_name RESET ( attribute\_option [, ... ] )**

Sets or resets per-attribute options.

Currently, the only defined per-attribute options are **n\_distinct** and **n\_distinct\_inherited**. **n\_distinct** affects statistics of a table, while **n\_distinct\_inherited** affects the statistics of the table and its subtables. Currently, only **SET/RESET n\_distinct** is supported, and **SET/RESET n\_distinct\_inherited** is forbidden.

- **ALTER [ COLUMN ] column\_name SET STORAGE { PLAIN | EXTERNAL | EXTENDED | MAIN }**

Sets the storage mode for a column. This clause specifies whether this column is held inline or in a secondary TOAST table, and whether the data should be compressed. Only row-store tables can be set. SET STORAGE itself does not change anything in the table. It sets the strategy to be pursued during future table updates.

**column\_constraint** is as follows:

```
[CONSTRAINT constraint_name]
{ NOT NULL |
 NULL |
 CHECK (expression) |
 DEFAULT default_expr |
 GENERATED ALWAYS AS (generation_expr) STORED |
 UNIQUE index_parameters |
 PRIMARY KEY index_parameters |
 REFERENCES reftable [(refcolumn)] [MATCH FULL | MATCH PARTIAL | MATCH SIMPLE]
 [ON DELETE action] [ON UPDATE action] } [DEFERRABLE | NOT DEFERRABLE |
INITIALLY DEFERRED | INITIALLY IMMEDIATE]
```

- **table\_constraint\_using\_index** used to add the primary key constraint or unique constraint based on the unique index is as follows:

```
[CONSTRAINT constraint_name]
{ UNIQUE | PRIMARY KEY } USING INDEX index_name
[DEFERRABLE | NOT DEFERRABLE | INITIALLY DEFERRED | INITIALLY IMMEDIATE]
```

- **table\_constraint** is as follows:

```
[CONSTRAINT constraint_name]
{ CHECK (expression) |
 UNIQUE (column_name [, ...]) index_parameters |
 PRIMARY KEY (column_name [, ...]) index_parameters |
 PARTIAL CLUSTER KEY (column_name [, ...]) }
FOREIGN KEY (column_name [, ...]) REFERENCES reftable [(refcolumn [, ...])]
[MATCH FULL | MATCH PARTIAL | MATCH SIMPLE] [ON DELETE action] [ON UPDATE
action] }
[DEFERRABLE | NOT DEFERRABLE | INITIALLY DEFERRED | INITIALLY IMMEDIATE]
```

**index\_parameters** is as follows:

```
[WITH ({storage_parameter = value} [, ...])]
[USING INDEX TABLESPACE tablespace_name]
```

- Rename a table. The renaming does not affect stored data.

```
ALTER TABLE [IF EXISTS] table_name
 RENAME TO new_table_name;
```

- Rename the specified column in the table.

```
ALTER TABLE [IF EXISTS] { table_name [*] | ONLY table_name | ONLY (table_name) }
 RENAME [COLUMN] column_name TO new_column_name;
```

- Rename the constraint of the table.

```
ALTER TABLE [IF EXISTS] { table_name [*] | ONLY table_name | ONLY (table_name) }
 RENAME CONSTRAINT constraint_name TO new_constraint_name;
```

- Set the schema of the table.

```
ALTER TABLE [IF EXISTS] table_name
SET SCHEMA new_schema;
```

#### NOTE

- The schema setting moves the table into another schema. Associated indexes and constraints owned by table columns are migrated as well. Currently, the schema for sequences cannot be changed. If the table has sequences, delete the sequences, and create them again or delete the ownership between the table and sequences. In this way, the table schema can be changed.
- To change the schema of a table, you must also have the CREATE permission on the new schema. To add the table as a new child of a parent table, you must own the parent table as well. To alter the owner, you must also be a direct or indirect member of the new owning role, and that role must have the CREATE permission on the table's schema. These restrictions enforce that the user can only rebuild and delete the table. However, a system administrator can alter the ownership of any table anyway.
- All the actions except for RENAME and SET SCHEMA can be combined into a list of multiple alterations to apply in parallel. For example, it is possible to add several columns or alter the type of several columns in a single statement. This is useful with large tables, since only one pass over the tables need be made.
- Adding a CHECK or NOT NULL constraint will scan the table to validate that existing rows meet the constraint.
- Adding a column with a non-null default or changing the type of an existing column will rewrite the entire table. Rewriting a large table may take much time and temporarily needs doubled disk space.
- Add columns.  

```
ALTER TABLE [IF EXISTS] table_name
ADD ({ column_name data_type [COLLATE collation] [column_constraint [...]] } [, ...]);
```
- Update columns.  

```
ALTER TABLE [IF EXISTS] table_name
MODIFY ({ column_name data_type | column_name [CONSTRAINT constraint_name] NOT NULL
[ENABLE] | column_name [CONSTRAINT constraint_name] NULL } [, ...]);
```

## Parameters

- **IF EXISTS**  
Sends a notice instead of an error if no tables have identical names. The notice prompts that the table you are querying does not exist.
- **table\_name [\*] | ONLY table\_name | ONLY ( table\_name )**  
**table\_name** is the name of the table that you need to modify.  
If **ONLY** is specified, only the table is modified. If **ONLY** is not specified, the table and all subtables are modified. You can add the asterisk (\*) option following the table name to specify that all subtables are scanned, which is the default operation.
- **constraint\_name**  
Specifies the name of an existing constraint to drop.
- **index\_name**  
Specifies the name of an index.
- **storage\_parameter**  
Specifies the name of a storage parameter.  
The following option is added for creating an index:
  - **parallel\_workers** (int type)

Number of bgworker threads started when an index is created. For example, value **2** indicates that two bgworker threads are started to create indexes concurrently.

Value range: [0,32]. The value **0** indicates that this function is disabled.

Default value: If this parameter is not set, the concurrent index creation function is disabled.

– **hasuids** (Boolean type)

Default value: **off**

If this parameter is set to **on**, a unique table-level ID is allocated to a tuple when the tuple is updated.

The following option is added to fix optimizer statistics:

– **min\_tuples** (float8 type)

Default value: **0**

The optimizer selects the larger value of the estimated statistics and the parameter to calculate the data volume based on the estimation table of statistics.

- **new\_owner**

Specifies the name of the new table owner.

- **new\_tablespace**

Specifies the new name of the tablespace to which the table belongs.

- **column\_name, column\_1\_name, column\_2\_name**

Specifies the name of a new or existing column.

- **data\_type**

Specifies the type of a new column or a new type of an existing column.

- **collation**

Specifies the collation rule name of a column. The optional COLLATE clause specifies a collation for the new column; if omitted, the collation is the default for the new column. You can run the **select \* from pg\_collation;** command to query collation rules from the pg\_collation system catalog. The default collation rule is the row starting with **default** in the query result.

- **USING expression**

Specifies how to compute the new column value from the old; if omitted, the default conversion is an assignment cast from old data type to new. A USING clause must be provided if there is no implicit or assignment cast from the old to new type.

 **NOTE**

**USING** in ALTER TYPE can specify any expression involving the old values of the row; that is, it can refer to any columns other than the one being cast. This allows general casting to be done with the ALTER TYPE syntax. Because of this flexibility, the USING expression is not applied to the column's default value (if any); the result might not be a constant expression as required for a default. This means that when there is no implicit or assignment cast from old to new type, ALTER TYPE might fail to convert the default even though a USING clause is supplied. In such cases, drop the default with DROP DEFAULT, perform ALTER TYPE, and then use SET DEFAULT to add a suitable new default. Similar considerations apply to indexes and constraints involving the column.

- **NOT NULL | NULL**  
Sets whether the column allows null values.
- **ENABLE**  
Specifies that the constraint is enabled. By default, the constraint is enabled.
- **integer**  
Specifies the constant value of a signed integer. When using PERCENT, the range of **integer** is from 0 to 100.
- **attribute\_option**  
Specifies an attribute option.
- **PLAIN | EXTERNAL | EXTENDED | MAIN**  
Specifies a column-store mode.
  - **PLAIN** must be used for fixed-length values (such as integers). It must be inline and uncompressed.
  - **MAIN** is for inline, compressible data.
  - **EXTERNAL** is for external, uncompressed data. Use of **EXTERNAL** will make substring operations on **text** and **bytea** values run faster, at the penalty of increased storage space.
  - **EXTENDED** is for external, compressed data. **EXTENDED** is the default for most data types that support non-**PLAIN** storage.
- **CHECK ( expression )**  
New rows or rows to be updated must satisfy for an expression to be true. If any row produces a false result, an error is raised and the database is not modified.  
  
A CHECK constraint specified as a column constraint should reference only the column's value, while an expression in a table constraint can reference multiple columns.  
  
Currently, **CHECK ( expression )** does not include subqueries and cannot use variables apart from the current column.
- **DEFAULT default\_expr**  
Assigns a default data value to a column.  
  
The data type of the default expression must match that of the column.  
  
The default expression will be used in any INSERT operation that does not specify a value for the column. If there is no default value for a column, then the default value is **NULL**.
- **GENERATED ALWAYS AS ( generation\_expr ) STORED**  
This clause creates a column as a generated column. The value of the generated column is calculated by **generation\_expr** when data is written (inserted or updated). **STORED** indicates that the value of the generated column is stored as an ordinary column.

 **NOTE**

- The generation expression cannot refer to data other than the current row in any way. The generation expression cannot reference other generation columns or system columns. The generation expression cannot return a result set. No subquery, aggregate function, or window function can be used. The function called by the generation expression can only be an immutable function.
- Default values cannot be specified for generated columns.
- The generated column cannot be used as a part of the partition key.
- Do not specify the generated column and the CASCADE, SET NULL, and SET DEFAULT actions of the ON UPDATE constraint at the same time. Do not specify the generated column and the SET NULL, and SET DEFAULT actions of the ON DELETE constraint at the same time.
- The method of modifying and deleting generated columns is the same as that of ordinary columns. Delete the ordinary column that the generated column depends on. The generated column is automatically deleted. The type of the column on which the generated column depends cannot be changed.
- The generated column cannot be directly written. In the INSERT or UPDATE statement, values cannot be specified for generated columns, but the keyword DEFAULT can be specified.
- The permission control for generated columns is the same as that for ordinary columns.
- Columns cannot be generated for column-store tables and memory-optimized tables (MOTs). In foreign tables, only **postgres\_fdw** supports generated columns.

- **UNIQUE index\_parameters**

**UNIQUE ( column\_name [, ... ] ) index\_parameters**

Specifies that a group of one or more columns of a table can contain only unique values.

- **PRIMARY KEY index\_parameters**

**PRIMARY KEY ( column\_name [, ... ] ) index\_parameters**

Specifies that a column or columns of a table can contain only unique (non-duplicate) and non-NULL values.

- **REFERENCES reftable [ ( refcolumn ) ] [ MATCH matchtype ] [ ON DELETE action ] [ ON UPDATE action ] (column constraint)**

**FOREIGN KEY ( column\_name [, ... ] ) REFERENCES reftable [ ( refcolumn [, ... ] ) ] [ MATCH matchtype ] [ ON DELETE action ] [ ON UPDATE action ] (table constraint)**

The foreign key constraint requires that the group consisting of one or more columns in the new table should contain and match only the referenced column values in the referenced table. If **refcolumn** is omitted, the primary key of **reftable** is used. The referenced column should be the only column or primary key in the referenced table. A foreign key constraint cannot be defined between a temporary table and a permanent table.

There are three types of matching between a reference column and a referenced column:

- **MATCH FULL:** A column with multiple foreign keys cannot be **NULL** unless all foreign key columns are **NULL**.
- **MATCH SIMPLE** (default): Any unexpected foreign key column can be **NULL**.
- **MATCH PARTIAL:** This option is not supported currently.

In addition, when certain operations are performed on the data in the referenced table, the operations are performed on the corresponding columns in the new table. The ON DELETE clause specifies the operations to be executed after a referenced row in the referenced table is deleted. The ON UPDATE clause specifies the operation to be performed when the referenced column data in the referenced table is updated. Possible responses to the ON DELETE and ON UPDATE clauses are as follows:

- **NO ACTION** (default): When a foreign key is deleted or updated, an error indicating that the foreign key constraint is violated is reported. If the constraint is deferrable and there are still any referenced rows, this error will occur when the constraint is checked.
- **RESTRICT**: When a foreign key is deleted or updated, an error indicating that the foreign key constraint is violated is created. It is the same as **NO ACTION** except that the constraint is not deferrable.
- **CASCADE**: deletes any row that references the deleted row from the new table, or update the column value of the referenced row in the new table to the new value of the referenced column.
- **SET NULL**: sets the referenced columns to **NULL**.
- **SET DEFAULT**: sets the referenced columns to their default values.
- **DEFERRABLE | NOT DEFERRABLE | INITIALLY DEFERRED | INITIALLY IMMEDIATE**

Sets whether the constraint can be deferrable.

- **DEFERRABLE**: deferrable to the end of the transaction and checked using SET CONSTRAINTS.
- **NOT DEFERRABLE**: checks immediately after the execution of each command.
- **INITIALLY IMMEDIATE**: checks immediately after the execution of each statement.
- **INITIALLY DEFERRED**: checks when the transaction ends.

#### NOTE

Ustore tables do not support the **DEFERRABLE** and **INITIALLY DEFERRED** constraints.

- **WITH ( {storage\_parameter = value} [, ... ] )**  
Specifies an optional storage parameter for a table or an index.
- **tablespace\_name**  
Specifies the name of the tablespace where the index locates.
- **new\_table\_name**  
Specifies the new table name.
- **new\_column\_name**  
Specifies the new name of a specific column in a table.
- **new\_constraint\_name**  
Specifies the new name of a table constraint.
- **new\_schema**  
Specifies the new schema name.

- **CASCADE**  
Automatically drops objects that depend on the dropped column or constraint (for example, views referencing the column).
- **RESTRICT**  
Refuses to drop the column or constraint if there are any dependent objects. This is the default behavior.
- **schema\_name**  
Specifies the schema name of a table.

## Examples of Altering a Table

- Rename a table.  

```
openGauss=# CREATE TABLE aa(c1 int, c2 int);
openGauss=# ALTER TABLE IF EXISTS aa RENAME TO test_alt1;
```
- Alter the schema of a table.  

```
-- Create test_schema.
openGauss=# CREATE SCHEMA test_schema;
-- Change the schema of the test_alt1 table to test_schema.
openGauss=# ALTER TABLE test_alt1 SET SCHEMA test_schema;
-- Query table information.
openGauss=# SELECT schemaname,tablename FROM pg_tables WHERE tablename = 'test_alt1';
schemaname | tablename
-----+-----
test_schema | test_alt1
(1 row)
```
- Change the owner of a table.  

```
-- Create test_user.
openGauss=# CREATE USER test_user PASSWORD 'XXXXXXXXXX';
-- Change the owner of the test_alt1 table to test_user.
openGauss=# ALTER TABLE IF EXISTS test_schema.test_alt1 OWNER TO test_user;
-- Query.
openGauss=# SELECT tablename, schemaname, tableowner FROM pg_tables WHERE tablename = 'test_alt1';
tablename | schemaname | tableowner
-----+-----+-----
test_alt1 | test_schema | test_user
(1 row)
```
- Alter the tablespace of a table.  

```
-- Create the tbs_data1 tablespace.
openGauss=# CREATE TABLESPACE tbs_data1 RELATIVE LOCATION 'tablespace1/tbs_data1';
-- Change the tablespace of the test_alt1 table to tbs_data1.
openGauss=# ALTER TABLE test_schema.test_alt1 SET TABLESPACE tbs_data1;
-- Query.
openGauss=# SELECT tablename, tablespace FROM pg_tables WHERE tablename = 'test_alt1';
tablename | tablespace
-----+-----
test_alt1 | tbs_data1
(1 row)

-- Drop.
openGauss=# DROP TABLE test_schema.test_alt1;
openGauss=# DROP TABLESPACE tbs_data1;
openGauss=# DROP SCHEMA test_schema;
openGauss=# DROP USER test_user;
```

## Examples of Changing a Column

- Change column names.  

```
-- Create a table.
openGauss=# CREATE TABLE test_alt2(c1 INT,c2 INT);
-- Change column names.
```

```
openGauss=# ALTER TABLE test_alt2 RENAME c1 TO id;
openGauss=# ALTER TABLE test_alt2 RENAME COLUMN c2 to areaid;
-- Query.
openGauss=# \d test_alt1
 Table "public.test_alt1"
 Column | Type | Modifiers
-----+-----+-----
 id | integer |
 areaid | integer |
```

- Add a column.

```
-- Add a column to the test_alt1 table.
openGauss=# ALTER TABLE IF EXISTS test_alt2 ADD COLUMN name VARCHAR(20);
-- Query.
openGauss=# \d test_alt2
 Table "public.test_alt1"
 Column | Type | Modifiers
-----+-----+-----
 id | integer |
 areacode | integer |
 name | character varying(20) |
```

- Alter the data type of a column.

```
-- Change the type of the name column in the test_alt1 table.
openGauss=# ALTER TABLE test_alt1 MODIFY name VARCHAR(50);
-- Query.
openGauss=# \d test_alt1
 Table "public.test_alt2"
 Column | Type | Modifiers
-----+-----+-----
 id | integer |
 areaid | integer |
 name | character varying(50) |
-- Change the type of the name column in the test_alt1 table.
openGauss=# ALTER TABLE test_alt2 ALTER COLUMN name TYPE VARCHAR(25);
-- Query.
openGauss=# \d test_alt2
 Table "public.test_alt2"
 Column | Type | Modifiers
-----+-----+-----
 id | integer |
 areaid | integer |
 name | character varying(25) |
```

- Drop a column.

```
-- Drop the areaid column from test_alt1.
openGauss=# ALTER TABLE test_alt2 DROP COLUMN areaid;
-- Query.
openGauss=# \d test_alt2
 Table "public.test_alt2"
 Column | Type | Modifiers
-----+-----+-----
 id | integer |
 name | character varying(25) |
```

- Modify the column-store mode.

```
-- View table details.
openGauss=# \d+ test_alt2
 Table "public.test_alt2"
 Column | Type | Modifiers | Storage | Stats target | Description
-----+-----+-----+-----+-----+-----
 id | integer | | plain | |
 name | character varying(25) | | extended | |
Has OIDs: no
Options: orientation=row, storage_type=USTORE

-- Change the storage mode of the name column in the test_alt2 table.
openGauss=# ALTER TABLE test_alt2 ALTER COLUMN name SET STORAGE PLAIN;

-- Query.
openGauss=# \d+ test_alt2
```

```
Table "public.test_alt2"
Column | Type | Modifiers | Storage | Stats target | Description
-----+-----+-----+-----+-----+-----
id | integer | | plain | |
name | character varying(25) | | plain | |
Has OIDs: no
Options: orientation=row, storage_type=USTORE

-- Drop.
openGauss=# DROP TABLE test_alt2;
```

## Examples of Changing a Constraint

- Add a NOT NULL constraint to a column.

```
-- Create a table.
openGauss=# CREATE TABLE test_alt3(pid INT, areaid CHAR(5), name VARCHAR(20));
-- Add a NOT NULL constraint to pid.
openGauss=# ALTER TABLE test_alt3 MODIFY pid NOT NULL;
-- Query.
openGauss=# \d test_alt3
Table "public.test_alt3"
Column | Type | Modifiers
-----+-----+-----
pid | integer | not null
areaid | character(5) |
name | character varying(20) |
```

- Cancel the NOT NULL constraint on a column.

```
openGauss=# ALTER TABLE test_alt3 MODIFY pid NULL;
-- Query.
openGauss=# \d test_alt3
Table "public.test_alt3"
Column | Type | Modifiers
-----+-----+-----
pid | integer |
areaid | character(5) |
name | character varying(20) |
```

- Alter the default value of a column.

```
-- Alter the default value of id in the test_alt1 table.
openGauss=# ALTER TABLE test_alt3 ALTER COLUMN areaid SET DEFAULT '00000';
-- Query.
openGauss=# \d test_alt3
Table "public.test_alt3"
Column | Type | Modifiers
-----+-----+-----
pid | integer |
areaid | character(5) | default '00000':bpchar
name | character varying(20) |
-- Drop the default value of id.
openGauss=# ALTER TABLE test_alt3 ALTER COLUMN areaid DROP DEFAULT;
-- Query.
openGauss=# \d test_alt3
Table "public.test_alt3"
Column | Type | Modifiers
-----+-----+-----
pid | integer |
areaid | character(5) |
name | character varying(20) |
```

- Add a table-level constraint.

- Directly add a constraint.

```
-- Add a primary key constraint to the table.
openGauss=# ALTER TABLE test_alt3 ADD CONSTRAINT pk_test3_pid PRIMARY KEY (pid);
-- Query.
openGauss=# \d test_alt3
Table "public.test_alt3"
Column | Type | Modifiers
-----+-----+-----
```

```
pid | integer | not null
areaid | integer |
name | character varying(20) |
Indexes:
 "pk_test3_pid" PRIMARY KEY, btree (pid) TABLESPACE pg_default
```

- Create an index and then add a constraint.

```
-- Create a table.
openGauss=# CREATE TABLE test_alt4(c1 INT, c2 INT);
-- Create an index.
openGauss=# CREATE UNIQUE INDEX pk_test4_c1 ON test_alt4(c1);
-- Associate the created index when adding a constraint.
openGauss=# ALTER TABLE test_alt4 ADD CONSTRAINT pk_test4_c1 PRIMARY KEY USING
INDEX pk_test4_c1;
-- Query.
openGauss=# \d test_alt4
 Table "public.test_alt4"
 Column | Type | Modifiers
-----+-----+-----
c1 | integer | not null
c2 | integer |
Indexes:
 "pk_test4_c1" PRIMARY KEY, btree (c1) TABLESPACE pg_default
-- Drop.
openGauss=# DROP TABLE test_alt4;
```

- Drop a table-level constraint.

```
-- Drop a constraint.
openGauss=# ALTER TABLE test_alt3 DROP CONSTRAINT IF EXISTS pk_test3_pid;
-- Query.
openGauss=# \d test_alt3
 Table "public.test_alt3"
 Column | Type | Modifiers
-----+-----+-----
pid | integer | not null
areaid | integer |
name | character varying(20) |
Indexes:
 "pk_test3_pid" PRIMARY KEY, btree (pid) TABLESPACE pg_default
-- Drop.
openGauss=# DROP TABLE test_alt3;
```

[CREATE TABLE](#) and [DROP TABLE](#)

## 7.13.27 ALTER TABLE PARTITION

### Description

Alters table partitions, including adding, deleting, splitting, merging, clearing, exchanging, and renaming partitions, moving partition tablespaces, and modifying partition attributes.

### Precautions

- Only the owner of a partitioned table or users granted the ALTER permission on the partitioned table can run the **ALTER TABLE PARTITION** command. System administrators have the permission to run the command by default.
- The tablespace of the added partition cannot be PG\_GLOBAL.
- The name of the added partition must be different from names of existing partitions in the partitioned table.
- The key value of the added partition must be consistent with the type of partition keys in the partitioned table.

- If a range partition is added, the key value of the added partition must be greater than the upper limit of the last range partition in the partitioned table.
- If a list partition is added, the key value of the added partition cannot be the same as that of an existing partition.
- Hash partitions cannot be added.
- If the number of partitions in the target partitioned table has reached the maximum (**1048575**), partitions cannot be added.
- If a partitioned table has only one partition, the partition cannot be deleted.
- Use PARTITION FOR() to choose partitions. The number of specified values in the brackets should be the same as the number of columns specified when you define a partition, and they must be consistent.
- The **Value** partitioned table does not support the ALTER PARTITION operation.
- Partitions cannot be added to an interval partitioned table.
- Hash partitioned tables do not support splitting, combination, addition, and deletion of partitions.
- List partitioned tables do not support partition splitting or partition combination.
- If **enable\_gpi\_auto\_update** is set to **on**, the global index is automatically updated even if the UPDATE GLOBAL INDEX clause is not declared.

## Syntax

- Modify the syntax of the table partition.  

```
ALTER TABLE [IF EXISTS] { table_name [*] | ONLY table_name | ONLY (table_name) }
 action [, ...];
```

**action** indicates the following clauses for maintaining partitions. For the partition continuity when multiple clauses are used for partition maintenance, GaussDB runs **DROP PARTITION** and then **ADD PARTITION**, and finally runs the rest clauses in sequence.

```
move_clause |
exchange_clause |
row_clause |
merge_clause |
modify_clause |
split_clause |
add_clause |
drop_clause |
truncate_clause
```

  - The move\_clause syntax is used to move the partition to a new tablespace.  

```
MOVE PARTITION { partition_name | FOR (partition_value [, ...]) } TABLESPACE tablespacename
```
  - The exchange\_clause syntax is used to move the data from an ordinary table to a specified partition.  

```
EXCHANGE PARTITION { (partition_name) | FOR (partition_value [, ...]) }
 WITH TABLE {[ONLY] ordinary_table_name | ordinary_table_name * | ONLY
 (ordinary_table_name)}
 [{ WITH | WITHOUT } VALIDATION] [VERBOSE] [UPDATE GLOBAL INDEX]
```

The ordinary table and partition whose data is to be exchanged must meet the following requirements:

    - The number of columns of the ordinary table is the same as that of the partition, and their information should be consistent, including

column name, data type, constraint, collation information, and storage parameter.

- The number and information of indexes of the ordinary table and partition should be consistent.
- The number and information of constraints of the ordinary table and partition should be consistent.
- An ordinary table cannot be a temporary table. A partitioned table can only be a range partitioned table, list partitioned table, hash partitioned table, or interval partitioned table.
- Ordinary tables and partitioned tables do not support dynamic data masking and row-level security constraints.

---

**NOTICE**

- When the exchange is done, the data and tablespace of the ordinary table and partition are exchanged. The statistics about ordinary tables and partitions become unreliable, and they should be analyzed again.
- A non-partition key cannot be used to create a local unique index. Therefore, if an ordinary table contains a unique index, data cannot be exchanged.
- If the DROP COLUMN operation is performed on an ordinary or partitioned table, the dropped column still exists physically. Therefore, you need to ensure that the dropped column of the ordinary table is strictly aligned with that of the partition.

- 
- The row\_clause syntax is used to set row movement of a partitioned table.

```
{ ENABLE | DISABLE } ROW MOVEMENT
```

- The merge\_clause syntax is used to merge partitions into one. Currently, only range partitions can be merged.

```
MERGE PARTITIONS { partition_name } [, ...] INTO PARTITION partition_name
[TABLESPACE tablespacename] [UPDATE GLOBAL INDEX]
```

---

**NOTICE**

Ustore tables do not support ALTER TABLE MERGE PARTITIONS in transaction blocks and stored procedures.

- 
- The modify\_clause syntax is used to set whether a partitioned index is usable.

```
MODIFY PARTITION partition_name { UNUSABLE LOCAL INDEXES | REBUILD UNUSABLE LOCAL INDEXES }
```

- The split\_clause syntax is used to split one partition into partitions. Currently, only range partitions can be split.

```
SPLIT PARTITION { partition_name | FOR (partition_value [, ...]) } { split_point_clause | no_split_point_clause } [UPDATE GLOBAL INDEX]
```

- The syntax of split\_point\_clause is as follows:

```
AT (partition_value) INTO (PARTITION partition_name [TABLESPACE
tablespacename] , PARTITION partition_name [TABLESPACE tablespacename])
```

#### NOTICE

- The size of the split point should be in the range of partition keys of the partition to be split. The split point can only split one partition into two new partitions.

- The syntax of **no\_split\_point\_clause** is as follows:  
INTO { ( partition\_less\_than\_item [, ...] ) | ( partition\_start\_end\_item [, ...] ) }

#### NOTICE

- The first new partition key specified by **partition\_less\_than\_item** should be greater than that of the previously split partition (if any), and the last partition key specified by **partition\_less\_than\_item** should equal that of the partition being split.
- The first new partition key specified by **partition\_start\_end\_item** should equal that of the former partition (if any), and the last partition key specified by **partition\_start\_end\_item** should equal that of the partition being split.
- **partition\_less\_than\_item** supports a maximum of 4 partition keys, while **partition\_start\_end\_item** supports only one partition key. For details about the supported data types, see • [PARTITION BY RANGE\(partition\\_key\)](#).
- **partition\_less\_than\_item** and **partition\_start\_end\_item** cannot be used in the same statement.

- The syntax of **partition\_less\_than\_item** is as follows:  
PARTITION partition\_name VALUES LESS THAN ( { partition\_value | MAXVALUE } [, ...] )  
[ TABLESPACE tablespacename ]

- The **partition\_start\_end\_item** syntax is as follows. For details about the constraints, see [START END](#).

```
PARTITION partition_name {
 {START(partition_value) END (partition_value) EVERY (interval_value)} |
 {START(partition_value) END ({partition_value | MAXVALUE})} |
 {START(partition_value)} |
 {END({partition_value | MAXVALUE})}
} [TABLESPACE tablespacename]
```

- The **add\_clause** syntax is used to add one or more partitions to a specified partitioned table.

```
ADD PARTITION (partition_col1_name = partition_col1_value [, partition_col2_name =
partition_col2_value] [, ...])
[LOCATION 'location1']
[PARTITION (partition_colA_name = partition_colA_value [, partition_colB_name =
partition_colB_value] [, ...])]
[LOCATION 'location2']
ADD {partition_less_than_item | partition_start_end_item| partition_list_item }
```

The **partition\_list\_item** syntax is as follows:

```
PARTITION partition_name VALUES (list_values_clause)
[TABLESPACE tablespacename]
```

#### NOTICE

- **partition\_list\_item** supports only one partition key. For details about the data types supported by **partition\_list\_item**, see • [PARTITION BY LIST\(partition\\_key\)](#).
- Interval and hash partitioned tables do not support partition addition.

- The drop\_clause syntax is used to remove a partition from a specified partitioned table.

```
DROP PARTITION { partition_name | FOR (partition_value [, ...]) } [UPDATE GLOBAL INDEX]
```

#### NOTICE

- Hash partitioned table does not support partition deletion.
- If a partitioned table has only one partition, the partition cannot be deleted.

- The truncate\_clause syntax is used to remove a specified partition from a partitioned table.

```
TRUNCATE PARTITION { partition_name | FOR (partition_value [, ...]) } [UPDATE GLOBAL INDEX]
```

- Alter the name of a partition.

```
ALTER TABLE [IF EXISTS] { table_name [*] | ONLY table_name | ONLY (table_name) }
```

```
RENAME PARTITION { partition_name | FOR (partition_value [, ...]) } TO partition_new_name;
```

## Parameters

- **table\_name**  
Specifies the name of a partitioned table.  
Value range: an existing partitioned table name.
- **partition\_name**  
Specifies the name of a partition.  
Value range: an existing partition name.
- **tablespacename**  
Specifies which tablespace the partition moves to.  
Value range: an existing tablespace name.
- **partition\_value**  
Specifies the key value of a partition.  
The value specified by **PARTITION FOR ( partition\_value [, ...] )** can uniquely identify a partition.  
Value range: partition keys for the partition to be renamed.
- **UNUSABLE LOCAL INDEXES**  
Sets all the indexes unusable in the partition.
- **REBUILD UNUSABLE LOCAL INDEXES**  
Rebuilds all the indexes in the partition.
- **{ ENABLE | DISABLE } ROW MOVEMENT**  
Specifies whether to enable row movement.

If the tuple value is updated on the partition key during the UPDATE operation, the partition where the tuple is located is altered. Setting this parameter enables error messages to be reported or movement of the tuple between partitions.

Value range:

- **ENABLE**: Row movement is enabled.
- **DISABLE**: Row movement is disabled.

It is enabled by default.

- **ordinary\_table\_name**

Specifies the name of the ordinary table whose data is to be migrated.

Value range: an existing ordinary table name.

- **{ WITH | WITHOUT } VALIDATION**

Checks whether the ordinary table data meets the specified partition key range of the partition to be migrated.

Value range:

- **WITH**: checks whether the ordinary table data meets the partition key range of the partition to be migrated. If any data does not meet the required range, an error is reported.
- **WITHOUT**: does not check whether the ordinary table data meets the partition key range of the partition to be migrated.

The default value is **WITH**.

The check is time consuming, especially when the data volume is large. Therefore, use **WITHOUT** when you are sure that the current ordinary table data meets the partition key range of the partition to be migrated.

- **VERBOSE**

When **VALIDATION** is **WITH**, if the ordinary table contains data that is out of the partition key range, insert the data into the correct partition. If there is no correct partition where the data can be inserted, an error is reported.

---

**NOTICE**

Only when **VALIDATION** is **WITH**, **VERBOSE** can be specified.

---

- **partition\_new\_name**

Specifies the new name of a partition.

Value range: a string that complies with the [Identifier Naming Conventions](#).

## Examples

See [Examples](#) in "CREATE TABLE PARTITION."

## Helpful Links

[CREATE TABLE PARTITION](#) and [DROP TABLE](#)

## 7.13.28 ALTER TABLE SUBPARTITION

### Description

Alters partitions from a level-2 partitioned table, including adding, deleting, clearing, and splitting partitions.

### Precautions

- Currently, partitions from the level-2 partitioned table can be added, deleted, cleared, or split only.
- The tablespace of the added partition cannot be PG\_GLOBAL.
- The name of the added partition must be different from the names of the existing level-1 and level-2 partitions in the partitioned table.
- The key value of the added partition must be consistent with the type of partition keys in the partitioned table.
- If a range partition is added, the key value of the added partition must be greater than the upper limit of the last range partition in the partitioned table. To add a partition to a table with the **MAXVALUE** partition, you are advised to use the SPLIT syntax.
- If a list partition is added, the key value of the added partition cannot be the same as that of an existing partition. To add a partition to a table with the **DEFAULT** partition, you are advised to use the SPLIT syntax.
- Hash partitions cannot be added. However, if the level-2 partition mode of an level-2 partitioned table is hash but the level-1 partition mode is not hash, you can add a level-1 partition and create the corresponding level-2 partition.
- If the number of partitions in the target partitioned table has reached the maximum (**1048575**), partitions cannot be added.
- If the partitioned table contains only one level-1 or level-2 partition, the partition cannot be deleted.
- Hash partitions cannot be deleted.
- Use PARTITION FOR() to choose partitions. The number of specified values in the brackets should be the same as the number of columns specified when you define a partition, and they must be consistent.
- Only level-2 partitions (leaf nodes) can be split. Only range and list partitioning policies can be used and hash partitioning policies are not supported. The list partitioning policy can be used only when the default partition is used.
- Only the owner of a partitioned table or users granted the ALTER permission on the partitioned table can run the **ALTER TABLE PARTITION** command. System administrators have the permission to run the command by default.
- If the ALTER statement does not contain UPDATE GLOBAL INDEX, the original GLOBAL index is invalid. In this case, other indexes are used for query. If the ALTER statement contains UPDATEGLOBAL INDEX, the original GLOBAL index is still valid and the index function is correct.
- If **enable\_gpi\_auto\_update** is set to **on**, the global index is automatically updated even if the UPDATE GLOBAL INDEX clause is not declared.

## Syntax

- Modify the syntax of the table partition.  
`ALTER TABLE [ IF EXISTS ] { table_name [*] | ONLY table_name | ONLY ( table_name ) }  
action [, ... ];`

**action** indicates the following clauses for maintaining partitions.

```
add_clause |
drop_clause |
split_clause |
truncate_clause
```

- The `add_clause` syntax is used to add one or more partitions to a specified partitioned table. The syntax can be used in level-1 partitions.  
`ADD {partition_less_than_item | partition_list_item } ( ( subpartition_definition_list ) )`

It can also be used in level-2 partitions.

```
MODIFY PARTITION partition_name ADD subpartition_definition
```

**partition\_less\_than\_item** defines a range partition. The syntax is as follows:

```
PARTITION partition_name VALUES LESS THAN (partition_value | MAXVALUE) [TABLESPACE
tablespacename]
```

**partition\_list\_item** defines a list partition. The syntax is as follows:

```
PARTITION partition_name VALUES (partition_value [, ...] | DEFAULT) [TABLESPACE
tablespacename]
```

**subpartition\_definition\_list** contains the **subpartition\_definition** object of one or more level-2 partitions. The syntax is as follows:

```
SUBPARTITION subpartition_name [VALUES LESS THAN (partition_value | MAXVALUE) | VALUES
(partition_value [, ...] | DEFAULT)] [TABLESPACE tablespacename]
```

---

### NOTICE

If the level-1 partition is a hash partition, you cannot use ADD to add a level-1 partition. If the level-2 partition is a hash partition, you cannot use MODIFY to add a level-2 partition.

- The `drop_clause` syntax is used to remove a partition from a specified partitioned table. The syntax can be used in level-1 partitions.

```
DROP PARTITION { partition_name | FOR (partition_value) } [UPDATE GLOBAL INDEX]
```

It can also be used in level-2 partitions.

```
DROP SUBPARTITION { subpartition_name | FOR (partition_value, subpartition_value) } [UPDATE
GLOBAL INDEX]
```

---

### NOTICE

- If the level-1 partition is a hash partition, the level-1 partition cannot be deleted. If the level-2 partition is a hash partition, the level-2 partition cannot be deleted.
- At least one sub-partition must be retained.

- The `split_clause` syntax is used to split one partition into partitions.  
`SPLIT SUBPARTITION { subpartition_name } { split_point_clause } [ UPDATE GLOBAL INDEX ]`

The `split_point_clause` syntax used to specify a split point in the range partitioning policy is as follows:

```
AT (subpartition_value) INTO (SUBPARTITION subpartition_name [TABLESPACE tablespacename] ,
SUBPARTITION subpartition_name [TABLESPACE tablespacename])
```

The `split_point_clause` syntax used to specify a split point in the list partitioning policy is as follows:

```
VALUES (subpartition_value) INTO (SUBPARTITION subpartition_name [TABLESPACE
tablespacename] , SUBPARTITION subpartition_name [TABLESPACE tablespacename])
```

#### NOTICE

- The size of the split point should be in the range of the splitting partition key.
  - One partition can be split into only two new partitions.
  - In the range partitioning policy, the current partition is split based on the split point into one partition with the range of smaller values and the other with the range of larger values. Therefore, only one split point can be used in this policy. In the list partitioning policy, there can be multiple but no more than 64 split points. These split points are extracted from the boundary values of the current partition as a new partition, and the remaining boundary values of the current partition are used as another new partition.
  - Only the default list partition can be split.
- 
- The `truncate_clause` syntax is used to remove a specified partition from a partitioned table.  
`TRUNCATE SUBPARTITION { subpartition_name } [ UPDATE GLOBAL INDEX ]`

#### NOTICE

When `truncate_clause` is executed in a level-2 partition, `AccessExclusiveLock` of the main table is obtained, blocking operations on the table.

## Parameters

- **table\_name**  
Specifies the name of a partitioned table.  
Value range: an existing partitioned table name.
- **subpartition\_name**  
Specifies the name of a level-2 partition name.  
Value range: an existing level-2 partition name.
- **tablespacename**  
Specifies which tablespace the partition moves to.  
Value range: an existing tablespace name.

## Examples

See [Examples](#) in "CREATE TABLE SUBPARTITION."

## Helpful Links

[CREATE TABLE SUBPARTITION](#) and [DROP TABLE](#)

## 7.13.29 ALTER TABLESPACE

### Description

Alters the attributes of a tablespace.

### Precautions

- Only the tablespace owner or a user granted the ALTER permission can run the **ALTER TABLESPACE** command. System administrators have this permission by default. To modify a tablespace owner, you must be the tablespace owner or a system administrator and a member of the new owner role.
- To change the owner, you must also be a direct or indirect member of the new owning role.

#### NOTE

If **new\_owner** is the same as **old\_owner**, the current user will not be verified. A message indicating successful **ALTER** execution is displayed.

### Syntax

- The syntax of renaming a tablespace is as follows:  

```
ALTER TABLESPACE tablespace_name
 RENAME TO new_tablespace_name;
```
- The syntax of setting the owner of a tablespace is as follows:  

```
ALTER TABLESPACE tablespace_name
 OWNER TO new_owner;
```
- The syntax of setting the attributes of a tablespace is as follows:  

```
ALTER TABLESPACE tablespace_name
 SET ({tablespace_option = value} [, ...]);
```
- The syntax of resetting the attributes of a tablespace is as follows:  

```
ALTER TABLESPACE tablespace_name
 RESET ({ tablespace_option } [, ...]);
```
- The syntax of setting the quota of a tablespace is as follows:  

```
ALTER TABLESPACE tablespace_name
 RESIZE MAXSIZE { UNLIMITED | 'space_size'};
```

### Parameters

- **tablespace\_name**  
Specifies the tablespace to be modified.  
Value range: an existing tablespace name.
- **new\_tablespace\_name**  
Specifies the new name of a tablespace.  
The new name cannot start with **PG\_**.  
Value range: a string that complies with the [Identifier Naming Conventions](#).
- **new\_owner**  
Specifies the new owner of the tablespace.  
Value range: an existing username.
- **tablespace\_option**

Sets or resets the parameters of a tablespace.

Value range:

- **seq\_page\_cost**: sets the optimizer to calculate the cost of obtaining disk pages in sequence. The default value is **1.0**.
- **random\_page\_cost**: sets the optimizer to calculate the cost of obtaining disk pages in a non-sequential manner. The default value is **4.0**.

 **NOTE**

- The value of **random\_page\_cost** is relative to that of **seq\_page\_cost**. It is meaningless when the value is equal to or less than the value of **seq\_page\_cost**.
- The prerequisite for the default value **4.0** is that the optimizer uses indexes to scan table data and the hit ratio of table data in the cache is about 90%.
- If the size of the table data space is smaller than that of the physical memory, decrease the value to a proper level. On the contrary, if the hit ratio of table data in the cache is lower than 90%, increase the value.
- If random-access memory like SSD is adopted, the value can be decreased to a certain degree to reflect the cost of true random scan.

Value range: Positive number of the floating-point type.

- **RESIZE MAXSIZE**

Resets the maximum size of tablespace.

Value range:

- **UNLIMITED**: No limit is set for the tablespace.
- Determined by **space\_size**. For details about the format, see [CREATE TABLESPACE](#).

 **NOTE**

- If the adjusted quota is smaller than the current tablespace usage, the adjustment is successful. You need to decrease the tablespace usage to a value less than the new quota before writing data to the tablespace.
- You can also use the following statement to change the value of **MAXSIZE**:

```
ALTER TABLESPACE tablespace_name RESIZE MAXSIZE
{ 'UNLIMITED' | 'space_size'};
```

## Examples

See [Examples](#) in "CREATE TABLESPACE."

## Helpful Links

[CREATE TABLESPACE](#) and [DROP TABLESPACE](#)

## 7.13.30 ALTER TRIGGER

### Function

**ALTER TRIGGER** renames a trigger.

 **NOTE**

Currently, only the name can be modified.

## Precautions

Only the owner of a table where the trigger is created and a system administrator can run the **ALTER TRIGGER** statement.

## Syntax

```
ALTER TRIGGER trigger_name ON table_name RENAME TO new_name;
```

## Parameter Description

- **trigger\_name**  
Specifies the name of the trigger to be modified.  
Value range: an existing trigger
- **table\_name**  
Specifies the name of the table where the trigger to be modified is located.  
Value range: an existing table having a trigger
- **new\_name**  
Specifies the new name after modification.  
Value range: a string, which complies with the identifier naming convention. A value contains a maximum of 63 characters and cannot be the same as other triggers on the same table.

## Examples

See examples in [CREATE TRIGGER](#).

## Helpful Links

[CREATE TRIGGER](#), [DROP TRIGGER](#), and [ALTER TABLE](#)

## 7.13.31 ALTER TYPE

### Description

Alters the definition of a type.

### Precautions

Only the type owner or a user granted with the ALTER permission can run the **ALTER TYPE** command. System administrators have this permission by default. To modify the owner or schema of a type, you must be a type owner or system administrator and a member of the new owner role.

### Syntax

- Modify a type.  

```
ALTER TYPE name action [, ...];
```

The clauses corresponding to **action** are as follows:

  - Add a new attribute to a composite type.  

```
ADD ATTRIBUTE attribute_name data_type [COLLATE collation] [CASCADE | RESTRICT]
```

- Drop an attribute from a composite type.  
DROP ATTRIBUTE [ IF EXISTS ] attribute\_name [ CASCADE | RESTRICT ]
- Alter the type of an attribute in a composite type.  
ALTER ATTRIBUTE attribute\_name [ SET DATA ] TYPE data\_type [ COLLATE collation ] [ CASCADE | RESTRICT ]
- Add a new attribute to a composite type.  
ALTER TYPE name ADD ATTRIBUTE attribute\_name data\_type [ COLLATE collation ] [ CASCADE | RESTRICT ];
- Drop an attribute from a composite type.  
ALTER TYPE name DROP ATTRIBUTE [ IF EXISTS ] attribute\_name [ CASCADE | RESTRICT ];
- Alter the type of an attribute in a composite type.  
ALTER TYPE name ALTER ATTRIBUTE attribute\_name [ SET DATA ] TYPE data\_type [ COLLATE collation ] [ CASCADE | RESTRICT ];
- Alter the owner of a type.  
ALTER TYPE name OWNER TO { new\_owner | CURRENT\_USER | SESSION\_USER };
- Alter the name of a type.  
ALTER TYPE name RENAME TO new\_name;
- Alter the name of an attribute in a composite type.  
ALTER TYPE name RENAME ATTRIBUTE attribute\_name TO new\_attribute\_name [ CASCADE | RESTRICT ];
- Move a type to a new schema.  
ALTER TYPE name SET SCHEMA new\_schema;
- Add a new value to an enumerated type.  
ALTER TYPE name ADD VALUE [ IF NOT EXISTS ] new\_enum\_value [ { BEFORE | AFTER } neighbor\_enum\_value ];
- Alter an enumerated value in the value list.  
ALTER TYPE name RENAME VALUE existing\_enum\_value TO new\_enum\_value;

## Parameters

- **name**  
Specifies the name of an existing type that needs to be modified (optionally schema-qualified).
- **new\_name**  
Specifies the new name of the type.
- **new\_owner**  
Specifies the new owner of the type.
- **new\_schema**  
Specifies the new schema of the type.
- **attribute\_name**  
Specifies the name of the attribute to be added, modified, or deleted.
- **new\_attribute\_name**  
Specifies the new name of the attribute to be renamed.
- **data\_type**  
Specifies the data type of the attribute to be added, or the new type of the attribute to be modified.
- **new\_enum\_value**  
Specifies a new enumerated value. It is a non-null string with a maximum length of 63 bytes.

- **neighbor\_enum\_value**  
Specifies an existing enumerated value before or after which a new enumerated value will be added.
- **existing\_enum\_value**  
Specifies an enumerated value to be changed. It is a non-null string with a maximum length of 63 bytes.
- **CASCADE**  
Determines that the type to be modified, its associated records, and subtables that inherit the type will all be updated.
- **RESTRICT**  
Refuses to update the associated records of the modified type. This is the default action.

---

#### NOTICE

- **ADD ATTRIBUTE, DROP ATTRIBUTE, and ALTER ATTRIBUTE** can be combined for processing. For example, it is possible to add several attributes or change the types of several attributes at the same time in one command.
  - To change a schema of a type, you must have the CREATE permission on the new schema. To change the owner, you must be a direct or indirect member of the new owning role, and the member must have the CREATE permission on the schema of this type. (These restrictions enforce that the user can only rebuild and drop the type. However, system administrators can change ownership of any type in any way.) To add an attribute or change the type of an attribute, you must also have the USAGE permission of this type.
- 

## Examples

See [Examples](#) in "CREATE TYPE."

## Helpful Links

[CREATE TYPE](#) and [DROP TYPE](#)

## 7.13.32 ALTER USER

### Description

Alters the attributes of a database user.

### Precautions

Session parameters modified by ALTER USER apply to a specified user and take effect in the next session.

## Syntax

- Modify user permissions or other information.

```
ALTER USER user_name [[WITH] option [...]];
```

The option clause is as follows:

```
{ CREATEDB | NOCREATEDB }
| { CREATEROLE | NOCREATEROLE }
| { INHERIT | NOINHERIT }
| { AUDITADMIN | NOAUDITADMIN }
| { SYSADMIN | NOSYSADMIN }
| { MONADMIN | NOMONADMIN }
| { OPRADMIN | NOOPRADMIN }
| { POLADMIN | NOPOLADMIN }
| { USEFT | NOUSEFT }
| { LOGIN | NOLOGIN }
| { REPLICATION | NOREPLICATION }
| { VCADMIN | NOVCADMIN }
| { PERSISTENCE | NOPERSISTENCE }
| CONNECTION LIMIT connlimit
| [ENCRYPTED | UNENCRYPTED] PASSWORD { 'password' [EXPIRED] | DISABLE | EXPIRED }
| [ENCRYPTED | UNENCRYPTED] IDENTIFIED BY { 'password' [REPLACE 'old_password' |
EXPIRED] | DISABLE }
| VALID BEGIN 'timestamp'
| VALID UNTIL 'timestamp'
| PERM SPACE 'spacelimit'
| PGUSER
```

- Change the username.

```
ALTER USER user_name
 RENAME TO new_name;
```

- Lock or unlock.

```
ALTER USER user_name
 ACCOUNT { LOCK | UNLOCK };
```

- Change the value of a specified parameter associated with the user.

```
ALTER USER user_name
 SET configuration_parameter { { TO | = } { value | DEFAULT } | FROM CURRENT };
```

- Reset the value of a specified parameter associated with the user.

```
ALTER USER user_name
 RESET { configuration_parameter | ALL };
```

## Parameters

- **user\_name**

Specifies the current username.

Value range: an existing username. If a username contains uppercase letters, enclose the name with double quotation marks ("").

- **new\_password**

Specifies a new password.

The new password must:

- Differ from the old password.
- Contain at least eight characters. This is the default length.
- Differ from the username or the username spelled backward.
- Contain at least three of the following character types: uppercase characters, lowercase characters, digits, and special characters (limited to ~!@#\$%^&\*()-\_+=\|[]{};,:<.>/?). If the password contains characters other than the preceding characters, an error will be reported during statement execution.

- The user password should be enclosed in single quotation marks (').
- Value range: a string.
- **old\_password**  
Specifies the old password.
- **ACCOUNT { LOCK | UNLOCK }**
  - **ACCOUNT LOCK**: locks an account to forbid login to databases.
  - **ACCOUNT UNLOCK**: unlocks an account to allow login to databases.
- **PGUSER**  
In the current version, the **PGUSER** attribute of a user cannot be modified.

For details about other parameters, see "Parameters" in [CREATE ROLE](#) and [ALTER ROLE](#).

## Examples

See [Examples](#) in "CREATE USER."

## Helpful Links

[CREATE ROLE](#), [CREATE USER](#), and [DROP USER](#)

## 7.13.33 ALTER USER MAPPING

### Description

ALTER USER MAPPING is used to change the definition of the mapping from a user to a foreign server.

### Precautions

- If the **password** option is displayed, ensure that the **usermapping.key.cipher** and **usermapping.key.rand** files exist in the *\$GAUSSHOME/bin* directory of each node in GaussDB. If the two files do not exist, use the `gs\_guc` tool to generate them and use the `gs\_ssh` tool to release them to the *\$GAUSSHOME/bin* directory on each node.
- When multi-layer quotation marks are used for sensitive columns (such as **password**) in **OPTIONS**, the semantics is different from that in the scenario where quotation marks are not used. Therefore, sensitive columns are not identified for anonymization.

### Syntax

```
ALTER USER MAPPING FOR { user_name | USER | CURRENT_USER | PUBLIC }
 SERVER server_name
 OPTIONS ([ADD | SET | DROP] option ['value'] [, ...])
```

In **OPTIONS**, **ADD**, **SET**, and **DROP** are operations to be performed. If these operations are not specified, **ADD** operations will be performed by default. **option** and **value** are the parameters and values of the corresponding operation.

## Parameters

- **user\_name**  
Specifies username of the mapping.  
**CURRENT\_USER** and **USER** match the name of the current user. **PUBLIC** is used to match all current and future usernames in the system.
- **server\_name**  
Specifies name of the server to which the user is mapped.
- **OPTIONS**  
Changes an option for the user mapping. The new option overwrites any previously specified option. **ADD**, **SET**, and **DROP** are operations to be performed. If the operation is not specified explicitly, ADD operations will be performed. The option name must be unique and will be validated with the foreign data wrapper of the server.

## Examples

For details, see [Examples](#) in "CREATE USER MAPPING."

## Helpful Links

[CREATE USER MAPPING](#) and [DROP USER MAPPING](#)

## 7.13.34 ALTER VIEW

### Description

ALTER VIEW alters the auxiliary attributes of a view. If you want to change the query definition of a view, use CREATE OR REPLACE VIEW.

### Precautions

Only the view owner or a user granted the ALTER permission can run the **ALTER VIEW** command. System administrators have this permission by default. The following are permission restrictions depending on attributes to be modified:

- To modify the schema of a view, you must be the owner of the view or a system administrator and have the CREATE permission on the new schema.
- To modify the owner of a view, you must be the owner of the view or a system administrator and a member of the new owner role, with the CREATE permission on the schema of the view.
- Do not change the type of a column in a view.

### Syntax

- Set the default value of a view column.  

```
ALTER VIEW [IF EXISTS] view_name
 ALTER [COLUMN] column_name SET DEFAULT expression;
```
- Remove the default value of a view column.  

```
ALTER VIEW [IF EXISTS] view_name
 ALTER [COLUMN] column_name DROP DEFAULT;
```

- Change the owner of a view.  

```
ALTER VIEW [IF EXISTS] view_name
OWNER TO new_owner;
```
- Rename a view.  

```
ALTER VIEW [IF EXISTS] view_name
RENAME TO new_name;
```
- Set the schema of a view.  

```
ALTER VIEW [IF EXISTS] view_name
SET SCHEMA new_schema;
```
- Set the options of a view.  

```
ALTER VIEW [IF EXISTS] view_name
SET ({ view_option_name [= view_option_value] } [, ...]);
```
- Reset the options of a view.  

```
ALTER VIEW [IF EXISTS] view_name
RESET (view_option_name [, ...]);
```

## Parameters

- **IF EXISTS**  
If this option is used, no error is generated when the view does not exist, and only a message is displayed.
- **view\_name**  
Specifies the view name, which can be schema-qualified.  
Value range: a string that complies with the [Identifier Naming Conventions](#).
- **column\_name**  
Specifies an optional list of names to be used for columns of the view. If not given, the column names are deduced from the query.  
Value range: a string that complies with the [Identifier Naming Conventions](#).
- **SET/DROP DEFAULT**  
Sets or drops the default value of a column. This parameter does not take effect.
- **new\_owner**  
Specifies the new owner of a view.
- **new\_name**  
Specifies the new view name.
- **new\_schema**  
Specifies the new schema of the view.
- **view\_option\_name [ = view\_option\_value ]**  
Specifies an optional parameter for a view.  
Currently, **view\_option\_name** supports only the **security\_barrier** parameter.  
Use this parameter when the view provides row-level security.  
Value range: Boolean type, **TRUE** or **FALSE**.

## Examples

```
-- Create a schema.
openGauss=# CREATE SCHEMA tpcds;

-- Create the tpcds.customer table.
openGauss=# CREATE TABLE tpcds.customer
```

```
(
c_customer_sk INTEGER NOT NULL,
c_customer_id CHARACTER(16) NOT NULL
);

-- Insert multiple records into the table.
openGauss=# INSERT INTO tpcds.customer VALUES (1, 'AAAAAAAAABAAAAAAA'),(100,
'AAAAAAAAACAAAAAAA'),(150, 'AAAAAAAADAAAAAAA');

-- Create a view consisting of rows with c_customer_sk less than 150.
openGauss=# CREATE VIEW tpcds.customer_details_view_v1 AS
 SELECT * FROM tpcds.customer
 WHERE c_customer_sk < 150;

-- Rename a view.
openGauss=# ALTER VIEW tpcds.customer_details_view_v1 RENAME TO customer_details_view_v2;

-- Change the schema of a view.
openGauss=# ALTER VIEW tpcds.customer_details_view_v2 SET schema public;

-- Drop a view.
openGauss=# DROP VIEW public.customer_details_view_v2;

-- Drop the tpcds.customer table.
openGauss=# DROP TABLE tpcds.customer;

-- Drop the schema.
openGauss=# DROP SCHEMA tpcds CASCADE;
```

## Helpful Links

[CREATE VIEW](#) and [DROP VIEW](#)

## 7.13.35 ANALYZE | ANALYSE

### Description

- ANALYZE collects statistics about ordinary tables in a database and stores the results in the PG\_STATISTIC and PG\_STATISTIC\_EXT system catalogs. After you run the **ANALYZE** command, you can query the collected statistics in the preceding system catalogs or system views PG\_STATS and PG\_EXT\_STATS. The execution plan generator uses these statistics to determine which one is the most effective execution plan.
- If no parameters are specified, ANALYZE analyzes each table and partitioned table in the database. You can also specify **table\_name**, **column\_name**, and **partition\_name** to limit the analysis to a specified table, column, or partitioned table.
- **ANALYZE | ANALYZE VERIFY** is used to check whether data files of ordinary tables (row-store tables) in a database are damaged.

### Precautions

- Non-temporary tables cannot be analyzed in an anonymous block, transaction block, function, or stored procedure. Temporary tables in a stored procedure can be analyzed but their statistics updates cannot be rolled back.
- Remote read is not involved in the ANALYZE VERIFY scenario. Therefore, the remote read parameter does not take effect. If the system detects that a page is damaged due to an error in a key system catalog, the system directly reports an error and does not continue the detection.

- With no parameter specified, ANALYZE processes all the tables on which the current user has permission to analyze in the current database. With tables specified, ANALYZE processes only the specified tables.
- To perform ANALYZE operation to a table, you must be a table owner or a user granted the VACUUM permission on the table. By default, system administrators have this permission. However, database owners are allowed to analyze all tables in their databases, except shared catalogs. (The restriction for shared catalogs means that a true database-wide ANALYZE operation can only be executed by system administrators). ANALYZE skips tables on which users do not have permissions.
- ANALYZE does not collect columns for which comparison or equivalent operations cannot be performed, for example, columns of the cursor type.

## Syntax

- Collect statistics information about a table.  

```
{ ANALYZE | ANALYSE } [VERBOSE]
[table_name [(column_name [, ...])]] ;
```
- Collect partition statistics information about a partitioned table. This syntax is not supported currently.  

```
{ ANALYZE | ANALYSE } [VERBOSE]
table_name [(column_name [, ...])] PARTITION (partition_name) ;
```

### NOTE

An ordinary partitioned table supports the syntax but not the function of collecting statistics about specified partitions.

- Check the data files in the current database.  

```
{ANALYZE | ANALYSE} VERIFY {FAST|COMPLETE};
```

### NOTE

- In fast mode, DML operations need to be performed on the tables to be verified concurrently. As a result, an error is reported during the verification. In the current fast mode, data is directly read from the disk. When other threads modify files concurrently, the obtained data is incorrect. Therefore, you are advised to perform the verification offline.
- You can perform operations on the entire database. Because a large number of tables are involved, you are advised to save the results in redirection mode.  

```
gsql -d database -p port -f sqlfile> sqllog.txt 2>&1
```
- NOTICE is used to check only tables that are visible to external systems. The detection of internal tables is included in the external tables on which NOTICE depends and is not displayed externally.
- This statement can be executed with error tolerance.
- If a key system catalog is damaged during a full database operation, an error is reported and the operation stops.
- Check data files of tables and indexes.  

```
{ANALYZE | ANALYSE} VERIFY {FAST|COMPLETE} {table_name|index_name} [CASCADE];
```

 **NOTE**

- Operations on ordinary tables and index tables are supported, but **CASCADE** operations on indexes of index tables are not supported. The **CASCADE** mode is used to process all index tables of the main table. When the index tables are checked separately, the **CASCADE** mode is not required.
- When the main table is checked, the internal tables of the main table, such as the TOAST table and cudesc table, are also checked.
- When the system displays a message indicating that the index table is damaged, you are advised to run the **reindex** command to rebuild the index.
- Check the data files of the table partition.  
`{ANALYZE | ANALYSE} VERIFY {FAST|COMPLETE} table_name PARTITION (partition_name) [CASCADE];`

 **NOTE**

You can check a single partition of a table, but cannot perform the **CASCADE** operation on the indexes of an index table.

## Parameters

- **VERBOSE**

Enables the display of progress messages.

 **NOTE**

If **VERBOSE** is specified, **ANALYZE** displays the progress information, indicating the table that is being processed. Statistics about tables are also displayed.

- **table\_name**

Specifies the name (possibly schema-qualified) of a specific table to analyze. If omitted, all regular tables (but not foreign tables) in the current database are analyzed.

Currently, you can use **ANALYZE** to collect statistics only from row-store tables.

Value range: an existing table name.

- **column\_name, column\_1\_name, column\_2\_name**

Specifies the name of a specific column to analyze. All columns are analyzed by default.

Value range: an existing column name.

- **partition\_name**

For a partitioned table, you can specify **partition\_name** following the keyword **PARTITION** to analyze the statistics of this table. Currently, **ANALYZE** can be performed on partitioned tables, but statistics of specified partitions cannot be analyzed.

Value range: a partition name of a table.

- **index\_name**

Specifies the name of the specific index table to be analyzed (possibly schema-qualified).

Value range: an existing table name.

- **FAST|COMPLETE**

For a row-store table, the **FAST** mode verifies the CRC and page header of the row-store table. If the verification fails, an alarm is generated. In **COMPLETE** mode, the pointer and tuple of the row-store table are parsed and verified.

- **CASCADE**

In **CASCADE** mode, all indexes of the current table are verified.

## Examples

-- Create a table.

```
openGauss=# CREATE TABLE customer_info
(
 WR_RETURNED_DATE_SK INTEGER
 WR_RETURNED_TIME_SK INTEGER
 WR_ITEM_SK INTEGER NOT NULL,
 WR_REFUNDED_CUSTOMER_SK INTEGER
)
;
```

-- Create a partitioned table.

```
openGauss=# CREATE TABLE customer_par
(
 WR_RETURNED_DATE_SK INTEGER
 WR_RETURNED_TIME_SK INTEGER
 WR_ITEM_SK INTEGER NOT NULL,
 WR_REFUNDED_CUSTOMER_SK INTEGER
)
PARTITION BY RANGE(WR_RETURNED_DATE_SK)
(
 PARTITION P1 VALUES LESS THAN(2452275),
 PARTITION P2 VALUES LESS THAN(2452640),
 PARTITION P3 VALUES LESS THAN(2453000),
 PARTITION P4 VALUES LESS THAN(MAXVALUE)
)
ENABLE ROW MOVEMENT;
```

-- Use ANALYZE to update statistics.

```
openGauss=# ANALYZE customer_info;
openGauss=# ANALYZE customer_par;
```

-- Use ANALYZE VERBOSE to update statistics and display table information.

```
openGauss=# ANALYZE VERBOSE customer_info;
INFO: analyzing "public.customer_info"(datanode pid=38661)
INFO: ANALYZE INFO : estimate total rows of "customer_info": scanned 0 pages of total 0 pages with 1
retry times, containing 0 live rows and 0 dead rows, estimated 0 total rows(datanode pid=38661)
INFO: ANALYZE INFO : "customer_info": scanned 0 of 0 pages, containing 0 live rows and 0 dead rows; 0
rows in sample, 0 estimated total rows(datanode pid=38661)
ANALYZE
```

### NOTE

If any environment-related fault occurs, check the logs of the primary node of the database.

-- Drop the table.

```
openGauss=# DROP TABLE customer_info;
openGauss=# DROP TABLE customer_par;
```

## 7.13.36 BEGIN

### Description

BEGIN may be used to initiate an anonymous block or a single transaction. This section describes the syntax of BEGIN used to initiate an anonymous block. For details about the BEGIN syntax that initiates transactions, see [START TRANSACTION](#).

An anonymous block is a structure that can dynamically create and execute stored procedure code instead of permanently storing code as a database object in the database.

### Precautions

None

### Syntax

- Enable an anonymous block.  

```
[DECLARE [declare_statements]]
BEGIN
 execution_statements
END;
/
```
- Start a transaction.  

```
BEGIN [WORK | TRANSACTION]
[
 {
 ISOLATION LEVEL { READ COMMITTED | SERIALIZABLE | REPEATABLE READ }
 | { READ WRITE | READ ONLY }
 } [, ...]
];
```

### Parameters

- **declare\_statements**  
Declares a variable, including its name and type, for example, **sales\_cnt int**.
- **execution\_statements**  
Specifies the statement to be executed in an anonymous block.  
Value range: DML operations (such as select, insert, delete, and update) or registered functions in the system catalog.

### Examples

```
-- Generate a string using an anonymous block.
openGauss=# BEGIN
dbe_output.print_line('Hello');
END;
/
```

### Helpful Links

[START TRANSACTION](#)

## 7.13.37 CALL

### Description

**CALL** calls defined functions and stored procedures.

### Precautions

The owner of a function or stored procedure, users granted the EXECUTE permission on the function or stored procedure, or users granted the EXECUTE ANY FUNCTION permission can call the function or stored procedure. System administrators have the permission to call the function or stored procedure by default.

### Syntax

```
CALL [schema.|package.] {func_name| procedure_name} (param_expr);
```

### Parameters

- **schema**  
Specifies the name of the schema where a function or stored procedure is located.
- **package**  
Specifies the name of the package where a function or stored procedure is located.
- **func\_name**  
Specifies the name of the function or stored procedure to be called.  
Value range: an existing function name.
- **param\_expr**  
Specifies a list of parameters. Use := or => to separate a parameter name and its value. This method allows parameters to be placed in any order. If only parameter values are in the list, the value order must be the same as that defined in the function or stored procedure.  
Value range: an existing function parameter name or stored procedure parameter name.

#### NOTE

The parameters include input parameters (whose name and type are separated by **IN**) and output parameters (whose name and type are separated by **OUT**). When you run the **CALL** command to call a function or stored procedure, the parameter list must contain an output parameter for non-overloaded functions. You can set the output parameter to a variable or any constant. For details, see [Examples](#). For an overloaded package function, the parameter list can have no output parameter, but the function may not be found. If an output parameter is contained, it must be a constant.

### Examples

```
-- Create a function named func_add_sql, calculate the sum of two integers, and return the result.
openGauss=# CREATE FUNCTION func_add_sql(num1 integer, num2 integer) RETURN integer
AS
BEGIN
RETURN num1 + num2;
```

```
END;
/

-- Pass by parameter value.
openGauss=# CALL func_add_sql(1, 3);

-- Pass by naming tag method.
openGauss=# CALL func_add_sql(num1 => 1,num2 => 3);
openGauss=# CALL func_add_sql(num2 := 2, num1 := 3);

-- Drop the function.
openGauss=# DROP FUNCTION func_add_sql;

-- Create a function with output parameters.
openGauss=# CREATE FUNCTION func_increment_sql(num1 IN integer, num2 IN integer, res OUT integer)
RETURN integer
AS
BEGIN
res := num1 + num2;
END;
/

-- Specify a constant as an output parameter.
openGauss=# CALL func_increment_sql(1,2,1);

-- Drop the function.
openGauss=# DROP FUNCTION func_increment_sql;
```

## Helpful Links

[CREATE FUNCTION](#) and [CALL](#)

## 7.13.38 CHECKPOINT

### Function

A checkpoint is a point in the transaction log sequence at which all data files have been updated to reflect the information in the log. All data files will be flushed to a disk.

**CHECKPOINT** forces a transaction log checkpoint. By default, WALs periodically specify checkpoints in a transaction log. You may use **gs\_guc** to specify run-time parameters **checkpoint\_segments**, **checkpoint\_timeout**, and **incremental\_checkpoint\_timeout** to adjust the atomized checkpoint intervals.

### Precautions

- Only the system administrator and O&M administrator can invoke **CHECKPOINT**.
- **CHECKPOINT** forces an immediate checkpoint when the related command is issued, without waiting for a regular checkpoint scheduled by the system.

### Syntax

```
CHECKPOINT;
```

### Parameter Description

None

## Examples

```
-- Set a checkpoint.
openGauss=# CHECKPOINT;
```

## 7.13.39 CLEAN CONNECTION

### Description

Clears database connections. You may use this statement to delete a specific user's connections to a specified database.

### Precautions

- GaussDB does not support specified nodes and supports only TO ALL.
- This function can be used to clear the normal connections that are being used only in force mode.

### Syntax

```
CLEAN CONNECTION
 TO { COORDINATOR (nodename [, ...]) | NODE (nodename [, ...]) | ALL [CHECK] [FORCE] }
 [FOR DATABASE dbname]
 [TO USER username];
```

### Parameters

- **CHECK**  
This parameter can be specified only when the node list is specified as **TO ALL**. Setting this parameter will check whether a database is accessed by other sessions before its connections are cleared. If any sessions are detected before **DROP DATABASE** is executed, an error will be reported and the database will not be dropped.
- **FORCE**  
This parameter can be specified only when the node list is specified as **TO ALL**. Setting this parameter will send **SIGTERM** signals to all the threads related to the specified **dbname** and **username** and forcibly shut them down.
- **COORDINATOR ( nodename [, ... ] ) | NODE ( nodename [, ... ] ) | ALL**  
Only **TO ALL** is supported. This parameter must be specified. All specified connections on the node will be deleted.
- **dbname**  
Deletes connections to a specified database. If this parameter is not specified, connections to all databases will be deleted.  
Value range: an existing database name.
- **username**  
Deletes connections of a specific user. If this parameter is not specified, connections of all users will be deleted.  
Value range: an existing username.

## Examples

```
-- Create the test_clean_connection database.
openGauss=# CREATE DATABASE test_clean_connection;
```

```
-- Create user jack.
openGauss=# CREATE USER jack PASSWORD '*****';

-- Clean the user jack's connections to the template1 database.
openGauss=# CLEAN CONNECTION TO ALL FOR DATABASE template1 TO USER jack;

-- Clean all connections of user jack.
openGauss=# CLEAN CONNECTION TO ALL TO USER jack;

-- Clean all the connections to the test_clean_connection database.
openGauss=# CLEAN CONNECTION TO ALL FORCE FOR DATABASE test_clean_connection;

-- Drop user jack.
openGauss=# DROP USER jack;

-- Drop the test_clean_connection database.
openGauss=# DROP DATABASE test_clean_connection;
```

## 7.13.40 CLOSE

### Function

**CLOSE** frees the resources associated with an open cursor.

### Precautions

- After a cursor is closed, no subsequent operations are allowed on it.
- A cursor should be closed when it is no longer needed.
- Every non-holdable open cursor is implicitly closed when a transaction is terminated by **COMMIT** or **ROLLBACK**.
- A holdable cursor is implicitly closed if the transaction that created it aborts by **ROLLBACK**.
- If the cursor creation transaction is successfully committed, the holdable cursor remains open until an explicit **CLOSE** operation is executed, or the client disconnects.
- GaussDB does not have an explicit **OPEN** cursor statement. A cursor is considered open when it is declared. You can view all available cursors by querying the **pg\_cursors** system view.

### Syntax

```
CLOSE { cursor_name | ALL } ;
```

### Parameter Description

- **cursor\_name**  
Specifies the name of a cursor to be closed.
- **ALL**  
Closes all open cursors.

### Examples

See [Examples](#) in **FETCH**.

## Helpful Links

[FETCH](#) and [MOVE](#)

### 7.13.41 CLUSTER

#### Description

- Clusters a table based on an index.
- CLUSTER instructs GaussDB to cluster the table specified by **table\_name** based on the index specified by **index\_name**. The index must have been defined by **table\_name**.
- When a table is clustered, it is physically reordered based on the index information. Clustering is a one-time operation. When the table is subsequently updated, the changes are not clustered. That is, no attempt is made to store new or updated rows according to their index order.
- When a table is clustered, GaussDB records which index the table was clustered by. CLUSTER table\_name reclusters the clustered index that was previously recorded in the table. You can also use ALTER TABLE table\_name CLUSTER on index\_name to set the index of a specified table for subsequent CLUSTER operations, or use ALTER TABLE table\_name SET WITHOUT CLUSTER to clear the previously clustered index of a specified table.
- If CLUSTER does not contain parameters, all tables that have been clustered in the database owned by the current user will be reprocessed. If a system administrator uses this command, all clustered tables are reclustered.
- When a table is being clustered, an ACCESS EXCLUSIVE lock is acquired on it. This prevents any other database operations (both read and write) from being performed on the table until the CLUSTER operation is finished.

#### Precautions

- Only row-store B-tree indexes support CLUSTER.
- In the case where you are accessing single rows randomly within a table, the actual order of the data in the table is unimportant. However, if there are many accesses to some data and an index groups the data, using the CLUSTER index improves performance.
- If you use an index to query a table for a range or multiple rows, CLUSTER will also help because once the index identifies the table page for the first row that matches, all other rows that match are probably already on the same table page. This saves disk accesses and speeds up the query.
- During clustering, the system creates a temporary backup of the table created in the index sequence and a temporary backup of each index in the table. Therefore, ensure that the disk has sufficient free space during clustering, which is at least the sum of the table size and all index sizes.
- CLUSTER records which indexes have been used for clustering. Therefore, you can manually specify indexes for the first time, cluster specified tables, and set a maintenance script that will be executed periodically. You only need to run the **CLUSTER** command without parameters. In this way, tables that you want to periodically cluster can be automatically updated.
- The optimizer records table clustering statistics. After clustering a table, you need to execute the ANALYZE operation to ensure that the optimizer has the

latest clustering information. Otherwise, the optimizer may select a non-optimal query plan.

- **CLUSTER** cannot be executed in transactions.
- If the GUC parameter **xc\_maintenance\_mode** is not set to **on**, the **CLUSTER** operation skips all system catalogs.

## Syntax

- Cluster a table.  
`CLUSTER [ VERBOSE ] table_name [ USING index_name ];`
- Cluster a partition.  
`CLUSTER [ VERBOSE ] table_name PARTITION ( partition_name ) [ USING index_name ];`
- Recluster a table.  
`CLUSTER [ VERBOSE ];`

## Parameters

- **VERBOSE**  
Enables the display of progress messages.
- **table\_name**  
Specifies the table name.  
Value range: an existing table name.
- **index\_name**  
Specifies the index name.  
Value range: name of an existing index.
- **partition\_name**  
Specifies the partition name.  
Value range: an existing partition name.

## Examples

```
-- Create a schema.
openGauss=# CREATE SCHEMA tpcds;

-- Create a partitioned table.
openGauss=# CREATE TABLE tpcds.inventory_p1
(
 INV_DATE_SK INTEGER NOT NULL,
 INV_ITEM_SK INTEGER NOT NULL,
 INV_WAREHOUSE_SK INTEGER NOT NULL,
 INV_QUANTITY_ON_HAND INTEGER
)
PARTITION BY RANGE(INV_DATE_SK)
(
 PARTITION P1 VALUES LESS THAN(2451179),
 PARTITION P2 VALUES LESS THAN(2451544),
 PARTITION P3 VALUES LESS THAN(2451910),
 PARTITION P4 VALUES LESS THAN(2452275),
 PARTITION P5 VALUES LESS THAN(2452640),
 PARTITION P6 VALUES LESS THAN(2453005),
 PARTITION P7 VALUES LESS THAN(MAXVALUE)
);

-- Create an index named ds_inventory_p1_index1.
openGauss=# CREATE INDEX ds_inventory_p1_index1 ON tpcds.inventory_p1 (INV_ITEM_SK) LOCAL;
```

```
-- Cluster the tpcds.inventory_p1 table.
openGauss=# CLUSTER tpcds.inventory_p1 USING ds_inventory_p1_index1;

-- Cluster the p3 partition.
openGauss=# CLUSTER tpcds.inventory_p1 PARTITION (p3) USING ds_inventory_p1_index1;

-- Recluster a table.
openGauss=# CLUSTER;

-- Drop the index.
openGauss=# DROP INDEX tpcds.ds_inventory_p1_index1;

-- Drop the partitioned table.
openGauss=# DROP TABLE tpcds.inventory_p1;

-- Drop the schema.
openGauss=# DROP SCHEMA tpcds CASCADE;
```

## 7.13.42 COMMENT

### Description

Defines or changes the comment of an object.

### Precautions

- Each object stores only one comment. Therefore, you need to modify a comment and issue a new **COMMENT** command to the same object. To delete the comment, write **NULL** at the position of the text string. When an object is deleted, the comment is automatically deleted.
- Currently, there is no security protection for viewing comments. Any user connected to a database can view all the comments for objects in the database. For shared objects such as databases, roles, and tablespaces, comments are stored globally so any user connected to any database in the cluster can see all the comments for shared objects. Therefore, do not put security-critical information in comments.
- To comment objects, you must be an object owner or user granted the COMMENT permission. System administrators have this permission by default.
- Roles do not have owners, so the rule for COMMENT ON ROLE is that you must be a system administrator to comment on a SYSADMIN role, or have the CREATEROLE permission to comment on non-SYSADMIN roles. A system administrator can comment on all objects.

### Syntax

```
COMMENT ON
{
 AGGREGATE agg_name (agg_type [, ...]) |
 CAST (source_type AS target_type) |
 COLLATION object_name |
 COLUMN { table_name.column_name | view_name.column_name } |
 CONSTRAINT constraint_name ON table_name |
 CONVERSION object_name |
 DATABASE object_name |
 DOMAIN object_name |
 EXTENSION object_name |
 FOREIGN DATA WRAPPER object_name |
 FOREIGN TABLE object_name |
 FUNCTION function_name ([{[argname] [argmode] argtype} [, ...]]) |
 INDEX object_name |
```

```
LARGE OBJECT large_object_oid |
OPERATOR operator_name (left_type, right_type) |
OPERATOR CLASS object_name USING index_method |
OPERATOR FAMILY object_name USING index_method |
[PROCEDURAL] LANGUAGE object_name |
ROLE object_name |
SCHEMA object_name |
SERVER object_name |
TABLE object_name |
TABLESPACE object_name |
TEXT SEARCH CONFIGURATION object_name |
TEXT SEARCH DICTIONARY object_name |
TEXT SEARCH PARSER object_name |
TEXT SEARCH TEMPLATE object_name |
TYPE object_name |
VIEW object_name |
TRIGGER trigger_name ON table_name
}
IS 'text';
```

## Parameters

- **agg\_name**  
Name of an aggregate function.
- **agg\_type**  
Data type of the aggregate function parameters.
- **source\_type**  
Source data type in the type conversion.
- **target\_type**  
Target data type in the type conversion.
- **object\_name**  
Object name.
- **table\_name.column\_name**  
**view\_name.column\_name**  
Column name You can add the table name or view name as the prefix.
- **constraint\_name**  
Table constraint whose comment is defined or modified.
- **table\_name**  
Table name.
- **function\_name**  
Function name.
- **argname,argmode,argtype**  
Name, schema, and type of the function parameters.
- **large\_object\_oid**  
OID of a large object.
- **operator\_name**  
Operator name.
- **left\_type,right\_type**  
Data type of the operator parameters (optionally schema-qualified). If the prefix or suffix operator does not exist, the **NONE** option can be added.

- **trigger\_name**  
Trigger name.
- **text**  
Comments.

## Examples

```
-- Create a schema.
openGauss=# CREATE SCHEMA tpcds;

-- Create the tpcds.customer table.
openGauss=# CREATE TABLE tpcds.customer
(
 c_customer_sk INTEGER NOT NULL,
 c_customer_id CHAR(16) NOT NULL
);

-- Insert multiple records into the table.
openGauss=# INSERT INTO tpcds.customer VALUES (50, 'AAAAAAAAABAAAAAA'),(100,
'AAAAAAAAACAAAAAA'),(150, 'AAAAAADAAAAAA');

-- Create the tpcds.customer_demographics_t2 table.
openGauss=# CREATE TABLE tpcds.customer_demographics_t2
(
 CD_DEMO_SK INTEGER NOT NULL,
 CD_GENDER CHAR(1) ,
 CD_MARITAL_STATUS CHAR(1) ,
 CD_EDUCATION_STATUS CHAR(20) ,
 CD_PURCHASE_ESTIMATE INTEGER ,
 CD_CREDIT_RATING CHAR(10) ,
 CD_DEP_COUNT INTEGER ,
 CD_DEP_EMPLOYED_COUNT INTEGER ,
 CD_DEP_COLLEGE_COUNT INTEGER
)
;

-- Comment out the tpcds.customer_demographics_t2.cd_demo_sk column.
openGauss=# COMMENT ON COLUMN tpcds.customer_demographics_t2.cd_demo_sk IS 'Primary key of
customer demographics table.';

-- Create a view consisting of rows with c_customer_sk less than 150.
openGauss=# CREATE VIEW tpcds.customer_details_view_v2 AS
 SELECT *
 FROM tpcds.customer
 WHERE c_customer_sk < 150;

-- Comment out the tpcds.customer_details_view_v2 view.
openGauss=# COMMENT ON VIEW tpcds.customer_details_view_v2 IS 'View of customer detail';

-- Drop the view.
openGauss=# DROP VIEW tpcds.customer_details_view_v2;

-- Drop the tpcds.customer_demographics_t2 table.
openGauss=# DROP TABLE tpcds.customer_demographics_t2;

-- Drop the tpcds.customer table.
openGauss=# DROP TABLE tpcds.customer;

-- Drop the schema.
openGauss=# DROP SCHEMA tpcds CASCADE;
```

## 7.13.43 COMMIT | END

### Description

COMMIT or END commits all operations of a transaction.

### Precautions

Only the creator of a transaction or system administrators can run the **COMMIT** command. The creation and commit operations do not need to be in different sessions.

### Syntax

```
{ COMMIT | END } [WORK | TRANSACTION] ;
```

### Parameters

- **COMMIT | END**  
Commits the current transaction and makes all changes made by the transaction become visible to others.
- **WORK | TRANSACTION**  
Specifies an optional keyword, which has no effect except increasing readability.

### Examples

```
-- Create a schema.
openGauss=# CREATE SCHEMA tpcds;

-- Create a table.
openGauss=# CREATE TABLE tpcds.customer_demographics_t2
(
 CD_DEMO_SK INTEGER NOT NULL,
 CD_GENDER CHAR(1) ,
 CD_MARITAL_STATUS CHAR(1) ,
 CD_EDUCATION_STATUS CHAR(20) ,
 CD_PURCHASE_ESTIMATE INTEGER ,
 CD_CREDIT_RATING CHAR(10) ,
 CD_DEP_COUNT INTEGER ,
 CD_DEP_EMPLOYED_COUNT INTEGER ,
 CD_DEP_COLLEGE_COUNT INTEGER
);

-- Start a transaction.
openGauss=# START TRANSACTION;

-- Insert data.
openGauss=# INSERT INTO tpcds.customer_demographics_t2 VALUES(1,'M', 'U', 'DOCTOR DEGREE', 1200,
'GOOD', 1, 0, 0);
openGauss=# INSERT INTO tpcds.customer_demographics_t2 VALUES(2,'F', 'U', 'MASTER DEGREE', 300,
'BAD', 1, 0, 0);

-- Commit the transaction to make all changes permanent.
openGauss=# COMMIT;

-- Query data.
openGauss=# SELECT * FROM tpcds.customer_demographics_t2;

-- Drop the tpcds.customer_demographics_t2 table.
```

```
openGauss=# DROP TABLE tpceds.customer_demographics_t2;
-- Drop the schema.
openGauss=# DROP SCHEMA tpceds CASCADE;
```

## Helpful Links

[ROLLBACK](#)

## 7.13.44 COMMIT PREPARED

### Description

Commits a prepared two-phase transaction.

### Precautions

- The function is only available in maintenance mode (when the GUC parameter **xc\_maintenance\_mode** is **on**). Exercise caution when enabling the mode. It is used by maintenance engineers for troubleshooting. Common users should not use the mode.
- Only the creator of a transaction or system administrators can run the command. The creation and commit operations do not need to be in different sessions.
- The transaction function is maintained automatically by the database, and should be not visible to users.

### Syntax

```
COMMIT PREPARED transaction_id [WITH commit_sequence_number];
```

### Parameters

- **transaction\_id**  
Specifies the identifier of the transaction to be committed. The identifier must be different from those for current prepared transactions.
- **commit\_sequence\_number**  
Specifies the sequence number of the transaction to be committed. It is a 64-bit, incremental, unsigned number.

### Examples

```
-- Start.
openGauss=# begin;

-- Prepare a transaction whose identifier is trans_test.
openGauss=# PREPARE TRANSACTION 'trans_test';

-- Create a table.
openGauss=# CREATE TABLE item1(id int);

-- Commit the transaction whose identifier is trans_test.
openGauss=# COMMIT PREPARED 'trans_test';

-- Drop the table.
openGauss=# DROP TABLE item1;
```

## Helpful Links

[PREPARE TRANSACTION](#) and [ROLLBACK PREPARED](#)

## 7.13.45 COPY

### Description

COPY copies data between tables and files.

COPY FROM copies data from a file to a table, and COPY TO copies data from a table to a file.

### Precautions

- When the **enable\_copy\_server\_files** parameter is disabled, only the initial user is allowed to run the **COPY FROM FILENAME** or **COPY TO FILENAME** command. When the **enable\_copy\_server\_files** parameter is enabled, users with the SYSADMIN permission or users who inherit the permissions of the built-in role `gs_role_copy_files` are allowed to run the **COPY FROM FILENAME** or **COPY TO FILENAME** command. By default, database configuration files and key files are not allowed, and you can run the **COPY FROM FILENAME** or **COPY TO FILENAME** command for certificate files and audit logs to prevent unauthorized users from viewing or modifying sensitive files. When **enable\_copy\_server\_files** is set to **on**, administrators can use the GUC parameter **safe\_data\_path** to set the path for common users to import and export to the subpath of the set path. If this GUC parameter is not set (by default), the path used by common users is not blocked.
- **COPY** applies only to tables but not views.
- COPY TO requires the SELECT permission on the table to be read, and COPY FROM requires the INSERT permission on the table to be inserted.
- If a list of columns is specified, COPY copies only the data of the specified columns between the file and the table. If a table has any columns that are not in the column list, COPY FROM inserts default values into those columns.
- If a data source file is specified, the server must be able to access the file. If **STDIN** is specified, data flows between the client and the server. When entering data, use the **TAB** key to separate the columns of the table and use a backslash and a period (\.) in a new row to indicate the end of the input.
- COPY FROM throws an error if any row in the data file contains more or fewer columns than expected.
- The end of the data can be represented by a line that contains only backslashes and periods (\.). If data is read from a file, the end flag is unnecessary. If data is copied between client applications, an end tag must be provided.
- In COPY FROM, **\N** is an empty string. To enter the actual value **\N**, use **\\N**.
- COPY FROM can preprocess data using column expressions, but column expressions do not support subqueries.
- When a data format error occurs during **COPY FROM** execution, the transaction is rolled back. However, the error information is insufficient, making it difficult to locate the error data from a large amount of raw data.

- COPY FROM and COPY TO apply to low concurrency and local import and export of a small amount of data.
- If the target table has triggers, COPY is supported.
- Ensure that the generated column is not in the list of the specified column in the COPY statement. When COPY... TO is used to export data, if no column list is specified, all columns except the generated columns in the table are exported. When COPY... FROM is used to import data, the generated columns are automatically updated and saved as ordinary columns.
- During the export using COPY TO, if the column data in the table contains the '\0' character, the column data will be truncated during the export. Only the data before '\0' will be exported.

## Syntax

- Copy data from a file to a table.

```
COPY table_name [(column_name [, ...])]
 FROM { 'filename' | STDIN }
 [[USING] DELIMITERS 'delimiters']
 [WITHOUT ESCAPING]
 [LOG ERRORS]
 [REJECT LIMIT 'limit']
 [WITH (option [, ...])]
 | copy_option
 | TRANSFORM ({ column_name [data_type] [AS transform_expr] } [, ...])
 | FIXED FORMATTER ({ column_name(offset, length) } [, ...]) [(option [, ...]) | copy_option
 [...]]];
```

### NOTE

In the syntax, **FIXED FORMATTER ( { column\_name( offset, length ) } [, ...] )** and non-conflicting items of **[ copy\_option [ ...] ]** can be in any sequence.

- Copy data from a table to a file.

```
COPY table_name [(column_name [, ...])]
 TO { 'filename' | STDOUT }
 [[USING] DELIMITERS 'delimiters']
 [WITHOUT ESCAPING]
 [WITH (option [, ...])]
 | copy_option
 | FIXED FORMATTER ({ column_name(offset, length) } [, ...]) [(option [, ...]) | copy_option
 [...]]];
```

```
COPY query {(SELECT) | (VALUES)}
 TO { 'filename' | STDOUT }
 [WITHOUT ESCAPING]
 [WITH (option [, ...])]
 | copy_option
 | FIXED FORMATTER ({ column_name(offset, length) } [, ...]) [(option [, ...]) | copy_option
 [...]]];
```

### NOTE

1. The restrictions on the COPY TO syntax are as follows:  
(**query**) is incompatible with **[USING] DELIMITERS**. If the data comes from a query result, COPY TO cannot specify **[USING] DELIMITERS**.
2. Use spaces to separate **copy\_option** following **FIXED FORMATTER**.
3. **copy\_option** is the native parameter, while **option** is the parameter imported by a compatible foreign table.
4. In the syntax, **FIXED FORMATTER ( { column\_name( offset, length ) } [, ...] )** and non-conflicting items of **[ copy\_option [ ...] ]** can be in any sequence.

The optional parameters of the option clause are as follows:

```
FORMAT 'format_name'
| OIDS [boolean]
| DELIMITER 'delimiter_character'
| NULL 'null_string'
| HEADER [boolean]
| USEEOF [boolean]
| FILEHEADER 'header_file_string'
| FREEZE [boolean]
| QUOTE 'quote_character'
| ESCAPE 'escape_character'
| EOL 'newline_character'
| NOESCAPING [boolean]
| FORCE_QUOTE { (column_name [, ...]) | * }
| FORCE_NOT_NULL (column_name [, ...])
| ENCODING 'encoding_name'
| IGNORE_EXTRA_DATA [boolean]
| FILL_MISSING_FIELDS [boolean]
| COMPATIBLE_ILLEGAL_CHARS [boolean]
| DATE_FORMAT 'date_format_string'
| TIME_FORMAT 'time_format_string'
| TIMESTAMP_FORMAT 'timestamp_format_string'
| SMALLDATETIME_FORMAT 'smalldatetime_format_string'
```

The optional parameters of the `copy_option` clause are as follows:

```
OIDS
| NULL 'null_string'
| HEADER
| USEEOF
| FILEHEADER 'header_file_string'
| FREEZE
| FORCE_NOT_NULL column_name [, ...]
| FORCE_QUOTE { column_name [, ...] | * }
| BINARY
| CSV
| QUOTE [AS] 'quote_character'
| ESCAPE [AS] 'escape_character'
| EOL 'newline_character'
| ENCODING 'encoding_name'
| IGNORE_EXTRA_DATA
| FILL_MISSING_FIELDS [{ 'one' | 'multi' }]
| COMPATIBLE_ILLEGAL_CHARS
| DATE_FORMAT 'date_format_string'
| TIME_FORMAT 'time_format_string'
| TIMESTAMP_FORMAT 'timestamp_format_string'
| SMALLDATETIME_FORMAT 'smalldatetime_format_string'
| SKIP int_number
| WHEN { (start - end) | column_name } { = | != } 'string'
| SEQUENCE ({ column_name (integer [, incr]) [, ...] })
| FILLER ({ column_name [, ...] })
| CONSTANT ({ column_name 'constant_string' [, ...] })
```

## Parameters

- **query**  
Specifies that the results are to be copied.  
Value range: Only one `SELECT` or `VALUES` command is supported. A semicolon (;) is not required at the end of the command.
- **table\_name**  
Specifies the name (possibly schema-qualified) of an existing table.  
Value range: an existing table name.
- **column\_name**  
Specifies an optional list of columns to be copied.  
Value range: any columns. All columns will be copied if no column list is specified.

- **STDIN**  
Specifies that input comes from the standard input.
- **STDOUT**  
Specifies that output goes to the standard output.
- **FIXED**  
Fixes column length. When the column length is fixed, **DELIMITER**, **NULL**, and **CSV** cannot be specified. When **FIXED** is specified, **BINARY**, **CSV**, and **TEXT** cannot be specified by **option** or **copy\_option**.

 **NOTE**

The definition of fixed length is as follows:

1. The column length of each record is the same.
2. Spaces are used for column padding. Columns of the numeric type are left-aligned and columns of the string type are right-aligned.
3. No delimiters are used between columns.

- **[USING] DELIMITERS 'delimiters'**

The string that separates columns within each row (line) of the file, and it cannot be larger than 10 bytes.

Value range: The delimiter cannot include any of the following characters:  
\\abcdefghijklmnopqrstuvwxyz0123456789

Value range: The default value is a tab character in text format and a comma in CSV format.

- **WITHOUT ESCAPING**

Specifies, in text format, whether to escape the backslash (\\) and its following characters.

Value range: text only.

- **LOG ERRORS**

If this parameter is specified, the error tolerance mechanism for data type errors in the COPY FROM statement is enabled.

Value range: a value set while data is imported using COPY FROM.

 **NOTE**

The restrictions of this error tolerance parameter are as follows:

- This error tolerance mechanism captures only the data type errors (DATA\_EXCEPTION) that occur during data parsing of COPY FROM on the primary node of the database.
- If existing error tolerance parameters (for example, **IGNORE\_EXTRA\_DATA**) of the COPY statement are enabled, the error of the corresponding type will be processed as specified by the parameters and no error will be reported. Therefore, the error table does not contain such error data.

- **LOG ERRORS DATA**

The differences between **LOG ERRORS DATA** and **LOG ERRORS** are as follows:

- a. **LOG ERRORS DATA** fills the **rawrecord** column in the error tolerance table.
- b. Only users with the super permission can use the **LOG ERRORS DATA** parameter.

#### NOTICE

If error content is too complex, it may fail to be written to the error tolerance table by using **LOG ERRORS DATA**, causing the task failure.

For errors that cannot be read in certain code, the error codes are `ERRCODE_CHARACTER_NOT_IN_REPERTOIRE` and `ERRCODE_UNTRANSLATABLE_CHARACTER`. The **rawrecord** column is not recorded.

- **REJECT LIMIT 'limit'**

Used with the **LOG ERROR** option to set the upper limit of the tolerated errors in the COPY FROM statement. If the number of errors exceeds the limit, later errors will be reported based on the original mechanism.

Value range: a positive integer (1 to `INTMAX`) or **'unlimited'**.

Default value: If **LOG ERRORS** is not specified, an error will be reported. If **LOG ERRORS** is specified, the default value is **0**.

#### NOTE

In the error tolerance mechanism described in the description of **LOG ERRORS**, the count of **REJECT LIMIT** is calculated based on the number of data parsing errors on the primary node of the database where the **COPY FROM** statement is executed, not based on the number of all errors on the primary node.

- **FORMATTER**

Defines the place of each column in the data file in fixed length mode.

Defines the place of each column in the data file in the **column(offset,length)** format.

Value range:

- The value of **offset** must be larger than 0. The unit is byte.
- The value of **length** must be larger than 0. The unit is byte.

The total length of all columns must be less than 1 GB.

Replace columns that are not in the file with null.

- **OPTION { option\_name ' value ' }**

Specifies all types of parameters of a compatible foreign table.

- **FORMAT**

Specifies the format of the source data file in the foreign table.

Value range: **CSV**, **TEXT**, **FIXED**, and **BINARY**.

- The CSV file can process newline characters efficiently, but cannot process certain special characters well.
- The TEXT file can process certain special characters efficiently, but cannot process newline characters well.
- In FIXED files, the column length of each record is the same. Spaces are used for padding, and the excessive part will be truncated.
- All data in the BINARY file is stored/read as binary format rather than as text. It is faster than the text and CSV formats, but a binary-format file is less portable.

Default value: **TEXT**

– DELIMITER

Specifies the character that separates columns within each row (line) of the file.

 NOTE

- The value of **delimiter** cannot be `\r` or `\n`.
- A delimiter cannot be the same as the value of **null**. The delimiter for the CSV format cannot be same as the value of **quote**.
- The delimiter for the TEXT format data cannot contain lowercase letters, digits, or special characters (.,\).
- The data length of a single row should be less than 1 GB. A row that has many columns using long delimiters cannot contain much valid data.
- You are advised to use multi-character delimiters or invisible delimiters. For example, you can use multi-characters (such as `$^&`) and invisible characters (such as `0x07`, `0x08`, and `0x1b`).

Value range: a multi-character delimiter within 10 bytes.

Default value:

- A tab character in text format.
- A comma (,) in CSV format.
- No delimiter in FIXED format.

– NULL

Specifies the string that represents a null value.

Value range:

- A null value cannot be `\r` or `\n`. The maximum length is 100 characters.
- A null value cannot be the same as the **delimiter** or **quote** value.

Default value:

- The default value for the CSV format is an empty string without quotation marks.
- The default value for the TEXT format is `\N`.

– HEADER

Specifies whether a file contains a header with the names of each column in the file. **header** is available only for CSV and FIXED files.

When data is imported, if **header** is **on**, the first row of the data file will be identified as the header and ignored. If **header** is **off**, the first row will be identified as a data row.

When data is exported, if header is **on**, **fileheader** must be specified. If **header** is **off**, an exported file does not contain a header.

Value range: **true**, **on**, **false**, and **off**.

Default value: **false**

– HEADER

Does not report an error for \. in the imported data.

Value range: **true**, **on**, **false**, and **off**.

Default value: **false**

– QUOTE

Specifies a quoted character string for a CSV file.

Default value: double quotation marks ("").

 NOTE

- The value of **quote** cannot be the same as that of the **delimiter** or **null** parameter.
- The value of **quote** must be a single-byte character.
- You are advised to set **quote** to an invisible character, such as **0x07**, **0x08**, or **0x1b**.

– ESCAPE

Specifies an escape character for a CSV file. The value must be a single-byte character.

Default value: double quotation marks (""). If the value is the same as that of **quote**, it will be replaced by \0.

– EOL 'newline\_character'

Specifies the newline character style of the imported or exported data file.

Value range: multi-character newline characters within 10 bytes. Common newline characters include \r (0x0D), \n (0x0A), and \r\n (0x0D0A). Special newline characters include \$ and #.

 NOTE

- The **EOL** parameter supports only the TEXT format for data import and export and does not support the CSV or FIXED format for data import. For forward compatibility, the EOL parameter can be set to **0x0D** or **0x0D0A** for data export in the CSV or FIXED format.
- The value of **EOL** cannot be the same as that of the **delimiter** or **null** parameter.
- The EOL parameter value cannot contain the following characters: .abcdefghijklmnopqrstuvwxyz0123456789.

– FORCE\_QUOTE { ( column\_name [, ...] ) | \* }

In **CSV COPY TO** mode, forces quotation marks to be used for all non-null values in each specified column. **NULL** values are not quoted.

Value range: name of an existing column.

– FORCE\_NOT\_NULL ( column\_name [, ...] )

In **CSV COPY FROM** mode, the value for a specified column cannot be null.

Value range: name of an existing column.

– ENCODING

Specifies the encoding of data files. If this option is omitted, the current client-side encoding is used.

– IGNORE\_EXTRA\_DATA

Specifies whether to ignore excessive columns when the number of data source files exceeds the number of foreign table columns. This parameter is used only during data import.

Value range: **true**, **on**, **false**, and **off**.

- If this parameter is set to **true** or **on** and the number of source data files exceeds the number of foreign table columns, excessive columns will be ignored.
- When the parameter is **false** or **off**, and the number of data source files is more than the number of foreign table columns, the following error information will be displayed:  
extra data after last expected column

Default value: **false**

#### NOTICE

If a newline character at the end of a row is missing and the row and another row are integrated into one, data in another row is ignored after the parameter is set to **true**.

#### – COMPATIBLE\_ILLEGAL\_CHARS

Specifies whether to tolerate invalid characters during data import. The parameter is valid only for data import using COPY FROM.

Value range: **true**, **on**, **false**, and **off**.

- If this parameter is set to **true** or **on**, invalid characters are tolerated and imported to the database after conversion.
- If this parameter is set to **false** or **off** and an error occurs when there are invalid characters, the import will be interrupted.

Default value: **false** or **off**.

#### NOTE

The rules for converting invalid characters are as follows:

1. **\0** is converted to a space.
2. Other invalid characters are converted to question marks.
3. When **compatible\_illegal\_chars** is set to **true** or **on**, after invalid characters such as **NULL**, **DELIMITER**, **QUOTE**, and **ESCAPE** are converted to spaces or question marks, an error message like "illegal chars conversion may confuse COPY escape 0x20" will be displayed to remind you of possible parameter confusion caused by the conversion.

#### – FILL\_MISSING\_FIELDS

Specifies how to handle the problem that the last column of a row in a source data file is lost during data import.

Value range: **true**, **on**, **false**, and **off**.

Default value: **false** or **off**.

#### – DATE\_FORMAT

Specifies the DATE format for data import. The BINARY format is not supported. When data of such format is imported, error "cannot specify

bulkload compatibility options in BINARY mode" will occur. The parameter is valid only for data import using COPY FROM.

Value range: a valid DATE value. For details, see [Date and Time Processing Functions and Operators](#).

#### NOTE

You can use the **TIMESTAMP\_FORMAT** parameter to set the DATE format to **TIMESTAMP** for data import. For details, see **TIMESTAMP\_FORMAT** below.

- **TIME\_FORMAT**  
Specifies the TIME format for data import. The BINARY format is not supported. When data of such format is imported, error "cannot specify bulkload compatibility options in BINARY mode" will occur. The parameter is valid only for data import using COPY FROM.  
Value range: a valid TIME value. Time zones cannot be used. For details, see [Date and Time Processing Functions and Operators](#).
- **TIMESTAMP\_FORMAT**  
Specifies the TIMESTAMP format for data import. The BINARY format is not supported. When data of such format is imported, error "cannot specify bulkload compatibility options in BINARY mode" will occur. The parameter is valid only for data import using COPY FROM.  
Value range: a valid TIMESTAMP value. Time zones cannot be used. For details, see [Date and Time Processing Functions and Operators](#).
- **SMALLDATETIME\_FORMAT**  
Specifies the SMALLDATETIME format for data import. The BINARY format is not supported. When data of such format is imported, error "cannot specify bulkload compatibility options in BINARY mode" will occur. The parameter is valid only for data import using COPY FROM.  
Value range: a valid SMALLDATETIME value. For details, see [Date and Time Processing Functions and Operators](#).
- **COPY\_OPTION { option\_name ' value ' }**  
Specifies all types of native parameters of COPY.
  - **NULL null\_string**  
Specifies the string that represents a null value.

---

#### NOTICE

When using COPY FROM, any data item that matches this string will be stored as a null value, so make sure that you use the same string as you used with COPY TO.

---

Value range:

- A null value cannot be **\r** or **\n**. The maximum length is 100 characters.
- A null value cannot be the same as the **delimiter** or **quote** value.

Default value:

- The default value for the TEXT format is `\N`.
- The default value for the CSV format is an empty string without quotation marks.
- HEADER  
Specifies whether a file contains a header with the names of each column in the file. **header** is available only for CSV and FIXED files.  
When data is imported, if **header** is **on**, the first row of the data file will be identified as the header and ignored. If **header** is **off**, the first row will be identified as a data row.  
When data is exported, if header is **on**, **fileheader** must be specified. If **header** is **off**, an exported file does not contain a header.
- HEADER  
Does not report an error for `\.` in the imported data.
- FILEHEADER  
Specifies a file that defines the content in the header for exported data. The file contains data description of each column.

---

**NOTICE**

- This parameter is available only when **header** is **on** or **true**.
  - **fileheader** specifies an absolute path.
  - The file can contain only one row of header information, and ends with a newline character. Excess rows will be discarded. (Header information cannot contain newline characters.)
  - The length of the file including the newline character cannot exceed 1 MB.
- 
- FREEZE  
Sets the **COPY** loaded data row as **frozen**, like these data have executed **VACUUM FREEZE**.  
This is a performance option of initial data loading. The data will be frozen only when the following three requirements are met:
    - The table being loaded has been created or truncated in the same transaction before copying.
    - There are no cursors open in the current transaction.
    - There are no original snapshots in the current transaction.

 **NOTE**

When COPY is completed, all the other sessions will see the data immediately. However, this violates the general principle of MVCC visibility, and users should understand that this may cause potential risks.

- FORCE NOT NULL column\_name [, ...]  
In **CSV COPY FROM** mode, the specified column is not null. If the column is null, its value is regarded as a string of 0 characters.

Value range: name of an existing column.

- FORCE QUOTE { column\_name [, ...] | \* }

In **CSV COPY TO** mode, forces quotation marks to be used for all non-null values in each specified column. **NULL** values are not quoted.

Value range: name of an existing column.

- BINARY

Specifies that data is stored and read in binary mode instead of text mode. In binary mode, you cannot declare **DELIMITER**, **NULL**, or **CSV**. When **BINARY** is specified, **CSV**, **FIXED**, and **TEXT** cannot be specified through **option** or **copy\_option**.

- CSV

Enables the CSV mode. When **CSV** is specified, **BINARY**, **FIXED**, and **TEXT** cannot be specified through **option** or **copy\_option**.

- QUOTE [AS] 'quote\_character'

Specifies a quoted character string for a CSV file.

Default value: double quotation marks ("").

#### NOTE

- The value of **quote** cannot be the same as that of the **delimiter** or **null** parameter.
- The value of **quote** must be a single-byte character.
- You are advised to set **quote** to an invisible character, such as **0x07**, **0x08**, or **0x1b**.

- ESCAPE [AS] 'escape\_character'

Specifies an escape character for a CSV file. The value must be a single-byte character.

Default value: double quotation marks (""). If the value is the same as that of **quote**, it will be replaced by **\0**.

- EOL 'newline\_character'

Specifies the newline character style of the imported or exported data file.

Value range: multi-character newline characters within 10 bytes. Common newline characters include **\r** (0x0D), **\n** (0x0A), and **\r\n** (0x0D0A). Special newline characters include **\$** and **#**.

#### NOTE

- The **EOL** parameter supports only the TEXT format for data import and export and does not support the CSV or FIXED format. For forward compatibility, the **EOL** parameter can be set to **0x0D** or **0x0D0A** for data export in the CSV or FIXED format.
- The value of **EOL** cannot be the same as that of the **delimiter** or **null** parameter.
- The EOL parameter value cannot contain the following characters: .abcdefghijklmnopqrstuvwxyz0123456789.

- ENCODING 'encoding\_name'

Specifies the name of a file encoding format.

Value range: a valid encoding format.

Default value: current encoding format.

– IGNORE\_EXTRA\_DATA

Specifies that when the number of data source files exceeds the number of foreign table columns, excess columns at the end of the row are ignored. This parameter is used only during data import.

If this parameter is not used and the number of columns in the data source file is greater than that defined in the foreign table, the following error information is displayed:

extra data after last expected column

– COMPATIBLE\_ILLEGAL\_CHARS

Specifies that invalid characters are tolerated during data import. Invalid characters are converted and then imported to the database. No error is reported and the import is not interrupted. The BINARY format is not supported. When data of such format is imported, error "cannot specify bulkload compatibility options in BINARY mode" will occur. The parameter is valid only for data import using COPY FROM.

If this parameter is not used, an error is reported when invalid characters are encountered during the import, and the import is interrupted.

 NOTE

The rules for converting invalid characters are as follows:

1. \0 is converted to a space.
2. Other invalid characters are converted to question marks.
3. When **compatible\_illegal\_chars** is set to **true** or **on**, after invalid characters such as **NULL**, **DELIMITER**, **QUOTE**, and **ESCAPE** are converted to spaces or question marks, an error message like "illegal chars conversion may confuse COPY escape 0x20" will be displayed to remind you of possible parameter confusion caused by the conversion.

– FILL\_MISSING\_FIELDS [ { 'one' | 'multi' } ]

Specifies how to handle the problem that the last columns of a row in a source data file are lost during data import. If **one** or **multi** is not specified or **one** is specified, the missing of the last column is handled in the default mode. If **multi** is specified, the missing of the last multiple columns are handled in the default mode.

Value range: **true**, **on**, **false**, and **off**.

Default value: **false** or **off**.

---

NOTICE

Do not specify this option. Currently, it does not enable error tolerance, but will make the parser ignore the said errors during data parsing on the primary node of the database. Such errors will not be recorded in the COPY error table (enabled by using **LOG ERRORS REJECT LIMIT**) but will be reported later by database node. Therefore, do not specify this option.

---

– DATE\_FORMAT 'date\_format\_string'

Specifies the DATE format for data import. The BINARY format is not supported. When data of such format is imported, error "cannot specify

bulkload compatibility options in BINARY mode" will occur. The parameter is valid only for data import using COPY FROM.

Value range: a valid DATE value. For details, see [Date and Time Processing Functions and Operators](#).

#### NOTE

You can use the **TIMESTAMP\_FORMAT** parameter to set the DATE format to **TIMESTAMP** for data import. For details, see **TIMESTAMP\_FORMAT** below.

- **TIME\_FORMAT** 'time\_format\_string'  
Specifies the TIME format for data import. The BINARY format is not supported. When data of such format is imported, error "cannot specify bulkload compatibility options in BINARY mode" will occur. The parameter is valid only for data import using COPY FROM.  
Value range: a valid TIME value. Time zones cannot be used. For details, see [Date and Time Processing Functions and Operators](#).
- **TIMESTAMP\_FORMAT** 'timestamp\_format\_string'  
Specifies the TIMESTAMP format for data import. The BINARY format is not supported. When data of such format is imported, error "cannot specify bulkload compatibility options in BINARY mode" will occur. The parameter is valid only for data import using COPY FROM.  
Value range: a valid TIMESTAMP value. Time zones cannot be used. For details, see [Date and Time Processing Functions and Operators](#).
- **SMALLDATETIME\_FORMAT** 'smalldatetime\_format\_string'  
Specifies the SMALLDATETIME format for data import. The BINARY format is not supported. When data of such format is imported, error "cannot specify bulkload compatibility options in BINARY mode" will occur. The parameter is valid only for data import using COPY FROM.  
Value range: a valid SMALLDATETIME value. For details, see [Date and Time Processing Functions and Operators](#).
- **TRANSFORM** ( { column\_name [ data\_type ] [ AS transform\_expr ] } [, ...] )  
Specify the conversion expression of each column in the table. **data\_type** specifies the data type of the column in the expression parameter. **transform\_expr** is the target expression that returns the result value whose data type is the same as that of the target column in the table. For details about the expression, see [Expressions](#).
- **SKIP** int\_number  
Specifies that the first *int\_number* rows of the data file are skipped during data import.
- **WHEN** { ( start - end ) | column\_name } { = | != } 'string'  
When data is imported, each row of data is checked. Only the rows that meet the WHEN condition are imported to the table.
- **SEQUENCE** ( { column\_name ( integer [, incr] ) [, ...] } )  
During data import, columns modified by SEQUENCE do not read data from the data file. The values are incremented by the value of **incr** based on the specified integer. If **incr** is not specified, the values are incremented from 1 by default.

- FILLER ( { column\_name [, ...] } )

When data is imported, the column modified by FILLER is discarded after being read from the data file.

#### NOTE

To use FILLER, you need to specify the list of columns to be copied. During data processing, data is processed based on the position of the **filler** column in the column list.

- CONSTANT ( { column\_name 'constant\_string' [, ...] } )

When data is imported, the column modified by CONSTANT is not read from the data file, and **constant\_string** is used to assign a value to the column.

The following special backslash sequences are recognized by COPY FROM:

- **\b**: Backslash (ASCII 8)
- **\f**: Form feed (ASCII 12)
- **\n**: Newline character (ASCII 10)
- **\r**: Carriage return character (ASCII 13)
- **\t**: Tab (ASCII 9)
- **\v**: Vertical tab (ASCII 11)
- **\digits**: Backslash followed by one to three octal digits specifies that the ASCII value is the character with that numeric code.
- **\xdigits**: Backslash followed by an x and one or two hex digits specifies the character with that numeric code.

## Permission Control Examples

```
openGauss=> copy t1 from '/home/xy/t1.csv';
ERROR: COPY to or from a file is prohibited for security concerns
HINT: Anyone can COPY to stdout or from stdin. gsql's \copy command also works for anyone.
openGauss=> grant gs_role_copy_files to xxx;
```

This error occurs because a non-initial user does not have the COPY permission. To solve this problem, set the **enable\_copy\_server\_files** parameter to **on**. Then, administrators can use the COPY function. To perform the COPY operation, common users must also join the **gs\_role\_copy\_files** group.

## Examples

```
-- Create a schema.
openGauss=# CREATE SCHEMA tpcds;

-- Create the tpcds.ship_mode table.
openGauss=# CREATE TABLE tpcds.ship_mode
(
 SM_SHIP_MODE_SK INTEGER NOT NULL,
 SM_SHIP_MODE_ID CHAR(16) NOT NULL,
 SM_TYPE CHAR(30) ,
 SM_CODE CHAR(10) ,
 SM_CARRIER CHAR(20) ,
 SM_CONTRACT CHAR(20)
);

-- Insert a single data record into the tpcds.ship_mode table.
openGauss=# INSERT INTO tpcds.ship_mode VALUES (1,'a','b','c','d','e');
```

```
-- Copy data from the tpcds.ship_mode file to the /home/omm/ds_ship_mode.dat file.
openGauss=# COPY tpcds.ship_mode TO '/home/omm/ds_ship_mode.dat';

-- Output tpcds.ship_mode to STDOUT.
openGauss=# COPY tpcds.ship_mode TO STDOUT;

-- Output the data of tpcds.ship_mode to STDOUT. The parameters are as follows: The delimiter is ','
(delimiter ',') and the encoding format is UTF8 (encoding 'utf8').
openGauss=# COPY tpcds.ship_mode TO STDOUT WITH (delimiter ',', encoding 'utf8');

-- Output the data of tpcds.ship_mode to STDOUT. The parameters are as follows: The import format is
CSV (format 'CSV'), and the exported content of the SM_SHIP_MODE_SK column is enclosed in quotation
marks (force_quote(SM_SHIP_MODE_SK)).
openGauss=# COPY tpcds.ship_mode TO STDOUT WITH (format 'CSV', force_quote(SM_SHIP_MODE_SK));

-- Create the tpcds.ship_mode_t1 table.
openGauss=# CREATE TABLE tpcds.ship_mode_t1
(
 SM_SHIP_MODE_SK INTEGER NOT NULL,
 SM_SHIP_MODE_ID CHAR(16) NOT NULL,
 SM_TYPE CHAR(30) ,
 SM_CODE CHAR(10) ,
 SM_CARRIER CHAR(20) ,
 SM_CONTRACT CHAR(20)
)
;

-- Copy data from STDIN to the tpcds.ship_mode_t1 table.
openGauss=# COPY tpcds.ship_mode_t1 FROM STDIN;

-- Copy data from the /home/omm/ds_ship_mode.dat file to the tpcds.ship_mode_t1 table.
openGauss=# COPY tpcds.ship_mode_t1 FROM '/home/omm/ds_ship_mode.dat';

-- Copy data from the /home/omm/ds_ship_mode.dat file to the tpcds.ship_mode_t1 table, convert the
data using the TRANSFORM expression, and insert the 10 characters on the left of the SM_TYPE column
into the table.
openGauss=# COPY tpcds.ship_mode_t1 FROM '/home/omm/ds_ship_mode.dat' TRANSFORM (SM_TYPE AS
LEFT(SM_TYPE, 10));

-- Copy data from the /home/omm/ds_ship_mode.dat file to the tpcds.ship_mode_t1 table, with the
import format set to TEXT (format 'text'), the delimiter set to '\t' (delimiter E'\t'), excessive columns
ignored (ignore_extra_data 'true'), and characters not escaped (noescaping 'true').
openGauss=# COPY tpcds.ship_mode_t1 FROM '/home/omm/ds_ship_mode.dat' WITH(format 'text',
delimiter E'\t', ignore_extra_data 'true', noescaping 'true');

-- Copy data from the /home/omm/ds_ship_mode.dat file to the tpcds.ship_mode_t1 table, with the
import format set to FIXED, fixed-length format specified (FORMATTER(SM_SHIP_MODE_SK(0, 2),
SM_SHIP_MODE_ID(2,16), SM_TYPE(18,30), SM_CODE(50,10), SM_CARRIER(61,20),
SM_CONTRACT(82,20))), excessive columns ignored (ignore_extra_data), and headers included (header).
openGauss=# COPY tpcds.ship_mode_t1 FROM '/home/omm/ds_ship_mode.dat' FIXED
FORMATTER(SM_SHIP_MODE_SK(0, 2), SM_SHIP_MODE_ID(2,16), SM_TYPE(18,30), SM_CODE(50,10),
SM_CARRIER(61,20), SM_CONTRACT(82,20)) header ignore_extra_data;

-- Drop tables and the schema.
openGauss=# DROP TABLE tpcds.ship_mode;
openGauss=# DROP TABLE tpcds.ship_mode_t1;
openGauss=# DROP SCHEMA tpcds;
```

## 7.13.46 CREATE AGGREGATE

### Description

Defines a new aggregate function.

### Syntax

```
CREATE AGGREGATE name (input_data_type [, ...]) (
 SFUNC = sfunc,
```

```
SType = state_data_type
[, FINALFUNC = ffunc]
[, INITCOND = initial_condition]
[, SORTOP = sort_operator]
)

or the old syntax

CREATE AGGREGATE name (
 BASETYPE = base_type,
 SFUNC = sfunc,
 STYPE = state_data_type
 [, FINALFUNC = ffunc]
 [, INITCOND = initial_condition]
 [, SORTOP = sort_operator]
)
```

## Parameters

- **name**  
Name (optionally schema-qualified) of the aggregate function to be created.
- **input\_data\_type**  
Data type of the input to be processed by the aggregate function. To create a zero-parameter aggregate function, you can use an asterisk (\*) instead of a list of input data types. (count(\*) is an instance of this aggregate function.)
- **base\_type**  
In the CREATE AGGREGATE syntax, the input data type is specified by the **basetype** parameter instead of following **name**. Note that the previous syntax allows only one input parameter. To create a zero-parameter aggregate function, you can set **basetype** to **ANY** instead of \*.
- **sfunc**  
Name of the state conversion function that will be called on each input line. For an aggregate function with *N* parameters, **sfunc** must have *N*+1 parameters. The first parameter is of the **state\_data\_type** type, and the other parameters match the declared input data types. The function must return a value of the **state\_data\_type** type. This function accepts the current state value and the current input data, and returns the next state value.
- **state\_data\_type**  
Data type of the aggregation status value.
- **ffunc**  
Final processing function called after all the input lines have been converted, which calculates the result of aggregation. This function must accept a parameter of **state\_data\_type**. The output data type of the aggregation is defined as the return type of this function. If **ffunc** is not specified, the state value of the aggregation result is used as the aggregation result, and the output type is **state\_data\_type**.
- **initial\_condition**  
Initial setting (value) of a state value. It must be a text constant value acceptable to **state\_data\_type**. If not specified, the initial state value is **NULL**.
- **sort\_operator**  
Sort operator used for MIN or MAX aggregation. This is just an operator name (optionally schema-qualified). This operator assumes that the input data type is the same as that of aggregation.

## Examples

```
-- Create a user-defined function.
openGauss=# CREATE OR REPLACE FUNCTION int_add(int,int)
returns int as $BODY$
declare
begin
return $1 + $2;
end;
$BODY$ language plpgsql;

-- Create an aggregate function.
openGauss=# CREATE AGGREGATE sum_add(int)
(
sfunc = int_add,

stype = int,

initcond = '0'
);

-- Create a test table and add data.
openGauss=# CREATE TABLE test_sum(a int,b int,c int);
openGauss=# INSERT INTO test_sum VALUES(1,2),(2,3),(3,4),(4,5);

-- Execute the aggregate function.
openGauss=# SELECT sum_add(a) FROM test_sum;
sum_add

10

-- Drop the aggregate function.
openGauss=# DROP AGGREGATE sum_add(int);

-- Drop the user-defined function.
openGauss=# DROP FUNCTION int_add(int,int);

-- Drop the test table.
openGauss=# DROP TABLE test_sum;
```

## 7.13.47 CREATE AUDIT POLICY

### Description

Creates a unified audit policy.

### Precautions

Only users with the POLADMIN or SYSADMIN permission, or the initial user can perform this operation.

The masking policy takes effect only after the security policy is enabled, that is, **enable\_security\_policy** is set to **on**.

### Syntax

```
CREATE AUDIT POLICY [IF NOT EXISTS] policy_name { privilege_audit_clause | access_audit_clause } [, ...]
[filter_group_clause] [ENABLE | DISABLE];
```

- **privilege\_audit\_clause**  
PRIVILEGES { DDL | ALL } [ ON LABEL ( resource\_label\_name [, ... ] ) ]
- **access\_audit\_clause**  
ACCESS { DML | ALL } [ ON LABEL ( resource\_label\_name [, ... ] ) ]

- **filter\_group\_clause**  
FILTER ON { FILTER\_TYPE ( filter\_value [, ... ] ) } [, ... ]

## Parameters

- **policy\_name**  
Specifies the audit policy name, which must be unique.  
Value range: a string that complies with the [Identifier Naming Conventions](#).
- **resource\_label\_name**  
Specifies the resource label name.
- **DDL**  
Specifies the operations that are audited in the database: **CREATE**, **ALTER**, **DROP**, **ANALYZE**, **COMMENT**, **GRANT**, **REVOKE**, **SET**, **SHOW**, **LOGIN\_ANY**, **LOGIN\_FAILURE**, **LOGIN\_SUCCESS**, and **LOGOUT**.
- **DML**  
Specifies the operations that are audited in the database: **SELECT**, **COPY**, **DEALLOCATE**, **DELETE**, **EXECUTE**, **INSERT**, **PREPARE**, **REINDEX**, **TRUNCATE**, and **UPDATE**.
- **ALL**  
Specifies all operations supported by the specified DDL or DML statements in the database. When the form is { DDL | ALL }, **ALL** indicates all DDL operations. When the form is { DML | ALL }, **ALL** indicates all DML operations.
- **FILTER\_TYPE**  
Specifies the types of information to be filtered by the policy, including **APP**, **ROLES**, and **IP**.
- **filter\_value**  
Specifies the detailed information to be filtered.
- **ENABLE|DISABLE**  
Enables or disables the unified audit policy. If **ENABLE|DISABLE** is not specified, **ENABLE** is used by default.

## Examples

```
-- Create users dev_audit and bob_audit.
openGauss=# CREATE USER dev_audit PASSWORD '*****';
openGauss=# CREATE USER bob_audit PASSWORD '*****';

-- Create table tb_for_audit.
openGauss=# CREATE TABLE tb_for_audit(col1 text, col2 text, col3 text);

-- Create a resource label.
openGauss=# CREATE RESOURCE LABEL adt_lb0 ADD TABLE(tb_for_audit);

-- Perform the CREATE operation on the database to create an audit policy.
openGauss=# CREATE AUDIT POLICY adt1 PRIVILEGES CREATE;

-- Perform the SELECT operation on the database to create an audit policy.
openGauss=# CREATE AUDIT POLICY adt2 ACCESS SELECT;

-- Create an audit policy to audit only the CREATE operations performed on the adt_lb0 resource by users dev_audit and bob_audit.
openGauss=# CREATE AUDIT POLICY adt3 PRIVILEGES CREATE ON LABEL(adt_lb0) FILTER ON
ROLES(dev_audit, bob_audit);
```

```
-- Create an audit policy to audit only the SELECT, INSERT, and DELETE operations performed on the
adt_lb0 resource by users dev_audit and bob_audit using client tool gsql on the servers whose IP
addresses are 10.20.30.40 and 127.0.0.0/24.
openGauss=# CREATE AUDIT POLICY adt4 ACCESS SELECT ON LABEL(adt_lb0), INSERT ON LABEL(adt_lb0),
DELETE FILTER ON ROLES(dev_audit, bob_audit), APP(gsql), IP('10.20.30.40', '127.0.0.0/24');

-- Drop audit policies.
openGauss=# DROP AUDIT POLICY adt1, adt2, adt3, adt4;

-- Drop a resource label.
openGauss=# DROP RESOURCE LABEL adt_lb0;

-- Drop the tb_for_audit table.
openGauss=# DROP TABLE tb_for_audit;

-- Drop the dev_audit and bob_audit users.
openGauss=# DROP USER dev_audit, bob_audit;
```

## Helpful Links

[ALTER AUDIT POLICY](#) and [DROP AUDIT POLICY](#)

## 7.13.48 CREATE CAST

### Description

Defines a conversion.

### Syntax

```
CREATE CAST (source_type AS target_type)
 WITH FUNCTION function_name (argument_type [, ...])
 [AS ASSIGNMENT | AS IMPLICIT]

CREATE CAST (source_type AS target_type)
 WITHOUT FUNCTION
 [AS ASSIGNMENT | AS IMPLICIT]

CREATE CAST (source_type AS target_type)
 WITH INOUT
 [AS ASSIGNMENT | AS IMPLICIT]
```

### Parameters

- **source\_type**  
Type of the source data to be converted.
- **target\_type**  
Type of the target data to be converted.
- **function\_name(argument\_type [, ...])**  
Function used for conversion. The function name can be modified with a schema name. If it is not modified with a schema name, the function will be found in the schema search path. The result data type of the function must match the target type of the conversion. Its parameters are discussed below.
- **WITHOUT FUNCTION**  
Indicates that the source type is a binary castable to the target type, so no function is needed to perform this conversion.
- **WITH INOUT**

Indicates that the conversion is an I/O conversion, which is performed by calling the output function of the source data type and transferring the result to the input function of the target data type.

- **AS ASSIGNMENT**

Indicates that the conversion can be implicitly called in assignment mode.

- **AS IMPLICIT**

Indicates that the transformation can be implicitly called in any environment.

A conversion implementation function can have one to three parameters. The type of the first parameter must be the same as that of the source type to be converted, or can be forcibly converted from the binary of the source type to be converted. If the second parameter exists, it must be of the integer type. It receives these type modifiers associated with the target type, or **-1** if nothing is present. If the third parameter exists, it must be of the Boolean type. If the conversion is an explicit type conversion, **true** is received. Otherwise, **false** is received.

The return type of a conversion function must be the same as the target type of the conversion, or the two types can be binary coercible.

Typically, a transformation must have different source and target data types. However, if there is a conversion implementation function with more than one parameter, it is allowed to declare a conversion with the same source and target types. This is used to represent a length enforcement function of a specific type in the system catalog. The named function is used to force a value of this type to be the type modifier value given by the second parameter.

If the source type and target type of a type conversion are different and more than one parameter is received, it indicates that only one step is required to convert one type to another and the length conversion is performed at the same time. If no such conversion is available, converting to a type that uses a type modifier involves two steps, one to convert between data types, and the other to apply a conversion specified by the modifier.

Currently, domain type conversion does not take effect. Transformations are typically targeted to the domain-related data types to which they belong.

#### NOTE

Cast is executed depending on the permission of the user who calls it. When calling a cast created by others, check the execution content of the cast function to prevent the cast creator from performing unauthorized operations with the permission of the executor.

## Examples

To create an assignment mapping from type bigint to type int4, use the int4(bigint) function:

```
CREATE CAST (bigint AS int4) WITH FUNCTION int4(bigint) AS ASSIGNMENT;
```

(The conversion has been predefined in the system.)

## Compatibility

The CREATE CAST instruction complies with the SQL standard. Except that the SQL does not have extra parameters that can be forcibly converted to binary types or implement functions.

## Helpful Links

[DROP CAST](#)

## 7.13.49 CREATE CONVERSION

### Description

Defines a new conversion between two character set encodings.

### Precautions

- The **DEFAULT** parameter indicates that the conversion between the source encoding and the target encoding is executed by default between the client and the server. To support this usage, bidirectional conversion must be defined, that is, both conversion from A to B and conversion from B to A are supported.
- To perform conversion, you must have the EXECUTE permission on function and the CREATE permission on the target schema.
- SQL\_ASCII cannot be used for either source encoding or target encoding because the server behavior is hardwired when SQL\_ASCII "encoding" is involved.
- You can remove user-defined conversions using DROP CONVERSION.

### Syntax

```
CREATE [DEFAULT] CONVERSION name
FOR source_encoding TO dest_encoding FROM function_name
```

### Parameters

- **DEFAULT**  
Specifies that the conversion is the default conversion from the source encoding to the target encoding. There should be only one default conversion for each encoding pair in a schema.
- **name**  
Specifies the name of the conversion, which can be restricted by the schema. If not restricted by a schema, the conversion is defined in the current schema. The conversion name must be unique in a schema.
- **source\_encoding**  
Source encoding name.
- **dest\_encoding**  
Target encoding name.
- **function\_name**

Function used for conversion. A function name can be restricted by a schema. If not, the function is found in the path.

```
conv_proc(
 integer, -- Source encoding ID
 integer, -- Target encoding ID
 cstring, -- Source character string (C character string ending with a null value)
 internal, -- Target (filled with a null-terminated C character string)
 integer -- Length of the source string
) RETURNS void;
```

## Examples

```
-- Use myfunc to create an encoding conversion from UTF8 to LATIN1.
CREATE CONVERSION myconv FOR 'UTF8' TO 'LATIN1' FROM myfunc;
```

## 7.13.50 CREATE DATABASE

### Description

Creates a database. By default, the new database will be created only by cloning the standard system database **template0**.

### Precautions

- A user who has the CREATEDB permission or a system administrator can create a database.
- It cannot be executed inside a transaction block.
- During the database creation, an error message indicating that permission denied is displayed, possibly because the permission on the data directory in the file system is insufficient. If an error message, indicating no space left on device is displayed, the possible cause is that the disk space is used up.

### Syntax

```
CREATE DATABASE database_name
[[WITH] { [OWNER [=] user_name] |
 [TEMPLATE [=] template] |
 [ENCODING [=] 'encoding'] |
 [LC_COLLATE [=] 'lc_collate'] |
 [LC_CTYPE [=] 'lc_ctype'] |
 [DBCOMPATIBILITY [=] 'compatibilty_type'] |
 [TABLESPACE [=] tablespace_name] |
 [CONNECTION LIMIT [=] connlimit] }[...] ;
```

### Parameters

- **database\_name**  
Specifies the database name.  
Value range: a string that complies with the [Identifier Naming Conventions](#).
- **OWNER [=] user\_name**  
Specifies the owner of the new database. If omitted, the default owner is the current user.  
Value range: an existing username.
- **TEMPLATE [=] template**  
Specifies a template name. That is, the template from which the database is created. GaussDB creates a database by copying data from a template

database. GaussDB has two default template databases **template0** and **template1** and a default user database **postgres**.

Value range: **template0**.

- **ENCODING [ = ] 'encoding'**

Specifies the character encoding used by the database. The value can be a string (for example, **SQL\_ASCII**) or an integer.

By default, the encoding format of the template database is used, and the codes of the template databases **template0** and **template1** are related to the OS environment. The character encoding of **template1** cannot be changed. To change the encoding, use **template0** to create a database.

Common values are **GBK**, **UTF8**, **Latin1**, and **GB18030**. The supported character sets are as follows:

**Table 7-104** GaussDB character set

| Name         | Description                       | Language            | Server-side Encoding | ICU Support | Number of Bytes/Characters | Alias              |

---

**NOTICE**

Note that not all client APIs support the preceding character sets.

The SQL\_ASCII setting is different from other settings. If the character set of the server is SQL\_ASCII, the server interprets the byte values 0 to 127 according to the ASCII standard. The byte values 128 to 255 are regarded as the characters that cannot be parsed. If this parameter is set to SQL\_ASCII, no code conversion occurs. Therefore, this setting is not basically used to declare the specified encoding used, because this declaration ignores the encoding. In most cases, if you use any non-ASCII data, do not use the SQL\_ASCII setting because the database will not be able to convert or verify non-ASCII characters.

---

**NOTICE**

- The character set encoding of the new database must be compatible with the local settings (**LC\_COLLATE** and **LC\_CTYPE**).
- When the specified character encoding set is **GBK**, some uncommon Chinese characters cannot be directly used as object names. This is because the byte encoding overlaps with the ASCII characters @A-Z[\]^\_`a-z{[] when the second byte of the GBK ranges from 0x40 to 0x7E. @[\\]^\_{'[] is an operator in the database. If it is directly used as an object name, a syntax error will be reported. For example, the GBK hexadecimal code is **0x8240**, and the second byte is **0x40**, which is the same as the ASCII character @. Therefore, the character cannot be used as an object name. If you need to use this function, you can add double quotation marks ("" ) to avoid this problem when creating and accessing objects.
- If the client code is A and the server code is B, the conversion between encoding formats A and B must exist in the database. For details about encoding format conversion supported by the database, see the system catalog **PG\_CONVERSION**. (If the encoding format cannot be converted, it is recommended that the encoding format on the client be the same as that on the server. You can change the encoding format on the client by setting the GUC parameter **client\_encoding**.)

- **LC\_COLLATE [ = ] 'lc\_collate'**

Specifies the character set used by the new database. For example, set this parameter by using **lc\_collate = 'zh\_CN.gbk'**.

The use of this parameter affects the sort order of strings (for example, the order of using **ORDER BY** for execution and the order of using indexes on text columns). By default, the sorting order of the template database is used.

Value range: character sets supported by the OS.

- **LC\_CTYPE [ = ] 'lc\_ctype'**

Specifies the character class used by the new database. For example, set this parameter by using **lc\_ctype = 'zh\_CN.gbk'**. The use of this parameter affects the classification of characters, such as uppercase letters, lowercase letters, and digits. By default, the character classification of the template database is used.

Value range: character classes supported by the OS.

 **NOTE**

The value ranges of **lc\_collate** and **lc\_ctype** depend on the character sets supported by the local environment. For example, in the Linux OS, you can run the **locale -a** command to obtain the list of character sets supported by the OS. When using the **lc\_collate** and **lc\_ctype** parameters, you can select the required character sets and character categories.

- **DBCOMPATIBILITY [ = ] 'compatibility\_type'**

Specifies the compatible database type. The default compatible database is the **O** database.

Value range: **A**, **B**, **C**, and **PG**, indicating the **O**, **MY**, **TD**, and **POSTGRES** databases, respectively.

 NOTE

- For A compatibility, the database treats empty strings as **NULL** and replaces **DATE** with **TIMESTAMP(0) WITHOUT TIME ZONE**.
  - When a character string is converted to an integer, if the input is invalid, the input will be converted to 0 due to B compatibility, and an error will be reported due to other compatibility issues.
  - For PG compatibility, CHAR and VARCHAR are counted by character. For other compatibility types, they are counted by byte. For example, for the UTF-8 character set, CHAR(3) can store three Chinese characters in PG compatibility scenarios, but can store only one Chinese character in other compatibility scenarios.
- **TABLESPACE [ = ] tablespace\_name**  
Specifies the tablespace of the database.  
Value range: an existing tablespace name.
  - **CONNECTION LIMIT [ = ] connlimit**  
Specifies the maximum number of concurrent connections that can be made to the new database.

---

**NOTICE**

- System administrators are not restricted by this parameter.
- The number of concurrent connections of each primary database node is calculated separately (which is the value of **connlimit**). Number of all connections of the database = Value of **connlimit** x Number of normal primary database nodes.

---

Value range: an integer in the range  $[-1, 2^{31} - 1]$ . The default value is **-1**, indicating that there is no limit.

The restrictions on character encoding are as follows:

- If the locale is set to **C** (or **POSIX**), all encoding types are allowed. For other locale settings, the character encoding must be the same as that of the locale.
- If the character encoding mode is SQL\_ASCII and the modifier is an administrator, the character encoding mode can be different from the locale setting.
- The encoding and region settings must match the template database, except that **template0** is used as a template. This is because other databases may contain data that does not match the specified encoding, or may contain indexes whose sorting order is affected by **LC\_COLLATE** and **LC\_CTYPE**. Copying this data will invalidate the indexes in the new database. **template0** does not contain any data or indexes that may be affected.

## Examples

```
-- Create users jim and tom.
openGauss=# CREATE USER jim PASSWORD '*****';
openGauss=# CREATE USER tom PASSWORD '*****';

-- Create database music using GBK (the local encoding type is also GBK).
openGauss=# CREATE DATABASE music ENCODING 'GBK' template = template0;

-- Create database music2 and specify user jim as its owner.
```

```
openGauss=# CREATE DATABASE music2 OWNER jim;

-- Create database music3 using template template0 and specify user jim as its owner.
openGauss=# CREATE DATABASE music3 OWNER jim TEMPLATE template0;

-- Set the maximum number of connections to database music to 10.
openGauss=# ALTER DATABASE music CONNECTION LIMIT= 10;

-- Rename database music to music4.
openGauss=# ALTER DATABASE music RENAME TO music4;

-- Change the owner of database music2 to user tom.
openGauss=# ALTER DATABASE music2 OWNER TO tom;

-- Set the tablespace of database music3 to PG_DEFAULT.
openGauss=# ALTER DATABASE music3 SET TABLESPACE PG_DEFAULT;

-- Disable the default index scan on database music3.
openGauss=# ALTER DATABASE music3 SET enable_indexscan TO off;

-- Reset the enable_indexscan parameter.
openGauss=# ALTER DATABASE music3 RESET enable_indexscan;

-- Drop databases.
openGauss=# DROP DATABASE music2;
openGauss=# DROP DATABASE music3;
openGauss=# DROP DATABASE music4;

-- Drop the jim and tom users.
openGauss=# DROP USER jim;
openGauss=# DROP USER tom;

-- Create a database compatible with the TD format.
openGauss=# CREATE DATABASE td_compatible_db DBCOMPATIBILITY 'C';

-- Create a database compatible with the A format.
openGauss=# CREATE DATABASE ora_compatible_db DBCOMPATIBILITY 'A';

-- Drop the databases that are compatible with the TD and A formats.
openGauss=# DROP DATABASE td_compatible_db;
openGauss=# DROP DATABASE ora_compatible_db;
```

## Helpful Links

[ALTER DATABASE](#) and [DROP DATABASE](#)

## Suggestions

- **create database**  
Database cannot be created in a transaction.
- **ENCODING LC\_COLLATE LC\_CTYPE**  
If the setting of **Encoding** of the new database does not match that of the template database (SQL\_ASCII) ('GBK', 'UTF8', 'LATIN1', or 'GB18030'), **template [=] template0** must be specified.

## 7.13.51 CREATE DIRECTORY

### Description

**CREATE DIRECTORY** creates a directory. The directory defines an alias for a path in the server file system and is used to store data files used by users.

## Precautions

- When **enable\_access\_server\_directory** is set to **off**, only the initial user is allowed to create directory objects. When **enable\_access\_server\_directory** is set to **on**, the user with the SYSADMIN permission and the user who inherits permissions of the built-in role **gs\_role\_directory\_create** can create directory objects.
- By default, the user who creates a directory has the read and write permissions on the directory.
- The default owner of a directory is the user who creates the directory.
- A directory cannot be created for the following paths:
  - The path contains special characters.
  - The path is a relative path.
  - The path is a symbolic link.
- The following validity check is performed during directory creation:
  - Check whether the path exists in the OS. If it does not exist, a message is displayed, indicating the potential risks.
  - Check whether the database initial user **omm** has the R/W/X permissions for the OS path. If the user does not have all the permissions, a message is displayed, indicating the potential risks.
- In the database, ensure that the path is the same on all the nodes. Otherwise, the path may fail to be found on some nodes when the directory is used.

## Syntax

```
CREATE [OR REPLACE] DIRECTORY directory_name
AS 'path_name';
```

## Parameters

- **directory\_name**  
Specifies the name of a directory.  
Value range: a string that complies with the [Identifier Naming Conventions](#).
- **path\_name**  
Specifies the OS path for which a directory is to be created.  
Value range: a valid OS path

## Examples

```
-- Create a directory.
openGauss=# CREATE OR REPLACE DIRECTORY dir as '/tmp/';
```

## Helpful Links

[ALTER DIRECTORY](#) and [DROP DIRECTORY](#)

## 7.13.52 CREATE FUNCTION

### Description

Creates a function.

## Precautions

- If the parameters or return values of a function have precision, the precision is not checked.
- When creating a function, you are advised to explicitly specify the schemas of tables in the function definition. Otherwise, the function may fail to be executed.
- **current\_schema** and **search\_path** specified by **SET** during function creation are invalid. **search\_path** and **current\_schema** before and after function execution should be the same.
- If a function has output parameters, the SELECT statement uses the default values of the output parameters when calling the function. When the CALL statement calls the function, it requires that the output parameters must be specified. When the CALL statement calls an overloaded PACKAGE function, it can use the default values of the output parameters. For details, see examples in [CALL](#).
- Only the functions compatible with PostgreSQL or those with the PACKAGE attribute can be overloaded. After **REPLACE** is specified, a new function is created instead of replacing a function if the number of parameters, parameter type, or return value is different.
- You can use the SELECT statement to specify different parameters using identical functions. The syntax does not support calling identical functions without the PACKAGE attribute.
- When you create a function, you cannot insert other agg functions out of the avg function or other functions.
- By default, the permissions to execute new functions are granted to PUBLIC users. For details, see [GRANT](#). By default, a user inherits the permissions of the PUBLIC role. Therefore, the user has the permission to execute a function and view the definition of the function. In addition, to execute the function, the user must have the USAGE permission on the schema to which the function locates. When creating a function, the user can revoke the default execution permissions from **PUBLIC** and grant them to other users as needed. To avoid the time window during which new functions can be accessed by all users, create functions and set function execution permissions in a transaction. After the database object isolation attribute is enabled, common users can view only the definitions of functions that they have permission to execute.
- When calling functions without parameters inside another function, you can omit brackets and call functions using their names directly.
- When functions with output parameters are called inside another function which is an assignment expression, you can omit the output parameters of the called functions.
- Functions which are compatible to A-style database support viewing, exporting, and importing parameter comments.
- Functions which are compatible to A-style database support viewing, exporting, and importing comments between IS/AS and plsql\_body.
- Users granted with the CREATE ANY FUNCTION permission can create or replace functions in the user schemas.

- The default permission on a function is SECURITY INVOKER. To change the permission to SECURITY DEFINER, set the GUC parameter **behavior\_compat\_options** to '**plsql\_security\_definer**'.
- For PL/pgSQL functions, after **behavior\_compat\_options** is set to '**proc\_outparam\_override**', the behaviors of **out** and **inout** change. In the functions, **return**, **out**, and **inout** can be returned at the same time. Before the parameter is set to '**proc\_outparam\_override**', only **return** is returned. For details, see [Examples](#).
- Formal parameters cannot be overloaded if only the custom ref cursor type is different from the sys\_refcursor type.
- When an overloaded function is called, the variable type must be specified.
- Functions with the **OUT** parameter do not support nested calling. For example, you are advised to change **b := func(a,func(c,1));** to **tmp := func(c,1); b := func(a,tmp).**
- For PL/pgSQL functions, of **behavior\_compat\_options** is set to '**proc\_outparam\_override**', the restrictions are as follows:
  - a. If a function with the **out/inout** parameter already exists in the same schema or package, you cannot create another function with the same name with the **out/inout** parameter.
  - b. An **out** parameter must be added no matter whether the SELECT or CALL statement is used to call a stored procedure.
  - c. In some scenarios, functions cannot be used in expressions (compared with those before the parameter is enabled), for example, left assignment in a stored procedure and **call function**. For details, see [Examples](#).
  - d. Functions without return cannot be called. The perform function can be used to call functions.
  - e. When a function is called in a stored procedure, **out** or **inout** parameters cannot be set to constants. For details, see [Examples](#).
- If a function with the definer specified is created in a schema of another user, the function will be executed by another user, which may cause unauthorized operations. Therefore, exercise caution when performing this operation.

## Syntax

- Syntax (compatible with PostgreSQL) for creating a user-defined function:

```
CREATE [OR REPLACE] FUNCTION function_name
[([{ argname [argmode] argtype [{ DEFAULT | := | = } expression] } [, ...]])]
[RETURNS rettype [DETERMINISTIC] | RETURNS TABLE ({ column_name column_type }
[, ...])]
LANGUAGE lang_name
[
 { IMMUTABLE | STABLE | VOLATILE }
 | { SHIPPABLE | NOT SHIPPABLE }
 | WINDOW
 | [NOT] LEAKPROOF
 | { CALLED ON NULL INPUT | RETURNS NULL ON NULL INPUT | STRICT }
 | [{ EXTERNAL } SECURITY INVOKER | [EXTERNAL] SECURITY DEFINER | AUTHID DEFINER |
AUTHID CURRENT_USER]
 | { fenced | not fenced }
 | { PACKAGE }
 | COST execution_cost
 | ROWS result_rows
 | SET configuration_parameter { { TO | = } value | FROM CURRENT }
][...]
{
```

```
 AS 'definition'
 }
}

• A-style database syntax of creating a user-defined function:
CREATE [OR REPLACE] FUNCTION function_name
([{ argname [argmode] argtype [{ DEFAULT | := | = } expression] } [, ...]])
RETURN rettype [DETERMINISTIC]
[
 {IMMUTABLE | STABLE | VOLATILE }
 | {SHIPPABLE | NOT SHIPPABLE}
 | {PACKAGE}
 | {FENCED | NOT FENCED}
 | [NOT] LEAKPROOF
 | {CALLED ON NULL INPUT | RETURNS NULL ON NULL INPUT | STRICT }
 | [{ EXTERNAL] SECURITY INVOKER | [EXTERNAL] SECURITY DEFINER |
AUTHID DEFINER | AUTHID CURRENT_USER
}
]
[COST execution_cost
| ROWS result_rows
| SET configuration_parameter { {TO | =} value | FROM CURRENT
| LANGUAGE lang_name
][...]

{
 IS | AS
} plsql_body
/
```

## Parameters

- **function\_name**  
Specifies the name of the function to create (optionally schema-qualified).  
Value range: a string that complies with the [Identifier Naming Conventions](#).  
The value contains a maximum of 63 characters. If the value contains more than 63 characters, the database truncates it and retains the first 63 characters as the function name.
- **argname**  
Specifies the parameter name of the function.  
Value range: a string that complies with the [Identifier Naming Conventions](#).  
The value contains a maximum of 63 characters. If the value contains more than 63 characters, the database truncates it and retains the first 63 characters as the function parameter name.
- **argmode**  
Specifies the parameter mode of the function.  
Value range: **IN**, **OUT**, **INOUT**, and **VARIADIC**. The default value is **IN**. Only the parameters of **OUT** can be followed by **VARIADIC**. The parameters of **OUT** and **INOUT** cannot be used in the function definition of **RETURNS TABLE**.  
 **NOTE**  
**VARIADIC** specifies parameters of the array type.
- **argtype**  
Specifies the parameter type of the function. **%TYPE** or **%ROWTYPE** can be used to indirectly reference a variable or table type. For details, see [Variable Definition Statements](#).
- **expression**

Specifies the default expression of a parameter.

 **NOTE**

It is recommended that you define all default parameters after all non-default parameters.

- **rettype**

Specifies the return data type. Same as **argtype**, **%TYPE** or **%ROWTYPE** can also be used to indirectly reference types.

When there is **OUT** or **INOUT** parameter, the **RETURNS** clause can be omitted. If the clause exists, the result type of the clause must be the same as that of the output parameter. If there are multiple output parameters, the result type of the clause is **RECORD**. Otherwise, the result type of the clause is the same as that of a single output parameter.

The **SETOF** modifier indicates that the function will return a set of items, rather than a single item.

 **NOTE**

In **FUNCTION argtype** and **rettype** outside **PACKAGE**, **%TYPE** cannot reference the type of the *PACKAGE* variable.

- **column\_name**

Specifies the column name.

- **column\_type**

Specifies the column type.

- **definition**

Specifies a string constant defining a function. Its meaning depends on the language. It can be an internal function name, a path pointing to a target file, an SQL query, or text in a procedural language.

- **DETERMINISTIC**

Specifies an API compatible with the SQL syntax. You are advised not to use it.

- **LANGUAGE lang\_name**

Specifies the name of the language that is used to implement the function. It can be **SQL**, **internal**, or the name of a customized process language. To ensure downward compatibility, the name can use single quotation marks. Contents in single quotation marks must be capitalized.

Due to compatibility issues, no matter which language is specified when an A-style database is created, the language used is PL/pgSQL.

- **WINDOW**

Indicates that this function is a window function. The **WINDOW** attribute cannot be changed when replacing an existing function definition.

---

**NOTICE**

For a customized window function, the value of **LANGUAGE** can only be **internal**, and the referenced internal function must be a window function.

---

- **IMMUTABLE**  
Specifies that the function always returns the same result if the parameter values are the same.
- **STABLE**  
Specifies that the function cannot modify the database, and that within a single table scan it will consistently return the same result for the same parameter value, but its result varies by SQL statements.
- **VOLATILE**  
Specifies that the function value can change in a single table scan and no optimization is performed.
- **SHIPPABLE|NOT SHIPPABLE**  
Specifies whether the function can be pushed down for execution. This port is reserved and is not recommended.
- **FENCED|NOT FENCED**  
**FENCED** indicates that a function is called in worker threads to prevent the server from crashing due to incorrect C code implementation. The **NOT FENCED** mode is not recommended.
- **PACKAGE**  
Specifies whether the function can be overloaded. PostgreSQL-style functions can be overloaded, and this parameter is designed for functions of other styles.
  - All PACKAGE and non-PACKAGE functions cannot be overloaded or replaced.
  - PACKAGE functions do not support parameters of the VARIADIC type.
  - The PACKAGE attribute of functions cannot be modified.
- **LEAKPROOF**  
Specifies that the function has no side effects. **LEAKPROOF** can be set only by system administrators.
- **CALLED ON NULL INPUT**  
Declares that some parameters of the function can be called in normal mode if the parameter values are **NULL**. This parameter can be omitted.
- **RETURNS NULL ON NULL INPUT**  
**STRICT**  
Specifies that a function always returns **NULL** when the value of any of its parameters is **NULL**. If this parameter is specified, the function is not executed when there are null parameters; instead a null result is returned automatically.  
**RETURNS NULL ON NULL INPUT** and **STRICT** have the same functions.
- **EXTERNAL**  
The purpose is to be compatible with SQL statements and it is optional. This feature applies to all functions, not only external functions.
- **SECURITY INVOKER**  
**AUTHID CURRENT\_USER**  
Specifies that the function will be executed with the permissions of the user who calls it. This parameter can be omitted.

**SECURITY INVOKER** and **AUTHID CURRENT\_USER** have the same functions.

- **SECURITY DEFINER**

**AUTHID DEFINER**

Specifies that the function will be executed with the permissions of the user who created it.

**AUTHID DEFINER** and **SECURITY DEFINER** have the same functions.

- **COST execution\_cost**

Estimates the execution cost of a function.

The unit of **execution\_cost** is **cpu\_operator\_cost**.

Value range: a positive integer.

- **ROWS result\_rows**

Estimates the number of rows returned by the function. This is only allowed when the function is declared to return a set.

Value range: a positive number. The default value is **1000**.

- **configuration\_parameter**

- **value**

Sets a specified database session parameter to a specified value. If the value is **DEFAULT** or **RESET**, the default setting is used in the new session. **OFF** disables the setting.

Value range: a string.

- **DEFAULT**
    - **OFF**
    - **RESET**
    - Specified default value

- **FROM CURRENT**

Uses the value of **configuration\_parameter** of the current session.

- **plsql\_body**

Specifies the PL/SQL stored procedure body.

---

**NOTICE**

When you perform password-related operations, such as user creation, password change, and encryption/decryption, in a function body, the password will be recorded in the system catalogs and logs in plaintext. To prevent sensitive information leakage, you are advised not to perform operations on the function body related to sensitive information, such as passwords or keys.

---

## Examples

```
-- Define a function as SQL query.
openGauss=# CREATE FUNCTION func_add_sql(integer, integer) RETURNS integer
AS 'select $1 + $2;'
```

```
LANGUAGE SQL
IMMUTABLE
RETURNS NULL ON NULL INPUT;

-- Add an integer by parameter name using PL/pgSQL.
openGauss=# CREATE OR REPLACE FUNCTION func_increment_plsql(i integer) RETURNS integer AS $$
BEGIN
 RETURN i + 1;
END;
$$ LANGUAGE plpgsql;

-- Return the RECORD type.
openGauss=# CREATE OR REPLACE FUNCTION func_increment_sql(i int, out result_1 bigint, out result_2
bigint)
RETURNS SETOF RECORD
AS $$
BEGIN
 result_1 = i + 1;
 result_2 = i * 10;
RETURN next;
END;
$$LANGUAGE PL/SQL;

-- Return a record containing multiple output parameters.
openGauss=# CREATE FUNCTION func_dup_sql(in int, out f1 int, out f2 text)
AS $$ SELECT $1, CAST($1 AS text) || ' is text' $$
LANGUAGE SQL;

openGauss=# SELECT * FROM func_dup_sql(42);

-- Compute the sum of two integers and return the result (if the input is null, the returned result is null).
openGauss=# CREATE FUNCTION func_add_sql2(num1 integer, num2 integer) RETURN integer
AS
BEGIN
RETURN num1 + num2;
END;
/
-- Alter the execution rule of function func_add_sql2 to IMMUTABLE (that is, the same result is returned if
the parameter remains unchanged).
openGauss=# ALTER FUNCTION func_add_sql2(INTEGER, INTEGER) IMMUTABLE;

-- Rename the func_add_sql2 function as add_two_number.
openGauss=# ALTER FUNCTION func_add_sql2(INTEGER, INTEGER) RENAME TO add_two_number;

-- Change the owner of function add_two_number to omm.
openGauss=# ALTER FUNCTION omm(INTEGER, INTEGER) OWNER TO omm;

-- Drop functions.
openGauss=# DROP FUNCTION add_two_number;
openGauss=# DROP FUNCTION func_increment_sql;
openGauss=# DROP FUNCTION func_dup_sql;
openGauss=# DROP FUNCTION func_increment_plsql;
openGauss=# DROP FUNCTION func_add_sql;

-- Set parameters.
openGauss=# SET behavior_compat_options='proc_outparam_override';
-- Create functions.
openGauss=# CREATE OR REPLACE FUNCTION func1(in a integer, out b integer)
RETURNS int
AS $$
DECLARE
 c int;
BEGIN
 c := 1;
 b := a + c;
 return c;
END; $$
LANGUAGE 'PL/SQL' NOT FENCED;
-- Return return and output parameters at the same time.
```

```
openGauss=# DECLARE
 result integer;
 a integer := 2;
 b integer := NULL;
BEGIN
 result := func1(a => a, b => b);
 raise info 'b is: %', b;
 raise info 'result is: %', result;
END;
/
INFO: b is: 3
INFO: result is: 1
ANONYMOUS BLOCK EXECUTE
-- Left assignment expressions are not supported.
openGauss=# DECLARE
 result integer;
 a integer := 2;
 b integer := NULL;
BEGIN
 result := func1(a => a, b => b) + 1;
 raise info 'b is: %', b;
 raise info 'result is: %', result;
END;
/
ERROR: when invoking function func1, maybe input something superfluous.
CONTEXT: compilation of PL/SQL function "inline_code_block" near line 3
-- out/inout in a stored procedure cannot be set to a constant.
openGauss=# DECLARE
 result integer;
 a integer := 2;
 b integer := NULL;
BEGIN
 result := func1(a => a, b => 10);
 raise info 'b is: %', b;
 raise info 'result is: %', result;

## 7.13.53 CREATE GROUP

### Description

Creates a user group.

### Precautions

CREATE GROUP is an alias for CREATE ROLE, and it is not a standard SQL syntax and not recommended. Users can use CREATE ROLE directly.

### Syntax

```
CREATE GROUP group_name [[WITH] option [...]] [ENCRYPTED | UNENCRYPTED] { PASSWORD | IDENTIFIED BY } { 'password' [EXPIRED] | DISABLE };
```

The syntax of the option clause is as follows:

```
{SYSADMIN | NOSYSADMIN}
| {MONADMIN | NOMONADMIN}
```

```
| {OPRADMIN | NOOPRADMIN}
| {POLADMIN | NOPOLADMIN}
| {AUDITADMIN | NOAUDITADMIN}
| {CREATEDB | NOCREATEDB}
| {USEFT | NOUSEFT}
| {CREATEROLE | NOCREATEROLE}
| {INHERIT | NOINHERIT}
| {LOGIN | NOLOGIN}
| {REPLICATION | NOREPLICATION}
| {VCADMIN | NOVCADMIN}
| {PERSISTENCE | NOPERSISTENCE}
| CONNECTION LIMIT connlimit
| VALID BEGIN 'timestamp'
| VALID UNTIL 'timestamp'
| PERM SPACE 'spacelimit'
| TEMP SPACE 'tmpspacelimit'
| SPILL SPACE 'spillspacelimit'
| IN ROLE role_name [, ...]
| IN GROUP role_name [, ...]
| ROLE role_name [, ...]
| ADMIN role_name [, ...]
| USER role_name [, ...]
| SYSID uid
| DEFAULT TABLESPACE tablespace_name
| PROFILE DEFAULT
| PROFILE profile_name
| PGUSER
```

## Parameters

See [Parameters](#) in "CREATE ROLE."

## Examples

```
-- Create group my_group.
openGauss=# CREATE GROUP my_group PASSWORD '*****';

-- Drop the group.
openGauss=# DROP GROUP my_group;
```

## Helpful Links

[ALTER GROUP](#), [DROP GROUP](#), and [CREATE ROLE](#)

## 7.13.54 CREATE INCREMENTAL MATERIALIZED VIEW

### Description

CREATE INCREMENTAL MATERIALIZED VIEW creates a fast-refresh materialized view, and you can refresh the data of the materialized view by using REFRESH MATERIALIZED VIEW (complete-refresh) and REFRESH INCREMENTAL MATERIALIZED VIEW (fast-refresh).

CREATE INCREMENTAL MATERIALIZED VIEW is similar to CREATE TABLE AS, but it remembers the query used to initialize the view, so it can refresh data later. A materialized view has many attributes that are the same as those of a table, but does not support temporary materialized views.

### Precautions

- Fast-refresh materialized views cannot be created on temporary tables or global temporary tables.

- Fast-refresh materialized views support only simple filter queries and UNION ALL queries of base tables.
- Distribution keys cannot be specified when an incremental MV is created.
- After a fast-refresh materialized view is created, most DDL operations in the base table are no longer supported.
- IUD operations cannot be performed on fast-refresh materialized views.
- After a fast-refresh materialized view is created, you need to run the **REFRESH** command to synchronize the materialized view with the base table when the base table data changes.

## Syntax

```
CREATE INCREMENTAL MATERIALIZED VIEW mv_name
 [(column_name [, ...])]
 [TABLESPACE tablespace_name]
 AS query;
```

## Parameters

- **mv\_name**  
Name (optionally schema-qualified) of the materialized view to be created.  
Value range: a string that complies with the [Identifier Naming Conventions](#).
- **column\_name**  
Column name in the new materialized view. The materialized view supports specified columns. The number of specified columns must be the same as the number of columns in the result of the subsequent query statement. If no column name is provided, the column name is obtained from the output column name of the query.  
Value range: a string that complies with the [Identifier Naming Conventions](#).
- **TABLESPACE tablespace\_name**  
Specifies a tablespace to which the new materialized view belongs. If it is not specified, the default tablespace is used.
- **AS query**  
**SELECT** or **TABLE** command. This query will be run in a security-constrained operation.

## Examples

```
-- Create an ordinary table.
openGauss=# CREATE TABLE my_table (c1 int, c2 int);

-- Create a fast-refresh materialized view.
openGauss=# CREATE INCREMENTAL MATERIALIZED VIEW my_imv AS SELECT * FROM my_table;

-- Write data to the base table.
openGauss=# INSERT INTO my_table VALUES(1,1),(2,2);

-- Fast refresh the fast-refresh materialized view my_imv.
openGauss=# REFRESH INCREMENTAL MATERIALIZED VIEW my_imv;

-- Drop a fast-refresh materialized view.
openGauss=# DROP MATERIALIZED VIEW my_imv;

-- Drop the ordinary table my_table.
openGauss=# DROP TABLE my_table;
```

## Helpful Links

[ALTER MATERIALIZED VIEW](#), [CREATE MATERIALIZED VIEW](#), [CREATE TABLE](#), [DROP MATERIALIZED VIEW](#), [REFRESH INCREMENTAL MATERIALIZED VIEW](#), and [REFRESH MATERIALIZED VIEW](#)

## 7.13.55 CREATE INDEX

### Description

Creates an index in a specified table.

Indexes are primarily used to enhance database performance (though inappropriate use can result in database performance deterioration). You are advised to create indexes on:

- Columns that are often queried.
- Join conditions. For a query on joined columns, you are advised to create a composite index on the columns. For example, for **select \* from t1 join t2 on t1.a=t2.a and t1.b=t2.b**, you can create a composite index on columns **a** and **b** in table **t1**.
- Columns having filter criteria (especially scope criteria) of a WHERE clause.
- Columns that appear after ORDER BY, GROUP BY, and DISTINCT

Partitioned tables do not support partial index creation when indexes contain the GLOBAL or LOCAL keyword or the created index is a GLOBAL index.

### Precautions

- Indexes consume storage and computing resources. Creating too many indexes has negative impact on database performance (especially the performance of data import. Therefore, you are advised to import the data before creating indexes). Therefore, create indexes only when they are necessary.
- All functions and operators used in an index definition must be immutable, that is, their results must depend only on their parameters and never on any outside influence (such as the contents of another table or the current time). This restriction ensures that the behavior of the index is well-defined. To use a user-defined function in an index or WHERE clause, mark it as an immutable function.
- Partitioned table indexes are classified into local indexes and global indexes. A local index binds to a specific partition, and a global index corresponds to the entire partitioned table.
- A user granted with the CREATE ANY INDEX permission can create indexes in both the public and user schemas.
- If a user-defined function is called in the expression index, the expression index function is executed based on the permission of the function creator.

### Syntax

- Create an index on a table.  

```
CREATE [UNIQUE] INDEX [CONCURRENTLY] [[schema_name.]index_name] ON table_name
[USING method]
```

```
(({ column_name | (expression) } [COLLATE collation] [opclass] [ASC | DESC] [NULLS
{ FIRST | LAST }] }, ...)
[INCLUDE (column_name [, ...])]
[WITH ({ storage_parameter = value } [, ...])]
[TABLESPACE tablespace_name]
[WHERE predicate];
```

- **Create an index on a partitioned table.**

```
CREATE [UNIQUE] INDEX [[schema_name.]index_name] ON table_name [USING method]
(({ column_name | (expression) } [COLLATE collation] [opclass] [ASC | DESC] [NULLS
LAST] }, ...)
[LOCAL [({ PARTITION index_partition_name | SUBPARTITION index_subpartition_name
[TABLESPACE index_partition_tablespace] } [, ...])] | GLOBAL]
[INCLUDE (column_name [, ...])]
[WITH ({ storage_parameter = value } [, ...])]
[TABLESPACE tablespace_name]
[WHERE predicate];
```

## Parameters

- **UNIQUE**

Creates a unique index. In this way, the system checks whether new values are unique in the index column. Attempts to insert or update data which would result in duplicate entries will generate an error.

Currently, only B-tree indexes and UB-tree indexes support unique indexes.

- **CONCURRENTLY**

Creates an index (with ShareUpdateExclusiveLock) in a mode that does not block DML statements. When an index is created, other statements cannot access the table on which the index depends. If this keyword is specified, DML is not blocked during the creation.

- This option can only specify a name of one index.
- The CREATE INDEX statement can be run within a transaction, but CREATE INDEX CONCURRENTLY cannot.
- Partitioned tables do not support index creation in CONCURRENTLY mode. For temporary tables, you can use CONCURRENTLY to create indexes. However, indexes are created in blocking mode because no other sessions concurrently access the temporary tables and the blocking mode is more cost-effective.

 **NOTE**

- This keyword is specified when an index is created. The entire table needs to be scanned twice and built. When the table is scanned for the first time, an index is created and the read and write operations are not blocked. During the second scan, changes that have occurred since the first scan are merged and updated.
  - The table needs to be scanned and built twice, and all existing transactions that may modify the table must be completed. This means that the creation of the index takes a longer time than normal. In addition, the CPU and I/O consumption also affects other services.
  - If an index build fails, it leaves an "unusable" index. This index is ignored by the query, but it still consumes the update overhead. In this case, you are advised to delete the index and try CONCURRENTLY again to create the index.
  - After the second scan, index creation must wait for any transaction that holds a snapshot earlier than the snapshot taken by the second scan to terminate. In addition, ShareUpdateExclusiveLock (level 4) added during index creation conflicts with a lock whose level is greater than or equal to 4. Therefore, when such an index is created, the system is prone to hang or deadlock. For example:
    - If two sessions create an index by using CONCURRENTLY for the same table, a deadlock occurs.
    - If a session creates an index by using CONCURRENTLY for a table and another session drops a table, a deadlock occurs.
    - There are three sessions. Session 1 locks table **a** and does not commit it. Session 2 creates an index by using CONCURRENTLY for table **b**. Session 3 writes data to table **a**. Before the transaction of session 1 is committed, session 2 is blocked.
    - The transaction isolation level is set to repeatable read (read committed by default). Two sessions are started. Session 1 writes data to table **a** and does not commit it. Session 2 creates an index by using CONCURRENTLY for table **b**. Before the transaction of session 1 is committed, session 2 is blocked.
    - When the I/O and CPU resources are not limited, the service performance deterioration caused by online index creation can be controlled within 10%. However, in special scenarios, the service performance deterioration may exceed 10%. This is because online index creation is a long transaction that consumes a large number of I/O and CPU resources. It consumes more resources than offline index creation. The longer the online index creation transaction lasts, the greater the impact on service performance. The time for creating indexes online is positively correlated with the data volume of base tables and the data volume generated by concurrent DML statements. When the I/O and CPU resources are not limited, the time for creating indexes online is about two to six times that for creating indexes offline. However, when the number of concurrent transactions is large (> 10000 TPS) or resource contention occurs, the time may be even longer. You can create indexes in parallel to shorten the index creation time. The performance of online parallel index creation increases to a certain value and becomes stable as the number of parallel worker threads increases. Compared with the performance of creating indexes in serial mode, the performance of creating indexes in parallel online is improved by about 30%. You are advised to create indexes online during off-peak hours to avoid great impact on services. Although online index creation provides the capability of uninterrupted services to some extent, it still needs to be implemented with caution.
- **schema\_name**  
Specifies the schema name.  
Value range: an existing schema name.
  - **index\_name**  
Specifies the name of the index to be created. The schema of the index is the same as that of the table.

Value range: a string that complies with the [Identifier Naming Conventions](#).

- **table\_name**

Specifies the name of the table to be indexed (optionally schema-qualified).

Value range: an existing table name.

- **USING method**

Specifies the name of the index method to be used.

Value range:

- **btree**: B-tree indexes store key values of data in a B+ tree structure. This structure helps users to quickly search for indexes. B-tree indexes support comparison queries with ranges specified. When an index is created in a Ustore table, the index is automatically changed to UB-tree.
- **ubtree**: Multi-version B-tree index used only for Ustore tables. The index page contains transaction information and can be recycled. By default, the INSERTPT function is enabled for UB-tree indexes.

Row-store tables (Astore) support the index type: **btree** (default). Row-store tables (Ustore) support the index type: **ubtree**.

- **column\_name**

Specifies the name of the column on which an index is to be created.

Multiple columns can be specified if the index method supports composite indexes. A global index supports a maximum of 31 columns, and other indexes support a maximum of 32 columns.

- **expression**

Specifies an expression based on one or more columns of the table. The expression usually must be written with surrounding parentheses, as shown in the syntax. However, the parentheses can be omitted if the expression has the form of a function call.

Expression can be used to obtain fast access to data based on some transformation of the basic data. For example, an index computed on upper(col) would allow the clause WHERE upper(col) = 'JIM' to use an index.

If an expression contains IS NULL, the index for this expression is invalid. In this case, you are advised to create a partial index.

- **COLLATE collation**

Assigns a collation to the column (which must be of a collatable data type). If no collation is specified, the default collation is used. You can run the **select \* from pg\_collation** command to query collation rules from the pg\_collation system catalog. The default collation rule is the row starting with **default** in the query result.

- **opclass**

Specifies the name of an operator class. An operator class can be specified for each column of an index. The operator class identifies the operators to be used by the index for that column. For example, a B-tree index on the type int4 would use the **int4\_ops** class; this operator class includes comparison functions for values of type int4. In practice, the default operator class for the column's data type is sufficient. The operator class applies to data with multiple sorts. For example, if you want to sort complex numbers by absolute value or real number, you can define two operator classes and select a proper class when creating an index.

- **ASC**  
Specifies an ascending (default) sort order.
- **DESC**  
Specifies a descending sort order.
- **NULLS FIRST**  
Specifies that null values appear before non-null values in the sort ordering. This is the default when **DESC** is specified.
- **NULLS LAST**  
Specifies that null values appear after non-null values in the sort ordering. This is the default when **DESC** is not specified.
- **LOCAL**  
Specifies that the partitioned index to be created is a local index.
- **GLOBAL**  
Specifies the partitioned index to be created as a global index. If no keyword is specified, a global index is created by default.
- **INCLUDE ( column\_name [, ...] )**  
The optional INCLUDE clause specifies that some non-key columns are included in indexes. Non-key columns cannot be used as search criteria for accelerating index scans, and they are omitted when the unique constraints of the indexes are checked.  
  
An index-only scan can directly return content in the non-key columns without accessing the heap table corresponding to the indexes.  
  
Exercise caution when adding non-key columns as INCLUDE columns, especially for wide columns. If the size of an index tuple exceeds the maximum size allowed by the index type, data insertion fails. Note that in any case, adding non-key columns to an index increases the space occupied by the index, which may slow down the search speed.  
  
Currently, only UB-tree indexes access mode supports this feature. Non-key columns are stored in the index leaf tuple corresponding to the heap tuple and are not included in the tuple on the upper-layer index page.
- **WITH ( {storage\_parameter = value} [, ... ] )**  
Specifies the storage parameter used for an index.  
Value range:  
Indexes except for psort support the **FILLFACTOR** parameter. Only UB-tree indexes support **INDEXSPLIT**.
  - **FILLFACTOR**  
The fill factor of an index is a percentage from 10 to 100.  
Value range: 10–100.
  - **INDEXSPLIT**  
Specifies the splitting policy of UB-tree indexes. The **DEFAULT** policy is the same as the splitting policy of B-tree indexes. The **INSERTPT** policy can significantly reduce the index space usage in some scenarios.  
Value range: **INSERTPT** and **DEFAULT**.  
Default value: **INSERTPT**.

- **TABLESPACE tablespace\_name**  
Specifies the tablespace for an index. If no tablespace is specified, the default tablespace is used.  
Value range: an existing tablespace name.
- **WHERE predicate**  
Creates a partial index. A partial index is an index that contains entries for only a portion of a table, usually a portion that is more useful for indexing than the rest of the table. For example, if you have a table that contains both billed and unbilled orders where the unbilled orders take up a small fraction of the total table and yet that is an often used portion, you can improve performance by creating an index on just that portion. In addition, the WHERE clause with a UNIQUE constraint can be used to enforce uniqueness over a subset of a table.  
Value range: The predicate expression can only refer to columns of the underlying table, but it can use all columns, not just the ones being indexed. Currently, subqueries and aggregate expressions are forbidden in WHERE. You are advised not to use numeric types such as int for predicate, because such types can be implicitly converted to bool values (non-zero values are implicitly converted to **true** and **0** is implicitly converted to **false**), which may cause unexpected results.  
For a partitioned table index, if the created index contains the GLOBAL or LOCAL keyword or the created index is a GLOBAL index, the WHERE clause cannot be used to create an index.
- **PARTITION index\_partition\_name**  
Specifies the name of an index partition.  
Value range: a string that complies with the [Identifier Naming Conventions](#).
- **SUBPARTITION index\_subpartition\_name**  
Specifies the name of a level-2 index partition.  
Value range: a string that complies with the [Identifier Naming Conventions](#).
- **TABLESPACE index\_partition\_tablespace**  
Specifies the tablespace of an index partition.  
Value range: If this parameter is not specified, the value of **index\_tablespace** is used.

## Examples

```
-- Create the tpcds.ship_mode_t1 table.
openGauss=# CREATE SCHEMA tpcds;
openGauss=# CREATE TABLE tpcds.ship_mode_t1
(
 SM_SHIP_MODE_SK INTEGER NOT NULL,
 SM_SHIP_MODE_ID CHAR(16) NOT NULL,
 SM_TYPE CHAR(30) ,
 SM_CODE CHAR(10) ,
 SM_CARRIER CHAR(20) ,
 SM_CONTRACT CHAR(20)
)
;

-- Create a common unique index on the SM_SHIP_MODE_SK column in the tpcds.ship_mode_t1 table.
openGauss=# CREATE UNIQUE INDEX ds_ship_mode_t1_index1 ON
tpcds.ship_mode_t1(SM_SHIP_MODE_SK);
```

```
-- Create a B-tree index on the SM_SHIP_MODE_SK column in the tpcds.ship_mode_t1 table.
openGauss=# CREATE INDEX ds_ship_mode_t1_index4 ON tpcds.ship_mode_t1 USING
btree(SM_SHIP_MODE_SK);

-- Create an expression index on the SM_CODE column in the tpcds.ship_mode_t1 table:
openGauss=# CREATE INDEX ds_ship_mode_t1_index2 ON tpcds.ship_mode_t1(SUBSTR(SM_CODE,1,4));

-- Create a partial index on the SM_SHIP_MODE_SK column where SM_SHIP_MODE_SK is greater than 10
in the tpcds.ship_mode_t1 table.
openGauss=# CREATE UNIQUE INDEX ds_ship_mode_t1_index3 ON
tpcds.ship_mode_t1(SM_SHIP_MODE_SK) WHERE SM_SHIP_MODE_SK>10;

-- Rename an existing index.
openGauss=# ALTER INDEX tpcds.ds_ship_mode_t1_index1 RENAME TO ds_ship_mode_t1_index5;

-- Set the index as unusable.
openGauss=# ALTER INDEX tpcds.ds_ship_mode_t1_index2 UNUSABLE;

-- Rebuild an index.
openGauss=# ALTER INDEX tpcds.ds_ship_mode_t1_index2 REBUILD;

-- Drop an existing index.
openGauss=# DROP INDEX tpcds.ds_ship_mode_t1_index2;

-- Drop the table.
openGauss=# DROP TABLE tpcds.ship_mode_t1;

-- Create a tablespace.
openGauss=# CREATE TABLESPACE example1 RELATIVE LOCATION 'tablespace1/tablespace_1';
openGauss=# CREATE TABLESPACE example2 RELATIVE LOCATION 'tablespace2/tablespace_2';
openGauss=# CREATE TABLESPACE example3 RELATIVE LOCATION 'tablespace3/tablespace_3';
openGauss=# CREATE TABLESPACE example4 RELATIVE LOCATION 'tablespace4/tablespace_4';
-- Create the tpcds.customer_address_p1 table.
openGauss=# CREATE TABLE tpcds.customer_address_p1
(
 CA_ADDRESS_SK INTEGER NOT NULL,
 CA_ADDRESS_ID CHAR(16) NOT NULL,
 CA_STREET_NUMBER CHAR(10) ,
 CA_STREET_NAME VARCHAR(60) ,
 CA_STREET_TYPE CHAR(15) ,
 CA_SUITE_NUMBER CHAR(10) ,
 CA_CITY VARCHAR(60) ,
 CA_COUNTY VARCHAR(30) ,
 CA_STATE CHAR(2) ,
 CA_ZIP CHAR(10) ,
 CA_COUNTRY VARCHAR(20) ,
 CA_GMT_OFFSET DECIMAL(5,2) ,
 CA_LOCATION_TYPE CHAR(20)
)
TABLESPACE example1
PARTITION BY RANGE(CA_ADDRESS_SK)
(
 PARTITION p1 VALUES LESS THAN (3000),
 PARTITION p2 VALUES LESS THAN (5000) TABLESPACE example1,
 PARTITION p3 VALUES LESS THAN (MAXVALUE) TABLESPACE example2
)
ENABLE ROW MOVEMENT;
-- Create the partitioned table index ds_customer_address_p1_index1 without specifying the index
partition name.
openGauss=# CREATE INDEX ds_customer_address_p1_index1 ON
tpcds.customer_address_p1(CA_ADDRESS_SK) LOCAL;
-- Create the partitioned table index ds_customer_address_p1_index2 with the name of the index partition
specified.
openGauss=# CREATE INDEX ds_customer_address_p1_index2 ON
tpcds.customer_address_p1(CA_ADDRESS_SK) LOCAL
(
 PARTITION CA_ADDRESS_SK_index1,
 PARTITION CA_ADDRESS_SK_index2 TABLESPACE example3,
 PARTITION CA_ADDRESS_SK_index3 TABLESPACE example4
)
```

```
)
TABLESPACE example2;

-- Create a global partitioned index.
openGauss=# CREATE INDEX ds_customer_address_p1_index3 ON
tpcds.customer_address_p1(CA_ADDRESS_ID) GLOBAL;

-- If no keyword is specified, a global partitioned index is created by default.
openGauss=# CREATE INDEX ds_customer_address_p1_index4 ON
tpcds.customer_address_p1(CA_ADDRESS_ID);

-- Change the tablespace of the partitioned table index CA_ADDRESS_SK_index2 to example1.
openGauss=# ALTER INDEX tpcds.ds_customer_address_p1_index2 MOVE PARTITION
CA_ADDRESS_SK_index2 TABLESPACE example1;

-- Change the tablespace of the partitioned table index CA_ADDRESS_SK_index3 to example2.
openGauss=# ALTER INDEX tpcds.ds_customer_address_p1_index2 MOVE PARTITION
CA_ADDRESS_SK_index3 TABLESPACE example2;

-- Rename a partitioned table index.
openGauss=# ALTER INDEX tpcds.ds_customer_address_p1_index2 RENAME PARTITION
CA_ADDRESS_SK_index1 TO CA_ADDRESS_SK_index4;

-- Drop the indexes and the partitioned table.
openGauss=# DROP INDEX tpcds.ds_customer_address_p1_index1;
openGauss=# DROP INDEX tpcds.ds_customer_address_p1_index2;
openGauss=# DROP TABLE tpcds.customer_address_p1;
-- Drop tablespaces.
openGauss=# DROP TABLESPACE example1;
openGauss=# DROP TABLESPACE example2;
openGauss=# DROP TABLESPACE example3;
openGauss=# DROP TABLESPACE example4;
```

## Helpful Links

[ALTER INDEX](#) and [DROP INDEX](#)

## Suggestions

- create index

You are advised to create indexes on:

- Columns that are often queried.
- Join conditions. For a query on joined columns, you are advised to create a composite index on the columns. For example, for **select \* from t1 join t2 on t1.a=t2.a and t1.b=t2.b**, you can create a composite index on columns **a** and **b** in table **t1**.
- Columns having filter criteria (especially scope criteria) of a WHERE clause.
- Columns that appear after ORDER BY, GROUP BY, and DISTINCT

Constraints:

- An index of an ordinary table supports a maximum of 32 columns. A GLOBAL index of a partitioned table supports a maximum of 31 columns.
- The size of a single index cannot exceed the size of the index page (8 KB). The size of a B-tree or UB-tree index cannot exceed one-third of the page size.
- Partial indexes cannot be created in a partitioned table.
- When a GLOBAL index is created on a partitioned table, the following constraints apply:

- Expression indexes and partial indexes are not supported.
- Only B-tree indexes are supported.
- In the same attribute column, the local index and global index of a partition cannot coexist.
- If the ALTER statement does not contain UPDATE GLOBAL INDEX, the original global index is invalid. In this case, other indexes are used for query. If the ALTER statement contains UPDATE GLOBAL INDEX, the original global index is still valid and the index function is correct.

## 7.13.56 CREATE LANGUAGE

This version does not support this syntax.

## 7.13.57 CREATE MASKING POLICY

### Description

Creates a masking policy.

### Precautions

Only users with the POLADMIN or SYSADMIN permission, or the initial user can perform this operation.

The masking policy takes effect only after the security policy is enabled, that is, **enable\_security\_policy** is set to **on**.

### Syntax

```
CREATE MASKING POLICY policy_name masking_clause[, ...]* policy_filter [
policy_filter_clause
][ENABLE | DISABLE];
```

- **masking\_clause**  
masking\_function ON LABEL(label\_name[, ...])

- **masking\_function**

The maskall function is not preset. It is hard-coded and cannot be displayed by running **\df**.

The masking methods during presetting are as follows:

```
{ maskall | randommasking | creditcardmasking | basicemailmasking | fullemailmasking |
shufflemasking | alldigitsmasking | regexprmasking }
```

- **policy\_filter\_clause:**  
FILTER ON { FILTER\_TYPE ( filter\_value [, ...] ) } [, ...]
- **FILTER\_TYPE:**  
IP | APP | ROLES

### Parameters

- **policy\_name**  
Specifies the audit policy name, which must be unique.  
Value range: a string that complies with the [Identifier Naming Conventions](#).

- **label\_name**  
Specifies the resource label name.
- **masking\_clause**  
Specifies the masking function to be used to anonymize database resources labeled by **label\_name**. **schema.function** can be used to specify the masking function.
- **policy\_filter**  
Specifies the users for which the masking policy takes effect. If this parameter is left empty, the masking policy takes effect for all users.
- **FILTER\_TYPE**  
Specifies the types of information to be filtered by the policy, including **IP**, **APP**, and **ROLES**.
- **filter\_value**  
Specifies the detailed information to be filtered, such as the IP address, app name, and username.
- **ENABLE|DISABLE**  
Enables or disables the masking policy. If **ENABLE|DISABLE** is not specified, **ENABLE** is used by default.

## Examples

```
-- Create users dev_mask and bob_mask.
openGauss=# CREATE USER dev_mask PASSWORD '*****';
openGauss=# CREATE USER bob_mask PASSWORD '*****';

-- Create table tb_for_masking.
openGauss=# CREATE TABLE tb_for_masking(col1 text, col2 text, col3 text);

-- Create a resource label for sensitive column col1.
openGauss=# CREATE RESOURCE LABEL mask_lb1 ADD COLUMN(tb_for_masking.col1);

-- Create a resource label for sensitive column col2.
openGauss=# CREATE RESOURCE LABEL mask_lb2 ADD COLUMN(tb_for_masking.col2);

-- Create a masking policy for the operation of accessing sensitive column col1.
openGauss=# CREATE MASKING POLICY maskpol1 maskall ON LABEL(mask_lb1);

-- Create a masking policy that takes effect only for scenarios where users are dev_mask and bob_mask,
the client tool is gsql, and IP addresses are 10.20.30.40, and 127.0.0.0/24.
openGauss=# CREATE MASKING POLICY maskpol2 randommasking ON LABEL(mask_lb2) FILTER ON
ROLES(dev_mask, bob_mask), APP(gsql), IP('10.20.30.40', '127.0.0.0/24');

-- Drop masking policies.
openGauss=# DROP MASKING POLICY maskpol1, maskpol2;

-- Drop resource labels.
openGauss=# DROP RESOURCE LABEL mask_lb1, mask_lb2;

-- Drop the tb_for_masking table.
openGauss=# DROP TABLE tb_for_masking;

-- Drop the dev_mask and bob_mask users.
openGauss=# DROP USER dev_mask, bob_mask;
```

## 7.13.58 CREATE MATERIALIZED VIEW

CREATE MATERIALIZED VIEW creates a complete-refresh materialized view, and you can use REFRESH MATERIALIZED VIEW (full refresh) to refresh the data in the materialized view.

CREATE MATERIALIZED VIEW is similar to CREATE TABLE AS, but it remembers the query used to initialize the view, so it can refresh data later. A materialized view has many attributes that are the same as those of a table, but does not support temporary materialized views.

### Precautions

- Complete-refresh materialized views cannot be created in temporary tables or global temporary tables.
- Complete-refresh materialized views do not support NodeGroups.
- After a complete-refresh materialized view is created, most DDL operations in the base table are no longer supported.
- IUD operations cannot be performed on complete-refresh materialized views.
- After a complete-refresh materialized view is created, if the base table data changes, you need to run the **REFRESH** command to synchronize the materialized view with the base table.
- Ustore does not support the creation and use of materialized views.

### Syntax

```
CREATE MATERIALIZED VIEW mv_name
[(column_name [, ...])]
[WITH ({storage_parameter = value} [, ...])]
[TABLESPACE tablespace_name]
AS query
[WITH [NO] DATA];
```

### Parameters

- **mv\_name**  
Name (optionally schema-qualified) of the materialized view to be created.  
Value range: a string that complies with the [Identifier Naming Conventions](#).
- **column\_name**  
Column name in the new materialized view. The materialized view supports specified columns. The number of specified columns must be the same as the number of columns in the result of the subsequent query statement. If no column name is provided, the column name is obtained from the output column name of the query.  
Value range: a string that complies with the [Identifier Naming Conventions](#).
- **WITH ( storage\_parameter [= value] [, ...] )**  
Specifies an optional storage parameter for a table or an index. For details, see [CREATE TABLE](#).
- **TABLESPACE tablespace\_name**  
Specifies a tablespace to which the new materialized view belongs. If it is not specified, the default tablespace is used.

- **AS query**

Specifies the **SELECT**, **TABLE**, or **VALUES** command. This query will be run in a security-constrained operation.

## Examples

```
-- Create an ordinary table.
openGauss=# CREATE TABLE my_table (c1 int, c2 int);

-- Create a complete-refresh materialized view.
openGauss=# CREATE MATERIALIZED VIEW my_mv AS SELECT * FROM my_table;

-- Write data to the base table.
openGauss=# INSERT INTO my_table VALUES(1,1),(2,2);

-- Completely refresh the complete-refresh materialized view my_mv.
openGauss=# REFRESH MATERIALIZED VIEW my_mv;

-- Drop a complete-refresh materialized view.
openGauss=# DROP MATERIALIZED VIEW my_mv;

-- Drop the ordinary table my_table.
openGauss=# DROP TABLE my_table;
```

## 7.13.59 CREATE OPERATOR

### Description

Defines a new operator.

### Precautions

CREATE OPERATOR defines a new name operator. The user who defines the operator becomes the owner of the operator. If a schema name is given, the operator is created in the specified schema. Otherwise, it will be created in the current schema.

The operator name is a character string consisting of the following characters:

+ - \* / < > = ~ ! @ # % ^ & | ` ?

When selecting a name, note the following restrictions:

- -- and /\* cannot appear anywhere in the operator name, because they are regarded as the beginning of a comment.
- A multi-character operator cannot end with + or - unless the name contains at least one of the following characters:  
~ ! @ # % ^ & | ` ?
- => is no longer used in an operator name.

Operator! = is mapped to <> when being entered. Therefore, the two names are always equivalent.

At least one LEFTARG and one RIGHTARG must be defined. For binocular operators, both need to be defined. For the right operator, only LEFTARG needs to be defined. For the left operator, only RIGHTARG needs to be defined.

Also, the function\_name procedure must have been defined with CREATE FUNCTION, and must be defined to accept the correct number of specified type parameters (one or two).

Other clauses declare optional operator optimization clauses, as defined in [35.13. Operator Optimization Information](#).

To create an operator, you must have the USAGE permission on the parameter type and return type, and the EXECUTE permission on the underlying function. If exchange or negative operators are specified, you must have them.

## Syntax

```
CREATE OPERATOR name (
 PROCEDURE = function_name
 [, LEFTARG = left_type] [, RIGHTARG = right_type]
 [, COMMUTATOR = com_op] [, NEGATOR = neg_op]
 [, RESTRICT = res_proc] [, JOIN = join_proc]
 [, HASHES] [, MERGES]
)
```

## Parameters

- **name**  
Operator to be defined. The available characters are listed above. The name can be schema-qualified, for example, CREATE OPERATOR myschema.+ (...). If there is no schema, the operator is created in the current schema. Two operators in the same schema can have the same name as long as they perform operations on different data types. This is a reloading process.
- **function\_name**  
Function used to implement the operator.
- **left\_type**  
Parameter data type on the left of the operator, if any. This parameter can be omitted if the left operator is used.
- **right\_type**  
Parameter data type on the right of the operator, if any. This parameter can be omitted if the right-view operator is used.
- **com\_op**  
Exchange operator corresponding to the operator.
- **neg\_op**  
Negative operator corresponding to the operator.
- **res\_proc**  
This operator constrains the selectivity evaluation function.
- **join\_proc**  
This operator joins the selectivity evaluation function.
- **HASHES**  
Indicates that the operator supports hash joins.

- **MERGES**

Indicates that this operator supports a merge join.

Use the OPERATOR() syntax to provide a schema-qualified operator name in com\_op or other optional parameters. For example:

```
COMMUTATOR = OPERATOR(myschema.===) ,
```

## Examples

The following command defines a new operator: equal area for the box data type.

```
CREATE OPERATOR === (
 LEFTARG = box,
 RIGHTARG = box,
 PROCEDURE = area_equal_procedure,
 COMMUTATOR = ===,
 NEGATOR = !==,
 RESTRICT = area_restriction_procedure,
 JOIN = area_join_procedure,
 HASHES, MERGES
);
```

## Helpful Links

[ALTER OPERATOR](#) and [DROP OPERATOR](#)

## 7.13.60 CREATE OPERATOR CLASS

### Description

Defines a new operator class.

### Precautions

CREATE OPERATOR CLASS defines a new operator class. An operator class defines how to use a specified data type together with an index. The operator class declares that certain operators will provide particular roles or "strategies" for this data type and this index method. The operator class also declares the supported programs used by the index method when the operator class is selected for an index column. All the operators and functions used by an operator class must be defined before the operator class is created.

If a schema name is given, then the operator class is created in the specified schema. Otherwise, it is created in the current schema. Two operator classes in the same schema can have the same name only if they are for different index methods.

The user who defines an operator class becomes the owner. Currently, the creator must be a super user.

CREATE OPERATOR CLASS does not check whether the class definition includes all the operators and functions required by the index method, nor whether the operators and functions form a self-contained set.

Related operator classes can be grouped into operator families. To add a new operator class to an existing family, specify a FAMILY option in CREATE OPERATOR CLASS. Without this option, the new class is placed into a family with the same name (a family is created if it does not exist).

## Syntax

```
CREATE OPERATOR CLASS
name [DEFAULT] FOR TYPE data_type
USING index_method [
FAMILY family_name] AS
{ OPERATOR strategy_number operator_name [(
op_type, op_type)] [FOR SEARCH | FOR ORDER BY sort_family_name]
| FUNCTION
support_number [(op_type [, op_type])] function_name (argument_type [,
...])
| STORAGE storage_type
} [, ...]
```

## Parameters

- **name**  
Specifies the name of the operator class to be created (which can be schema-qualified).
- **default**  
Specifies that the operator class will become the default operator class for its data type. At most one operator class can be the default for a specific data type and index method.
- **data\_type**  
Specifies the column data type processed by the operator class.
- **index\_method**  
Specifies the name of the index method processed by the operator class.
- **family\_name**  
Specifies the name of an existing operator family where an operator class is added. If it is not specified, the class is placed into a family with the same name (a family is created if it does not exist).
- **strategy\_number**  
Specifies the strategy number of the index method associated with the operator class.
- **operator\_name**  
Specifies the name (which can be schema-qualified) of the operator associated with the operator class.
- **op\_type**  
Specifies the data type of the operator's operand in an OPERATOR clause. The value **NONE** represents a left unary operator or right unary operator. The data type of the operand can be omitted if it is the same as that of the operator class.  
  
In a FUNCTION clause, if the data type of the function's operand is different from the input data type of the function (such as B-tree comparison functions and hash functions) or the class's data type, the data type of the operand supported by this function must be included in this clause. These default values are correct. Therefore, **op\_type** need not be specified in FUNCTION clauses, except in cases where the B-tree sort support function supports cross-type comparisons.
- **sort\_family\_name**

Specifies the name of an existing B-tree operator family that describes the sort ordering associated with a sort operator.

The default value is **FOR SEARCH**.

- **support\_number**

Specifies the number of an index method for a function associated with the operator class.

- **function\_name**

Specifies a function name of an index method for an operator class.

- **argument\_type**

Specifies a data type of a function parameter.

- **storage\_type**

Specifies the data type stored in the index. Normally, this is the same as the column data type, but some index methods allow it to be different. The **STORAGE** clause must be omitted unless the index method allows a different type to be used.

## Examples

```
-- Define a function.
CREATE FUNCTION func_add_sql(num1 integer, num2 integer) RETURN integer AS BEGIN
RETURN num1 + num2;
END;
/
-- Create an operator class and associate it with the preceding function.
CREATE OPERATOR CLASS oc1 DEFAULT FOR TYPE _int4 USING btree AS FUNCTION 1 func_add_sql
(integer, integer);
```

## 7.13.61 CREATE PACKAGE

### Description

Creates a package.

### Precautions

- Only the centralized mode support packages.
- The functions or stored procedures declared in the package specification must be defined in the package body.
- During instantiation, the stored procedure with **commit** or **rollback** cannot be called.
- Package functions cannot be called in triggers.
- Variables in a package cannot be directly used in external SQL statements.
- Private variables and stored procedures in a package cannot be called outside the package.
- Usage that other stored procedures do not support are not supported. For example, if **commit** or **rollback** cannot be called in a function, they cannot be called in the function of a package, either.
- The name of a schema cannot be the same as that of a package.
- Only A-version stored procedures and function definitions are supported.

- Variables with the same name in a package, including parameters with the same name in a package, are not supported.
- The global variables in a package are at the session level. The variables in packages cannot be shared in different sessions.
- When a function of an autonomous transaction is called in a package, the cursor variables in the package and recursive functions that use the cursor variables in the package are not allowed.
- The package does not declare the ref cursor variables.
- The default permission on a package is SECURITY INVOKER. To change the default permission to SECURITY DEFINER, set the GUC parameter **behavior\_compat\_options** to '**plsql\_security\_definer**'.
- A user granted with the CREATE ANY PACKAGE permission can create packages in the public and user schemas.
- If the name of a package to be created contains special characters, spaces cannot be contained between special characters. You are advised to set the GUC parameter **behavior\_compat\_options** to "**skip\_insert\_gs\_source**". Otherwise, an error may occur.
- When you create a package function, the default parameter value cannot contain variables.

## Syntax

- CREATE PACKAGE SPECIFICATION

```
CREATE [OR REPLACE] PACKAGE [schema] package_name
[invoker_rights_clause] { IS | AS } item_list_1 END package_name;
```

**invoker\_rights\_clause** can be declared as **AUTHID DEFINER** or **AUTHID INVOKER**, which indicate the definer permission and invoker permission, respectively.

**item\_list\_1** can be a declared variable, stored procedure, or function.

The package specification (header) declares public variables, functions, and exceptions in a package, which can be called by external functions or stored procedures. It can only declare stored procedures and functions but cannot define them.

- CREATE PACKAGE BODY

```
CREATE [OR REPLACE] PACKAGE BODY [schema] package_name
{ IS | AS } declare_section [initialize_section] END package_name;
```

The package body defines private variables and functions in a package. If a variable or function is not declared by the package specification, it is a private variable or function.

The package body also has an initialization part to initialize the package. For details, see the example.

## Examples

- Example of CREATE PACKAGE SPECIFICATION

```
CREATE OR REPLACE PACKAGE emp_bonus IS
var1 int:=1;-- Public variable
var2 int:=2;
PROCEDURE testpro1(var3 int);-- Public stored procedure, which can be called by external systems.
END emp_bonus;
/
```

- Example of CREATE PACKAGE BODY

```
drop table if exists test1;
create or replace package body emp_bonus is
```

```
var3 int:=3;
var4 int:=4;
procedure testpro1(var3 int)
is
begin
create table if not exists test1(col1 int);
insert into test1 values(var1);
insert into test1 values(var4);
end;
begin: --The instantiation starts.
var4:=9;
testpro1(var4);
end emp_bonus;
/
```

- Example of ALTER PACKAGE OWNER

```
ALTER PACKAGE emp_bonus OWNER TO omm;
-- Change the owner of PACKAGE emp_bonus to omm.
```

- Example of calling a package

```
call emp_bonus.testpro1(1); -- Use call to call the stored procedure of a package.
select emp_bonus.testpro1(1); -- Use select to call the stored procedure of a package.
-- Call the stored procedure of a package in an anonymous block.
begin
emp_bonus.testpro1(1);
end;
/
```

## 7.13.62 CREATE PROCEDURE

### Description

Creates a stored procedure.

### Precautions

- If the parameters or return values of a stored procedure have precision, the precision is not checked.
- When creating a stored procedure, you are advised to explicitly specify the schemas of all operations on table objects in the stored procedure definition. Otherwise, the stored procedure may fail to be executed.
- **current\_schema** and **search\_path** specified by **SET** during stored procedure creation are invalid. **search\_path** and **current\_schema** before and after function execution should be the same.
- If a SELECT statement calls a stored procedure with output parameters, output parameters cannot be specified. When a CALL statement calls a stored procedure involving a non-overloaded function, output parameters must be specified. When a CALL statement calls an overloaded PACKAGE function, the output parameters may not be specified. For details, see examples in [CALL](#).
- A stored procedure with the PACKAGE attribute can use overloaded functions.
- When you create a procedure, you cannot nest average functions within aggregate or other functions.
- When stored procedures without parameters are called in another stored procedure, you can omit brackets and call stored procedures using their names directly.
- When functions with output parameters are called in a stored procedure which is an assignment expression, you can omit the output parameters of the called functions.

- The stored procedure supports viewing, exporting, and importing parameter comments.
- The stored procedure supports viewing, exporting, and importing parameter comments between IS/AS and plsql\_body.
- The default permission on a stored procedure is SECURITY INVOKER. To change the default permission to SECURITY DEFINER, set the GUC parameter **behavior\_compat\_options** to '**plsql\_security\_definer**'.
- Users granted the CREATE ANY FUNCTION permission can create or replace stored procedures in the user schemas.
- An **out** or **inout** parameter must be set to a variable but not a constant.
- In a centralized environment, if you want to call a stored procedure with the same in parameters but different out parameters, you need to set the GUC parameter **behavior\_compat\_options** to '**proc\_outparam\_override**'. After the parameter is enabled, you must add **out** parameters no matter whether you use the SELECT or CALL statement to call the stored procedure. After the parameter is enabled, you cannot use **perform** to call a stored procedure or function.
- When an overloaded stored procedure is called, the variable type must be specified.
- If a stored procedure with the definer specified is created in a schema of another user, the stored procedure will be executed by another user, which may cause unauthorized operations. Therefore, exercise caution when performing this operation.

## Syntax

```
CREATE [OR REPLACE] PROCEDURE procedure_name
[(([argname] [argmode] argtype [{ DEFAULT | := | = } expression]) [, ...])]
[
 { IMMUTABLE | STABLE | VOLATILE }
 | { SHIPPABLE | NOT SHIPPABLE }
 | { PACKAGE }
 | [NOT] LEAKPROOF
 | { CALLED ON NULL INPUT | RETURNS NULL ON NULL INPUT | STRICT }
 | [{ EXTERNAL } SECURITY INVOKER | [EXTERNAL] SECURITY DEFINER | AUTHID DEFINER | AUTHID
CURRENT_USER }
 | COST execution_cost
 | SET configuration_parameter { TO value | = value | FROM CURRENT }
][...]
{ IS | AS }
plsql_body
/
```

## Parameters

- **OR REPLACE**  
Replaces the original definition when two stored procedures are with the same name.
- **procedure\_name**  
Specifies the name of the stored procedure that is created (optionally with schema names).  
Value range: a string that complies with the [Identifier Naming Conventions](#).
- **argmode**  
Specifies the mode of an argument.

---

**NOTICE**

**VARIADIC** specifies parameters of the array type.

---

Value range: **IN**, **OUT**, **INOUT**, and **VARIADIC**. The default value is **IN**. Only the parameters in **OUT** mode can follow the **VARIADIC** parameter.

- **argname**

Specifies the argument name.

Value range: a string that complies with the [Identifier Naming Conventions](#).

- **argtype**

Specifies the type of an argument. **%TYPE** or **%ROWTYPE** can be used to indirectly reference a variable or table type. For details, see [Variable Definition Statements](#).

Value range: a valid data type.

 **NOTE**

In **PROCEDURE argtype** outside *PACKAGE*, **%TYPE** cannot reference the type of the *PACKAGE* variable.

- **expression**

Specifies the default expression of a parameter.

 **NOTE**

- It is recommended that you define all default parameters after all non-default parameters.

- **configuration\_parameter**

- **value**

Sets the specified configuration parameter to a specified value. If the **value** is **DEFAULT**, the default setting is used in the new session. **OFF** disables the setting.

Value range: a string.

- **DEFAULT**
    - **OFF**
    - Specified default value

- **from current**

Uses the value of **configuration\_parameter** of the current session.

- **IMMUTABLE, STABLE,...**

Specifies a constraint. The function of each parameter is similar to that of **CREATE FUNCTION**. For details, see [CREATE FUNCTION](#).

- **plsql\_body**

Specifies the PL/SQL stored procedure body.

**NOTICE**

When you perform password-related operations, such as user creation, password change, and encryption/decryption, in a stored procedure, the password will be recorded in the system catalogs and logs in plaintext. To prevent sensitive information leakage, you are advised not to perform password-related operations in a stored procedure.

 **NOTE**

No specific order is applied to **argname** and **argname**. The following order is advised: **argname**, **argmode**, and **argtype**.

## Helpful Links

[DROP PROCEDURE](#)

## Suggestions

- analyse | analyze
  - Do not run **ANALYZE** in a transaction or anonymous block.
  - Do not run **ANALYZE** in a function or stored procedure.

## 7.13.63 CREATE RESOURCE LABEL

### Description

Creates a resource label.

### Precautions

Only users with the POLADMIN or SYSADMIN permission, or the initial user can perform this operation.

### Syntax

```
CREATE RESOURCE LABEL [IF NOT EXISTS] label_name ADD label_item_list[, ...]*;
```

- label\_item\_list  
resource\_type(resource\_path[, ...]\*)
- resource\_type  
TABLE | COLUMN | SCHEMA | VIEW | FUNCTION

### Parameters

- **IF NOT EXISTS**  
If a resource label with the same name already exists, no error is generated. Instead, a message is displayed, indicating that the resource label already exists.
- **label\_name**  
Specifies the resource label name, which must be unique.  
Value range: a string that complies with the [Identifier Naming Conventions](#).

- **resource\_type**  
Specifies the type of database resources to be labeled.
- **resource\_path**  
Specifies the path of database resources.

## Examples

```
-- Create table tb_for_label.
openGauss=# CREATE TABLE tb_for_label(col1 text, col2 text, col3 text);

-- Create schema schema_for_label.
openGauss=# CREATE SCHEMA schema_for_label;

-- Create view view_for_label.
openGauss=# CREATE VIEW view_for_label AS SELECT 1;

-- Create function func_for_label.
openGauss=# CREATE FUNCTION func_for_label RETURNS TEXT AS $$ SELECT col1 FROM tb_for_label; $$
LANGUAGE SQL;

-- Create a resource label based on a table.
openGauss=# CREATE RESOURCE LABEL IF NOT EXISTS table_label add TABLE(public.tb_for_label);

-- Create a resource label based on columns.
openGauss=# CREATE RESOURCE LABEL IF NOT EXISTS column_label add
COLUMN(public.tb_for_label.col1);

-- Create a resource label based on a schema.
openGauss=# CREATE RESOURCE LABEL IF NOT EXISTS schema_label add SCHEMA(schema_for_label);

-- Create a resource label based on a view.
openGauss=# CREATE RESOURCE LABEL IF NOT EXISTS view_label add VIEW(view_for_label);

-- Create a resource label based on a function.
openGauss=# CREATE RESOURCE LABEL IF NOT EXISTS func_label add FUNCTION(func_for_label);

-- Drop resource labels.
openGauss=# DROP RESOURCE LABEL func_label, view_label, schema_label, column_label, table_label;

-- Drop the func_for_label function.
openGauss=# DROP FUNCTION func_for_label;

-- Drop the view_for_label view.
openGauss=# DROP VIEW view_for_label;

-- Drop the schema_for_label schema.
openGauss=# DROP SCHEMA schema_for_label;

-- Drop the tb_for_label table.
openGauss=# DROP TABLE tb_for_label;
```

## Helpful Links

[ALTER RESOURCE LABEL](#) and [DROP RESOURCE LABEL](#)

## 7.13.64 CREATE ROLE

### Description

Creates a role.

A role is an entity that owns database objects and permissions. In different environments, a role can be considered a user, a group, or both.

## Precautions

- If a role is added to the database, the role does not have the login permission.
- Only the user who has the CREATE ROLE permission or a system administrator is allowed to create roles.

## Syntax

```
CREATE ROLE role_name [[WITH] option [...]] [ENCRYPTED | UNENCRYPTED] { PASSWORD | IDENTIFIED BY } { 'password' [EXPIRED] | DISABLE };
```

The syntax of option clauses for configuring role information is as follows:

```
{SYSADMIN | NOSYSADMIN}
| {MONADMIN | NOMONADMIN}
| {OPRADMIN | NOOPRADMIN}
| {POLADMIN | NOPOLADMIN}
| {AUDITADMIN | NOAUDITADMIN}
| {CREATEDB | NOCREATEDB}
| {USEFT | NOUSEFT}
| {CREATEROLE | NOCREATEROLE}
| {INHERIT | NOINHERIT}
| {LOGIN | NOLOGIN}
| {REPLICATION | NOREPLICATION}
| {VCADMIN | NOVCADMIN}
| {PERSISTENCE | NOPERSISTENCE}
| CONNECTION LIMIT connlimit
| VALID BEGIN 'timestamp'
| VALID UNTIL 'timestamp'
| USER GROUP 'groupuser'
| PERM SPACE 'spacelimit'
| TEMP SPACE 'tmpspacelimit'
| SPILL SPACE 'spillspacelimit'
| NODE GROUP logic_cluster_name
| IN ROLE role_name [, ...]
| IN GROUP role_name [, ...]
| ROLE role_name [, ...]
| ADMIN rol e_name [, ...]
| USER role_name [, ...]
| SYSID uid
| DEFAULT TABLESPACE tablespace_name
| PROFILE DEFAULT
| PROFILE profile_name
| PGUSER
```

## Parameters

- **role\_name**

Specifies the name of a role.

Value range: a string that follows the [Identifier Naming Conventions](#) with a maximum of 63 characters. If a value contains more than 63 characters, the database truncates it and retains the first 63 characters as the role name.

When a role is created, the database will display a message.

 **NOTE**

The identifier must be letters, underscores (\_), digits (0-9), or dollar signs (\$) and must start with a letter (a-z) or underscore (\_).

- **password**

Specifies the login password.

A new password must:

- Contain at least eight characters. This is the default length.

- Differ from the username or the username spelled backward.
- Contain at least three of the following character types: uppercase characters, lowercase characters, digits, and special characters (limited to ~!@#\$%^&\*()-\_+=\|[{]}<.>/?).
- The password can also be a ciphertext character string that meets the format requirements. This mode is mainly used to import user data. You are advised not to use it directly. If a ciphertext password is used, you need to know the plaintext corresponding to the ciphertext password and ensure a complex plaintext password. The database does not verify the complexity of the ciphertext password, so you should ensure the password security.
- When creating a role, enclose the user password in single quotation marks.

Value range: a character string that cannot be empty.

- **EXPIRED**

When creating a user, you can specify the **EXPIRED** parameter to create a user whose password is invalid. The user cannot perform simple or extended queries. The statement can be executed only after the password is changed.

- **DISABLE**

By default, you can change your password unless it is disabled. To disable the password of a user, use this parameter. After the password of a user is disabled, the password will be deleted from the system. The user can connect to the database only through external authentication, for example, Kerberos authentication. Only administrators can enable or disable a password. Common users cannot disable the password of an initial user. To enable a password, run **ALTER USER** and specify the password.

- **ENCRYPTED | UNENCRYPTED**
